1647. "Buildings situated in the country appear to possess a great advantage over those in populous and smoky towns, owing to lichens, with which they almost invariably become covered in such situations, and which, when firmly established over their entire surface, seem to exercise a protective influence against the ordinary causes of the decomposition of the stone upon which they grow.

1648. "As an instance of the difference in degree of durability in the same material subjected to the effects of the atmosphere in town and country, we may notice the several frusta of columns and other blocks of stone that were quarried at the time of the erection of St. Paul's Cathedral in London, and which are now lying in the island of Portland, near the quarries from whence they were obtained. These blocks are invariably found to be covered with lichens, and although they have been exposed to all the vicissitudes of a marine atmosphere for more than 150 years, they still exhibit, beneath the lichens, their original forms, even to the marks of the chisel employed upon them, whilst the stone which was taken from the same quarries (selected, no doubt, with equal, if not greater, care than the blocks alluded to) and placed in the cathedral itself, is, in those parts which are exposed to the south and south-west winds, found in some instances to be fast mouldering away. Colour is of more importance in the selection of a stone for a building to be situated in a populous and smoky town, than for one to be placed in an open country, where all edifices usually become covered, as before stated, with lichens; for although in such towns those fronts which are not exposed to the prevailing winds and rains will soon become blackened*, the remainder of the building will constantly exhibit a tint depending upon the natural colour of the material employed.

1649. "Before we proceed to adduce a few examples of the present condition of the various buildings we have examined, we would wish to observe that those which are highly decorated, such as the churches of the Norman and pointed styles of architecture, afford a more severe test of the durability of any given stone, all other circumstances being equal, than the more simple and less decorated buildings, such as the castles of the fourteenth and fifteenth centuries, inasmuch as the material employed in the former class of buildings is worked into more disadvantageous forms than in the latter, as regards exposure to the effects of the weather; and we would further observe, that buildings in a state of ruin, from being deprived of their ordinary protection of roofing, glazing of windows, &c., constitute an equally severe test of the durability of the stone employed in them.

1650. "As examples of the degree of durability of various building stones in particular localities, the following may be enumerated. Of the sandstone buildings which we examined, we may notice the remains of Ecclestone Abbey, of the thirteenth century, near Barnard Castle, constructed of a stone closely resembling that of the Stenton quarry in the vicinity, as exhibiting the mouldings and other decorations, even to the dog's-tooth ornament, in excellent condition. The circular keep of Barnard, apparently also built of the same material, is in fine preservation. Tintern Abbey may also be noticed as a sandstone

* We must take leave to question this statement; as, for instance, in St. Paul's Cathedral we find the northern front peculiarly black, whilst the south front and south-western angle are comparatively white This we have always considered to have arisen from the more constant action of the sun's rays upon them.

edifice that has to a considerable extent resisted decomposition; for although it is decayed in some parts, it is nearly perfect in others. Some portions of Whitby Abbey are likewise in a perfect state, whilst others are fast yielding to the effects of the atmosphere. The older portions of Ripon Cathedral, constructed of sandstone, are in a fair state of preservation. Rivaulx Abbey is another good example of an ancient sandstone building in a fair condition. The Norman keep of Richmond Castle in Yorkshire affords an instance of a moderately hard sandstone which has well resisted decomposition.

1651. "As examples of sandstone buildings of more recent date in a good state of preservation, we may mention Hardwicke Hall, Haddon Hall, and all the buildings of Craigleith Stone in Edinburgh and its vicinity. Of sandstone edifices in an advanced state of decomposition we may enumerate Durham Cathedral, the churches at Newcastle upon Tyne, Carlisle Cathedral, Kirkstall Abbey, and Fountains Abbey. The sandstone churches of Derby are also extremely decomposed; and the church of St. Peter at Shaftesbury is in such a state of decay that some portions of the building are only prevented from falling by means of iron ties.

1652. "As an example of an edifice constructed of a calciferous variety of sandstone, we may notice Tisbury Church, which is in unequal condition, the mouldings and other enrichments being in a perfect state, whilst the ashler, apparently selected with less care, is fast mouldering away.

1653. "The choir of Southwell Church, of the twelfth century, may be mentioned as affording an instance of the durability of a magnesio-calciferous sandstone, resembling that of Mansfield, after long exposure to the influences of the atmosphere.

1654. "Of buildings constructed of magnesian limestone we may mention the Norman portions of Southwell Church, built of stone similar to that of Bolsover Moor, and which are throughout in a perfect state, the mouldings and carved enrichments being as sharp as when first executed. The keep of Koningsburgh Castle, built of a magnesian limestone from the vicinity, is also in a perfect state, although the joints of the masonry are open in consequence of the decomposition and disappearance of the mortar formerly within them. The church at Hemmingborough, of the fifteenth century, constructed of a material resembling the stone from Huddlestone, does not exhibit any appearance of decay. Tickhill Church, of the fifteenth century, built of a similar material, is in a fair state of preservation. Huddlestone Hall, of the sixteenth century, constructed of the stone of the immediate vicinity, is also in good condition. Roche Abbey, of the thirteenth century, in which stone from the immediate neighbourhood has been employed, exhibits generally a fair state of preservation, although some portions have yielded to the effects of the atmosphere.

1655. "As examples of magnesian limestone buildings in a more advanced state of decay, we may notice the churches at York, and a large portion of the Minster, Howden Church, Doncaster Old Church, and others in that part of the country, many of which are so much decomposed that the mouldings, carvings, and other architectural decorations are often entirely effaced.

1656. "We may here remark, that, as far as our observations extend, in proportion as the stone employed in magnesian limestone buildings is crystalline, so does it appear to have resisted the decomposing effects of the atmosphere; a conclusion in accordance with the opinion of Professor Daniell, who has stated to us that from the results of experiments, he is of opinion 'the nearer the magnesian limestones approach to equivalent proportions of carbonate of lime and carbonate of magnesia, the more crystalline and better they are in every respect.'

1657. "Of buildings constructed of oolitic and other limestones, we may notice the church of Byland Abbey, of the twelfth century, especially the west front, built of stone from the immediate vicinity, as being in an almost perfect state of preservation. Sandysfoot Castle, near Weymouth, constructed of Portland oolite in the time of Henry VIII., is an example of that material in excellent condition; a few decomposed stones used in the interior (and which are exceptions to this fact) being from another oolite in the immediate vicinity of the castle. Bow and Arrow Castle, and the neighbouring ruins of a church of the fourteenth century, in the Island of Portland, also afford instances of the Portland oolite in perfect condition. The new church in the island, built in 1766, of the variety of the Portland stone termed *roach*, is in an excellent state throughout, even to the preservation of the marks of the chisel.

1658. "Many buildings constructed of a material similar to the oolite of Ancaster, such as Newark and Grantham Churches, and other edifices in various parts of Lincolnshire, have scarcely yielded to the effects of atmospheric influences. Windrush Church, built of an oolite from the neighbouring quarry, is in excellent condition, whilst the Abbey Church of Bath, constructed of the oolite in the vicinity of that city, has suffered much from decomposition; as is also the case with the cathedral, and the churches of St. Nicholas and St. Michael in Gloucester, erected of a stone from the oolitic rocks of the neighbourhood.

1659. "The churches of Stamford, Ketton, Colley Weston, Kettering, and other places in that part of the country, attest the durability of the Shelley oolite, termed *Barnack Rag*, with the exception of those portions of some of them for which the stone has been ill-selected. The excellent condition of those parts which remain of Glastonbury Abbey show the value of a shelly limestone similar to that of Doulting, whilst the stone employed in Wells Cathedral, apparently of the same kind and not selected with equal care, is in parts decomposed. The mansion, the church, and the remains of the abbey at Montacute, as also many other buildings in that vicinity, constructed of the limestone of Ham Hill, are in excellent condition. In Salisbury Cathedral, built of stone from Chilmark, we have evidence of the general durability of a siliciferous limestone; for, although the west front has somewhat yielded to the effects of the atmosphere, the excellent condition of the building generally is most striking.

1660. "In the public buildings of Oxford, we have a marked instance both of decomposition and durability in the materials employed; for whilst a shelly oolite, similar to that of Taynton, which is employed in the more ancient parts of the cathedral, in Merton College Chapel, &c., and commonly for the plinths, string-courses, and exposed portions of the other edifices in that city, is generally in a good state of preservation, a calcareous stone from Heddington, employed in nearly the whole of the colleges, churches, and other public buildings, is in such a deplorable state of decay, as in some instances to have caused all traces of architectural decoration to disappear, and the ashler itself to be in many places deeply disintegrated.

1661. "In Spofforth Castle we have a striking example of the unequal decomposition of two materials, a magnesian limestone and a sandstone; the former employed in the decorated parts, and the latter for the ashler or plain facing of the walls. Although the magnesian limestone has been equally exposed with the sandstone to the decomposing effects of the atmosphere, it has remained as perfect in form as when first employed, while the sandstone has suffered considerably from the effects of decomposition.

1662. "In Chepstow Castle, a magnesian limestone in fine preservation, and a red sandstone in an advanced state of decomposition, may be observed, both having been exposed to the same conditions as parts of the same archways; and in Bristol Cathedral there is a curious instance of the effects arising from the intermixture of very different materials, a yellow limestone and a red sandstone, which have been indiscriminately employed both for the plain and decorated parts of the building; not only is the appearance in this case unsightly, but the architectural effect of the edifice is also much impaired by the unequal decomposition of the two materials, the limestone having suffered much less from decay than the sandstone.

1663. "Judging, therefore from the evidence afforded by buildings of various dates, there would appear to be many varieties of sandstone and limestone employed for building purposes which successfully resist the destructive effects of atmospheric influences; amongst these the sandstones of Stenton, Whitby, Tintern, Rivaulx, and Cragleith, the magnesio-calciferous sandstones of Mansfield, the calciferous sandstone of Tisbury, the crystalline magnesian limestones, or *Dolomites* of Bolsover, Huddlestone and Roche Abbey, the oolites of Byland, Portland, and Ancaster, the Shelly oolites and limestones of Barnack and Ham Hill, and the siliciferous limestone of Chilmark appear to be amongst the most durable. To these, which may all be considered as desirable building materials, we are inclined to add the sandstones of Darley Dale, Humbie, Longannet, and Crowbank, the magnesian limestones of Robin Hood's Well, and the oolite of Ketton, although some of them may not have the evidence of ancient buildings in their favour." The Report upon which we have drawn so largely, and from which we shall extract still larger drafts, then proceeds to close by a preference to limestones on account "of their more general uniformity of tint, their comparatively homogeneous structure, and the facility and economy of their conversion to building purposes," of which it prefers the crystalline; on which account, and its combination with a close approach to the equivalent proportions of carbonate of lime and carbonate of magnesia, for uniformity in structure, facility and economy in conversion, and for advantage of colour, the parties to the Report prefer the magnesian limestone or dolomite of Bolsover Moor and its neighbourhood. The Report deserves every commendation; upon the whole it has been well done, and is the first scientific step the government of this country has ever taken in respect of practical architecture. It, moreover, only cost the moderate sum of £1,400, including the many collections of specimens deposited in various institutions for reference.

1664. The following table presents a synoptical, and, to the architect, important view of the relative value, in every respect, of the principal species of stone which the various provinces of England afford for building purposes. It is taken from the Report so much quoted, the list of stones being considerably abridged. We should direct attention to the fact that facilities of conveyance have greatly modified the cost of each stone in London. It will be well also to notice the valuable "Quarry Returns" of building and other stones, the produce of the United Kingdom of Great Britain and Ireland, published in the *Memoirs of the Geological Survey of Great Britain*, &c., and edited by Robert Hunt, being Part II. for 1858, but published in 1860.

SANDSTONES.

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.			s. d.	
Abercarne and New-bridge, near Newport, Monmouthshire	Sir B. Hall, Bart.	Quartz and siliceous grains, moderately fine, with argillo-siliceous cement; micaceous, and with remains of fossil plants	Dark bluish grey.	167 15	1 to 10 tons, in thicknesses of 5 feet.	4½d., or 5s per ton	1 5	Old churches and modern buildings in vicinity; new Docks at Newport and Cardiff.
Ball Cross	- -	Siliceous grains with argillo-siliceous cement; occasionally micaceous, ferruginous.	Ferruginous brown striped, and zoned in deeper tints.	- -	- -	- -	- -	At Chatsworth and Bakewell.
Barradoes, Tintern, Monmouthshire.	Duke of Beaufort.	Fine and coarse quartz, and other siliceous grains, with argillo-siliceous cement, ferruginous spots, and plates of mica.	Light greyish brown.	146 12	1 to 10 tons, thickest bed 10 to 12 ft.	10d. to 1s.	- -	Tintern Abbey.
Binnie, Uphall, and in Linlithgowshire.	Earl of Buchanan.	Fine quartz grains, with argillo-siliceous cement, micaceous, chiefly in planes of beds.	Brownish grey.	140 1	Bands 14 to 18 ft. thick (3 in number).	1s. 1d. to 2s. for largest blocks.	2 9 to 3 8	New club-house in Prince's Street, Edinburgh, and numerous private houses there and in Glasgow.
Bolton's Quarry, Aislaby, Yorkshire.	Messrs. Elgie and Lawson, as executors of the late Mr. Noble, of York.	Moderately fine siliceous grains, with argillo-siliceous cement, plates of mica, and spots of carbon disseminated.	Warm light brown.	126 11	100 ft. cube; top beds for house building, bottom beds for docks. Beds 3 to 8 ft. thick.	10d. to 1s.	1 9 to 2 1	Whitby Abbey, New University Library at Cambridge, Scarborough and Bridlington Piers, Sheerness and St. Katharine's Docks, &c.
Bramley Fall (Old Quarry), near Leeds, Yorkshire.	Earl of Cardigan.	Quartz grains (often coarse), and decomposed felspar, with argillo-siliceous cement. Mica rare. Small ferruginous spots disseminated.	Light ferruginous brown.	142 3	Up to 18 tons.	- -	- -	In numerous bridges, waterworks, &c.
Calverley, Tunbridge Wells, Kent.	John Ward, Esq., Holwood Park, Bromley, Kent.	Fine siliceous grains, with a slightly calcareous cement.	Variegated browns.	118 1	70 or 80 ft., and upwards to 500. Beds to 3½ ft.	4d. to 6d.	1 2 to 1 4	Upper part of new church at Tunbridge Wells; Catholic Chapel, the Calverley Hotel, new Market House, and Victoria National School, and about 100 houses, &c., at Tunbridge Wells and its vicinity.

				lb. oz.		s. d.	s. d.	
Gatton, Gatton, Surrey.	Lord Monson.	Fine siliceous grains, with a calcareo-siliceous cement, containing green silicate of iron and plates of mica.	Greenish light brown.	103 1	35 to 60 ft. cube, from 4 to 10 ft. long.	1 4 to 1 6	- -	Hampton Court and Windsor Castle, &c.; many churches in Surrey; Town Hall and Almshouse Establishment at Croydon; and several modern buildings in the parish of Gatton.
Glammis, Forfarshire.	Earl of Strathmore's trustees.	Siliceous grains of moderate size; cement slightly calcareous; mica abundant in planes of beds.	Purple grey.	161 2	Any practicable size; thickest bed 6 ft.	0 7 to 1 0	about 19*s.* per ton.	Glammis Castle and Inverquharity Castle, supposed of the tenth century; Cortachy Castle; and in modern buildings; Lendertis House, &c.
Heddon, near Newcastle, Northumberland.	Mrs. Bewick, near Newcastle upon Tyne.	Coarse quartz grains, and decomposed felspar, with an argillo-siliceous cement, ferruginous spots.	Light brown ochre.	130 11	Beds 4 to 12 ft. thick.	0 6 to 0 10	1 8 to 2 0	Church at Heddon, steeple, 1764; Norman chancel; columns of portico to theatre, and Grey Monument at Newcastle; and nearly all the buildings, ancient and modern, in and about Newcastle.
Hollington, Staffordshire.	Sir J. Gibbons, Bart., near Staines, Middlesex.	Quartz grains of moderate size, with an argillo-siliceous cement; plates of mica.	Light brownish grey.	133 1	30 to 40 ft. square, and 8 ft. thick.	0 7 to 1 0	2 6	Trentham Hall, Drayton Manor, Heathhouse, and various public and private buildings in Staffordshire; Town Hall, Derby; Mear Hall, Cheshire, &c.
Humbie, Humbie, Linlithgowshire.	Earl of Hopetoun.	Fine quartz grains, with siliceous cement; slightly calcareous: mica chiefly in planes of beds.	Pale grey and light brown.	White 140 3 grey 135 13	90 cubic ft. and upwards, if required; thickest bed 8 ft.	1 0 to 1 10	2 6 to 3 2	Newliston House, Kirkliston; Dundas Castle; additions to the Royal Institution; front of Surgeons' Hall, spire of Tron Church, and various other public buildings in Edinburgh; also in Glasgow.
Longannet, near Kincardine, in Perthshire.	Trustees of late Lord Keith.	Fine quartz grains, with siliceous cement, containing oxide of iron; a few plates of mica.	Light ferruginous brown.	131 11	4 to 5 tons; thickest beds 5 ft.	0 8 to 2 6	1 8 to 3 6	Staadt House, Amsterdam; Exchange, Edinburgh; Tulle Mare Castle, Perthshire; and part of a street in Perth.

				lb. oz.		s. d.	s. d.	
Bolsover, near Chesterfield, Derbyshire.	Earl Bathurst.	Chiefly carbonate of lime and carbonate of magnesia; semi-crystalline.	Light yellowish brown.	151 11	56 ft. cube, in beds from 8 in. to 2 ft. thick.	0 10	2 0	Southwell Church, and numerous buildings in the vicinity.
Brodsworth, near Doncaster, Yorkshire.	Lord Rendlesham.	Chiefly carbonate of lime and carbonate of magnesia, with sub-oolitic grains; friable.	Light brown tint.	133 10	Thickest bed 3 ft. 6 in.	- -	- -	Doncaster Old Church and Mansion-house, Brocklesby Hall, &c.
Cadeby, near Doncaster, Yorkshire.	Sir Joseph Copley, Bart.	Chiefly carbonate of lime and carbonate of magnesia, with sub-oolitic and irregularly formed oolitic grains; friable.	Cream.	126 9	Central beds (the best) 4 ft. thick.	- -	1 10	Day and Martin's, in High Holborn; almshouses at Edgware, &c.

MAGNESIAN LIMESTONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.		*s. d.*	*s. d.*	
HUDDLESTONE, near Sherburne, Yorkshire.	Oliver Gascoigne, Esq., near Abberford.	Chiefly carbonate of lime and carbonate of magnesia, semi-crystalline.	Whitish cream.	137 13	50 to 250 cubic ft. Beds have been met with 4ft. thick.	2 0	3 0	York Minster, Selby Cathedral, Huddlestone Hall, Sherburne Church, Westminster Hall, Galeforth Hall, &c.
JACKDAW CRAIG, near Tadcaster, Yorkshire.	Sir Edward Vavasour, Bart.	Chiefly carbonate of lime and carbonate of magnesia.	Dark cream.	- -	Beds irregular, from a few inches to 3 feet.	- -	- -	York Minster, and probably most of the churches in York; also for the late restorations of York Minster.
ROCHE ABBEY, near Bawtry, Yorkshire.	Earl of Scarborough.	Chiefly carbonate of lime and carbonate of magnesia, with occasional dendritic spots of iron or manganese, semi-crystalline.	Whitish cream.	139 2	8 or 10 tons, thickest bed will work 2ft. 6 in.	0 8 to 1 6	2 1½ 2 11½	Roche Abbey Church, Tickhill Castle, and Church and Bridge, Sandbeck Hall, Selby Hall, two churches at Retford, Bawtry Church, and numerous churches in Yorkshire and Lincolnshire.
SMAWSE, near Tadcaster, Yorkshire. (Bramham Moor).	Thomas Perrott, Esq.	Chiefly carbonate of lime and carbonate of magnesia, slightly crystalline.	Light yellowish brown.	127 8	Largest obtained 8·0 × 3·0 × 30.	0 7	2 1½	Hull Old Church, Ripon Minster, St. Mary's Church and the minster at Beverley, the minster and several churches at York, and a new church at Appleby, in Lincolnshire.

OOLITIC STONES.

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.
				lb. oz.		*s. d.*	*s. d.*	
ANCASTER, near Sleaford, Lincolnshire.	Mrs. Myers, Grantham.	Fine oolitic grains, cemented by compact, and often crystalline, carbonate of lime.	Cream.	139 4	3 to 5 tons, beds, 18 inches.	0 9 to 1 5	2 7	Wollaton Hall, Belvoir Castle, Belton House, and numerous mansions and churches in Lincolnshire.
BARNACK MILL, near Stamford, Northamptonshire.	Mr. John Martin, Ufford, near Stamford.	Carbonate of lime, compact and oolitic, with shells, often in fragments, coarsely laminated in planes of beds.	Light whitish brown.	136 12	Up to 30 ft., beds, 9 to 18 in.	1 0	2 3	Burleigh House, Peterborough Cathedral, Croyland Abbey, and the greater proportion of churches in Lincolnshire and Cambridgeshire.

OOLITIC STONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.

BATH LODGE HILL, Combe Down, near Bath, Somersetshire.	W. V. Jenkins, Esq., Combe Grove House, Bath.	Chiefly carbonate of lime, in oolitic grains.	Cream.	116 00	12 to 96 ft cube. Thickest bed, 4½ ft.	0 6	- -	Restoration of Henry VII.'s chapel, twenty years since. Kennet and Avon Canal, and other works.
BATH BAYNTON Quarry, Box, near Chippenham.	Thomas Strong, of Box, near Chippenham.	Chiefly carbonate of lime, in moderately fine oolitic grains, with fragments of shells (weather bed).	Cream.	123 00	Up to 10 tons. Thickest bed, 5 ft.	0 7	1 11	Laycock Abbey, Longleat, Bowood, south front of Wilton House, Windsor Castle, &c.
BATH (DREWE'S QUARRY), Monkton Farleigh, near Bath.	Wade Brown, Esq., Monkton Farleigh.	Chiefly carbonate of lime, in oolitic grains of moderate size.	Cream.	122 10	120 to 125 ft. Several beds, the deepest about 4 ft. 2 in. thick.	0 6	1 10	Buckingham New Palace; St. James's Square, Bath.
CRANMORE, near Doulting, Wiltshire.	- -	Carbonate of lime, with a few oolitic grains, and an abundance of small shells, commonly in fragments, often crystalline.	Light brown.	131 4	Of large size. The thickest beds will work 20 in.	0 7	- -	Cathedral of Wells, Glastonbury Abbey, &c.
HAYDOR, near Grantham, Lincolnshire.	John Archer Houblon, Esq., near Bishop's Stortford.	Carbonate of lime, with oolitic grains, often crystalline.	Brownish cream.	133 7	14 ft. × 3 ft. × 4 ft.	0 8	2 4	Lincoln Cathedral, Boston Church, Grantham Church, Newark Church, and most of the churches in the neighbourhood, and in the lower part of Lincolnshire; Culverthorpe House, Belvoir Castle, &c.
KETTON, in Rutlandshire, near Stamford.	Lord Northwick.	Oolitic grains of moderate size, slightly cemented by carbonate of lime.	Dark cream colour.	128 5	Up to 100 ft., beds vary very much: one 3 ft. 6 in. thick, called rag.	1 9	3 4	Cambridge, Bedford, Bury St. Edmund's, Stamford, London, &c.; many of the ancient and modern buildings at Cambridge; also in the modern works of Peterborough and Ely Cathedral, and at St. Dunstan's New Church, in London.
PORTLAND (TRADE QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.

OOLITIC STONES — *continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.

PORTLAND (KING BARROW EAST END QUARRY) adjoining WAYCROFT, Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (VERN-STREET QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	134 10 top bed.	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (CASTLE'S QUARRY), Island of Portland.	Messrs. Weston.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 3	Various public buildings in London.
PORTLAND (WAYCROFT QUARRIES). Island of Portland.	The Crown, on lease to Messrs. Stewards and Co.	Oolitic carbonate of lime, with disseminated fragments of shells.	Whitish brown.	135 8 top bed.	Any practicable size.	1 4½	2 3	Goldsmiths' Hall, Reform Club House, and other public buildings in London.
PORTLAND (MAGGOTT QUARRY).	The Crown, on lease to Messrs. Stewards and Co.	Oolitic carbonate of lime, with fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 2	Various public buildings in London.
PORTLAND (GOSLING'S QUARRY).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with fragments of shells.	Whitish brown.	126 13 Roach	Any practicable size.	1 4½	2 3	Several public buildings in London.
PORTLAND (GROVE QUARRY BEVERS).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with numerous fragments of shells.	Whitish brown.	147 10 best bed. 145 9 carf.	Any practicable size.	1 4½	2 3	St. Paul's Cathedral, and several churches in London, built during the reign of Queen Anne.
PORTLAND (GROVE QUARRY, RED CROFT).	Messrs. Stewards and Co.	Oolitic carbonate of lime, with a few fragments of shells.	Whitish brown.	- -	Any practicable size.	1 4½	2 0	St. Paul's Cathedral, and many churches in London, of Queen Anne's reign.

Of the Portland stones, it is to be observed generally, that the dirt bed is full of fossil roots, trunks, and branches of trees, in the position of their former growth. The top cap is a white, hard, and closely compacted limestone. The skull cap is irregular in texture, and is a well-compacted limestone. The roach beds are always incorporated with the freestone beds, that invariably lie below them, and are full of cavities formed by the moulds of shells and the like. The top bed is the best stone, the bottom one ill cemented, and will not stand the weather. A middle or curf bed occurs only in the southernmost quarries on the east cliff: it is soft to the north, and hard to the south. The good workable stone in the east cliff quarries is generally less in depth than in the same bed in the west cliff quarries, but the east cliff stone is harder, more especially to the south of the island. The stone, even in the same quarries, varies considerably. That which contains flints will not stand the weather. The bottom bed on the west cliff is not a durable stone, though sold as a good stone in the London market. The best stone is in the north-eastern part of the island; the worst in the south-western part. The annual consumption of the whole of the quarries in the island is equal to an area of one acre of the good workable stone, or about 24,000 tons. The entire area unworked is about 2000 acres. There are 56 quarries in the island, and about 240 quarrymen employed, of which number Messrs. Stewards employ usually about 138. (See Subsection 1666*f. et seq.*)

OOLITIC STONES—*continued.*

Name of Quarry, and where situated.	Proprietor of Quarry.	Component Parts of Stone.	Colour.	Weight of a Cubic Foot in its ordinary State.	Weight of Block, and the Thickness procurable.	Price per Cubic Foot at the Quarry.	Price per Cubic Foot, delivered in London.	Where used.

Taynton, or Teynton, near Burford, Oxon.	Lord Dynevor.	Carbonate of lime, partly oolitic and friable, with very small fragments of shells, irregularly laminated.	Streaky brown.	135 15	Any practicable size. Thickest bed, about 7 ft.	0 10 to 1 0	2 4	Blenheim, Cornbury Park, Barrington Park, the interior of St. Paul's and many other churches in London and Oxford, and in various bridges in Oxfordshire.
Wass, near Thirsk, Yorkshire.	Martin Stapleton, Esq.	Compact carbonate of lime, with oolitic grains and an argillo-calcareous cement; carbon disseminated.	Brown.	141 11 soft. 162 8 hard.	Beds variable, about 16 in.	- -	- -	West front and a large proportion of Byland Abbey.
Windrush, near Burford, Gloucestershire.	Lord Shelburne.	Fine oolitic grains, with calcareous cement, and a few fragments of shells.	Cream.	118 2 soft. 135 15 hard.	5 to 40 ft. Thickest bed, 2 ft. 6 in.	0 8	2 7	Windrush Church, Barrington House, and all the old buildings within many miles of the quarry.

1665. The following very useful enumeration of the stones used in buildings of the island, arranged under that head, and divided into the sorts of stone employed in them, we add, *verbatim*, from the Report which we have so much used. The heads are under Sandstone buildings, Limestone buildings, and Magnesian Limestone buildings.

SANDSTONE BUILDINGS.

Bakewell, Derbyshire. The houses generally are of sandstone, and in fair condition. A new bank now erecting of sandstone from Bakewell Edge.

Bakewell Church (14th century), of a sandstone of the vicinity, very much decomposed.

Barnard Castle, Durham (14th century). Circular keep, apparently of Stenton stone, in excellent condition. In modern works, the Joint Stock Bank and Market-house of Stenton stone, in good condition.

Belper New Church, Derbyshire. Built 10 years since, of sandstone from Hungerhill, in an incipient state (in parts) of decomposition.

Blandford Parish Church, Dorsetshire (1769). Of a green siliceous fine-grained sandstone, the dressings being of a stone similar to the Portland oolite; the former much decomposed; the latter in very good condition. Town Hall, about 80 years old, of stone similar to the Portland oolite, in good condition.

Brancepeth Castle, Durham. Of ancient date, of sandstone of the vicinity; recently restored extensively; older parts in various states of decomposition.

Briavel's, St., Castle, Gloucestershire. In ruins (13th or 14th century). Entrance gateway (the chief remains of the castle) built of red sandstone, decomposed.

Bristol Cathedral (13th and 14th centuries). Built of red sandstone and a yellow limestone (magnesian?) strangely intermixed; the red sandstone in all cases decomposed, the limestone more rarely decayed; the tracery, &c. of the windows, which are of the limestone, are in good condition; but the pinnacles and other dressings, which are of the same material, are much decomposed. The east end of the cathedral is a remarkable instance of the decay and preservation of the two stones employed. Norman gateway, west of the cathedral (the upper part of the 15th century); the Norman archway and its enrichments, which are of a very florid character, built of yellow limestone (magnesian?), in excellent condition.

Byland Abbey (12th century). In part of a siliceous grit (principally in the interior), and in part (chiefly on the exterior) of a compact oolite, from the Wass quarries in the vicinity. The west front, which is of the oolite, is in perfect condition, even in the dog's-teeth and other florid decorations of the doorways, &c. This building is *covered generally* with lichens.

Carlisle. Ancient buildings: Cathedral (13th century), of red sandstone, in various states of decomposition. Modern buildings: Many of red sandstone, more or less in a state of decomposition.

Castle Howard, Yorkshire. Built generally of a siliceous fine-grained sandstone from the park; generally in good condition, but in some parts, such as the parapets, cupolas, and chimney shafts, much decomposed. The pilasters of the north front from a quarry at Appleton; in good condition, except where subjected to alternations of wet and dry, as in the plinths, where there are signs of decomposition. The stables are of Appleton stone, and in good condition.

Chatsworth House, Derbyshire. Original house built of Bell Crop sandstone from Bakewell Edge, not in very good condition, particularly in the lower parts of the building. In the recent additions the same stone is employed, together with that of Bailey Moor and Lindrop Hill.

Chepstow Castle, Monmouthshire (11th and 12th centuries, with additions of the 14th century). Of mountain limestone and old red sandstone; the former in good condition; the latter decomposed. Dressings of doors, windows, archways, and quoins are for the most part of magnesian limestone, in perfect condition; the remainder is of red sandstone, and is generally much decomposed. Chapel (of the 12th century); mouldings and carvings of the windows, &c., which are of magnesian limestone, are in perfect condition.

Coxwold Church, Yorkshire (15th century). Generally of fine siliceous grit of the vicinity, and in part of a calcareous nature. Tower in good condition; porch decomposed; lichens abundant on the north side.

Derby. St. Peter's Church (13th century), of the variegated coarse sandstone of the vicinity, similar to that of Little Eaton. The whole in bad condition; but the red stones less so than the grey or white. St. Almund's Church (of the 14th century), of a coarse sandstone of the vicinity, in a very decomposed state, to the obliteration of the mouldings and other details; it has lately been scraped and painted, to preserve it from further destruction. All Saints Church (tower of the 15th century), of sandstone, similar to that of Duffield Bank, partly in fair condition, and partly much decomposed, particularly the great western entrance. The body of the church, built 110 years since, of sandstone, in part decomposing. Modern buildings: Town Hall, of sandstone from Morley Moor, built a few years since, in very good condition.

Durham Cathedral (11th and 12th centuries). Of a sandstone of the vicinity, elected indiscriminately, and in all stages of decomposition; few stones are quite perfect. Castle (of the 11th century). Of similar stone, and in a similar state.

Easby Abbey, Yorkshire (13th and 14th centuries). Of sandstone of the vicinity; mouldings and carvings decomposed and in part obliterated. Walls built very rudely, and in various states of decomposition; some parts, however, maintain their original surface.

Eccleston Abbey, Yorkshire (13th century). Of stone similar to that of the Stenton quarry. The mouldings and other decorations, such even as the dog's-teeth enrichments, are in perfect condition.

Edinburgh. Ancient buildings: Holyrood Chapel (12th century), of sandstone from the vicinity, in part much decomposed; in other parts, such as the west door, almost perfect. The palace (built in the 16th and 17th centuries) of similar stone, generally in good condition, the older parts being slightly decomposed. The oldest part of the Tron Church (1641), of sandstone, much decomposed. A house on the Castle Hill (1591), of sandstone, only slightly decomposed.

Modern buildings, wholly erected of sandstones from the Cragleith, Red Hall, Humbie, and Binnie quarries, for the most from the first-mentioned quarry. None of them exhibit any appearance of decomposition, with the exception of ferruginous stains, which are produced upon some stones. Among the oldest is the Registry Office, which is of Cragleith stone, and built above sixty years since; it is in a perfect state.

Fountain's Abbey, Yorkshire (11th and 12th centuries, with additions of the 16th century). Of coarse sandstone of the vicinity, generally in bad condition, particularly the west front, which is much decomposed. The nave and transept, which are the earliest portions of the building, are the best preserved.

Fountain's Hall, Yorkshire (1677). Of sandstone of the vicinity, and magnesian limestone in the dressings. The whole in fair condition.

Forest of Dean, Gloucestershire. Park End new church, built fifteen years since, of sandstone, similar to that of Colford. No appearance of decomposition.

Glasgow. Ancient buildings: High Church (12th century), sandstone of the vicinity, generally very much decomposed, particularly on the south side Old quadrangle of the College (James II.), of sandstone, decomposed.

Modern buildings: Hunterian Museum (1804); superstructure said to be of stone from the President quarry; slight traces of decomposition on the south-west front. The basement of another sandstone, in a more advanced state of decomposition; other parts of the building are in an almost perfect state. The other buildings are generally erected of stone from the Giffneuch and other quarries in the immediate neighbourhood, except the new Exchange buildings, which are of stone from the Humbie quarry, thirty miles from Glasgow, recently erected, in which there are not any apparent symptoms of decomposition.

Gloucester Cathedral (Norman for the greater part, altered and cased in the 15th century), built of a fine grained and ill-cemented oolite, a shelly oolite, and a red sandstone (north side) intermixed, of which the former constitutes the greater portion. The tower (15th century), of shelly oolite, in perfect condition. The early turrets of the south transepts are also in good condition. The body of the building is much decomposed. The great cloister is built of the same materials as the cathedral. The moulded and decorated work is in good condition, the other parts are more or less decomposed. The small cloister is built of a fine oolite with a compact cement, and is in good condition. The New Bridge, of Whitchurch sandstone, parapets of Ruordean fine-grained sandstone, in good condition.

Haddon Hall, Derbyshire (15th and 16th centuries). Of a fine-grained sandstone, similar to that of Lindrop Hill. The dressings, parapets, chimney shafts, quoins, &c. are wrought and rubbed; the remainder of the walls is of rough walling. The whole in fair condition.

Harrowgate. Cheltenham Pump Room, of sandstone from Woodhouse, near Leeds. Built recently. In good condition. Swan Hotel and other modern buildings, of a coarse sandstone of the vicinity; generally in good condition.

Hardwicke Hall, Derbyshire. (1597). Of a fine-grained sandstone, chiefly from a quarry in the hill on which the house is built, intermixed with a calciferous grit, similar to that of Mansfield; generally in good condition. The ashler is in parts decomposed, especially where it is set on edge.

Howden Church, Yorkshire (15th century); partly of magnesian limestone, of a deep yellow colour, and partly of a coarse siliceous grit, of a ferruginous colour. Dressings and enrichments and the central tower are of the former stone; generally decomposed, particularly at the top of the tower. The other parts of the building, which are of the grit, are very much decomposed.

Kirkstall Abbey, Yorkshire (11th century). Of coarse sandstone of the vicinity, in various stages of decomposition according to the aspect. The east side is in fair condition; some of the zig-zag enrichments and early capitals and other enrichments of mouldings are in perfect condition. The windows of the chancel and tower (inserted in the 16th century) of a yellow sandstone, are for the most part gone, and what remains is much decomposed.

Mansfield Town Hall, Nottinghamshire. Built three years since, of magnesio-calciferous sandstone from Mansfield: no appearance of decomposition.

Newcastle-upon-Tyne. Ancient buildings: St. Nicholas' Church (14th century), of sandstone of the vicinity, similar to that of the Heddon Quarry, very much decomposed. Parts restored within the last century, with the same stone, now decomposing. The upper part of the tower and spire restored within the last five years, and painted to preserve the stone from decay. Other ancient buildings, of the same stone, more or less in a state of decomposition, according to the date of their erection.

Modern buildings, built within the last 25 years, of sandstone from the Felling and Church quarries at Gateshead and the Kenton quarry: parts already show symptoms of decomposition.

Pontefract Castle, Yorkshire (14th century). Built generally of a coarse grit, of a dark brown colour, occasionally mixed with an inferior magnesian limestone. The whole in a very decomposed state, more particularly the sandstone, in which all traces of the original surface are effaced. Fragments of magnesian limestone are embedded in several parts of the walls, with mouldings of the 12th century, in perfect condition.

Raby Castle, Durham (14th century). Of sandstone of the vicinity: parts in a perfect state, others slightly decomposed.

Richmond Castle, Yorkshire (11th century). The keep, of sandstone, similar to that of Gatherly Moor, generally in good condition; mouldings and carvings in columns of window in a perfect state.

Ripon, Yorkshire. An obelisk in the market-place (1781), of coarse sandstone, much decomposed in laminations parallel to the exposed faces.

Ripon Cathedral. Lower part, east end, and south-east angle (Norman), of coarse sandstone of the vicinity, in good condition. The west front, the transepts, and tower (of the 12th and 13th centuries), of the coarse sandstone of the vicinity, in fair condition. The mouldings, although generally decomposed, are not effaced. The dog's-teeth ornaments in most parts nearly perfect. The aisles of the naves, the clerestory, and the choir (of the 14th and 15th centuries), of coarse sandstone and magnesian limestone intermixed, not in good condition; the latter stone, on the south side, often in fair condition. The lower parts of the building generally, but particularly the west fronts, which are of coarse sandstone, are very much decomposed.

Rivaulx Abbey, Yorkshire (12th century). Of a sandstone at Hollands, one mile from the ruins; generally in excellent condition. West front slightly decomposed; south front remarkably perfect, even to the preservation of the original toolmarks.

Shaftesbury, Dorsetshire. St. Peter's Church (15th century). Of a green siliceous sandstone, from quarries half a mile south of the church. The whole building much decomposed. The tower is bound together by iron, and is unsafe, owing to the inferior quality of the stone.

Spofforth Castle, Yorkshire (14th century). Of coarse red sandstone; more or less, but generally much, decomposed. The dressings of the windows and doors, of a semi-crystalline magnesian limestone, are in perfect state, the mouldings and enrichments being exquisitely sharp and beautiful.

Tintern Abbey (13th century). Considerable remains of red and grey sandstones of the vicinity, in part laminated. In unequal condition, but for the most part in perfect condition; covered with grey and green lichens.

Tisbury Church (13th and 14th centuries; the lower part of the tower of the 12th century). Of calciferous limestone from Tisbury. The dressings are composed of stone throughout, in perfect condition. The ashlar variable; in part much decomposed; the undecomposed portions are covered with lichens. Tombstones in the churchyard generally in good condition, some being more than a century old. The houses of the village built generally of the Tisbury stone, and are in very good condition. The whole covered with lichens.

Wakefield Parish Church, Yorkshire (tower and spire of the 16th century). Of sandstone, much decomposed. The body of the church, of recent date, of sandstone strongly laminated, and generally decomposed between the laminæ.

Whitby Abbey (13th century). Of stone similar to that of Aislaby Brow, in the vicinity; generally in good condition, with the exception of the west front, which is very much decomposed. The stone used is of two colours, brown and white; the former, in all cases, more decomposed than the latter. The dog's-teeth and other enrichments in the east front are in good condition.

LIMESTONE BUILDINGS.

Bath. Abbey church (1576), built of an oolite in the vicinity. The tower is in fair condition. The body of the church, in the upper part of the south and west sides, much decomposed. The lower parts, formerly in contact with buildings, are in a more perfect state; the reliefs in the west front of Jacob's ladder are in parts nearly effaced. Queen's Square, north side, and the obelisk in the centre, built above 100 years since, of an oolite with shells, in fair condition. Circus (built about 1750), of an oolite in the vicinity, generally in fair condition, except those portions which have a west and southern aspect, where the most exposed parts are decomposed. Crescent (built above 50 years since), of an oolite of the vicinity, generally in fair condition, except in a few places, where the stone appears to be of inferior quality.

Bristol Cathedral (of the 13th and 14th centuries). Built of red sandstone and apparently a yellow limestone (magnesian?) strangely intermixed. The red sandstone in all cases decomposed; the limestone more rarely decayed. The tracery, &c. of the windows, which are of the limestone, are in good condition, but the pinnacles and dressings of the same material much decomposed. The east end of the cathedral is a remarkable instance of the decay and preservation of the two stones employed. Norman gateway, west of the cathedral (the upper part of the 15th century), the Norman archway and its enrichments, which are of a very florid character, built of yellow limestone (magnesian?), in excellent condition.

———, St. Mary Redcliffe (tower of the 12th century; body of the church of the 15th century). Of oolitic limestone, from Dundry; very much decomposed.

Burleigh House (15th century). Of a shelly oolite (Barnack rag), in excellent condition throughout. The late additions are of Ketton stone.

Byland Abbey, Yorkshire (12th century). In part of a siliceous grit (principally in the interior), and in part (chiefly on the exterior) of a compact oolite, from the Wass quarries in the vicinity. The west front, which is of the oolite, is in perfect condition, even in the dog's-teeth and other florid decorations of the doorways, &c. This building is generally covered with lichens.

Colley Weston Church, Northamptonshire (14th century). Of a shelly oolite (Barnack rag), in perfect condition throughout.

Dorchester. St. Peter's Church (15th century). Of laminated oolite, somewhat similar to that of Portland, and of a shelly limestone, somewhat resembling that of Hamhill. The latter used in pinnacles, parapets, and dressings. The whole in a decomposed state.

Glastonbury — Abbey. Joseph of Arimathea's Chapel. Considerable ruins; Norman, of shelly limestone, similar to that of Doulting; generally in good condition; the zig-zag and other enrichments perfect; the capitals of the columns, corbels, &c. are of blue lias, much decomposed, and in some cases have disappeared. The *Church.* Considerable remains of the choir, and a small portion of the nave (11th century), of shelly limestone, similar to that of Doulting, in good condition. *St. Benedict's Parish Church* (14th century). Of limestone, similar to that of Doulting, in good condition. *St. John the Baptist's Parish Church* (15th century). Of stone similar to that of Doulting, generally in fair condition.

Glocester — Cathedral, (Norman for the greater part, altered and cased in the 15th century). Built of a fine-grained and ill-cemented oolite, a shelly oolite, and a red sandstone (north side) intermixed, the former constituting the greatest portion of the edifice. The tower (15th century), of shelly oolite, in perfect condition. The early turrets of the south transept are also in good condition. The body of the building is much decomposed. The great cloister is built of the same materials as the cathedral. The moulded and decorated work is in good condition; the other parts are more or less decomposed. The great cloister is built of a fine oolite, with a compact cement, and is in good condition. *St. Nicholas's Church* (body Norman; tower and spire, 15th century), of a shelly and inferior kind of oolite intermixed, and in unequal condition. *St. Michael's Church* (15th century), built of same stone as that of St. Nicholas, and in the same condition.

Grantham Church (13th century). Lofty tower and spire at the west end. Built of an oolite, similar to that of Ancaster, in good condition, more especially the tower, except as to some portions of the base mouldings.

Ketton Church, Rutlandshire. (West entrance door, Norman; tower of the 12th or 13th century; nave, aisles, and chancel of the 14th century). Of a shelly oolite (Barnack rag), in good condition. Dog's-teeth, carved corbels, and other enrichments in a perfect state.

Kettering Church (14th and 15th centuries). Of a shelly oolite, fine-grained, the greater portion resembling Barnack rag. The tower and spire in perfect condition. The body of the church in parts slightly decomposed.

Kirkham Priory, Yorkshire (13th century). Inconsiderable remains. The western front and great entrance slightly decomposed throughout; the portions which remain of the body of the church very perfect, but many of the stones are much decomposed. The stone is very similar to that of the Hildenly quarry. The whole is covered with lichens.

Lincoln Cathedral (the minster generally of the 12th and 13th centuries). Of oolitic and calcareous stone of the vicinity; generally in fair condition, more especially the early portions of the west front. The ashler and plain dressings of the south front are, however, much decomposed. The mouldings and carvings of the east front are in a perfect state. *Roman Gate*, of a ferruginous oolite, in fair condition. *The Castle Gateway* (13th century), of an oolitic limestone; ashler much decomposed, dressings perfect.

Melton Old Church, Yorkshire (12th century). Light semi-compact limestone, similar to that of the Hildenly quarry; generally in good condition, particularly the great west door (of the 11th century), where the zig-zag and other enrichments are perfect. Some stones are much decomposed.

Montacute, Somersetshire — Parish Church (15th century). Of Hamhill stone, in perfect condition, covered with lichens. The Abbey (15th century). Supposed abbot's house and gateway, of Hamhill stone, in good condition. *Montacute House* (17th century), of Hamhill stone, in excellent condition.

Martock Church, Somersetshire (15th century). Of a shelly ferruginous brown limestone from Hamhill, in good condition, except the plinth and base mouldings, which are much decomposed. Covered with lichens.

Newark Church (15th century; the tower, in part, of the 12th century). Of an oolite, similar to that of Ancaster; generally in fair condition, with the exception of parts of the base mouldings. The building is covered with a grey lichen. *The Castle* (Norman, with additions in the 15th century). Chiefly of sandstone of the vicinity; in unequal condition. A large portion of the dressings of the windows, &c. are of oolite.

probably from Ancaster. *Town Hall* (50 or 60 years old). Built of the Ancaster oolite; in good condition; in some blocks, however, there is an appearance of lamination, where decomposition has to a slight extent taken place.

OXFORD CATHEDRAL, Norman (12th century). Chiefly of a shelly oolite, similar to that of Taynton; Norman work in good condition, the latter work much decomposed. *Merton College Chapel* (13th century). Of a shelly oolite, resembling Taynton stone; in good condition generally. *New College Cloisters* (14th century). Of a shelly oolite (Taynton), in good condition. The whole of the colleges, churches, and other public buildings of Oxford, erected within the last three centuries, are of oolitic limestone from Heddington, about one mile and a half from the university, and are all, more or less, in a deplorable state of decomposition. The plinth, string-courses, and such portions of the buildings as are much exposed to the action of the atmosphere, are mostly of a shelly oolite from Taynton, fifteen miles from the university, and are universally in good condition.

PAUL'S, ST., CATHEDRAL, LONDON (finished about 1700). Built of Portland oolite, from the Grove quarries on the east cliff. The building generally in good condition, especially the north and east fronts. The carvings of flowers, fruit, and other ornaments are throughout nearly as perfect as when first executed, although much blackened; on the south and west fronts, larger portions of the stone may be observed of their natural colour than on the north and east fronts, occasioned by a very slight decomposition of the surface. The stone in the drum of the dome, and in the cupola above it, appears not to have been so well selected as the rest; nevertheless scarcely any appreciable decay has taken place in those parts.

PICKERING CHURCH, Yorkshire (13th and 14th centuries). Oolite rock of the neighbourhood; very much decomposed; the windows, mullions, and buttress angles obliterated.

PICKERING CASTLE (14th century). The walls of the oolite of the neighbourhood, and the quoins of a siliceous grit. The whole in fair condition.

PORTLAND, Dorsetshire — New Church (built 1766), of Portland oolite, fine roach; in a perfect state, still exhibiting the original tool marks. Wakeham Village, Tudor House, of Portland oolite, in excellent condition. *Old Church*, in ruins, near Bow and Arrow Castle (15th century), of Portland oolite, resembling top bed; in very good condition; original chisel marks still appear on the north front. *Bow and Arrow Castle.* Considerable remains of the keep, many centuries old, of Portland oolite; the ashlar resembles the top bed, and is in perfect condition; the quoins and corbels of the machicolated parapet appear to be of the cap bed of Portland oolite, and are in good condition.

SALISBURY CATHEDRAL (13th century). Of siliciferous limestone from Chilmark quarry. The entire building is in excellent condition, except the west front, which in parts is slightly decomposed. The building generally covered with lichens.

SANDYSFOOT CASTLE, near Weymouth (temp. Hen. VIII.). Considerable remains of keep, chiefly of Portland oolite, partly of the top bed and partly of the fine roach; generally in excellent condition, with the exception of a few and apparently inferior stones. The inside ashlar of the walls is of large-grained oolite, apparently from the immediate vicinity of the castle, much decomposed.

SOMERTON CHURCH, Somersetshire (14th century). Built chiefly of blue lias; the quoins, buttresses, parapets, and other dressings of a coarse ferruginous shelly limestone, in various stages of decay. The parapet of the clerestory of a lighter-coloured stone, in good condition.

STAMFORD — St. Mary's Church (13th century). Of a shelly oolite (Barnack rag), in fair condition. *St. John's Church* (14th century). Of similar stone, ill selected, and consequently decomposed in parts and in laminations, according to the direction of the beds of shells. *St. Martin's Church* (14th century). Of similar stone, in good condition. *All Saints* (lower part of the body of the church 13th century; the remainder 15th century). Tower and spire in fine condition; body of the church decomposed. *Standwell's Hotel*, built twenty-four years since of an oolite similar to that of Ketton; in perfect condition. *St. Michael's New Church.* Built four years since; no appearance of decomposition.

WELLS, THE CATHEDRAL. West front (13th century), upper part of tower (14th century), of shelly limestone, similar to that of Doulting, generally decomposed, but not to any great extent. North flank (porch and transept 13th century, the remainder of the 14th century), of similar stone, in good condition, except lower part of flank and west tower. The central tower (of the 14th century) in very good condition. South side of the cathedral generally in good condition. *Chapter House* (13th century, with additions of the 15th century). The whole in good condition excepting the west front of the gateway, which is decomposed. Close gates (15th century) much decomposed, but especially on the south and south-west. The cloisters (15th century) generally decomposed, particularly the mullions and tracery.

Westminster Abbey (13th century). Built of several varieties of stone, similar to that of Gatton or Ryegate, which is much decomposed, and also of Caen stone, which is generally in bad condition; a considerable portion of the exterior, especially on the north side, has been restored at various periods, nevertheless abundant symptoms of decay are apparent. The cloisters, built of several kinds of stone, are in a very mouldering condition, except where they have been recently restored with Bath and Portland stones. The west towers, erected in the beginning of the 18th century with a shelly variety of Portland oolite, exhibit scarcely any appearance of decay. Henry the Seventh's Chapel, restored about twenty years since with Combe Down Bathstone, is already in a state of decomposition.

Windrush Church (15th century). Of an oolite from the immediate vicinity; in excellent condition. A Norman door on the north side, enriched with the bird's-beak and other characteristic ornaments, is in perfect condition. Tombstones in the churchyard, very highly enriched and bearing the dates of 1681, 1690, apparently of Windrush stone, are in perfect condition.

Wyke Church, Dorsetshire (15th century). Of oolite, similar to Portland, the whole in good condition, except the mullions, tracery, and dressings of doors and windows, which are constructed of a soft material, and are all decomposed. On the south side, the ashler is in part covered with rough-cast. The entire building is thickly covered with lichens.

MAGNESIAN LIMESTONE BUILDINGS.

Beverley, Yorkshire. The minster (12th, 13th, and 14th centuries), of magnesian limestone from Bramham Moor, and an oolite from Newbold; the former, which is used in the west tower, central tower, and more ancient parts of the minster, generally in good condition; but in other parts of the building the same material is decomposed. The Newbold stone, chiefly employed on the east side, is altogether in a bad condition. Some of the pinnacles are of Oulton sandstone, and are in bad condition. The building is partly covered with lichens. *St. Mary's Church* (14th century), now in course of restoration, of magnesian limestone and oolite, supposed to be from Bramham Moor and Newbold, respectively. The ancient parts are in a very crumbling state, even to the obliteration of many of the mouldings and enrichments.

Bolsover Castle, Derbyshire (1629). Mostly in ruins; of magnesian limestone of several varieties, and of a calcareous fine-grained sandstone. The dressings, which are generally of sandstone, are much decomposed, in some instances to the entire obliteration of the mouldings and other decorations, and to the destruction of the form of the columns, rustications, &c. Most of the string courses, a portion of the window dressings, and the ashler, which are of magnesian limestone, are generally in excellent condition.

Bolsover Church, Derbyshire (15th century). Of a magnesio-calciferous sandstone, more or less in a decomposed state throughout.

Chepstow Castle, Monmouthshire (11th and 12th centuries, with additions of the 14th century). Of mountain limestone and old red sandstone; the former in good condition, the latter decomposed. Dressings of door, window, archway, and quoins are for the most part of magnesian limestone, and in perfect condition. The remainder is of red sandstone, and is generally much decomposed. Chapel (of the 12th century), mouldings and carvings of windows, &c., which are of magnesian limestone, in perfect condition

Doncaster (Old) Church (15th century). Of an inferior magnesian limestone, generally much decomposed, more especially in the tower, and on the south and west sides; now under general and extensive repair.

Hemingborough Church, Yorkshire (15th century). Of a white crystalline magnesian limestone. The entire building is in a perfect state, even the spire, where no traces of decay are apparent.

Howden Church, Yorkshire (15th century). Partly of magnesian limestone of a deep yellow colour, and partly of a coarse siliceous grit of a ferruginous colour. Dressings and enrichments, and the central tower, are of the former stone, generally decomposed, particularly at the top of the tower. The other parts of the edifice, built of the grit, are very much decomposed.

Huddlestone Hall, Yorkshire (15th century). Of semi-crystalline magnesian limestone from the neighbouring quarry. In excellent condition, even to the entire preservation of the mouldings of the chapel window in the south-west front. The outer gate piers in the fence wall, also of magnesian limestone, very much decomposed.

Knaresborough Castle, Yorkshire (12th century). Magnesian limestone, carious in part;

generally in very good condition, except on the south and south-west portions of the circular turrets, where the surface is much decomposed. The mouldings generally are in a perfect state. The joints of the masonry, which is executed with the greatest care, are remarkably close. The stone of the keep, which is of a deep brown colour, and much resembles sandstone, is in good condition, especially on the south-west side.

Koningsborough Castle, Yorkshire (Norman). Coarse-grained and semi-crystalline magnesian limestone, from the hill eastward of the castle; in perfect condition. The masonry is executed with great care, the joints very close, but the mortar within them has disappeared.

Ripon Cathedral. Lower part, east end, south-east angle (Norman), of coarse sandstone from the vicinity, in good condition. The west front, the transepts, and tower (of the 12th and 13th centuries), of coarse sandstone of the vicinity, in fair condition. The mouldings, although generally decomposed, are not effaced. The dog's-teeth ornament in most parts nearly perfect. The aisles of the nave, the clerestory, and the choir (of the 14th and 15th centuries), of coarse sandstone and magnesian limestone intermixed, not in good condition. The latter stone, on the south side, often in fair condition. The lower parts of the building generally, particularly the west fronts, which are of coarse sandstone, are much decomposed. An obelisk, in the market-place (1781), of coarse sandstone, is much decomposed, and in laminations parallel to the exposed faces.

Robin Hood's Well, Yorkshire (1740). A rusticated building, of magnesian limestone, in perfect condition.

Roche Abbey, Yorkshire (12th century). Inconsiderable remains, of semi-crystalline magnesian limestone from the neighbouring quarry, generally in fair condition. The mouldings and decorated portions are perfect. Gate-house (12th century) generally decomposed, with the exception of the dressings and mouldings, which are perfect.

Selby Church, Yorkshire (nave and lower part of the tower of the 11th century; the west front and aisles of the 12th century; and the choir with its aisles of the 14th century). The Norman portion of the building, which is of grey magnesian limestone, is in excellent condition, particularly the lower part. The early English portions of the building are also of magnesian limestone, and in a partially decomposed state. The later portions of the building, which also are of magnesian limestone, are much decomposed and blackened.

Southwell Church, Notts (of the 10th century). Of magnesian limestone, similar to that of Bolsover Moor, in perfect condition. The mouldings and enrichments of the doorway appear as perfect as if just completed. The choir, which is of the 12th century, and built of a stone similar to that of Mansfield, is generally in good condition.

Spofforth Castle, Yorkshire (14th century). Of coarse red sandstone, generally much decomposed. The dressings of the windows and doors, of a semi-crystalline magnesian limestone, are in a perfect state, the mouldings and enrichments being eminently sharp and beautiful.

Studley Park, Yorkshire. Banquetting house, about 100 years old, of yellowish magnesian limestone, in perfect condition.

Thorpe Abbey Village. The houses generally of this village are built of magnesian limestone from the vicinity; they are in excellent condition, and of a very pleasing colour.

Thorpe Salvin, near Worksop. Manor-house (15th century), in ruins. Of a siliciferous magnesian limestone and a sandstone, in unequal condition; the quoins and dressings are generally in a perfect state. *Parish Church* (15th century), also of a siliciferous variety of magnesian limestone and a sandstone, in unequal but generally fair condition. A Norman doorway under the porch is well preserved.

Tickhill Church, Yorkshire, (15th century). Of magnesian limestone, in excellent condition. The lower part of the tower (of the 12th century) also in fair condition.

York. *Ancient Buildings:* Cathedral (transepts, 13th century; tower, nave, &c., 14th century). Of magnesian limestone, from Jackdaw Craig. West end and towers restored thirty years since; they are generally in fair condition, but some of the enriched gables and other decorations are obliterated. The transepts are in many places much decomposed, especially in the mouldings and enrichments. The central tower is generally in good condition, but several of the enriched parts are decomposed. *St. Mary's Abbey* (12th century), of magnesian limestone. West front of the church generally much decomposed; the north flank in better condition, but in parts much decomposed. The gateway, which is of Norman origin, is in fair condition. *Roman Multangular Tower.* Built of small stones; such as are of magnesian limestone are in good condition. *St. Denis's Church.* Norman doorway, of magnesian limestone; south side highly enriched with zig-zag and other ornaments; the columns are gone; the parts which remain are in good condition. *St. Margaret's Church* (15th century), of magnesian limestone; east front much exposed, and in good condition. The porch is of Norman date, and has been reconstructed; four bands of enrichment in the head, in tolerably fair condition, but many stones, particularly those of a deep yellow brown colour, are much decomposed. *The other churches of York* (which are of the 14th and 15th centuries) are built of magnesian limestone, and are generally in an extremely decomposed state; in many instances all architectural detail is obliterated. *Modern Buildings:* THE MUSEUM, of Hackness sandstone, built nine years since, much decomposed wherever it is subject to the alternation of wet and dry, as at the bottom of the columns of the portico, plinth, &c. THE CASTLE (recently erected); the plinth of the boundary wall (which is of Bramleyfall sandstone) already exhibits traces of decomposition. *York Savings Bank.* Huddersfield stone (?), in good condition.

WORKSOP CHURCH (principally of the 13th century), of a siliciferous variety of magnesian limestone and of a sandstone; in very unequal condition. Some parts are very much decomposed, whilst others are in a perfect state.

TABLE OF THE CHEMICAL ANALYSIS OF SIXTEEN SPECIMENS OF STONE.

	Sandstones.					Magnesian Limestones.				Oolites.				Limestones

1666. In the above table the names of the quarries are inserted under the general divisions of the different species of stone, and the specimens were considered as fair average samples of the workable stone in such quarries. The experiments were conducted by Messrs. Daniel and Wheatstone. As a conclusion to the report, it may be satisfactory to name the actual stones used in the construction of the first portions (1840) of the Houses of Parliament. The foundation was laid with Penryn granite, rising to the level of the ground, therefore but little seen. Above it is Fog-tor granite from Dartmoor. A small portion only of the superstructure, to the top of the basement windows, was built with Bolsover Moor stone from near Chesterfield; after which Anston stone was used for the remainder of the outside works. In the interior, Painswick and Caen stones have been employed; St. Stephen's crypt is of Beer stone. It has been asserted that had Government employed a supervision at the quarries to prevent imperfect blocks being sent up to London, the present unsightly appearance of many parts of the building would not have resulted.

1666*a* In *par.* 1500–1502 is supplied tables of the *crushing weights* of many of the stones herein mentioned. Hereto is added a further table of the *weights* of a large number of building stones, taken from the one prepared by the late C. H. Smith for R. Hunt's *Mineral Statistics of the United Kingdom, &c.* Part II for 1858, published 1860; it was also given in the *Transactions* of the Institute of British Architects, 1859-60.

1606*b*. Table of the Weights of Building Stones, (in Continuation).

Name of Quarry.	Post Towns.	Weight per cubic foot avoirdupois. lb. oz.
Tisbury	Tisbury, Wilts	111 2

Mumble	"	170 7

1666c. In the year 1858, the present editor contributed to the *Builder Journal* (pp. 632–3) a list of the *Building Stones used externally in and near the Metropolis*, with the names and dates of erection of the buildings in which they had been used. This list cannot be here inserted, but the following are among the stones named:—Anston, Aubigny, Bath, Bramley Fall, Broomhill, Cadeby, Caen, Craigleith, Godstone, Great Barrington, Harehill, Kentish rag, Yorkshire stone, Ketton, Portland Prudholme or Prudham, Reigate, Roche Abbey, Swanage or Purbeck, and Whitby (Egton Quarries) stones, besides Granite, and Flint. The paper by E. J. Tarver, on *The Architecture of London Streets*, read May 10, 1887, at the Society of Arts, is also applicable.

1666d. The North Anston stone of Yorkshire, not mentioned in the preceding *Report*, belongs to the magnesian limestone formation, and is of a yellowish brown colour. As examples of its use we point to the Museum of Practical Geology in Jermyn Street, Pall Mall, in the façades of which there is scarcely a bad stone to be seen. This well conceived structure was erected from the design of James Pennethorne during the years 1837 to 1848. At the New Hall and Library, Lincoln's Inn, designed 1843–45 by P. Hardwick, R.A., this stone is in a lamentable state of decay, occasioned (as is reported in the discussion on G. R. Burnell's paper, *On Building Stones, &c.*, read at the Society of Arts in 1860), by the use of two particular beds, the blocks of which were in a state of decay before they left the quarry, and supposed to have been selected by the builder as yielding him the best profit. The labour upon Anston stone is intermediate between Yorkshire and Portland stones: it can be obtained of any required dimensions. The office of the Amicable Life Assurance Company, in Fleet Street, was erected 1843, with the Mansfield Woodhouse or Bolsover stone, in the façade of which there is scarcely any trace of decay.

1666e. From the Mansfield quarries are now sent up the red Mansfield stone, the white Mansfield stone, and the yellow magnesian or Bolsover limestone The former is much introduced for colonnettes, short shafts, and bands in coloured coursed ashlar work. For similar decorative work, the following stones have been used (1865) at the new offices of the Crown Assurance Company in Fleet Street; namely, Portland stone in the piers and caps; Forest of Dean, red Mansfield, and blue Warwick, in other portions of the front; and Sicilian marble over the arches.

1666f. In consequence of the reintroduction of Portland stone of late years, we would refer, in addition to what has been stated on p. 467, as to the quarries of Portland stone, to the article *Lithology*, written by the late C. H. Smith, and published in the *Transactions* of the Institute of British Architects, 1842. Also to a report, published in the *Builder* of 1863, p. 859, by F. A. Abel, being the result of his examination into the comparative qualities and fitness for building purposes, of samples of stone from different quarries, and made under the direction of the Inspector General of Fortifications.

1666g. These results "show that all the superior descriptions of 'whit bed' stone combine strength and compactness in a considerably higher degree than the varieties of 'base-bed' stone. Some kinds of the 'whit-bed' stone, however (i.e. those from the New Maggot and Inmosthay quarries), though ranking with the best as regards strength, exhibit a greater degree of porosity. Again, other 'whit-bed' stones (from Old Maggot, Waycroft, and Independent quarries) exhibit but little superiority, in point either of strength or compactness, over the generality of the 'base-bed' stones, and are, indeed, inferior to the best 'base-bed' variety."

1666h. "The 'base-bed' stones are, undoubtedly, more generally uniform in structure than those of the 'whit-bed;' this being mainly due to the comparative freedom of the former from distinct petrifactions. Though such petrifactions were shown, by the results of experiments, to impart, in many instances, great additional strength to the stone, they frequently give rise by their existence to cavities sometimes of considerable size, which not only serve to weaken those particular portions of the stone, but may also, if they exist in proximity to exposed surfaces of a block of stone, promote its partial disintegration by the action of frost. Greater care is, therefore, unquestionably required in the selection of 'whit-bed' stone than need be employed in the case of all the better varieties of 'base-bed' stone." The results of my experiments lead me to the following conclusions regarding the comparative merits of the various descriptions of Portland stone in question, for building purposes:—

"For *External* work, in the order of their merit:—I. Stone from War Department quarry, Vern Hill; and 'whit bed' stone, Admiralty quarry.

II. 'Whit-bed' stone, New Maggot quarry; 'base bed' stone, Admiralty quarry (this may be considered quite equal in quality to 'whit-bed' stone); and 'whit-bed' stone, Inmosthay quarry (particularly adapted from its texture and uniformity for ornamental work).

III. 'Whit-bed' stone, Old Maggot quarry: *a* marked LI; and *b* marked IT and IE. The 'roach' stone, from War Department quarry, is an invaluable stone for external work in localities where any considerable strength and power of resisting mechanical wear are required, as in connection with those portions of work which may become exposed to the continual abrasive action of water. The rough 'whit-bed' stone from Admiralty quarry, is also a highly valuable stone for work of a similar kind, where great strength is required, and particularly where the numerous irregularities in the 'roach' stone may be objectionable.

For *Internal* work, the following rank highest, on account of uniformity and comparative strength:—'base-bed' stone, Old Maggot quarry, IT; 'whit-bed' stone, Independent quarry; 'base-bed' stone, Waycroft quarry; and 'base-bed' stone, New Maggot quarry. The following are inferior to those just named, both in texture and uniformity:—'Whit-bed' stone, Waycroft quarry; 'base-bed' stone, Old Maggot quarry, IE; and 'base-bed' stone, Inmosthay quarry. The 'base-bed' stone, from Old Maggot quarry, marked LI, and that from Independent quarry, are of low quality, as compared with the remainder; and no reliance can be placed on the durability of the 'roach' stone from Independent quarry, judging from the specimens received."

1666*i*. *Hopton Wood stone* is obtained from quarries situated near Middleton and Wirksworth, in Derbyshire, in the mountain limestone districts of that part of the country. An analysis of it gives:—lime 55·09, magnesia ·17, carbonic acid 44·30, water ·16, organic matter ·05, siliceous matter insoluble in acids ·15, oxide of iron ·10, alumina a trace, and silica soluble in acids a minute trace = 100 02. It is well adapted for paving purposes, owing to the closeness and evenness of the grain; these properties give this stone its principal recommendation; its durability does not depend, apparently, upon any necessity for placing it on its quarry bed. The late Mr. C. H. Smith has stated in the *Builder*, 1864, p. 912, that "these extensive quarries have been worked from time immemorial; the material is decidedly *marble*, for it is fine grained, compact in texture, and quite hard enough to take a brilliant polish. The colour is a pale brownish white, certainly as white as Sicilian marble, which approaches to a bluish grey. It is much heavier than Portland stone, but lighter than Carrara marble. Blocks of very large dimensions may be obtained free from serious defects; and as it is an aqueous formation, hard, and well crystallised, there is no doubt of it standing weather extremely well. Both material and workmanship are less than those of Sicilian marble. A quantity of it was laid down about the year 1854, for foot-pavements, close to the Parliament Houses in Old Palace-yard, and part of Abingdon Street; and, though in constant use, no symptoms of decay, or of the surface wearing away, are perceptible."

1666*j*. *Bath stone* (noticed p. 460) is an oolite, obtained from several quarries in the neighbourhood of the city of Bath, in Somersetshire. Its colour, a light cream, is more agreeable than the cold tone of Portland stone; its texture is similar, but as it is softer and more absorbent, precautions must be observed in the manner of using it, and to prevent its rapid decay. It may be sawn dry. Much depends on the bedding of the stone in the works. The *Corsham Down* stone is usually free from the bars and vents which are found in the Combe Down stone; it is a sound stone, blocks being obtained of any movable dimensions; the beds vary from 1 foot to 4 feet in thickness. It is finer in texture and more regular in quality than any other description of Bath stone, and is well adapted both for external and internal purposes, except plinths. Below the beds of good stone are two beds of a harder quality, called Corn Grit, which cannot well be used for any purpose on which labour is required. It does well for steps and landings. One of these beds runs 2 feet 9 inches deep; the other about 4 feet 6 inches. The blocks average 24 feet cube. *Combe Down* stone, when well selected, is considered to be an excellent weather stone, for use in plinths, copings, and other work; but the blocks have bars and vents, which are defects. The beds vary from 10 inches to 4 feet 6 inches in thickness, and are occasionally found up to 6 feet; in length from 5 to 6 feet; with an average size of block of about 15 feet cube. *Box Ground* stone is coarse in texture, but sound in quality, and a good weather stone; harder than Combe Down stone, and with less vents. The beds vary from 1 to 4 feet in thickness, with blocks of average size of 20 cubic feet. *Farleigh Down* stone is at some distance. The upper or white beds vary in thickness from 10 inches to 2 feet 6 inches. The lower or reddish beds are coarser in texture, but are supposed to stand the weather better than the upper beds, which are more suitable for internal purposes. The average size of block is 14 feet.

1666*k*. The Monk's Park quarry stone is stated to be durable and reliable, with uniformity of colour and evenness of texture. Bath stone, on the whole, is one of the most fragile of freestones, for when first quarried it is as soft as cheese, and although it hardens in the open air to some extent, yet it soon disintegrates, as it consists only of minute globules cemented together by yellowish earthy calcareous matter, and contains a considerable portion of broken shells. It has been said that for outside work the stone from Murhill Down quarry and the weather bed of the Combe Down quarry are the only two stones that will really stand the weather. This material has been well described by writers in the *Builder* for the years 1845 and 1860, and the detailed mode of working at the quarries in 1862, p. 613. The weight of Bath stone is about 123 lbs. per cube foot, and the crushing weight about 1800 to 2000 lbs. per inch superficial. In an experiment in 1864, a 3-inch cube of Box Bath stone crushed with 8 tons 7 cwts 0 qr. 16 lbs., while the same of Corsham Bath stone crushed with 11 tons 11 cwts. 1 qr. 20 lbs. A $1\frac{1}{2}$-inch cube Box Ground crushed with 1 ton 3 cwts. 3 qrs. 12 lbs., and another of Corsham with 1 ton 10 cwts. 2 qrs. 4 lbs. In some other experiments Box Ground stone was first fractured at an average of 46 tons 5 cwts. 2 qrs. 22 lbs. and crushed at 54 tons; while Corsham was fractured at 73 tons 14 cwts. 1 qr. 4 lbs., and crushed at 83 tons 2 cwts. 3 qrs. 12 lbs.

1666*l*. The *Bath Baynton* quarries supplied the stone for Queen Square, at Bath; it is the coarsest, hardest, and most expensive and most durable variety. The *Combe Down* stone from the Bath Lodge Hill quarries is softer and finer grained, is said to have been used between 1808 and 1822 in the restoration of King Henry VII.'s chapel at Westminster; while *Farleigh Down* stone from the Monckton Farleigh quarries is said to have been used from 1821 to 1840 on the north side of Westminster Abbey, since renewed.

1666*m*. Messrs. Pictor and Sons, Messrs. Randell, Saunders & Co., Mr. Isaac Sumsion, the Corsham Bath Stone Co., Messrs. R. J. Marsh & Co., Mr. S. R. Noble, and Messrs. Stones Brothers, have amalgamated the several Bath stone businesses into one, under the style of "The Bath Stone Firms, Limited," with the office at Bath. A vast quantity of Bath stone of the best quality is thrown away at the quarries because the pieces are not of sufficient size to make useful blocks. These would yield a large and reliable supply for ashlar, quoins, &c., to serve as inside linings to walls with advantage, as non-cracking and non-peeling, absence of water trickling down the wall, uniform and mellow tint, and far better appearance than cement or plaster.

1666*n*. *Ancaster stone* from quarries near Grantham has been used locally for upwards of five hundred years. It is an oolite (p. 459), a good-looking stone, easily worked, and, though soft when first quarried, becomes hard with exposure, and is very durable. Wollaton Hall in Nottinghamshire, and most of the ancient churches in Lincolnshire, are built of this stone.

1666*o*. *Hollington stone*, a sandstone from near Ashbourne, in Staffordshire (p. 455), or Rocester, near Uttoxeter. The three qualities are—fine, medium, and very coarse.

1666*p*. *Little Casterton stone*, an oolite, from quarries near Stamford, Lincolnshire, is now used in lieu of the Barnack stone formerly obtained from quarries in Northamptonshire, long since abandoned. It is said to be of a compact character, to stand all weather, and to have been used in waterworks. It works freely with the saw. It is about 4 feet thick in the bed, and can be raised in blocks of large size; in ashlar work it is not essential that it should be placed on its quarry bed. The colour is of a lightish brown, resembling Ketton and Bath stones.

1666*q*. *Tisbury*, in Wiltshire. The quarry gives a calciferous sandstone, close and fine grained, of a light greenish-brown colour; a good weather stone when placed on its bed; easily worked with the saw, or with sand and water, when in block, and carries a fine arris. The *Chilmark* and the *Wardour* quarries also give stones of the same qualities. Their chemical composition, specific gravity, and resistance to strains, are the same as those of Portland stone, in which they are placed geologically, but they have more grit. The *Chilmark* stone, a siliciferous limestone of the same colour, was used for Salisbury Cathedral, 1220–58 (p. 467). It is very non-absorbent, and weighs 153 lbs. 7 oz. These stones have been used from 1864 in the restorations at Westminster Abbey. The houses at Tisbury, built generally of Tisbury stone, are in very good condition, the whole covered with lichens. The Chilmark stone does not absorb one thirty-sixth of its bulk, while a specimen of Cadeby stone absorbed one quarter. The latter absorbed 519·8 grains, the former only 57·5 grains. This table shews its chemical analysis:

Name of Stone	Mineral designation	Silica	Carbonate of Lime	Carbonate of Magnesia	Iron Alumina	Water and Loss
Chilmark -	Limestone Siliciferous	10·4	79·0	3·7	2·0	4·2
Portland - -	Oolite - - -	1·20	95·16	1 20	0·50	1·94
Bath Box -	Oolite - - -	—	94 52	2·50	1·20	1·78
Mansfield -	Sandstone - -	49·4	26·5	16·1	3·2	4·8
Park Nook -	Magnesian Limestone	—	55·7	41·6	0·4	2 3

1666*r*. The "trough" or "hard" bed is of a close, even texture, of yellowish-brown colour, weighing 143 lbs. to the foot cube in its ordinary state. It will bear a tensile strain of 500 lbs. per square inch, and a crushing weight of 196 tons per foot super. The average bed is 3 feet, and it can be obtained of any reasonable length and breadth; the random rubble blocks average 16 cubic feet. The "Scott" or "Brown" bed is of a warmer colour, weighs 135 lbs. per foot cube, bears a tensile strain of 206 lbs. per square inch, and a crushing weight of 104 tons per foot super. The average thickness of the bed is 3 feet 6 inches to 4 feet. The random rubble blocks average 16 cubic feet. This bed is principally used for ashlar, mouldings, carving, balustrades, plinths, cornices, coping,

&c. The "General bed" of the Garden quarry supplies a stone of a rich yellow tint and fine texture, applicable to the most elaborate designs, equal to Caen, and superior to it in colour and durability. It will bear a tensile strain of 355 lbs. to the square inch, and a crushing weight of 100 tons per foot super. Thickness of bed from 4 to 5 feet.

1666*s*. *Ketton stone* is an oolite, from quarries in Rutlandshire (p. 460). It is very similar to Barnack stone in colour, being a warm cream tint, but is harder and more difficult to work; from some cause at the quarry it is more expensive. It bears a much greater crushing weight.

1666*t*. *Robin Hood*, *Park Spring*, *Potter Newton*, *Bretton*, and *Hare Hill* are among the Yorkshire stones now much used in sawn landings and slabs, and steps. Potter Newton and Hare Hill in blocks, with Portland and Bramley Fall.

1666*u*. *Endon stone*, from near Macclesfield, is put forward as the best of its class, and as having been quarried for nearly one hundred years. It is of a hard and fine texture, almost non-absorbent, bright in colour, and of great durability; it is sawn out of the solid rock, not being a laminated flag rock. It is used for bases, steps, hearths, landings, thresholds, &c., wall courses, tombs, kerbs, setts and channel stone, and other purposes.

1666*v*. *Corncockle quarry*, one of the oldest of the new red sandstone quarries in the south-west of Scotland, is situated about three miles from Nethercleugh station, on the Caledonian railway. It is obtained in any sized blocks up to 10 tons. The colour is a light red, and very uniform; slight black streaks occur here and there, which are a form of mica, but they disappear entirely after twelve to fourteen months' exposure. The beds are from 1 to 3 feet thick, with an occasional one up to 4 feet 6 inches. The stone is considered locally to be the most durable of all the Dumfries red sandstones, and to keep its colour best. It contains a very high percentage of silica, and stands frost well, as also the sea air, and is a free-working although a strong stone. Its crushing strain is ·2·38 tons per square inch, applied on a block of $1\frac{1}{2}$ inch cube.

1666*w*. *Prudham quarry* is situated near the Fourstones station, on the Newcastle and Carlisle railway. The stone is of a light creamy-brown colour, very strong and durable, and the crushing strain is 2·834 tons per square inch. It is well known in the north of England and south of Scotland. It was used in the central station, post-office, and other buildings at Newcastle; the town-hall and corn-market at Hexham, and in other towns; also in London, at the Army and Navy Hotel; St. James's Residential Chambers, Duke Street, Piccadilly; and at Winchester House, Old Broad Street (1886).

1666*x*. *Scotgate Ash stone*, also called *Pateley Bridge* stone, near Leeds, is a sandstone of the millstone grit series. The quarries afford every class of Yorkshire stone, so that it is stated a building of any size can be supplied entire, without going to several quarries for the stones required. Landings up to 130 feet superficial, suitable for hard wear; one (in 1876), being 17 feet 6 inches long by 7 feet wide, was supplied for a floor and ceiling in a London bank. The crushing weight is over 700 tons per super. foot. It resists the strongest acids. The stone is similar to Elland Edge, Idle Moor, Park Spring, and others. It was used at Fountains Abbey.

1666*y*. The *Spinkwell* and *Cliff Wood* quarries are situated at Bradford, and are now considered to be among the best of the Yorkshire quarries. These stones have been largely used in London and throughout the kingdom, as at the town-halls at Manchester in 1868, at Bradford in 1870, at Wakefield, 1877, &c. The crushing weight is 7,647 lbs. per cubic inch, as tested by Sir W. Fairbairn; Aberdeen granite being 7,770 lbs.; Portland stone being on bed 2,600 lbs. It contains 88·5 per cent. of pure silex.

1666*z*. There are several red-coloured stones now in use in London and elsewhere. The *Red Corsehill* stone is obtained from quarries near Annan, Dumfriesshire. It is a fine grained micaceous sandstone from the lower new red sandstone. It is of a rich red colour, even texture, and of great durability; some beds are a bright pink. Its crushing weight is 509 tons; that of Bramley Fall 265 tons. It was used for the Hand-in-Hand Insurance Office in 1873. The red *Dumfries* stone differs from it. The edifices in that town are built of stone from Craig, which is of moderate hardness and durability; and also from Locharbriggs. *Shawk* stone is from quarries in Cumberland. It is red in colour and a fairly good stone, very similar in quality and texture to red Corsehill, but runs in very much smaller sized blocks, and in much thinner lifts. All up the valley, there is a very large quantity of stone covered with a great depth of débris, which is stone of a coarser texture. It is loaded at Cwithwaite station, on the Maryport and Carlisle line. It has been used at the stores in the Haymarket. It is supposed to dry red, and not whiten on the surface as do some red stones. The red *Mansfield* stone (par. 1666*e*.) has blocks which vary in beds from 1 to 7 feet thick, and has landings of very large dimensions. The deep bed, selected quality, is esteemed for durability, fineness of grain, and splendid colour.

1666*aa*. The *Minera stone*, from Berwig quarries. Minera, near Wrexham. They are situated at some distance from the outcrop of the Wrexham coal field, close adjoining the carboniferous limestone. The stone differs in character very materially from the whole of the sandstones found in the Wrexham and Ruabon coal fields, being much more durable. It nearly resembles the Darley Dale stone in colour and appearance, and is considered by many judges superior in every respect.

Analysis of this freestone, by H. K. Bamber, F.C.S.:

Silica	85·05	Magnesia	0·75
Alumina	8·25	Alkali	Trace
Oxide of iron	2·30	Water and organic matter	2·22
Lime	1·00		99·57

The beds run from 1 to 5 feet in thickness, and blocks of any size can be supplied. The stone costs considerably less to work than the best of the Yorkshire stones. It is much less absorbent than any other stone, and is not affected by atmospheric changes, by damp, smoke, or chemical gases. It is very strong, and capable of sustaining a greater crushing strain than most other stones. It was used largely at the Municipal Offices at Liverpool, by Mr. T. H. Wyatt, as well as at Owens College at Manchester, by Mr. Alfred Waterhouse, R.A.; also the National Safe Deposit Company's premises in London, by Mr. James Whichcord, who in 1876 wrote: "After seeing and testing various samples of sandstones, I decided upon adopting the Minera stone for its fire-resisting qualities; a block of it about 6 ins. cube was put into the middle of a furnace, where it remained for about an hour and a half. It was then taken out quite perfect, and on being plunged into cold water it neither cracked nor calcined in the least degree. Its cost in London was about the same as Portland stone, and it was quite as hard to work. The coarseness of the grain rendered it unsuited for small mouldings or delicate carving, but as solidity and boldness were required in this particular design, no difficulty was found in adapting the detail to this condition." The weight is about 138 to 143 lbs. per cubic foot. The Moss and Cefn quarries afford a softer variety of the same stone.

1666*bb*. The *Mountain limestone* is highly absorbent, but, according to Mr. E. Clark's experiments for the Britannia Bridge, it is of the extreme density of $13\frac{1}{2}$ cubic feet to the ton, as great as the average density of granite. It resisted a crushing weight of 7,576 lbs. per super. inch, whilst granite resists about 8,000 lbs. As lintels, it has been used in stones 24 feet long, 10 feet wide, and 4 feet thick, which must have been perfectly homogeneous in character or they would not have borne the shocks they were exposed to in the workshops, or have carried the weight that was brought upon them. This stone yields with great ease to the plate saw, as it is composed of a pure carbonate of lime, is sub-crystalline, and without planes of bedding; granite cannot be sawn by the ordinary methods. There are several localities where the mountain limestone occurs in great abundance, and where the experience of centuries as to its powers of resistance to the atmosphere, or to tidal action, can be brought forward. It is met with in great masses in the hills that constitute the lower counties of England and Scotland; it forms the range of the Derby hills, the Mendip, the hills round Plymouth, those of the Great Orme's Head, the mainland of Anglesea, the outcrop of the carboniferous series of Ruabon, and many other places in England. In Ireland this formation is largely worked, as at the Sheephouse quarries, Drogheda, by A. and N. Hammond. In Belgium it is universally used in all cases where it is desired to unite strength with durability, as in docks, river and canal works. The price of labour upon this material must be at least half as much as that on granite. The late Mr. Burnell, in *Practical Mechanics' Journal*, 1865, notices that it was excluded from the Thames Embankment works, because it was considered objectionable on account of its being worked by the saw with sand; because it was feared that the planes of bedding would be distinctly marked, and would easily yield under the influence of the weather; and on account of the action of the acids present in Thames water.

1666*cc*. We do not purpose to enter into a description of quarrying stone; but would refer to the useful treatise by Burgoyne, published among Weale's Elementary Treatises.

1666*dd*. The *Kentish ragstone* is a limestone with a very small proportion of earthy matters, frequently subcrystalline, but ordinarily of a confused texture. When well chosen it is very hard and dense, and the labour upon it so expensive that it is very rarely used for anything but rubble masonry in districts remote from the quarries. The custom has been, therefore, to execute all the moulded or carved portions of the buildings in Caen or Bath stones, and even to carry up the quoins and jambs in those materials, whilst the intervening spaces, or the wall, are filled in with the rag. The colour varies from a lightish green to a deep blue, and although the colour of the two materials is at first very different, a few years' exposure causes them to harmonise in tint.

1666*ee*. The district in which ragstone is quarried extends about thirty miles east and west through the central part of Kent, and averages from four to ten miles in breadth, comprising the towns of Sevenoaks, Maidstone, Lenham, &c. Reigate or firestone, and Tunbridge sandstone, are also afforded by the same formation, greensand. The ragstone is found in beds varying from six inches to three feet in thickness, alternated with fine sand known as *Hassock*, which in some beds becomes so consolidated as to form an occasional useful auxiliary to the ragstone, in buildings. The quality of the rag differs very greatly, according to the place in which it is quarried; some quarries only yielding stone of a hard flinty nature, almost unfit for building, while the stone obtained from others is almost as free working as Portland stone. The finest qualities are at present obtained from quarries situated at Boughton, near Maidstone, where they have been worked for several centuries. A section of them is given by J. Whichcord, in his pamphlet on the subject, published in 1846; wherein also are given the local names of the various beds.

1666*ff*. *Flint work*. This material, as used for a description of rubble work, was formerly much employed in the counties of Cambridge, Norfolk, Suffolk, Sussex, and Kent, where the chalk formation abounds, and is still used for the purpose in such localities. Flint is the name accorded to the nearly pure siliceous earth, which by the action of fire becomes opaque and white, and is harder than quartz, which it scratches. The colour is usually grey, of various shades, but is sometimes black, brown, red, and even yellow. Flint is fragile, with a perfect and large conchoidal fracture, and, being rarely laminated, it is broken with equal facility in almost every direction; the fragments are sharp. In the chalk formation it occurs in regular beds, consisting either of nodules or of flat tabular masses. At Brandon, in Suffolk, one of the places where flint forms an article of commerce, it is obtained from pits sunk in the chalk, which is within 6 feet of the surface. The first stratum is found in the clay overlying the chalk; when this has been removed, a shaft is sunk 6 feet in depth; if no flint is there found, a tunnel is driven for three feet horizontally, and another shaft is sunk; and so on alternately with tunnel and shaft till a depth of 40 feet is reached. The flint is found in *floors* about 8 feet below each other, and is obtained by tunnels being driven, sometimes a furlong in length, under each floor, and the flint broken down by crowbars. The small tunnels in the shaft form tables, upon which men stand and hand up the flint to each other from below to the surface; no machinery or tackling is used.

1666*gg*. Flint is split upon the workman's knee, by sharp blows from a hammer with an oblate face, and squared upon a steel stake let into a wood block, with a blunt axe formed by passing a handle through an old flat file about a foot long, the cutting edge being $1\frac{3}{4}$ inches wide by $\frac{1}{12}$ of an inch thick. (See Specification).

French Building Stones.

1666*hh*. Of these stones imported into the London market, a few only will be mentioned. *Aubigny* stone is stated to be obtained from quarries situated at St. Pierre Canivet, a short distance from Falaise, in Normandy. It is probably of the same nature as Caen stone, namely, oolitic, but much more crystalline in its structure, with semi-transparent crystals, showing no appearance of ova; very fine grained; as hard or harder than Anston stone; nearly as heavy as granite; and able to support a greater crushing weight than Caen stone; when worked it requires to be sawn wet with sand. There are two workable beds, one averaging 24 inches, the other 15 inches, in thickness. G. R. Burnell (in his remarks on the works at Bayeux Cathedral, read at the Institute of British Architects, 1861, p 257) stated that he "was convinced the use of Aubigny stone in London would be attended with danger. M. Flachat chose this stone because it yielded more satisfactory results under the trials to which he exposed the various local stones, so far as their resistances to crushing weights were concerned; but his assistants expressly state, in their published accounts of the works at Bayeux, that the Aubigny stone yielded easily under the action of frost, if used exteriorly, as may be seen in the mediæval buildings in Falaise." Perhaps the only building erected with this stone in London is that part of the old Schomberg House, Nos. 81 and 82 Pall Mall, which was rebuilt in 1851.

1666*ii*. *Caen stone* is obtained from the great oolitic formation in Normandy, and has been imported into England from a very early period; but it first appears to be named in documents after the year 1300. There was a cessation of its use after 1448, when Normandy was lost to this country; and it is not until the commencement of the present century that its employment here was resumed. This stone is now generally obtained from quarries situated at Allemagne, a small village on the right bank of the Orne at the gates of Caen, or from those of St. Germain de Blancherbe, commonly called La Maladrerie, the commune immediately adjoining that city, on the left bank.

1666*kk*. The Caen stone of commerce is of a pale yellow colour and of a loose open grain which when freshly quarried soils the fingers like chalk, and is very friable. In many places it appears to have lost its oolitic character; and in others it is harder and more compact, being entirely formed of a species of lamellous spath, without any trace of oolites; the latter appearance is, however, principally to be observed in the beds which are worked between Caen and Falaise; at Allemagne and La Maladrerie the former prevails. Neither of these two latter quarries appear to have been opened for any great length of time, the stone used in the old city having been chiefly got on its site; and it is remarkable that the portions of the public buildings which required stones of larger dimensions than could be obtained from the upper beds of the oolitic formation immediately around the town were executed in the Creuilly, Ranville, or Fontaine Henri stones, never in the stone obtained from the beds now worked exclusively for both the French and the English markets, and which beds have been rendered available with the advance of mechanical science. The upper beds, called the *bancs de bittes*, which yielded the stone in olden times, is generally speaking of a harder character, of a finer grain, and presenting a more crystalline appearance than that obtained from the lower beds; but even in these upper beds care is required in the selection, for the texture is far from uniform; while the small size of the stones is too often considered an objection to it, as the eight layers, between each of which occurs a bed of flint 2 inches in thickness, are of variable depth (between 11 inches and 26 inches), being about 18 inches on the average.

1666*ll*. The lower beds comprise the *banc de chambranle*, 16 inches thick; the *banc de deux pieds un quart*, about 30 inches English thick, yielding a good stone, disfigured unfortunately by the fossils it contains; the *banc rouge*, 22 inches thick, of very bad quality and stained by ochreous iron ore, besides being traversed by numerous vertical vents; then the *gros banc*, 40 inches thick, a very good stone, but likewise disfigured by fossils; the *banc de fond*, usually from 18 inches to 30 inches thick, of a closer and finer grain than the last named; and then the *banc de* 81 *centimètres*, of very inferior quality, worked only for the immediate neighbourhood.

1666*mm*. Experience proves that Caen stone will not resist the dissolving power of water charged with carbonic acid gas; and as the rain water of our large towns contains a considerable quantity of that gas, it is not expedient to employ this stone in any situation where water is likely to lodge, or even to be taken up by capillary action, unless, indeed, the projecting parts be protected by metal. In upright walling above the plinths, and in the sheltered portions of cornices, it can be employed when judiciously selected; and in internal work, with safety and economy. The bedding of the stone should be observed. From the state of some buildings at Hâvre, it is considered that sea air is particularly destructive to this stone; and it is generally believed that the stone from La Maladrerie is inferior to that from Allemagne. In Caen itself, the plinths or basements of houses are executed in granite, or in Ranville, Cherence, or Creuilly stones, which are practically non-absorbent; and, moreover, the Creuilly stone is used in the best buildings for the exposed portions of the elevation, although, of course, "Caen stone" is found at the very gates of the town.

1666*nn*. More lengthened notices will be found in the accounts given in the *Builder*, vols. vi. and vii., entering into the qualities of the stone, from personal surveys of the quarries. When freshly quarried, this stone can be cut with the toothed saw, and carved with ordinary chisels, even more easily than Bath stone.

1666*oo*. The new façade of Buckingham Palace, erected in 1846–7, is perhaps the most remarkable failure of Caen stone. Mr. H. T. Hope's house, in Piccadilly, built 1849-50, has been considered one of the best specimens of its employment in London, as it has stood well. The projections were protected by lead or by slates. The crushing weight of Caen stone is about 2000 lbs. per inch superficial.

1666*pp*. The *Charente stone* is a magnesian limestone of good quality, has been used in France from time immemorial almost exclusively, not only in the departments which produce it, but also on the sea coast, for Government works, as lighthouses, harbours, fortifications, bridges, docks, &c.; for churches, and other public and private edifices; the château of the Emperor Napoleon III. at Biarritz, and other villas. Blocks of about 8 or 9 cubic feet to about 33 cubic feet are always in stock. The quarries are Crazannes, Montarneuf, St. Savinien, and Ste. Merue, and the average resistance for the square centimètre (about ·155 square inch English measure) gave about 157 lbs., 152 lbs., 148 lbs., and 130 lbs. avoirdupois respectively.

1666*qq*. Table of the Weights per Cubic Foot Avoirdupois of some French Stones.

DECAY OF STONE.

1667. In the paragraphs 1640 to 1648 have already been quoted some of the causes of decay and decomposition in stones, as stated in the Report of the Commissioners, and after the lapse of nearly thirty years since its publication but few additional facts have been obtained on the subject. One of the most commendable essays relating to it is that by G. R. Burnell, read at the Society of Arts, in March, 1860, which is likewise useful for the discussion thereon by some of the members learned in chemistry. We quote a few of the paragraphs for further elucidating some important points.

1667*a*. Atmospheric moisture, when absorbed into building stones, acts upon them quite as much through the changes in its own volume. When the stone is placed in such a manner as that water can accumulate in any perceptible quantities between its various layers, and the position of those layers be such that the expansion of the water in freezing cannot take place freely, the respective layers containing the water will be violently detached from one another. This is a more important consideration in the case of the *bedding* of stones, and it is unfortunate that the system of competition throws so great a temptation in the way of the practical builder as to render it a mere matter of chance whether this constructive law be observed or not, unless a costly system of supervision be organised, and thus the precautions often taken by the stone merchant to indicate the upper bed of the material he delivers, are defeated.

1667*b*. The chemical reactions which take place in building stones are mainly those arising from the oxygenation, or the hydration of the various ingredients of which those stones are composed. These reactions are independent of those resulting, in the interior of the country, from the agents directly presented by atmospheric moisture in the form of carbonic acid gas, sulphur, and ammonia; or upon the sea-shore, in the form of hydrochloric acid, or of common salt itself, in minute particles. Thus, if the oxide of iron be present in any notable proportions, it is likely to undergo changes of a nature to disturb the stability of the compound, and even the crystalline sulphates of lime are exposed to chemical decomposition, in consequence of the liberation of the sulphuric acid gas they contain. The other mineral salts, such as the silicates and the sulphates of iron, so often met with in building stones, are at times susceptible of very injurious decomposition; and the soda, potassa, or the organic matters the stones may contain, frequently give rise to the formation of new salts; mainly under the action of atmospheric moisture, it is true, but also under the influence of the partial decompositions which take place around them. It is to be observed, however, that the danger to building stones from this peculiar class of influences, is very small and very slow in its action, compared with the dangers arising from the mechanical disintegration produced by atmospheric causes: and that, with the exceptions of the actions of free carbonic acid upon the felspar of granites, the changes of state produced in limestones by the same agent, and the modifications of the abundant salts of iron in some peculiar stones, there is little practical necessity for dwelling upon this interesting but obscure branch of applied chemistry.

1667*c*. The actions capable of affecting the stability of the composition of ordinary building stones, by reason of the new forms of matter they superinduce, may principally be considered to be those resulting from the absorption of the gases of the atmosphere, and especially the process known by the name of *saltpetring*, or more correctly, of nitrification. This process displays itself in the formation of minute crystals, efflorescing from the interior to the exterior of the stone, and it leads to the destruction of the exposed surfaces of the latter, through the gradual removal of the minute particles, in consequence of the disintegration produced by the expansive action of the crystals in process of formation.

1667*d*. It is supposed that the organic matter diffused through nearly all stratified deposits gives rise to the formation of certain nitrates, such as the nitrate of lime and nitrate of soda, under the influences of damp, of air, and of light of certain descriptions —for nitrification certainly takes place most abundantly near damp ground, rising in a wall *pari passu* with the range of the capillary attractions of its materials, and upon the northern or shaded faces of the said walls. Not only does this nitrification throw off the minute and less adherent particles of the building materials themselves, whether they be of *stone* or *brick*, but it is also able to detach any protecting coat which may be put upon them, if the adhesion of that coat to the subjacent material should not be of a very energetic nature. Let the adhesion, however, be ever so energetic, if once the action of nitrification should have been established, it must run its course, and the amount of evil it is capable of producing will simply depend upon the quantity of organic matter originally contained in the materials, or susceptible of being absorbed by them from the atmosphere.

1667*e*. The secondary limestones which have not been affected by plutonic action, the loamy clays, some kinds of pit sand, sea sand, and some descriptions of natural cements, are particularly exposed to the danger of nitrification in damp situations, rendering it in vain to expect to be able to preserve any mural paintings, or even any sculpture of a delicate character.

1667*f*. Practically, then, the great agent of destruction of building stones, in any of its modes of exhibition, is the damp, or the water supplied by the atmosphere, directly or indirectly; the efforts of those who seek to prevent this destruction must be directed to combating this primary source of evil. Fortunately the precautions to be observed for this purpose are very simple, and they only require a little common sense on the part of the builders charged with their application, to the materials at least, which have been long before the public. The first and foremost rule is never to employ a porous absorbent stone in the ground, or in elevation; unless, in the former case, it be maintained constantly wet; or, in the second case, the absorption of moisture from the ground be prevented by the interposition of some impermeable material. Porous stones should not be used for the copings, parapets, window-sills, weather-beds of cornices, plinths, strings or other parts of a building where water may lodge. Care must also be taken to bed such stones with mortars which are not exposed to develope in themselves, or are not likely to excite in the stones, the efflorescence of any of the nitrates of soda, potassa, or of lime. If porous stones be used, it will be found that decay will commence, and be most apparent in the zone of alternate dryness and humidity, or, as the workmen say, "between wind and water." The stonework about that part should therefore be executed in such a manner as to allow of its being easily replaced, if necessary; and in case the decay exhibits towards the interior (as it will do when the exterior surface is covered with a coating impervious to the air), care must be taken to isolate the decorative plastering or wall linings from the surfaces which are likely to be covered by efflorescence.

The effects of *wind* on stone. Wind is both a destroying and a preserving agent. Its action as a destroyer cf building stone consists in blowing dust and dirty particles against the building; also into the cuttings, holes, and lines in exposed mouldings, filling them up, adding much to the disfiguration of ornamented work. A strong wind accompanied by rain, by blowing the rain hard against a building causes it to penetrate into the stone farther than it would otherwise do, and thus the chemical action of the water and the effects of frost on the stone are increased. The principal preservative action of wind is in its drying out moisture from stone; and the acids, &c., contained in the moisture have, therefore, less time to act on it. The action of the sun has much to do with the preservation of stone by drying it. Stone exposed to very different degrees of heat on its different faces is liable to crack from unequal expansion and contraction (Wray, *On Stone*). In the paper on *The Stones of Egypt*, read at the Royal Institute of British Architects, Nov. 24, 1887, Mr. Brindley referred to their decay. Mr W. Topley stated that, under ordinary temperatures, water got into the pores of the rock, carrying in carbonic acid, which attacked felspar, or whatever the soluble constituents of the rock might be. The rock then broke down. In northern climates the water froze and the rocks broke off. In a dry climate . . . the great alterations of temperature acted so strongly in expanding and contracting rocks that they broke off as rapidly through heat as with intense cold. During the night a cracking sound was often heard by travellers owing to the contraction of rocks which had been expanded by the heat during the day. The effect of a *fire* on some exceedingly durable building stones is very disastrous, and especially on those which were formed by heat.

1667*g*. A committee appointed by the First Commissioner of Public Works and Buildings, on the 23rd March 1861, "to inquire into the decay of the stone of the New Palace of Westminster and into the best means of preserving the stone from further injury," reported on—I. The extent and position of the decay. II. The causes to which it is attributable, taking into consideration the composition of the stone, and the influence exerted upon it by moisture, and by the acids diffused in the London atmosphere. III. The best means of preserving the stone from further injury. IV. The qualities of the stones to be recommended for future use in public buildings to be erected in London." This report was ordered to be printed 1st August, 1861. It is also given in Adcock's *Engineers' Pocket-book* for 1862, p. 205–211.

PRESERVATION OF STONE.

1667*h*. Even when all the best precautions, as above detailed, have been taken, it is occasionally found necessary to protect the exposed surfaces of the soft and absorbent, or hygrometric, stones, with some coating which shall prevent their absorbing the injurious atmosphere. This is done in various ways.

1667*i*. I. *By Painting*:—The objection to this process consists in the fact that, as the oil evaporates, the stone becomes again exposed, and even the absorbent powers of the stone itself contribute to this action; thus this costly palliative has to be often repeated, to the destruction of any delicate moulded work.

1667*j*. II. *By the injection of oleaginous, fatty, or waxy matters*:—These, it must be evident, can only act mechanically by closing the pores of the stone, and therefore, unless the surfaces be protected from the extremes of heat and cold, the heterogeneous materials thus affected must be acted upon in very different manners. Experience has confirmed this theoretical inference, and it has been found in practice that the protecting coats of any of the materials alluded to are gradually detached from the stone, and that they require to be renewed quite as frequently as does oil painting itself.

1667*k*. III. *By washing the face with a solution able to convert the material into an insoluble non-absorbent substance*:—This is the process introduced by M. Kühlmann, in which the carbonates of lime are washed with a solution of an alkaline silicate, as silicate of soda, or potassa, or "water glass" as he called it, with a view to converting them into silicates of lime through the elective affinities of the lime and the silica. In some cases this system has succeeded, and very great hardness, very great resisting powers, have been communicated to the stones operated upon. But, unfortunately, the action of the silicic acid is a very slow one, and when the surfaces washed in the manner described are exposed to rain, it is by no means rare to find the solution carried away. Another objection is, that when the alkaline silicate acts upon the stone, the soda and potassa generally used are left free, and in efflorescing they are likely to carry away the finer details of the sculpture; at the same time, as they form to some extent deliquescent salts upon the face of the stone, they attract to it a dangerous amount of humidity. This process is only applicable to the preservation of the stones in which the carbonates of lime predominate.

1667*l*. IV. *By filling in the pores of the stone with an insoluble material which should effectually exclude water*:—This may be said to have been effected by the process patented by Mr. Ransome. The stone is first cleaned carefully from dust or other extraneous matters; then it is made to absorb as large a quantity as possible of the silicate of soda or potassa. When this solution has dried into the stone, a second wash is applied, consisting of the chloride of calcium or of baryta. The silicate of soda and the chloride of calcium are most frequently employed; and the effect of the respective applications is, that a double decomposition takes place in the washes, giving rise to the precipitation of a finely crystallised silicate of lime or of baryta in the pores of the stone, and an efflorescence of extremely soluble salts of the chlorides of soda or of potassa. The former remain in the pores, the latter are speedily washed away by rain. As the rate of contraction and expansion of the silicate of lime is, as nearly as may be, the same as that of the stone it is intended to protect, there is no danger of the precipitate being detached by this cause. This process, in contradistinction to that of Kühlmann, is applicable to limestones, sandstones, bricks, plasters, and cements. It has even been suggested that it may be advantageously applied to chalk.

1667*m*. It must not be forgotten, however, that it is as important to prevent a stone from decaying as it is to afford a protection to it when that effect has commenced. If any internal decay or any organic decomposition, so to speak, be once allowed to establish itself in a building stone, it will be impossible effectually to arrest its progress. Efflorescence, for instance, will continue, however effectually the exposed surface of the stone may be closed by a mechanical or a chemical deposit, and thus even some of the results of Mr. Ransome's process appear equivocal. The student should make himself master of the attempts lately made to discover a universal remedy for protecting the surfaces of various materials. The following inventions were described by the late Sir W. Tite, at the Royal Institute of British Architects, January 1861:—I. Bethell's patent, 1838, perhaps never applied to stone. II. Hutchinson's, 1847, which has been chiefly applied to the Calverley stone of Tunbridge. III. Daine's, 1854. IV. Szerelmey's, 1857. V. Newton's, 1841. And VI. Ransome's, 1856. We consider it needless to notice here the inventions in detail. It is difficult to pronounce on their respective merits, but Ransome's perhaps promised the best results.

1667*n*. Sylvester, in 1846, suggested the following very useful and simple recipe for protecting stone or brickwork from the absorption of water; it has been repeatedly tried, and answers well in exposed situations, but requires a fresh application about every three or four years. Mix $\frac{3}{4}$ lb. of mottled soap in a gallon of nearly boiling water, and apply it in a boiling state over the surface of the work, steadily and carefully, with a large flat brush, making no lather, and filling up the crusty surface of the work, either of brick or stone. This is to remain for twenty-four hours to become dry and hard. Then $\frac{1}{2}$ lb. of alum is to be mixed with four gallons of water and left standing for about twenty four hours, so that the alum may be completely dissolved; this solution is to be applied in the same manner. Sir G. G. Scott has used for the internal work of Westminster Abbey a solution of shell-lac in spirits of wine, which, squirted into the stone work, appears to answer perfectly in securing the face from further decay arising from damp only. He also found it of some effect in the open air where defended from rain, but it failed when exposed to its action.

After cleaning down Bath stone of the best quality, it generally may with advantage be washed over with two coats of lime-water prepared as follows:—Fill a tub with water, and into it put some lime; stir it up well when slaked and let it settle. If any impurities should rise to the surface remove them, and when clear apply it with a clean brush to the stonework. This is an excellent preservative, and reinstates the skin or crust removed with the drag, without altering the colour of the stone. (Sumsion, of Bath).

Tabary's metallic cement has been in use in France during the last twenty-six years, under the French government and the municipality of Paris, for restoring monuments. It is stated to be permanent and to resist all attacks of acids in the atmosphere. The whole of the decayed stone need not be removed. It is carved and worked in situ. It costs less than stone. Restorations are more rapidly done than in ordinary stone. The colour of the original stone can be matched, and it can be used in all weathers. "This metallic cement is composed of a stone of Trachytic origin, reduced to powder, and the molecules are reunited by an acid and softened without being decomposed. The cement is mixed with the acid, and the stone reconstructed to its original condition." The process has been used, 1887, at the Church for the Deaf and Dumb, in Oxford Street; the Church of S. Paul, London Docks; and the Infant Orphan Asylum, Wanstead, besides other places.

ARTIFICIAL STONE.

1667*o*. The term is sometimes made to comprise not only *Terra-Cotta*, which is noticed in this work in the section Brick, but also the many *Concretes*, which are described in the section Lime, &c. Those mixtures or concreted masses having more affinity to the original they profess to imitate are here described.

1667*p*. *Austin's artificial stone* was invented about fifty years since, during which period it has been well tested. It is used chiefly in the manufacture of statues, garden ornaments, chimney shafts, and the like. This material is generally considered to be little else than ordinary cement, but it is plain there is much more ingenuity in the matter; at all events, it is evidently a concrete of sand and so on. cemented by lime; it is not burnt as is often supposed. and much of its value is no doubt due to the manipulation of the materials.

1667*q*. *Ransome's siliceous stone* was patented in 1844. Calcined flints ground to a fine powder were mixed with common soda (sub-carbonate of soda) rendered caustic, and water, the mixture being boiled under steam pressure; he thus obtained the silicate of soda in a liquid form. To one part of this *water glass* he added ten parts of sand, a little pounded flint, and a little clay; mixed the whole to a putty; made castings of the desired form under compression; dried these, *burnt* them in a kiln to a bright red heat, and so made them into blocks of stone. The chemical question was this:—the alkali of the soluble silicate of soda combined with a portion of the natural silica or sand, and thus formed an insoluble silicate or glass, as a cement, wherewith the remainder of the sand became concreted together. A sandstone was produced, and technically one of a silicious type; but its connecting medium was not crystalline as in nature, but as an equivalent, professedly vitreous. This vitreous element, however, was always seen to be its blemish, and the manufacture is now discontinued for the following more recent invention by the same patentee.

1667*r*. During the experiments made for obtaining a liquid or liquids wherewith to wash the surface of stone after it has been worked, Ransome selected and applied the silicate of soda, and upon the saturated surface a solution of chloride of calcium. A double decomposition then follows, not slowly but instantly, and the silicate of soda and chloride of calcium, the one, an insoluble substance filling the pores of the stone, and the other, common salt to be washed out by the weather. Pieces of the putty out of which the previously described silicious stone was daily made, *i.e.* sand mixed up with silicate of soda, were dipped in chloride of calcium, out of which it came changed to a hard and solid stone. This rather unexpected result led to the formation of an entirely new species of artificial stone, in a manner which was related by Professor Kerr at a meeting of the Institute of British Architects in 1863, from whose account we have been quoting.

1667*s*. *Ransome's Concrete stone* is the name given to this new material, invented in 1861. The process of manufacture now followed is first to dissolve flints in caustic alkali at a temperature of 350° Fahr., leaving them in a boiler for twenty-four hours. The liquid then produced, consisting of silicate of soda, is drawn off, and is allowed to evaporate until it becomes a thick matter like treacle. It is next mixed with clean pit sand incorporated with five to ten per cent. of chalk in a pug mill, and in four to five minutes this mixture is formed into a stiff putty. It is then pressed into a mould and afterwards either saturated with, or immersed in, a solution of chloride of calcium, which being rapidly imbibed, the formation of an insoluble silicate of lime and a soluble chloride of sodium or common salt results. This latter (about three per cent.) has to be removed by washing. to effect which it is placed in a hot-water bath for many hours. The employment of this new material as stone in building is gaining ground; for cast ornaments and moulded work it has been longer used, and probably it may yet be brought to serve for the chisel of the carver.

1667*t*. The committee of the Institute experimented on this material in 1864. Four-inch cubes were made of equal parts of sand and coarse ballast, with a quarter part of clay; on the third day a cube crushed with a weight of 9.35 tons; on the tenth day with 15·25 tons. With six parts of sand to one of chalk, on the third day a cube crushed with 6 tons; at ten days old, 9·40 and 13·25 tons. Other samples, however, proved to be weaker, as at eight and thirty-six weeks old, they crushed with 8·4 and 8·4 tons respectively, yet one of twenty-eight weeks crushed with 14 tons, apparently depending on the depth of the induration which in the weaker samples was only from 1 to 3 inches. A block formed of five parts of sand to one of fine silex bore 30 tons when three weeks old, without showing the least effect; it had been previously tested up to 20 tons. It will be well to contrast another sample formed of "all road scrapings from the neighbourhood of Ipswich" which at only *three days* old crushed with 28 tons; this was probably due to the silex contained in it. As another proof that its strength is entirely due to the complete induration of the material, a nine-inch brick made of four parts of sand, four of fine sand, and one of chalk, cracked when thirteen weeks old with 14 tons and crushed with 35 tons; this specimen was gradually filled with chloride of calcium being *poured* over it, and took fifteen minutes to saturate. Another at eight weeks with 4·2 and 30·0 tons; another with 20·15 and 38·8 tons; while a fourth cracked at 6 tons and crushed with 6·65 tons; these were *soaked* in the chloride of calcium. The tensile strength at twenty-eight weeks old varied as 47, 74 and 67 lbs. per square inch; while two specimens made of road scrapings, only three days old, broke with 101 and 97 lbs. per square inch, a strength also, no doubt, due to the silex contained in it.

1667*u*. A gallon of each solution is sufficient to produce a cubic foot of stone of the finer quality; but the cost of a block of coarser quality would be less than about half what the other would be. To render this concrete stone perfectly non-absorbent, the surface of the stone, after it is formed into blocks, is treated a second time with a wash of the silicate of soda, and a second application of the solution of chloride of calcium. These solutions are also applied for the preservation of other stones, or of brickwork; the silicate being diluted with water in proportions according to the absorbent character of the material, which must be clean and thoroughly dry before being operated upon. Tinting solutions are also supplied for harmonising with the natural colour of the stones. About four gallons of each solution will be, under ordinary circumstances, sufficient for each 100 yards superficial of surface.

1667*v*. Experiments conducted by G. R. Burnell, and reported upon by Professor Ansted in a paper read at the British Association at Cambridge, 1862, showed that the transverse strength of a beam 4 inches square resting one inch at each end, with 16 inches clear span, sustained a weight of 2,122 lbs. or 132 lbs. per inch superficial; whilst a similar bar of Portland stone broke with 759½ lbs., or nearly 42 lbs. per inch. The adhesive or tensile strength was proved by pieces of stone notched for the purpose, the sectional area at the weakest part being 5½ inches.

The patent concrete stone sustained - -	1980 lbs. =	360 lbs.	per inch.
Portland stone broke with - - -	1104 lbs. =	200 lbs.	,,
Bath stone ,, ,, - - -	796 lbs. =	say 150 lbs.	,,
Caen stone ,, ,, - - -	768 lbs. =	say 150 lbs.	,,

A 4-inch cube of the patent stone sustained a weight of 30 tons, nearly 2 tons per inch, before it was crushed.

1667*w*. The following result of chemical tests of this artificial stone, as compared with natural ones, will be found instructive. They were made by Mr. E. Frankland at St. Bartholomew's Hospital in December 1861. "The experiments were made in the following manner. The samples were cut as nearly as possible of the same size and shape, and were well brushed with a hard brush. Each sample was then thoroughly dried at 212°, weighed, partially immersed in water until saturated, and again weighed; the *porosity* or absorptive power of the stone was thus determined. It was then suspended for forty-eight hours in a very large volume of each of the following acid solutions, the alteration in weight after each immersion being separately estimated. The sample was then boiled with water until all acid was removed, and again weighed. Finally, it was dried at 212°, brushed with a hard brush, and the total degradation or loss since the first brushing was ascertained. The following numbers were obtained."

Name of Stone.	Porosity. Water absorbed by dry Stone. per cent.	Alteration in weight by immersion in dilute acid.						Loss by action of acid and boiling in water. per cent.	Further loss by brushing.	Total degradation from all causes.
		of 1 per cent.		of 2 per cent		of 4 per cent.				
		Loss	Gain	Loss	Gain	Loss	Gain			
Bath - - -	11·57	1·28	—	2·82	—	2·05	—	5·91	·26	6·17
Caen - - -	9·86	2·13	—	4·80	—	·67	—	11·73	1·60	13·33
Aubigny - -	4·15	1·18	—	4·00	—	—	1·01	3·56	·29	3·85
Portland - -	8·86	1·60	—	1·10	—	1·35	—	3·94	·24	4·18
Anston - -	6·09	3·52	—	3·39	—	3·11	—	11·11	·27	11·38
Whitby - -	8·41	1·07	—	—	·53	none	none	1·25	·18	1·43
Hare Hill - -	4·31	·75	—	—	·60	none	none	·98	·15	1·13
Park Spring -	4·15	·71	—	—	·10	·15	—	·81	none	·81
Ransome's - -	6·53	—	·95	none	none	none	none	·63	·31	·94

"Whilst Portland, Whitby, Hare Hill, and Park Spring stones (from the quarries, Farnley Wood, near Leeds) are thus pointed out as the natural stones best adapted to withstand the influences of town atmospheres, it is also indicated that Ransome's patent concrete stone will be found equal to the best of these, and there is nothing in the composition which would lead one to anticipate that it would suffer from exposure to the saline influences of the atmosphere upon the sea coast."

1667*x*. Bousfield's patent, 1856, consists of 80 or 85 parts of chalk and 15 or 20 of slaked lime, mixed together, moulded under pressure, and dried in the open air, when the blocks, says the patentee, "will be found to possess a degree of compactness and firmness resembling stone, which increases indefinitely with age, and if the ingredients are pure, will rival marble in whiteness and beauty." Barff's patent for an artificial stone was obtained in 1861. He takes 1 part of an aqueous aluminate of potash, with 3 parts of an alkaline silicate, or water glass (silicate of potash, however, not of soda), which will in a few hours set into a sort of dull glass, an artificial felspar in fact, perfectly brittle and of no very great tenacity, but altogether insoluble in water. With this silicate of alumina, while in a liquid state, he makes up sand or any dust (as pounded stone) into a paste, moulding it into blocks, and drying them in the open air, until they have set hard. Silicate of soda and potash are extremely viscid, and anything mixed up or coated by them is rendered thereby impermeable; to get another solution into such silicates, much less behind it, to effect their decomposition, is considered impossible, the only alternative, therefore, is to put on the two solutions as one. Decomposition then setting in, mere dryness is all that is necessary to produce the material; but if the silicate of potash and the aluminate of potash be mixed up in a liquid, they remain liquid for any period within reason, and they may be mixed up with any materials selected, or washed over their surface. When put into stone it hardens and produces an artificial stone, without heat or further process. A previous patent, dated 1860, describes that silicate of soda or silicate of potash may be combined with, or decomposed by, carbonate of lead, carbonate of zinc, or other suitable material insoluble in water, which will decompose or chemically unite with the said silicates; proportionate quantities of chalk, sand, or other similar substance may also be incorporated with the compound, and thus enable it to be obtained at less cost, in accordance with the nature or description of the work to which it is intended to be applied. A piece of stone manufactured with carbonate of lead, powdered pumice stone, and silicate of soda, in proportions stated in the specification, produces a very hard stone, without the application of any heat

1667*y*. Fluo-silicic acid and silicate of potash are also applied to the surfaces of stones.

1667*z*. The patent *Victoria stone* has stood the test of twenty years as paving. The floor of the entrance-hall at the "Colinderies" in 1886 sustained the traffic also of the years 1884 and 1885, having had some five million people passing over it. In the course of 1886 it was laid on London Bridge, where the foot traffic is stated to exceed 80,000 passengers per day—the heaviest traffic in the world. It bears a crushing weight of 8321 lbs. per cubic inch; a tensile strain of from 794 lbs. to 1125 lbs. per square inch; its porosity is 7·6 per cent. in twenty-four hours, as against 17·0 for Bath, 13·5 for good Portland, or 8·0 for Park Spring stones. See also Paving.

The Leopold Foreign Rock Asphalte in one of the main corridors was also severely tested by traffic. It is manufactured of Groby granite crushed until sufficiently small to pass through a certain sieve: it is then washed thoroughly to remove all earthy particles. This is mixed with Portland cement and well-burnt clinker, ground fine, and a metal-lined mould is filled with it. In a few days the slab has "set" into a hard concrete, and is then immersed for about ten days in silica fluid.

Hodges, Butler, and Dale manufacture an "Imperial stone" for copings, window sills, steps, coal-plate stones, silicated stone sewers, and water pipes, &c.

Sect. II.

GRANITE.

1668. Among the primitive rocks of the globe, whose period of creation is considered by geologists as antecedent to that of organic beings, is that of granite, whose use in architecture seems to bid defiance to time itself. The term granite appears to be a corruption of the Latin word *geranites*, used by Pliny to denote a particular species of stone. Tournefort, the naturalist, in the *Account of his Voyage to the Levant* in 1699, is the first of modern writers who uses the name. The word seems to have been applied by antiquaries to every granular stone susceptible of use in architecture or sculpture, in which vague sense it was used by mineralogists until about fifty years since, when true granite was classed as a particular mountain rock. Its constituent parts are concretions of felspar, quartz, and mica, intimately joined together, but without any basis or ground. These parts are variable in quantity, so that sometimes one, sometimes the other, and frequently two of them, predominate over the third. The felspar is, however, generally in excess, as mica is the least considerable ingredient of the rock. In some varieties the quartz is wanting, in others the mica; but where these peculiarities occur, the granites must be considered as varieties, not as distinct species.

1669. The constituent parts differ in their magnitude, alternating from large to small and very fine granular. The colour, moreover, is very variable, depending principally on the predominating ingredient—the felspar, the quartz, and the mica having usually a grey colour. The felspar is mostly white, inclining to grey and yellow, sometimes red, and even grey, seldom milk-white, and always translucent. The mica is usually grey, and sometimes nearly black. The felspar in granite has usually a vitreous lustre, and of perfectly foliated fracture; yet in some varieties it becomes quite earthy, with the loss of its hardness and lustre; in other words, it has passed into porcelain earth. The appearance in question is sometimes produced by the weathering of the felspar, and sometimes it appears to be in its original state. When pyrites are found in the veins which traverse granite, the vicinous felspar and mica are converted into a species of steatitical matter by the action of the sulphuric acid formed during the decomposition of the pyrites. In Cornwall, there is a considerable portion of its granite in which earthy felspar is found. When felspar occurs in abnormal quantities, the granite becomes porphyritic, as the Devonshire granite, and that of St. Honorine (Calvados): the name being derived from the colour, which is purple. Schorl takes the place of the mica in some parts of Devonshire; and even the quartz is sometimes wanting, as is often the case in the elvans or courses laden with mineral matters in that district. When hornblende occurs instead of mica, the granite becomes syenite, as at Malvern, and at Syene, in Egypt; and when present with mica in about equal quantities, the material is called Syenitic granite. When mica is present in such quantities as to cause the rock to assume a slaty cleavage, it is called gneiss.

1670. Granite is not decomposed by acids, and is only imperfectly and slowly calcinable in a great heat. Those species which contain much white felspar, and only a small portion of quartz, like the greater part of the granites of Cornwall and Devonshire, are liable to decomposition much sooner than many of the Scotch granites, in which the quartz is more abundant, and equally disseminated. In the selection of the Cornish and Devon granites, those are to be preferred which are raised in the largest blocks and are easiest worked, which, for common purposes, answer well enough, such as for paving-stones and the like; but harder granite must be sought for than Devonshire or Cornwall produces, where the construction is of importance; for the masses in these counties are mostly in a condition of rapid disintegration and decay, which seems chiefly attributable to their containing a large portion of potassa. The Naval Hospital at Plymouth is built of a granite whose parts appear to have been well selected. It was erected between the years 1756 and 1764, and, except in the columns of the colonnades, does not exhibit symptoms of decay. In these, on their more exposed sides, the disintegration of the felspar has commenced, and lichens have already attached their roots to some parts of the surfaces.

1670*a*. The cause of the *decomposition* of granite is a point yet unsolved by chemists. Some state that the felspar, being acted upon by the carbonic acid in rain water, becomes decomposed, and is then easily removed, leaving the mica and the quartz in relief without any cementing material; and that the decay of the felspar does not take place by any known rules, for the more crystalline it may be, more perfectly does it resist the decomposing action of atmospheric agents. Other scientific men are of opinion that the felspars containing soda generally decompose, whereas those which contain potash do not decay. It has also been considered that the kaolin or China clay was produced by the decomposition of the felspar with the granite; but it has been stated that so far as human observation could go, China clay never was true granite, and that atmospheric decomposition acting upon felspar, had never gone to the depth of 300 feet, at which depth finer China clay was found than nearer the surface: miles of country could be shown strewed with felspar; the quartz was gone, but the felspar remained. We must leave the decision in far more able hands.

1671. Red granite, sometimes yellowish, and generally interspersed with black mica, is found in Devonshire; at Mount Edgcombe there are tables of it equal to the finest oriental granite, and it is found also in other parts of England. For hardness, and in works where durability is indispensable, the granites from Mount Sorrel, in Leicestershire; Aberdeen and Dundee, in Scotland; and the Cheesewring of Cornwall, are to be preferred by the architect. These take an admirable polish, and are superior to all others which this island produces. The increasing demand of late years for this material, has caused many new quarries to be opened up in various localities. The red is generally harder than the grey sorts, and more difficult to work. The Peterhead, from the vicinity of Aberdeen, is perhaps the best, and it is, moreover, in appearance the most beautiful which Scotland affords; indeed, in point of beauty, it is only surpassed by the oriental granites.

1671*a*. Dartmoor granite is, in general, coarse grained, varying much in colour. The grey sort is chiefly quarried and worked at Hay Tor on the east side, shipped at Teignmouth; and at King Tor and Rigmoor Down, on the west side, shipped at Plymouth. The Brown Willy district, worked at the Cheesewring quarries, near Liskeard; the granite is of a light grey colour, and was used in the piers of the new Westminster bridge. The granite of the eastern portion of the Hensbarrow district, near St. Austell, worked above Par, is of good quality; it is shipped from that port, and known as Lostwithiel granite; the western portion is remarkable for its liability to decomposition, and is worked for kaolin clay. The Carn Menelez district supplies the granite generally known as Cornish, shipped from Penryn and Port Navis: blocks of several hundred tons are often raised, varying from 20 to 70 feet in length, and of proportionate breadth and thickness. The finest grain is obtained in the Carnseu quarries, near Penryn, from whence were got the stones for the lodges and piers at the British Museum, the plinths to the Royal Exchange, the pedestal for the statue of Lord Clive at Shrewsbury, and that for the statue of Carlo Alberto at Turin. It was used, 1887, for the monolithic columns to Messrs. Lloyd's new banking premises in Lombard Street. The columns at the entrance of the royal mausoleum at Frogmore are from Lamorna, south of Penzance; which, with Boswarvah and New Mill, to the west, have, with those at Penryn, supplied granite to most public works. Fremator granite, largely used at the steam dock-yard at Keyham, is white in colour, and being very close grained, it can be brought to a highly finished surface, and is said to be very durable.

1671*b*. Hay Tor granite company supplies a granite of a very fine grain, hard, of unquestionable durability, and generally of a beautiful blue or grey colour; it can be obtained in blocks of any size that is capable of being removed with existing machinery. The quarries have supplied the Nelson column and its pedestals; the granite plinth and steps of the Royal Exchange; the statue and pedestal of King William IV.; part of the river wall of the Houses of Parliament; the plinth of the Sun Fire Office, &c.; the large landings and steps of the terraces at the Crystal Palace; the graving docks at all H.M. Dockyards, as well as the ashlar steps and landings for the royal mausoleum at Frogmore. Grey granite from Lundy island, off the coast of Devonshire, is supplied for the first section of the Thames embankment.

1671*c*. The Port Nant granite, in Carnarvon bay, near Port Dinllaen, has been used at Liverpool for paving, for some years; for the tramway on Westminster bridge; for the Metropolitan drainage outfalls, and for the foundation works and pavement of the Thames embankment.

1671*d*. Granite is supplied from a comparatively limited extent in the north-eastern part of Aberdeenshire. The first or central portion is somewhat circular in form, having a diameter of about six miles, within which the rocks are of red granite of different varieties, typified by the fine warm coloured Stirling Hill stones; and secondly, of an annular space surrounding this nucleus, in which the grey and blue granites abound. Of these, the Cairngall is close-grained, hard and dense, and as obdurate as any of the red granites. At Pitsligo is obtained a light coloured bluish-white stone, which when fresh from the quarry, is wrought with greater facility than even some of the Scottish sandstones. It stands the weather well.

1671*e*. Rubislaw quarry was the first known quarry in Aberdeenshire, about two hundred and fifty years since, and furnished stones for paving London, and later for works at Portsmouth Docks and the Bell Rock Lighthouse. Since its introduction about 1820, various quarries have supplied granite for works at Waterloo Bridge (the balustrading), Sheerness Docks, upper side of London Bridge, &c. About 1822 Mr. A. Macdonald, of Aberdeen, reduced to practice the difficult problem of giving any required form to so stubborn a material, and communicating to its surface an enduring polish, which it is said, is retained under all atmospheric changes; nor does the material contract any stain with vegetation. The red granite quarries of Stirling Hill, near Peterhead, about thirty miles from Aberdeen, supplied the shaft of the Duke of York's column; the pillars in Fishmongers' Hall; the columns in the king's library in the British Museum about 1830; the pedestals for the statues in the same building; the columns at St. George's Hall, Liverpool, 25 feet in length in one block; and is now used in numerous buildings in nearly all the cities in Great Britain.

1671*f*. Grey or blue granite is supplied from the quarry of Rubislaw, but principally from Cairngall, which is more of a syenite than a granite, a clear blue finely-grained material, used for the finest work. This has been employed for portrait statues, as at Aberdeen, at Portsmouth, &c.; for the sarcophagus for the Duchess of Kent, and for that of the Prince Consort, both at Frogmore.

1671*g*. Argyleshire has only within the last twenty years been opened up for granite. Furnace quarry, near Inverary, is more of a Syenitic or porphyritic character than that of true granite, and is remarkably hard, in fact harder than that of Aberdeen. It is used chiefly for paving the streets of Glasgow. Bonaw Island quarry, near Oban, gives an excellent large-grained grey granite; it has been used in the harbour works, the flight of steps at the West End Park, &c., all at Glasgow, being obtainable in large blocks. Bonaw

Causeway quarry, near the above, though fine grained, does not supply large blocks; it is used for paving stones. Ardsheal quarry, north-east of Oban, has a good grey granite for general purposes. It is easily quarried in layers of any required length or breadth, and varies in thickness from 6 inches up to 3 feet. It is said to be less noisy and more safe as a paving stone than the generality of granites employed for that purpose.

1671*h*. The Ross of Mull quarries, in the island of the same name, supply granite of two sorts, red and pink, the felspar being in the former of a brilliant red, and in the latter of a delicate pink, tint. In its physical character it resembles the Aberdeen granite It is now sent in large quantities to the polishing works at Aberdeen, and, moreover, these quarries can supply larger blocks than can those of Peterhead. Both the red and pink varieties, after having been polished at Mr. Sim's works at Glasgow, were used in the Prince Consort's mausoleum at Frogmore; at the Skerryvore lighthouse; the Liverpool Docks; the Londonderry Docks; the Glasgow Water Works, &c.; and the pink granite in the foundations of the early work at the new Westminster Bridge: the Tormore or red granite being used for the curb to the footways.

1671*i*. The only quarries in the south-west of Scotland are Kirkmabreck quarry, near Creetoun, Wigtown Bay, which furnishes a silver grey granite, used for the obelisk sent by Mr. Sim to the Exhibition of 1862; and used for many years in the Liverpool Docks. Blocks of any size are readily attainable. Dalbeattie quarry, near Dumfries, has a large-grained grey granite, taking a high polish; there is a difficulty in getting large blocks free from black marks, but it is largely worked for general purposes, kerbing, &c., and for ornamental purposes.

1671*j*. The granites of Ireland are in general a speckled grey, inclining to white, as those of Wicklow, Dublin, &c.; also greenish from hornblende, as Mourne, Newry, &c.; reddish, as Galway. The granite of the Wicklow range is used more extensively than that of any other district in the island. It varies considerably even within a limited distance. Near Kingstown it is very hard, the quartz predominating; this is only used for plain heavy work. For more ornamental purposes granite is brought from Ballyknocken, or Golden Hill, about twenty miles distant. It contains a larger proportion of felspar and less quartz than that of Kingstown, and is therefore more easily worked, and is of a lighter and more uniform and handsome colour, though less durable. Granite of the Carlow portion of the same range is similar. Granite of Down is generally of a darker colour, and more finely crystallized; it is quarried at several places, especially at Newry, from whence it is conveyed by water to several parts of the north of Ireland; it can be worked into fine mouldings, and is of a dark speckled colour. Galway granite is commonly of a reddish colour, containing large crystals of flesh-red felspar; occasionally it has a bluish tint. To the west of Clifden blocks of a moderate thickness, but of great length and width, can be obtained. Granite to the west of Mayo is similar, but the greater part of it in that county is of a dark bluish-grey colour, difficult to work and seldom used. In Donegal and Tyrone it is gneissose, and of the same character, and reddish. Cavan granite is similar to that of Down, and but little employed. In the counties of Kilkenny and Wexford it generally resembles that of the great Carlow range before noticed.

1671*k*. The Bagnalstown quarries, in Carlow, supply four different qualities of granite; I. For plain work, portions being soft, others hard; some fine-grained, and others coarse; and red, blue, grey, and brown in colour; all are obtained from the surface of the land. II. A fine grit, employed for ornamental work even in the Gothic style, is very durable, and of a very white colour. III. Not quite so fine, but much used for buildings and ornamental work, being very white in colour. It lies in horizontal beds of about 1 foot to 15 feet in thickness, and from 15 to 20 feet in length; some beds run 40 feet long. In the hall of the Oxford University Museum is a slab of it, about 10 feet long, 5 feet wide, and 7 inches thick. IV. A very hard granite used for street crossings in and near Cork, not slippery. All these granites are approved for terrace steps, from 6 to 15 feet in length; for floors in stores, porches and halls, as in damp weather it absorbs the moisture from the atmosphere.

1672. Granite used for *paving* purposes is imported for *curbs and trams*, from Guernsey, Jersey, Aberdeen, and Devonshire. For *pitching and macadam*, from Aberdeen; Mount Sorrel, Markfield, and Grooby, all in Leicestershire; Guernsey; and a small quantity from Wales. Mount Sorrel granite is red in colour, and was employed for the altar steps in St. Paul's Cathedral. Granite from the Furnace quarries, at Inverary, as before noticed, is much used in the streets at Glasgow. Markfield and Grooby granites are dark green. The granite from the island of Herm, near Guernsey, was used for the steps to the Duke of York's column, but the cost of working and difficulty of shipping it at the quarry, have led to much discontinuance of its use.

1672*a*. Aberdeen granite is most extensively employed for *curbs, trams, and pitching*; the latter in thin cubes about 9 inches in depth, 3 inches in thickness, and not exceeding 18 inches in length, fair dressed throughout, it being considered the best granite adapted for the traffic of London, as it is very durable and less slippery than most other granites, such as that of Guernsey, for instance, which is therefore now seldom adopted. The Welsh granite has the same fault, for, with a large amount of traffic in dry weather, it becomes necessary to throw gravel over it. Guernsey macadam, broken to pass through a 2½ inch mesh at the largest, is found to be by far the best material for the purpose, one coat properly applied outlasting two of any other granite. The Devon granite being coarse in grain, is used only in curbs for second-rate streets, while for pitching it is not to be compared in price or quality with that of Aberdeen. Blue Bombay, and blue Port Philip granites, are hard and tough, and make good second-class roads; while grey China granite is soft and friable, and only good for the foundation of a new road.

1672*b*. We are indebted for several of the details here given on this subject, to the article in the *Dictionary of Architecture* of the Architectural Publication Society. The *Builder* for 1866 has also entered on the merits of Scottish granites.

1672*c*. Table of the Weights of Granites.

Name.	Country.	Weight per cubic foot, Avoirdupois. lbs	oz.	dr.
Stirling Hill	Stirling	165	14	5
High Rock, Breadalbane		166	0	9
Black Hill	Stirling	166	10	4
Dalkey	Dublin	169	9	7

„ red	„	165	4	0
Cornish grey	Cornwall	166	12	0
„ red	„	164	0	0

Sect. III.

MARBLE.

1673. With the architect and sculptor the name of marble is applied to all stones, harder than gypsum, that are found in large masses, and are susceptible of a good polish. On this principle, under the head of marble, are included many varieties of limestone, porphyry, and even granite and fine-grained basalts. But with mineralogists the word is used in a much more restricted sense, and is confined to such varieties of dolomite, swinestone, and compact and granularly foliated limestone as are capable of receiving a good polish.

1674. The *external characters* are as follows: colours white, grey, red, yellow, and green. Has generally but one colour, though it is often spotted, dotted, striped, and veined. Occurs massive, and in angulo-granular distinct concretions. Internally it alternates from shining to glistening and glimmering; lustre intermediate between pearly and vitreous. Fracture foliated, but oftentimes inclining to splintery. Fragments indeterminate, angular, and rather blunt-edged. More or less translucent. Brittle, and easily frangible. Its *chemical characters* are, that it generally phosphoresces when pounded, or when thrown on glowing coals. It is infusible before the blow-pipe. Dissolves with effervescence in acids.

Constituent parts,	Lime	56·50
	Carbonic acid	43·00
	Water	0·50
		100·00

1675. All the varieties may be burnt into quicklime; but it is found that in many of them the concretions exfoliate and separate during the volatilization of their carbonic acid, so that by the time that they become perfectly caustic, their cohesion is destroyed, and they fall into a kind of sand, which renders a common kiln inapplicable.

1676. The varieties of marble are almost infinite. Those employed by the ancients, as well as porphyry, are noticed in the Glossary. Besides the paper *On Marbles* read in 1887 by Mr. Brindley, and quoted hereafter, the book by G. H. Blagrove *On Marble Decoration*, 8vo. 1888, and that by A. Lee, *Marble and Marble Workers*, 8vo. 1888, are valuable contributions to the subject.

1677. The principal part of the supply to England of whitish marble is from Carrara, a small town or village of Tuscany, in Italy. The quarries at this place were celebrated from an early period, and spots are still shown about them whence they dug the marble for the Pantheon. Masses of marble are sometimes procured there nine feet in length and from four to six in breadth. The quarries are the property of the principal inhabitants of the town, who carry on an extensive trade in the article; but the difficulty of choosing the marble has induced artists to settle there for the execution of their works, and the consequence is, that sculpture abounds and flourishes in the town. The white or Statuary, Italian-veined, Dove-coloured, Pavonazzo or purple veined, and Ravaccione (called Sicilian, supposed to have obtained its name from early shiploads of it having been reshipped or sent on from some port in Sicily, at which the vessel touched in its voyage) marbles, are but very slight variations of the same substance; the Dove and "Sicilian" have a little more carbonaceous matter in their composition; but they are all procured from quarries in the immediate neighbourhood of Carrara. Serravezza, in Lucca, produces Statuary, Ravaccione, veined or Bianco chiaro, Mischio di Serravezza, Bardiglio, and Bardiglio fiorito.

1677*a*. All varieties of Carrara marble have perishable qualities, which ought to preclude them from being ever applied to external purposes in this country. After exposure to the weather for thirty or forty years, disintegration through its entire mass, but mostly on or near the surface, evidently takes place; after the lapse of about a century, more or less, according to the quality of the marble, the entire substance falls into a kind of sparkling sand. The group of Queen Anne, &c., in front of St. Paul's Cathedral, sculptured by Francis Bird in the beginning of the last century, had been painted long since, and was in 1887 entirely renewed. A mural monument by J. Nollekens, erected about 1780 over the centre door within the portico of Bloomsbury Church, fell on to the pavement during the winter of 1837–8, so thoroughly pulverised as to resemble a fall of snow rather than bits of marble. Milan Cathedral is built of the white marble of Monte Candoglio or Candido, on the Toce, a tributary of the Lago Maggiore, selected as better fitted to stand the atmosphere than Carrara marble, of which it is usually said to be built: the "7,000 statues" (1863) are most probably all of the latter material.

1677*b*. The Ravaccione, or so called "Sicilian" marble, is expected to resist the action of an English atmosphere longer than Italian veined, or white Carrara marble. On examination, however, it will be found that its chemical and mineralogical character scarcely differs from them, except in weight, hardness, and as containing a little more carbonaceous matter. The Marble Arch, erected 1825–7 in front of Buckingham Palace, was removed to its present site 1850–1, when it was found necessary to rub the exposed surfaces with sand and stone, as they were in a state of disintegration. Perhaps the tomb by Sir F. Chantrey, executed about 1820, in the burial-ground of St. John's Wood Chapel, is the oldest specimen in London, if not in England. The surface may now be abraded with the fingers, like sand. This material has of late years been extensively used in the cemeteries round London. But on a careful inspection of stones of three years' date, it will be found that the polish is nearly gone; and even the paint of the lettering has entirely disappeared. Frequent changes of temperature also tend to destroy Carrara marble more rapidly than atmospheric influences; thus the mantel of a chimneypiece is invariably disintegrated long before any other part. The late C. H. Smith, in the *Builder* of 1864, strongly urged the employment of Hopton Wood stone (par. 1666*i*.) in lieu of it for all out-door works.

1677*c*. *Massa Carrara* quarries. The special produce now is—I. The ordinary marble called "Sicilian," having a white ground variously marked with grey veins, spots, &c.: it is good for interiors as it is easily worked. II. A very hard ordinary "Silician," of a bluish white with dark veins, adapted for steps and out-door work. When well polished it has great resisting power. It has been used for the principal staircase of the Merchant Venturers' school at Bristol, where the final polish was omitted; and in some "flats" in Portland Place. III. A dark grey marble with black veins, called *Bardiglio*, which has been largely used as a building stone in Naples, and as altar steps in Sweden. IV. A marble called *Blanc P.*, a bluish white without veins, but not so lustrous nor so pure a white as statuary marble. It is much used in Belgium, France, and Ireland, for statues, tombs, and floral carvings; and is little known in London. The quarry which supplied the *Blanc P.* is stated to have been worked out long since; but another marble so called is merely a superior class of "veined white;" a large quantity is used in London. *Tyrolese marble* possesses all the beauties of that obtained from the Carrara quarries, and is, moreover, from its intense hardness, almost indestructible, and better adapted for exposure to the climate of this country.

1678. There is a beautiful species of yellow marble obtained from the quarries near Siena, in Italy, and known in England as Siena marble; but the quantity now imported is not very great, and what is introduced is very poor in colour. A good quality, both in colour and vein, can, however, be procured at the quarries by special orders.

1678*a*. The marbles of Sicily, little, if at all, employed in this country, are enumerated as follows:—Marmo di Trapani, of a grey colour; M. di Castelnuovo, of a yellow colour; M. di Segesta, of a yellow colour; M. di Taormina, of a red colour; M. di Parco, of a yellow colour; M. d' Ogliastro, of a red colour; and M. di Castelaccio, of a grey colour. The two last-named marbles are readily obtainable in blocks 12 or 13 feet long. Specimens of some, if not all of these, are included in the fine collection of polished marbles made by the learned Corsi of Rome, an account of which he published: the collection was subsequently brought to England, and is believed to exist at Liverpool. Each specimen it contained is no less than 8 inches Italian long, 4 inches wide, and 2 inches thick, and highly polished on all sides.

1679. Many of the marbles of France and Belgium are extremely beautiful. They are chiefly used in this country for chimney pieces. The following is a list (including others) of those so worked, supplied from one of the Belgian workshops:—Rouge royal; Bleu Belge; Rouge Griotte; French red; Saint Anna; Noir Belge; Noir Belge, second quality; Breccia (Brêche); Breccia and black; Breccia Romana; Breccia rose; Saint Gerard; Sicilian; Sicilian, white veined; Pavonazzo; Statuary; Statuary, second quality; Malachite; Ver de Mer; Black and green; Porphyry; Brocatello; Siena; Siena, second quality; Italian Griotte; Black and gold; Black and gold, second quality; Bardilla; and Sarracolin. Another marble, named Saint Mont Clarie, is a pure black.

1680. The marbles of Spain are likewise very fine, but are not exported. A specimen of the "Emperor's Red," of unusually fine quality, was presented to the Queen by the late Don Pedro, King of Portugal, for the royal mausoleum at Frogmore.

1681. The marbles of the British Islands deserve more notice from the English architect than they have hitherto received. In England there are but few as yet quarried of granular foliated limestone, the greater number of varieties of them belonging to the floetz or secondary limestone. The most remarkable, and perhaps most beautiful, of the English marbles, is that of Anglesea, called *Mona marble*, and much resembling Verd antique. Its colours are greenish black, leek green, and sometimes purple, irregularly blended with white, but they are not always seen together in the same piece. The white part is limestone, the green shades are said to be owing to serpentine and asbestus. The Isle of Man marbles are—I. Black flagstone (Posidonia schist) from Poolvash, the quarries of which have been worked for upwards of two hundred years; and furnished the steps in St. Paul's Cathedral, presented by Bishop Thomas Wilson. II. Grey marble (encrinital and shelly limestone) from Poolvash, used for tables and chimney ornaments. III. Black marble (lower carboniferous) limestone, from Port St. Mary, extremely hard and durable, taking a good polish; raised in blocks and flags of great size, and used for piers, floorings, and tombstones. IV. Pale marble (carboniferous limestone (from Scarlett. Castle Rushen, nine hundred years old, and other places, are built with this most durable material. V. Spanish Head flagstone (clay schist), Port St. Mary; is a durable material, and used for lintel and gate posts; it is slightly elastic when in thin flags, and can be raised in square slabs of 16 feet. VI. Peel freestone (old red sandstone), from Craig Millin; of this stone a large portion of Peel Cathedral was built in 1226. (Cumming. *Isle of Man, &c.*)

1681*a*. The ornamental marbles of Derbyshire are mostly confined to the 1st, 2nd, and 3rd classes of limestones, which are separated from each other by the *toadstone*, an amygdaloidal trap rock. These marbles are usually distinguished by their colour, as white, grey, dove, blue, black, and russet; or by physical peculiarities, depending mostly on their fossil contents, as bird's-eye, dog-tooth or muscle, entrochal, shelly, and breccia marbles. Quarries of *black marble* are situated near Ashford, where machinery for cutting and polishing these marbles was first used in 1748. The beds of black marble seldom exceed 7 or 8 inches; it is difficult to be obtained of any considerable surface free from "shakes," or small veins of white spar. It is also procured at Matlock and Monsaldah. A brown marble, in thin bands of various depths of colour, is called "rosewood," as it presents the appearance of it when polished. It is one of the hardest and most durable of the Derbyshire marbles. A red marble, resembling Rosso antico, is found chiefly near Newhaven, in lumps of no great size. These and other Derbyshire marbles are principally used for inlaying work, as vases, tables, &c., but chimney pieces, columns, &c., are now made at Ashford, Bakewell, Buckland Hollow, and at Derby. This Florentine work, as it is called, is remarkable for fineness of execution and beauty of design, and is almost confined to the county.

1681*b*. A beautiful greyish-black coralloid marble is also found in Derbyshire and in Wales. The corals it contains are of the porous kind, of the most elegant species, lodged at all angles and in all directions, and are in general about one inch and a half long and three quarters of an inch broad. The other species of coralloid marble is equally beautiful and compact, fine, even texture, very hard, of a deep jet black, and capable of a very high polish. It is variegated with species similar to the above, but smaller, and of a less elegant texture; among these it has usually a great number of sea shells, both turbinated and bivalve, the coral and shells being of a pure snow white.

1681c. The North Devonshire marbles are abundant and diversified. There are varieties of black and white, from Bridestow, South Tawton, and Drewsteignton. Some of the Chudley, Staverton, and Berry Pomeroy, marbles, have a black ground with large veins of calcareous spar traversing it in all directions. The variegated marbles are generally reddish, brownish, and greyish, variously veined with white and yellow, and the colours are often intimately blended. The South Devonshire marbles, now chiefly worked at St. Mary Church, Torquay, from the Babbacombe limestone, are called after the name of the estate or quarry from whence they are taken, such as the Petiton, Ogwell, Ashburton, Babbacombe, &c. The colours are red, grey, and variegated, of almost every tint. The sizes of the blocks vary from 1 to 10 tons; the ordinary length runs from 4 to 5 feet; 7 to 8 feet is considered as a good length. At Ipplepen are reddish varieties that are extremely handsome. They are of different qualities, as compact, porcellanic, granular, crystalline, shelly, magnesian, pozolanic or water, stinking or swine. The Bartons quarry at Ipplepen, belonging to Mr. Field, of Parliament Street, is worked at 80 to 100 feet in depth; the lowest beds are about 8 feet thick, and of a mottled character, being dark red and white in colour; the deposit over it is streaky and lighter in colour. Blocks of 18 feet square are now conveyed to London. This quarry has lately supplied the monolithic polished shafts for the forty columns (18 out of one block), each 12 feet 3 inches in length, and 18½ inches diameter on the fillet, with many others, for the new building of the National Provincial Bank of England, in Bishopsgate Street. The bases are of Irish black marble, and the caps of the cream-coloured Huddlestone stone. In the corridor of the new Freemasons' Hall are four columns, two being from the Bartons quarries, and two of Languedoc marble: eight others are placed in the coffee-room of the Charing Cross Hotel. The limestones of Plymouth are not so fine. They are of two sorts; one, an ash colour shaded with black veins; the other blackish grey and white, shaded in concentric spots interspersed with irregular red spots; or black with white veins about a quarter to an inch in width.

1681*d*. *Serpentine*, "beyond all question, the most beautiful of the ornamental stones of this country" (Hunt), is chiefly found in the sea-bound peninsula called the Lizard, the most southerly land in Great Britain. This rock, with another called diallage, constitute nearly half of the Lizard peninsula. Serpentine has evidently been under the influence of heat. At one spot it seems to shade off into the hornblende slate in which it is embedded; at another, it has every appearance of having been thrust up among the hornblende slate. Sir Henry de la Beche wrote, many years since, that serpentine *ought* to be employed for decorative purposes. He named Landewednack, Cadgwith, Kennack, Cove, and Goosehilly Downs, as four sites whence beautiful specimens might be obtained, varying in colour, as, an olive green base striped with greenish-blue steatite veins; another specimen, very hard, with a reddish base studded with crystals of the mineral called *diallage*, which when cut through and polished, gives forth a beautiful metallic green glitter, heightened still further by the reddish tint of the mass in which it is embedded. To the Exhibition of 1851, Penzance sent fine specimens in all kinds of ornaments. The blocks are small, but sometimes they have been obtained 7 feet in length and 4 or 5 tons in weight; the largest was 8 feet long, 3 feet wide, and 2½ feet thick; from 2 to 3 feet long is the usual size. The best blocks are worth from 5 to 10 guineas per ton, according to their weight, the larger the size the higher is the value in an increasing proportion. Chemically, steatite and serpentine differ little from each other, and as they are quarried in juxtaposition, specimens of both kinds are selected for use; but serpentine being much harder and more richly coloured, is appropriated to the larger articles.

1681*e*. In the *Builder* of 1865, p. 877, it is stated that serpentine is not a marble, but a talc containing a tolerable quantity of chromate of iron. It is sometimes good for external ornamentation, but never when it has the white streaks so commonly seen in it. Hunt's *Handbook to the* 1851 *Exhibition*, gives the following analysis of serpentine obtained at the Lizard:—Magnesia, 38·68; silica, 42·50; lime and alumina, 2·10; oxide of iron, 1·50; oxide of manganese, 1·0; oxide of chromium, 0·30; the colouring matter is probably a combination of chromium, iron, and manganese. In his *Handbook to the* 1862 *Exhibition*, it is called a hydrated silicitate of magnesia, composed of silica, 43·64; magnesia, 43·35; and water, 13·01 = 100. Besides the supply from the Lizard, it is obtained in Anglesea, Portsoy in Banffshire, Unst and Fetlar in Scotland. The "green marble," or serpentine, of Connemara, is noticed among the Irish marbles. This material is sawn by steam power with sand and water; and when brought into the form required, it is ground, turned, rubbed, and polished until it presents a beautiful glossy surface, said to be capable of resisting grease and acids, which is not the case with marble in general.

1681*f*. It is said that two brackets of old monuments in Westminster Abbey; the panel-bordering of the monument erected to the memory of Addison; the brackets of a chimney-piece at Hampton Court, are all carved in serpentine, and the present condition of these specimens shows the durability of it. "Equal to granite in durability," is the statement made in advertisements, but probably some further time must elapse before such a statement can be endorsed, though it may be allowed that it appears to stand atmospheric influences remarkably well. Experiments on the strength of serpentine have been noticed in par. 1502*g*. Therein is mentioned a shaft of Poltesco grey-green Devonshire serpentine, one of the weakest examples, which went across and not with the vein: the latter running in the line of the diameter. The green serpentine has been used lately on the outside of some offices in Cornhill; and the red quality in 1853 in Leicester Square.

1681*g*. Purbeck, Petworth, or Sussex marble, is the name of a material common to Derbyshire, Dorsetshire, the Isle of Wight, Kent, Surrey, and Sussex. It is found at Dinton, near Aylesbury, and it occurs at Boulogne and at Beauvais, in France. In some places, as in the most westerly quarries near Corfe Castle, and at the top of the Isle of Portland, the Purbeck stone is so highly coloured and fine-grained, that it is chiefly identified as belonging to the fresh water deposits by the fossils it contains. In general, the stone may be said to be fine grained in the quarries north and west; while in those approaching the east the pattern is larger, the shells well defined, and scarcely any of them broken; the marble from this district is therefore handsomer, and more in request for ornamental purposes. Purbeck was well known for its quarries during the middle ages, when the marble was in great request for decorating the clustered shafts and sepulchral tombs, and for pavements, in churches. At the present time, there is scarcely sufficient demand to keep more than a few men at work, and this at Woody-hyde, near Corfe Castle, where the genuine material or Purbeck marble can be obtained, and that quarry is a *hole* more than a quarry. It has been stated that, during the middle ages, this material was also obtained from quarries at Parham Park, six miles north-east of Arundel, but there are now no traces of it left on the surface.

1681*h*. All varieties of Purbeck marble contain a large proportion of clay in their composition, which is one chief cause of their perishable nature. In the interior of buildings the moisture in the air will be condensed, and absorbed into the argillaceous portion of the marble. While this process is going on, the lustre of the polish is gradually diminished, the colour is altered, its hardness and cohesion destroyed, until the surface is completely changed to a dull earthy appearance, and decay results, which will be facilitated in proportion to the amount of clay contained in a given mass. When, as in small columns, this material is placed with the planes of lamination in a vertical position, there results another and a greater tendency to decay. The clustered columns in the Temple church, though renewed in 1840–42, had already lost much of their polish in 1853, a preliminary stage towards decay. The large ancient columns supporting the clere-story at Westminster Abbey, have now scarcely a trace left of their original surface. (C. H. Smith, *Transactions*, Institute of British Architects, 1853). As already stated, this sort of marble is obtained in Kent, where it is also known as Bethersden marble, and likewise as Lovelace marble, obtained near Ashford. In the east and west sides of the new quadrangle of St. John's College, Oxford, are sixteen entire columns of "Bletchingden marble," which were put up in 1631–35. It may be seen in Hythe Church and in some of the neighbouring churches, where it is often varnished in lieu of being polished. The Purbeck marble columns used in Lincoln Minster, in 1186–1200 are asserted to have been worked up by vinegar.

1682. Of the Scotch marbles the principal are the *Tiree*, of which there are two varieties, red and white. The *Iona*, whose colours are a greyish white and snow white, sometimes intermixed with steatite, giving it a green or yellow colour in spots and known under the name of Iona or Icolmkill pebbles. It does not take a high polish. The *Skye* marble, of greyish hue, with occasionally various veins. The *Assynt* varieties of white, of grey, and dove colour. *Glen Tilt* marble, white and grey, with occasionally yellow and green spots. Marble of *Balliculish*, of a grey or white colour, and capable of being produced in considerable blocks. *Boyne* marble, grey or white, and taking a good polish. *Blairgowrie*, in Perthshire, of a pure white colour, fit, it is said, to be employed in statuary and for architectural purposes; and *Glenavon*, a white marble, said by Williams (*Natural History of the Mineral Kingdom*) to be a valuable marble, is not used, from the remoteness of its situation and the difficulty of access to it.

1683. Ireland is rich in marbles. The dark colours vary from jet black to dark dove colour, purple, blue, and grey; the light colours, from the pure snow white to the celined, cream coloured, pink, and light grey. The variegated consist of the serpentine, black and white veined, mottled, and those marked with fossil organic remains. The black marbles, which are those of most value in Ireland, are extensively met with, and belong to the lower limestone. The merchantable beds of the best quality, which have been extensively worked, are met with in the counties of Galway, Limerick, Carlow, and Kilkenny. It is also found in the counties of Mayo and Waterford. The best quarries are considered to be those close to the town of Galway, near the bank of Lough Corrib. It occurs in three beds, varying from about 9 to 12 inches in thickness. One is called the "London bed," as it supplies most of the black marble exported to London. Blocks are raised of an average size of about 5 to 10 feet in length, and 4 to 5 feet in width; others 20 feet in length can be obtained. Some blocks 16 feet in length were sent over for a staircase for the Duke of Hamilton's seat in Scotland, who was also furnished with landings and solid balustrades worked to a fine polish. Angliham and Merlin Park quarries supply black marble of the very finest description, receiving a high polish. Steps of it were supplied for the porticos at St. Paul's, the staircases at Marlborough House, Hampton Court, and Kensington Palace, under Sir C. Wren, cir. 1700. At Oughterard, the beds contain more or less silica, rendering them not so valuable. At Kilkenny, it abounds with shells, which become more conspicuous as the marble dries Kilkenny marble was once extensively employed in Ireland, but the black is now preferred. The polish of black marble, while it is considerably affected by dampness, is much improved and preserved by being kept dry.

1683*a*. Dark grey and dark mottled grey marbles are met with chiefly in King's county and in several parts of the county of Cork. Near Tullamore, marble is obtained in large blocks capable of receiving a fine polish, and is much used for chimney-pieces and ornamental works. The limestone around Cork produces easy working marble of a light grey or dove colour, and more or less mottled, receiving a good polish. In the primary districts of Donegal, a light grey and bluish grey coloured marble of close grain is found to a great extent; most of it, however, is hard to work from the quantity of silex it contains. The same kind of a bluish tint is very frequent in Connemara. It is compact in texture, but does not always produce a satisfactory polish. *White marble* occurs in the western portion of county Donegal, differing much from that of Connemara. It is of comparatively easy conversion, and can be obtained in cubical blocks in great quantities; its very coarsely granular texture, however, is prejudicial to it for many purposes; for boldly executed works in sculpture, where the expense of carriage would be avoided, it might be advantageously employed for many purposes; but it will not vie with the marble of Carrara. The Connemara white marble is hard and fine, and the strongest yet found; it cannot, however, be procured in large blocks free from streaks, which pass through the blocks parallel with the beds. At Chevy, near Dungannon, county Tyrone, a very delicate cream coloured marble is obtained, very compact in texture, receiving a high degree of polish, and blocks of great length can be procured. The coarsely crystalline and fossiliferous limestone at Ardbraccan produces light coloured marble of easy conversion.

1683*b*. Of the variegated marbles, the *Siena* of the best quality is perhaps the most beautiful. It is obtained in several places in King's county; but the best, the veined or mottled Siena, is found near the Seven Churches. It is susceptible of a high polish, and exhibits many bright and distinct colours. Marble of the same character also prevails, having a dove coloured ground, varied or mottled with Siena colour. In the county of Armagh, a Siena, or rather a brownish red marble, is found, containing a great number of fossil shells; several varieties of colour, from a very light reddish brown to a rather dark red, are also met with, more or less marked with shells. At Pallaskenry in the county of Limerick, a dark red and mottled marble is abundant, and has been much used. A red coloured marble, of a compact but slaty texture, occurs in the county of Cork, extending from the city in a narrow seam, for a distance of several miles. It is hard to work and dull in colour: at one time it was extensively used.

1683*c*. The serpentine, or *green marble*, as it is usually called, of Connemara, in county Galway, is of a dull green colour. Blocks are raised of considerable size, from which slabs can be obtained, at Barnanoraun quarry, near that at Recess; and at Letternaphy quarry, near Clifden; the latter being rather coarse in quality; while at Tievebaun quarry, near Recess, the marble is dark green, very sound, and free from shakes of any kind. Black and white marble, and that of a mottled character, occur near Cork, in the counties of Waterford, Longford, and Kerry; some of the varieties are very fine; that obtained near Mitchelstown is well marked and receives a high polish. The limestone obtained near the Seven Churches in King's county, when polished, produces a good marble of an even grey colour. It is strongly mottled with very numerous fossil organic remains. It is easily worked, and raised from the quarries in thin beds. This marble, in a polished state, has been used in the construction of one of the principal ruins at the Seven Churches; some of the stones retain their polish to this time, while others exhibit decay. (Wilkinson, *Geology, &c. of Ireland*, 1845). A fine purple marble is found at Loughlougher in county Tipperary, which is said to be beautiful when polished. Some of a purple colour, and purple and white intermixed with yellow spots, were to be procured in the islands near Dunkerron in the river Kenmare.

1683*d*. Table of the Weights of Marbles.

Name.	County or Country.	Weight per cubic foot, avoirdupois. lbs.	oz.	dr.
Black - - - -	Kilkenny - - -	171	6	0
Tiree - - - -	Hebrides, Scotland - -	172	5	0
Carrara, Statuary - -	Tuscany - - -	168	10	5
„ Ravaccione - -	„ - - -	169	2	8
Ipplepen, Bartons quarry -	Devonshire - - -	163	6	0

Its tenacity is stated at 6,000 lbs. per square inch, and its crushing weight is also put at 6,000 lbs. per square inch. (Hunt.) (1520*q*.)

Sect. IV.

TIMBER.

1684. The information we propose here to lay before the reader relative to the different species of timber is extracted from Miller's *Gardener's Dictionary*, Rondelet's *Art de Bâtir*, *Rees's Cyclopædia*, and Hunter's edition of Evelyn's *Sylva*. To give any thing like the information that would satisfy the botanist would be out of place in an architectural work; and we therefore confine our observations to those which will be useful to the student.

1685. Oak. Of this most valuable timber for building purposes Vitruvius (lib. ii. cap. ix.) enumerates five species, which it would now be difficult to identify. That some species of the Quercus of the botanists are more valuable for building purposes than others no doubts exist. Evelyn seems to commend especially the Irish oak, because of its withstanding the efforts of the worm; but it is not easy to ascertain the particular species to which he alludes In the present day the Sussex oak is esteemed the most valuable; a value, according to some authors, derived from the nature of the soil and from good management in the culture, which is an object of no small importance.

1686. Generally, it has been usual to consider England as producing, without difference in quality, but one species of oak; but two sorts are well known to the English botanist, the *Quercus Robur* and the *Quercus Sessiliflora*. The former is found throughout the temperate parts of Europe, and is that most common in the southern parts of England. Its leaves are formed with irregular sinuosities, and their footstalks are short, occasionally almost without any at all. It attains a very large size, and the wood is tolerably straight-grained and pretty free from knots, in many instances resembling the German species called wainscot. It is easily split for making laths for plasterers and slaters, and is beyond doubt the best sort for joist, rafters, and other purposes where stiff and straight-grained timber is a desideratum. In the Quercus Sessiliflora, which, though found about Dulwich and Norwood, according to Miller, appears to be the common oak of Durham, and perhaps of the north of England, the leaves have long footstalks, frequently an inch in length, and their sinuosities are not so deep, but are more regular than those of the Robur just described. The acorns are so close to the branches as to have scarcely any stalks. The wood is of a darker hue, and the grain is so smooth that it resembles chesnut. Than the Robur it possesses more elasticity, hardness, and weight, but in seasoning it is subject to warp and split; hence unfit for laths, which in the north of England are rarely of oak. There is no reason for supposing, as has been conjectured, that the oak of the Gothic roofs of the country is of this species, though we are aware of the great durability of the oak in the buildings in the northern part of the island.

1687. The specific gravity of the species first named, that is, the Quercus Robur, may be taken at about ·800, and the weight of a cube foot 50·45 lbs. That of the last-named at ·875, and the weight of a cube foot at about 55·00 lbs. Their cohesive force and toughness are proportionable.

1688. The American species scarcely claim a notice here, because their use in England is, from every circumstance, out of the question. Of the red oak of Canada (Quercus rubra), the only one of which the use could be contemplated, we merely observe, that it is a light, spongy, and far from durable wood, though, in the country, in many instances useful. Its growth is rapid, and it rises to the height of 90 or 100 feet.

1689. There is a species of oak imported from Norway, which has received the name of *clapboard*, and another imported from Holland, known under the name of *Dutch wainscot*, though grown in Germany, whence it is floated down the Rhine for exportation. The latter is destitute of the white streaks which cross the former, and is thereby distinguished from it. The use of these woods has latterly much diminished in England. They are both softer than common oak, and the clapboard far inferior to wainscot. They are more commonly used for fittings and fixtures, whereto they are well adapted. In damp situations, oak decays gradually from its external surface to the centre of the tree; the ring on the outside, which it acquired in the last year of the growth of the tree, decaying first; but if the tree be not felled till past its prime, its decay is reversed by its commencement at the centre. An oak rarely reaches its prime under the age of an hundred years; after that period, which is that of its greatest strength, it cannot be considered as fit for building purposes; and, indeed, it may be taken as a rule, that oak before arriving at its maturity is stronger than that which has passed it.

1690. If the architect has the opportunity of selecting the timber whilst in a state of growth, he will, of course, choose healthy, vigorous, and flourishing trees. Those in which the trunks are most even are to be preferred. A mark of decay is detected in any swelling above the general surface of the wood. Dead branches, especially at the top of the tree, render it suspicious, though the root is the best index to its soundness. The notion of Alberti (*De Re Ædificatoria*), of using all the timber in the same building from the same forest, is a little too fanciful for these days. though we confess we have some misgivings in impugning an authority which, in most other respects, we are inclined to receive with the highest veneration.

1691. In felling not only the oak, but all other large trees, the great branches should be first cut off, so that the tree may not be injured or strained in its fall; and the trunk, moreover, must be sawed as close to the ground as possible. When felled, but not before, it is to be barked, trimmed of its branches, and left to season. Before, however, leaving it for this purpose, it is considered by workmen better to square it, which, it is thought, prevents its tendency to split. If to be employed for posts or bearing pieces, boring it has been employed with success; but it is needless to observe, that in pieces subject to transverse strains such a practice is not to be recommended.

1692. The pieces selected for building must be chosen with the straightest grain; but there are pieces which are occasionally employed, as for knees and braces, wherein a curvilinear direction of the fibres of the timber is extremely desirable. It may, however, be generally stated, that, in the case of two equal-sized and seasoned pieces, the heavier is the piece to be preferred.

1693. In oak, as in all other woods, the boughs and branches are never so good as the body of the tree; the great are stronger than the small limbs, and the wood of the heart stronger than all. When green, wood is not so strong as when thoroughly dry, which it rarely is till two or three years after it is felled. It is scarcely necessary to say, that, containing much sap, it is not only weaker, but decays sooner. It is weakened by knots, at which, in practice, it is found that fractures most frequently occur; and it is important to the architect to recollect that he should always reject cross-grained pieces.

1694. The great use of oak in this country is more for ship-building purposes than for architectural, its use, except in the provinces, being principally confined to pieces which are much liable to compression, or where great stiffness is required, or in pieces like sills to windows and door-cases, where there is much alternation of dryness and damp. So early as 1788, the consumption of oak for ship-building purposes was, in that year. upwards of 50,000 loads.

1695. When of good quality, it is more durable than any other wood which is procurable of a like size. In a dry state, it is ascertained to have lasted nearly a thousand years. The open-fibred porous oak of Lincolnshire, and some other places, is a bad sort. The best is that with the closest grain and the smallest pores. The colour, as is well known, is a fine brown; that which partakes of a reddish hue is not so good as the other. The smell of it is peculiar; it contains gallic acid, and it assumes a black purple colour when damp, by contact with iron. It warps and twists much in seasoning, and shrinks in width about one thirty-seventh part.

1696. CHESTNUT. One of the finest of the European timber trees, the *Fagus castanea* of botanists, was heretofore so common in this country, that Fitzstephen, in his description of London about the time of Henry II., mentions a fine forest of chesnuts as growing on the northern side of the city. It is stated to have been used in the buildings of our ancestors, but it is very doubtful if it was so employed. The young tree vies with the oak in durability, from the small proportion of sapwood it contains. Of its durability, the roofs of Westminster Hall, that of King's College, Cambridge, and that of Notre Dame, at Paris, are cited as examples, though the fact of the latter being of chesnut is doubted by Rondelet, who says that Buffon and D'Aubenton thought it a species of oak, which is now well known to be the case in the roof first named.

1697. Chestnut, however, is not to be trusted like oak. As Evelyn observed, it is often well-looking outside, when decayed and rotten within. Belidor says it soon rots when the ends of timbers of it are closed round in a wall.

1698. It is, perhaps, from the circumstance of its colour so nearly resembling that of oak, that one timber has so often been mistaken for the other. The difference, however, is, that the pores of the sapwood of the oak are larger and more thickly set and easily distinguished, whilst those in the chesnut require magnifying powers to be distinguished. But a more decided difference is, that the chesnut has no large transverse septa. It is far easier to work than oak, and is not very susceptible of swelling and shrinkage. From what has been mentioned above, it may be inferred that the wood, though tough and compact, is, when young, hardest and most flexible, the old wood being often shaky and brittle.

1699. Water pipes of this tree endure much longer than those of elm; and for tubs and vessels to hold water, it is superior to oak; for when once thoroughly seasoned, it will neither shrink nor swell, on which account it is used by the Italians for wine tuns and casks. It will thrive on most soils, but rather delights in a rich loamy land, succeeding well, also, on that which is gravelly, clayey, or sandy. Mixed soils are suitable to it, and it is found in the warmer mountainous situations of most parts of Europe.

1700. From the experiments, the cohesive force of a square inch of chesnut, when dry varies from 9570 to 12,000 lbs., and the weight of a cubic foot, when dry, is from 43 to 55 lbs.

1701. Beech (*Fagus Sylvatica*). A beautiful tree, growing to a considerable height, and carrying a proportionable trunk. It flourishes most in a dry warm soil, and grows moderately quick. The wood is hard, close, has a dry even grain, and, like the elm, bears the drift of spikes. The sorts of beech are the brown or black, and the white beech. It is common throughout Europe. In the southern parts of Buckinghamshire, where the soil is chalky, it is particularly abundant; and such is the case near Warbleton, in Sussex, on the southern range of chalk hills, where the beeches are very fine.

1702. Constantly immersed in water, the beech is very durable; such also is the case with it when constantly dry; but mere damp is injurious to it, and it is very liable to injury by worms, though to these Duhamel considers it much less liable when water-seasoned, than when seasoned in the common way. To render it less liable to the worm, it has been recommended to fell it about a fortnight after Midsummer, to cut it immediately into planks, which are to be placed in water about ten days and then dried. Beech is little used in building, except for piles, in which situation, if constantly wet, they are very durable. From its uniform texture and hardness, it is a good material for tools and furniture, and of it, in boards and planks, large quantities are brought to London. It is without sensible taste and smell, easy to work, and susceptible of a very smooth surface. The white sort is the hardest, though the black is tougher, and, according to Evelyn, more durable. The weight of a cube foot varies from 43 to 53 pounds.

1703. Walnut (*Juglans, quasi Jovis glans*) is of several sorts. The Juglans Regia, or common walnut, was formerly much cultivated in this island, as well for the sake of its timber as of its fruit. On the former account the importation of mahogany has long since rendered its cultivation less common. It flourishes better in a thin limestone soil, than in one that is rich and deep, and, if raised for timber, should not be transplanted, but remain in the place where it is sown. For furniture, from its rich brown colour, it is by many persons preferred to mahogany. Its scarcity renders its employment rare for building purposes, though by the ancients it was so employed. One of its properties is, that it is less liable to be affected by worms than any other timber, cedar only excepted; but from its brittle and cross-grained texture, it is not generally useful for the main timbers of a building.

1704. The heart-wood is of a greyish brown with dark brown pores, often veined with darker shades of the same colour, which are much heightened by oiling. The texture is not so uniform as that of mahogany, nor does it work so easily, but it may be brought to a smoother surface. The weight of a cubic foot is about 45 pounds.

1705. Cedar (*Pinus Cedrus*) is an evergreen cone-bearing tree, of which though several have been grown in this country, it is too scarce to be employed in building. Its durability is very great; such, indeed, that Pliny states cedar to have been found in the Temple of Apollo at Utica, which must have been 1200 years old. Its colour is a light rich yellow brown, with the annual rings distinct. It is resinous, and has a powerful smell. The taste is slightly bitter, and it is not subject to worms. It is very straight in the grain, works easily and splits readily. Weight of a cubic foot from 30 to 38 pounds.

1706. Fir (*Pinus Sylvestris*). The red or yellow fir is produced on the hills of Scotland; but the forests of Russia, Denmark, Norway, Lapland, and Sweden produce the finest timber of this species. It is imported, under the name of red wood, in *logs* and *deals*. From Norway the trees are never more than 18 inches diameter, whence there is much sap-wood in them; but the heart is a stronger and more durable wood than is had from larger trees of other countries. From Riga a great deal of timber is received under the name of *masts* and *spars*: the former are usually 70 or 80 feet in length, and from 18 to 25 inches diameter; when of less diameter they take the latter name. Yellow deals and planks are imported from Stockholm, Frederickshall, Christiana, and various other parts of Sweden, Russia, Norway, and Prussia. Of the pine species the red or yellow fir is the most durable; and it was said by the celebrated Brindley, that red Riga deal, or pine wood, would endure as long as oak in all situations. In Pontey's *Forest Pruner*, on the authority of Dr. Smith, an instance is given of the durability of natural-grown Scotch fir. It is therein stated, that some was known to have been 300 years in the roof of an old castle, and that it was as fresh and full of sap as timber newly imported from Memel, and that part of it was actually wrought up into new furniture. It is to be observed, that foreign timber has an advantage too seldom allowed to that which is grown at home, the former being always in some degree seasoned before it arrives in this country, and therefore never used in so unseasoned a state as is usually the latter timber.

1707. From its great lightness and stiffness it is superior to any other material for beams, girders, joists, rafters, and framing in general. In naval architecture it is used for masts and various other parts of vessels. In joinery, both internal and external, it stands better, is nearly as durable as oak, and is much cheaper.

1708. There is great variety in the colours of the different sorts of this fir: it is generally of a red or honey yellow of different degrees of brightness, and consists in section of hard and soft circles alternately, one part of each annual ring being soft and light coloured, the other harder and dark coloured, and possessing a strong resinous taste and smell. When not abounding in resin it works easily. That from abroad shrinks in the log, from seasoning, about one thirtieth part of its width.

1709. The annual rings of the best sort of this timber do not exceed one tenth of an inch in thickness, their dark parts are of a bright red colour. That from Norway is the finest of the sort, to which the best Riga and Memel are much inferior. The inferior timber of this kind, which is not so durable nor so capable of bearing strains, has thick annual rings, and abounds with a soft resinous matter, which is clammy and chokes the saw. Much of the timber of this sort is from Sweden, but it is inferior in strength and stiffness. That which is produced in the colder climates is superior to that which is the product of warmer countries, the Norway timber being much harder than that of Riga. The weight of a cubic foot of this fir, when seasoned, varies from 29 to 40 pounds. That of English growth, seasoned, from 28 to 33.

1710. White Fir (*Pinus abies*), commonly called the spruce of Norway, whose forests produce it in abundance. This is the sort which in deals and planks is imported from Christiana, in which condition it is more esteemed than any other sort. The trees from which these are generally obtained are of 70 or 80 years' growth, and are usually cut into three lengths of about 12 feet each, which are sawn into deals and planks, each length yielding three deals or planks. Their most usual thickness is 3 inches, and they are generally 9 inches wide. In this country they are sold by the hundred, which in the case of white as well as yellow deals, contains 120 deals, be their thickness what it may, reduced to a standard one of an inch and a half, a width of 11 inches, and a length of 12 feet. What is called whole deal is an inch and a quarter thick, and slit deal is one half of that thickness. It unites better by means of glue than the yellow sort, is used much for interior work in joinery, and is very durable when in a dry state.

1711. The colour of the spruce fir is a yellow or rather brown white, the annual ring consisting of two parts, one hard, the other softer. The knots are tough, but it is not difficult to work. Besides the importation above named, there is a considerable quantity received from America. Of the Christiana fir a cubic foot weighs from 28 to 32 pounds when seasoned. That from America about 29 pounds; and the Norway spruce grown in Britain about 34 pounds. In seasoning it shrinks about a seventieth part, and after being purchased as dry deals at the timber yards, about one ninetieth.

1712. American Pines. The *Pinus Strobus*, or what is called the Weymouth or white pine, is a native of North America, imported in logs often more than 2 feet square and upwards of 30 feet in length. It is an useful timber, light and soft, stands the weather tolerably well, and is much used for masts. For joiners' work it is useful from its clean straight grain. But it should not be used for large timbers, inasmuch as it is not durable, and is moreover very susceptible of the dry rot. Its colour is a brown yellow, and it has a peculiar odour. The texture is very uniform, more so, indeed, than any other of the pine species, and the annual rings are not very distinct. It stands well enough when well seasoned. A cubic foot of it weighs about 29 pounds.

1713. The yellow pine, or *Pinus variabilis*, is imported into England, but it is not much used; it is the produce of the pine forests from New England to Georgia.

1714. The pitch pine (*resinosa*), remarkable for the quantity and fragrance of the resin it produces, is a native of Canada. It is brittle when dry, and, though heavy, not durable. It is of a much redder hue than the Scotch pine, and from its glutinous property difficult to plane. The weight of a cubic foot is 41 pounds.

1715. The silver pine (*picea*) is common in the British plantations. This species of timber is produced in abundance, and is much used on the Continent both for carpentry and ship-building. It is light and stiff, and according to Wiebekin, lasts longer in air than in water A cubic foot weighs about 26 pounds.

1716. The Chester pine (*pinaster*) is occasionally cultivated in the British plantations. It is better suited to water than exposure to the air, and has a finer grain, but contains less resin, than the pine or silver fir. A cubic foot weighs about 26 pounds.

1717. Larch (*Pinus Larix*). A timber tree only lately to any considerable extent adopted in the plantations of Great Britain, among whose cultivators the Duke of Athol has been one of the most ardent and successful. It grows straight and rapidly, is said to be durable in all situations, and appears to have been known and appreciated by Vitruvius, who regretted the difficulty of its transport to Rome, where, however, it was occasionally used. Wiebekin prefers it to the pine, pinaster, and fir, for the arches of timber bridges. To flooring boards and stairs, where there is much wear, it is well suited, and when oiled assumes a beautiful colour, such, indeed, that when used for internal joinery, a coat of varnish gives it a more beautiful appearance than it could receive from any painting. The American larches do not produce turpentine; but the timber has been considered equal to the European sorts. It is of a honey yellow colour, and more difficult to work than the Riga or Memel timber, though, when obtained, the surface is better. It bears the driving to nails and bolts, and stands well if properly seasoned. A cubic foot weighs from 30 to 40 pounds.

1718. Poplar. The *Populus* of botanists, whereof five species are grown in England: the common white poplar, the black, the aspen or trembling poplar, the abele or great white poplar, and that of Lombardy. The wood of this tree is only fit for the flooring of inferior rooms where there is not much wear. Evelyn attributes to this wood the property of burning "*untowardly*," rather mouldering than maintaining any solid heat. Its colour is a yellow or brown white. The annual rings, whereof one side is a little darker than the other, making each year's growth visible, are of an uniform texture. The best sorts are the Lombardy, the black, and the common white poplar. Of the Lombardy poplar, the weight of a cubic foot is about 24 pounds; of the aspen and black poplar, 26 pounds; and of the white poplar, about 33 pounds.

1719. Alder (*Betula alnus*). A tree delighting in wet places by the banks of rivers, and which furnished the material, says Vitruvius, for the piles whereon the whole of the buildings of Ravenna stand. In a dry situation it is unfit for employment, on account of its early rot when exposed to the weather or to mere damp, and its susceptibility of engendering worms. Evelyn says that it was used for the piles upon which the celebrated bridge of the Rialto at Venice was founded in 1591; but we have no certain data by which such assertion can be maintained. There is, however, no doubt that it may be advantageously employed in situations where it is constantly under water.

Its colour is of a red yellow, of different shades, but nearly uniform; which latter quality is exhibited in its texture.

From its softness it is easily worked, and seems adapted, therefore, for carving. In a dry state the weight of a cubic foot varies from 36 to 50 pounds.

1720. Elm (*Ulmus*). In Great Britain five species of this tree abound, whereof the *Ulmus campestris*, common in the woods and hedges of the southern parts of England, is a hard and durable wood, but is rarely used except for coffins. The *Ulmus suberosa*, or cork-barked elm, is an inferior sort, and is very common in Sussex.

1721. The *Ulmus Montana* is the most common species in Europe, and particularly in the northern counties of England. It is more generally known by the name of the broad-leaved elm or wych hazel. Without enumerating the other varieties, whereof the Dutch elm (*Ulmus major*) is good for nothing, we shall merely observe, that the *Ulmus glabra*, common in Herefordshire, Essex, and the north and north-eastern counties of England, grows to the largest size and is most esteemed, whilst the Dutch elm is the worst. The elm is a durable timber when constantly wet, as a proof whereof we have only to mention that it was used for the piles on which the old London Bridge stood. Indeed, its durability under water is well known; but for the general purposes of building it is of little value, and it rarely falls to the lot of the architect to be obliged to use it.

1722. The colour of the heart-wood is darker than that of oak, and of a redder brown. The sapwood is of yellow or brown-white colour. It is porous, cross and coarse grained, has a peculiar smell, twists and warps very much in drying, and shrinks considerably in breadth and length. Though difficult to work, it bears the driving of bolts and nails better than most other sorts of timber. The weight of a cubic foot, when dry, varies from 36 to 46, seasoned from 37 to 50 pounds. From experiment it seems that in seasoning it shrinks one forty-fourth part of its width.

1723. Ash (*Fraxinus excelsior*). This, the most valuable of the genus, is common throughout Europe and the northern parts of Asia. It grows rapidly, and of it the young is more valuable than the old wood. It is much affected by the difference of the soils in which it grows. It will not endure when subject to alternations of damp and moisture, though sufficiently durable when constantly in a dry situation. Its pores, if cut in the spring, are of a reddish colour, and it is improved by water-seasoning. Evelyn says, that when felled in full sap, the worm soon takes to it; and therefore recommends its being felled in the months from November to February. The texture is compact and porous, the compact side of the annual ring being dark in colour, whence the annual rings are distinct. The general colour is brown, resembling that of oak; but it is more veined, and the veins darker than those of oak. The timber of the young tree is a white, approaching brown, with a greenish hue. It has no peculiar taste or smell, is difficult to work, and is too flexible for use in building, beside the important want of the character of durability. The weight of a cubic foot varies from 35 to 52 pounds; and it is to be observed, when the weight is much less than 45 pounds the timber is that of an old tree.

1724. Sycamore (*Acer pseudo-platanus*), usually called the plane tree in the northern part of the island, is common in Britain and on the mountains of Germany. It is rapid in growth, and the wood is durable when it escapes the worm, to which it is quite as liable as beech. The use of it in buildings is not common, but for furniture it is valuable. The colour is a brown white, yellowish, and sometimes inclining to white. Texture uniform; annual rings indistinct. It is not so hard as beech, brittle, and generally easy to work. A cubic foot, when seasoned, weighs from 34 to 42 pounds. Ware says that there are old houses in this country floored with sycamore and wainscoted with poplar. It seems well enough calculated for floors.

1725. Birch. *Betula alba*, or common birch, is a species of alder, to which article the reader is referred (1719). The American birch, from Canada, is but little superior to the European birch. The Russian birch, on account of its clean light colour and silvery grain, has been for many years extensively employed for bedroom furniture.

1726. A description of fir (*Wellingtonia gigantea*) has been lately introduced from the colony of Victoria, in Vancouver's Island, on the western side of North America. It is sent in logs, deals, and planks. Instead, however, of being only 14 to 16 inches square, and 60 feet long at the maximum, as in the case of Baltic timber, one stick of this timber has been sent not less than 127 feet long, and about 42 inches square at one third of the height measuring from the butt end, which end was about 50 inches square. It contained 1307 cubic feet of timber; this is not an exceptional size. A tree is reported to have been cut down lately, the circumference of which was 90 feet, and its height 325 feet; the bark was in some places 4 feet thick. The tree, sound and solid, contained 250,000 feet of timber. It was supposed to be 3,100 years old. G. R. Burnell states the tenacity of this timber to be greater than, and its resistance to a crushing weight apparently superior to, Baltic timber. When loaded in the centre to the point of instantaneous rupture, the Vancouver's island wood bore weights which were to those borne by English oak as 13 to 12, and to those borne by the Baltic fir as 13 to 8. Three-inch cubes of the three woods were subjected to weights of 45 tons each, or 5 tons (11,240 lbs.) on the inch superficial, when the permanent elasticity of oak was not affected, that of the fir only slightly so, whilst the Baltic timber was permanently and perceptibly compressed.

1726*a*. For joiner's work, the straightness, freedom from knots, deep warm colour, and beauty of the grain, places this timber above any other of the fir or pine woods; whilst its greater hardness would in staircases, floors, &c., compensate for any slight increase in the price of labour for working it. It has been employed by Mr. Burnell in the joiner's work of an office in Lincoln's Inn Fields. It seems to affect iron somewhat as does oak.

1727. Mahogany (*Swietenia Mahogoni*) is a native of the West Indies and the country round the Bay of Honduras. The tree is said to be of rapid growth; its trunk often exceeds 40 feet in length and 6 feet in diameter. Its Spanish name is *caôba*. *Spanish* mahogany is imported from Cuba, Jamaica, Hispaniola, St. Domingo, and some other of the West India Islands and the Spanish Main. The best quality is considered to come from the sea-board on the south part of the island of San Domingo or Hayti. The logs are from 20 to 26 inches square, and about 10 feet in length. It is close grained, hard, sometimes strongly figured, and generally of a rich brown colour, darker than Honduras; but its pores frequently appear as if chalk had been rubbed into them. It takes a very high polish with hand labour; and French polishing brings out its flower with great lustre.

1727*a*. *Honduras* mahogany is imported in logs of larger size than the above, that is, from 2 to 4 feet square, and from 12 to 18 feet in length; logs 40 feet in length have been obtained; planks 6 to 7 feet wide are occasionally imported; but 5 feet square and 15 feet long are the more ordinary dimensions. It is so distinctly inferior to the Spanish quality, that no ordinary judge can possibly be mistaken in the normal samples. In weight it is lighter; and it is of a straighter and more open or spongy grain, without much flower, and therefore little sought after by cabinet-makers. The worst kinds are those most filled with grey specks, from which Spanish mahogany, except the Cuba, is comparatively free.

1727*b*. Spanish mahogany is in this country far too valuable to be used in common building. It sometimes sells for as much as 6*l*. per foot cube, when good fir, of nearly equal value for such purposes, would only cost 2*s*. at the maximum. In Jamaica, mahogany has been frequently employed for floors, joists, rafters, shingles, &c.; and ships have been built of it; for which last purpose, the circumstance of its allowing shot to be buried in it without splintering, makes it peculiarly suitable. Soon after its introduction into this country in 1724, when a specimen was sent to Dr. Gibbons by his brother, a West India captain, it was employed for doors, as at the Treasury, by W. Kent, in 1733. The better qualities are reserved for small articles of cabinet-work and furniture, the best being employed in the form of veneers, of which twenty-one cuts are now got out of an inch thickness. Solid work for more general purposes, such as handrails of stairs, sashes, sash-doors, and ordinary counting-house and office fittings, &c., is worked out of Honduras mahogany, which is also employed as the groundwork for veneers of the finer quality.

1727*c*. It is generally sold at per foot superficial, one inch thick; the common qualities at 5*s*. to 5*s*. 6*d*. per cubic foot. It holds with glue better than any other wood. Of Honduras mahogany, the quality called 'common southern' weighs about 26 lbs.; 'superior northern' about 42½ lbs.; 'good northern' about 32 lbs; and 'common northern' about 36 lbs., per cubic foot. All these qualities are used in shipbuilding; the lightest, for furniture. Spanish mahogany weighs 48 lbs. 6 oz., the best from 50 lbs. to 54 lbs. per cubic foot. All kinds of this timber are said to be very durable, and free from the attack of worms when kept constantly dry. They do not warp or crack under the influence of the sun, but they do not resist alternations of great wetness and dryness. They shrink but little in drying, and twist and warp less than any other wood.

1727*d*. *African* mahogany (*Swietenia* or *Khaya Senegalensis*), from Gambia, is a more recent importation; it twists much more than either of the above, and is decidedly inferior to them in all respects except hardness. Small quantities of mahogany are also received from Jamaica and the other West India islands, but they are of a quality so inferior even to the Honduras variety, that they are practically unknown to timber merchants. Florida *cedar* and other varieties are frequently made to pass as mahogany in cheap works.

1728. Teak (*Tectona grandis*), has of late years formed a valuable timber for shipbuilding; and to a small extent in house, and even carriage, joinery. The best varieties are obtained from the ports of Rangoon or Moulmein (called Moulmein teak), and from the coast of Malabar (called East Indian teak). It is by no means rare to meet with sticks of perfectly straight teak 60 or 70 feet long, and about 24 to 30 inches square. The wood is of a light brown colour, porous, very hard, tough, and when sound, of great strength and tenacity. It derives much of its value from the aromatic oily substance with which it is more or less saturated in the fresh state; but this does not prevent its attack by insects whilst in the forest, consequently the trees turn out to be very defective. The wood works well; takes a good polish, and though porous, it is very durable in exposed situations: it is considered that its oily properties render it less injurious to iron than oak. The tenacity of Moulmein teak is 15,000 lbs. per superficial inch. Some fine planks from Rangoon were nearly 3½ feet wide.

1728*a*. Morung saul (*Shorea robusta*), of Nepaul, in the East Indies, is in great repute for shipbuilding. It is a heavy, close-grained, light brown wood. This timber is considered to be the most valuable and extensively used of all the trees of India, but the value of it is much diminished from the injudicious mode in which it is squared. The *saul* or *sâl* timber brought to Calcutta is seldom more than 30 feet in length. In strength and tenacity it is considerably superior to the best teak, compared with which, Captain Baker's experiments prove that its strength is about as 1121 to 869. From Major H. Campbell's experiments, unseasoned saul broke with a weight of 1308 lbs.; seasoned saul with 1319 lbs.; and teak wood with 1091 lbs. Considered as a building wood, it is somewhat apt to shrink unless very well seasoned, (*Juror's Reports*, 1851).

1728*b*. Morra (*Mora excelsa*), sometimes called Demerara locust, is sent from Demerara in South America. It is a valuable timber for shipbuilding.

1728*c*. Greenheart (*Laurus chloroxylon*, or *Nectandra rodiæi*), imported from the English colony of British Guiana, and Brazil, possesses the reputation of immunity from the attacks of marine boring worms; and for this reason it is now largely used in hydraulic works Mr. Burnell has stated his conviction from what he saw, especially of two logs, in the West India Docks in 1860, that this timber does suffer from the attacks of land insects; and he was at that time in possession of a piece of the timber from Victor Bay, Panama, which was completely riddled by the *Teredo navalis*. A writer, commenting on this statement, says that "his experience proves that greenheart is exempt from the therosion by the *teredo*, but that a mollusc is found alive in it when arriving here from the West Indies. The worm is found in sizes from the *lymexylon* to the *teredo*, but it is of a different species, and seems not to live when this wood is used in such constructions as dock gates, in this country." The timber squares from 18 to 24 inches, but usually arrives about 16 inches square and 70 feet in length. It is a hard, heavy, fine, but not even-grained wood; it proves strong and durable in positions that are alternately wet and dry.

1728*d*. Among the other useful hard woods are:—I. The Peon, or *Poon wood*, an Indian wood of Travancore, East Indies, formerly imported to some extent, from 2 to 4 feet in circumference and 80 feet in length; but latterly it has been regarded with such disfavour that it is now hardly ever imported. II. The Kowrie, a New Zealand wood. III. The Australian Red Cedar. IV. The Sabicue, from Cuba, which was used for the steps of the stairs in the Great Exhibition building of 1851, and are now in the Crystal Palace at Sydenham. It makes excellent beams and planks. A heavy specimen obtained of this wood was "a portion of a large beam, which broke merely in falling from a truck!" V. The Iron Bark, of Van Diemen's Land, Australia, is a very hard and compact wood, with a specific gravity heavier than water. VI. Borneo wood, imported from Sarawak, was used in 1865 for the floors and staircase in a warehouse in Gresham Street West. It is of so peculiar a character that it broke nearly all the saws used to reduce it to battens: it is light brown in colour, with a texture very similar to teak. It may probably be the *Bilian*, or iron wood of that country, said to be impervious to the attacks of the white ant. It has not been known to decay when immersed either in fresh or salt water. An engineer who had resided in Borneo for five years, states he had never seen a rotten piece of *Bilian* wood.

1728*e*. Besides the weights of various woods given in the text (as marked *) the subjoined list of the weight per foot cube in pounds avoirdupois, may be useful.

1728*f*. The chief woods employed in shipbuilding and acknowledged as "first-rate" by the authorities at Lloyds, are eight in number These are. I. English oak; II. American live oak; III. African oak; IV. Morung Saul; V. East Indian Teak; VI. Greenheart; VII. Morra; and VIII. Iron Bark.

1729. In timber yards, deals are sold by the long hundred or six score; thus the "standard" of deals is reckoned as 120—12 ft. × 1½ in. × 11 ins., but varying lengths and thicknesses are imported (See par. 2362 and 2363).

Names.	No.	Ft. long.	Ins. thk.	Wide.	Sup. ins.	Cube ft.

Ditto, short - -	120	10	3	11	2750 of 1″	229⅙
London and Dublin -	120	12	3	9	3240 of 1″	270

The measurements have been reduced to one standard of 12 ft. long, 3 in. thick, and 9 in. wide. Two of the latest works for calculating deals according to this, the Petersburg standard hundred, are, J. Smith, *Companion to Hoppus; Handbook of Tables for the use of Timber Merchants, &c.*, London, 1860; and Grandy, *Timber Importers', &c. Standard Guide*, 8vo., London, 1865, to which latter work we are glad to refer the student, and from which we select the following extracts:—

1729*a*. "American Ports.—At *Quebec*, there are three qualities of spruce deals, 1st, 2nd, and 3rd. Irregular size scantlings are scarcely ever shipped from this port, the general run being battens, 7 × 3; deals, 9 × 3; and planks, 11 × 3, 7 × 2, 9 × 2, and 11 × 2; general lengths from 8 to 14 feet. All under 8 feet are classed as "ends." Yellow pine battens, deals, and planks are shipped as 1st, 2nd, and 3rd qualities. Battens are not so valuable as deals and planks, some of the latter running 11 to 30 inches; the finer qualities bear a high rate.

1729*b*. *St. John's* deals rank after those of Quebec in quality. Battens, deals, and planks run from 8 to 26 feet; all lengths under 8 feet being classed as ends. All deals are scarcely ever classed into 1st, 2nd, and 3rd, but taken by the run; the sizes 7 × 3, 9 × 3, and 11 × 3, being the highest in price. Irregular scantlings, such as 3 × 3, 4 × 3, 6 × 3, 5 × 2½, &c., are less per thousand.

1729*c*. *Pugwash, Miramichi, and other Lower Ports.* Battens, deals, and planks are obtained as at St. John's. The deal is a closer grain, but coarser, and hence not so valuable. The lengths run from 8 to 14 feet, all under 8 feet being 'ends.' Scarcely any irregular scantlings are shipped from these ports. The square timber at the American ports is generally purchased by the cubic foot.

1729*d*. Baltic Ports.—*Memel.* Battens and deals are scarce; planks form the bulk of the timber imported. They all run from 8 to 20 feet. They are generally sold by 120 feet run of 11 × 3, = 1 Petersburg standard. Battens and deals run 7 × 3 and 9 × 3. *Christiania.* Battens and deals, and *Drammen* deals run 9 × 3, 7 × 3, or 7 × 2½. *Crown Memel.* Square timber is generally sold by the 50 running feet, as 1st middling, and 2nd middling. But "undersized" timber, that is, under 12 inches square, is sold by 50 cubic feet, or by 50 running feet. There are also "short lengths of undersized" timber.

1729*e*. Home Trade.—At *London*, pine deals are sold by the Petersburg, and spruce deals by the London, standard. Square timber is sold by the load, or 50 cube feet, or by the cube foot, calliper measurement. At *Liverpool and Bristol*, deals are sold by the Petersburg standard; square timber by the load or foot, string measurement. At *Glasgow*, deals are sold by the cube foot; square timber by the cube foot, string measurement. At *Dublin*, deals are sold by the London or Dublin standard of 120, 12 × 9 × 3; square timber by the ton of 40 feet, string measurement."

1729*f*. These timbers are used in building for the undermentioned purposes:—
Joists and main timbers: The largest, of Dantzic, Memel or Riga, fir; those of 10 or 12 inches square, from Sweden; those of 8 inches square, from Norway.

Partitions and minor timbers: American red wood or red pine, which not being so strong as that from the Baltic, must be cut to a little larger size.
Sleepers, window sills, and some parts of the roof: Oak.
Framing: Norway and Christiania white deals; Christiania yellow deals are sappy; Swedish deals are bad, as they warp much.
Panelling: Christiania white pine; or American yellow pine.
Best ordinary floors: Drammen and Christiania white deals; American pitch pine; American deals are bad for floors, as they are a softer wood.
Ground floors: Stockholm and Gefle yellow deals.
Warehouse floors, and Staircases: Archangel and Onega planks, and American pitch pine.
Best floors: Petersburgh, Onega, and Christiania battens.
Interior finishings generally: Baltic red and white wood, and American red and yellow pine.

1729*g*. Memel timber is generally considered the most convenient for size, and is superior in strength to the Swedish, or Norwegian; Riga, the best in quality; Dantzic, when free from large knots, the strongest; and the Swedish, the toughest, but weakest. Riga can always be depended upon, and although the dearest in price, is the cheapest in the end.

1730. We shall now place before the reader, observations on timber made by the celebrated Evelyn though perhaps at the risk of repetition in what follows after them.

1731. "Lay up your timbers very dry, in an airy place, yet out of the wind or sun, and not standing very upright, but lying along, one piece upon another, interposing some short blocks between them, to preserve them from a certain mouldiness which they usually contract while they sweat, and which frequently produces a kind of fungus, especially if there be any sappy parts remaining.

1732. "Some there are yet who keep their timber as moist as they can by submerging it in water, where they let it imbibe, to hinder the cleaving; and this is good in fir, both for the better stripping and seasoning; yea, not only in fir, but other timber. Lay, therefore, your boards a fortnight in the water (if running the better, as at some mill-pond head); and there, setting them upright in the sun and wind, so as it may freely pass through them (especially during the heats of summer, which is the time of finishing buildings), turn them daily; and thus treated, even newly sawn boards will floor far better than many years' dry seasoning, as they call it. But, to prevent all possible accidents, when you lay your floors, let the joints be shot, fitted, and tacked down only for the first year, nailing them for good and all the next; and by this means they will lie staunch, close, and without shrinking in the least, as if they were all one piece. And upon this occasion I am to add an observation, which may prove of no small use to builders, that if one take up deal boards that may have lain in the floor a hundred years, and shoot them [plane their edges] again, they will certainly shrink (*toties quoties*) without the former method. Amongst wheelwrights the water seasoning is of especial regard, and in such esteem amongst some, that I am assured the Venetians, for their provision in the arsenal, lay their oak some years in water before they employ it. Indeed, the Turks not only fell at all times of the year, without any regard to the season, but employ their timber green and unseasoned; so that though they have excellent oak, it decays in a short time, by this only neglect.

1733. "Elm felled ever so green, for sudden use, if plunged four or five days in water (especially salt water), obtains an admirable seasoning, and may immediately be used. I the oftener insist on this water seasoning, not only as a remedy against the worm, but for its efficacy against warping and distortions of timber, whether used within or exposed to the air. Some, again, commend burying in the earth; others in wheat; and there be seasonings of the fire, as for the scorching and hardening of piles, which are to stand either in the water or in the earth.

1734. "When wood is charred it becomes incorruptible; for which reason, when we wish to preserve piles from decay, they should be charred on their outside. Oak posts used in enclosures always decay about two inches above and below the surface. Charring that part would probably add several years to the duration of the wood, for that to most timber it contributes its duration. Thus do all the elements contribute to the art of seasoning.

1735. "Timber which is cleft is nothing so obnoxious to reft and cleave as what is hewn; nor that which is squared as what is round: and therefore, where use is to be made of huge and massy columns, let them be bored through from end to end. It is an excellent preservative from splitting, and not unphilosophical; though to cure the accident painter's putty is recommended; also the rubbing them over with a wax cloth is good; or before it be converted the smearing the timber over with cow-dung, which prevents the effects both of sun and air upon it, if of necessity it must lie exposed. But, besides the former remedies, I find this for the closing of the chops and clefts of green timber, to anoint and supple it with the fat of powdered beef broth [we do not quite agree with our author here], with which it must be well soaked, and the chasms filled with sponges dipped into it. This to be twice done over.

1736. "We spake before of squaring; and I would now recommend the quartering of such trees as will allow useful and competent scantlings to be of much more durableness and effect for strength, than where (as custom is and for want of observation) whole beams and timbers are applied in ships or houses, with slab and all about them, upon false suppositions of strength beyond these quarters.

1737. "Timber that you have occasion to lay in mortar, or which is in any part contiguous to lime, as doors, window cases, groundsils, and the extremities of beams, &c., have sometimes been capped with molten pitch, as a marvellous preserver of it from the burning and destructive effects of the lime; but it has since been found rather to heat and decay them, by hindering the transudation which those parts require; better supplied with loam, or strewings of brick-dust or pieces of boards; some leave a small hole for the air. But though lime be so destructive, whilst timber thus lies dry, it seems they mingle it with hair to keep the worm out of ships, which they sheathe for southern voyages, though it is held much to retard their course.

1738. "For all uses, that timber is esteemed the best which is the most ponderous, and which, lying long, makes the deepest impression in the earth, or in the water being floated; also what is without knots, yet firm and free from sap, which is that fatty, whiter, and softer part called by the ancients *albumen*, which you are diligently to hew away. My Lord Bacon (Exper. 658.) recommends for trial of a sound or knotty piece of timber, to cause one to speak at one of the extremes to his companion listening at the other; for if it be knotty, the sound, says he, will come abrupt."

PRESERVATION OF TIMBER.

1739. The preservation of timber, when employed in a building, is the first and most important consideration. Wherever it is exposed to the alternations of dryness and moisture, the protection of its surface from either of those actions is the principal object, or, in other words, the application of some substance or medium to it which is imperviable to moisture; but all timber should be perfectly dry before the use of the medium. In Holland the application of a mixture of pitch and tar, whereon are strewn pounded shells, with a mixture of sea sand, is general; and with this, or small and sifted beaten scales from a blacksmith's forge, to their drawbridges, sluices, and gates, and other works, they are admirably protected from the effects of the seasons. Semple, in his work on aquatic building, recommends, that "after your work is tried up, or even put together, lay it on the ground, with stones or bricks under it to about a foot high, and burn wood (which is the best firing for the purpose) under it, till you thoroughly heat, and even scorch it all over; then, whilst the wood is hot, rub it over plentifully with linseed oil and tar, in equal parts, and well boiled together, and let it be kept boiling while you are using it; and this will immediately strike and sink (if the wood be tolerably seasoned) one inch or more into the wood, close all the pores, and make it become exceeding hard and durable, either under or over water." Semple evidently supposes the wood to have been previously well seasoned.

1740. Chapman (on the preservation of timber) recommends a mixture of sub sulphate of iron, which is obtained in the refuse of copperas pans, ground up with some cheap oil, and made sufficiently fluid with coal-tar oil, wherein pitch has been infused and mixed.

1741. For common purposes, what is called *sanding*, that is, the strewing upon the painting of timber, before the paint dries, particles of fine sand, is very useful in the preservation of timber.

1742. Against worms we believe nothing to be more efficacious than the saturation of timber with any of the oils; a process which destroys the insect if already in the wood, with that of turpentine especially, and prevents the liability to attack from it. Evelyn recommends nitric acid, that is, sulphur immersed in aquafortis and distilled, as an effectual application. Corrosive sublimate, lately introduced under Kyan's patent, has long been known as an effectual remedy against the worm. Its poisonous qualities of course destroy all animal life with which it comes in contact; and we believe that our readers who are interested in preserving the timbers of their dwellings may use a solution of it without infringing the rights of the patentee. But the best remedy against rot and worms is a thorough introduction of air to the timbers of a building, and their lying as dry and as free from moisture as practicable. Air holes from the outside should be applied as much as possible, and the ends of timbers should not, if it can be avoided, be bedded up close all round them. This practice is, moreover, advisable in another respect, that of being able, without injury to a building, to splice the ends of the timbers should they become decayed, without involving the rebuilding of the fabric; a facility of no mean consideration.

1743. The worm is so destructive to timber, both in and out of water, that we shall not apologise for closing this part of our observations with Smeaton's remarks upon a species of worm which he found in Bridlington piers. "This worm appears as a small white soft substance, much like a maggot; so small as not to be seen distinctly without a magnifying glass, and even then a distinction of its parts is not easily made out. It does not attempt to make its way through the wood longitudinally, or along the grain, as is the case with the common ship worm, but directly, or obliquely, inward. Neither does it appear to make its way by means of any hard tools or instruments, but rather by some species of dissolvent liquor furnished by the juices of the animal itself. The rate of progression is, that a three inch oak plank will be destroyed in eight years by action from the outside only." For resisting the effects of these worms, Smeaton recommends the piles to be squared, to be fitted as closely as possible together, and to fill all openings with tar and oakum, to make the face smooth, and cover it with sheathing.

1744. The destructive effects of the white ant are so little known here, that it is unnecessary to make further mention of them, than that in India they are the most inveterate enemies with which timber has to contend. From Young's *Annals* we extract the following curious statement of experiments made upon inch and a half planks, from trees of thirty to forty-five years' growth, after an exposure of ten years to the weather.

Cedar was perfectly sound.
Larch, sap quite decayed, but the heart, sound
Spruce fir, sound.
Silver fir, in decay.
Scotch fir, much decayed.
Pinaster, in a perfectly rotten state.
Chesnut, very sound.
Abele, sound.
Beech, ditto.
Walnut, decayed.
Sycamore, considerably decayed.
Birch, worthless.

Whence we may be led to some inference of the value of different sorts of timber in resisting weather; though we must not be altogether guided by the above table, inasmuch as it is well known that the soil on which timber is grown much increases or deteriorates its value, and that split timber is more durable and stronger than that which is sawn, from the circumstance of the fibres, on account of their continuity, resisting by means of their longitudinal strength; whereas when severed by the saw, the resistance depends more on the lateral cohesion of the fibres. Hence whole trees are invariably stronger than specimens, unless these be particularly well selected, and of a straight and even grain; but in practice the results of experiments are on this account the more useful.

DECAY OF TIMBER.

1745. If timber, whatever its species, be well seasoned, and be not exposed to alternate dryness and moisture, its durability is great, though from time it is known to lose its elastic and cohesive powers, and to become brittle if constantly dry. On this account it is unfit, after a certain period, to be subjected to variable strains: however, in a quiescent state it might endure for centuries. Dryness will, if carried to excess, produce this category. The mere moisture it absorbs from the air in dry weather is not sufficient to impair its durability. So, also, timber continually exposed to moisture is found to retain for a very long period its pristine strength. Heat with moisture is extremely injurious to it, and is in most cases productive of rot, whereof two kinds are the curse of the builder, the *wet* and the *dry* rot, though perhaps there be but little difference between the two. They appear to be produced by the same causes, excepting that the freedom of evaporation determines the former, and an imperfect evaporation the latter. In both cases the timber is affected by a fungus-like parasite, beginning with a species of mildew; but how this fungus is generated is still a *vexata quæstio*; all we know is, that its vegetation is so rapid, that often before it has arrived at its height, a building is ruined. From our inquiries on the Continent, we believe the disease does not occur to the extent that it does in this country; a fact which we are inclined, perhaps erroneously, to attribute to the use of the timber of the country, instead of imported timber. Our opinion may be fanciful, but there are many grounds on which we think that is not altogether the case. Our notion is, that our imported timber is infected with the seeds of decay long before its arrival here (we speak of fir more especially), and that the comparative warmth and moisture of the climate bring more effectually the causes of decay into action, especially where the situation is close and confined. Warmth is, doubtless, known to be a great agent in the dry rot, and most especially when moisture co-operates with it, for in warm cellars and other close and confined situations, where the vapour which feeds the disease is not altered by a constant change of air, the timbers are soon destroyed, and become perfectly decomposed.

1746. The lime, and more especially the damp brickwork, which receive the timbers of a new building, are great causes of decay to the ends of them; but we do not think that the regulations of the 19 Car. II. cap. 3., which directed the builders after the fire of London, to bed the ends of their girders and joists in loam instead of mortar, would, if followed out in the present day, be at all effective in preventing the decay incident to the ends of timbers. Timber, in a perfectly dry state, does not appear to be injured by dry lime; and indeed, lime is known to be effectual in the protection of wood against worms. Timber in contact with masonry is constantly found to decay, when the other parts of the beam have been sound. This will be entirely obviated by inserting the wood in an iron shoe, or by placing a thin piece of iron betwixt the wood and the stone. Cases are known in which the iron shoe appeared to have proved a complete protection against dry rot and decay; a hard crust being formed on the timber in contact with the metal. The system of grouting must contribute to the early decay of wood bond; but at Manchester, where it was used very generally, it appeared to answer well, for the high temperature kept up in the buildings may cause the walls to dry very soon. Sea-sand, used for outside and inside purposes, in a spirit of economy, soon shows the result by inducing the appearance of rot in timber. Wood laid in sandy soil is well preserved, as was found to be the case in the specimens lately dug up at Birkenhead from depths varying from 8 feet to 32 feet; they were considered to have been buried for centuries.

1747. Nothing is more injurious to the floors of a building than covering them with painted floorcloth, which entirely prevents the access of atmospheric air, whence the dampness of the boards never evaporates; and it is well known that oak and fir posts have been brought into premature decay by painting them before their moisture had evaporated; whilst in the timber and pewing of old churches, which have never been painted, we see them sound after the lapse of centuries. Semple, in his *Treatise on Building in Water*, notices an instance of some field gates made of the fir of the place, part whereof, near the mansion, were painted, and had become rotten, while those more distant from the mansion, which had never been painted, were quite sound.

1747*a*. According to Baron Liebig, the decay of wood takes place in the three following modes:—I. The oxygen in the atmosphere combines with the hydrogen of the fibre, and the oxygen unites with the portion of carbon of the fibre, and evaporates as carbonic acid; this process is called decomposition. II. The actual decay of the wood which takes place when it is brought in contact with rotting substances. And III. The inner decomposition of the wood in itself, by losing its carbon forming carbonic acid gas, and the fibre under the influence of the latter is changed into white dust; this is called putrefaction.

PREVENTION OF DECAY.

1748. After timber is felled, the best method of preventing decay is the immediate removal of it to a dry situation, where it should be stacked in such a manner as to secure a free circulation of air round it, but without exposure to the sun and wind, and it should be rough squared as soon as possible. When thoroughly seasoned before cutting it into scantlings it is less liable to warp and twist in drying. The ground about its place of deposit should be dry and perfectly drained, so that no vegetation may rise on it. Hence a timber yard should be strewed with ashes, or the scales from a foundry or forge, which supply an admirable antidote to all vegetation. It is thought that the more gradually timber is seasoned the greater its durability; and as a general rule, it may be stated, that it should not be used till a period of at least two years from its being felled, and for joiners' work at least four years. Much, however, is dependent on the size of the pieces. By some, water seasoning has been recommended; by others the steaming and boiling it; smoke-drying, charring, and scorching have also been recommended. The latter is, perhaps, the best for piles and other pieces that are to stand in the water or in the ground. It was practised by the ancients, and is still in use generally for the posts of park paling and the like.

1749. In Norway the deal planks are seasoned by laying them in salt water for three or four days, when newly sawed, and then drying them in the sun, a process which is considered to be attended with advantage; but it does not prevent their shrinking. Mr. Evelyn recommends the water seasoning for fir.

1749*a*. The effectual seasoning obtained by Davison and Symington's patent process of forcing heated air in a continued current through timber under pressure, effectually dries it, and coagulates the albumen. The timbers for the flooring of the Coal Exchange at London have been so treated, and show no signs of shrinkage. The wood was taken in its natural state, and in less than ten days it was thoroughly seasoned; in some cases from 10 to 48 per cent of moisture was taken out of it. The air when heated to about 110° or 120° is sent through the timber at a rate of about 48 miles per hour; the heat being regulated according to the quality of the timber. Honduras mahogany exposed to a heat of 300°, would have the whole of the moisture taken from it in 48 hours. This process, however, sometimes splits the timber. Out of a hundred specimens of wood experimented upon, varying from one inch to twelve inches square, not one of them split: even some openings which were visible before the process was applied, were found to be closer after it. Perhaps 9 inches square is the limit to which the operation can be successfully applied.

1750. Notwithstanding, however, all care in seasoning, when timber is employed in a damp situation it soon decays; and one of the principal remedies against that is good drainage, without which no precautions will avail. It is most important to take care that earth should not lie in contact with the walls of a building, for the damp is quickly communicated, in that case, by their means to the ends of timbers, and rot soon follows. No expedient to guard against this contingency is so good as what are called air drains.

1751. When the carcass of a building is complete, it should be left as long as possible to dry, and to allow to the timbers what may be called a second seasoning. The modern practice of finishing buildings in the quickest possible period, has contributed more to dry rot than perhaps any other cause; and for this the architect has been blamed instead of his employer, whose object is generally to realize letting or to enjoy occupation of them as early as possible. After the walls and timbers of a building are once thoroughly dry, all means should be employed to exclude an accession of moisture, and delay is then prejudicial.

1752 Among the many inventions to preserve wood from decay, those of England have proved the most successful. In 1737 a patent was granted to Mr. Emerson to prepare timber with hot oil. This was followed by various recommendations early in the present century; those of later date consist of:—I. Kyan's process, 1832, who steeped the timber in a solution of *bichloride of mercury*, known as corrosive sublimate (*par.* 1742.) It appears to penetrate fir less than some other woods (Faraday). The wood thus treated becomes of less specific gravity, less flexibility, and more brittle. II. Sir William Burnett's patent of 1836, was for using the chloride of zinc. III. M. Bréant in 1837 suggested sulphate of iron, which was found not to alter the qualities of the timber as did the corrosive sublimate. IV. Margary's patent, 1837, is for steeping timber in a solution made of one pound of sulphate of copper with eight gallons of water. Wood impregnated with sulphate of copper (blue vitriol) will not last longer in sea water than any other wood. But wood so treated will last longer in the soil than if either tarred or charred. Its application for the prevention of rot is beneficial, and it might be used where not exposed to the action of water, on account of the solubility of the salts. The proportion of the sulphate should be one pound to four gallons of water; we have also met with the proportion of one pound to two gallons; perhaps the strongest is the best (*par.* 1752*b*.) V. Payne, 1841, patented a system for using two solutions; first, sulphate of iron, which would form an oxide of iron in the cells; and secondly, carbonate of soda: some very good results were obtained, but the process must be done under pressure and with the greatest care.

1752*a*. VI. Bethell's patent, 1838, consists in the injection of oil of tar, containing creasote and a crude solution of acetate of iron, commonly called pyrolignite of iron, after the air in the wood has been extracted. This process is effective to a great extent, and full particulars are given by G. R. Burnell in his paper read before the Society of Arts 1860, from which we have been quoting. It, however, can only be recommended for railways and other large works; the offensive smell and increased danger by fire should deter its use in house building. In the best creasoting works, the oil is injected at a temperature of 120° and under a pressure of 150 lbs. on the square inch, so that ordinary fir timber absorbs 10 lbs. weight of the creasote per cubic foot; the wood should be weighed to ascertain that it did absorb that quantity. For all engineering purposes, fir timber thus treated is far more durable than the best oak, teak, or other hard woods, and the cost of the operation is very small. Timber which has just been taken out of water contains so large a quantity that it resists the entrance of the oil; unless time, therefore, be given for it to be first dried, it would necessarily be badly prepared.

1752*b*. VII. Dorsett and Blythe, 1863, patented the injection of heated solutions of sulphate of copper (*par.* 1752, IV.), a process said to have been adopted by French, Spanish, Italian, and other railway companies. Amongst its advantages, they state that wood so prepared is rendered to a great extent incombustible; and that for out-door purposes it has a clean yellowish surface, without odour, requires no painting, remaining unchanged for any length of time.

1752*c*. Experience of the English processes shows that creasoting is the most generally successful; the application of the sulphate of copper is satisfactory in many cases; while the other processes, although no doubt of occasional value, have been practically abandoned. They all depend for their success upon the skilful and conscientious manner in which they are applied; for as they involve chemical actions on a large scale, their efficiency must depend upon the observation of the minute practical precautions required to exclude any disturbing causes.

1752*d*. Carbolineum Aveuarius is said (1887) to be an efficient preservative of wood against all external and internal injurious influences, driving the moisture out of it by making it impervious to damp, and is stated to be a preservative against the attack of white ants in hot climates. Being thin and liquid it soaks into the wood readily. One gallon will cover from 30 to 50 square yards.

1753. It is no easy matter to *cure the dry rot* where it has once taken root. If it be found necessary to substitute new timbers for old ones, every particle of the fungus, known as the *Merulius lacrymans*, must be removed from the neighbourhood of such new timbers. After scraping it from the adjoining walls and timbers, perhaps no better application than one of the washes above mentioned can be employed. About 300° of heat would effect the same purpose, but this is difficult in application. Coal tar has been found useful, but its odour, arising at a moderate degree of heat, is an objection to its use. A weak solution of vitriolic acid with water will generally stop the rot if it have not gone too far. Pyroligneous acid is recommended for preventing the spreading of the disease. The precautions indicated above for the prevention of decay, although not always successful, must be deemed preferable to the application of after remedies.

Sect. V.

IRON.

1754. Iron is a metal found in almost all parts of the world, and though not mentioned by Homer, and hence, we may suppose, in his time extremely scarce, it is now more abundant than any of the other metals, and is, at the same time, the most useful. Although, with the exception of tin, it is the lightest of all metals; yet it is, when pure, very malleable and extremely hard. Its malleability is increased by heat, whereas most other metals, as they are heated, become more brittle. It is the only known substance whereon the loadstone acts, and its specific gravity to water is as 7632 to 1000.

1755. The iron manufactured in Great Britain is obtained from three species of the ore. The *Lancashire*, which is very heavy, fibrous in texture, and of a dark purple colour inclining to black, and lodged in veins. The *Bog ore*, which has the appearance of a deep yellow clay, and is found in strata of from twelve to twenty inches in thickness. And lastly, *Iron stones*, of an irregular shape, frequently in beds of large extent, similar to other stony masses, and often intersected with seams of pit coal. It is principally from the argillaceous ore or clay iron-stone that iron is extracted in this country.

1756. After raising, the ores are selected and separated as much as possible from heterogeneous substances. They are then roasted in large heaps in the open air, for the purpose as well of freeing them from the arsenic and sulphur they contain as to render them friable or easy of reduction to a powder. The roasting is performed by means of bituminous coal, and the result is a substance full of fissures, friable, and a deprivation of all vitreous lustre. After this it is transferred to the crushing mill for complete pulverization, whence it is carried to the smelting furnace for conversion into iron. Herein it undergoes two separate processes: first, the reduction of the oxide to a metallic state; second, the separation of the earthy particles in the form of scoria. These operations are conducted by submitting the ore, ordinarily mixed with certain fluxes, to the action of carbon at a very high temperature, in what are called blast furnaces, which vary in height from twelve to sixty feet, and are of the form of truncated cones, sometimes however of pyramids, terminating usually in cylindrical chimneys, whose internal diameter is from four to six feet. The interior of these furnaces is usually of a cylindrical form, whose internal diameter is from four to six feet. Their cavity is usually of a circular form, except at the *crucible* or *hearth*, where it becomes a right rectangular prism, oblong in a direction perpendicular to the blast orifices or *tuyeres* of the bellows. The sides of the crucible are most commonly formed of gritstone. The *boshes*, which are in the form of an inverted quadrangular pyramid approaching a prismatic shape, are placed above the crucible, and above them rises the conical body of the furnace, which is lined with fire-bricks, and, in ascending, is contracted similarly to the narrow end of an egg, until it terminates in the chimney. The furnace is of course constructed in the most solid manner, and strengthened by iron bands and bars. The bellows employed are mostly of a cylindrical form, and their pistons worked either by water or steam. The blast holes, which are in the upper part of the crucible, and frequently placed on opposite sides, but so that the two opposite currents may not impinge upon one another, are two in number. Openings are provided at the lower part of the crucible for the discharge of the metal and scoria, and are kept stopped by clay and sand upon the exterior when the furnace is in operation. The reduction is commenced by gradually heating up the furnace until capable of being entirely filled with fuel, and then, as its contents begin to sink, alternate changes of ore, mingled with *flux*, and of charcoal and coke, are added. The blast is now let on, and the metal in the ore, parting with its oxygen, flows by degrees, subsiding to the bottom of the crucible, covered with a melted *slag*, which is occasionally let off by removing the clay from one or more, if necessary, apertures in the crucible; and on the bottom of the furnace becoming filled with the metal, which generally occurs after nine to twelve hours, the iron itself is discharged by one of these openings into a fosse of sand mixed with clay. When the iron has flowed out the aperture is again closed, and by this method the furnace is kept in constant action.

1757. Limestone of the best quality is employed as a flux to assist the fusion of the ore, which it accomplishes by vitrefying the earths wherewith it is mixed up with the oxide of iron. The iron when run out from the blast furnace in the state of cast iron is far from being in a pure state, having a coarse grain, and being brittle. In its conversion to bar iron, it undergoes one of the two following processes, as charcoal or coke may be employed. In the former case a furnace much resembling a smith's hearth is used, having a sloping cavity sunk from ten to twelve inches below the blast pipe. After the cavity has been filled with charcoal and scoria, a pig of cast iron, well covered with hot fuel, is placed opposite the blast pipe. The blast being introduced, the pig of iron lying in the very hottest part soon begins to melt, and runs down into the cavity below, where, being out of the influence of the blast, it becomes solid, and is replaced in its former position, and the cavity is again filled with charcoal. It is there again fused, and so on a third time, all these processes being accomplished in three or four hours. The iron, thus again solid, is taken out, and very slightly hammered, to free it from the attached scoria; after this it is returned to the furnace, in a corner whereof it is stacked, out of the action of the blast, and well covered with charcoal, where it remains gradually to cool until sufficiently compact to bear the *tilt* or *trip hammer* (to be *shingled*, to force out the cinders), which is moved by machinery, and whose weight is from 600 to 1200 lbs. Thus it is beaten till the scoriæ are forced out, and the particles of iron welded together, when it is divided into several portions, which by repeated heating and hammering are drawn into bars, in which state it is ready for sale.

1758. There are various methods of procuring the blast; the first, and most ancient, is by means of bellows; the latest, which has been found in the mining districts to be a contrivance of great importance, is the placing a series of vanes attached to an axis, which, by machinery, are made to revolve in a box with great rapidity. A pipe passing from the outside of the box to the furnace conveys the air to it as the vanes revolve, a new portion continually entering by a hole at the axis. The air thus driven through at its natural temperature constitutes a *cold blast* in contradistinction to air heated by artificial means or *hot bla t.* This latter system was discovered by J. B. Neilson, of Glasgow, about the year 1826; his patent expired in 1842. At the present day air is forced into the furnaces at a temperature of 600°, and even of 800° Fahr., although at the commencement it was rarely used above 300°. The irons obtained from the former process are considered to be tougher and stronger than those obtained from the latter process, and present a closer texture and a smaller crystallization than the latter irons. The Blaenavon, Coed Talon, Lowmoor, and Muirkirk irons are amongst the most esteemed varieties. Perhaps it may be laid down as a general principle that where pig-iron is remelted with coke in the cupola furnace, for the purposes of the ironfounder, or refined with coke in the conversion of forge pig into bar iron, it is of little consequence whether the reduction of the ore has been effected with the *hot* or the *cold* blast; but where large castings have to be run directly from the smelting furnace, the quality of the metal will, no doubt, suffer from the use of the hot blast.

1759. The proportion of pig or cast iron from a given quantity of ore varies as the difference in the metallic contents of different parcels of ore and other circumstances, but the quantity of bar obtained from pig iron is not valued at more than 20 per cent.

1760. The other process for manufacturing bar iron, which is that chiefly employed in this country, is conducted in reverberatory furnaces, usually called *puddling furnaces.* The operation begins with the fusion of the cast iron in refinery furnaces, like the one above described. When the iron is fully melted, a tap-hole is opened in the crucible, and the metal and slag flow out together into a fosse covered with clay well mixed with water, by which a coating is formed that prevents the metal from sticking to tne ground. The finer metal forms a slab about ten feet long, three feet broad, and from two to two and a half inches in thickness. For the purpose of slightly oxidizing it, and to make it brittle, it is much sprinkled over with cold water. In this part of the process it loses in weight from 12 to 17 per cent. After this, it is broken up into pieces, and placed on the hearth of a reverberatory furnace, in portions heaped up to its sides in piles which rise nearly to the roof, leaving a space open in the middle to give room for puddling the metal as it flows down in streams. When the heat of the furnace has brought it to a pasty state, the temperature is reduced, a little water being sometimes thrown on the melted mass. The semi-liquid metal is stirred up by the workman with his *puddle*, during which it swells, and parts with a large quantity of oxide of iron, which burns with a blue flame, so that the mass appears ignited. As it refines, the metal becomes less fusible, or, as the workmen say, it begins to *dry.* The puddling goes on until the whole charge assumes the form of an incoherent sand, when the temperature is gradually increased to give it a red white heat, at which period the particles begin to agglutinate, and the charge, in technical language, *works heavy.* The refining is now considered finished, and the metal has only to be formed into balls, and condensed under the rolling cylinder. From this state it is brought into *mill bar iron.* After this last operation, several pieces are welded together, from which it acquires ductility, uniformity, and cohesion. A lateral welding of four pieces together now follows, and the mass passes through a series of cylinders as in the first case, and becomes English bar-iron.

1761. The lamination of iron into sheets is by a refinery furnace, with a charcoal instead of a coke fire.

1762. Malleable iron is often obtained from the ores directly, by one fusion, if the metallic oxide be not too much mixed with foreign substances. It is a mode of working much more economical than that above described, and from the circumstance of its having been long known and used in Catalonia, it is known by the name of the *method of the Catalonian forge.* The furnace employed is similar to the refiner's forge already described. The crucible is a kind of semicircular or oblong basin, eighteen inches in diameter, and eight or ten in depth, excavated in an area, or small elevation of masonry, eight or ten feet long, by five or six broad, and covered in with a chimney. The tuyere is placed five or six inches above the basin, inclining a little downwards, and the blast is received from a water blowing machine. The first step consists in expelling the water combined with the oxide, as well as the sulphur and arsenic when these are present. This, as usual, is done by roasting in the open air, after which it is reduced to a tolerably fine powder, and thrown at intervals by shovels-full upon the charcoal fire of the forge hearth, the sides and bottom of the basin being previously lined with *brasques* (coats of pounded charcoal). It gradually softens and unites into lumps more or less coherent, which finally melt and accumulate in the bottom of the crucible or basin. A thin slag is occasionally let off from the upper surface of the melted metal in the basin through holes which can be closed and opened at the discretion of the workman. The melted iron preserves a pasty condition owing to the heat communicated from above. When a mass sufficiently great has accumulated, it is removed, put under the hammer, and forged at once. A lump, or bloom, of malleable iron is thus produced in the space of three or four hours. Four workmen are employed at one forge, and by being relieved every six hours, they are enabled to make 86 cwt. of iron per week. In the Catalonian forge, 100 lbs. of iron are obtained from 300 lbs. of ore (a mixture of sparry iron, or carbonate and hematite), and 310 lbs. of charcoal, being a produce of 33 per cent.

1763. A visit to some of the iron districts is necessary fully to understand the processes we have above shortly described; but the founding of iron may be well enough observed in the metropolis, though not on so large a scale as in some of the provinces. A succinct description, however, is given under the heading FOUNDRY, Chap. III. Sec. xi.

1764. We here subjoin a summary of the modern observations on iron (collected from various authorities) as given in Rankine's *Civil Engineering*. The metallic products of the iron manufacture are of three kinds: I. MALLEABLE OR WROUGHT IRON; II. CAST IRON; and III. STEEL: both the latter being certain compounds of iron with carbon. Some investigators affirm that nitrogen is one of the essential constituents of steel, but this requires confirmation. The strength and other good qualities of these products depend mainly on the absence of impurities, and especially of certain substances which are known to cause brittleness and weakness, of which the most important are sulphur, phosphorus, silicon, calcium, and magnesium. Sulphur, and (according to Mushet) calcium, and probably also magnesium, make iron what is termed *red short*, that is, brittle at high temperatures. Phosphorus and (according to Mushet) silicon make it *cold short*, that is, brittle at low temperatures. These are both serious imperfections, but the latter is the worst defect.

1764*a*. WROUGHT OR MALLEABLE IRON in its perfect condition is pure, or nearly pure, iron; its strength is in general greater or less according to the greater or less purity of the ore and fuel employed in its manufacture. Malleable iron is distinguished by the property of *welding*. Two pieces, if raised nearly to a white heat and pressed or hammered firmly together, adhering so as to form one piece. It is essential that the surfaces to be welded should be perfectly clean and free from oxide of iron, cinder, and all foreign matter. Where several bars are to be faggoted or rolled into one, they require careful *piling*, so as to ensure the pressure exerted by the hammer or the rollers being transmitted through the whole mass; otherwise the finished bar or piece may show flaws marking the divisions between the bars of the pile. Wrought iron, although it is at first made more compact and strong by *reheating* and hammering, or otherwise working it, soon reaches a maximum strength, after which all reheating and working rapidly makes it weaker. Good *bar iron* has in general attained its maximum strength, and therefore, in all operations of forging it, the desired size and figure ought to be given to it with the least possible amount of reheating and working. In large forgings, the tenacity is only about *three fourths* of that of the bars from which the forgings were made, and sometimes even less.

1764*b*. It is still a matter of dispute to what extent and under what circumstances wrought iron loses its *fibrous* structure and toughness, and becomes *crystalline* and brittle. By some authorities it is asserted that all shocks and vibrations tend to produce that change; others maintain that only sharp shocks and vibrations do so; and others that no such change takes place; but that the same piece of iron which shows a *fibrous* fracture, if *gradually broken* by a steady load, will show a *crystalline* fracture, if *suddenly broken* by a *sharp* blow. It is certain, at all events, that iron, whether cast or wrought, ought to be as little as possible exposed to sharp blows and rattling vibrations. Kirkaldy, *Wrought Iron and Steel*, 1863, p. 52, and in his concluding observations (p. 92), states further, that "the appearance of iron may be changed from fibrous to crystalline by merely altering the shape of the specimen so as to render it more liable to snap," and that "iron is less liable to snap the more it is worked and rolled. In the fibrous fractures the threads are drawn out, and are viewed externally, whilst in the crystalline fractures the threads are snapped across in clusters, and are viewed externally or sectionally. In the latter cases the fracture of the specimen is always at right angles to the length; in the former it is more or less irregular."

1764*c*. The *continuity of the fibres* near the surface should be as little interrupted as possible. For example, projections formed out of a block by turning, rolling, and hammering, were broken off by blows with a 6 lb. hammer, with the first, fifth, and eighth blows respectively (Rankine, *Proceedings of Inst. of Civil Engineers*, 1843). In iron work which is to sustain shocks and vibrations abrupt variations of dimensions and angular figures must be avoided as much as possible, especially those with reentering angles; for at those points fractures are apt to commence. If two parts of a beam are to be of different thicknesses, they should be connected by means of curved surfaces.

1764*d*. The fibres of wrought iron are always an indication of its strength, but in the application of such iron we are to be cautious. If the iron be impure in its elements, or has been badly worked, it may be very fibrous and also strong, but in exposing it to a welding heat it loses all its fibre, and is converted into brittle *granulated iron*. This happens frequently with puddled iron and sometimes with charcoal iron. It follows, therefore, that iron which does not retain its fibre after receiving a welding heat is not to be trusted. Only good charcoal iron should be used where strength is required, in case any smithing is to be done to the iron before it is put to use. Where iron is exposed to heat, the very purest and best kinds only should be used: with constant heat, even of low temperature, wrought iron, if not very pure, becomes *granulated*. Very fibrous puddled iron may carry 80,000 lbs. per inch square, when newly made, but it may in a short time be converted into granular iron, and reduced to 20,000 lbs., and be inferior in strength to cast iron. Where this change in the iron would be detrimental to the work steel should be substituted, as its strength is not impaired by any degree of heat beyond a red heat.

1764*e*. The quality of iron for boiler plates must be attended to from the first stages of its manufacture from the ore, which should be of good quality: even then it may be spoiled in the furnaces. Above all things, states Overman, (whom we are now quoting), hot blast ought to be excluded in these cases; it ought to be a criminal offence to employ hot blast iron for boiler plates. Iron may be fibrous, and when cold very tenacious; but the test consists in heating it red hot and cooling it in cold water. If it continues tenacious it may be considered good; if not it is bad, and unfit for boiler plate.

1764*f*. Strength and toughness in *bar iron* are indicated by a fine, close, and uniform fibrous structure, free from all appearance of crystallization, with a clear bluish grey colour, and a silky lustre on a torn surface where the fibres are shown. *Plate iron* of the best kind consists of alternate layers of fibres crossing each other, and ought to be nearly of the same tenacity in all directions. The breaking strain and contraction of area of puddled *steel plates*, as in iron plates, are greater in the direction in which they are rolled; whereas in cast steel they are less. (Kirkaldy.)

1765. CAST IRON is the product of the process of smelting iron ores. The total quantity of carbon in *pig iron* ranges from 2 to 5 per cent. of its weight. Different kinds of pig iron are produced from the same ore in the same furnace, under different circumstances as to temperature and quantity of fuel. A high temperature and a large quantity of fuel produce *grey* cast iron, which is further distinguished into Nos. 1, 2, and 3, and so on; No. 1 being that produced at the highest temperature. A low temperature and a deficiency of fuel produce *white* cast iron. *Grey* cast iron is of different shades of bluish grey in colour, granular in texture, softer and more easily fusible than *white* cast iron, which latter is silvery white, either granular or crystalline, comparatively difficult to melt, brittle, and excessively hard. It appears that the differences between these kinds of irons depend on the proportions of carbon in them. Thus *grey* cast iron contains 1 per cent., and sometimes less, of carbon in chemical combination with the iron, and from 1 to 3 or 4 per cent. of carbon in the state of plumbago in mechanical mixture; while *white* cast iron is a homogeneous chemical compound of iron with from 2 to 4 per cent. of carbon. Of the different kinds of *grey* cast iron, No. 1 contains the greatest proportion of plumbago (which renders iron comparatively weak and pliable), No. 2 the next, and so on.

1765*a*. There are two kinds of *white* cast iron, the granular and the crystalline. The granular sort can be converted into *grey* cast iron by fusion and slow cooling. *Grey* cast iron can be converted into granular *white* cast iron by fusion and sudden cooling. This takes place most readily in the best iron. Crystalline *white* cast iron is harder and more brittle than granular, and is not capable of conversion into *grey* cast iron by fusion and slow cooling. It is said to contain more carbon than granular *white* cast iron, but the exact difference in their chemical composition is not yet known. *Grey* cast iron No. 1 is the most easily fusible, and produces the finest and most accurate castings; but it is deficient in hardness and strength.

1765*b*. The order of strength of cast iron among different kinds from the same ore and fuel is as follows:—Granular *white* cast iron, *grey* cast iron No. 3, No. 2, and No. 1. Crystalline *white* cast iron is not introduced into this classification, because its extreme brittleness makes it unfit for use in engineering structures. Granular *white* cast iron also, although stronger and harder than *grey* cast iron, is too brittle to be a safe material for the entire mass of any girder, or other large piece of a structure. It is used to form a hard and impenetrable *skin* to a piece of *grey* cast iron by the process called *chilling*. This consists in lining the portion of the mould where a hardened surface is required with suitably shaped pieces of iron. The melted metal, on being run in, is cooled and solidified suddenly where it touches the cold iron; and for a certain depth from the chilled surface, varying from about $\frac{1}{8}$ to $\frac{1}{2}$ inch in different kinds of iron, it takes the *white* granular condition, while the remainder of the casting takes the *grey* condition. Even in castings which are not chilled by an iron lining to the mould, the outermost layer, being cooled more rapidly than the interior, approaches more nearly to the *white* condition, and forms a skin harder and stronger than the rest of the casting. The best kinds of cast iron for large structures are No. 2 and No. 3; because being stronger than No. 1, and softer and more flexible than *white* cast iron, they combine strength and pliability in the manner which is best suited for safely bearing loads that are in motion. A strong kind of cast iron called *toughened cast iron*, is produced by the process, invented by Morries Stirling, of adding to the cast iron, and melting amongst it, from one-fourth to one-seventh of its weight of wrought iron scrap.

1766. Soft grey cast iron is the best sort; it yields easily to the file when the external crust is removed, and is slightly malleable in a cold state. It is, however, more subject to rust than the white cast iron, which sort is also less soluble in acids. Grey cast iron has a granulated fracture with some metallic lustre. White cast iron in a recent fracture has a white and radiated appearance, indicating a crystalline structure.

1767. Cast iron, when at a certain degree of heat, may be cut like a piece of wood with a common saw. This discovery was announced in a letter from M. Dunford, director of the iron works at Montalaire, to M. d'Arcet, and published in the *Annales de Chimie*. The experiment was tried in 1813 by a gentleman of the Philosophical Society at Glasgow, who with the greatest ease cut a bar of cast iron, previously heated to a cherry-red, with a common carpenter's saw, in the course of less than two minutes. The saw was not in the least injured by the operation.

1768. The security afforded by iron for supporting weight, and against fire, has, of late years, very much increased the use of it, and may in many cases entirely supersede the employment of timber. Again, it is valuable from its being not liable to sudden decay, nor soon destroyed by wear and tear, and, above all, from its plasticity.

STEEL.

1769. Steel, the hardest of the metals and the strongest of known substances, is a compound of iron with from 0·5 to 1·5 per cent. of its weight of carbon. These, according to most authorities, as noticed by Rankine, are the only essential constituents of steel. Impurities of different kinds affect steel injuriously in the same way as with iron. A very small part of its weight, $\frac{1}{2000}$th, of silicon causes steel to cool and solidify without bubbling or agitation; a larger proportion would make the steel brittle. Manganese improves the steel by increasing its toughness, and making it easier to weld and forge.

1769*a*. The term *steely iron*, or *semi steel*, may be applied to compounds of iron with less than 0·5 per cent. of carbon. They are intermediate in hardness and other properties between steel and malleable iron. In general, such compounds are the harder and the stronger, and also the more easily fusible, the more carbon they contain; those sorts which contain less carbon, though weaker, are more easily welded and forged, and from their greater pliability are the fitter for structures that are exposed to shocks.

1769*b*. Steel is distinguished by the property of *tempering*, that is to say, it can be hardened by sudden cooling from a high temperature, and softened by gradual cooling; and its degree of hardness or softness can be regulated with precision by suitably fixing that temperature. The elevation of temperature previous to the *annealing* or gradual cooling is produced by plunging steel into a bath of a fusible metallic alloy, ranging from 430° to 560° Fahr.

1770. *Steel* is made by various processes which have of late become very numerous. They may all be classed under two heads, viz., *adding* carbon to malleable iron, used in making steel for cutting tools and other fine purposes; the other, *abstracting* carbon from cast iron, used for making great masses of *steel* and *steely iron* rapidly and at a moderate expense. Among the processes are the following:—

1771. I. *Blister steel* is made by *cementation*, by embedding bars of the purest wrought iron in a layer of charcoal and subjecting them for several days to a high temperature. Each bar absorbs carbon, and its surface becomes converted into steel. *Cementation* may also be performed by exposing the surface of the iron to a current of carburetted hydrogen gas at a high temperature. *Cementation* is also applied to the surfaces of articles of malleable iron in order to give them a skin or coating of steel, and is called *casehardening*.

1772. II. *Shear steel* is made by breaking bars of blister steel into lengths, faggoting them, and rolling them out at a welding heat; repeating the process until a near approach to uniformity of composition and texture has been obtained. It is used for tools and cutting implements.

1773. III. *Cast steel* is made by melting bars of blister steel with a small additional quantity of carbon (in the form of coal tar), and some manganese. It is the purest, most uniform, and strongest, steel, and is used for the finest cutting implements. Another process requiring a higher temperature, is to melt bars of the purest malleable iron with manganese and with the whole quantity of carbon required in order to form steel. The quality as to hardness is regulated by the proportion of carbon. A sort of *semi steel* or *steely iron*, made by this process and containing a small proportion of carbon only, is known as *homogeneous metal*.

1774. IV. *Steel made by the air blast* is produced from molten pig iron by Bessemer's process, wherein the molten pig iron, having been run into a suitable vessel or *converter*, has jets of air blown into it through tubes as the liquid is poured in. The oxygen of the air combines with the silicon and the carbon of the pig iron, and in so doing produces enough of heat to keep the iron in a melted state till it is brought to the malleable condition; it is then run into large ingots, which are hammered and rolled in the usual way. About two hours suffice to convert cold iron into pure steel.

1775. V. *Puddled steel* is made by puddling pig iron, and stopping the process at the instant when the proper quantity of carbon remains. The bloom is shingled and rolled like bar iron. VI. *Granulated steel*, the invention of Capt. Uchatius, is made by running melted pig iron into a cistern of water over a wheel, which dashes it about so that it is found at the bottom of the cistern in the form of grains or lumps of about the size of a hazel nut. These are imbedded in pulverized hæmatite or sparry iron ore, and exposed to a heat sufficient to cause part of the oxygen of the ore to combine with, and extract, the carbon from the superficial layer of each of the lumps of iron, each of which is reduced to the condition of malleable iron at the surface, while its heart continues in a state of cast iron. A small additional quantity of malleable iron is produced by the reduction of the ore. These ingredients being melted together produce steel.

1776. Kirkaldy observes that "Steel invariably presents, when fractured slowly, a silky fibrous appearance. When fractured suddenly, the appearance is invariably granular; in which case also the fracture is always at right angles to the length. When the fracture is fibrous, the angle diverges always more or less from 90°. The granular appearance presented by steel suddenly fractured is nearly free of lustre, and unlike the brilliant crystalline appearance of iron suddenly fractured: the two combined in the same specimen are shown in iron bolts partly converted into steel. Steel which previously broke with a silky fibrous appearance is changed into granular by being hardened. Steel is reduced in strength by being hardened in water, while the strength is vastly increased by being hardened in oil. The increase of strength is greater the higher steel is heated (not being burned) and so treated."

1777. "In a highly converted or hard steel the increase in strength and in hardness is greater than in a less converted or soft steel. Steel plates hardened in oil and joined together with rivets are fully equal in strength to an unjointed soft plate; or the loss of strength by riveting is more than counterbalanced by the increase in strength by hardening in oil. The most highly converted steel does not, as some may suppose, possess the greatest density. In cast steel, the density is much greater than in puddled steel, which is even less than in some of the superior descriptions of wrought iron."

1778. This subject may, perhaps, be considered of greater importance to the architect and engineer, if those experienced scientific men be right, who predict that the time is not far hence when there will be no such metals as either wrought or cast iron; steel taking the place of both for all practical purposes. As one instance among many, it has been urged that the absolute strength of any cast iron girder may be doubled by the judicious use of a very few pounds of steel, costing but a trifle. (*See* 1632.)

Corrosion and Preservation of Iron.

1779. Cast iron will often last for a long time without rusting, if the skin be not injured, which is coated with a film of the silicate of the protoxide of iron, produced by the action of the sand of the mould on the iron. Chilled surfaces of castings are without this protection, and therefore rust more rapidly. The corrosion of iron is more rapid when partly wet and partly dry, than when wholly immersed in water or wholly exposed to the air. It is accelerated by impurities in water, and especially by the presence of decomposing organic matter, or of free acids. It is also accelerated by the contact of the iron with any metal which is electro-negative relatively to the iron, or in other words, has less affinity for oxygen, or with the rust of iron itself. If two portions of a mass of iron are in different conditions, so that one has less affinity for oxygen than the other, the contact of the former makes the latter oxidate more rapidly. In general, hard and crystalline iron is less oxidable than ductile and fibrous iron. Cast iron and steel decompose rapidly in warm or impure sea water. The purest and the most malleable irons are the most easily attacked by sea water, *when used alone;* for it is to be observed that the fine grained, crystalline, white and brittle metal, which usually resists the action of air and water most successfully, is also the most easily attacked by the dilute acids present in the woods so often used in connection with iron in ship building, or in timber structures in sea water. The most extreme care, and the greatest practical skill, are therefore required in the selection of the irons to be used in certain positions. To R. Mallet we are indebted for a valuable communication to the Institute of Civil Engineers in May 1840, *On the Corrosion of Cast and Wrought Iron in Water*, under protected and unprotected states : an abstract is given in the *Civil Engineer Journal,* iii. p. 424, from the Proceedings of the Institute.

1779*a*. In the Reports of the British Association, 1843 and 1849, Mallet, *On Corrosion of Iron*, further states that iron kept constantly in a state of vibration oxidates less rapidly than that which is at rest. Thus the rails of a railway on which a constant traffic runs, do not rust so quickly as those on which there may be no traffic.

1779*b*. Spencer, *Iron, its active and inactive states*, read before the Liverpool Polytechnic Society, stated that "It required a mixture of air and water, or what is usually termed dampness, to produce rust on iron—one without the other would not do it. Steel filings became rusty in water, because they absorbed the oxygen in the water; if a second quantity of filings be put in, they would not rust, as there was no more oxygen. A coating of carbon effectually prevents iron from oxidation, and it can protect it from a body so strong as even aqua-fortis itself. If the aqua-fortis be diluted with water, the protective power no longer exists. The slightest scratch or abrasion on the surface of the metal also prevented the action of the protecting influence. A piece of solid carbon also imparts a protective property to iron, little short of that given to it by platinum."

1779*c*. Sugar exercises a material influence on iron and other metals : *Athenæum,* Sept. 1853 and May 1854.

1779*d*. The iron wire suspension bridges of France, which have fallen within the last few years, appear to have done so principally through the oxidation of the wires in the portion passing into the anchoring wells: this was notoriously the case with the bridge at Angers. The constant state of humidity prevailing in these wells must sooner or later have rusted the wires, and although the precaution, recommended by Vicat, of surrounding the cables with rich lime had been adopted, the vibration of the bridge had detached the cables from their supposed protecting case and the spaces between the wires allowed moisture from the exterior to permeate the interior of the cable; at Angers the cables were thus almost entirely rusted through. In such places it is better to employ bar chains.

1779*e*. Before painting iron work it is usual to give it a coat of boiled linseed oil, applied hot; it forms a kind of varnish, and is an excellent preparation, and should be done after the blue shales are removed. Lead paints, when of good quality and mixed with good oil without spirits, are recommended. As it is difficult to test both oils and colours, others prefer iron oxide paints, especially as they are cheaper. Tar paints are used chiefly for iron work out of sight; it is cheap, and is said not to foul so readily as lead or other finer paints. A good rough paint is to be made by heating coal tar and mixing with it finely sifted slaked lime, say three-quarters of a pound of lime to a gallon of tar, and adding naphtha to render it of a convenient consistency for laying on; it must not be allowed to get too hot, and is to be used hot. Where sanding is possible, it adds to its durability.

1780. The following recommendations have been made for preserving iron. I. Boiling the iron in coal tar, especially if the pieces have first been heated to the temperature of melting lead. II. Heating the pieces to the temperature of melting lead and smearing their surfaces whilst hot with cold linseed oil, which dries and forms a varnish. This is recommended by Smeaton, and is a good preparation for painting upon.

1780*a*. III. Painting with white lead in oil, which must be renewed from time to time. Mr. John Braithwaite has stated that his father had used red lead for fifty years with good result; white lead was of no use, as the acid used in the preparation of it produced swelling effects. He had placed rods in a well 200 feet deep forty-five years since, having painted them with pure red lead, and on taking them up in 1863 he found that their weight was precisely the same. Red lead and one-third litharge made into paint with nut oil will last longer than when mixed with linseed oil. Iron heated and covered with mineral bitumen or asphaltum in the solid state had resisted a moist atmosphere for fifteen years; the natural asphaltum was the best, the liquid asphalte not answering so well; with all other materials the rust had penetrated beneath. C. H. Smith, in a communication to the *Builder*, 1864, p. 318, brought forward the advantages of lime whiting as a preservative of iron from rust. In support of the use of lime, he notices that polished steel goods may be preserved by beating a little powdered lime upon them; and that bricklayers always smear their bright trowels even with damp mortar when leaving work.

1780*b*. IV. Coating with a metal, commonly called *galvanizing*. Zinc is efficient, provided it is not exposed to the acids capable of dissolving it; but it is destroyed by sulphuric acid in the air of places where much coal is burnt; and by muriatic acid in the neighbourhood of the sea. All attempts to use galvanized iron for roofs in large towns or smoky districts have failed. The use of this material will be noticed in the section on ZINC. Tinned iron does not now answer so well even as good zinc. It is known that during the mediæval period, iron nail-heads, anchors, dogs, and such like articles were tinned over, no doubt to prevent oxidation; and tinned iron is greatly used for the covering of houses in America. In St. Petersburg and in Moscow iron is mostly used, but it requires painting. The coppering of iron has failed unless it was done in so expensive a manner as not to be practicable in any extended employment of it. A coating of lead, or of lead and antimony, is wanted to iron, so as to combine the stiffness and cheapness of iron with the durability of lead. Messrs. Morewood have recently introduced metal plates covered with a uniform coating of lead. These plates are supposed to possess all the advantages of sheet lead, and they can be rendered serviceable at a considerably reduced cost (Hunt, *Handbook*, 1862). Enamelled iron is a late invention, and one tending to be very serviceable. (*See* also *par.* 2264.)

1780*c*. Professor Barff's recently (1877) discovered method of coating iron with magnetic or black oxide is effected by subjecting it to steam at a high temperature of about 1,200 degrees of Fahr. for six or seven hours. It is said that iron so treated will resist a rasp, and bear any amount of exposure to the weather without showing any signs of corrosion. Difficulties which have hitherto stood in the way of the adequate working of the process have since (1882), we are informed, been removed, and this preservative process will no doubt be largely adopted, as adequate apparatus has been provided.

SECT. VI.

LEAD.

1781. Lead, the heaviest of the metals except gold and quicksilver, is found in most parts of the world. It is of a bluish white when first broken, is less ductile, elastic, and sonorous than any of the other metals: its specific gravity is from 11,300 to 11,479, and a cubic foot, therefore, weighs about 710 lbs. It is soluble in all acids and alkaline solutions, fusible before ignition, and easily calcined. The ore, which is easily reduced to the metallic state by fusion with charcoal, is found mineralised with sulphur, with a slight mixture of silver and antimony, in diaphanous prismatical crystals, generally hexagonal, white, yellowish, or greenish, in Somersetshire, about the Mendip Hills. About Bristol, and in Cumberland, it takes the form of a white, grey, or yellowish spar, without the least metallic appearance: in some places it is in a state of white powder or native ceruse; and in Monmouthshire it has been found native, or in a metallic state.

1782. Exposure to air and water does not produce much alteration in lead, though it quickly tarnishes and acquires a white rust, by which the internal parts are defended from corrosion. Pure water, however, does not alter it; hence the white crust on the inside of lead pipes through which water flows must probably be owing to some saline particles in the water. Lead will form an union with most other metals: one exception, however, is iron. Next to tin, it is the most fusible of metals. It is run from the furnace into moulds; the main form is called a *sow*, the smaller ones *pigs*: from these it is run into sheets, pipes, &c.

1783. Sheet lead is of two sorts, *cast* and *milled*. The thicker sort of the former, or the common cast sheet lead, is manufactured by casting it on a long table formerly made of wood but now of cast iron, (with a rising edge all round it) from 16 to 20 feet in length, and 6 feet in width, which is covered with fine pressed sand beaten and smoothed down with a strike and smoother's plane. The pig lead is melted in a large vessel, near this table, and is ladled into a pan of the shape of a concave triangular prism, whose length is equal to the width of a sheet, from which pan it is poured on to the table or mould. Between the surface of the sand and the *strike*, which rides upon the edges of the table, a space is left which determines the thickness of the sheet. The strike bears away the superfluous liquid lead before it has time to cool, as it moves by hand along the edges of the table before mentioned. When lead is required to be cast thin, a linen cloth is stretched on an appropriate table over a woollen one; in which case the heat of the lead, before spreading it on the cloth, must be less than will fire paper, or the cloth would be burnt. The strike must for the purpose be passed over it with considerable rapidity.

1784. In manufacturing milled lead, it is usual first to cast it into sheets from 8 to 10 feet long according to circumstances, but the width is regulated by the length of the rollers through which it is to be passed in milling; the thickness varies from 2 to 5 inches. By a mechanical action it is made to pass through rollers whose distance from each other is gradually lessened until the sheet is reduced to the required thickness. For a long time a great prejudice prevailed against milled sheet lead; but it is now generally considered that, for the prevention of leakage, milled is far superior to cast lead, wherein *pin holes*, which have naturally formed themselves in the casting, often induce the most serious consequences. The sheets rolled out are about 30 feet long and 6 feet 6 inches in width. The lead from the mines of Walter Beaumont, M.P., in Northumberland, when manufactured for the market is known as "W.B. lead," and is considered the best in quality. Lead melts at a temperature of about 612° to 630° Fahr. The tenacity of sheet lead is 3,300 lbs; and the modulus of elasticity 720,000 lbs.

1785. In *distilled* water which has been freed and kept from the contact of the air, lead undergoes no change; but if the lead be exposed to air and water, it is oxidized and converted into a carbonate with considerable rapidity. This carbonate has the appearance of shining brilliant scales. The presence of saline matter in the water very much retards the oxidation of the lead. So small a quantity as a 30,000th part of the phosphate of soda or iodide of potassium in distilled water, prevents lead from being much corroded, the small deposit which is formed preventing the further corrosion of the metal.

1785*a*. The danger of using water from leaden pipes or cisterns was known even to the Romans. The rarity of any fatal results shows that the risk has been much overrated. This is sufficiently explained by the protecting power of the insoluble salts of lead, formed by the action of the ingredients of the water on the lead, hindering the subsequent supplies of water from coming in contact with the metal. Distilled waters and waters which are remarkably *pure* dissolve lead, and become impregnated with it. The more *impure* the water, such as Thames water, the more it will form a protecting incrustation. A new cistern should be allowed to form this coating, by the water standing in it for some time without being renewed. To expedite the action a little phosphate of soda, or iodide of potassium, or a few drops of sulphuric acid may be added. The lid or cover of cisterns should not be of lead, as the vapour condensing in it possesses all the solvent power of distilled water. Water which has flowed over leaden roofs, more particularly in towns, carries with it from the surface some soluble salt. The holes with which lead is often riddled are caused by the larva of an insect, the *Callidium bajulus*, in the stomach of which lead is often found (Kirby and Spence, *Entomology*, i. p. 235). A pipe conveying water impregnated with sulphur salts, has after a time been coated with a sulphate or sulphide, and this sulphide being perfectly insoluble in pure water, and equally so in water not too excessively charged with foreign matters to be potable, renders the leaden vehicle perfectly harmless. Dr. Schwarz, a chemist of Breslau, has stated that by passing a hot solution of sulphide of potassium through leaden pipes, the face is transmuted from the metallic state to that of a sulphide in a few minutes, at a cost too insignificant to mention. It is said that water in the mines of galena, the sulphide of lead, can be drank with impunity.

1786. *Wetterstedt's patent marine metal* for roofing and other purposes is the invention of a native of Germany, introduced into England in 1837 by Messrs. Young, Dowson, and Co., and manufactured by Messrs. Johnson, both of Limehouse. It is composed of lead and antimony, and is adapted to all purposes to which lead is usually put. Its advantages are its malleability, its great tenacity, elasticity and durability, and resistance to acids, oxidation, and the action of the sun and atmosphere. It does not lose in weight. It is manufactured in sheets:—I. 9 feet by 3 feet, at 3 lbs. and 2 lbs. per square foot; II. 8 feet by 2 feet 9 inches at 1½ lbs. and 1 lb. per square foot; and III. 8 feet by 2 feet 6 inches, at 8 ounces per square foot. No. I. sizes are employed for flats, large roofs, covering to stairs, and small sloping and curb roofs. No. II. sizes for verandahs. No. III. for lining damp walls; it should be fixed with wrought copper nails. The roof of the Royal Polytechnic Institution was covered with this patent metal in 1838; it is still in a perfect condition. In price it is somewhat under that of lead per cwt., but a much less weight per foot superficial than of that material is used. The *patent metallic canvas*, is a combination of Wetterstedt's patent metal No. III., with canvas of various substances and strength, as calico, japanned cloth, woollen, &c., varying according to the purposes to which it is to be applied. By this combination, sufficient strength is given to a metal weighing only eight ounces per foot to enable it to be used as a perfectly waterproof and secure covering. When used to damp walls, the calico is placed outside, forming a good surface for papering, painting, &c. The cement with which the combination is effected is stated to be elastic and impervious to damp, and a thorough disinfectant.

SECT VII.

COPPER.

1787. Copper, among the first of the metals employed by the early nations of the world, is neither scarce nor difficult to work and extract from its ore. When pure it is of a pale red colour; a cubic foot of cast copper will weigh 537 lbs., in sheet 549 lbs., and when hammered 556 lbs.; the weight of a bar 1 foot long and 1 inch square varies from 3·63 lbs. to 3·81 lbs.; all the weights depending upon the copper being more or less hammered. Its elasticity and hardness are very considerable, and it is so malleable that it may be hammered into fine leaves. It is also very tenacious, a wire of a tenth of an inch in diameter being capable of sustaining 360 lbs. The tenacity of cast copper is 19,000; in sheet, 30,000; in bolts, 36,000; and in wire, 60 000. The modulus of elasticity or resistance to stretching being 17,000 000. The transverse elasticity or resistance to distortion is 6,200,000 lbs. Copper is diminished to about two-thirds by a temperature of 600° Fahr.

1788. The sixteen copper smelting works at Swansea and Neath are supplied with ore from Cornwall, Devonshire, Ireland, and from some foreign and colonial sources. There are six smelting establishments at Liverpool and St. Helens, which obtain their ore from the Cumberland mines, from Alderley Edge, and such ores as arrive at the port of Liverpool. The single works at Cheadle produce a very fine copper, which is used in the manufacture of brass wire; the ore is selected carefully from different mines somewhat widely scattered. The Mona smelting works obtain the ores from the Mona and Pary's mines in Anglesea and from those in North Wales. The "once famous" mines in Pary's mountain formerly yielded the yellow sulphuretted ore of copper, to an annual amount of from 40,000 to 80,000 tons. This ore usually contains from one and a half to twenty-five per cent. of copper, and is partly dug in what are called *packages*, and partly blasted by gunpowder, and then broken into small pieces previous to its being roasted. This operation is performed in kilns, whose shape has a resemblance to lime-kilns, in which expedients are used for removing the ore as it is roasted, and adding fresh ore. The kilns are arched level with the upper surface of the ore, and adjoining and communicating with the kiln is the floor of a condensing chamber to receive the sulphureous vapours generated in the kiln, which fall down in the form of the finest flowers of sulphur. Several hundred tons at one time are put into the kiln, and for completing the operation six months are required. The ore is reduced to one fourth of its previous quantity by roasting, and is then washed and pressed to remove the impurities. The richer ores are then dried, and removed for smelting and refining in reverberatory furnaces, from which it is at length produced in short bars or pigs. The water which filters through the fissures is often highly impregnated with sulphate of copper, and this water is pumped up into rectangular pits about thirty feet long, twelve broad, and two deep, to mix with that in which the roasted ore has been washed; and in it are immersed pieces of iron, which, combining with the sulphuric acid, precipitate the copper in the form of a red-coloured powder slightly oxidated. The precipitate thus obtained very frequently gives above 50 per cent. of pure copper, and is even more profitable to the worker than the metal produced from the crude ore.

1788*a*. In the process of copper smelting the specimens produced are—I. Calcined ore, or copper ore after the extraction of the sulphur. II. Coarse metal, obtained by the second process of smelting, producing about 40 per cent. of copper. III. Calcined coarse metal, for extracting the sulphur from II. IV. Metal "brych," producing about 65 per cent. of copper. V. Close regule, producing about 70 per cent. VI. Spongy regule, producing about 80 per cent. VII. Blister copper, producing about 95 per cent. VIII. Select ingot, the fine metal as prepared for market. IX. Tough ingot, ready for market. X. Tough cake, hammered out by hand. XI. Tough bar copper, as prepared for the manufacture of wire.

1789. Sheet copper was formerly much used for its lightness to cover roofs and flats; but it is almost superseded now by the use of zinc, which is much cheaper, and at times nearly as durable; and, moreover, it is not so liable to be corrugated by the action of the sun. The low price of copper (1887) has again brought it into the market as a competitor with other metals for roofing purposes. It is only about one-fifth the weight of lead, and not so readily acted upon by fire. Zinc, however, is only about one-third the usual price of copper; the cost of labour is nearly the same. The durability of copper may be taken to be three or four times that of zinc. It requires to be laid by skilled workmen.

1789*a*. Copper is reduced to sheet by being passed through large rollers, by which it can be rendered very thin. The thickness generally used is from 12 to 18 oz. to the foot superficial. Exposed to the air its lustre is soon gone; it assumes a tarnish of a dull brown colour, gradually deepening by time into one of bronze; and, lastly, it takes a green rust or calx, called *patina* by the antiquaries, which, unlike the rust of iron, does not injure and corrode the internal parts, confining itself to the surface, and rather preserving than destroying the metal. Hence one of the most important applications of copper is in cramps for stone work, especially when they are exposed to the air, when its cost, which is about six or eight times that of iron fastenings, can be afforded. Copper nails for fastening slates in roofing are recommended in lieu of even zinc nails.

1789*b*. It may be here well to observe, that if water is collected from roofs for culinary purposes, copper must not be used about them, neither should any reservoirs for collecting and holding it be made of that metal, as on the surface is formed a film of verdigris, which is poisonous.

Brass.

1790. Alloyed with zinc, it forms *brass* for the handles of doors, shutters, locks, drawers, and the furniture generally of joinery. The usual proportion is one part of zinc to three of copper; it is then more fusible, and is of a fine yellow colour, less liable to tarnish from the action of the air, and so malleable and ductile that it can be beaten into very thin leaves and drawn into very fine wire. The extremes of the proportions of zinc used in it are from 12 to 25 per cent. of the whole. Even with the last, if well manufactured, it is quite malleable, although zinc by itself scarcely yields to the hammer. The appearance of brass is frequently given to other metals by washing them over with a yellow lacquer or varnish. Cast brass weighs 525 lbs. per cubic foot.

1790*a*. *Delta metal* is an alloy, an improved brass, hard, durable, and strong as mild steel, possessing a beautiful fine colour. When melted it produces sound castings of fine grain; it can be forged and rolled hot and cold, and takes a very high polish. It is being used for all kinds of machinery, house, door, and harness fittings, stair plates, &c. To test the action of acids on wrought iron, steel, and delta metal, rolled bars of each were immersed for six and a half months in acid water; the weights when put in were 1·1805 lbs., 1·2125 lbs., and 1·2787 lbs. respectively. After that period they were found to be 0·6393 lbs., 0·6614 lbs., and 1·2633 lbs. respectively; showing a loss of 46·3, 45·45, and 1·2 per cent. respectively. This Delta metal is said to be now extensively used for underground machinery in mines.

Bronze or Bell-metal.

1791. Copper with *tin* (which last melts at 426° Fahr. and resists oxidation better than any of the more common metals) in the proportion of one-tenth to one-fifth of the whole forms a composition called *bronze* or *bell-metal*, used in the foundery of statues, bells, cannons, &c. When tin forms nearly one-third of the alloy, a beautiful white close-grained brittle metal is formed, susceptible of a very high polish, which is used for the specula of reflecting telescopes. Bronze weighs 513 lbs. per cubic foot.

Sect. VIII.

ZINC.

1792. Zinc is found in all quarters of the globe. In Great Britain it is abundant, though therein never found in a native state. It usually contains an admixture of lead and sulpur. When purified from these, it is of a light blue colour, between lead and tin, inclining to blue. The ore, after being hand-dressed to free it from foreign matter, is first calcined, by which the sulphur of the calamine and the acid of the blende are expelled The product is then washed to separate the lighter matter, and the heavy part which remains, being ground in a mill, is mixed with one eighth of its weight of charcoal, or with one third of its bulk of powdered coal. This mixture is placed in pots, resembling oil jars, to be smelted. A tube passes through the bottom of each, the upper end being terminated by an open mouth near the top of the pot, and the lower end going through the floor of the furnace into water. By the intense heat of a furnace the ore is reduced, the zinc is volatilized, escaping through the tube into the water, wherein it falls in globules, which are afterwards melted and cast into moulds. Thus procured, however, it is not pure, as it almost invariably contains iron, manganese, arsenic, and copper. In order to free it from these, it is again melted and stirred up with sulphur and fat, the former whereof combines with the heterogeneous metals, leaving the zinc nearly pure, and the latter preventing the metal from being oxidated. At the Vieille Montagne Zinc Company's Works, the pots are placed in the furnaces at six o'clock every morning; at six o'clock in the evening the smelting is complete; the metal is then drawn out and run into metal moulds, after which it passes into the rolling house, and is again melted and recast in a metal mould to produce ingots of the proper size and weight for the required gauge of the sheets to be rolled; this second melting is also desirable to obtain proper purity.

1793. Under rollers at a high temperature, zinc may be extended into plates of great tenuity and elasticity, or drawn into wire. These rollers are from 2 feet 8 inches to 6 feet in length, and the original thickness of the plate subjected to them is about 1 inch. A wire, one tenth of an inch diameter, will support 26 pounds. If zinc be hammered at a temperature of 300°, its malleability is much increased, and it becomes capable of much bending. Its fracture is thin, fibrous, and of a grain similar to steel. It can be drawn into wire $\frac{1}{200}$th of an inch in diameter, which is nearly as tenacious as that of silver. The specific gravity is somewhat below 7·0, but hammering increases it to 7·2. When heated, it enters into fusion at a heat of about 680° or 700°: at a higher temperature it evaporates; and if access of air be not permitted, it may be distilled over, by which process it is rendered purer than before, although then not perfectly pure. When heated red hot, with access of air it takes fire, burns with an exceedingly beautiful greenish or bluish flame, and is at the same time converted into the only oxide of zinc with which we are acquainted, consisting of 23·53 parts of oxygen combined with 100 of metal.

1794. Zinc, though subject to oxidize, has this peculiarity, that the oxide does not scale off as that of iron, but forms a permanent coating on the metal, impervious to the action of the atmosphere, and rendering the use of paint wholly unnecessary. Dr. von Petenkoffer, however, has stated that zinc is oxidized to the extent of 130 grains per square foot in twenty-seven years, about two-fifths of the oxide being removed by the moisture of the atmosphere. Its expansion and contraction are greater than those of any other metal: thus, supposing 1·0030 to represent the expansion, 1·0019 is that of copper, and 1·0028 that of lead; but the thicker the zinc, the less its contraction and expansion. The tenacity of zinc is from 7,000 to 8,000. The weight of a cubic foot varies from 424 lbs. to 449 lbs. The tenacity of zinc to lead is as 16·616 to 3·328, and to copper as 16·616 to 22·570; hence a given substance of zinc is equal to five times the same substance in lead, and about three-fourths of copper.

1795. On the first introduction of zinc into this country as a material, the trades with which it was likely to interfere used every exertion to prevent its employment; and, indeed, the workmen who were engaged in laying it, being chiefly tinmen, were incompetent to the task of so covering roofs as to secure them from the effects of the weather. Hence, for a considerable period after its first employment, great reluctance was manifested by architects in its introduction. A demand for it has, however, gradually increased of late, and the comparatively high prices of lead and copper will not entirely account for the disparity of consumption. The Vieille Montagne Zinc Mining Company, about the year 1861, took steps to improve the quality of the zinc for use in this country, the mode of laying zinc roofs, and for the prevention of the use of thin gauges of sheets which are unfit for the purpose. Their zinc possesses a reputation for its purity and excellence. The result of this care, and the better understanding of the merits of the material, has caused it to be now extensively used for purposes which are noticed in the following chapter.

1795*a*. A sheet of pure zinc, as stated by J. Edmeston in his *Report on Zinc*, will be of an even colour, without black spots or blotches; it will be very ductile, bending readily backwards and forwards in the hand; and it will not easily break. If impure, it will be the opposite of all this. If there be any iron in it, it will be worthless; if it contain any lead, it will still, though to a less extent, contain the germs of destruction within itself.

1795*b*. Common zinc is destroyed by the sulphuric acid in the atmosphere where much coal is burned; and by muriatic acid in the neighbourhood of the sea. Cement does not injure zinc; but lime, and calcareous waters destroy it; and zinc pipes to flues over wood fires are destroyed by them.

1796. Galvanized Iron is a designation misapplied to that iron which may have received a coating of zinc ; it should be called *zinked iron*. The metal is first cleaned perfectly by the joint action of dilute acid and friction, and then plunged into a bath of melted zinc, covered with sal ammoniac, and stirred until the iron is sufficiently coated with zinc. No galvanic action whatever occurs between the metals ; it is simply a coating. This process, it is stated, was invented in France by Maloin, in 1742, but not patented until 1836 by Sorel. The efficacy of the process depends upon the skill employed in removing every trace of the scales of the hydrous oxide of iron, and in its further treatment. The coating must not become loosened, or any hole be made through it, as moisture obtaining access to the iron will rapidly extend, and the scales of the oxide of iron will force up the slight zinc covering, when the iron will be gradually destroyed, unless it be at once painted. When well executed it may perhaps be durable for a lengthened period, but when badly prepared it is not so valuable as iron well painted (*par.* 1779*b*.). At the Houses of Parliament, where the iron roofing plates were galvanized, it was found necessary from 1860 to commence coating them with paint or some other material.

1796*a* The other process, which might be properly called *zinked-tinned iron*, is thus performed :—The sheets of iron are pickled, scoured, and cleaned, as for ordinary tinning. A wooden bath is half filled with a solution—the proportion of 2 quarts of muriate of tin with 100 quarts of water. Over the bottom of the bath is spread a thin layer of finely granulated zinc, then a cleaned plate, and so on alternately; the zinc and iron and the fluid constitute a weak galvanic battery, and the tin is deposited from the solution so as to coat the iron, in about two hours, with a dull uniform layer of metal. The iron in this state is then passed through a bath containing fluid zinc covered with sal ammoniac mixed with an earthy matter, to lessen the volatilization of the sal ammoniac, which becomes as fluid as treacle. Two iron rollers are driven by machinery to carry the plates through the fluid at any velocity previously determined ; the plates thus take up a very regular and smooth layer of zinc, which owing to the presence of the tin beneath, assumes its natural crystalline character. This is said to be the process adopted by Messrs. Morewood and Rogers, whose patents date in 1846 and 1850. It is asserted that iron thus prepared does not warp or buckle ; that the plate is not affected by the heat of the zinc, whereas thin sheet iron, kept in molten zinc for a few minutes, becomes so brittle that it will not bear folding or grooving ; that the plate is equally covered with zinc, whereas by the dipping process the lower half receives more than the upper : and that zinc is not contaminated by iron as when dipped, the contamination increasing with each dipping until the zinc in the bath becomes so injured as to be worthless, it being well known that the alloy of zinc and iron is more oxidizable than zinc alone, or than zinc and tin. Professor Brande has stated that in common tinned plate, the combination is such that the oxidization of the iron is accelerated by the tin, so that the iron is the protecting, and the tin the protected, metal, but in this case the reverse effect ensues, the iron is the protected metal, and the zinc the protector.

1796*b*. Time has proved that galvanized iron has corroded after *seven years* in a roof-gutter ; and the state of most of the roofs to railway sheds and stations and such like places, proves that at least some sorts of galvanized iron will decay ; the difficulty always is to ascertain what description of coating the iron has undergone. Galvanized iron bolts do not act upon oak either in sea or in fresh water, when care has been taken not to remove the zinc in driving them.

1796*c*. Galvanized iron is said to be nearly the same cost as zinc, and to be less than one quarter as liable to expansion or contraction : to be equally as durable as lead ; less in first cost, and not to require boarding ; to be not quite one-third the price of copper, and to be equally as durable ; and as compared with plain iron, the cost is increased about two-thirds, but that it increases the strength and durability of the iron.

1797. The soldering used is composed of spirits of salts killed by putting about three ounces of zinc to a pint of spirit ; care must be taken that this solder soaks well between the laps.

Sect. IX.

SLATE.

1798. Slate is a species of argillaceous stone, and is an abundant and most useful mineral. This material is so soft, that the human nail will slightly scratch it, and is of a bright lamellated texture. Its constituent parts are argill, earth, silex, magnesia, lime, and iron ; of the two first and the last in considerable proportion. The building slate is the *schistus tegularis*

1799. *Mica slate* is a species of gneiss, distinguishable by containing little or no felspar, so that it consists chiefly of quartz and mica. It has a laminated or slaty structure, with the silky lustre of mica; it is a tough material in directions parallel to its layers, but is more perishable than gneiss. In thin layers it may be used for roofing purposes. *Chlorite slate* is also laminated, soft, and easily cut, but more opaque than talc, and is sometimes used for roofing purposes. It has a green or greenish grey colour and silky lustre. *Hornblende slate* is hard, tough, durable, and impervious to water, and is used for flagstones. *Grauwacke slate* is a laminated claystone, containing sand and sometimes fragments of mica and other minerals. It is used for roofing and flag stones. All these descriptions of slate are inferior to the ordinary *clay slate*.

1800. Slate quarries usually lie near the surface; and, independent of the splitting grain, along which they can be cleft exceedingly thin, they are mostly divided into *stacks*, by breakings, cracks, and fissures. Slate is separated from its bed, like other stones, by means of gunpowder, and the mass is then divided into scantlings by wedges, and, if necessary, sawn to its respective sizes by machinery. The blue, green, purple, and darker kinds are most susceptible of thin cleavage, the lighter-coloured slates being coarser. The instruments used in quarrying and splitting slates, are slate knives, axes, bars, and wedges.

1801. The tenacity of slate is from 9,600 to 12,800. The modulus of elasticity varies from 13,000,000 to 16,000,000. The resistance to rupture is 5000. The weight of a cubic foot is from 175 lbs. to 181 lbs. The transverse strength of Welsh slate is greater than any other mineral product of the stone kind. For such qualities as strength, space, and cleanliness, no other material is so cheap as slate.

1802. The slates used about London are brought chiefly from Bangor in Carnarvonshire. The slate quarries of North Wales are the most important in this country. The chief works are situated as follows, and belong respectively to the geological formations named:—

Penrhyn, Bangor } Cambrian.	Llangollen, Llangollen: Upper Silurian.
Llanberis, Dinorwic } Cambrian.	Machynlleth, Aberdovey, Lower Silurian.
Ffestiniog, Port Madoc: Lower Silurian.	Royal Slate, Bangor: Cambrian.

The large quarries at Penrhyn near Bangor, belonging to Colonel Pennant, and from which the best Bangor slates are obtained, are worked in successive terraces; the slate is obtained in immense masses by blasting, therefore the waste is enormous, but being got rid of without difficulty, the price is kept moderate. These quarries have been variously estimated as yielding from 30,000*l.* to 40,000*l.* worth of slates per annum. Many smaller ones have lately been opened near Bangor, all supplying "best Bangor" slates, without affecting the produce of the well-established works at that place. The Llangollen quarries are remarkable for the size of the slates they can obtain.

1803. The Delabole quarries in Cornwall have been worked for a considerable period; these slates are shipped from Tintagel and Boscastle. This grey-blue slate, confined till lately to the western counties, is now obtained in London; the Wellington College at Sandhurst, Berkshire, is roofed with them. The Tavistock slates from Devonshire were at one period in considerable demand. One of the most esteemed slates is of a pale blue-green, brought from Kendal in Westmoreland, and called Westmoreland slate. There are quarries in the neighbourhood of Ulverstone, in Lancashire; and the Cumberland sea-green slate works are at Maryport.

1804. The extended use of this material for paving, shelving, cisterns, &c., has caused numerous companies to be formed for the working of old, and of many new, quarries, chiefly in North and South Wales. Amongst the companies putting forth peculiarities of slate, are the Dorothea West, Green, Blue, and Red, Slate Company, situate in Carnarvonshire, which supplied the pale green slates for the Charing Cross Railway Hotel, the London Bridge Hotel, and the Star and Garter Hotel at Richmond. The Llanfair Green and Blue Slate Company is also to be noticed.

1805. The slates of Scotland are not in much repute. The Balahulish quarries in the north of Scotland are very extensive, as between five and seven millions of roofing slates are quarried annually. The weight of this number would be about 10,000 tons, and the quantity of rubbish being generally five or six times as much as the slates, some 50,000 or 60,000 tons of refuse have to be disposed of, which in this case are thrown directly into the sea, securing an immense saving of expense.

1806. The more important slate quarries in Ireland are in the southern division of the country, viz., Killaloe, county Tipperary; Valentia, county Kerry; Bendulf, near Glandore Harbour, county Cork; and near Ashford Bridge, county Wicklow. The chief one is at Curraghbally, situate about six miles from Killaloe. The colour of the slates is a dull bluish grey, preferred by many to the decided blue of the Bangor quarries; they are greatly used in the west of Ireland, where they have superseded the Welsh slates. The colour of the Valentia slates is rather greener than those above mentioned. They are generally thicker and more uneven on the surface, and so are better suited for the exposed aspects of buildings in the western counties. This quarry has more capabilities for sawn flags and slabs, of which a large amount is now exported to England for cisterns, baths, urinals &c. The Banduff quarry is nearly given up. The slates from Ashford Bridge both in colour and quality closely resemble the Bangor slates. (Wilkinson, *Geology, &c. of Ireland*, 1845.)

1807. A fine sound texture is the most desirable among the properties of a slate; for the expense of slating being greatly increased by the boarding whereon it is placed, if the slate absorbs and retains much moisture, the boarding will soon become rotten. But a good slate is very durable. Its goodness may readily be judged by striking it as a piece of pottery is struck; a sonorous, clear bell-like sound is a sign of excellence; but many pieces of the slate should be tried before a conclusion can be arrived at. It is thought to be a good sign, if, in hewing, it shatters before the edge of the *zax*. The colour, also, is some guide, the light blue sort imbibing and retaining moisture in a far less degree than the deep black-blue sort. The feel of a slate is some indication of its goodness: a good one has a hard and rough feel, whilst an open absorbent slate feels smooth and greasy. The best method, however, of testing the quality of slates is by the use of water, in two ways. The first is, to set the pieces to be tried edgewise in a tub of water, the water reaching above half way up the height of the pieces: if they draw water, and become wet to the top in six or eight hours' time, they are spongy and bad; and as the water reaches less up them, so are the pieces better. The other method is, to weigh the pieces of slate, and note their weights. Let them then remain for twelve hours in water, and take them out, wiping them dry. Those that on re-weighing are much heavier than they were previous to their immersion should be rejected. Where the character of a slate quarry is not previously known, experiments of these sorts should never be omitted.

1808. The following comparison of the advantages of slates over tiles is given by R. Watson, former Bishop of Llandaff. That sort of slate, other circumstances being the same, is esteemed the best which imbibes the least water; for water not only increases the weight of the covering, but in frosty weather, being converted into ice, swells and shivers the slate. This effect of frost is very sensible in tiled houses, but is scarcely felt in those which are slated, for good slates imbibe but little water; though tiles, when well glazed, are rendered in some measure similar to slate in this respect The bishop took a piece of Westmoreland slate and a piece of common tile and weighed each of them carefully. The surface of each was about thirty square inches. Both the pieces were immersed in water about ten minutes, then taken out and weighed as soon as they had ceased to drip. The tile had imbibed about a seventh part of its weight of water, and the slate had not imbibed a two-hundredth part of its weight; indeed, the wetting of the slate was merely superficial. He placed both the wet pieces before the fire; in a quarter of an hour the slate was perfectly dry, and of the same weight as before it was put into the water; but the tile had lost only about twelve grains it had imbibed, which was, as near as could be expected, the very same quantity that had been spread over its surface; for it was the quantity which had been imbibed by the slate, the surface of which was equal to that of the tile. The tile was left to dry in a room heated to sixty degrees, and it did not lose all the water it had imbibed in less than six days.

1809. Professor Ansted states that the best slates are those which are most crystalline, and which, when breathed upon, give out a faint argillaceous odour; when this was given out strongly, then the slates would readily decompose.

1810. The largest slab of slate, perhaps, ever as yet obtained, was the one sent by the Llangollen Slate Company to the International Exhibition of 1862. It was 20 feet long, 10 feet wide, and weighed $4\frac{1}{2}$ tons; the thickness, however, was not named. The Welsh Slate Company, whose quarries are at Festiniog, in Merionethshire, sent several slabs averaging 14 feet by 7 or 8 feet. All the slate from this neighbourhood possesses the remarkable quality of splitting with great facility, and with wonderful accuracy of surface, into thin laminæ or sheets. Some of these thinly divided sheets are obtained 5 to 10 feet long from 6 to 12 inches wide, and not more than the sixteenth of an inch in thickness. They are so elastic as to bend like a veneer of wood. (Hunt, *Handbook*, 1862.)

Sect. X.

BRICK AND TILE.

1811. A brick is a factitious sort of stone, manufactured from argillaceous or clayey earth, well tempered and squeezed into a mould. When so formed, bricks are stacked to dry in the sun, and finally burnt to a proper degree of hardness in a clamp or kiln. The use of bricks is of the highest antiquity. They are frequently mentioned in the historical books of the Old Testament; but whether they were merely sun-dried or burnt in a kiln seems uncertain. We are inclined to doubt the burning of them at a very remote period. It will immediately occur to the reader that the making of bricks was one of the tasks imposed upon the Israelites during their servitude in Egypt. Though the oldest remains in Egypt are of stone, Pococke describes a pyramid of unburnt bricks, which are composed of a black sandy earth, intermixed with pebbles and shells, the sediment deposited by the overflowing of the Nile. This species of bricks is still common in Egypt and many other parts of the East. By the ancient Greeks and Romans, both burnt and unburnt bricks were used; the method of making the latter whereof is thus described by Vitruvius, in the third chapter of his second book: "I shall first," says that author, "treat of bricks, and the earth of which they ought to be made. Gravelly, pebbly, and sandy clay are unfit for that purpose; for if made of either of these sorts of earth, they are not only too ponderous, but walls built of them, when exposed to the rain, moulder away, and are soon decomposed; and the straw, also, with which they are mixed, will not sufficiently bind the earth together, because of its rough quality. They should be made of earth, of a red or white chalky, or a strong sandy nature. These sorts of earth are ductile and cohesive, and not being heavy, bricks made of them are more easily handled in carrying up the work. The proper seasons for brick-making are the spring and autumn, because they then dry more equably. Those made in the summer solstice are defective, because the heat of the sun soon imparts to their external surfaces an appearance of sufficient dryness, whilst the internal parts of them are in a very different state; hence, when thoroughly dry, they shrink and break those parts which first dried; and thus broken, their strength is gone. Those are best which have been made at least two years; for in a period less than that, they will not dry thoroughly. When plastering is laid and set hard on bricks which are not perfectly dry, the bricks, which will naturally shrink, and consequently occupy a less space than the plastering, will thus leave the latter to stand of itself. From its being extremely thin, and not capable of supporting itself, it soon breaks to pieces; and in its failure, involves sometimes even that of the wall. It is not, therefore, without reason that the inhabitants of Utica allow no bricks to be used in their buildings which are not at least five years old, and also approved by a magistrate.

1812. "There are three sorts of bricks: the first is that which the Greeks call *Didoron* (διδῶρον), being the sort we use; that is one foot long and half a foot wide. The other two sorts are used in Grecian buildings; one is called *Pentadoron*, the other *Tetradoron*. By the word *doron*, the Greeks mean a palm, because the word δῶρον signifies a gift which can be borne in the palm of the hand. That sort, therefore, which is five palms each way, is called Pentadoron; that of four palms, Tetradoron. The former of these two sorts is used in public buildings, the latter in private ones. Each sort has half bricks made to suit it, so that when a wall is executed, the course on one of the faces of the wall shows sides of whole bricks, the other face of half bricks; and being worked to the line on each face, the bricks on each bed bond alternately over the course below." Vitruvius concludes the chapter with the mention of the bricks made at Calentum in Spain, at Marseilles in France, and Pitane in Asia, which are specifically lighter than water.

1813. It is to be regretted that plastering with cement, a practice which is more to the interest of the brickmaker and bricklayer than to the consumer, has become so prevalent in this country. These tradesmen thus get rid of their worst bricks, which are hidden by a coat of plaster; the building soon decaying when the heart of the wall is bad. Colour seems to be the objectionable quality about this material, the commonplace architect forgetting that form is much more essential to beauty than colour. In the times of Jones and Wren, red brick was beautifully wrought into architectural forms, of which a few examples still remain in the metropolis: and by Palladio, bricks were occasionally used for columns without smearing them over with plaster.

1814. In England, the best earth for making bricks is a clayey loam, neither abounding with too much sand, which renders them brittle, nor with too large a portion of argillaceous matter, which causes them to shrink and crack in drying. It should be dug at the least a year before it is wrought, that by exposure to the atmosphere it may part with all extraneous matter which it possessed when first dug. The general practice is, however, to dig it in the autumn, and allow it to remain through the winter to mellow and pulverize, by which the operation of tempering is greatly facilitated. Upon this operation the quality of the brick mainly depends, and great attention should be bestowed upon performing this part of the process in a proper manner. This branch of the manufacture was formerly executed by throwing the clay into shallow pits, and subjecting it to be trodden by men and oxen; a method which has been advantageously superseded by a clay or pug-mill, with a horse track.

1815. As soon as the clay has been thoroughly tempered by one of the methods above named, it is taken to the moulder's bench, where it is cut by the moulder's assistant, generally a woman or a lad, into pieces rather larger than the mould, which are passed on to the moulder, who throws it with some force into the mould, which has been previously dipped in sand. He presses it down, so that it may fill the whole of the cavity, striking off the superfluous clay with a flat wooden rule. The newly-formed brick is then turned out of the mould on to a thin board, somewhat larger than a brick, and it is removed by a boy to a latticed wheelbarrow, and conveyed, covered with fine dry sand, to the *hack*. A handy moulder, working fifteen hours, will mould 5000 bricks. In the hacks, which are eight courses in height, the bricks are arranged diagonally above each other, with a passage between each for the circulation of air round them. The time required for drying in the hacks will of course depend on the fineness of the weather; it is but a few days if the season be propitious; and they are then turned and reset wider apart, after which, in about six or eight days, they are ready for the clamp or kiln. If the weather be rainy, the bricks in the hack must be covered with wheat or rye straw; and as they ought to be thoroughly dry before removing to the clamp or kiln, a few are generally selected from different parts, and broken, to ascertain if the operation of drying has been well performed. The moisture arising from bricks when burning is very injurious to their soundness.

1816. The quantity of clay necessary to make 1000 bricks will be somewhere about 54 cube feet, which allows about 5 feet for shrinkage in drying and burning; for 1000 × $8\frac{1}{2}$ in. × $2\frac{1}{2}$ in. × 4 in. = 49 2 3″ 4‴. The cost of making 1000 bricks, in the neighbourhood of London, is nearly as follows:—

	£	s.	d.
Digging, wheeling, carting, &c. - - - - -	0	1	6
Moulding, stacking, &c. - - - - - -	0	11	6
Sand, one-sixth of 2*s*. - - - - - - -	0	0	4
Straw for hacks - - - - - - - -	0	0	9
Barrows, moulds, planks, &c. - - - - -	0	0	6
Fuel 9 cwt. per 1000 - - - - - -	0	10	6
	=£1	5	1

1817. In the brickfields about London, bricks are mostly burnt in what are called *clamps*. These are generally oblong in form, and their foundations are made with the driest of the bricks from the hacks, or with common worthless bricks, called place bricks. The bricks for burning are then arranged, tier over tier, to the height assigned to the clamp, according to the quantity to be burnt, and a layer of breeze or cinders, two or three inches deep, is placed between each course of bricks, and the whole, when built up, covered with a thick stratum of breeze. On the western face of the clamp a vertical fireplace is formed, about 3 feet in height, from which flues are driven out by arching the bricks over, so as to leave a space about one brick wide. The flues run in a straight direction through the clamp, and are filled with a mixture of coals, breeze, and wood, closely pressed together. If the bricks are required to be burnt quickly, the flues should not be more than 6 feet apart; but if time do not press, the flues need not be nearer than 9 feet to each other, and the clamp is allowed to burn slowly. It is possible, if required, to burn a clamp in a period of from 20 to 30 days, according to the dryness of the weather. The practice of steeping bricks in water after they have been burnt, and then again burning them, has been found to have the effect of considerably improving their quality.

1818. A new mode of burning bricks in clamps has been patented by Robert White at Erith, wherein the advantages are stated to be that, 1st, nearly all the bricks are burnt into stocks, and the yield of inferior bricks is reduced from 35 to about 10 per cent. of the total make; and, 2ndly, the bricks are so much improved in colour and soundness as to give them a considerable additional value in the market over common stocks.

1819. The *kilns* which are used for burning bricks are usually 13 feet long, by 10 feet 6 inches in width, and 12 feet in height. The walls are one brick and a half thick, and incline inwards as they rise. A kiln is generally built to contain 20,000 bricks at each burning. The fireplace consists of three arches, which have holes at top for distributing heat to the bricks. These are placed on a lattice-like floor, and first undergo a gentle action of the fire for two or three days, in order to dry them thoroughly. As soon as they thus become ready for burning, the mouth of the fireplace is dammed up with what is called a *shinlog* (which consists of pieces of brick piled against each other, and closed with wet brick earth), leaving about it sufficient room to introduce a faggot. The kiln is then supplied with brushwood, furze, heath, faggots, &c., and the fire is kindled and kept up until the arches assume a white appearance, and flames appear through the top of the kiln. The fire is then slackened, and the kiln gradually cooled. This process of alternately raising and slacking the heat of the kiln is repeated till the bricks are thoroughly burnt, which is usually accomplished in about eight and forty hours.

1820. The malm or marl stock, which is of a bright yellowish uniform colour and texture, is not always to be had, especially in the London districts; in consequence of which, several years ago, it was discovered that chalk mixed in certain portions with loam, and treated in the usual manner, proved an excellent substitute for it. It not only was found to improve the colour, but to impart soundness to the brick; and the practice is now generally adopted about London. At Emsworth in Hampshire, and also at Southampton, ooze, or sludge, from the sea-shore, containing much saline matter, is used for a similar purpose: these bricks, however, have not the rich brimstone colour of the London malm stock, nor the regular stone-coloured hue of the Ipswich or Suffolk bricks.

1821. The finest marl stocks, which are technically called *firsts*, or *cutters*, are principally used for arches of doorways and windows, quoins, &c., for which purposes they are rubbed and cut to their proper dimensions and form. There is also a red cutting brick, whose texture is similar to the malm cutter, which must not be confounded with the red stock. The next best, which are chiefly used for principal fronts, are called *seconds*; they are not quite so uniform in colour, nor so bright as the last, but are, nevertheless, a handsome and durable brick.

1822. *Stocks* are red and grey, both sorts being equal in texture. The red sort are burnt in kilns. The grey stocks are less uniform in their colour than seconds, and are of rather an inferior quality. They are used for common fronts, and walls.

1823. *Place bricks*, or *peckings*, sometimes also called *sandel*, or *samel bricks*, are those which, having been outermost or furthest from the fire in the clamp, or kiln, have not received sufficient heat to burn them thoroughly. They are consequently soft, uneven in texture, and of a red colour. These should never be used in a building where durability is required. The name was formerly applied to the second quality of bricks, and these are still so called in Ireland, being used for inside walls: the Irish harder burnt brick, having a semi-glazed surface, is called *firebrick*, and is used for exterior work where expense is not an object; of course it lasts much longer than the other sorts.

1824. *Burrs* and *clinkers* are such bricks as have been violently burnt, or masses of several bricks run together in the clamp or kiln.

1825. *Compass bricks* are circular on the plan, and are chiefly employed for *steyning*, or walling round wells.

1826. *Concave* or *hollow bricks* are made like common bricks, but hollowed on one side in the direction of their length, and are adapted to the construction of drains and water-courses. Other *hollow* and *pierced bricks* of several shapes and sizes are supplied by various manufacturers. A *beaded brick*, drilled with holes, for garden walls, to avoid the necessity of nailing in training trees, are made at Stony Stratford, in Northamptonshire.

1827. *Firebricks*, so called from their capability of resisting the most violent action of the fire, are of a dark red colour, and of a very close texture; they are made about 9 inches long, 4½ inches broad, and 1½ inches thick. The loam of which they are made is yellow, harsh to the touch, and contains a considerable portion of sand. Their quality renders them highly serviceable in furnaces and ovens. The greater part of those used about London was formerly brought from Hedgerly, a village near Windsor, whence they obtained the name of Windsor bricks. This sort of brick is also made in various parts of Wales, whence they are called *Welsh lumps*; also at Newcastle; at Poole in Dorsetshire; at the Hurlford works, near Glasgow; and at Stourbridge; the latter supplies chiefly the London market, but the material is one of the dearest. Fire clay, and flue linings for furnaces, are extensively used. The Dinas brick, manufactured by the Ynisymudu Company, near Swansea, stands a heat that will melt the Stourbridge brick.

1828. *Paving bricks* are for the purpose which their name implies, and their dimensions are the same as those of the foregoing sort.

1829. *Dutch clinkers* and *Flemish bricks* vary little in quality; they are exceedingly hard, and are used for the paving of stables, yards, &c., though they are by some objected to, as being too hot for the horses' feet. The former are 6 inches long, 3 inches broad, and 1 inch thick, and are often laid on edge in various fanciful forms, as the herring-bone, &c. The *adamantine clinker* is noticed in the next chapter. Tebbutt's patent "safety" brick is used for stables, yards, lavatories, and such places, as it gives a good foothold and a dry walking surface.

1830. *South Staffordshire* supplies a blue vitrified sewerage and paving brick (as used on Charing-cross suspension bridge, 1856, and on Chelsea new bridge), and a channeled stable brick. It is stated that the *Tipton blue brick*, when used for facings, lets in the wet most thoroughly, either through the brick or through the mortar joints, so that walls of this material should be built hollow. The construction of the work was questioned, as 9 and 14 inch walls have been erected with these bricks with success. As they are scarcely absorbent, mortar does not thoroughly adhere to them; this want of adhesion might be remedied by well soaking the bricks before using them. *Blue bricks* of various forms are also used for paving, copings, channels, gutters, border tiles, plinths, &c.

1831. Amongst the many qualities and varieties of bricks now in use in the metropolis, the following may be enumerated in addition to those already mentioned. The *Cowley, Essex, and Kent bricks*. From Cowley are sent stocks, best yellow and white cutters, yellow and white seconds, paviours, pickings, &c. The *Aylesford and Burham* works, near Maidstone, on the river Medway, formerly the property of the late Thomas Cubitt, produce *gault* bricks of good quality. *Pickwell's* patent white brick is sound, has a uniformity of colour, resists frost and the action of acids much longer than others. They are manufactured at Hull.

1831*a*. The *Suffolk bricks*, called white Suffolks, are of two or more qualities, expressly made for facings, and are expensive; the *best* are rarely to be obtained in London, being sold in the locality of their manufacture. They have a disagreeable cold hue, rendered still more dull after a few years' wear in the smoky atmosphere even of a provincial town. They are not so well burnt as those which are somewhat of a light pink or salmon tint. These latter are to be bought at the kiln at about 17*s*. per thousand, and by some persons are thought to make better brickwork than those which fetch 60*s*. or more per thousand in London. The works supply superior white and red (kilnburnt) *Suffolk* facings, splays, door-jambs, coping bricks, stable clinkers, &c.; dark red facings, rubbers, splays, paving bricks, &c.; bright yellow malm facings, and cutters of best quality. Mean quality, and pale malm seconds, pickings, paviours, &c. A dark-coloured brick from *Huntingdon* is of a finer colour, uniform, much smoother than ordinary, and equal to those made in Kent.

1831*b*. *Beart's patent bricks* are made at Arsley, near Hitchin, on the Great Northern Railway, of the following qualities, ranged according to price:—White rubbers; hand made moulded solid brick, equal to the best Suffolks; No. 1 best selected white facing brick (pierced); and ordinary; these two are of uniform colour, hard and well burnt, and used extensively for facings; No. 2 mingled, red and pink, vary from the above only in colour, and are equal in every respect to the best made stock bricks. These bricks are made from the *Gault* clay, one of the subcretaceous formations interposed between the chalk and the wealden deposits, or between the chalk and the upper oolite. The composition varies, for although it is of a tolerably uniform dark blue colour, it sometimes contains large quantities (comparatively) of the hydrous oxide of iron; and in others it contains much of the bicarbonate of lime, in combination. The former burn in the kiln into a deep red brick or tile of rather inferior quality; the latter are used for the pierced hard white bricks above described. It is stated that these bricks are required to be burnt with great care, for if the calcination of the lime should take place under such conditions as to leave the lime in a caustic state, it will slack on exposure to the weather, or when moisture is applied to it. There is some difference of opinion as to whether mortar can be made to adhere to the smooth hard face of these bricks to make sound and strong work.

1831*c*. The *red bricks* derive their colour from the nature of the soil whereof they are composed, which is generally very pure. The best of them are used for cutting-bricks, and are called red rubbers. In old buildings they are frequently found set in lime putty, and often carved into ornaments over arches, windows, doorways, &c. The Fareham reds are noted bricks. The Rowlands Castle (Hampshire) brick, tile and terra-cotta works supply reds in colour and appearance similar to Fareham. They are very hard and strong. At a mean pressure of 76,867 lbs., or 686 cwts., they cracked slightly, and with 140,617 lbs., or 1255 cwts., they cracked generally; giving 141·9 and 259·5 tons per square foot. The Thurstonland brick, from near Huddersfield, is made from a deep bed of shale, producing when burnt a rich red colour; each brick undergoes a pressure of 14 tons, is well burnt, and being of a vitreous nature is impervious to atmospheric and other destructive influences. Moulded bricks can be made. They have been used at some of the London Board Schools, and largely at Blackburn and Sheffield. The crushing strain is over 399 tons per square foot, and the brick contains 65 per cent. of silica.

1831*d*. *Black bricks* are obtained from Cowbridge, in South Wales; these were used at All Saints' Church, Margaret Street, and cost £4 per thousand. The Ballingdon or Ewell deep black rubbing and building bricks, probably so rendered by manganese, are soft in make and dead-looking in colour. The same factory, and Chalfont, supply dark, and bright, red rubbers; with black headers, glazed and unglazed. Red and black bricks are sent from Burgess Hill, Sussex; and from Maidenhead, in Berkshire.

1831*e*. Bricks are now made glazed white and also many other plain colours; others with patterns on the face as borders and for decorative purposes. The white glazed bricks are used in lieu of tiles for the reflection of light; others for securing perfect cleanliness of wall surface; and for obtaining quiet and neutral tones of colour for the walls of wards of hospitals, and other similar purposes.

1832. By the 17th Geo. III. cap. 42, all bricks made for sale were directed, when burnt, to be not less than $8\frac{1}{2}$ inches long, $2\frac{1}{2}$ inches thick, and 4 inches wide. This statute, which was enacted for the purpose of levying a duty, is now no longer in force, and the manufacturer is at liberty to make bricks and tiles of whatever size and form may be best suited to the work for which they are used. This Act having been rescinded, has led to the introduction of *moulded* and *ornamental* bricks to a vast extent, which will probably be still further extended as brickmaking machines become more useful and certain in their operations. The patents for them are now very numerous: some of them are stated to make up to 20,000 per day, as may be required. The size of the brick, however, has been retained, and habit will, no doubt, continue it in favour, especially for repairs.

1832*a*. Bricks laid in the summer season should be well saturated with water previous to laying; and if the work be left for a day only, the walls should be as carefully covered up as in the winter, for in hot weather the mortar sets too rapidly, and hence the necessary cohesion is destroyed; an evil much aggravated by the dust constantly hanging about the bricks, more especially at that season of the year. (See 1900*d*.)

1833. A valuable paper, *On the Transverse Strength of Bricks*, was delivered by Mr. W. Hawkes at the Institute of British Architects, January, 1861. He stated that he had always tested bricks by their transverse power in preference to the crushing weight, which was but seldom called in question, as it tells nothing if the bricks will resist from 30 to 100 tons dead weight. It would often be useful to know if in a 9 inch wall we could distribute a weight, say of 13 tons, over an opening 90 inches wide, having only 40 inches depth, supposing that the bricks be of moderate strength and the mortar be as strong as the bricks. The pressure and weights were applied in each case in the centre of the brick.

1833*a*. He experimented on *Dutch clinkers* (made at Moor, near Gouda, in South Holland, from the slime deposited on the banks of the river Yssel; and formerly from that of Haarlem Meer; the clay or slime is washed to get rid of the earthy matter before being moulded; the colour is lightish yellow brown); Tipton blue bricks; Birmingham, hand and machine made; Leeds, ditto; Bridgewater; Colchester; Oxford; and London, &c.; with *tiles* of various kinds. As, however, these experiments were made to a calculated standard size of 7 inches long, 4·5 inches wide, and 3 inches thick, the results are not generally useful for a work of this description. But we give the few actual weights borne by certain bricks. Thus the 9 Leicester bricks carried at the ordinary size, 1,462 lbs., 1,392 lbs., 1,252 lbs., 1,132 lbs., 1,052 lbs., 1,002 lbs., 902 lbs., and 892 lbs. The 9 from Rugby carried 1,222 lbs., 1,022 lbs., 1,012 lbs., 862 lbs., 822 lbs., 552 lbs., 422 lbs., and 362 lbs. The 7 London bricks carried 1,142 lbs., 1,042 lbs., 952 lbs., 662 lbs., 652 lbs., 422 lbs., all being *stocks*; the last, a *place* brick, carried 270 lbs. The 7 London bricks (second set) carried 970 lbs., 690 lbs., 580 lbs., 400 lbs., all *stocks*; and 650 lbs., 490 lbs., 340 lbs., all *place*; the *frog* was not allowed for in the calculation.

1833*b*. The following are the ascertained weights of bricks of the sizes stated:—

	ins. ins. ins.	lbs.	cwts. per 1000.
London stocks - - - -	$8\frac{3}{4} \times 4\frac{1}{4} \times 2\frac{3}{4}$	= 6·81	= $60\frac{3}{4}$
Red kiln - - - -	$8\frac{3}{4} \times 4\frac{1}{4} \times 2\frac{3}{4}$	= 7·00	= 63
Welsh fire - - - - -	$9 \times 4\frac{1}{2} \times 2\frac{3}{4}$	= 7·84	= 65 to 75
Paving - - - - -	$9 \times 4\frac{1}{2} \times 1\frac{3}{4}$	= 5·00	= 45
Dutch clinkers - - - -	$6\frac{1}{4} \times 3 \times 1\frac{1}{2}$	= 1·55	= 14
Irish fire - - - - -	$8\frac{3}{4} \times 4\frac{1}{8} \times 2\frac{5}{8}$		= 67
Worcestershire, solid, machine made - -		8·75	
Ditto, perforated - - - - -		6·00	
Staffordshire, solid, hand made - - -		9·50	
London stock, hand made - - - -		5·75	

1833*c*. Brickwork expands with great heat. Mr. Hawkes's experiments, already noticed, on a furnace chimney, 54 feet 7 inches in height, showed that the result of six trials was an elongation of 1·425 inches. The great heat of the furnace chimney for melting iron is never reached in house flues, but since the introduction of hot air cockles and hot water furnaces, particularly the high-pressure, the heat of these flues is increased fivefold compared with flues from open fireplaces. An iron bar might perhaps be heated to redness in some of the furnace flues. In another chimney, at Thames Bank, in a height of 80 feet, the brickwork showed an expansion at times of $\frac{5}{8}$ of an inch.

1833*d*. Burnt Clay Ballast. This is now extensively used for forming the foundations of the new formed roads round the metropolis, and for footpaths in the suburban gardens. The clay obtained in making the excavations for the new houses is run to a convenient locality adjacent; a log of old timber is fixed upright in the ground; a horizontal flue 6 or 8 feet long is formed with bricks on edge, with an opening on the top near the log. Shavings are laid round the post and in the flue, outside of which pieces of timber are piled in a conical form about 8 feet wide and 5 feet high; and then coated with about half a ton of coal, which is covered with the newly excavated clay to a convenient thickness. The shavings are then lighted, if the wind suit; and in a short time the top of the heap falls in, lumps of coal are then thrown in, and on them more lumps of clay. The object to be attained is to have a mass of red hot fire in the middle of the heap. For a heap of about 100 solid yards of clay, about 11 loads of breeze or ashes and 4 tons of slack or fine coal will be needed. The heap, once fairly alight, is covered with clay. The tendency of the fire being to burn upwards, the fireman, with a long rake, drags the outer surface downwards every time the burning heap is fed; this is done by scattering the slack over it with a shovel to quicken the fire, and the breeze is then laid on to retain it; while a fresh layer of clay is subsequently put on all over the heap. When this clay is nearly burnt through, the operation is repeated. When there is a gentle smoke all over the heap the fire is going on properly; if too little, an iron rod is pushed in to stir it up;

if too much, shields must be put up to break the wind. The general form of the heap, which is cone-shaped at starting, becomes of a flattened circular top in course of being worked. It should not be made too high, as that increases the labour of wheeling the clay. When all the clay is used, such portions as are not sufficiently burnt are raked off and thrown up to the top to the greater heat: the heap is then trimmed off and left to cool. When *well burnt*, the ballast may be worth the trouble; when badly done, as is usually the case, it is not much better than rubbish, in fact not nearly so good as the usual dry brick rubbish of which roads should be made. When well burnt, ground fine, and mixed with an equal portion of sand, and a less than the ordinary proportion of good lime, it makes a mortar which will set as hard as cement. The ballast may also be sifted through a 65 or 70 wire sieve, and the fine stuff, hard and clean, used for mortar or for the plasterer; the coarse and the rough for concrete, in addition to gravel. When used as *core* for a road, it should be at once covered with the Cowley or other gravel, or the clay beneath it rises up with traffic, and much rain will soon render the road as bad as though the soil had not been covered; in fact it turns into mud, and the scamping builder finds it pays to mix his bad lime in the roadway dirt, and to use the mixture for mortar.

1833*e*. *Coke breese* or *breeze* is akin to the above in the use now made of it. It is extensively used for mortar; ground in a mill, in lieu of sand or burnt ballast, it is said to set harder, being cleaner and sharper than sand, and requires less lime or cement. It is employed in artificial stonework, in concrete, and in paving. In ballast burning it burns the clay harder, and is cheaper than small coal. For roads and pathways it is clean, not picking up in wet weather, and is good for surface drainage. In some places it may be cheaper than sand or ballast.

TILES.

1834. Tiles, which in their constituent parts partake much of the nature of bricks, are plates of clay baked in a kiln, and used instead of slates, or other covering of the roofs of houses. The clay whereof tiles are formed will always make good bricks, though the converse does not hold, from the toughness required on account of their being so much thinner than bricks. The common kinds are made of a blue clay, found in many parts about London, and mostly deeper seated than brick earth. The best season for digging it is in September and October, and it should then lie exposed during the winter. It may, however, be turned up in January, and worked in February; and, as in brick, so in tile-making, the more care bestowed on beating and tempering the clay, the better will be the tiles. In 1477, 17th Edward IV., c. 4, it was enacted that clay should be dug before November, and be stirred and turned before March. Tiles are burnt in a kiln constructed on the same principles as the brick-kiln, but with the addition of a cone, having an opening at top round the chamber of the kiln. They require much care in burning. If the fire be too slack, they will not burn sufficiently hard; and if too violent, they glaze, and suffer in form.

1835. *Plain* or *crown tiles* are such as have a rectangular form and plane surface. They were made $10\frac{1}{2}$ inches long, $6\frac{1}{4}$ inches broad, and $\frac{5}{8}$ of an inch thick, by the statute. They are manufactured with two holes in them, through which, by means of oak pins, they hang upon the laths. In using all coverings of this species, one tile laps over another, or is placed over the upper part of the one immediately below; that part of the tile which then appears uncovered is called the *gauge* of the tiling. *Terro-metallic* tiles for roofs, with two projections at the back to catch on the laths in lieu of pegs, are now in use. *Terro-metallic* Staffordshire goods in red, blue, and buff colours; also blue and red, plain, capped and rolled ridge tiles in 18 inch lengths. *Broseley* roofing tiles in various colours and patterns. The best pressed roofing tiles are of superior manufacture and quality, of very hard metal, impervious to moisture, and will not allow of vegetation growing on them. The *Kennington and Naccolt tile yards*, Ashford, Kent, supply a dark brown tile, about $9\frac{1}{2}$ inches by 6 inches, of which 1,400 go to a ton; the timbering of a roof is not more than for slates. It was there that the abbots of Battel manufactured tiles for their own use and for sale. On stripping old roofs these tiles have been found sound and were used again; the heart of oak laths had perished from age. *Italian tiles*, which were made about 1840, by Brown, of Surbiton, differ somewhat from their first prototype, as, instead of being flat, they are slightly curved, fit easily one into the other, with a horizontal indentation across the upper part, to prevent the wind drifting the rain over the tile head; they have either wide or narrow vertical rolls. Such tiles are usefully employed in picturesque buildings in the country. Taylor's *new roofing tiles* have a plane surface and a slight turned up edge at the sides, a lump on the surface near the upper edge prevents the upper tile slipping; a cover tile is of a similar size and form; these tiles were used about 1872 at the new railway station in Liverpool Street. They are recommended as being half the weight of ordinary plain tiling, each tile weighing under 4 lbs., and as light as slating; they may be laid to as flat a pitch as slates; and that 180 will cover a square of roofing.

1836. *Ridge roof* and *hip tiles* are formed cylindrically, to cover the ridges of houses.

They should be 13 in. long, and girt about 16 inches on the outside. Weight about 5 lbs. Ridge tiles, plain, and with cresting, are now introduced in red, blue, black, and green ware. Plain, flanged, rolled top, and ornamental grooved ridging tiles, are commonly seen.

1837. *Gutter tiles* are about the same weight and dimensions as ridge tiles, though differing in form, and are for the valleys of a roof. They are now rarely used, their place having been supplied by lead, and lately by zinc in common work.

1838. *Pan* or *Flemish tiles* have a rectangular outline, with a surface both convex and concave, thus . They have no holes for pins, as plain tiles have, but are hung on to the laths by a knot of their own earth on their underside, nearest the ridge, formed when making. They are often glazed, and should be $14\frac{1}{2}$ inches long and $10\frac{1}{2}$ inches broad. The *Bridgewater double roll tiles* are shown in fig. 614*a*. Three stubs are formed on the back to catch the lath. They lap over two inches, and afford good ventilation for farm buildings, with good protection from rain and snow. Phillips' patent *lock jaw* roofing tiles, with single grip and double grip, are ornamental, and stated to be wind, rain, and snow proof. The grip consists of each tile locking on to its neighbour by one or two rounded grooves or beads.

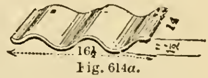

Fig. 614*a*.

1839. The following are the *weights* of the undermentioned sizes of tiles used for various purposes:—

Paving tiles at per 100.	cwts.	qrs.
$9 \times 9 \times 2\frac{1}{4}$ =	0 13	2
$9 \times 9 \times 1\frac{3}{4}$ =	0 9	2
$9 \times 9 \times 1\frac{1}{4}$ =	0 7	3
$9 \times 9 \times 1\frac{1}{2}$ =	9 lbs. each	
$12 \times 12 \times 1\frac{1}{2}$ =	16 ,,	
$12 \times 12 \times 2$ =	22 ,,	
$14 \times 14 \times 2\frac{3}{8}$ =	$35\frac{1}{2}$,,	
$16 \times 16 \times 2\frac{3}{8}$ =	44 ,,	
$18 \times 18 \times 2\frac{1}{2}$ =	$64\frac{1}{2}$,,	
$20 \times 20 \times 2\frac{5}{8}$ =	84 ,,	
$22 \times 22 \times 2\frac{7}{8}$ =	104 ,,	
$24 \times 24 \times 3$ =	133 ,,	
Ridge tiles 18 in., about	15 ,,	
10 to 14 cwts. per 100.		
,, rolled, 18 to 24 in.		
23 to 29 lbs. each.		
12 to 18 cwts. per 100.		

	lbs. each	cwts. per 1000
Malt kiln tiles		
$12 \times 12 \times 2$ = 16 lbs. each.		
Hothouse flue tiles		
$12 \times 12 \times$ = 13 ,,		
Plain tiles		
$11\frac{1}{4} \times 6\frac{1}{2} \times \frac{1}{2}$ =		
$10\frac{1}{2} \times 6\frac{1}{2} \times \frac{5}{8}$ =	2·51 =	$22\frac{1}{4}$
$11 \times 7 \times \frac{5}{8}$ =	2·90 =	$26\frac{1}{4}$
Pan tiles		
$13\frac{1}{2} \times 9\frac{1}{2} \times \frac{1}{2}$ =	5·25 =	47
Bridgewater double roll tiles		
$16\frac{1}{2} \times 14 \times \frac{1}{2}$ to $\frac{5}{8}$ =	8·80	
Paving tiles, squares		
$6 \times 6 \times 1$ =	2·16 =	$19\frac{1}{4}$
$9\frac{3}{4} \times 9\frac{3}{4} \times 1$ =	5·70 =	50
$11\frac{3}{4} \times 11\frac{3}{4} \times 1\frac{1}{2}$ =	12·42 =	111
Ditto, hexagons		
$6 \times 6 \times \frac{7}{8}$ =	1·63 =	$14\frac{1}{2}$
$6 \times 6 \times 1$ =	1·86 =	$16\frac{1}{2}$

1839*a*. *White glazed* tiles of Dutch and English manufacture are used for lining the walls of baths, larders, dairies, butchers' and other shops, kitchen ranges, areas for reflected light, and other such like purposes. For walls of entrance lobbies and similar places, glazed tiles are stamped with a pattern, giving a decorative appearance. *Mathematical* tiles are employed for covering the vertical surfaces on the outside of walls, in imitation of brickwork, and to prevent wet being absorbed.

1839*b*. *Ornamental Pavements*. The use of hardened clay for pavement is of the highest antiquity. Our own country furnishes numerous examples of the varieties employed by the Romans. The tiles are usually made of the clay found in the immediate neighbourhood in which they have been used; and ornamented, sometimes with colour, but more frequently with merely an impressed or raised design. During the Mediæval age, encaustic and other tiles were largely employed. Many varieties of plain and ornamental tiles are now made in the Potteries, as at Broseley; also at Poole, in Dorsetshire. The coarser kinds, for streets and doorways, have a red or a buff colour, and are prepared from the Staffordshire clay, which is found associated with coal. By mixing metallic oxides with the finer clays, blue and other colours are produced. The manufacture consists in bringing the clay into a state of fine powder, containing a certain amount of moisture; the mass is then placed in a mould of iron which it completely fills, when the ram of an hydraulic press, exactly fitting the mould, gives a pressure of from 150 to 200 tons, compressing the clay into a comparatively very small space; on being removed from the mould it is polished or smoothed off on the surface, and then it is ready for being baked in the kiln. The *encaustic* or variegated tile is composed, in the body, of ordinary red or buff clay; it is pressed in a mould under a common screw press, the mould not only producing the outer form of the tile, but also certain impressions on the face of the clay, about a quarter of an inch in depth. It is then taken out of the mould, and allowed to acquire a certain state of dryness. Devonshire or Cornish clay, coloured, is then poured over the whole surface, filling the impressions, in the state of a very thick *slip*; when this has been dried to a certain extent, the slip is scraped until the face of the common clay or body is seen, the impressed spaces only being filled with the coloured matter. A layer of clay is also applied to the back, and is sometimes pierced with holes to prevent the bending of the tiles in the process of baking.

1839*c*. The *Tesseræ* are manufactured by a similar process. In Lambeth, clay being properly prepared and stained of the desired colour, as black, red, blue, &c., is made into long narrow ribbons, by means of a squeezing machine. These ribbons are cut into squares, which are placed one on another, 15 or 20 high, previously oiled to prevent adhesion. These piles are then placed upon a frame sliding in two perpendicular grooves, with fine steel wires stretched tightly across, so that by pressing the frame downwards the wires subdivide the slices into the square, oblong, triangular, or other shaped tesseræ required; these are then dried and baked in the ordinary way. Messrs. Minton manufacture their tesseræ by pressure as for making tiles.

1839*d*. The mode of forming tesseræ into *mosaic paving slabs* is as follows:—The tesseræ are laid face downwards on a perfectly flat slate, in the pattern or design required. The size and shape of the slab is given by strips of wood or slate fastened round the tesseræ. Portland cement is poured on the backs of the tesseræ, and two layers of common red tiles are added in cement; thus forming a flat and strong slab, which is fitted for laying down as pavement. (Hunt, *Handbook*, 1851.) The better tiles, and the larger tesseræ for pavements, are laid separately on a carefully prepared foundation of fine concrete, and then set in fine sand. The durability of a tesselated pavement consists greatly in the solidity of the foundation given to it. With a floor subjected to vibrations such a work will go to pieces. The encaustic tiles with raised patterns should only be used as wall linings, as at Granada, and never for pavements, as is sometimes done.

1839*e*. Stoneware is a dense and highly vitrified material, impervious to the action of acids, and of peculiar strength. Until about 1836, when the duty was taken off, this material was chiefly used for common spirit bottles, oil jars, &c. The clay used is found near the coast in Devonshire and Dorsetshire. It is dug in square lumps of about 40 lbs. each, and transported in ships to London. After being perfectly dried it is ground to a powder, mixed with water, and, after being allowed to become of uniform consistency, the mass is passed through pug mills, and taken to the workmen. For making large articles, portions of the burnt material, finely ground, are mixed with the new clay; also some white sand found in the neighbourhood of Woolwich and Reigate.

1839*f*. Almost all round articles are formed by the potter, on wheels turning with the required rapidity. The potter's wheel was known in Egypt some 2,500 years B.C., and it remains practically the same. It was worked by hand; then by the feet, keeping a steadier constant motion; larger articles caused the disc to be attached to a large flywheel, worked by an assistant, who was directed by the potter; lastly came the addition of steam and the conical drum, enabling the potter to regulate the speed required. For articles of other shapes, the composition in a soft and plastic state is laid in plaster of Paris moulds; the porous plaster gradually absorbs the moisture from the clay, and when sufficiently firm it is removed. Some thousand articles are frequently made from one mould before it is destroyed. When thoroughly dry, the ware is placed in ovens or kilns, and exposed to a gradually increasing heat, so intense as to become, before finishing, quite white; salt is then thrown in, and, being decomposed, the fumes act chemically on the surface of the ware, and fuse the particles together, giving the glaze so well known. *Stoneware* differs from all other kinds of *glazed earthenware* in this important respect, that the *glazing* is the actual material itself fused together; in other kinds of ware it is a composition in which the article is dipped while in what the potters call the *biscuit*, or half-burnt, state. (Hunt, *Handbook*, 1851.)

TERRA-COTTA.

1839*g*. Terra-cotta, that is, burnt earth, embraces every kind of pottery, but the term has now come to be applied exclusively to that class of ware used in building, and is more or less ornamental and of a higher class than the ordinary, or even the better make of bricks, demanding more care in the choice and manipulation of the clay, and much harder firing, hence it is more durable. The best terra-cotta is a species of stoneware, which does not after years of use show signs of decay from contact with acids and alkalies.

1839*h*. Terra-cotta, like stone, may be good, bad, or indifferent in quality, but good terra-cotta will hold its own against good stone as a sound building material. Bad terra-cotta is that which is imperfectly burnt, and when it is "slack burnt," as it is termed, the material will go back to clay again. Flower-pots are common terra-cotta, and often throw off a scale of red earth each time the plant is watered. A well burnt stock brick is also terra-cotta; and where is the ordinary stone which is equally durable with it? Good terra-cotta is easily tested; when struck with steel it should emit sparks and merely show a black line, and ring like a bell. It should be free from fire cracks, have true lines, its surfaces be not chipped or rubbed after burning, and each piece should be properly chambered with cross-pieces.

1839*i*. The clays best suited for terra-cotta are found in the tertiary beds, or those occurring above the chalk, and corresponding with the lower Bagshot sands of the London district. Also those in the oolite and lias formations. It is procurable at Tamworth in Staffordshire; Watcombe in Dorsetshire; Poole in Dorsetshire; Everton in Surrey; Ruabon in North Wales; in Cornwall, and in Northamptonshire. The clay should be as free from iron and limestone as possible, and should be cleansed from all impurities. Natural terra-cotta clay contains 60 to 65 parts of silica to about 28 parts of alumina. The Roman material consisted usually of the following ingredients: Silica, 71·45; alumina, 2·25; protoxide of iron, 1·2; protoxide of manganese, 0·17; lime, 8·14; soda, 16·62; magnesia, a trace. Sand is an essential ingredient, and should be free from iron. The chief materials constituting the paste are clay, sand, flint, glass, and phosphate of lime.

1839*k*. All clays require careful preparation before use, and their after characteristics are often as much determined by this as by anything; the same clay being different under different treatment. 1st. Kneading, or pugging, which consists of well mixing the clay and reducing it to a perfect consistency throughout; this is now done by a pug-mill. Most clays are too fat, and require an alloy to make them more workable; their shrinking is too great, and they are liable to twist and warp in drying and burning, so that rough stuff or burned clay ground fine is added in proper quantities to prevent this, and it gives the potter more certain command over the clay. When mixed it is raised in a dry state into the mixers, water is added, and it is then passed through the pug-mills, when it is ready for use. Sometimes the clay is rendered more homogeneous by being struck continuously with an iron bar, to assimilate the parts and to expel any air, which on being expanded by the heat of the kiln would shatter the work. 2nd. A ball of this clay is supplied to the potter, who proceeds to form the article by hand; or it is pressed into a mould, which is of plaster, when repetitions are required. Care is necessary to have an equal thickness throughout, to prevent unequal shrinkage. This thickness is not much more than one inch. When required of a greater thickness, the blocks are formed hollow with cross webs to strengthen them. When necessary these cavities may be filled with concrete; this filling also prevents the accumulation of moisture, to which the blocks would be liable were they left open. 3rd. The article so formed in the rough is removed to be dried. Drying is evaporating the water, which must be done very gradually and evenly or there would be a liability to crack and twist. When nearly as hard as a piece of soap it is placed on a lathe and smoothed or polished with an iron tool. If any part is required to be attached to it the part is moulded, and the clay moistened at the point of junction, and the two luted with a very little soft clay. The work is now ready to be burnt. 4th. Burning is a process of the utmost importance, as on it depends the lasting qualities of the material. A chemical action goes on in the firing which changes the whole nature of the clay; it never admits of being worked up again, as in its original state. To accomplish burning successfully requires much experience, skill, and patience. It is now removed to a kiln or reverberatory furnace, and carefully packed in fire-clay troughs called *seggars*, or placed one over the other. When the kiln is full the doorway is bricked up, and the fires are lighted in the furnace holes around the kiln. Large articles have to be fired very slowly for four or five days, then for about forty-eight hours fired sharply until a heat is attained sufficient to bake the ware, and to flux the ingredients of which the body is formed into a vitreous mass without melting the whole. The intensity usually necessary is stated to be that at which soft iron would melt. The articles have to be protected from the coal flame by the seggars, or by being coated with paper and clay, or by a muffle throughout the kiln, as the flame is apt to crack many clays openly exposed to it, and the vapour of coal is sure to discolour the ware, generally turning it a foxy red. A kiln of large goods takes about a week to cool.

1839*l*. Of late years terra-cotta has been used extensively for the facings and dressings of a building in the place of stone. It is generally made of hollow blocks, formed with webs inside so as to give strength to the sides and keep the work true while drying, whereas when required to bond with brickwork it must be at least 4½ inches thick.

1839*m*. The following result of experiments made by Mr. Blashfield for Mr. Charles Barry, were given in a paper by him on *Dulwich College*, read at the Royal Institute of British Architects, session June, 1868.

A block of Portland stone about 6 inches cube, bore a crushing weight equal to per foot super.	292 tons
A block of Bath stone, equal to per foot super.	104 ,,
A stock brick ,, ,,	82 ,,
A solid block of Terra-cotta, equal to per foot super.	523 ,,
A hollow block, slightly made and unfilled	80 ,,
The same, but filled with concrete	163 ,,
A hollow block, unfilled, but made with thicker walls	186 ,,

1839*n*. The *shrinkage* of terra-cotta clay in burning is very uncertain; it is one-eighth to one-twelfth. To obviate the risk of *warping*, large pieces should only be used where absolutely necessary. Blocks may average from 1 to 3 feet cube; never more than 4 feet; the block is usually from 12 ins. to 16 ins. long, by 6 ins. to 15 ins. high; $4\frac{1}{2}$ ins. to 9 ins. on the bed; if hollow, from 1 to 2 ins. thick. Larger blocks should have a division or web of terra-cotta across them. Joints should be joggled, stopped ends made solid, beds even, and samples should show extreme limit of colour and evenness. In the old Continental and English examples, brick dimensions are as much as possible adhered to. Large blocks require corresponding extension of time to be allowed in their manufacture.

1839*o*. As regards *economy* it compares favourably with good stone, while it is much more durable, stronger, and cheaper; for the use of the mould allows, where there is great repetition of parts, of most elaborate work, produced at a cost less than that of stone; as much as one-third is saved. The cost of the raw material of terra-cotta is only half the cost of Portland cement, and not one-fourth the cost of good stone. Mouldings having a girth of two feet can be bought at two shillings and sixpence per lineal foot; tracery for parapets, 4 inches thick, at three shillings per foot superficial.

1839*p*. Its *lightness* is a source of economy in comparison with stone, by which a saving is effected in carriage and lifting; the filling of the blocks can be done on the site with the broken bricks lying about. In a district where stone abounds, the saving in cost would not be so advantageous. In London it would be on an average, say 20 per cent. less than Bath stone, and 40 per cent. less than Portland stone. The subject will be further treated in the next book.

Sect. XI.

LIME, SAND, WATER, MORTAR, CONCRETE, AND CEMENT.

1840. Lime has not been found in a native state; it is always united to an acid, as to the carbonic in chalk. By subjecting chalk or limestone to a red heat it is freed from the acid, and the lime is left in a state of purity, and is then called caustic or quicklime, which dissolves in 680 times its weight of water. It is not our intention here to enter into any account of either of the theories relative to the formation of lime, facts being of more importance to the architect in its employment than the refined fancies of the scientific chemist. The calcareous minerals are mostly distinguished by their effervescing with, and dissolving in, an acid, as also by their being easily scratched or cut with a knife. In respect of the lime obtained from chalk, Dr. Higgins (in his work on *calcareous cements*, Lond. 1780) says, "It should be observed, that the difference between chalk lime and the lime obtained from the various limestones, chiefly consists in the greater retention or expulsion of the carbonic acid gas contained in them."

1841. An account of the stone from which lime may be obtained in the different counties of England would unnecessarily extend this article; we shall, therefore, after observing that the use of marble for burning to lime would be too expensive, state the varieties of limestone as, 1, the compact; 2, the foliated; 3, the fibrous; and 4, the peastone. The compact limestones are of various colours, in hues inclining to grey, yellow, blue, red, and green, and to a smoky sort of colour besides. It is usually found massive, often compounded with extraneous fossils, particularly shells. Its internal appearance is dull, the texture is compact, the fracture small, fine, and splintery; fragments indeterminately angular, more or less sharp-edged; semi-hard, sometimes soft, brittle, and easily frangible. Specific gravity varies from 2·500 to 2·700, and it is composed of lime, carbonic acid, and water, mostly with a portion of argyl and oxide of iron, and sometimes of inflammable matter.

1842. The foliated limestones are such as calcareous spar, statuary marble, &c.; the fibrous limestones, such as satin spar; and the peastone, another species of spar. It may be remarked, that the various sorts of marble, chalk, and limestone may be divided into those which are nearly pure carbonate of lime, and those containing in addition from one-twentieth to one-twelfth of clay and oxide of iron. "Though the best limestones are not such as contain the greatest quantity of clay, yet," observes Mr. Smeaton, "none have proved good for water building, but what, on examination of the stone, contained clay; and though," he continues, "I am very far from laying down this as an absolute criterion, yet I have never found any limestone containing clay in any considerable quantity, but what was good for water works, the proportion of clayey matter, being burnt, acting strongly as a cement; and limes of this kind all agree in one more property, that of being of a dead frosted surface on breaking, without much appearance of shining particles."

1843. Among the strongest limes, such as will set under water, those most in use in the metropolis are called *grey stone limes*, and are procured from Dorking, Merstham, and the vicinity of Guildford in Surrey. The Dorking and other limes of that part are burnt from a chalk formation so extremely hard that it is quarried even for the purposes of masonry. Those of Merstham particularly are obtained from an indurated chalk marl (clay and chalk) which is so hard that it partakes of the nature of stone.

1843*a*. The known property of the *blue lias* formation for setting under water renders it an invaluable material in the hands of the architect. In the neighbourhood of Bath it is called Bath brown lime, and when prepared for cementing with metallic cement, is said to be *wind slaked*; that is, after burning, it is placed in roofed sheds open at the sides, and the atmosphere is thus introduced to act upon it. The colour of the *lias*, previous to burning, is blue; after it has passed the kiln, it is of a rich brown colour.

1843*b*. It is extremely difficult to give any quantitative analysis of the *blue lias*. Every layer in a quarry will be found to differ more or less decidedly from those above or below it. The beds extracted for burning into lime may be said to consist principally of carbonate of lime (perhaps as much as 90 per cent.) in combination with silicate of alumina, some oxide of iron, potash, and a small quantity of sand, in mechanical mixture; but the ingredients insoluble in nitrous acid, such as silicate of alumina and sand, vary in every imaginable proportion between 5 and 18, or at times 20, per cent. The best blue lias lime is obtained from the beds of calcareous marl which contain about 16 per cent. of silicate of alumina; such as is brought from Aberthaw in South Wales, Watchet in Somersetshire, and Barrow, in Leicestershire: the limes from Whitby, in Yorkshire, and from Lyme Regis, in Dorsetshire, are nearly equal to them. The principal objection to this lime as used in London is founded upon the large proportion of underburnt or unburnt stone or *core* left in it. The weight of an imperial bushel of Aberthaw lime of a superior quality is 85 lbs.

1843*c*. The magnesian limestone of Sunderland lies north-west of the red sandstone. In the vicinity of South Shields, in the county of Durham, the formation becomes extensive, and is to be traced to the Tees below Winston Bridge. The Whitby quarry near Callercoats has been described in the 4th volume of the *Geological Transactions*. The Sunderland limestone is of a bronze colour, and from containing inflammable matter, does not require so much fuel to convert it into lime. The naturally hydraulic limestone of Arden, found near Glasgow, in Scotland, has been largely used in the local dock works, in the proportion, for concrete, of one part of ground lime, one part of iron mine dust, one part of sand, and four and a half parts of gravel and quarry chips. Pure hydraulic lime, as it is called, manufactured (in Flintshire) from the best Halkin Mountain limestone, is much used in the dock works at Liverpool and Birkenhead.

1843*d*. *Hydraulic limes* have been thus classed:—If they harden under water in periods varying from fifteen to twenty days after immersion, they are slightly hydraulic; if from six to eight days, simply hydraulic; if from one to four days, eminently hydraulic. Hydraulic works frequently burst from the *slaking* of the lime which has not been properly prepared for its office. It should be all hydrated before placing, and this requires more time than the slaking of ordinary lime; the heat developed is much less than in any other lime.

1844. Before limestone is burnt it seems to possess no external character by which a distinction can be made between the simple and the argillo-ferruginous limestones; whatever the colour of the former, they become white when burnt, whilst the latter partake more or less of a slight ochrey tint. Brown lime is the most esteemed for all sorts of cements, whilst for common purposes the white sorts, which are more abundant, are sufficiently useful. In England, the limestones in colour generally incline to a red or blue, and those which are found firm, weighty, and uniform in texture are to be preferred. Masses broken from large rocks and beds on the sides of hills, and those when newest taken and deepest dug, are most to be valued.

1845. The process of analysing limestones is so eminently useful to all concerned in building, that we cannot refrain from transcribing the method used by Smeaton in his own words. "I took about the quantity of five pennyweights (or a guinea's weight) of the limestone to be tried, bruised to a coarse powder, upon which I poured common aquafortis, but not so much at a time as to occasion the effervescence to overtop the glass vessel in which the limestone was put, and added fresh aquafortis after the effervescence of the former quantity had ceased, till no further ebullition appeared by any addition of the acid. This done, and the whole being left to settle, the liquor will generally acquire a tinge of some transparent colour; and if from the solution little or no sediment drops, it may be accounted a pure limestone (which is generally the case with white chalk and several others), as containing no uncalcareous matter in its composition. When this is well settled, pour off the water, and repeatedly add water in the same way, stirring it, and letting it settle till it becomes tasteless. After this, let the mud be well stirred into the water, and without giving it time to settle, pour off the muddy water into another vessel, and if there be any sand or gritty matter left behind (as will frequently be the case), this collected by itself will ascertain the quantity and species of sabulous matter that entered into the texture of the limestone. Letting, now, the muddy liquor settle, and pouring off the water till no more can be got without an admixture of mud, leave the rest to dry, which, when of the consistence of clay, or paste, is to be made into a ball, and dried for further examination."

1846. There are many sorts of kilns for burning limestone, varying in form with the fuel employed, and the combination of the process itself with some other, such, for instance, as making coke, and sometimes bricks. The limestone, however, is generally burnt in kilns whose plans are circular and section resembling an inverted truncated cone; of late more frequently made spheroidal. The heat is in either case obtained from a fireplace under the limestone, which rests on bars, that can, when the kiln is a perpetual one, egg-formed, or a draw kiln, be removed to let out the lime as it is burnt, whose deficiency, on extraction, is supplied by fresh stone at the top of the kiln. *Sod kilns* are sometimes used for lime burning. These are formed by excavating the earth in a conical form, and then building up the sides as the earth may require. In using these the limestone is laid in with alternate layers of fuel to the top of the kiln, and the top being covered with sods, so as to prevent the heat from escaping, the fire is lighted and the process effected. The lime is not removed till it is thoroughly cool. This mode is a tedious operation, and, because of the quantity of fuel consumed, far from economical. In the common lime-kiln, the fire is never suffered to go down, but as the well-burnt lime is removed, fresh lime is supplied. There is a species of kiln called a flame-kiln, in which the calcination is effected with peat. In this kiln the process of burning bricks is carried on at the same time. The loss of limestone by burning is about four-ninths of its weight, shrinking, however, but little. When completely burnt, it falls freely, in slaking, into powder, and then occupies about double its previous bulk.

1847. Lime burners have made the important observation, that the quantity of stone calcined and the quantity of fuel expended depend on the quality of the fuel. Hence the kiln is constructed with reference to the fuel, rather than to the nature of the stone to be calcined. Limestone, taking an average time, requires burning about sixty hours to reduce it to lime, when the heat is strong and well regulated: but of course no general rule can be laid down, as different species will require different periods of time. The principal object to be accomplished is the expulsion of the carbonic acid gas which enters into its composition.

1848. The lime generally most esteemed is that which heats most in slaking, and slakes the quickest, falling into a fine powder. If there be among it coarse unslakable lumps called *core*, that will not pass through the screen, either the stone has not been sufficiently burnt, or it originally contained extraneous matter; this not only indicates defect in quality, but that it will be, as they more or less abound, more costly in use. Lime in slaking absorbs a mean of 2·5 times its volume; and 2·25 its weight of water. The hydraulic limes absorb less water than the pure limes, and only increase in bulk from 1·75 to 2·5 times their original volume. Slaked lime is a hydrate of lime.

1849. From the experiments of Mr. Smeaton and of Dr. Higgins, it is sufficiently proved that, when chalk or stone lime is equally fresh when used, the cementitious properties of both are nearly, if not quite, equal; but from the circumstance of quicklime absorbing carbonic acid more or less in proportion as its texture is solid or spongy, so it gradually parts with its cementing nature, becoming at length altogether unfit for the purposes of mortar. Thus, though each of the sorts may be equally good, if properly burnt and quite fresh from the kiln, yet from the chalk lime so much more easily and rapidly taking in the carbonic acid than stone lime does, it is not so fit for general use; and, indeed, now the metropolis is so well supplied with the harder chalk and stone limes, there is no excuse for its use, and it should in sound building be altogether banished.

1850. The following table, from Smeaton, contains a list of the limestones he examined on the occasion of building the Eddystone Lighthouse:—

Species of Stone.	Proportion of Clay.	Colour of the Clay.	Reduction of Weight by burning.	Colour of Brick made of such Clay.
Aberthaw, on the coast of Glamorganshire	$\frac{3}{23}$	Lead colour	4 to 3	Grey stock brick.
Watchet, small sea-port in Somersetshire	$\frac{3}{23}$	Do.	4 to 3	Light colour, reddish hue.
Barrow, Leicestershire	$\frac{3}{11}$	Do.	3 to 2	Grey stock brick.
Long Bennington, a village in Lincolnshire	$\frac{3}{22}$	Do.	- -	Dirty blue.
Sussex Church, near Lewes in Sussex	$\frac{3}{16}$	Ash colour	3 to 2	Ash colour.
Dorking, Surrey	$\frac{1}{17}$	Do.		
Berryton grey lime, near Petersfield, Hants	$\frac{1}{12}$	Do.		
Guilford, Surrey	$\frac{2}{19}$	Do.		
Sutton, Lancashire	$\frac{3}{18}$	Brown		

1851. SAND should by all means, if possible, be procured from a running clear stream, in preference to that obtained from pits. It is cleaner and not so connected with clayey or muddy particles. About the metropolis it is the practice to use (and an admirable material it is) the sand of the Thames procured from above London Bridge. This sand has acquired a deserved reputation among the architects and builders of the capital. It contains, however, a vast portion of heterogeneous matter, such as calcareous fossil, quartzose, and flint sands, particles of coal alluvium, and much iron. The sharp drift sand of the Thames, therefore, before mixing with the lime, should be well screened and washed.

1852. If *pit sand* only can be procured, it should be repeatedly *washed* to free it from the earthy and clayey particles it contains, until it becomes bright in colour, and feels gritty under the fingers. Smeaton has stated that clay, even in very small quantities, materially interferes with the hardening of mortar, and disposes it to perish in a few years. When the architect is obliged to use *sea sand*, it must be well washed in fresh water until the salt is entirely removed; otherwise the cement for which it is used will never dry. So small a quantity as 3 per cent. of salt causes great inconveniences. Whenever the weather is dry, the walls show an efflorescence on the inside or outside. This, when there is damp in the atmosphere, will collect moisture, causing the wall to look wet, and will throw off any paper placed on it. In one case, where a builder indiscriminately employed sea sand for outside and inside purposes, the saline property soon introduced the rot to all adjoining timber. There is still (1887) much diversity of opinion as to the advisability of using sea sand. The washing is of primary importance; it is to be best effected by using an iron pipe of about three-quarters of an inch diameter and two feet long, joined on to an india-rubber pipe attached to the water main. This pipe is to stand in the centre of the tub; fill the tub with the sand, then turn on the water, which passing to the bottom of the tub, rises through the sand causing any salt to rise with it; if allowed to run, the tub overflows, and the salt is soon all carried off. The sand should be washed as soon as it is taken from the beach. (E. C. Morgan.)

1852*a*. It will be well to notice here that Professor Wilson, of the Edinburgh Laboratory, made in 1848 a report on the use of *sea sand* in mortar in a house, No. 10 Randolph Crescent, which was said to be damp from the use of it. On analysis he found that the mortar contained only 1-10,000th part of its weight of the chloride of magnesium, a highly deliquescent attracting substance. But he considered that the setting of the mortar mechanically enveloped and locked up within its mass the substance in question; and further, that it might chemically combine with the lime of the mortar to form a compound not readily to be dissolved in water. It was also thought that in consequence of a chemical action taking place between the lime in the mortar and the chlorine derived from the sea water contained in the sand, chloride of calcium (muriate of lime) would be produced, and this being a deliquescent substance, would attract moisture and render the walls damp. The amount, however, of chlorine in specimens of sea sands, was found to vary from a 2,174th to a 549th part of their weights; the mean amount was a 1,204th part. The quantity in the mortar was so minute that it could not sensibly produce the effects of damp. The mechanical envelopment of the chloride of calcium in the mortar would also shut up this deliquescent substance from moisture, and conduce to dryness. A further substance in sea sand, is chloride of sodium (common salt), and if the chlorine of this be transferred to the lime to form chloride of calcium, the sodium will become converted into carbonate of soda. These substances may co exist in the mortar, but as soon as they are separated from it, and diffused through the stone, or brought to its surface, the carbonate of soda will convert the chloride of calcium into carbonate of lime (chalk) and become itself chloride of sodium (common salt). A consideration of these facts led the analyst to affirm that the apprehension that chloride of calcium, as derived from sea sand, would render the house damp, was altogether chimerical. On an analysis of some of the pit sands in the neighbourhood, he found that one of them contained almost the same quantity of chlorine as in the sea sand, although no charge was made against it. It does not admit of doubt, he reported, that, other things being equal, sea-sand mortar will dry more quickly and keep more thoroughly dry than will pit-sand mortar; this sand, it must be noticed, contained about 13 per cent. of earthy matter, and was therefore not so *pure* as the sea sand.

1852*b*. Although all the professional publications of late years have described the bad effects likely to result from the use of unwashed *pit sand*, builders in the outskirts of the metropolis have taken to use road sweepings in lieu of sand, and this even without having washed it to free it from those impurities not only detrimental to its making good mortar, but also to the building itself, as it may be the cause of introducing the dry rot. Lately we have noticed a case in the professional journals where the lime, such as it was, was "mixed with a large proportion of garden mould and mud, the bricks being of an inferior quality and insufficient strength." We have already noticed the use of road dirt (*par.* 1839*i*.) In another case "the composition with which the portions of bricks were held together consisted of soap lees with a few small limestones and dirt." The interests of the poorer classes should be better protected.

1852c. *Metallic sand* for cement was introduced about 1843. It was sold in coarse or fine powder as required, to be mixed up with blue lias lime for joining bricks and stone, for concretes, for face work, or for moulded work. 1 measure of the sand, 1 of lime, and 6 of gravel were the proportions used in the foundations of the new Houses of Parliament, and at the great tunnels of the Birmingham railway. It has also been used for malt-house steeping troughs, and floors; for the latter purpose it can be polished. For exterior facings, as stucco, it was used at 57 Coleman Street; and at the Alfred Insurance Office, Lothbury: the latter building has lately (1866) been pulled down. The marine turret at Herne Bay was also coated with it.

1853. Water. Dr. Higgins recommends the use of lime-water for the composition of mortar. This, in practice, would be impossible. The water used, however, for the incorporation of the lime with the sand should be soft and pure. Mortar and concrete have both been recommended to be made up with *hot* water; with the latter especially, when it is desirable that it should set immediately: concrete thus made has been found exceedingly hard. Its employment with mortar dates from before 1520. It is probable that water charged with iron, as at Tunbridge Wells; a solution of chalk, as in Hertfordshire; sulphuretted hydrogen, as at Harrowgate; and salts, as at Epsom and elsewhere; may all affect lime when combined with it. Smeaton stated that he could not discover any difference in the strength of mortar, whether it were made with sea, or with fresh, water.

1854. In forming Mortar from lime, it must, when slaked, be passed through a sieve leaving only a fine powder, an operation usually performed with a quarter inch wire screen set at a considerable inclination to the horizon, against which the lime is thrown with a shovel after slaking. That which passes through is fit for use; the core falling on that side of the screen against which the lime is thrown, being entirely rejected for the purpose in question, though it is an excellent material for filling in the sides of foundations under wood floors where they would otherwise be next the earth, and the like. The sifted or screened lime is next to be added to the sand, whose quantity will vary as the quality of the lime, of which we shall presently speak. In making mortar, there is no point so important, as respects the manufacture itself, as the well tempering and beating up the lime with the sand after the water is added to them. In proportion, too, as this is effectually done, will a small proportion of lime suffice to make a good mortar. The best mode of tempering mortar is by means of a pug-mill with a horse-track similar to the clay mills used for making bricks. But if such cannot be had, the mortar should be turned over repeatedly, and beaten with wooden beaters, until it be thoroughly mixed. That this process should be carefully performed, will appear of the more importance when it is considered that it thereby admits a greater proportion of sand, which is not only a cheaper material, but the presence of it renders a less quantity of water necessary, and the mortar will consequently set sooner: the work, too, will settle less; for as lime will shrink in drying, while the sand mixed with it continues to occupy the same bulk, it follows that the thickness of the mortar beds will be less variable.

1855. Vitruvius recommends that mortar should be beaten with wooden staves by a number of men before being used. Smeaton reckoned it a fair day's work for a labourer to mix and beat up two or three hods of mortar for use. The pug-mill does this now in two or three minutes. Pliny expressly states that "in ancient specifications for buildings it was provided that no slaked lime less than three years old should be used by the contractor." Covent Garden Theatre was built in 1808–9 with lime while still hot from the kiln: when the walls were demolished a few years since, the mortar was found to be hard and solid. It was so used at Tothill Fields prison. At the new Royal Exchange, the lime was to be thoroughly and freshly burnt, to be kept in an enclosed shed, and no more mortar to be made than was sufficient for each day's consumption.

1856. In most of the public works executed in Great Britain of late years, the proportion of lime to sand is as 1 to 3; and when the former is made from good limestone, the sand is by no means too much in proportion. Dr. Higgins, in his experiments, has gone so far as to recommend 7 parts of sand to 1 of lime, which, for mortar, is perhaps carrying the point to the extreme. It may be taken as an axiom, that no more lime is necessary than will surround the particles of sand. C. H. Smith has stated, (*Builder*, 1865, p. 41), that if each particle of sand be covered with lime about the thickness of an ordinary coat of paint, he should be disposed to consider such an amount as very near the perfection of quantity. A superabundance of lime or sand, no matter how good it may be, is, under any circumstances, objectionable.

1857. Various opinions have long been entertained by chemists and others respecting the effect of sand and lime upon each other in the formation of mortar. The general impression is, that the slaked lime and sand in contact have a chemical affinity for each other; that the lime decomposes the surface of the sand, and the atoms or molecules interpenetrate each other, forming a sort of silicate of lime. This is an extremely ingenious theory, says C. H. Smith, but it has never been proved. It has been stated, he also adds, that the hardening of mortar arises from the presence of carbon and oxygen formed into carbonic acid, which is absorbed by the lime; but the source from whence the carbon is obtained is at present a mystery. Oxygen is abundant in the composition of water and atmosphere, and that quicklime has an astonishing affinity for it, is evinced by the practice of dusting steel goods with it when not in use, to prevent their rusting; or that of placing a small lump of it in any box or case containing such goods. Bricklayers smear their trowels with the mortar before leaving off work; and in the *Parentalia*, it is noticed that "in taking out cramps from stonework at least 400 years old, which were so bedded in mortar that all air was perfectly excluded, the iron appeared as fresh as from the forge."

1858. Various additions are made to mortar, in order to increase its hardness and tenacity; such as coal and wood ashes, forge scales, roasted iron ore, puzzuolana, and the like. The property of hardening under water or when excluded from the air, conferred upon a paste of lime, is effected by the presence of certain foreign substances, as silicon, alumina, iron, &c., when their aggregate presence amounts to one tenth of the whole. Artificial hydraulic limes do not attain, even under favourable circumstances, the same degree of hardness and power of resistance to compression as the natural limes of the same class.

1858*a*. As Burnell, in *Limes, Cements, &c.*, 1857, p. 71, says—"It is often a matter of importance to know the power of resistance of mortars; but as they differ within a very large range, it is not easy to state it very precisely. The best experiments, however, show that we may safely calculate upon a resistance of 14 lbs. per inch superficial for its cohesive force; of 42 lbs. to a crushing force; and of $5\frac{1}{4}$ lbs. to a force tending to make the particles slide upon one another. It would not be safe to expose new works to greater efforts than those which could be included within the above limits." In the construction of a wall, whether of brick or rough stone, it should be clearly understood that there is an important distinction between mere drying and the ultimate process of induration. The mortar may become sufficiently set, dry, and solid, in a few days or weeks, to enable the wall to bear a very considerable weight and pressure; but it does not acquire the maximum degree of hardness till after the lapse of many years and even of centuries. All cements and limes tend to reassume a state of carbonization similar to that in which they existed in the stones from whence they were extracted; they only do so to a very imperfect degree. The saying that lime at a hundred years is but a child, is perfectly true. Cements on the contrary harden very rapidly, but we have no instances of their acquiring the strength of the original stone.

1859. The *cendre de Tournay* is used in the Low Countries. This is an article procured from the lime-kilns bordering the Scheldt. The lime of this district contains a considerable portion of clay mixed with iron; and the pit-coal with which it is burnt contains a large quantity of an argillaceous schist, impregnated with iron. After the lime is taken out of the kilns, there remains the *cendre*, about one fourth of which consists of burnt lime-dust, and three fourths of coal-ashes. This material is sprinkled with water to slake the lime, and well mixed together, and put into a proper vessel and covered over with wet earth. In this state it is kept for a considerable time; and when taken out, and strongly beaten up for half an hour with an iron pestle in a wooden mortar or trough, it is reduced to a soft pasty consistence; it is then spread out for several days in a shady place, and the operation of beating repeated: the oftener this is done the better, except it should become unmanageable from being too much dried. In a few minutes, this cement, when applied to brick or stone, adheres so firmly that water may be immediately poured over it; and if kept dry twenty-four hours, it afterwards receives no injury even from the most violent action of a flowing stream.

1859*a*. In London, a mortar made of lime with sea-coal ashes from a smith's forge mixed with the iron scales, and called *blue* mortar, is used for covering parts of buildings much exposed to the weather; and if prepared with similar labour and attention, it might, in a great degree, possess the valuable properties of the mortar of the Scheldt, just mentioned.

1859*b*. Common *ashes* mortar is made by mixing two bushels of newly slaked lime and three bushels of wood ashes, which, when cold, must be well beaten, in which state it is usually kept for a considerable time, and indeed it improves by keeping if beaten two or three times previous to using it. This mixture is superior to terras mortar in resisting the alternate effects of dryness and moisture, but not comparable with it under water.

1859*c*. *Brick* and *tile* and *burnt clay ballast*, each well burnt and ground to a powder, combined with rich lime, possesses hydraulic energy. *Pulverised silica* burned with rich lime produces hydraulic lime of excellent quality. In some experiments made by MM. Chatonoy and Rivot, this lime hardened under water in from three to four days, and acquired in twenty-two months a hardness superior to Portland cement. The weight of the powdered lime never exceeded four times, and was never less than one half that of the powdered silica. Brick-dust mortar used to be considered in some cases better than mortar made of terras, for unless the terras was always wet it was not thought better than common mortar made of lime and sand; 2 bushels of hot lime, i.e., fresh slaked lime, added to 1 bushel of brick-dust made from red stock bricks, was to be well beaten and worked up before using, with but little water: the longer it was beaten the better it became. The dry brick rubbish of old walling broken down and *sifted*, was considered better than sand, as less sand is required, and it might be safely used in frosty weather. A tract on Old Charing Cross, mentions that it was "so cemented with mortar made of purest lime, callis sand, white of eggs, and the strongest wort, that it defied all hammers and hatchets whatsoever." The mortar used in bishop Gundulph's works at Malling and Rochester is described by B. Ferrey as consisting of a sort of tufa found only in the cliffs at Dover, which appears to have been exclusively used in his works.

1859*d*. *Slag* is applied to the vitrified earths left in furnaces, either for glass or iron. *Scoriæ* are the lighter, more porous, and less vitrified earths arising from the puddling and refining of iron. The *cinders* used are the earthy residues derived from the combustion of coal. When ground into powder, the two former, which contain a large proportion of the mineral oxides, make very good mortars if mixed with middling or perfectly hydraulic limes. Cinders appear to render the rich limes moderately hydraulic when properly mixed. They require a large quantity of water to render perfect the crystallization of the hydrate of lime. All these mortars may be usefully employed for works out of water.

1859*e*. The stones whereof the *Dutch terras* is made are found in the neighbourhood of Liege, and also, we believe, at Andernach on the Rhine, from the size of a pea to that of a middle-sized turnip. From their being brought down the rivers to Holland the cement has been called Dutch; the only operation they undergo in that country is the reduction of them to a coarse powder by means of mills. They are beaten by iron-headed stampers on an iron bed till they will pass through a sieve whose wires are about one eighth of an inch apart. This cement is sent from Holland in casks. *Trass*, *terras*, or *tarras*, is a blue-black trap. It is obtained from pits of extinct volcanoes, and has nearly all the distinguishing elements of puzzuolana, resembling it in composition, and in the requirements of its manipulation, having to be pulverised and added to rich lime to develope its hydraulic properties.

1859*f*. The *Puzzuolana*, or *terra Puteolana* of the Italians, which, as well as the last-named cement, has been almost if not quite superseded by the introduction of the Roman cement, is brought from Civita Vecchia. Its name is however derived from Puzzuoli, where it is principally found, though produced in other parts of Italy, in the neighbourhood of extinct volcanoes. It suddenly hardens when mixed with one third of its weight of lime and water, forming a cement more durable under water than any other. Bergman found 100 parts of it to contain 55 to 60 parts of siliceous earth, 20 of argillaceous, 5 or 6 of calcareous, and from 15 to 20 of iron; this last constituent is considered to be the cause of its property of hardening under water. The iron decomposes the water of the mortar, and thus in a very short time a new compound is formed. According to Vitruvius, when used for buildings in the water, 2 parts of puzzuolana were mixed with 1 of mortar. Artificial puzzuolana may be made by slightly calcining clay, and driving off the water of combination at a temperature of 1,200°.

1859*g*. Subsequently to the use of this material from Puzzuoli, a similar material has been found near Edinburgh; and in the Vivarais, a site of extinct volcanic action in the centre of France. Its aspect and colour, however, vary very much even in the same locality. Berthier gives the following analysis of two of these materials:—

	Puzzuolana from Civita Vecchia.	Terras from Andernach.
Silica	·445	·570
Alumina	·150	·120
Lime	·088	·026
Magnesia	·047	·010
Oxide of Iron (in a slight state of magnetism)	·120	·050
Potash	·014	·070
Soda	·040	·010
Water	·092	·096
	0·996	0·952

1859*h*. In the use of *blue lias* lime for mortar, workmen ignorant of its qualities invariably spoil it. In important works the lime should be supplied in an unground state, to prevent the *core* being mingled with the good lime. In slaking, the lumps should be broken into pieces of about the size of a nutmeg; then immersed upon a sieve in water, and kept therein until air bubbles freely rise to the surface: the lime so wetted is to be left in a heap, and covered with damp sand, for twenty-four hours. At the expiration of that time it should be screened and mixed with sand and the least possible quantity of water. When slaked, it does not sensibly increase in bulk, unlike the ordinary chalk or stone lime of the neighbourhood of London. The best descriptions of blue lias lime will not bear more than 1½ parts of sand to 1 of lime. Wood, of Bath, in his work on *Cottages*, 1788, has stated that "blue lias lime mixed with coal ashes in the manner prescribed by M. Loriot, will make the hardest cement I ever saw, as I have found by various experiments; it will hold water, resist frost, harden in a few hours in water, and will bear a very good polish. Coach or carriage ways are laid or pitched with blue lias, which wears very well, though it will not bear the frost."

1859*i*. A very useful *hydraulic mortar* for executing sea-walling, consists of 1 part of chalk lime, or of Halkin lime, with one part of puzzuolana from Civita Vecchia, and 1½ parts of sand; but the value of this mixture depends upon the influence exercised by the puzzuolana on the setting of the lime. A mixture of the natural calcareous cements, or of Portland cement with sand, is another good mortar. The presence of sulphate of lime in any composition intended to resist the action of sea water would be fatal, as it crystallises at a different rate of rapidity, and it is more easily soluble than the carbonate of lime. French authorities lay particular stress on the following qualities for the formation of good hydraulic mortar: I. It is essential that the materials should be perfectly pulverised before mixing, so that the combination may be as perfect as possible. II. Sufficient free lime must be present to allow the carbonic acid in the water to combine with it, and form a protective coating of carbonate. III. Long soaking of the materials is advisable, in order that the chemical combinations necessary for the ultimate stability of the mortar may take place before it is actually used.

1859*k*. Mr. Smeaton discovered, by a course of experiments, that the scales (grey oxide of iron) that fly off under the forge hammer from red hot iron, pulverised, sifted, and mixed with lime, form an admirable cement, equal to puzzuolana. He found, in pursuing his experiments, that roasted iron ore produced an effective water cement, by using a greater proportion of it than either terras or puzzuolana. Equal quantities of iron scales and argillaceous lime, with half the quantity of each of these of sand, produced a cement in every respect equal to terras mortar. If pure carbonate of lime be used, equal parts of each of the ingredients ought to be incorporated. We do not think it necessary here to give any account either of Loriot's cement, or that proposed by Semple: neither are to be depended on: indeed the first, as a water cement, is of inferior utility, and very little better than common mortar dried before the admission of water upon it.

1860. *Grout*, or *liquid mortar*, is nothing more than common mortar mixed with a sufficient quantity of water to make it fluid enough to penetrate the interstices and irregularities of the interior of brick walls, which common mortar will not reach. The mortar whereof it is made will bear 4 of sand to 1 of lime, but it should be thoroughly beaten. It may be kept a little longer, whereby its quick setting will be facilitated.

1861. Concrete is a compound of ballast, or stone chippings, and lime mixed together. It is so called from the speedy concretion that takes place between these particles. If, however, *gullets* or small stone chippings are used, sand in a large proportion to the lime must be used. The use of concrete was well known at an early period; it is mentioned by De Lorme in his work published in 1568; and it is by no means, therefore, a discovery of modern days. Wherever the soil is soft, and unequal for the reception of the foundations of a building, the introduction of concrete under them is an almost infallible remedy against settlement. The Thames ballast, commonly used for concrete, is a mixture of sand and small stones. With this, and lime in the proportion of never less than 4 to 1, and never properly exceeding 9 to 1, of stone lime, or such as is known to set hard in water, a mixture is made. The lime is generally used in powder, and the whole being shovelled together, it is wheeled in barrows to a stage over the spot where it is to be used, and let fall into the trench dug out for the reception of the foundation. The greater the height the concrete is made to fall, the sounder and stronger it becomes. It must always be recollected that no more lime is necessary than with the thinnest coat to surround the particles of the ballast, and that therefore the size of the pebbles or stones should influence the quantity of the lime. As the ground is more or less to be trusted, the thickness of the concrete must be regulated; when used on the best ground, a foot in thickness will be sufficient; while on the worst, as many as four feet or more may be required. The upper surface being levelled, it is usual to lay on it a tier of Yorkshire stone landings, for the reception of the brick-work or mason's work: in some cases, after carrying the wall a certain height, a second tier of landings has been introduced. When the soil is watery, no water should be put to the concrete, but the ballast and lime merely mixed and tumbled in. The usual practice of making concrete as above stated, is objected to by many practitioners, who recommend that the French method of making *béton* should be followed in lieu of it.

1862. In forming concrete, the stones or pebbles used should never exceed the size of a hen's egg, of which 2 parts may be combined with 1 part of the smaller substances used; this makes it about equal to Thames ballast. It has been calculated, that as the lime absorbs the water, and with the sand fills up the interstices of the larger material, if the proportion of the lime be about one eighth of the ballast, then 3¾ cubic feet of ground lime, and 30 cubic feet of ballast, with a sufficient quantity of water to effect the admixture (and this is generally rather less than a gallon to a cubic foot of ballast, or than equal measures of water and lime), will be required to make 27 cubic feet of concrete; that is, there is a loss of bulk equal to all the lime, and of about 10 per cent. of the ballast. But some experiments made in 1857–8, in which the present editor assisted, showed that the same measure which gave a cubic yard of ballast, held precisely the same ballast *with the addition* of one-sixth in bulk of ground stone lime made with it into concrete, besides about fourteen pails of water; and likewise tended to disprove the assertion that concrete swells in setting. This cubic yard of concrete weighed 27 cwt. In estimating, allowance must be made for the loss of material.

1862*a*. Expansion taking place in concrete made of *unground* lime, during its slaking, has been taken advantage of by G. L. Taylor in the underpinning of some walls at Chatham, as detailed in the *Transactions* of the Institute of British Architects, 1835. This expansion has been found to average about $\frac{3}{8}$ of an inch for each foot in height, and the size thus gained the concrete never loses. Care must be taken when using it for floors and for the spandrel of arches, to allow sufficient space, and to lay it in such a way that this increase may take place without thrusting out the walls, as has occasionally happened. In old malthouses in the West of England, with concrete floors 5 to 6 inches thick, stone walls 2 feet 6 inches to 3 feet thick have bulged out 3 or 4 inches on each side by the expansion of the concrete, as also noticed in the *Transactions* of the above named society, 1854, p. 74. When *ground* lime is used the assertion that concrete swells is very questionable, as stated in the previous paragraph. The Metropolitan Board of Works, under the Met. Man. and Building Acts Amend. Act, 1878, sec. 16, requires the cement "to be Portland cement, or other cement of equal quality, mixed with clean sharp sand or grit in the proportions of one of cement to four of sand or grit." *Concrete for walls* to be "of Portland cement and of clean Thames or pit ballast, or gravel, or broken brick or stone, or furnace clinkers, with clean sand in the following proportions: viz., 1 of Portland cement, 2 of clean sand, and 3 of the coarse material, which is to be broken up sufficiently small to pass through a 2-inch ring. The proportions of the materials to be strictly observed, and to be ascertained by careful admeasurement; and the mixing, either by machine or hand, to be most carefully done with clean water, and if mixed by hand, the material to be turned over dry before the water is added."

1862*b*. For water works required to set rapidly, an excellent concrete may be made by a mixture, the proportions of which were found by Treussart as follows:—30 parts of hydraulic lime, very energetic, measured in bulk, and before being slaked; 30 parts of terras of Andernach; 30 parts of sand; 20 parts of gravel; and 40 parts of broken stone, a hard limestone. These proportions diminish one-fifth in volume after manipulation; the mortar is made first. When the Italian puzzuolana is used, the proportions should be 33 parts of lime as before; 45 parts of puzzuolana; 22 parts of sand; and 60 parts of broken stone and gravel. The first of these concretes should be employed immediately it is made; the second requires to be exposed about twelve hours before it it is put in place. When burnt clay or pounded bricks are used, 30 parts will suffice, but this mortar must not be used in sea water. If only rich, instead of hydraulic, limes be used, the quantity of the natural or artificial puzzuolanas must be increased, and that of the stones and gravel be decreased. (Burnell, *Limes, &c.*) See par. 1864*c*.

1862*c*. After many experiments, M. Kuhlmann recommends a cement composed of 30 parts of rich lime, 50 of sand, 15 of uncalcined clay, and 5 of powdered silicate of potash, as having all the requisite hydraulic properties, especially for cisterns intended for spring water. In marine constructions care should be taken to add an excess of silicate to those portions of cement which are exposed to the immediate contact of the sea.

1862*d*. The object to be aimed at in making *hydraulic concrete*, is to give such a sufficiency of mortar as will produce the aggregation of the whole mass of rough rubble materials. In Portland cement concrete, for instance, the proportions for the mortar may be 1 of cement to 3 of sand, and this mortar may then be mixed with 6 parts of ballast or shingle. In blue lias lime concrete, the proportions may be 1 of unground lime to 2 or $2\frac{1}{2}$ of sand, and this mortar may be mixed with 3 or 4 parts of ballast; and it must be understood in all cases that the mortar must be made first, and that it then should be thoroughly incorporated with the ballast or shingle. This concrete as used at the recent extension of the London Docks by Mr. Rendel, consisted of 1 part of blue lias lime with 6 parts of gravel and sand. The proportions for the blocks of the mole at Marseilles were 3 parts of Theil lime to 5 parts of sand mixed up into mortar, and then added to 2 parts of broken stone. At the Metropolitan Main Drainage works, the proportion of 1 of Portland cement to $5\frac{1}{2}$ of ballast for sewers, and 1 of cement to 8 of ballast and sand for backing walls and other works except sewers. The usual proportions are 1 to 6. A report was delivered to the Aberdeen Harbour Board on the damage caused by the chemical action of the sea-water on the (Portland?) concrete entrance works of the graving dock. The surface had softened from the foundation up to the bottom of the ashlar lining, three feet above low water. The concrete behind four courses of the ashlar, between high and low water, was also softened, loosening the bond. The softened concrete under the water had been removed, and the face of the wall rebuilt up to low-water level with Roman cement concrete in bags plastered with Roman cement. The pressure on the foundations amounts at low water to 5 lbs. on the square inch of surface, and at high water to 11 lbs.; this caused a current of sea-water through the porous structure of concrete of theoretical velocity from 1500 to 2250 feet per minute, which continually washed the decomposed cement into the dock, and brought new particles of concrete and sea-water into contact. (*British Architect*, July 29, 1887; and *Architect*, March 9, 1888, p. 16 of Supplement.)

1862*e*. *Béton*, or concrete, as made in France, is invariably composed as follows:— I. The mixture of lime and sand, either by hand or by a pug-mill, as for ordinary mortar. Great importance is attached to the choice of the lime and to the mode of slaking it; and if a sufficiently good one cannot be obtained, artificial puzzuolanas are introduced. The *mode of slaking* is prescribed in the specification according to the nature of the lime, instead of being left to the choice of the workmen. II The *mortar* so prepared is then well mixed by rakes with broken stones or ballast in such proportions as shall insure its filling up the intervals between them; the volume having been ascertained by immersing the stones in a known quantity of water. These spaces are equal to about 0·38 to 0·46 of the cubical contents of the vessel; but in practice, about one fourth more mortar is added than necessary to ensure solidification of the mass, especially when the *béton* is intended to resist water pressure. III. The material is then wheeled to its situation, and rammed down carefully until the mortar begins to work up to the surface.

1862*f*. In an English patent, 1859, No. 2757, M. Coignet, of Paris, argues that the tenacity of mortar is not produced, as hitherto supposed, by the formation of silicate of lime and alumina, but by the crystallisation of lime. His concrete, called *Béton Aggloméré*, consists of about 180 parts of sand, 44 of lime produced by slaking, 33 of Portland cement, and 20 of water, combined by a process of two main operations: I. A complete consolidation of the materials with little water; and II., the steady but not violent compression of the consolidation in moulds. The cement is mixed with the sand and lime, and sprinkled whilst mixing with a *little* water. This mixture is thrown into a machine, formed like an endless screw enclosed in a cylinder, at the rate of two shovelfuls followed by about a quart of water, until the cylinder is full. The screw, turned by two men, delivers the mixture through a series of holes in the bottom of the cylinder; but on a large scale, a machine is used of 10 to 15 horse-power. This mixture, after its delivery from the machine, is put by degrees into moulds, and each layer is rammed in by workmen. He found by experience that the purer the lime the quicker was the crystallisation; and that, although pure hydrate of lime will take carbonic acid, silicate of lime and alumina will not take it, because silicic acid took the place which carbonic acid did with the pure lime; and frankly admitted that his first experiments in 1855, in marine works, had not entirely succeeded, but claimed perfect success for those at Marseilles since 1859, and for those executing (1864) in Paris and elsewhere.

1862*g*. The resistance of *béton* and *concrete* should never be regarded as being superior to those given for limes, if the superstructure be commenced upon them immediately. In both cases the resistances are found to increase with comparative rapidity during the first six or seven months.

CEMENT.

1863. Among those cements used in England, *Parker's*, also called *Roman* and *Sheppey* cement, was discovered in 1796 by Mr. James Parker, of Northfleet. It was manufactured principally from stone found in the Isle of Sheppey, and at Harwich, being septaria from the London clay, and properly classed among the limestones indigenous to this country. It consists of ovate or flattish masses of argillaceous limestone, arranged in nearly horizontal layers, chiefly imbedded in the clay of the cliffs. It was found at first on the beach, but as it became scarcer it was sought for by dredging out at sea. The substance, being coated with a calcareous spar or sulphate of barytes, forms the basis of the cement. About 1810–15 it was found possible to use this material in the depth of winter, but with inferior manufacture this is impossible. In 1840 it was stated that "the genuine Sheppey cement is now almost only a name," arising from the nodules first found having nearly disappeared in consequence of the great consumption of the cement. If this cement be of extremely good quality, 2 parts of sand to 1 of the cement may be used. The cement itself is a fine impalpable powder; yet when wetted it becomes coarse, and, unless mixed with great care, it will not take a good surface. When mixed with the sand and water, it sets very rapidly; it is necessary, therefore, to avoid mixing much at a time, or a portion will be lost. The colour of this cement, when finished, is an unpleasant dark brown, hence it has received the name of "black cement." The surface requires frequent colouring for appearance. It is impervious to water almost the moment it is used; hence it becomes highly serviceable on the backs of arches under streets, for the lining of cisterns, and for carrying up in it, or coating with it, damp walls on basement stories. It will not resist fire so well; and it should therefore never be employed for setting grates, ovens, coppers, or furnaces. This, with many other hydraulic cements, has been eclipsed by *Portland cement*.

1864. *Atkinson's* cement is a good material, preferable in colour to the last named, but, as we think, inferior in quality. It takes a much longer time to set than Parker's cement, than which it absorbs more moisture. It answers well enough in dry situations. Vicat formed a factitious Roman cement; but its efficacy was doubtful, though it had, for want of a better substitute, been much employed at Paris.

1864*a*. *Portland cement*, the latest (about 1843) of all these cements, is made from limestone and clay. The mud of the river Medway, corresponding to the argillo-calcareous stone of Roman cement, is mixed with chalk and ashes from former makings, and calcined at a heat amounting almost to that of vitrification. A larger quantity of sand may be mixed with it than with Roman cement, to which it is superior in colour and hardness of setting. The heaviest, considered the best in quality, weighs 110 lbs. to 112 lbs. per striked bushel.

1864*b*. The distinguishing peculiarities which should render *Portland* cement a permament substitute for *Roman* cement have been explained by a London manufacturer of both materials (*Builder*, 1863, p. 761). It may be condensed into the statement:—That the stone from which Roman cement is made, though composed of lime and the silicate of alumina, yet the proportion of the latter preponderates to such an extent as to prevent a perfect amalgamation of the ingredients in burning. The result is a cement loose in its texture, because containing inert foreign matter, which is retentive of moisture, and consequently attackable by frost and vegetable growth. In Portland cement the case is otherwise. The dose of lime to clay is in the ascertained correct proportion of two to one, and with this condition there is the power thoroughly to combine the ingredients by burning, and thus to give a density and compactness to the product which, in enabling it to resist water, frost, and other decomposing agencies, are the elements of its durability and of its superiority to the natural cements. Carelessness, or want of proper knowledge in its manufacture; an improper mixture of the ingredients; an imperfect calcination; its bad manipulation; and unfair handling when used as a cement, are all likely to result in disastrous effects on being used. When employed as a mortar or as a concrete, it has seldom been known to fail.

1864*c*. It is usual for the manufacturer to grind the cement after burning it. It is then placed in well-closed casks, which should not exceed 6 cwt. each, when the cement may be preserved for some time; but by contact with the atmosphere it is said to absorb humidity and carbonic acid, and thus becomes deteriorated. It should be ground very fine. For the sieve in sifting it, the French engineers required 185 meshes to the square of 4 inches on a side. One-third of the volume of the cement for the quantity of water is the best proportion, and the more that the cement is beaten up, the harder it becomes. The best cement will harden in about five or six minutes, and under water in about an hour; when mixed with sand it takes a little longer. When mixed with sea-water, and used in sea-water with a large quantity of sand, it may take even twenty-four hours before setting. (See pars. 1862*b*, *c*, and *d*.)

1864*d*. The resistance to rupture of pure cement after 20 days' exposure to the air is about 54 lbs. per inch square; if sand be added in the proportion of ½ to 1 of cement, it falls to 37 lbs.; and if it be in equal proportions, it falls to 27 lbs. The permanent load in any large works should never be more than one-sixth of that required to produce rupture: and if small materials be employed, only one-fifteenth should be calculated upon.

1864*e*. In testing Portland cement, the Admiralty, at the Chatham Dockyard extension works, specified that samples would be taken from about one sack in ten, and gauged in moulds, which, when set, would be placed in water and tested at the end of seven clear days. Each must bear without breaking a weight of 650 lbs. upon the test-block of 1½ inches square in section. In 1878 the Metropolitan Board of Works required the cement to be of the best quality, ground so fine that it will pass through a sieve of fifty meshes to the lineal inch. It must have a specific gravity of not less than 3·1, and weigh as delivered 114 lbs. or more to the imperial striked bushel. When brought upon the works it is to be put into dry sheds or buildings, which the contractor is to provide for the purpose, having wooden floors and all necessary subdivisions. The cement is to be emptied out upon this floor, every fifty bushels being kept separate, and is not to be used until it has been tested by samples taken out of every tenth sack. The samples to be gauged neat in moulds, put into water 24 hours after the briquettes have been made, and remain till tested, to bear without breaking a weight of 400 lbs. per square inch 7 days, and 600 lbs. 28 days after they have been made. The first to be considered as preliminary, and the second as decisive. Mr. John Grant's, C.E., specification is of a more extended character, and includes the quality of sand. The briquettes with three of sand to bear a weight of 150 lbs. per square inch after 28 days.

1864*f*. With cement at 112 lbs. per bushel, a cubic foot weighs 87·13 lbs., a cubic yard 2,352·6 lbs., and a ton occupies a space of 25·7 cubic feet.

1864*g*. With this cement, the ordinary proportions for walls may be 1 to 12 of gravel for common, and 1 to 6 of slag and sand for facing, concrete. A cubic yard of concrete takes about 1⅙ yard, or 31½ cubic feet, of loose gravel, exclusive of the cement, as made in a gauge or measuring-box. One-twelfth of 31½ cubic feet, or a little more than 2½ feet cube, goes to each gauge, and is easily calculated and prepared; or 218 lbs. by weight, if the cement weighs 112 lbs per bushel. For making good solid concrete, there should be sufficient sand to fill up the interstices between the stones; one-third of the entire bulk, or one-half of the shingle, is required for the sand—a point not so often attended to as it should be. Plenty of water is advocated for the mixing; and for making a *good face* against a wood shutter it is essential that the concrete should be wet.

1864*h*. Concrete constructions are described under BRICKLAYING.

1864*i*. STRENGTH OF LINTELS of various compositions, each 6 inches deep, $4\frac{1}{2}$ inches wide, and 3 feet 6 inches long, 28 days after manufacture; 3 feet clear space, and loaded gradually in the middle (see par. 1903*x*):—

Brown Portland stone	broke with	1905 lbs.
White ditto	,,	1420 ,,
Burnt clay ballast concrete	,,	1413 ,,
Coke breeze	,,	1119 ,,
Pit gravel ballast	,,	1016 ,,

These three were composed of 1 of cement, 4 of core, 1 piece of hoop iron $1\frac{1}{2}$ inches by $\frac{1}{16}$ thick in middle.

Box ground Bath stone	broke with	476 lbs.
Corsham Down ditto	,,	357 ,,

1864*j*. A natural cement deposit, of very large extent, has been worked at Barrington, Cambridgeshire, where it is found from 13 feet to 21 feet in thickness, immediately under the surface. It is considered as giving the material for the best quality of cement and lime, and it can be manufactured at about half the cost of the usual system (1887).

1865. *Hamelin's mastic* cement, though patented of late years, is an invention of P. Loriot, a century old; the medium for mixing the pounded brick-dust, limestone, and sand, is oil instead of water. It is much more difficult to use than the other cements, and requires great experience and care. A coat of it should never exceed one quarter of an inch in thickness; hence it is totally unfit for working mouldings in the solid. In the metropolis it is generally used in a very thin coat over a rough coat of Roman cement, in which case it is rarely more than an eighth of an inch thick. Thus used, it presents a beautiful surface, is durable, but it requires to be painted as often as do the other cements.

1866. *Keene's* cement is obtained by soaking plaster in alum water after a first calcination; it is then kiln-burnt a second time and ground. It is in reality only a plaster, and is capable of being worked to a very hard and beautiful surface. *Martin's* patent fireproof and ornamental cement is a plaster of somewhat similar make, and equally good-looking. It is manufactured in three qualities, coarse, fine, and superfine. It is said to be used with greater facility by workmen than any other cement yet produced, requiring only about an hour to set, which is less by one-half the time of other cements. It appears to be chiefly prepared at Derby. *Parian* cement (Keating's patent) is also composed of gypsum, but mixed with borax (borate of soda) in powder, and the mixture calcined and ground. A fine quality produces a hard scagliola imitation of marble. When applied to old brick or plastered work, as in repairs, these cements may be papered or painted upon in about 18 or 24 hours after execution. But on new work time must be given for any efflorescence, or damp, to disengage itself

1866*a*. *John's patent permanent stucco wash, stucco cement, and stucco paint*, were introduced about 1843. As a paint it is cheap, durable, agreeable in colour, and finishes without a gloss. It gives out no deleterious exhalations or odour in drying, and it is stated that as the oil cannot evaporate (?), but is held in intimate and indissoluble union with the other materials, there can be no decay, an objection to which oil mastic is so liable. It requires no driers or turpentine, and is applicable both for outside and inside work. The cement, which is stated not to deteriorate with age, is packed in casks, and requires to be mixed with 3 parts of good, sharp, clean sand to make a stucco, its application for which is the same as for any other stucco. It adheres well to glass, iron, slate and tiles in roofing, wood, old plaster, or Roman cement. When set it is hard, and impervious to wet and damp. One coat of its own paint, which it will take after twenty-four hours, is sufficient. Mouldings may be run in it, and castings made.

1866*b*. A cement which will withstand a moist climate, is stated to be composed of one bushel of lime with 15 gallons of water and half a bushel of fine gravel sand, mixed with $3\frac{1}{2}$ lbs. of copperas dissolved in hot water, and kept stirred while being incorporated and in use. Sufficient should be made for the day during which it is to be used, as the colour is not easily matched. The Bristol *Purimachos* cement is new, and is stated to be an effectual fire-resisting material, uniting readily with a metal, brick, stone, or like surface, and forming a permanent joint, impervious to air, gas, smoke, &c. It renews burnt-out parts of fire-brick without any taking down and rebuilding. It repairs cracked and holed iron boilers, ovens, stoves, pipes, &c. Used as a wash, it imparts a smooth glazed surface to the interior of retorts of gas works. It may for many purposes be used instead of white or red lead in making joints subject to the action of fire. Other similar materials will be noticed s. v. PLASTERER.

1866*c*. Gypsum, better known as *Plaster of Paris*, is a sulphate of lime It is found at Alston, in Cumberland; at Shotover Hill, Oxfordshire; at Orston, near Grantham; in Nottinghamshire, in Derbyshire, and in Cheshire; in France, in the neighbourhood of Paris, chiefly at Montmartre; and in the departments of the Saone, Loire, of the Rhone, and of many others; and in Tuscany, Savoy, Spain and Switzerland; in some parts of the British Colonies of North America, wherefrom it is exported principally to the United States. The stone is broken into small blocks, and burnt in a walled space with openings in the tiled roof to let out the steam. After its water of crystallization is driven off, it becomes pulverulent and like flour. On fresh water being added, it combines with the normal quantity of water, and reassumes the form of a hydrate, recovering its original density and strength to a very great degree. A heat of about 200° centigrade is sufficient. The London manufacturers adopt a kind of oven for burning the stone, which prevents the smoke from injuring the plaster. In France it has been proposed to throw a jet of steam heated above 400° Fahr. over the stone, which is broken very much smaller than usual: this jet takes up all the water present, and leaves the plaster in the state of a pure anhydrous sulphate of lime. The plaster obtained from Paris is considered the best of all in quality, probably arising from the fact that the stone is the hardest. Gypsum swells in setting in contradistinction to the cements, which generally shrink. The specific gravity of pure gypsum may be taken at 2·322; and its constituent parts to be sulphuric acid 46, lime 32, and water 21. (See Glossary, s. v.)

1867. The best *bituminous cements* are obtained from the natural *asphalte*, which is found in large quantities on the shores of the Dead Sea; in Albania; in Trinidad; at Lobsann, and Bekelbronn, in the department of the Bas Rhin; in the department of the Puy de Dôme; at Gaugeac in that of the Landès, &c. The asphalte which is found in inexhaustible quantities at Pyrimont Seyssel, in the Jura Mountains, in the department of the Aire in France, was introduced into England about 1838, under Claridge's patent. The principal ingredient in its composition is a bituminous limestone, of a rich brown colour. After it has been reduced to a fine powder, a certain portion of grit is mixed with it; it is then placed in cauldrons heated by strong fires with a sufficient quantity of *mineral tar* to prevent the asphalte from calcining. The whole mass is thoroughly incorporated and reduced to a *mastic*, in which state it is run into moulds to form blocks, each 1 foot 6 inches square, 6 inches in depth, and weighing 125 lbs.

1867*a*. The *mastic* is of three qualities, fine, gritted, and coarse gritted. The first, being without any admixture of grit, is used for magazine floors, and as a cement for making, in special cases, very close joints in brickwork. II. The fine gritted is used for covering terraces, roofs and arches, lining of tanks, and as a cement for brickwork, and for running the joints of stones. III. The coarse gritted is used for paving and flooring, and where great strength of work is desirable, such as gun-shed floors, tun-room floors, and margins of stable floors; while in gateways for heavy carriage traffic, small pieces of granite chippings are introduced. These mastics, and more particularly the first two, being ductile and readily yielding to any change that may take place on the surfaces upon which they are laid, require a proper foundation to be prepared.

1867*b*. When required for use, an iron cauldron having been prepared, 2 lbs. of mineral tar are put in and then 56 lbs. of asphalte broken into pieces of not more than 1 lb. in weight. These are mixed together until the asphalte becomes soft. After a quarter of an hour the stirring is repeated, and another 56 lbs. of asphalte added, and so on until a proportion of 112 lbs. of asphalte to each 1 lb. of tar, under ordinary circumstances, fills the cauldron and the whole is thoroughly melted. When fit for use the asphalte will emit jets of light smoke, and freely drop from the stirrer.

1867*c*. It will be well to note that it is stated asphalte never flames, but merely passes into a state of fusion. At the fire at Hamburg in 1842, it was remarked that when asphalted roofs fell in, "the asphalte, in which a sort of rubble is mixed up, was found to have resisted the effects of the heat, and, like a mass of dirt, served rather to smother the flames than to give them increased vitality." A like result is recorded of a fire that took place at the Bazaar Bordelais, at Bordeaux, in 1835; of another in Stangate, London, in 1855; and experiments were made by order of the authorities of the British Museum before this material was allowed to be applied to the snow gutters of the dome of the new Reading Room and other roofs, with a satisfactory result. Notice is not generally taken of the fact that if in works, asphalte or tar be used in places where it may be affected by heat, a smell arises which is very prejudicial to the comfort of the occupiers of the building.

1867*d*. The term *asphalte* has also been given to several compositions formed by the admixture of chalk, lime, gas tar, and other substances for cheapness. The *coal tars*, and vegetable pitch, although not so good as the bitumens, are fairly good substitutes in many cases, as in coating vaults, or walls exposed to the dampness of earth. The proportions in which to mix powdered calcareous stone must be regulated by practice, as also the heat, that the stone be not converted into quicklime, perhaps from 6 to 7 of the pitch in volume to 1 of limestone will suffice; and it is recommended to use these in greater thickness than the asphalte, being about half an inch for the latter material.

Sect. XII

GLASS.

1868. Glass is a combination of silex with fixed alkali, generally soda. The mixture when calcined receives the name of *frit*, which after the removal of all its impurities, is conveyed to the furnace and melted in large pots or crucibles till the whole mass becomes beautifully clear, and the dross rises to the top. After being formed into the figures required, it is annealed or tempered by being placed in an appropriate furnace. The fineness depends on the purity and proportion of the ingredients. An extremely fine crystal glass is obtained from 16 parts of quartz, 8 of pure potash, 6 of calcined borax, 3 of flake white, and 1 of nitre. The specific gravity of glass is about 2600; of French plates, 2840; of English flint glass, 3320. Glass is extremely elastic, and less dilatable by heat than metallic substances.

1868*a*. Four pieces of the common sort of glass being cut from one strip, each piece was 5 inches wide, 6 inches long, and 4 inches thick. In the trial of strength they were calculated out at a standard size, and gave 17,208 lbs., 15,435 lbs., 14,931 lbs., and 11,385 lbs.; the mean being 14,931 lbs. This great difference is the more singular from the circumstance of all the pieces being cut from the same plate. The weight of the glass at a size of 9·0 × 4·5 × 3, all in inches, would be 11·12 lbs. *Sheet* glass is stated to be stronger than *plate* or *crown* glass, but less flexible. The compressive strength of glass is about $12\frac{1}{4}$ tons per square inch. The resistance of glass to a crushing force is about 12 times its resistance to extension.

1869. Pliny gives the following account of the discovery of manufacturing glass, which was well known in Aristotle's time, 350 B.C. "A merchant vessel, laden with nitre or fossil alkali, being driven on the coast of Palestine, near the river Belus, the crew accidentally supported the kettles on which they dried their provisions on pieces of the fossil alkali; the sand about it was vitrified by its union with the alkali, and produced glass." Though, according to Bede, artificers skilled in making glass were brought into England in 674, glass windows were not generally used here till 1180, and were for a considerable time esteemed marks of great magnificence.

1870. The manufacture of window glass during the last thirty years has undergone entire alteration, especially since the abolition of the excise duty in 1845. There are now three special kinds of glass used for glazing purposes, and several varieties of them:

1870*a*. I. *Crown* glass, which is blown into large globes and opened out into circular flat tables. II. *Sheet* glass, which is blown into long cylinders or *muffs*; then split down and flattened. III. *Plate* glass, which is either cast on iron tables for large purposes, and polished; or for smaller squares, blown into a cylinder and polished

1871. *Crown* glass, the commonest window glass, differs from flint glass in its containing no lead or any metallic oxide except manganese, and sometimes oxide of cobalt, in minute portions, for correcting the colour, and not as a flux. It is compounded of sand, alkali, either potash or soda, the vegetable ashes that contain the alkali, and generally a small portion of lime. To facilitate fusion, a small dose of arsenic is frequently added. Zaffre or oxide of cobalt, in the proportion of 1 ounce for 1000 pounds, is added to correct the colour; but when the sand, alkali, and lime are very fine, and no other ingredients are used, zaffre is not required Its manufacture is conducted differently from that of flint-glass articles, the object being to produce a large flat thin plate, which is afterwards by the glazier's diamond cut into the requisite shape. It is blown in circular plates, varying from 3 feet 6 inches to 4 and 5 feet diameter: the process is as follows:—The workman, having a sufficient mass of melted metal on his blowpipe, rolls it on an iron plate, and then, swinging it backwards and forwards, causes it by its own gravity to form into a globe, which is made and brought to the required thinness by blowing with a fan of breath, which persons accustomed to the work know how to manage. The hollow globe is then opened by holding it to the fire, which expanding the air confined within it (the hole of the blowpipe being stopped), bursts it at the weakest part, and while still soft it is opened out into a flat plate by centrifugal force; and being disengaged from the rod, a thick knob is left in its centre. It is then placed in a furnace, or in a certain part of the furnace to undergo the process of annealing. When the table is cut for use, the centre part in which the knob remains is called *knob-glass*, and is used only for the very commonest purposes. Tables are now made of such a size that squares may be procured 38 inches by 24 inches as extra sizes.

1871*a*. The qualities of crown glass in common use are called best, seconds, thirds, and fourths or coarse; with two still coarser. The last is of a very green hue, and only used for inferior buildings. They were sold by the *crate*, at the same price, the difference being made up by varying the number of the tables contained in it. Thus a crate of best crown glass contained twelve tables; of seconds, a crate contained fifteen; and of thirds, eighteen tables. They are now sold (by Messrs. Hartley) in crates of eighteen tables of the usual thickness averaging 58 inches; and in crates of twelve tables of extra thickness averaging 52 inches. Flattened slabs of the same qualities are sold in crates of thirty-six slabs of the usual thickness, and in crates of twenty-four slabs of extra thickness, each averaging 24 inches, $22\frac{3}{4}$ inches, and $21\frac{1}{2}$ inches. The flattened slab is also made as 'obscured' glass. The sizes of both qualities vary from 'quarries'; under 9 by 7; up to, above $4\frac{1}{2}$ feet, and not above 5 feet superficial. Taking the usual thickness of

Best	as	60	extra thickness	150	
Seconds	,,	90	,,	135	
Thirds	,,	65	,,	110	
Fourths	,,	50	,,	85	
CC and CCC	,,	43 and 40	,,	63 and 50	(Adcock).

1872. *Sheet* glass has been manufactured in England with great improvements since 1832 to 1838 by Messrs. Chance and Hartley, with the co-operation of M. Bontemps, of Paris. Though inferior in colour, this glass is in other points generally superior to that of the foreign manufacture. It is composed of the same or similar materials to the above, in well ascertained proportions, and with sulphate of soda to give whiteness. In the manufacture of sheet glass a sufficient quantity of the metal is collected at the extremity of a blow-pipe, and then lengthened by swinging and blowing, till it acquires the form of a hollow cylinder, which is then detached, the neck being cut off with a thread of hot glass; and one side of the cylinder is cut down lengthwise with a heated iron or diamond. It is then taken to the flattening kiln, where the heat causes it gradually to open nearly flat on a bed called *largre*, where it is rubbed down by means of a block of wood called a *polissoir*, and then becomes *flattened sheet*. After this operation it is placed in the annealing oven to cool gradually. This operation is referred to by the monk Theophilus, who wrote about the end of the twelfth century or later, as in use in his time. The method was also employed by the Venetians especially for coloured glass, as it secured uniformity. But on the cessation for its demand, the employment of the cylinders was entirely superseded in France, England, and the North of Germany, for the rotary principle.

1872*a* The great advantage of *sheet* glass is that of affording plates of larger dimensions, and not only of avoiding the waste arising from the circular form of the *crown* tables, but also from the knob or bull's eye in the centre. The surface, however, is much less brilliant than that of crown glass, and is more wavy and undulated. Messrs. Chance, in 1838, introduced a thicker quality of sheet glass, which was at the same time of a better surface, and since then its use has become general.

1872*b*. In 1840 the same firm introduced a new variety of window glass under the name of *patent plate*, which they obtained from a thick sheet glass by a new process of grinding and polishing. They made plates of several degrees of thickness, and of sizes containing from 8 to 12 feet superficial. The surface of the glass obtained by this process, though not perfectly true, is very nearly so; and in brilliancy it is unsurpassed even by cast plate. For glazing sashes it has nearly superseded crown and sheet glass. But for squares of somewhat large dimensions, it may be calculated whether *plate* glass will not be as cheap or cheaper.

1872*c*. As will be perceived by the above short account of the mode of manufacture of *sheet* glass, its size is almost only limited by the strength of the workman. It is chiefly sold in crates as manufactured, in sheets of not less in width than 28 inches, and not less than 9 feet superficial area; with a limit of width not exceeding 45 inches, and a limit of length not exceeding 75 inches; but these extremes of width and length cannot be combined in the same sheet. Thus in glass of 15 ounces to the foot, the dimensions 55 by 36 inches, or $12\frac{1}{2}$ feet in area, is the largest plate. In 21 ounce glass, 75 by 45 inches, or 18 feet area: in 26 ounce glass, 75 by 45 inches, or 17 feet area: in 32 ounce glass, 65 by 44 inches, or 15 feet area: in 36 ounce glass, 60 by 42 inches, or $12\frac{1}{2}$ feet area: and in 42 ounce glass, 55 by 38 inches, or 11 feet area. The four first weights are made in qualities of best, seconds, thirds, and fourths; and the two first have two qualities A and B for pictures. There is no fourth quality to the two last named weights. All these sorts are cut into squares for glazing.

1872*d*. *Fluted sheet* glass of 15 ounce and 21 ounce is usually supplied in crates not above 43 inches long; but it is made up to 50 inches in length. *Obscured sheet glass* is supplied in all substances.

1873. *Patent plate* glass, already described (*par.* 1872*b*.) is made in three qualities, B or best, C or second, and CC or third, quality. Each of these are of four kinds known as No. 1, which is of an average thickness of $\frac{1}{16}$th of an inch, and is of an average weight of 13 ounces to the foot; No. 2 is $\frac{1}{12}$th thick, and 17 ounces; No. 3 is $\frac{1}{10}$th, and 21 ounces; and No. 4 is $\frac{1}{8}$th, or 24 ounces to the foot. No. 4 B is thus the very best quality made; the prices for the size required vary but about one or two pennies per foot in each kind; and from threepence to sevenpence in each quality. They are manufactured in sizes from 4 to 13 feet in area, not above 50 inches long, or 36 inches wide.

1874. *German sheet*, or *Belgian sheet* glass, as it is sometimes called, was formerly in much demand in England; and is still used for cheapness. Its appearance is more wavy and speckled than the English manufacture. *Crystal white sheet* glass, for glazing pictures and prints, is imported from Florence in cases of 100, 200 and 300 feet, in first, second and third qualities, and appears superior to other glass in whiteness, but it has the defect of 'sweating.' Similar named glass for such purposes made by Messrs. Chance, appears to us to be very green, and therefore detrimental to prints and pictures; but on the other hand it does not sweat.

1875. *Plate* glass is so called from its being cast in large sheets or plates. Its constituent parts are white sand, cleansed with purified pearl-ashes, and borax. If the metal should appear yellow, it is rendered pellucid by the addition, in equal small quantities, of manganese and arsenic. It is cast on a large horizontal table, and all excrescences are pressed out by passing a large roller over the metal. To polish it, it is laid on a large horizontal block of freestone, perfectly smooth, and then a smaller piece of glass, fastened to a plank of wood, is passed over the other till it has received a due degree of polish. For the purpose of facilitating the process, water and sand are used, as in the polishing of marble; and lastly, Tripoli, smalt, emery, and putty, to give it lustre; but to afford the finishing polish the powder of smalt is used. Except in the very largest plates, the workmen polish their glass by means of a plank having four wooden handles to move it, and to this plank a plate of glass is cemented.

1876. For the unsilvered polished plate glass for mirrors there are two qualities, second and best. The Paris factory supplied in 1865 two looking glasses for the Mayor's room in the Town Hall at Liverpool, each 15 feet by 10 feet. *Polished plate* glass is manufactured for general glazing purposes up to about 80 feet superficial, of two qualities, usual and best. The usual thickness is a quarter of an inch: higher prices are charged for glass selected to be cut above $\frac{3}{16}$ths, $\frac{5}{16}$ths., and $\frac{3}{8}$ths. thick; while for above $\frac{3}{8}$ths. thick, special prices are charged. The best quality is declared to be of the very purest colour, free from specks, and not subject to dampness or sweating.

1877. *Rough plate* glass, cast, is used for roofing, in skylights, windows, &c., in plates from not above 20 inches long, to above 120 inches long, in thicknesses of $\frac{1}{4}$, $\frac{3}{8}$, $\frac{1}{2}$, $\frac{3}{4}$, inch, $1\frac{1}{4}$, and $1\frac{1}{2}$ inch; but these thicknesses have certain limited lengths. The widths are the same as for plate glass. This glass is not ground or polished, but rough from the table, and showing the table marks on its underside.

1878. The *patent rough plate* glass, which is also cast, must not be confounded with the above. It is extensively used for ridge and furrow roofs, conservatories, manufactories, skylights, workshops, and other places where "obscured" glass is required to intercept the vision without diminishing the light. Blinds are unnecessary, and when it is used in greenhouses, no scorching of the plants occurs. The quality known as $\frac{1}{8}$th. of an inch thick, weighing about 2 lbs., or 32 ounces to the foot, is usually provided for these purposes, and is no more, weight for weight, than common crown glass. When greater strength is required, $\frac{3}{16}$ths. and $\frac{1}{4}$ inch thick is said to be cheaper and of a finer quality than the common rough plate; but we demur to this statement, as of late years the manufacture appears to have decreased in strength from the greater use of sand for cheapness; in moveable window frames in warehouses, a lamentable quantity of broken squares is to be seen almost before the floors are occupied.

1878*a*. This glass is made of two kinds; I. Plain, which is merely marked by the fine grain of the casting table, and is that above noticed; and II. Fluted, of two sorts, No 1, large pattern, having $3\frac{1}{2}$ flutes to the inch; and No. 2, small pattern, having 12 flutes to the inch. Both the plain and the fluted kinds are made $\frac{1}{8}$th. $\frac{3}{16}$ths. $\frac{1}{4}$. $\frac{3}{8}$ths. and $\frac{1}{2}$ inch in thickness. The width is about 3 feet, and the length usually not above 70 inches; but 75, 90, and 100 inches long are also made. When a clear glass and much non-transparency are required, No. 2 fluted is the best.

1879. *Quarry* glass is also made in this material; No. 1 being 6 inches by $4\frac{1}{8}$th inches from point to point; No 2 being 3 inches by $2\frac{1}{16}$ inch. A *stained ornamented patent quarry rough plate* is made for churches, chapels, schools, &c. A *patent diamond rough plate* glass is also manufactured. A patent rough plate, and sheet, *perforated* glass, polished or unpolished, for ventilation, can be obtained in sizes, which require consideration in arranging, on account of the length of the slits or perforations. It is usually made in columns $1\frac{1}{2}$ inches wide, and $2\frac{1}{2}$ inches apart; the space between each slit vertically being $1\frac{1}{2}$ inches. Larger sizes, or the columns wider apart, can be obtained from various manufacturers, or to order.

1880. Many other applications of glass will be noticed in the ensuing chapter. We must here state that the details given in this section are founded upon the price list issued by Messrs. Hartley, of Sunderland, and would state our regret that the manufacturers have not deemed it advisable for their own interests, to provide some place in London, and in other large towns, where the architect can call and compare the qualities of glass supplied under his specification with standards there placed. It was comparatively easy in former years to judge of good glass; now it is almost impossible.

CHAP. III.

USE OF MATERIALS, OR PRACTICAL BUILDING.

Sect. I.

FOUNDATIONS AND DRAINS.

1881. In the previous chapter, the principal *materials used in building* have been enumerated; this chapter will explain how those materials may be most advantageously employed; but we shall not, in the various branches of practical building, again touch on the materials themselves, which have been already sufficiently described. The most important of all considerations—a due regard to the foundations on which a building is to stand—will be first entered upon. The advice of Vitruvius may still be followed. In England, the recent introduction of concrete has superseded the use of wood under walls in the earth; and piles are now quite exploded, except sometimes for the piers of bridges and other situations in which they can constantly be kept wet.

1882. The best soils for receiving the foundations of a building are rock, gravel, or close-pressed strong sandy earth; "but," says L. B. Alberti, "we must never trust too hastily to any ground, though it may resist the pick-axe, for it may be in a plain, and be infirm, the consequence of which might be the ruin of the whole work. I have seen a tower at Mestre, a place belonging to the Venetians, which, in a few years after it was built, made its way through the ground it stood upon; this, as the fact evinced, was a loose weak soil, and buried itself in earth up to the very battlements. For this reason, they are very much to be blamed who, not being provided by nature with a soil fit to support the weight of an edifice, and lighting upon the ruins or remains of some old structure, do not take the pains to examine the goodness of the foundation, but inconsiderately raise great piles of building upon it, and out of the avarice of saving a little expense, throw away all the money they lay out in the work. It is, therefore, excellent advice, the first thing you do, to dig *wells*, for several reasons, and especially in order to get acquainted with the strata of the earth, whether sound enough to bear the superstructure, or likely to give way." It is important, previous to laying the foundations, to drain them completely, if possible, not only from the rain and other water that would lie about, but from the land water which is, as it were, pent up in the surrounding soil. In soft, loose, and boggy ground, the use of concrete will be found very great; and in these soils, moreover, the width and depth it should be thrown in should, as well as the lower courses of the foundation, be proportioned inversely to the badness of the soil. Clay of the plastic kind is a bad foundation, on account of the continual changes, from heat and moisture, to which it is subject, and which often cause it so to expand and contract as to produce very alarming settlements in a building. The best remedy against this inconvenience is to tie the walls together by means of chain plates, buried in the centre of the footings, and on the top of the landings that rest on the concrete; these plates to be, of course, connected at the returning angles, so as to encompass the whole building. In these cases, the clay must be excavated to make room for the concrete. This will be found an effectual remedy in clay soils.

1883. By the Metropolitan Building Act, no building can be erected upon any site which shall have been filled up or covered with impure matter enumerated in the Act; it must be removed first, and any holes, if not used for basements, must be filled in with hard brick or dry rubbish. Generally, if the soil be a sound gravel, it will want little more than ramming with heavy rammers; and if the building be not very heavy, not even that.

1884. Where vaults and cellars are practised, the whole of the soil must, of course, be excavated; but where they are not required, trenches are dug to receive the walls, which, in both cases, must be proportioned in strength to the weight of the intended superstructure and its height. In general terms, we may direct the depth of foundations to be a sixth part of the height of the building, and the thickness of the walls twice that of those that are raised upon them. Care must be taken that that which is to receive the footings of the walls be equable; otherwise, where external and internal walls are connected together, the former, being the heaviest, may settle more than the latter, thereby causing fractures, which, though not, perhaps, dangerous, are extremely disagreeable in appearance. The lower courses, which are called the footings of the wall, are often laid dry; and, perhaps, at all events, a sparing use of mortar in a spot loaded with the greatest pressure should be preferred. If the footings be of stone, very particular attention should be bestowed on placing the stone in the courses in the same direction or bed as it lay in the quarry, to prevent it splitting. The above mentioned Act requires that the foundations of the walls of every house or building shall be formed of a bed of concrete not less than

9 inches thick, and projecting at least 4 inches on each side of the lowest course of footings of such walls. If the site be upon a natural bed of gravel, concrete is not then required.

1885. In foundations where, from columns or small piers pressing upon particular parts, there would be a liability, from uneven bearing, to partial failure, it has been the practice, from a very early period, to turn inverted arches (see *fig.* 615) to catch on their springing the weight to be provided against, by which means such weight is equally distributed throughout the length of the foundation. "Standing thus," says our master Alberti, "they (the columns or weights) will be less apt to force their way into the earth in any one place, the weight being counterpoised and thrown equally on both sides on the props of the arches. And how apt columns are to drive into the ground by means of the great pressure of the weight laid on them, is manifest from that corner of the noble temple of Vespasian that stands to the north-west; for, being desirous to leave the public way, which was interrupted by that angle, a free and open passage underneath, they broke the area of their platform, and turned an arch against the wall, leaving that corner as a sort of pilaster on the other side of the passage, and fortifying it as well as possible with stout work, and with the assistance of a buttress. Yet this, at last, by the vast weight of so great a building, and the giving way of the earth, became ruinous." When inverted arches are proposed to be used, they should be shown in the drawings.

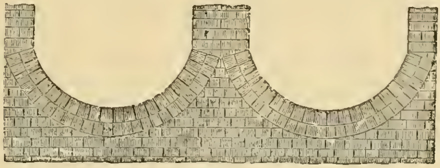

Fig. 615.

1885*a*. A method of forming foundations has lately come into vogue for bridges and other hydraulic constructions by the use of *cylinders*, or other shaped air-tight cases. In India the system of founding large masses of masonry on cylindrical piers built in the interior of wooden curbs, has prevailed for a long period. The method of constructing the piers is the same as that used in England in sinking the steining for ordinary wells; and when sunk the interior is filled up with concrete or ruble masonry. Some of the iron bridges lately erected over the river Thames and elsewhere have been placed on foundations formed by cast iron cylinders filled in with concrete. Further details must be sought in works devoted to *Civil Engineering*, as the system will seldom be applicable in strictly architectural constructions.

1886. *Air-drain.* It is most important, when the walls are raised on the foundations, and brought up a little above the level of the earth, to take care that the earth, most especially if moist, should not lie against them; for if walls, before they are dry and settled, imbibe moisture, they rarely ever part with it, and thence gradually impart rot to the timbers throughout the house. It is, then, most important to have a second thin wall outside the basement walls, so as to leave between it and them a cavity for the circulation of the air, such cavity being technically called an *air-drain*. In moist and loose soils it is essential for the durability of the building, as well as for the health of those who are to dwell in it. The *Hygeian rock* building composition, by W. White, of Abergavenny, has been largely used for preventing damp passing through a wall. A wall may be built with half-bricks on the flat and set in this composition, filling the middle joint of half an inch, and an inch or so of each bed. This is stated to be much stronger than an 18-inch wall built in the ordinary way. A brick flat with a brick on edge, as for cottages, or for economy, is quite damp-proof, and equal in strength to a 14-inch wall built with mortar only. No skill is required; an intelligent labourer can use it.

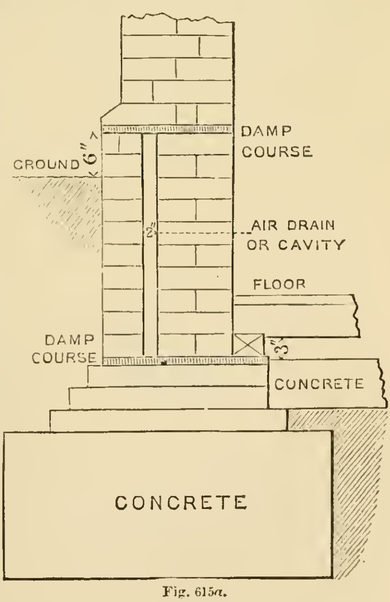

Fig. 615*a*.

1886*a*. It is important that the *air-drain* or *dry area* should commence at least as low as the foundations of the building; in very wet situations it should be provided with pipes to carry off the superabundant moisture, and be independent of the main drain of the building. Even when provided, the usual precautions to prevent damp arising in the main walls must not be neglected. The *air-*

drain, which should never be less than 8 inches wide, more if possible, is commonly covered with a half-brick arch, or with stone, slate, or tile, *below* the surface of the ground. This entirely does away with the benefit anticipated by its formation, because the surface drainage descends and injures the main wall, even when cemented above the covering; this covering should come some inches *above* ground. Unless care be taken it often degenerates into a hole for dirt and vermin. A good arrangement is to make a *dry area*, or a space wide enough to be easily cleared out, and to which a cat or dog can have access, and to cover it with stone with moveable gratings at convenient distances; the expense will not be much greater, while the result will be very effective. The most secure arrangement, however, is to form an *open area* all round the building. The want of such a precaution in the houses in the suburbs of towns renders a large majority of those having basements nearly uninhabitable from the disagreeable consequences of damp walls. (See also *fig.* 615*h*.)

1886*b*. *Damp courses.* This simple provision to prevent wet, which is likely to get into walls, from rising in them by capillary attraction, is too often neglected, especially in cheap work, for the present saving of a pound or two; but at the ultimate expenditure of many pounds. The simplest plan has generally been to work three courses of the brickwork above the footings and below the ground floor, in cement. Messrs. Smith of Darnick state that a coating of cement, done in a very substantial manner, did not appear to have the smallest effect, as the wall was as damp above it as below. For *small* cottages they found an effective plan was to build all the parts of the wall underground quite *dry*, and not to use any mortar until clear of the earth. This left the walls quite dry above. The next method is to bed a course of sound whole slate slabs, $\frac{1}{4}$ inch thick, in cement. When the soil is very damp, two or even three courses of ordinary slates may be laid in and well bonded, not only in the main walls, but in all cross partitions and dwarf walls. For some reason, probably that of the slates and cement having separated or crushed with the weight of the walls, allowing the damp to pass through, this method has fallen into disuse. As Portland cement will adhere to slate, probably, in solid works, if used instead of Roman cement, the result would be more satisfactory.

1886*c*. Sheet zinc bedded in loam has been found to decay. In extensive works, fine-gritted asphalte, applied in a hot state, is introduced as a layer, about half an inch in thickness. This material is stated, in the Appendix to the *Report of the Fine Arts Commissioners*, to have kept out the effects of damp, which would have shown themselves, as the foundations of the building referred to were always in water about 20 inches below the level of the ground floor. The brickwork should be dry and protected from rain during the operation, to prevent the asphalte becoming honeycombed. In buildings already erected, the walls can be underpinned to introduce the material. At the New Palace at Westminster the joints are only half filled with mortar, the asphalte filling the remainder when poured over the bricks. The bricks for the next course, having been heated at a coke fire, were placed on the asphalte in its fluid state, and the joints half flushed up. The outer courses, however, should be first laid for short distances, that they may set before the middle is filled in. In rubble masonry, it will be necessary to fill up all inequalities on the surface with fine concrete; when this has set sufficiently, the asphalte is to be laid as described for brickwork. Gas tar mixed with lime is said to be impervious to wet.

1886*d*. Two centuries ago, thin sheet lead was laid on the top course of a wall to prevent damp coming down it from the gutters; of late years, a layer of 4 lb. milled lead

Fig. 615*b*.

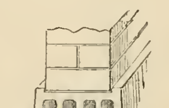

Fig. 615*c*.

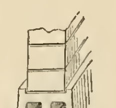

Fig. 615*d*.

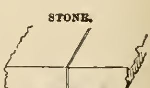

Fig. 615*e*.

has been proposed to prevent it rising; no doubt the best and most efficacious remedy, but the cost would be greater than usually allowed. But the best invention, having price also in its favour, is the *damp-proof course*, formed of brown stoneware, perforated throughout its entire width with a half air space, which remains open after the mortar beds are laid, on each side of the slab. In an executed work, a course of bricks can be cut out and the stoneware be inserted. This is one of the many building inventions of Mr. John Taylor, junior. *Fig.* 615*b*. shows one for an 18-inch wall; other sizes as well as angle blocks are provided. Each foot superficial is stated to be equal to the support of 25 tons or 600 feet of vertical brickwork. Jennings has patented earthenware *sleeper blocks*, "non-conductors of damp and a cheap substitute for brick sleeper walls;" they are also useful for carrying stone paving: *figs.* 615*c*., 615*d*., and 615*e*. describe themselves. *Fig.* 615*f*. shows the section of a sleeper-wall in brickwork, carrying stone paving on one side and timber joist on the other. There are four courses of brickwork, on which is laid the timber sleeper, 4 inches by 3 inches, to carry the joist.

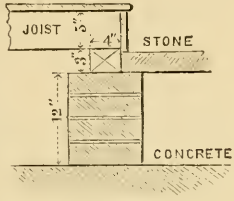

Fig. 615*f*.

1886*e*. *Fig.* 615*b*. is also useful for admitting air into the space under a floor, and then dispenses with the common cast-iron *air-brick* usually fixed for such a purpose. *Air gratings* are of a larger size. The following arrangement, shown in *Figs.* 615*g*. and 615*h*., has been carried out where it was thought advisable to provide for the admission of a large quantity of fresh air at times into the body of the building. Funnels or pipes were inserted in the side walls under the floor, say 1 ft. 9 in. diameter. An area protects the front, to which a small weeping drain is put to carry off any rain water, and is protected at the top by a grating to prevent animals getting in. On the inside is a plate or slide, which can be let down through the floor, paving, or boards into a groove, to regulate the quantity of air or to shut it off. The fresh air ascends through gratings, or by other means, in the floor, into the hall.

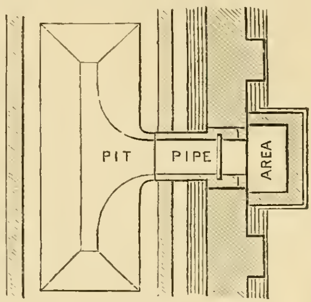

Fig. 615*g*.

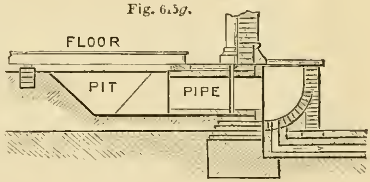

Section. Fig. 615*h*.

1886*f*. A preventive against the rise of damp in the inside of the building is to cover the whole area within the walls with a layer of *concrete*, about 4 to 6 inches thick. By a bye-law of the Metropolitan Board of Works, the site of every house or building shall be covered with a layer of good concrete at least 6 inches thick, and smoothed on the upper surface, unless the site thereof be gravel, sand, or natural virgin soil. But as concrete, especially if of a coarse character, is of a honey-comb character, even when fixed or set, being full of little cavities, there is some danger in placing it in *wet* soils, for it will often weep, and if cut, water will be seen to ooze through it. Also, when placed under a basement floor to keep out damp, water will invariably find its way through if there be any pressure, as from springs. To prevent vapours rising from decomposed matter in the soil, a good practice, even in dry localities, is to cover the soil, before the floor boards are laid, with a layer of two inches of unslaked lime, which on slaking with damp, or damp air, will destroy any vegetation that may have been left on the surface.

SEWERAGE AND DRAINAGE.

1887. Before a brick or stone of any building be laid, the architect neglects his duty if he has not provided for perfect drainage in the lowest parts of the structure. This should not be by the aid of a stagnant tank, called a *cesspool*, if it can possibly be avoided, although there are some localities where such a tank must be formed, and then the solid contents can possibly be made useful for manuring purposes, the surplus water being drained off, possibly into some running stream at a distance from the building, whose exhalations shall not be blown by any prevalent winds of the spot back upon the place where they were generated in a different form. The durability of the structure is quite as much involved in good drainage as is the health of the family whose dwelling-place the house is to become. London, with its suburbs, is now probably the best drained capital in Europe. The lines of sewers forming the Main Drainage scheme have relieved the noble river of nearly all the sewage matter which had been carried into it. Every street and alley has its public sewer, and nearly every house has its separate drain into the sewer. No new sewer can now be made in London without the previous approval of the Metropolitan Board of Works; and no drain can be laid into a sewer without the previous approval of the vestry or district board, which has to apply to the Metropolitan Board of Works for their sanction in both cases. Many towns in England have now their Board of Health supervising the drainage of the streets and houses, pursuant to "The Public Health Act, 1848," and "The Local Government Act, 1858."

1887*a*. *Sewers* are provided for carrying away foul water brought into them by the drains. Ordinary street sewers are built of hard bricks set in cement, and are now generally egg-shaped in section, being about 3 feet 3 inches wide at the top, and 2 feet

9 inches at the bottom, of the sides, which are formed by curves of a large radius, and 5 feet high in the clear. Smaller sewers are 2 feet 9 inches and 2 feet 3 inches wide, and 4 feet 6 inches clear height; and 2 feet 6 inches wide, and 4 feet clear height. The smaller end is placed downwards. The difference of friction or impediment in favour of a curved bottom is great, much power of the flow of water being lost by the use of a flat or flatly curved bottom. This part of the sewer is called the *invert*, and is often formed of stoneware, the core being filled in with coarse cement; thus the foul liquid does not percolate through them into the soil. The figure (615*i.*) shows Jennings' compound invert blocks, laid and jointed in Portland cement; the bricks at the angles set in blue lias lime. Smaller sewers are now made of large circular glazed stoneware pipes, and in a few exceptional instances of iron; and even *rock concrete tubes*, from 15 inches to 36 inches diameter, are made at Poole. The joints of these pipes are made watertight. These ordinary sewers pass into larger ones called "main sewers," all gradually inclined from the higher to the lower levels, joining one another either with curves or acute angles, so that the flow of one current shall not impede that of another; and they gradually become larger and larger, according to the requirements of the town, until they end in one or more outfall sewers discharging into a river, or to reservoirs for a system of irrigation or for other purpose.

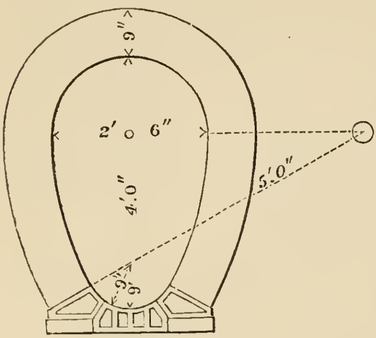

Fig. 615*i.*

1887*b*. The accumulation of foul deposits in sewers is caused by the want of sufficient fall or sufficient flushing with water, and so occasions foul air, or gas as it is wrongly called. Hence it is essential that the sewers should be well ventilated, in order that the foul air shall not escape or pass up the drains of the houses. This ventilation in a line of sewer is effected by a shaft carried up from the crown of the sewer to the surface of the street, where it is finished by a grating. Where there are plenty of these ventilating shafts, it is considered that no nuisance is produced by the bad air as a general rule, because the purer air is supposed to be continually passing into and out of the sewer through them, thus diluting the foul air. If a nuisance from foul air is complained of, it would show that something was wrong with that part of the sewer, or that another ventilator was wanted in the distance between the two already in position. Instead of these, it has also been proposed to ventilate sewers by means of pipes carried up houses and ending above the roofs, but this system is considered to be inefficient unless the pipes are of large size. The head of a system of sewers, or the end or head of a sewer, as to a court of houses, requires both a flushing apparatus to occasionally cleanse the sewer, and a pipe ventilator or ventilating shaft carried up to carry off the foul air which there collects. Other systems have been suggested. Various attempts have been made to create strong upcast draughts by furnace chimneys, cowls, or other artificial means, but these attempts have never been more than locally—and then only partially—successful.

1887*c*. Whilst on the subject of sewerage, it may be well to refer to the new system of raising the sewage from a low to a higher level by means of Shone's hydro-pneumatic sewage ejector. This successful system, as carried out at the Houses of Parliament, is described in the *Transactions* of the Royal Institute of British Architects, 1887, iii., new series, and in *British Architect* for January 28, 1887, p. 69. The work was performed thus: in the bottom of the old main brick sewer, about 1000 feet long, passing from north to south under the Houses, a 12-inch cast-iron drain was embedded in concrete, with a fall of about 1 in 212. This received all the sewage of, and rain falling on, the Houses and grounds, and was discharged into a receiver at the bottom of a sewage manhole. From the side of the receiver a 12-inch cast-iron inlet pipe is carried horizontally into the adjoining ejector chamber, in which are three cast iron ejectors, one being capable of discharging 480 gallons, and the other two 335 gallons each, per minute. The sewage is conveyed into them by a 6-inch cast-iron pipe. From the bottom of each ejector a 6-inch cast-iron pipe passes vertically upwards into a 12-inch cast-iron horizontal outlet pipe, which is carried through a dam built in the old main sewer, and discharges beyond it into the old outlet communicating with the Low Level Sewer, and above the normal flow of sewage therein.

1887*d*. Compressed air is used for ejecting the sewage, &c., from the ejectors by Atkinson's differential gas engines—four of them, each of 4 horse-power. Usually one only is employed. There is an automatic arrangement for conducting the air, and ball valves for admitting and expelling the sewage. The compressed air in the ejector is discharged by a pipe leading into the ventilating shaft passing up the clock tower. The amount of sewage ejected in *dry* weather is found to average no more than 40 gallons per minute, so that a 6-inch pipe would carry away all the sewage produced in the Houses. Fresh air is admitted into the subway and chamber, &c. There is also a 9-inch main branch drain under the basement along the west side of the Houses, which is also ventilated. The total cost of the works, including the four gas engines, the three compressed air receivers, the piping, and the three ejectors, has been a little over 11,500*l*.

Drains.

1888*a*. Into the public sewers are carried the *drains* from the houses. These drains were formerly made of brick, and called "gun-barrel drains" from their circular shape. In course of time they got out of order from decay, rats working their way through, and other causes, so that foul matters soaked through into the soil, which thus became saturated, and foul air ascended into the house. Such drains have been discarded since the introduction, about 1845, of *pipes* into the sewerage and drainage system. These pipes are made of vitrified stoneware, and are very different to the glazed or unglazed earthenware pipes sometimes substituted for cheapness. The sewage soon corrodes this glazing, which being removed, the half-burnt earthenware sucks in the foul water and decays. Nor is it nearly so strong as the stoneware pipes; these are also supplied with covers for occasional inspection. Pipes are also made specially, 3 feet long and of a thickness equal to one-tenth of the diameter, with Stanford's patent joints, by J. Cliff and Sons, near Leeds. Messrs. Doulton manufacture a patent self-adjusting joint, securing several advantages.

1888*b*. The main drain necessary for the service of the largest house (we suppose the case of one in the country), if the fall be even but moderate, requires no large dimensions. When we see a small river draining considerable tracts of country, often in section only 8, 9, or 10 feet superficial, it may easily be conceived that the surplus water from, and rain falling on, a mansion is a quantity, even in pressing times, that exacts no large area of discharge to free the place from damp. There are few cases in which the greatest mansion would demand more than a 12-inch or 9-inch pipe, with branches of 6-inch and 4-inch pipe; which, with $3\frac{1}{2}$-inch lead pipes for soil pipes, if properly connected and laid, will suffice for all purposes.

1888*c*. One object in draining a house, a mansion, a village, or a town is to make the drains and sewers so that the sewage in them shall never stagnate at any part, but be constantly flowing with a self-cleansing velocity; and so that the air in them shall never stagnate at any part, but be always flowing, by fresh air passing into their lowest parts, and by foul air discharging from their highest parts into the stratum of the atmosphere above that in which we live and breathe.

1888*d*. There are several systems of draining a country mansion. Near to the main outlet is fixed a large intercepting trap, to be ventilated. Into this passes, by drains on all sides of it, all the water by the rain-water pipes from the roofs, the soil by those from the water closets, and from the pantry and scullery sinks, as well as any surface water from trapped gratings. The waste pipe from the scullery sink should, previously to passing into the drain, be connected with a *grease trap* (see Plumbery). Some of the rain-water pipes may act as inlets of fresh air and also as ventilators to the drain; but occasionally, and especially near traps, other pipes for inlets of fresh air may be provided to prevent what is called "syphoning." These ventilating pipes are to be of the same diameter as the drain, as required by some authorities, or as the soil pipe as by others, to be carried up to the top of any gable or roof of the house, and to some feet above and clear of the chimney pots, so as to prevent foul air from passing down them by down draughts; the top is sometimes open, but they usually have a cap or exhaust ventilator.

1888*e*. The rain or surface water from houses in the country, or on open land, should be carried away into the natural streams by glazed stoneware or fireclay pipes, embedded in concrete if the soil require it, and of diameters varying from 3 to 24 inches or more, laid with a proper fall. Where a building has to be erected on soil which holds water, the site should be drained by the use of agricultural pipes, these being discharged into an open gully leading to the main drain, to a stream, or otherwise where convenient.

1888*f*. *Town drainage* consists of the comparatively clean surface and subsoil water; and of soiled and used water containing organic matters called sewage. The combination of these two waters was established in London towards the end of the last and the commencement of this century, at the time that water supply by pipes to houses became general. This was discharged into the cesspools, and thence by overflow drains into ditches, watercourses, and sewers, open and covered, and thence into natural streams and rivers. The two systems of drainage should, say many persons, be kept separate by the provision of one set of drains for receiving the clean water and discharging it into the natural streams; and of a second set for receiving the dirty water and sewage and conveying it by self-cleansing drains, as fast as it is produced, to prepared agricultural land. This system was recommended by Mr. John Phillips about 1849; but it has not found many advocates, chiefly as it appears to fail from the water in the first portion being removed from the second portion, and thus there is not sufficient to carry off the sedimentary matter, which would be done when the two systems are combined.

1888*g*. The position and size of the drains having been settled, the fall has to be arranged. It has been proved beyond a doubt that matters easily carried away by the increased velocity gained by using a small drain, remain as an obstruction in a large drain. A velocity of 2 feet per second is the least which will keep sewers clear of all ordinary obstructions; while house drains and small pipes require a velocity of 3 feet per second to keep them clear (Hurst). A fall of from 2 inches or 3 inches in 10 feet will be found quite sufficient for all practical purposes. A fall of 1 in 30 is considered by many to be a good fall, and not always to be obtained. Pipes half full, with a velocity of 3 feet per second require the following falls:—4 inch pipes, 1 in 100; 6 inch, 1 in 150; 9 inch, 1 in 225; 12 inch, 1 in 300; 15 inch, 1 in 350; 18 inch, 1 in 450; 24 inch, 1 in 600; 30 inch, 1 in 700. With a velocity of 2 feet per second, 4 inch pipes require a fall of 1 in 200; 6 inch, 1 in 300; 9 inch, 1 in 450; 12 inch, 1 in 600; 15 inch, 1 in 700; 18 inch, 1 in 900; 24 inch, 1 in 1200; 30 inch, 1 in 1400 (Sears).

1888*h*. Hence also the advantage of *flushing* a drain. One person has urged that his ten-roomed house and outbuildings have not, in the course of many years, ever been inconvenienced by the use of a 3-inch drain, whilst other houses of similar size, having 6-inch and even 9-inch drains, have been seriously affected. Much depends on the fall, and on the careful laying of the pipes, and something on the quantity of water used for household purposes. Where a water closet is placed at or near the head of a drain, a stoppage of its pipe often occurs; while grease from the kitchen sink incrusting in the pipe, for want of occasional flushing with hot water, is another frequent cause. Sewers also occasionally require assistance by flushing them from their head. One of the best arrangements proposed is that of an iron tilting cistern, to hold about 90 gallons, inserted in a brick pit at the head of a pipe sewer. This cistern, with its brass bearings and plates, brickwork, stone cover, and water tap, costs about nine pounds, and if one were placed at the head of each pipe sewer in a town, and all were turned off at the same time, a material assistance in keeping the main line also clear, would be found. The "self-acting syphon flush tank" is now much used for such purposes. Rogers Field's patent consists of two concentric tubes, the outer one being closed at the top and steadied by radial ribs projecting from the inner tube. The annular space between the tubes constitutes the ascending or shorter leg, and the inner tube the descending or longer leg, of the syphon (*Builder*, 1879, xxxvii. 1,002). There is another arrangement patented by him, combined with a grease intercepter. (See Water Waste Preventer.) A somewhat similar one is put forward as "Adams' patent flushing syphon." Another by Banner, as in *The Sanitarian's Companion*.

1888*i*. The house drain should be effectually cut off from aërial connection with the common sewer, or any other house drain; also, the house should be cut off from aërial connection with all soil and waste pipes; and all these external pipes and the house drain should be so formed and so connected that they shall at all times be freely flushed with fresh air, and all contribute to their mutual purification. "House drains," writes Mr. Honeyman, "as usually laid at present are not ventilated. A 4-inch drain, as recommended by Sir Robert Rawlinson (*Trans. of Sanit. Inst.*, vol. vi., p. 72) and others, cannot be ventilated by merely leaving openings at each end of it. The friction in such a pipe would neutralise a considerable amount of energy, and there is no energy. The movement of the air is sometimes in one direction, sometimes in the other, and the quantity which gains admission is just about sufficient to promote fermentation and the propagation of organisms, and to allow the escape of abominably polluted air at either end, or into the house if it have the chance. My advice is to increase the size of the drain, to confine the sewage in a narrow channel, and to keep the whole clean. I am not prepared to say that even a well-ventilated house drain would be superior to one absolutely without ventilation, from which atmospheric air is entirely excluded; but it appears to me to be indisputable that there must be either thorough ventilation or none, and that in this case the usual *via media* is the very worst course that can possibly be adopted."

1888*k*. A system has lately (1887) been patented by Mr. H. R. Newton, architect, whereby he shows the absolute necessity for the total enclosure of sewage from air in all ways, to prevent exhalations arising, and to absolutely control the method for their suppression. He points out the injurious influence of forcing air into fouled water in any way, or of allowing fouled water to have any contact with air; drains and sewers, he maintains, should be always full, instead of empty.

1888*l*. Various arrangements are advertised for obtaining access to drains for inspection without the necessity for breaking into them. or for clearing stoppages. At the end of the drain next the sewer (and perhaps at other places) should be formed a manhole or "inspection" chamber, having a syphon trap in it, or between it and the sewer. It may be formed of bricks in cement, sometimes set on a concrete bed, and is usually 3 feet 6 inches by 2 feet 6 inches in the clear, and finished with an air-tight cover, as by a

Yorkshire stone set in cement. The depth of the drain determines the depth of the chamber, which must be larger if very deep. At the bottom of it is an open channel about 9 inches deep, so that it can be ascertained at a glance whether the sewage is flowing properly or not. In the end next the sewer an eye-hole is fixed, to get at the drain between the trap and the sewer, for cleaning, if necessary. The cap to this eye-hole must at all times be securely fixed and sealed.

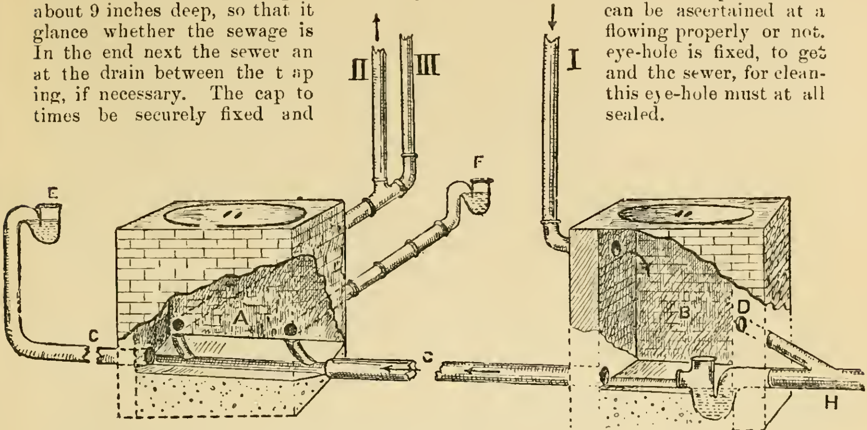

FIG. 615*k*.

A, Inspection chamber at the back of the house. B, Ditto, or manhole, in the front of the house. C, C, C, the drain running from the sewer at the end H, through B, wherein is shown a syphon trap, with a pipe D through which the drain can be cleansed, if necessary. This chamber B is ventilated by a pipe No. I. to let foul air out or fresh air in. The pipe No. II. is a ventilation pipe to the house drain, and also to a soil pipe, No. III. E and F are trapped gullies or gratings in the yards or gardens. Into A would also be carried the drain from the grease trap. This figure is obtained from Catherine M. Buckton's *Our Dwellings, Healthy and Unhealthy*, 8vo., Longmans, 1885, p. 65.

1888*m*. Fig. 615*l*. is a plan and section of the interior of an ordinary town house, showing the position of each sanitary apparatus, as urged by officials and by others. The figure is from Buckton's *Our Dwellings*, 1885, p. 62. *Plan*: E, back kitchen; F, front kitchen; G, front yard or area; H, yard or garden; D, steps down to the basement; *x*, the drain, taking the trapped gully in garden, passing through the inspection chamber *b*, which takes the drain from the water closet soil pipe, and from *a*, the grease trap, with its vent pipe No. IV. from *e*, the sink in the scullery. No. II. is the vent pipe to the house drain, and No. III. the vent pipe to the soil pipe. In the front area, G, is the inspection chamber *r*, through which passes the drain *x*, having *s*, the trap to separate it from the sewer, and into this chamber runs the trapped gully; No. I. is the vent pipe from it. *Section*: A and B are two water closets, the plans are given at the side; and as a sanitary arrangement there should be a lobby, lighted and ventilated, between the water closet and the staircase, somewhat as shown on plan B; *y*, slop sink, with syphon trap passing on to the head of a pipe into the drain. The other letters apply to the above description also.

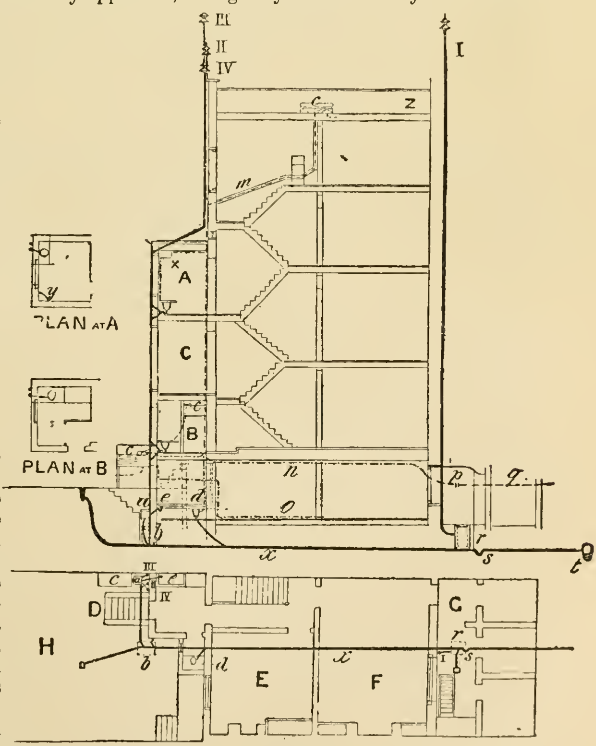

FIG. 615*l*.

Iron Drains.

1888*n*. The "Newman" complete system of *Cast Iron Drainage*, of which the first introducers and sole manufacturers are the North British Plumbing Company. A paper is published by them, *On the use of Cast Iron for House Drains*, by W. D. Scott Moncrieff, C.E., read at the National Health Society's Exhibition, 1883. The advantages of cast iron are put thus: 1, its superior strength and capacity to resist fracture; 2, the greater lengths in which it can be manufactured, and the corresponding reduction in the number of joints; 3, the greater facilities for making the joints secure by means of lead run in, sulphur, oxi ised iron filings, red lead and yarn, &c. The points to be considered in adopting cast iron are: 1, the available means for preserving it; 2, the determination of the capacity and weight of the pipes; 3, the character of the connections best suited to the material; 4, the nature of the joints; 5, the comparative cost. The preserving methods besides paint are: 1, the coating with a preparation of tar, known as Dr. Angus Smith's composition; and 2, the Bower-Barff process, consisting of coating the surfaces of the iron with magnetic oxide after a very careful cleansing, and then painting to protect the surface from being injured too deeply at any time, for if scratched, oxidation quickly follows. They can also be glazed inside. At each end of the drain a manhole can be formed, so that the drain could be swept clean from end to end by a sweep's machine. Some objections have been raised to iron drains, more especially that of the iron cracking, as it is well known iron rain-water pipes will crack, even when protected from the atmosphere.

1888*o*. The pipes in 6 to 9 feet lengths, with inspection covers, curved junctions, are to be laid on concrete, or on a dwarf wall, or on iron bearers, and in a trench or subway under the passage, so that the whole length can be open to inspection at any time. Five-inch pipes are usually adopted, $\frac{3}{8}$ths of an inch thick, giving about 120 lbs. as the weight of a 6 feet length. When the soil pipe is connected to the iron soil drain, a copper ferrule should be wiped on to the end of the soil pipe, the latter being threaded and caulked as for the ordinary iron joint. The joints may also be screw joints. The company also furnish the necessary house drain terminal, manhole covers, flush tank with annular syphon, rain-water flushing head, grease trap, water-waste preventer cistern, mica non-return valve, soil-pipe cowl, improved valve closets, air ventilator and tubes, Winser's channel pipes and bends, straight and taper, in best enamelled stoneware; white enamelled sinks for kitchen and scullery; caulking sleeve of brass, for securing lead pipes in iron sockets, with oakum and lead; and many others of similar modern appliances.

Testing a Drain.

1888*p*. There are several methods of ascertaining if the pipes are properly laid, as well as for finding the place of an escape of smell into the house. 1. By the peppermint test, relying upon smell. This is applied by pouring down the ventilating or other accessible pipe *outside* the house, about two ounces of strong (essence of) peppermint, quickly followed by about two quarts of hot water, the orifice of the pipe being instantly plugged up to prevent the escape into the atmosphere of the scent. If perceived in any room, or closet, or sink, there exists the evil. 2. By the *smoke* test, relying upon sight chiefly, the invention (1883) of Mr. C. Innes, C.E. Straw may be placed in the drain, say at the inspection shaft (if there be one), then saturated with petroleum, and lighted, with care on account of the flare. Then the drain must be covered over so that the smoke shall ascend the drain, escaping at the ventilating pipe, if there be no crack or defect by which also to escape. A pinhole in an iron pipe has thus been detected when the previous test failed to point out the exact spot. Pain's "smoke rockets" burn from ten to fifteen minutes, and emit a dense volume of smoke. "The Banner patent drain grenade" or "drain ferret" is made of thin glass, and charged with powerful pungent and volatile chemicals. When the grenade is dropped down any pipe it breaks, and the effect produced by its contents is distributed only as intended. When drains to be tested by the smell or smoke test pass through a house, care must be taken to close all openings; and when applied outside, the openings should be closed, to prevent any smell entering from the outside.

1888*q*. In places where the drain is deep and has been laid in clay with rubbish over, and perhaps finished by concrete with a coat of cement over, or tile, or other paving, if the ground be probed with an iron or steel rod to the bottom of the trench, it has been found that smoke was actually issuing from the drain; and it also showed the state of the ground, the point of the probe indicating the nature of the soil at the bottom of the trench. A third test is the *water test* to the main drain of a house. The pipes have to be stopped up at both ends in order to be filled with water, and some upright part formed, or selected, for the purpose of observing if the drain hold the water, or the reverse. The ends of the branches into it having been also stopped up, the water may then be turned on, and the pipes filled to a part marked on the upright pipe. It is then to be carefully watched to ascertain if the water falls below the mark; should it do so, it at once proves that there is a leak somewhere. (James Stewart, senr.)

1888*r*. Among other general and special recommendations (Woodward, in R.I.B.A. *Transactions*, with additions), are the following:—

1. Constant supervision during the laying of drains, to secure good workmanship both in the laying and jointing.

2. Drains are best laid when the carcase is completed and the roof put on. They are not required sooner, and they are then less likely to be disturbed. If left for a later time they may probably be hurried over.

3. Wherever possible, drains should be laid outside the house. When inside, their direction should be indicated on the floor by a sufficient width of the floor material being laid so as to be easily taken up at any time to obtain complete access to the drains.

4. All old drains and cesspools, and all soil which has been in contact with or saturated by any of them, should be entirely removed from the premises.

5. Junctions should always be made by a gentle curve or bend with the length of the pipe, and never at a right angle.

6. A regular and uniform fall should be secured; a too great fall may rapidly carry away the liquid while the soil remains.

7. The pipes should, if the soil be soft, be laid in a bed of concrete or on well-tempered clay puddle, and formed to suit the curve of the pipe.

8. The joints of all pipes should be well socketed, and the pipes should have a full bearing on the bed, not being allowed to bear only on the joint, so that channels should be formed in the bed, or be cut out for the sockets to rest in.

9. The joints should be carefully cemented or clayed in all round; not the least particle of cement or clay should remain on the inside of the pipes, as on hardening it forms an obstruction and the nucleus for stopping the drain.

10. All traps should be earthenware syphon traps, with inlets and covers, with ready access for cleaning out. Grease traps for scullery sinks should be ready of access for periodically removing the grease, which otherwise passes into the drain and assists in forming an obstruction. These traps should be ventilated.

11. As flushing plays an important part in all systems of drainage, the waste water from sinks, baths, rain-water pipes, &c., should pass down the house drain. Lately, in some systems, these have been kept distinct from the soil drains; but as very little water accompanies the one emptying of a water closet apparatus, there is much danger of soil remaining, an evil which is avoided by the flushing obtained from the other sources.

12. At the junction of pipes a shaft or inspection chamber should be formed, with a proper cover, to allow of access to the pipes, and by which rods may be passed up and down the drain in case of a stoppage.

13. Before the drain enters the sewer, and outside the house, a similar shaft should be built, with a stone or iron cover well cemented down, and a syphon trap fixed on the sewer side of the shaft, with a ventilating pipe carried up well above the roof of the house.

14. All overflows, wastes, and rain-water pipes should discharge over an open gully trap, and not be connected direct into the drain. Where practicable, gully traps should be fixed outside a building.

15. Air inlets should be fixed as far as possible from windows and doors.

16. If the drain has but a slight fall the use of a flushing tank is indispensable.

1888*s*. The importance of sanitary inspections may be shown in the necessity of some modifications to the existing drainage of a house. The following remarks and suggestions will be useful to the investigator:—"It cannot be too strongly impressed on the public mind, that to make a house fairly safe from dangerous inroads of sewer gas (or smell), as it is termed, is not by any means a gigantic undertaking. In the case of a new house, an architect of ordinary professional capacity is quite alive to the modern ideas of sanitation, and he will no doubt see that, so far as his client permits him, all that is proper to be done is thoroughly carried out. The difficulties become apparent when he has to deal with an old house, the drains of which he knows nothing about; but even here the task of securing safety from poison from the sewer is not such a very hard one. Take, for example, an *ordinary street house*. The water closet apparatus is of the old kind, perhaps set in an apartment in the centre of the house, without any communication with the open air. The sink waste is directly connected with the drain, supposed to be protected by an old bell-trap, which is of little use. The cistern has the old standing waste pipe, also directly connected with the drain, and serves the sink as well as the water closets. The rain-water pipes are also directly connected with the drains, which run under the kitchen floor or basement passage, and uninterruptedly onwards to the old iron flap trap (at the sewer), which, if it exists, or is in right action, is the only opposing force to direct contact with the main sewer in front.

1888*t*. "Now this is, apparently, a very alarming state of things, to be remedied only (some would say) by the removal of pipes, cisterns, and apparatus throughout the house, involving perhaps the dislocation of everything in it, and the substitution of the net-work of arrangements of modern sanitation. If the client be willing to carry out these elaborate notions, there can be no objection to his having them; but for the larger class the following will, in ordinary cases, be sufficient to arrest danger; first supposing that the water closets, sinks, and cisterns, are in a proper state of repair, and that the drains or other pipes are all clear.

1888*a*. "Take up the paving of the front area where the main drain runs through to the sewer. Cut out a length or so of the drain, and build, in 9 inch brickwork, a shaft 3 feet by 2 feet. Render it inside in Portland cement. At the bottom let in a half drain pipe, and at the sewer side fix a syphon trap. Connect with the shaft two 4-inch drain pipes, one on either side of the shaft; or carry up a 4-inch galvanized iron pipe a short distance to form inlets. If a rain-water pipe be near at hand, the joints may be caulked, and it may be connected with the shaft by one of the pipes; carry it well up above the roof, and treat it as the outlet ventilator. If a rain-water pipe is not near at hand, carry up from the shaft, and well above the roof, a separate 4-inch galvanized iron ventilating pipe. Cover the shaft with a York stone, or iron cover, and the drain job is done. As regards the water supply, the cistern should be well cleaned out periodically, say once a month, and there will not be much to fear in that direction."—Woodward, *London as it is and as it might be*, read at Royal Institute of British Architects, and printed in *Transactions*, new series, vol. ii. p. 46.

Sect. II.

BRICKLAYING AND TILING.

1889. Bricklaying, or the art of building with bricks, or of uniting them by cement or mortar into various forms, includes, in the metropolis, and mostly in the provinces, the business of walling, tiling, and paving with bricks or tiles, and sometimes plastering; but this last is rarely, if ever, undertaken by the London bricklayer; though in the country the trades of bricklaying and plastering are usually united, and not unfrequently that of masonry also. The materials used have been described in a previous part of the work, to which the reader is referred (1811. *et seq.*).

SHORING.

1889*a*. It is advisible that the student should be acquainted with the mechanical principles involved in the construction of shores, and the nature of the forces which are brought into play. G. H. Blagrove, in *Shoring and its Application*, 1887, writes: "Though the student has to learn the principles of Shoring, the practising architect has to apply them, often in the utmost haste, to prevent the most disastrous consequences, and occasionally surrounded with the most perplexing difficulties. Viollet-le-Duc says: 'Nothing enhances the respect of workmen for the architect like his being ready to shore properly . . . and nothing is more satisfying to the eye than a system of shoring well combined and well executed.'" The author divides his book into Raking, Flying and Dead Shoring, Needling, Centreing, Timbering for Excavations, Underpinning, and Straightening Walls. In Raking Shores is explained the danger of using timber unnecessarily heavy for the purpose, and the danger of the vertical sinking of a wall, causing the shores to separate it; also the advantage of shoring against the floors, and the proper precautions to be taken for shoring, of a more permanent and efficient kind than the rough and ready shoring so often resorted to. In the case of Flying Shores there is the risk of their sagging, though this may generally be obviated by using trusses, particularly when the flying shores are in more than one height. Little has to be said about "dead shores," but the rough way in which they are often put in is detrimental to the building. In the chapter on Needling the necessary precautious are carefully stated, but the proper calculation of the strength of the needles is not urged. The devices which have been put in practice at times to save expense, viz., the iron frames which enable the bressummer to be rolled in lengthwise, the case where the bressummer has to be enclosed in the frames, then got in parallel and rolled end on to its place, and where it is only put in parallel, are also explained. Two devices are not noticed: one where the middle of a wall has to be removed, but where an arch can be turned; the arch form is marked in chalk on both sides of the wall, holes beginning at the skewbacks are successively cut to the shape of the arch by men working on both sides, and the segments are then built in and wedged up, until the whole arch is turned without using needling, and, when the cement has set, the brickwork below is cut away. The other is executed thus: narrow iron girders, not exceeding one-fourth of the thickness of the wall, are cut in, and fixed on both sides, then York stone is pinned in on the top of them, connecting the two girders, which are also bolted together. The brickwork below is then removed. This system will in most cases supersede all others. Careful advice is given for shoring up defective arches and vaults; and a French plan of supporting centreing on wood by pistons fitted into iron cylinders filled with sand; by this means the centreing can be accurately slackened by letting out the sand. The familiar methods of Timbering Excavations are given. Where the earth will not stand, sheet piling is recommended, 4 ft. wide, but 4 ft. 6 in. is generally considered to be the least width in which men can conveniently excavate. In Underpinning, the author points out the difficulties of shoring when the defects have arisen from the ground being too soft; he shows the shoring necessary for crushed piers and columns, and adverts to the movements occasioned by underpinning, on parts apparently too distant to be affected by them. Descriptions are given of the methods employed in straightening walls, as at Armagh Cathedral, Beverley Minster, and St. Albans Abbey. (G. Aitchison, in R.I.B.A. *Proceedings*. *The Mechanics of Shoring*, in *Building News*, Sept. 14, 1877, p. 249.)

1890. The tools used by the bricklayer, who has always an attendant labourer to supply him with bricks, mortar, &c., are—1. A *brick trowel*, for taking up and spreading the mortar, and also for cutting the bricks to any required length. 2. A *hammer*, for cutting holes and chases in brickwork. 3. The *plumb rule*, being a thin rule, 6 or 7 inches wide, with a line and plummet swinging in the middle of it, in order to ascertain that the walls are carried up perpendicularly. 4. The *level*, which is about 10 or 12 feet long, with a vertical rule attached to it, in which a line and plummet are suspended, the use of which is to try the level of the walls at various stages of the building as it proceeds, and particularly at the window sills and wall plates. 5. The *large square*, for setting out right angles. 6. The *rod*, for measuring lengths, usually 5 or 10 feet long. 7. The *jointing rule*, about 8 or 10 feet long, as one or two bricklayers are to use it, and 4 inches broad, with which they *run* or mark the centre of each joint of the brickwork. 8. The *jointer*, which is of iron, shaped like the letter S. 9. The *compasses*, for traversing arches and vaults. 10. The *raker*, a piece of iron having two knees or angles, dividing it into three parts at right angles to each other, the two end parts being pointed and equally long, and standing upon contrary sides of the middle part. Its use is to rake out decayed mortar from the joints of old walls for the purpose of replacing it with new mortar, or, as it is called, *pointing* them. 11. The *hod*, which is a wooden trough shut close across at one extremity and open at the other. The sides consist of two boards at right angles to each other; from where they meet a handle projects at right angles to their union. It is used by the labourer for conveying bricks and mortar to the bricklayer; for which purpose, when he has the latter office to perform, he strews dry sand on its inside, to prevent the mortar from sticking. 12. The *line pins*, which are of iron, for fastening and stretching the line at proper intervals of the wall, that each course may be kept straight in the face and level on the bed. The pins have a line attached to them of 60 ft to each pin. 13. The *rammer*, used for trying the ground, as well as for beating it solid to the utmost degree of compression. 13. The *iron crow* and *pick axe*, for breaking and cutting through walls or moving heavy weights. 14. The *grinding stone*, for sharpening axes, hammers, and other tools. The following ten articles relate entirely to the preparation and cutting of gauged arches. 15. The *banker*, which is a bench from 6 to 12 ft. long, according to the number of workmen who are to work at it. It is 2 ft. 6 inches to 3 ft. wide, and about 2 ft. 8 in. high. Its use is for preparing the bricks for rubbed arches, and for other gauged work. 16. The *camber slip*, a piece of wood, usually about half an inch thick, with at least one curved edge, rising about 1 inch in 6 feet, for drawing the sofite line of straight arches. When the other edge is curved, it rises about half that of the other, that is, about half an inch in 6 feet, for the purpose of drawing the upper line of the arch, so as to prevent it becoming hollow by the settling of the arch. The upper edge is not always cambered, many preferring it straight. The slip being sufficiently long, it answers the width of many openings; and when the bricklayer has drawn his arch, he delivers it to the carpenter to prepare the centre for it. 17. The *rubbing stone*. This is of a cylindrical form, about 20 inches diameter, but may be less. It is fixed at one end of the banker, upon a bed of mortar. After the bricks for the gauged work have been rough-shaped by the axe, they are rubbed smooth on the rubbing stone. The headers and stretchers, in return, which are not axed, are called *rubbed returns* and rubbed headers and stretchers. 18. The *bedding stone*, which is a straight piece of marble 18 or 20 inches in length, of any thickness, and about 8 or 10 inches wide. It is used to try the rubbed side of a brick, which must be first squared to prove whether its surface be straight, so as to fit it upon the leading *skew back*, or leading end of the arch. 19. The *square*, for trying the bedding of the bricks, and squaring the sofites across the breadth of the bricks. 20. The *bevel*, for drawing the sofite line on the face of the bricks. 21. The *mould*, for forming the face and back of the brick, in order to reduce it in thickness to its proper taper, one edge of the mould being brought close to the bed of the brick when squared. The mould has a notch for every course of the arch. 22. The *scribe*, a spike or large nail, ground to a sharp point, to mark the bricks on the face and back by the tapering edges of the mould, for the purpose of cutting them. 23. The *tin saw*, used for cutting the sofite lines about one eighth of an inch deep, first by the edge of the level on the face of the brick, then by the edge of the square on the bed of the brick, in order to enter the brick axe, and to keep the brick from spalting. The saw is also used for cutting the sofite through its breadth in the direction of the tapering lines, drawn upon the face and back edge of the brick; but the cutting is always made deeper on the face and back of the brick than in the middle of its thickness, for the above-mentioned purpose of entering the axe. The saw is also used for cutting the false joints of headers and stretchers. 24. The *brick axe*, for axing off the sofites of bricks to the saw cuttings, and the sides to the lines drawn by the scribes. The bricks being always rubbed smooth after axing, the more truly they are axed the less labour will be requisite in rubbing them. 25. The *templet*. This is used for taking the length of the stretcher and width of the header. 26. The *chopping block*, for reducing the bricks to their intended size and form by axing them. It is made of any piece of wood that comes to hand, from 6 to 8 inches square, and generally supported upon two 14-inch brick piers, if only two men work at it; but if four men, the chopping block must be lengthened and supported by three piers, and so on according to the number employed at it. It is about 2 ft. 3 in. in height. 27. The *float-stone*, which is used for rubbing curved work to a smooth surface, such as the cylindrical backs and spherical heads of niches, to take out the axe marks. It is, before application to them, made of a form reversed to the surface whereon it is applied, so as to coincide with it as nearly as possible in finishing.

Bonding.

1891. Before adverting to the *bond*, as it is technically called, of brick walling, which is the form of connection of the bricks with each other, it must be observed that in working walls not more than 4 or 5 feet should be brought up at a time; for as, in setting, the mortar shrinks and a general subsidence takes place, the part first brought up, if too large in quantity, will have come to its bearing before the adjacent parts are brought up, and thus fissures in the work and unequal settlements will take place. In carrying up any particular part above another, it should always be regularly sloped back to receive the adjoining parts to the right and to the left. On no account should any part of a wall be carried higher than one scaffold, except for some very urgent object.

1892. Previous to the reign of William and Mary (1689–1702), brick buildings in England were constructed in what is called *English bond*; and subsequent to the reign in question, when, in building as in many other cases, Dutch fashions were introduced, much to the injury of our houses' strength, the workmen have become so infatuated with what is called *Flemish bond*, that it is difficult to drive them out of it. To the introduction of the latter has been attributed (in many cases with justice) the splitting of walls into two thicknesses; to prevent which, expedients have been adopted which would be altogether unnecessary if a return to the general use of English bond could be established.

1893. In chap. i. sect. ix. of this book (1503. *et seq.*) we have spoken generally on walls; our observations here, therefore, in respect of them, will be confined to brick walls and their bond.

1894. *English bond* is that disposition of bricks in a wall in which (expect at the quoins) the *courses* are alternately composed of *headers* and *stretchers*. In brick walling, and indeed in stone walling also, a *course* means the horizontal layer of bricks or stones of which the wall is composed, being contained between two faces parallel to the horizon, and terminated on each side by the vertical face of the wall. The mass formed by brick or stones in an arch are also termed courses, but receive the name of concentric courses. The term *header* is applied to a brick or stone whose small head or end is seen in the external face of the wall; and that of *stretcher* to a brick or stone whose length is parallel to the face of the wall. English bond is to be understood as a continuation either of header or stretcher, continued throughout in the same course or horizontal layer, and hence described as consisting of alternate layers of headers and stretchers (*fig.* 616.), the former serving to bind the wall together in a transverse direction or widthwise and thus prevent its splitting, whilst the latter binds it lengthwise, or in a longitudinal direction. None but the English bond prevents the former occurrence, as work executed in this way when so undermined as to cause a fracture, separates, but rarely breaks through the solid brick, as if the wall were composed of one entire piece.

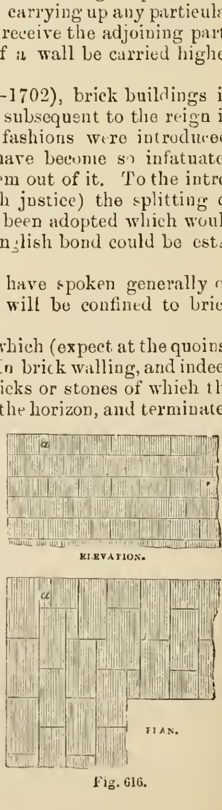

Fig. 616.

1895. The ancient Roman brickwork was executed on this principle; and its extraordinary durability is as much to be attributed to that sort of work being used for bonding it together, as to its extraordinary thickness.

1896. In this, as well as Flemish bond, to which we shall presently come, it will be observed, that the length of a brick being but 9 inches, and its width $4\frac{1}{2}$ inches, in order to *break* the joints (that is, that one joint may not come over another), it becomes necessary near the angles to interpose a quarter brick or *bat*, *a*, called a *queen closer*, in order to preserve the continuity of the bond in the heading course. The bond, however, may equally be preserved by a three-quarter bat at the angle in the stretching course, in which case this last bat is called a *king closer*. In each case an horizontal lap of two inches and a half is left for the next header. The figure above given is that of a two-brick or 18-inch wall, but the student will have no difficulty in drawing, on due consideration of it, a diagram of the bond for any other thickness of wall; recollecting, first, that each course is formed either of headers or stretchers. Secondly, that every brick in the same course and on the same face of the wall must be laid in the same direction, and that in no instance is a brick to be placed with its whole length against the side of another, but in such way that the end of one may reach to the middle of the others that lie contiguous to it, excepting in the outside of the stretching course, where three-quarter bricks, or king closers, will of course be necessary at the ends, to prevent a continued upright joint in the face of the work. Thirdly, that a wall crossing at right angles with another will have all the bricks of the same level course in the same parallel direction, whereby the angles will be completely bonded. We shall close these observations with a recommendation to the young architect, founded on our own experience, on no account, in any building where soundness of work is a desideratum, to permit any other than English bond to be executed under his superintendence.

1897. *Flemish bond* is that wherein the same course consists alternately of headers and stretchers, which, in appearance, some may fancy superior to that just described. Such is not our opinion. We think that the semblance of strength has much to do with that of beauty in architecture. But there is in the sufferance of Flemish bond a vice by which strength is altogether lost sight of, which we shall now describe. It was formerly, though now partially, the practice to face the front walls of houses with guaged or rubbed bricks, or with at least a superior species of brick, as the malm stock; in the former cases, the bricks being reduced in thickness, and laid with a flat thin joint frequently, what the workmen call a *putty joint*, for the external face, the outer and inner work of the same courses in the same wall, not corresponding in height, could not be bonded together except where occasionally the courses fell even, where a header was introduced from the outside to tie or bond the front to the internal work. Hence, as the work would not admit of this, except occasionally, from the want of correspondence between the interior and exterior courses, the headers would be introduced only where such correspondence took place, which would only occur in a height of several courses. Thus a wall two bricks in thickness, if faced on both sides, was very little indeed better than three thin walls, the two outer half a brick thick, and the middle one a brick or 9 inches thick. Bricklayers having little regard for their character will, if not prevented by the architect, not only practise this expedient, but will also, unless vigilantly watched, when a better sort of brick is used for the facing, cut the headers in half to effect a paltry saving of the better material. In walls of one brick and a half in thickness, the strength of the wall is not diminished by the use of Flemish bond so much as in those of greater thickness, as may be seen by the diagram (*fig.* 617.). Many expedients have been invented to obviate the inconveniences of Flemish bond; but we think it rather useful to omit them, lest we should be considered as parties to a toleration of its use, for the continuation whereof no substantial reason can be assigned. As we have before observed, all that can be alleged in its favour is a fancy in respect of its appearance: but were the English mode executed with the same attention and neatness bestowed on the Flemish method, we should say it was equally beautiful; and therefore we shall thus close our notice of it.

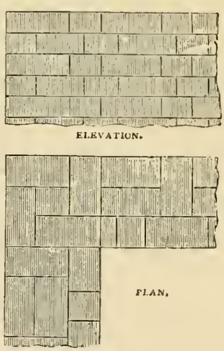

Fig. 617

1898. The two principal matters to be considered in brick walling are, first, that the wall be as strong as possible in the direction of its length. Secondly, that it be so connected in its transverse direction that it should not be capable of separating in thicknesses. To produce the first, independent of the extraneous aid of bond timbers, plates, &c., it is clear that the method which affords the greatest quantity of longitudinal bond is to be preferred, as in the transverse direction is that which gives the greatest quantity of bond in direction of the thickness. We will, to exemplify this, take a piece of walling 4 bricks long, 4 bricks high, and 2 bricks thick, of English bond: in this will occur 32 stretchers, 24 headers, and 16 half headers to break the joint, or prevent one joint falling over another. Now, in an equal piece of walling constructed in Flemish bond, there will occur only 20 stretchers and 42 headers; from which the great superiority of English bond may be at once inferred.

1899. *Bond Timber* should be used in pieces as long as circumstances will admit. In walls where the thickness will allow of it, some prefer that the timber should be laid in the centre, so that when it decays no material damage is done. Also that in case of fire, the bond timber is not affected by it. If so placed, when dressings of wood are required, wooden plugs must be provided to which to secure them. When a fire occurs and the bond is next the inside face, it is burnt out, and the strength of a thin wall, say 9 or 14 inches thick, is seriously affected thereby. Two or three tiers in the height of the room are usually employed.

1899*a*. However useful timber may be in bonding thin walls whilst the brickwork is yet green, it has for some years been entirely superseded by *hoop iron bond.* This consists of narrow and thin strips of iron (see SMITHERY) laid between two courses of bricks. The iron should be tarred and sanded, the former as a preservative from rust, the latter to afford a firmer hold to the mortar. Some authorities go so far as to state that hoop iron bond, unless it is set in a cement course, is not so efficient as wood bond. A tier of bond is placed in each three feet of height, one strip of iron to each half brick. In extensive works, or in special cases, two, three, or more, tiers are recommended. In addition to the use of concrete on clay soils, it may be occasionally useful to build all the footings for four or six courses in height of brickwork in cement, each course well bonded with hoop iron, laid both longitudinally and diagonally; it is perhaps better than a course of Yorkshire stone (par. 1882.) as the bond is continuous. During the execution of the works, the iron is continued through all openings as with wood bond; the latter is cut away when requisite, but the former should be turned down against the brickwork. The laps at a junction should be carefully made to secure the continuity of the tie. An addition to the plain band of iron has been introduced, and *Tyerman's patent notched hoop iron bond* has been extensively employed. It consists in forming a slight notch at intervals of $11\frac{3}{4}$ inches on both sides alternately, and turning it up in succession, in contrary directions, forming a triangular piece, whereby a better key is obtained upon the bricks and mortar.

1900. *Mortar joints.* The propriety of using mortar beds as thin as possible, has been inculcated in this work, and most specifications state that four courses of brickwork formed of the ordinary sized bricks are not to rise more than $11\frac{3}{4}$; sometimes 12 inches is named. as the joints should not exceed $\frac{3}{8}$ths of an inch. When good mortar is used that sets rapidly, the joint might be thicker than thus allowed. In Roman and most Eastern work, the joint was usually 1 and $1\frac{1}{4}$ inches thick, and where the mortar has been good, such buildings so executed are sound after centuries of wear. "In modern practice, in all masonry and brickwork where strength is required rather than ornament, thick beds and joints of good mortar will be useful. Thin bricks or tiles will also be better than thick bricks, as the material will be better burned, and consequently more enduring. More good mortar can also be used, which in such work gives strength." Such is the practical opinion of R. Rawlinson (*Builder*, xxi. page 152), who declares that "the proportion of mortar to rubble stonework should be about 1 to 3, that is, in 4 cubic yards of rubble wall there should not be less than 1 cubic yard of mortar. In brickwork (ordinary bricks) the proportion will be 1 to 4. If thin bricks be used, or if very small stone be used for rubble-work, the proportions may be as 1 to 1." It has been urged that the peculiarity of early Norman masonry, even of the period of bishop Gundulph, is that of very thick beds of mortar. Mr. Rawlinson further adds, "As a general rule, buildings whether of marble, limestone, sandstone, or of brickwork alone, or of brick and terracotta combined, which are ornamental in character, must all have *thin* joints and beds. Thick beds and joints of mortar would destroy the harmony of design by deteriorating the appearance of labour bestowed on the rich materials in such buildings."

1900*a*. The fine joints of rubbed brickwork are formed by lime putty, being mortar reduced to the consistency of cream; the bricks are dipped into it to take up a coating, and then driven close upon each other. Ashlar work is usually set in a putty formed of lime, white lead, and a small quantity of very fine sand.

1900*b*. The surfaces of many of the machine-made bricks are so hard as to prevent the mortar sticking, unless first coated with sand. Many walls on being pulled down have shown that the mortar had had no hold upon the bricks; a key had only been formed between two bricks by the holes at their ends. A wall, though built in first-rate work, was easily shaken to pieces, even after it had been built four or five years. Bricks, especially in hot weather, should be soaked in water (par. 1832*a*.); and even some of the courses of bricks should be sprinkled with water, to prevent the brick absorbing all moisture from the mortar before the lime has had time to crystallise. The walls, however, take longer to dry; as is also the case when grouting (par. 1860.) is employed. An interesting communication from Norway has been printed in the *Journals* of January, 1888, explaining how brickwork is carried on there in the winter; "such walls dry quicker than those raised in summer." The description is too long to be here further adverted to.

1900*c*. The mortar or cement should be such as will quickly set, to prevent the superincumbent weight pressing the joints closer, and thereby causing settlements, which even with the greatest care, often take place unequally. As often as it is conjectured, from the nature of the soil, or from the foundation being partly new and partly old, that the work will not come to its bearing equally, it is better to carry up the suspected parts separately, and to leave at their ends what are called *toothings*, by which junctions may be made when the weaker parts have come to their regular sound bearing.

1900*d*. The thickness of walls has furnished the subject of previous pages: we shall therefore only add, that too much care cannot be bestowed on strengthening all angles as much as possible, and well connecting the return of one wall into another; that piers or pilasters are exceedingly useful in strengthening walls, inasmuch as they act by increasing the base whereon the whole stands; and, lastly, that in carrying up walls to any considerable height, it is usual to diminish their thickness by *sets off* as they rise. In houses, above the ground-floor, the sets off are usually made on the inside, having the outside in one face; but, if it be possible, it is better to set off equally from both faces, because of the better balance afforded.

1900*e*. *Joints* in brickwork are finished on the face in several ways. The most common are the 'struck joint,' which is merely finishing the joint by drawing the point of the trowel along it: or 'jointed,' as done by a tool called a *jointer* (par. 1890, art. 8), so as to leave a line impressed on the mortar: or 'flush joint,' in which case the joint is drawn at top and bottom with the trowel when the brick is laid, and afterwards when the mortar is partially set, the middle of the joint is flushed flat with the 'jointer;' this is sometimes called a 'high joint.'

1901. A bricklayer, with the assistance of one labourer, can, if he be so inclined, lay in one day about 1000 bricks in common walling; but the trades unions now prevent him from laying more than about one-third that number. Occasionally, for a higher remuneration some non-union man may be found to lay near the former number, and then he would complete a rod of brickwork in four days and a half, its area being $272\frac{1}{4}$ feet superficial of the thickness of one brick and a half. When, however, there are many apertures or other interruptions to his work, he will be proportionably longer over it. The weight of a rod of brickwork is about 13 tons. Generally it may be taken as consisting of from 4300 to 4500 stock bricks, allowing for waste according to the quality of the bricks. 27 bushels of chalk lime, and 3 single loads of drift sand, or 18 bushels of stone lime and $3\frac{1}{2}$ single loads of sand. In cement, of 36 bushels, and the same quantity of sharp sand. A rod of brickwork laid dry contains 5370 bricks. A cubic yard contains 384 bricks, and requires about $6\frac{1}{2}$ cubic feet of sand and $2\frac{1}{2}$ of lime. A ton of bricks contains about 373 on an average. 330 well burnt bricks weigh generally about 20 cwt., so that a cubic foot weighs about 125 lbs.

1902. *Brick-nogging* is a method of constructing a wall or partition with a row of posts or quarters 3 feet apart, whose intervals are filled up with occasional plates of wood with brickwork between. It is rarely more than the width of a brick in thickness, and the bricks and timbers on the faces are flush. It should never be used where thickness can be obtained for a nine-inch wall. A half brick nogged partition will require about 500 bricks; a whole brick-nogged partition about 1000 bricks; and with brick on edge about 340.

1902*a*. A *half-brick partition* built in mortar is now adopted in many of the model lodging houses, sometimes with an occasional hoop iron bond. These are built four, five, and six stories in height, the joists of the floors steadying them as they are carried up. Of course the apartments in such places are small in all their dimensions, being about 12 feet long, 9 feet wide, and from 9 to 9 feet 6 inches in height. A half-brick wall of greater dimensions may be built in cement, and when the floor joists are laid upon it, it becomes very steady, strong, and little likely to be injured by a fire. Thin slabs of stone have been used as partitions in small houses near a quarry. Tiles in cement with wood plugs inserted for the dressings, make a sound partition, and when plastered direct upon the tiles, it takes up much less room than a one-brick wall.

1902*b*. Many varieties of *hollow bricks* are made for a similar purpose. The "patent bonded hollow bricks or rebated tiles" (*fig.* 617*a*.) of Hertslet and Co., were employed in 1846–7, by Henry Roberts in the model lodging house in George Street, St. Giles's; as also in the so-called Prince Albert's model houses, erected in Hyde Park in 1851, and removed to Kennington Park. A is a bond stone; B concrete, C floor boards, and D a tie rod. When used for partitions, or for roof and floor arches, these hollow bricks are fireproof, deaden sound more effectually, and are considerably ligher, than solid brickwork. Such bricks as a lining to stone or flint walls, supersede the necessity for battening. They are also well adapted for cottage floors. *Hollow bricks* can be made by any good tile machine,

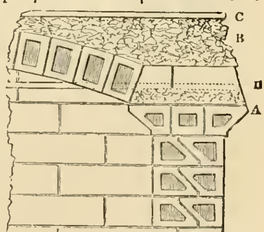

Fig. 617a.

in the same manner as ordinary drain-pipes. They are more compressed, require less drying, and are generally better burned than ordinary bricks. An interesting and complete paper on the subject, with illustrations on the English and French systems of making hollow bricks, is given in the *Building News* for 1858.

1902*c*. Hollow walls, formed of ordinary stock bricks, were employed for two-story cottages early in this century. Three methods are usually adopted in the construction of a wall. I. All the bricks placed on edge, as *fig.* 617*b*, the stretchers and headers breaking joints, and the headers forming the bond. Many persons consider that this arrangement produces a disagreeable appearance on the outside face. II. All the bricks laid flatways, but the stretchers are sawn in half, so as to leave a space of $4\frac{1}{2}$ ins. between them; and in laying the headers, as *fig.* 617*c*. care must be taken only to fill up with mortar the joints over the half brick on edge, so as to leave the middle of the joint open.

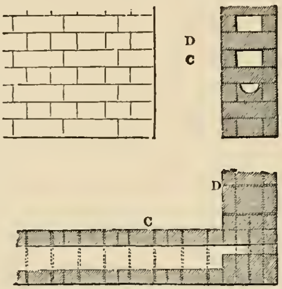

Fig. 617*c*.

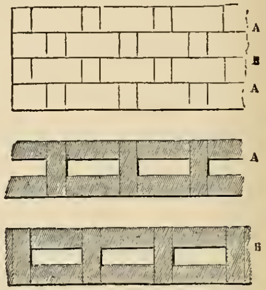

Fig. 617*b*.

III. To lay all the bricks flat in the usual English bond, leaving a space of about 2 inches between each face, and to make up the thickness thus caused, viz. 11 or $11\frac{1}{2}$ inches, by a bat to each header. This may be varied by using a less number of headers, and placing two or three stretchers together, according to the strength of the work required. At Southampton, and perhaps elsewhere, headers are not used, the two faces being bonded together by hoop-iron cramps (*fig.* 617*d*.), with forked ends, $\frac{13}{16}$ths by $\frac{1}{10}$th inch, tailing into the frogs of the brick (*fig.* 617*e*.), and having a bend in the middle of its length partly as a strut to the inside, and partly to prevent any moisture running along it to the inside face.

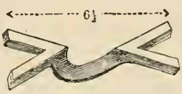

Fig. 617*f*.

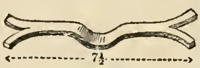

Fig. 617*d*.

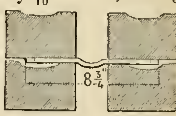

Fig. 617*e*.

A cast iron cramp (*fig.* 617*f*.) is also made, $\frac{1}{2}$ inch by $\frac{3}{16}$ths in. thick. Jennings has adopted *bonding bricks* of stoneware for hollow walls. *Fig.* 617*g*. shows the application of the three sizes; A is $13\frac{1}{2}$ inches long, to be used in garden walls and other places where an uniform face is not required; B is $11\frac{1}{4}$ inches long, where but one uniform face is required (the brick is shown to a larger size in *fig.* 617*h*.) the end of the bond brick being faced with a closure of the same material as the wall; and C is a brick 9 inches long, when both faces are to be uniform, closures being used at both ends of it. A 16 inch hollow wall can be built with a 9 inch inside wall, a 2 inch space, and a $4\frac{1}{2}$ inch wall outside, and so on. Such a wall is of very common erection in North America, and it is found to stand very well for country villas of good dimensions.

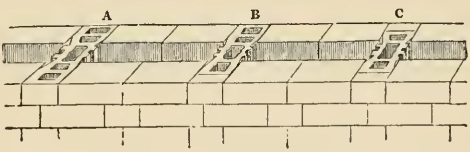

Fig. 617*g*.

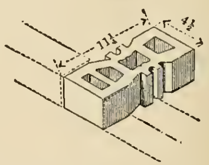

Fig. 617*h*.

1902*d*. Much diversity of opinion exists as to whether the space so left should be ventilated by air gratings just above the ground, and also by others under the coping, to obtain a current of air and secure dryness if water be blown through the outer brickwork. In exposed situations, especially on the sea-coast, if hollow walls are not built, either the wall has to be slated on the outside; or it has to be battened on the inside, even when cemented on the outside, to prevent damp showing on the interior surface. Hollow cement blocks have lately been introduced in France, and are said to be cheap, as durable as stone, ventilation easily secured, and provide for the ready formation of shafts for warm air or for flues. The blocks have a resistance of 430 lbs. to the square inch, and are adapted to walls about 20 inches thick as well as to partitions of less width.

1902*e*. Mr. Taylor has adopted an arrangement of an interior face of common bricks B, with an exterior *facing block* of a better manufactured brick A, in the shape of the letter

L, leaving a cavity of 2 or more inches between them, (*fig.* 617*i*).

1903. GROINED ARCHES. A groin is the angular curve formed by the intersection of two semi cylinders or arches. The centering for raising the more simple groins that occur in using brick arches, belongs to the section CARPENTRY. The turning a simple arch on a centre only requires care to keep the courses as close as possible, and to use very little mortar on the inner part of the joints. In executing a brick groin, the difficulty arises from the peculiar mode of making proper bond, at the intersection of the two circles as they gradually rise to the crown, where they form an exact point. At the intersection of these angles, the inner rib should be perfectly straight and perpendicular to a diagonal line drawn on the plan. After the centres are set, the application of the brick to the angle will immediately show in what direction it is to be cut. With respect to the sides, they are turned as for common cylindric vaults. Mr. George Tappen, an architect of great practical skill, introduced a method of constructing groins rising from octangular piers, which had the advantage of not only imparting strength to the angle, which in the common groin is extremely deficient, but of increasing the space for the stowage or removal of goods, and further, of strengthening the angles of the groin in this construction by carrying the band round the diagonals (*fig.* 617*k*.) of equal breadth, and thus affording better bond to the bricks.

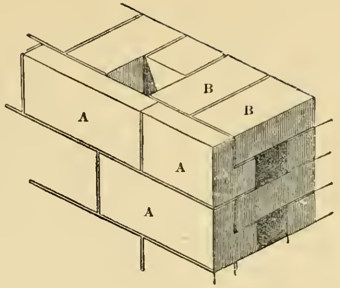

Fig. 617*i*.

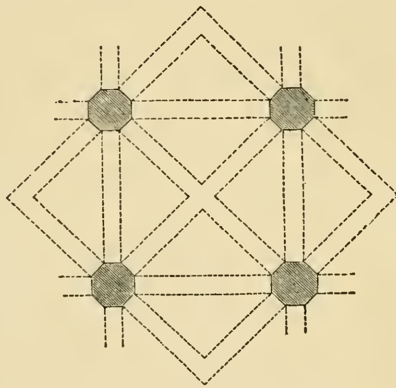

Fig. 617*k*.

1903*a*. The Metropolitan Building Act, 1855, requires that *under* a public way, an *arch*, if it be employed, of a span of not more than 10 feet, is to be at least 8½ inches thick; when not exceeding 15 feet, it must be 13 inches at least; and beyond that width the thickness requires special approbation. If of iron construction or other incombustible material, it must be built in a manner approved by the district surveyor. An arch *over* a public way must be formed in the above manner, but a span not exceeding 9 feet must be 8½ inches thick at least. A like special approval is required if the arch or floor be of iron.

FIREPROOF ARCHES, FLOORS, AND ROOFS.

1903*b*. *Light arched flat floors*, composed of bricks cemented with gypsum or plaster, have been in common use in Roussillon from time immemorial. Rondelet is of opinion that the segment of a circle is a better form for such arches than the low semi-ellipse. He describes apartments of 18 feet by 25 feet, as used at the War Office at Versailles, covered with brick arches of which the rise was only $\frac{1}{13}$th part of the span and in five stories. The coach-houses and stables of the Marshal de Belle Isle at Bisy near Vernon, were arched in an elliptical form, having a rise of $\frac{1}{5}$th of their span, which was 32 feet 9¾ inches. They were not finished until a year after the walls and roof had been completed. The walls were built of rubble-work having chains of cut stone at intervals of about 16 feet. They were 2 feet 8¼ inches thick, being about equal to $\frac{1}{12}$th part of the span. These arches were formed of a double thickness of bricks laid flat, and in plaster, built in succession, with the vertical joints broken. The haunches were filled up with rubble stone in plaster. The springing was formed by notches in the wall, above which the regular courses of stone projected inwards as gathering courses. Above all, a third course of flat bricks was laid horizontally, forming a pavement. Rondelet considers that arches of small and light materials cemented by gypsum become as it were one body, and exert little or no lateral pressure upon the abutments excepting at first, because that cement has a tendency to swell in setting. Rondelet relates that a stone of 4000 lbs. or 5000 lbs. weight was dropped upon one of these arches from a height of 4 or 5 feet, which made a large hole through the arch, without doing any further injury. If mortar be used the parts must be thicker, and the centering left, until the work has set. Portland and Roman cement might be better than gypsum for work in England. Rondelet also states that it is better to use coved arches springing from the four walls, than a common arch springing from two opposite walls only.

1903*c*. The *arch brick floors*, used in the dwellings for workmen at Birkenhead, by the architect, C. E. Lang, were 7 feet in span, worked in half-brick except at the springing and the skew-backs, with a few three-quarter and other parts of bricks inserted, so as to form a toothing or vertical bond with the concrete with which the spandrels were filled. The six or seven courses at the crown were wedged in with slate while the mortar was wet, and in no instance did the least subsidence take place at the crown, although subjected to very severe trials, such as that of men jumping from the walls upon the arches. The span of 7 feet is perhaps the limit of a half-brick arch turned in mortar with the ordinary rough brick. The arches rise about one inch to every foot in span. Tiles were laid in mortar on the concrete, which made the thickness of the floor at the crown of the arch $5\frac{3}{4}$ inches. There were altogether about 1200 arches of this kind turned, and without the slightest accident. This explains the usual method of forming fireproof floors, by turning brick arches between iron girders, which are in large spans tied together at the springing by iron tie rods; a subject which has been so often considered and discussed, and nowhere more so than at the Institute of Architects, as detailed in their *Transactions*.

1903*d*. The *Dennett arch*. A fireproof system, patented by Messrs. Dennett, of Nottingham, and used since about 1855. They execute a groin, dome, or circular ceiling of any length, width, or height, without tie rods or intermediate supports, at much less cost than can be done by any other fireproof material; circular ceilings of 36 feet diameter, with coffers in them, or any amount of decoration, can be executed on the soffits, and the upper surface can be finished smooth in itself, or with stone, wood, tiles cement, or asphalte, and a current of air ensured underneath. Very few iron girders are required. For floors, although in an arched shape, it is in reality a beam, as a complete floor can be turned from wall to wall, resting on a projection of brickwork, and the material be left without any abutment. Its durability equals stone; and its strength is equal to brickwork. The floors are bad conductors of heat; leave no harbour for vermin; ventilating pipes may be laid in them, and also flues. The material (a concrete of broken stone or brick embedded in gypsum calcined at a red heat) can be be used for a sound-proof construction, when laid in the old method between wood joists, as at St. Thomas's Hospital.

1903*e*. Three courses of *plain tiles* laid in cement and well bonded have been for many years employed for slightly curved roofs to form terraces; roofs for cellars under paving; as roofs over small back buildings, and for similar purposes. Where the walls are well backed up, tie rods may not be necessary. It has been asserted that the tiles should *not* be covered with the cement. Portland or other cements laid on brick arches, or on tile, or on a flat concrete roof supported by iron joists; also asphalted roofs; all generally crack and let in wet, especially where there is any traffic on them, or their foundations are not perfectly stable. At Austin and Seeley's artificial stone works, New Road, flat roofs, floors and steps are formed in their material. The terrace roofing is formed of plain tiles in three courses, rendered on the top to the thickness in all of about 4 inches, carried over by arches slightly cambered, springing from small brick piers, and tied by light iron rods, which form their chord line. These flats have an immense weight upon them, and are cast in one piece, as it were, there being no perceptible joint; they are completely water-tight, and can be easily cleaned.

1903*f*. Light arches may likewise be formed by placing thin *iron plates* between joisting of iron or wood, bending them to a slight curve, and filling in above them with concrete to form solid work. *Mallet's buckled wrought iron plates*, are usually made in square or oblong shapes, having a slight convexity in the middle, and a flat rim round the edge, called the *fillet*. These plates are considered the best form yet devised for the iron covering of a platform, and are usable for the above purposes. They are often placed so that the convex part is compressed, and the flat fillet stretched; when they give way under an excessive load, it is usually by the crushing or crippling of the convex part. The safe loads given in the tables published by the inventor, for a plate 3 feet square, $\frac{1}{4}$ inch thick, and with 1·75 inch of curvature, are 4·5 tons for a steady load, and 3 tons for a moving load. The square form, supported and fastened at all the four edges, is the most favourable to strength. The buckled plates used by Mr. Page for the platform of new Westminster bridge measure 84 inches by 36 inches, with a curvature of $3\frac{1}{2}$ inches, and thickness of $\frac{1}{4}$ inch; they bear 17 tons on the centre without giving way (Rankine, *Civil Engineering*).

1903*g*. In India, where all buildings of any importance have *flat roofs*, the long established practice is to form them of tiles, mostly 12 inches square and $1\frac{1}{2}$ inches thick; in Calcutta they are generally 18 inches square and 2 inches thick. These tiles are made with great care: they are burnt the same as pottery, and are used both for roofing and for flooring. In roofing a room of 20 feet span, it is first covered with teak beams 12 inches deep by $8\frac{1}{2}$ inches broad, placed 3 feet apart, which carry *burgahs* or joists, 3 inches square, fixed 1 foot apart, and on these the tiles are placed in two layers carefully jointed with each other. Above them is laid 6 inches of concrete, formed of broken bricks and lime, spread evenly and beaten down to 4 inches, and beaten until the mass is dry; finally it is plastered, and rubbed or polished. If well made and of good materials, it is impervious to wet, and will last as long as the timber under it.

1903h. A floor, or even a flat roof, patented by Bunnett in 1858, is formed of hollow bricks, having the two sides each composed of two parellel inclines, and each about half the depth of the block, connected by a horizontal or nearly horizontal plane, and the two inclines on one side are parallel with those on the opposite side. Through these bricks tie rods are passed, and secured at each end to wall plates formed of angle iron; the whole is then screwed up, when the bricks form a slight curved arch in section, and from the inclined sides they over and underlap one another and mutually give and receive support from the neighbouring blocks. This invention has been carried to 21 feet span with a rise of about $2\frac{3}{4}$ inches, and about 13 feet wide. Other arches have been constructed for the purpose of testing its bearing powers. One of the latter, 15 feet beween the bearing walls, and 2 feet 3 inches wide, was loaded with 4 tons 10 lbs. (or 267 lbs. to the square foot), and was quite elastic. The deflection was about $\frac{9}{16}$ths of an inch. The bricks are put together with Portland cement and sand. Each brick is $10\frac{3}{8}$ inches long, by $9\frac{3}{8}$ inches wide, and 6 inches thick, and weighs 21 lbs. 100 square feet comprise:—

	tons	cwt.	qrs.	lbs.
145 bricks, weighing - - - - - - - -	1	7	0	21
Cement and sand - - - - - - - - -	0	2	3	19
Angle iron and tension bars (bars being 4 feet apart) -	0	2	2	5
Total weight per square - - - - - - -	1	12	2	17

1903i. Pots and jars and hollow bricks have all been used in arched work to reduce its weight. Sir John Soane employed jars in the dome of the Rotunda at the Bank of England, which is about 65 feet in diameter. In floors of arched work either iron ties must be used to prevent the walls being forced out, or iron girders employed, thus subdividing the length, and the work arched across the length, i.e. between each girder. The *Builder* of 1849 records the use of hollow bricks in the vaulting of St. George's Hall, at Liverpool; and Daly's *Revue Générale* for the same year, the use of such bricks in walls.

1903k. The Indians about Nagpore build their *stone vaults* in a peculiar method, which might be followed with advantage in some cases in this country. At the springing, stones of a considerable depth are used, having the intrados cut to the form of the curve; six courses are laid, the upper one having a groove 5 inches wide and 2 deep. Then stones of a smaller depth are laid, each having a groove cut in one face, 2 inches in depth and 4 inches in breadth, with a corresponding projection in their other face, the groove being on the upper side to receive the projection formed in the next course. About eight courses having been laid, it then becomes necessary to prevent the work from falling inwards. At every 10 feet in length two strong rods are placed horizontally across the chasm, and the ends are forced into the grooves. From these courses as from a new base similar grooved stones to those already described are continued, the length of each course contracting until the key course is inserted. When this last course is completed, the rods are sawn across at either end of the finished vault, and the work continued. When the arch or vault is of considerable span, a series of bases may be adopted, each at higher points than the other, until one part is keyed. A slight scaffolding supports the workman, but no frame or centreing is used.

1903l. In view of a fire, and for the preservation of property and life, fireproof *floors* should be more constantly insisted upon to replace the common wood floors, which (as has been described) usually "consist of one inch of boards and one inch of plastering to separate each story in a dwelling." Even these can be improved by some modern inventions. An American (*Wight*) method is by fixing flat interlocking fireclay tiles, carried by iron clips screwed to the underside of the joists, the underside of these tiles being grooved to formed a key for the plaster. A space of 2 inches is thus left between the plaster and the wooden joists, and as the tiles themselves will stand almost any heat that can be brought to bear on them, the joists are absolutely protected; on the upper side fine concrete or pugging might be used. This system can be affixed to existing floors by simply hacking off the lath and plaster, and it is probably quite new in this country. (J. Slater, *New Inventions*, in Royal Inst. of British Architects, *Transactions*, 1887.)

1903m. In the so-called "flats" and suites of offices, the floors are now generally formed of fireproof construction. There are many modern systems. The core or material used to fill in between the wrought-iron joists, which are placed 2 feet to 3 feet apart, is generally determined by local circumstances, or the patent of the inventor of the system. These are, metallic concrete, coke breeze, pit or river ballast, broken stone, broken brick, well-burnt clay ballast, granite chippings, pumice, pots, &c., all generally set in cement. This preparation is covered by an asphaltic, granitic, or metallic surface. Lastly, the upper surface is finished with a floor of boards nailed to small wood joists or sleepers resting on the concrete; blocks are also used for fixing them.

1903n. Archibald D. *Dawnay's* fireproof flooring is stated to be the simplest, cheapest, and strongest ever introduced; suitable for all buildings to 40 feet span without columns, being composed only of steel or iron joists embedded in a high class concrete, finished flat on both sides, forming a solid block of one thickness, absolutely indestructible.

1903*o*. *Homan and Rodgers*' flat brick fireproof floors. They are constructed with hard burnt bricks, jointed in cement, and bonded on the upper face with tough concrete. The depth of the finished floor is 6 to 9 inches. "By the method of laying, the ironwork is protected from the action of fire. The brick soffit forms a key for the plaster; no laths or counterceiling are necessary, but, where desired, wood blocks can be fixed in the soffit to receive the ordinary lath and plastered ceiling, then making the most perfect sound-resisting fireproof floor known. The concrete being tough instead of friable, the boarded finish may be nailed down without the use of sleeper joists; but, since serious failures show that wood embedded in concrete, asphalte, or pitch, is liable to decay, it is recommended to use an inch strip as a sleeper fillet, which will also provide ventilation and space for gas and water pipes." The floor is stated to have no thrust.

1903*p*. *Lindsay and Co.'s* patent system, wherein a steel decking is introduced, and also their patent trussed concrete flooring. The steel flooring is manufactured of two different strengths, varying from 4 inches to 14 inches in depth, and suitable for spans of from 15 feet to 50 feet clear. It is stated as perfectly and equally distributing the floor loads to the surrounding walls, and as acting as a complete tie to the building; not affected by settlements of the walls; and is 30 per cent. lighter than ordinary arched floors. The trussed fireproof flooring is laid with pumice concrete, enclosing small joists joined by steel truss rods twisted together every 18 inches; or formed as an arch underneath between girders to 14 feet span. A slab of this concrete, 2 feet span and 4½ inches thick, was loaded to 22 cwt on the foot without injury. For a space of 30 feet the depth of the decking is only 5 in. to support a load of 1½ cwt. per foot super. Brick partitions can be placed on this decking and concrete in any position, independent of walls or girders underneath. This flooring has been largely used in the National Liberal Club, by R. W. Edis, architect. The top table is made thicker than the sides, and the sectional strength is thereby greatly increased, and the various sections are riveted together at a point which is very close indeed to the neutral axis. The concrete is called "pumice concrete," as it is very light and tough; considered to be a good material for constructing roofs, domes, &c.

1903*q*. The "*Doulton-Peto*" patent fireproof flooring, in principle consists of a series of hollow blocks of stoneware placed between rolled iron joists, making a flat ceiling, which may be plastered or not. The iron girders are fixed in the ordinary way, but not so close together as usual. The tile next to the side of the girder is specially shaped to set

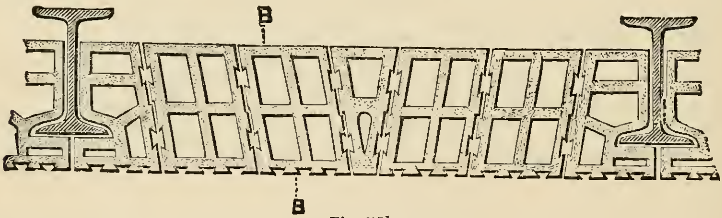

Fig. 617*l*.

against and beneath it, so as to isolate it completely. The *fig*. 617*l*. shows tiles made for a flat ceiling, and set in cement; if no ceiling, then the under side is made smooth to receive whitewash, &c. The tiles for ordinary floors are 6 inches high and about 1 foot thick. The floor is stated to be one-third lighter than concrete or brickwork. A flat roof can also be formed with them. Where an arch is desired between each girder, another form of springer (*fig*. 617*m*). has been adopted. It has stood the test of upwards of 6 cwt. to the foot dead weight on material only, and with an arch of 6 feet span and quite flat. On an arch of 8 feet span a cask of graphite weighing 7 cwt. has been rolled and rocked, the vibration doing no injury. A fire has been lighted beneath, making it red hot in parts, and while in that state a hose has been turned on with a considerable pressure of water without the least effect. It has also been tested with unevenly distributed weights, and with vibration and concussion, all which it has successfully withstood. This flooring has been used throughout at the London Pavilion, where it was found very advantageous from its lightness, the speed with which it was constructed, and its cleanliness. A large building of four stories at Messrs. Doulton's factory has been similarly constructed by

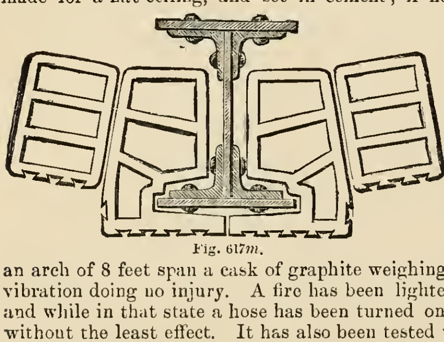

Fig. 617*m*.

that firm; the under side of the flooring has not been plastered. (*Builder*, Dec. 19, 1885, p. 877. *Transactions* of the Royal Institute of British Architects, 1886, p. 130.)

1903*r*. *Bunnett's* patent floor consists of hollow bricks laid in the form of a flat arch, resting on angle irons tied together by tension rods. Each brick is so arranged as to receive support from six adjoining bricks. *Measures'* patent floor consists of iron joists with iron fillets 9 inches apart, at right angles to the joists, and resting on their lower flanges, and cement concrete filled in, embedding joists and fillets. *Hyatt's* patent dovetailed corrugated iron sheets are used for fire-resisting iron and concrete floors, ceilings, and partitions, giving great strength combined with lightness. Partitions can be made of Portland cement, concrete, and iron, only two inches thick, the iron being completely protected. The *Wight* fireproofing Company of America has introduced many novelties (*Builder*, 1887, p. 704). *Porous terra-cotta* is made in America by mixing sawdust with the clay; having been burnt it was perfectly fireproof, and although spongy, unless dipped in water it was not absorbent, but was rather a dry material, besides being one of the best non-conductors of heat and sound. It weighed about half that of ordinary brick. It was used to line outside walls to keep them perfectly dry; also as fixing blocks, because the nails could be driven into it more easily than into deals. It makes a good fireproof roof by placing sheets of it on the flanges of ⊥ iron; it came a little above the edge, and the slates or tiles could be nailed directly on this. Fireproof flooring bricks were made of terra-cotta, and were a great saving in strength of materials.

1903*s*. A concrete floor to the various stories of a building has often been formed, but not always with success. A system is explained in the *Builder* for April 3, 1886, which should be well studied. Concrete slabs, the largest of which is 21 feet by 12 feet 6 inches, of an average thickness of 13 inches, sustained the great loads and rudely impactive forces of a wholesale provision trade, in a warehouse at Sunderland, erected by Mr. Frank Caws, whose description, though concise, is too long to be here inserted.

1903*t*. If properly mixed, care taken in laying, and thorough cleansing of all broken materials used, then the results may be satisfactory. To receive stone paving and for tramways, concrete is laid in successive layers of cement and gravel in proper proportions, not too moist, for the requisite thickness, well beaten down with iron beaters. For a floor finish, a thick layer of about an inch of the cement and gravel finished off with a smoother, care being taken not to work up too fine a surface. The proportions to be used are 1 part of Portland cement, 4 of gravel, and 6 of broken stone, the latter to pass through a $2\frac{1}{2}$-inch ring. Concrete flat floors are cheaper and equally as strong as arched floors, and should be at least from 5 to 6 inches thick. Such a floor will carry a safe load of about 5 cwt. per superficial foot. One tested went further. It was made of 1 of cement, 3 of gravel, and 3 of well-washed broken stones to pass a $1\frac{1}{2}$-inch ring, the finishing layer being of cement and gravel. The Portland cement should be tested, for its proper strength is of importance. (John Garthwaite, of Liverpool, 1885.)

1903*u*. For town buildings these various patents afford the means for obtaining *flat roofs*, which have many advantages for the inhabitants, as affording a promenade. They have to be thoroughly well constructed. Two of the latest constructions are at the new City police station, Cloak Lane, Cannon Street, having a superficial area of 2600 feet, formed of iron joists, carrying concrete covered by a layer of one inch of the finest Pyrimont-Seyssel asphalte, the skirtings being of the same material; a thin layer of very fine and clean pebbles from the sea shore were applied to the surface while hot. The other roof is to the Army and Navy Auxiliary Supply Association in Francis Street, Westminster, having a superfices of about 12,000 square feet, and is of the same construction.

CONCRETE BUILDING.

1903*v*. The Metropolitan Board of Works have approved of such structures, and have made the following regulations to be observed in their formation:—

I. The concrete to be used to be composed of Portland cement and of clean Thames ballast, or gravel, or crushed smiths' clinkers, or brick burrs, or small broken stones, or any hard and durable substance; and each to be passed through a screen having a mesh not exceeding 2 inches in diameter. Sand to be in, or added to, such materials in the proportion of one to two. All such materials to be perfectly clean, and free from all greasy, loamy, or clayey matter.

II. These materials and cement to be mixed in the proportion of not more than 8 parts of material as aforesaid, by measure, to one part by measure of the best Portland cement.

III. In making the concrete, a box 2 feet by 4 feet by 2 feet, or other like proportions, is to be used for the materials other than the cement, and another box, capable of holding one sack or half a cask containing 2 bushels, is to be used for the cement. The cement and the materials are to be turned over at least three times, and thoroughly mixed together with water.

IV. The walls of the buildings to be carried up all round in regular layers with concrete thus composed, and grouted with cement in the proportion of 1 of cement to 2 of clean sharp sand after each layer, until the walls are completed in height. The grout to be made as mortar first, and then thinned with water to the necessary consistence.

V. The concrete to be well and thoroughly bound together, so as to secure the complete adhesion of the materials and work during its progress.

VI. The thickness of walls to be equal, at the least, to the thicknesses for brickwork prescribed in the Building Act.

VII. Suitable cores to be used for flues, and also for recesses. Flues to be formed with stoneware or fireclay pipes, not less than half an inch in thickness, unless properly pargeted.

VIII. Door and window frames to be built into the walls.

IX. The portions of the party walls and chimney stacks above the roofs of buildings to be rendered externally with Portland cement.

X. The rules of the Metropolitan Building Act, 1855, as to the use of timber in walls, and other rules of that Act, so far as they may be applicable to concrete buildings, are to be observed.

1903*w*. This concession was made after many attempts to obtain it, by Philip Brannon, by Tall, Drake, and others. Mr. Wonnacott read a paper in 1871, *On the Use of Portland Cement Concrete as a Building Material*, which enters fully into the merits and demerits of this construction. It was supplemented by another paper, *Remarks on Concrete Building*, by A. W. Blomfield, who summarises the whole thus: The chief *advantages* are, I. Cheapness; II. Strength and durability; III. Rapidity of construction; IV. Economy of space. The chief *drawbacks* are: I. Its liability to failure, from the use of improper materials, or from the want of knowledge and proper care, or from the wilful misuse of good materials; II. The limits which the material and method of construction impose on architectural design and decoration.

1903*x*. *J. Tall* advertises concrete construction for cottages; door and window frames. *Drake and Co.*, concrete building apparatus; dovetailed self-fixing building slabs; marble and granite facing bricks; fireproof floors, doors, staircases, wall tiles, &c.; window heads, copings, terminals, steps; marble concrete baths. *W. H. Lascelles* has, panelled slabs and concrete backings screwed to stud work; walls built of Potter's patent cement slabs; plain and moulded concrete forms of all varieties in building and ornamentation, as window sills, door jambs, gables; concrete ceilings; and chimneypieces. The *Eureka Concrete Company* has steps, sills, strings, balusters, fireproof floors, mantelpieces, thresholds; copings; a concrete door of four panels, hung in position and fitted with lock. *Faija's concrete*, hardened by his new patent process. *J. Wright and Co.* have made an "improved concrete lintel," having a curved upper surface and a T iron passing through it lengthways; with their fixing block inserted to receive the sash or door frame. See also par. 1864*i*.; and Artificial Stone.

1903*y*. In 1887 Mr. W. Simpson read a paper before the Royal Institute of British Architects entitled *Mud Architecture*, relating many methods of construction of similar materials in various countries; further interesting references were made in the discussion and correspondence of that year.

1903*aa*. Concrete and cement blocks. Blocks formed of Roman cement, puzzuolana, lime, and sand, were soon suggested for such a purpose. Those made without the cement were found to be longer in setting, but eventually became the strongest. To these combinations potsherds were added, as Pliny relates was in use in the time of the Romans; increased toughness resulted. The late Mr. Walker, engineer, possessed specimens of Dutch terras, which had been used in Woolwich dockyard in the reign of George III. These were of very great hardness; in fact, gunpowder had to be used in breaking up the dock where it had been employed. For concrete and mortar for the river wall of the Houses of Parliament he used two measures of sand, 1 of puzzuolana, and 1 of lime. Mr. Lee used Portland cement, Portland stone chippings, sand, and shingle, in blocks in cubes of 16 feet and upwards, made in moulds, for the breakwater at Dover. Mr. Blashfield had made experiments for that work with Lancashire terras mixed with broken tiles and sand; but it was not deemed equal in hardness to the Portland cement concrete blocks.

1903*bb*. *Atkinson's* or *Mulgrave cement* was used by its patentee for concrete blocks of shingle, sand, and cement, used as ashlar stone in the case of a house at the corner of Mount Street, Grosvenor Square, still standing in a substantial condition. Concrete in small blocks, known as *Ranger's patent artificial stone*, has been used to a limited extent in the construction of domestic buildings. It was employed in the additions to the College of Surgeons, Lincoln's Inn Fields, 1835–6; a guard-house in St. James's Park; the Imperial Assurance Office, in Pall Mall; and in a row of houses in the Western Road, at Brighton, partly in blocks and partly in moulds as pisé work. This process is not continued, probably from the mortar not being properly mixed in the first instance, and the concrete being exposed too soon to the action of the weather, for it dries unevenly, and cracks in all directions.

1903*cc*. *Buckw ll's Granitic Breccia stone* was patented about 1858 to compete with brickwork in price, its strength and durability being greater, and its bulk and weight considerably less. It was impermeable to wet and never vegetated, so that for pavements and linings for tanks it appears to have answered well; but for some reason, not ascertained, the manufacture of it was lately given up. It could have been manufactured in a single piece, of a weight varying from 1 cwt. to 60 tons or more; also in slabs from 5 feet to 100 feet superficial; and to any contour. *Wheeble's Reading Abbey patent concrete stone*, formed with Bridgewater stone lime, when made into a brick, was found to be equal in strength to a common stock. Some specimens never attained the strength of concrete except in a case where large gravel or flint was the chief ingredient. *Messrs. Bodmer's patent compressed stone bricks*, compounded chiefly of 1 part of hydraulic lime and 7 of siliceous sand, well mixed, are subjected to great pressure in moulds. Upon removal, the bricks are piled up in the open air, when induration commences, and the material is converted into stone. They appear to be ready for use after six weeks' to two months' exposure, and experiments show a steady progressive increase in strength as they advance in age. When eleven days old they crushed at 3·77 tons; at twenty-two weeks from 5·4 to 6·95 tons; and at sixty-three weeks a pressure of upwards of 8 tons was reached without effect.

1903*dd*. *Coignet's Béton Aggloméré* has been employed in France in the construction of a church in the park of Vésinet, near St. Germain, from the designs of M. Boileau, and into the construction of which he has also introduced cast and wrought iron. The *béton* is formed with all the mouldings of Gothic architecture both externally and internally. It was built similar to pisé work, though it is also applicable for blocks, like stone, in which manner he has lately executed some bridges of 140 feet span. The very hard frosts of January, 1865, had not appeared to have had any effect on the *béton* at the church, which was being executed at the time, and is described in the *Builder* for November, 1864; views are also given in the volume for 1865. It is stated that such structures cost only about one-half or perhaps one-third of the expense of a stone building, with greater decoration.

1903*ee*. The system of building with *concrete blocks* at Sandown, Ventnor, and other places in the Isle of Wight, is well adapted for constructing walls to ensure dryness. The blocks are about 18 inches wide by 12 inches high, and are of two thicknesses, those for the outer wall being 4 or 5 inches, and for the inner about 3 or 3½ inches thick. These are tied together by pieces of iron, leaving a space of about 3 inches between them. This forms what looks, to those accustomed to the 2 feet thick solid walls of Scotch houses, a flimsy wall, but it appears to be sufficiently strong for carrying another story over the ground floor; and with a few openings above and below for the admission of air into the space between the walls, forms a structure which, in a sanitary point of view, may be considered perfect. Some would prefer to have the inner wall of brickwork.

1903*ff*. TABLE OF THE RESISTANCE TO THRUSTING STRESS OF NINE 2-INCH CUBES OF CONCRETE, BEDDED BETWEEN PINE THREE-EIGHTHS OF AN INCH THICK. By D. Kirkaldy, for W. H. Lascelles, May, 1881.

Cracked slightly.				Remarks.
	Stress.	Per sq. inch.	Per sq. foot.	*Builder*, xl. p. 619.
	lbs.	lbs.	tons.	
1	19,162	4,790	308·0	Neat cement, made Dec. 15, 1880.
2	18,628	4,657	299·4	Ditto.
3	16,298	4,074	261 9	Neat cement, made March 8, 1881.
4	12,982	3,245	208·6	3 of cement to 10 of ground material, made Jan. 18, 1881.
5	12,248	3,062	196·9	Ditto.
6	8,488	2,122	136·4	1 of cement to 4 of ground material, made Jan. 1, 1881.
7	8,023	2,006	129·0	Ditto.
8	5,838	1,459	93·8	1 of cement to 4 of ground material, made Jan. 1, 1881.
9	5,796	1,449	93·1	Ditto.

1903*gg*. The use of *concrete* has extended from the foundations of buildings, backings of wharfs, retaining walls, and abutments of arches, to the employment of it for the backing of vaults to produce a level surface; for the substance of fireproof floors; for the base of floors, pavements, and roads; for the walls, floors, &c. of houses, bridges, and moles; and various other purposes.

1904. Many ornamental brick cornices may be formed by but little cutting, and changing the position of the bricks employed, and several, indeed, without cutting, by chamfering only. Of late years the machines for making bricks have permitted the extensive use of moulded bricks of different forms, which have entirely superseded the more artistic advantages of cut brickwork to required outlines or ornamental details.

1905. *Niches* may be formed in brickwork. They constitute the most difficult part of the bricklayer's practice. The centre will be described under the section Carpentry. The difficulty in forming them arises from the thinness to which the bricks must be reduced at the inner circle, as they cannot extend beyond the thickness of one brick at the crown or top, it being the usual as well as much the neatest method to make all the courses standing.

1905*a*. *Flues.* It has been an established rule to build flues 14 inches by 9 inches, 14 inches square, or larger, for kitchen fireplaces, because it suited the size of the bricks and bonding, contained a sufficient amount of superficial area, and afforded a space for a boy sweeper to ascend them. Since then circular pipe flues, 8, 9, 10, 12 inches diameter, or oblong pipes with rounded corners, have been adopted by many, the inside being smooth. These are easily swept, and no lodgments of soot and brick rubbish take place. An objection has been made, if the pipes be glazed, that during a storm, or other concussion, the soot falls down into the room if the register flap be not shut. These pipes make good work at the gatherings. It is almost an invariable rule to make the flue the same size throughout; there is also the theory that the flue should be made larger at the top, and also smaller at the top, similar to a factory shaft. Also that a *tall-boy* is useless, for the top should only be finished by a terminal of a few inches, just sufficient to divide the rushing currents and allow them to pass between each pot. The fireplace should be covered over at the usual springing line by a slab of stone, or concrete, or iron plate, with an aperture in the centre of the size of the intended flue. On this the brickwork is carried up. Above it, in the breast, has been formed a chamber with sloping sides, to counteract any down draught.

1905*b*. A brick flue is *pargeted* inside to render it smoke proof, that the velocity of the draught should be assisted or improved, and to prevent as far as possible the lodgment and accumulation of soot. The parget, which is a mortar made of a mixture of lime and cow-dung, should be sparingly applied, but sufficient to fill up open joints and all irregularities in the brickwork. If applied thick, it shrinks and cracks, and falls off, and assists in making a chimney smoke. It is now recommended to use the ordinary mortar for this purpose, the brickwork being kept as smooth inside as possible, by careful pointing, as it has been found more successful for a number of years.

1905*c*. Paving. When neither slate, granite, Yorkshire or other stone, flint, nor shells, are used for paving, recourse is had to bricks, tiles, and asphalte. A yard superficial of *brick paving* requires 32 to 36 stocks laid flat; 48 to 52 laid on edge; 36 paving bricks laid flat, 82 on edge; 140 Dutch clinkers on edge; 9 twelve-inch tiles; and 13 ten-inch tiles. Brick paving is laid *flat* in sand; jointed in mortar; jointed in cement; and laid *on edge*, in the same manner. Tile paving is generally laid in sand or mortar (*par.* 2282*b*). Besides the ordinary brick, some others have been introduced, especially for stables and yards, such as the *Terro-metallic grooved bricks*, and Towers and Williamson's *Adamantine clinker* paving bricks for stables and yards; it is stated to be superior to the old *Dutch clinker* in shape, colour, density, and wear (*par.* 1829). Tebbutt's patent *safety brick* for stables and yards, &c., is considered to ensure perfect foothold, drainage, easy cleaning, saving in labour and straw, to form a durable floor, and to have a good appearance. Each brick is 5 inches by 10 inches by $2\frac{1}{2}$ inches; and the gutter brick is of the same size. Homan's *Quartz*, *Granite and Ferrolithic stone paving*, for streets, public buildings, breweries, warehouses, stables, schools, &c. Bennett's *improved Granitic stone*, for pavements, &c. (1887), is said to be fire, damp, and vermin proof; the surface, though hard and indestructible, is not slippery, it does not absorb moisture, it is laid from $1\frac{1}{2}$ to 3 inches in thickness, is unaffected by the weather, and hardens by time. Macleod's *Metallic concrete* is proof against fire, vermin, damp and frost, not slippery, and can be used for paving, wall linings, roofing, &c. It is very hard, and has been used in stabling, breweries, workshops, &c., from before 1870. Stuart's *Granolithic* and impenetrable pavement (1869), is very largely employed in this country and abroad. Wilkes' patent *metallic* paving and Eureka concrete is used at the war office, the fire-brigade stations, and police stations. W. B. Wilkinson & Co. patent a *specular granitic* concrete pavement, which is formed in 15-inch squares of $1\frac{1}{4}$ inch thickness, ground perfectly flat, presenting a spotted appearance of red and different shades of grey colours. It may be laid on ordinary mortar, can be used for outside purposes, and is stated to cost less than tiles.

1905*d*. Ordinary *tile paving* is made of about 8, 9, 10, 11, or 12 inch tiles, of a hard and well burnt clay. The 11-inch tiles used in the footpaths, which are each 14 feet 6 inches wide, of new Westminster bridge, were made by Blashfield, and were laid diagonally (*par.* 1839). The Staffordshire paving tiles, in blue, red, and buff, are very durable, and for general purposes as effective as the more expensive qualities for inlaid purposes.

1905*e*. *Floors and paths* are often finished with a face of ¾ inch, 1 inch, or 1¼ inch of Portland cement. They are considered to be best laid with the cement and sand thoroughly mixed and just wetted sufficient so that a handful pressed by the hand will not fall to pieces when the hand is opened. This laid down, and water brought through it by the hand float, stands well. Plasterers do not like to use it so stiff. To repair any worn places the old cement should be thoroughly wetted before the new work is applied.

1905*f*. Here may be mentioned the use of *encaustic* or inlaid tiles for paving; of mosaic tiles and of *tesseræ* for mosaic work, whether for pavements or for wall decoration; the *Roman* mosaic pavement; the *Venetian marble* mosaic tiles; Italian *marble mosaic* and marble mosaic granite. There is also a patent *wood mosaic*, made of small blocks of wood, end grain, and prepared in tiles to pattern 6 inches square.

1905*g*. To clean dirt off tiles, dilute muriatic acid, *i.e.* spirits of salts, may be used, but it must all be wiped off, and after washing, the moisture must be wiped off with a clean dry cloth.

1905*h*. Asphalte has now taken the place of most other sorts of manufactured pavements of the same character. A solid foundation is prepared by a bed of concrete of hydraulic lime and gravel, with a layer of finer concrete over it, to fill up the vacuities. When dry, the asphalte is put on, of a thickness for private purposes of about ⅝ths of an inch; for public purposes, from one to two inches: it should be applied as hot as possible. A small quantity of pure quick lime is added to the asphalte when in ebullition, to prevent it melting by the heat of the sun. This material has been much used for threshing floors of barns, for malt-houses, armouries, tun rooms (sometimes from 2 to 2½ inches thick), dissecting-rooms, dog-kennels, exercising yards, mills of many kinds, granaries, verandahs, and numerous factories and buildings. For carriage traffic, the asphalte is embedded with small Guernsey granite chippings. This material is *not* suitable for any floor where oil, tallow, or other greasy matter is employed. The Polonceau and Seyssel Asphalte Company indent the surface into small squares, affording a foothold for horses in a stable; this is also considered useful for flat roofs and paving generally. The granite rock and Seyssel asphaltes, for floors, paving, &c., are considered a certain preventive of damp and vermin. The Val de Travers compressed and mastic asphalte, for roadways, &c., roofs, basements, stables, warehouses, breweries, reservoirs, slaughter-houses, markets, laundries, lavatories, &c. The Limmer Asphalte Paving Company, and the Société Française des Asphalte, are also engaged in paving the thoroughfares of London and elsewhere. Wright's *marble tar pavement* for yards, play-grounds, &c. has been used for the platforms of the Windsor and the Waterloo stations, and in the middle part of the quadrangle of Somerset House.

Tiling.

1906. The tiler's tools are—the *lathing hammer*, with two gauge marks on it, one at 7 inches, the other at 7½ inches. The *lathing staff*, of iron, in the form of a cross, to stay the cross laths and clinch the nails. The *tiling trowel*, to take up the mortar and lay it on the tiles; it differs from the brick trowel, in being longer and narrower The *bosse*, made of wood, with an iron hook, to hang on the laths or on a ladder, for holding the mortar and tiles. The *striker*, a piece of lath about 10 inches long, for separating and taking away the superfluous mortar at the feet of the tiles. The *broom*, to sweep the tiling after it is struck.

1907. Tiling is the operation of laying the tiles on a roof for the covering of the building, and is effected with either plain or pan tiles; the former is the most secure description. Plain tiles are laid at different gauges (see *par.* 2301). 210 plain tiles laid flat will cover a square of tiling, which can be laid in a day by a man and his assistant. As old tiles are of a much better consistency than those now made, it may be desirable to re-use the best of them with new tiles to fill in; in which case the old ones are laid with the best effect in courses, say three or four rows of new and two of old tiles; or laid in a diapered pattern, according to the quantity. Pan tiles are generally pointed in mortar, which if it be not very strong will not stick; in consequence of this, tiled roofs require fresh pointing every few years, especially in exposed situations. A practice has obtained of late years, when plain tiles are set in mortar, not to peg more than about one tile in ten; this should not be permitted, as with the decay of the mortar the tiles slip down. An ancient custom prevailed, to bed the tiles in hay or moss, and when the roof is of the *full pitch* this suffices without mortar; they may even then be laid dry. But with any less pitch, some precaution must be used to keep out drifting snow, and such wet as may be blown up between the tiles lifted by the force of the wind. In lieu of oak pegs, extra large flat headed wrought nails, made of pure zinc or of zinc and copper, have been used, and it has the advantage of allowing a tile to be replaced from the *inside* of the roof, by lifting up the others to place in the tile and drop in the nails in a few seconds. The utility of the mortar is questioned in the *Builder* for 1865.

1907*a*. Pan tiling is laid to a 10 inch gauge; and 180 pan tiles will cover a square. From the frequent repairs necessary to tiled roofs, slating has become the most useful covering, and is generally employed, except for the most common buildings. See *par.* 2301, in Specifications.

1907*b*. Weather tiles were fixed either by nailing them to battens or boards, which rotted after about 20 years. Then nailing them to the mortar joints was bad, as a gauge of 3 inches was too small, 4 inches being the ordinary gauge for tiles. Mr. R. Nevill got blocks made $1\frac{1}{2}$ inches thick; and generally for the top story of buildings, to run in the inside of the wall two carriers and stretchers and a course of headers. Thus a course was obtained for each course of tiles. Weather tiling ought to be headed between the two tiles, and if they could get close to the wall the little space between the wall and the heading might be filled with cement. The bricks might be used on edge, thus giving a $4\frac{1}{2}$ inch height, when the tile could be fixed to the joint. Where the 4 inch gauge would not work, the tiler punched out a small hole at the side of the tile, when this gauge was obtained and the nail driven through the side of the tile: 3 inch French nails were preferable. (E. T. Hall.)

1907*c*. The bricklayer has often to provide temporary coverings to buildings whilst his other operations are being performed. The commonest method is that of merely nailing old boards laid weather-board fashion to any slope that may be desirable. The next is the use of tarpaulins supported by open boarding, and secured to posts or scaffolding rigged up for the purpose; this must be efficiently done, as in case of high winds the whole may be carried away. Felt is also used for temporary roofs, for which purpose, likewise, Messrs. Rigg and Co. have a new material composed of canvas covered with a waterproofing substance having vegetable oil as a basis, and consequently not liable to the desiccating action of the rays of the sun.

1907*d*. As the bricklayer has to provide for the removal of water refuse, so he has to provide for the deposit of dust, ashes, and rubbish, by a *dust-bin*. This was formerly, and is still in many places, built of brick with a wood cover, and is generally more than a nuisance. With the modern arrangements for the periodical removal of dust by the parish or other local authority, the dust-bin need be no other than a galvanised iron receptacle for such ashes or articles as cannot be dried and burnt up in the kitchen or other fire (see Specifications). Burton's *Combination Dust-bins* are of galvanized iron, and constructed of such a size and shape as to stand side by side, each being removed and emptied separately. They form two, four, six, or eight in a compartment, each being 22 inches high, 21 inches wide, and 14 inches from front to back, or about $3\frac{1}{2}$ cubic feet, a sufficient load for one man. When necessary, they can have a wood cover or be enclosed in wood or brick. An improved dust-bin is explained in *Builder*, 1885, xlviii., p. 779.

1907*e*. The difficulty and expense of removing this refuse has caused the invention of a *refuse destructor* on Fryer's principle. One is described lately as having twelve cells, each capable of destroying seven tons of house refuse every twenty-four hours. The smoke from these will pass through a furnace heated to 1500 or 2000 degrees Fahr. before pasing into a shaft 180 feet high. The waste heat from the furnaces will be utilised for a 30 horse-power engine for grinding the clinkers into powder for making concrete slabs. No fuel is required, as the "ashes" provide it. Leeds claims to be the first town to have adopted this invention. Mr. C. Jones, of Ealing, added a muffle furnace between the destructor furnaces and the main shaft, which effectually destroys the offensive properties of the gases and dust from the furnaces.

Terra-Cotta.

1908. The more modern use of this material includes the Persian and Moorish tiles, &c., its use by the Italians during the thirteenth, fourteenth and fifteenth centuries, as at the cities of Milan, Pavia, Padua, Verona, Pisa, Bologna, Brescia, Perugia, Venice, &c.; also in North Germany; many places presenting examples of colour decoration.

1908*a*. In England specimens of terra-cotta and moulded brickwork appear at Granby Church, Nottinghamshire, where at the east end is a window of considerable size, of Perpendicular date; the whole of the jambs and tracery are composed of contemporary moulded terra-cotta. Layer Marney Hall, Essex, dating 1500–25, supposed of foreign manufacture; Wolterton Manor House, Norfolk, circ. 1500; the tomb of John Young in the Rolls Chapel, London, 1516; medallions at Hampton Court Palace, commenced 1515, perhaps foreign; Sutton Place, Surrey, 1529; Eastbury Manor House, near Ilford, 1575; and other places. Generally it died out with the Tudor family. At the end of the sixteenth century nearly all pottery (except Oriental) had been what is termed *soft*, and although much of it was coated with a hard and durable enamel not easily injured, yet the body could be generally scratched with a knife. In the seventeenth century *stoneware* was sought after, and works for its manufacture were established at Stratford-le-Bow. Elers, from Nuremberg, settled at Burslem.

1908*b*. The first great advance was made by Coade, and, later, Seeley, of Lambeth, who began about 1762 to make statues, bassi-rilievi, &c. About 1825 Rossi made the statues, capitals, antefixæ, and other Grecian ornaments for St. Pancras Church, London, for the Inwoods; and Bubb executed in terra-cotta the frieze of the opera-house in the Haymarket, as also the pedimental sculpture and statues of Cumberland Terrace, Regent's Park. The terra-cotta made by Coade and Seeley was chiefly from the Poole clay, combined with flint and sand. It has withstood heat and frost, and is more perfect than the stonework or cement work around it of the same date, which in some cases has had to be painted to preserve it. Their well-tried ingredients and proportions of clay and siliceous materials, and the degree of vitrification, the essential to the durability of terra-cotta, were adopted by Mr. Pulham. One of the greatest revivals in pottery connected with architecture took place about 1833, when Mr. Wright, of Shelton, obtained a patent for making inlaid tiles, a patent bought by Mr. Herbert Minton, who improved upon it. The churches at Leverbridge, and at Platt, in Lancashire, by the late Mr. Edmund Sharpe, in 1845, were important examples of the revival of the use of terra-cotta.

1908*c*. At Buckingham Palace, near the stables, were placed, about 1836, several large vases made by Mr. Blashfield; these are in perfect preservation, while the stone coping on which they are placed is decayed. He also turned out some of the best work ever made in this material, as at Dulwich College, 1866, and at Lady Marriane Alford's house at Knightsbridge. The façade of the Science Schools, in Exhibition Road, South Kensington, is a large and florid example. The Natural History Museum at South Kensington, by Mr. Alfred Waterhouse, R.A., is of terra-cotta inside and outside. Mr. R. W. Edis has used it at the Constitutional Club in Northumberland Avenue; and many other buildings of late years show its use. Among those in progress are the new Law Courts at Birmingham, which have been specially designed for its use by Messrs. Webb and Bell.

1908*d*. In *works of art*, as in sculpture, the artist has only to model in the clay, as he is obliged to do before he commences to carve out the marble; the clay is at once burned, and all the after labour on the marble or stone is saved. Still it is attended with some risk, for an accident may happen in the burning, and then the modelling has to be redone. Large works should be done in conjunction with the potter, who would supply the proper clay, and see that the thicknesses throughout were as even as possible. The largest piece of sculpture ever executed in terra-cotta was the group of America at the Albert Memorial, executed in 1876 by Mr. John Bell. It consists of five figures, each 10 feet high, with a buffalo of like proportion; it is now at the Smithsonian Institute, Washington. Other similar, or ornamental, work can be finished up at once in clay by the artist, and burned, and are thus never repeated, in the sense of moulded work. Vases, 12 to 15 feet circumference, are made as true on the upper edge as rubbed stone. They have cost less than if they had been moulded and cast in compo or cement, and they have the sharpness of the best carved stone.

1908*e*. In 1880 it was alleged that English architects had not given to the architectural treatment of terra-cotta the degree of attention and experiment which it deserves. Sir G. G. Scott, in *Gothic Architecture, Secular and Domestic*, 1857, wrote: "Terra-cotta seems the natural accompaniment of brick, but it should not be used as an artificial stone. It is the highest development of brick, and should be used as such. By a judicious use of brick, moulded as well as plain, encaustic tiles, and terra-cotta, we might develop a variety of constructive decoration peculiarly our own."

1908*f*. A writer puts the use of terra-cotta and stone as follows:—"It is argued that it is improper, inartistic, and uneconomical to use terra-cotta constructively so as to imitate stonework, but it is eminently suited for surface decoration and architectural ornamentation, and when so used is capable of high artistic treatment at a moderate cost. Stone is a natural material, and when fixed every part of it does duty constructively. Terra-cotta is an artificial substance; it is but a shell or case, which generally has to be filled up with concrete or brickwork in walling, or with an iron core for a column, or with a girder for a lintel, before it can be used constructively. Terra-cotta used to imitate stonework is inartistic, for stone is worked with the greatest nicety, and fixed with perfect accuracy. With terra-cotta it is not possible, at its best, to secure perfect jointings or straight arrises; there is a monotony of texture in all its plain surfaces, as well as a general inability in the material to acquire additional charm under the influence of the mellowing touch of time. It is not economical to employ terra-cotta in a way to imitate stone constructively. The rough stone is brought to the works, squared, and fixed. The terra-cotta, however, arrives at the works in the form of a hollow body, to be added to before it can be worked in. Stone is easily corrected if it be found inaccurate; whereas for terra-cotta, chipping, cutting, and rasping has to be resorted to, to rectify twisted lines and other inaccuracies; or gaps in a building left for a time until defective or deficient blocks have been manufactured. As it is sent to the works so, probably, the material is fixed generally."

1908*g*. "Terra-cotta, as a superior sort of brick, has to be designed accordingly, and used in string courses, cornices, and such like places, where ordinary bricks so fixed are liable to be affected by the weather; and when manufactured in small pieces, for repetition work, it will come more true, will have a better appearance than when in large blocks, and these will fulfill all constructive requirements; while, as it can be highly decorated at a trifling expense, it can compete favourably with stone similarly used. Without doubt, it is best adapted, both as regards form and colour, for a purely decorative material. It is true there is a great difficulty in combining stone and terra-cotta in the same building effectively; but brick and terra-cotta go well together, and when used legitimately afford the happiest results. Ancient examples show its proper use, but not that as a counterfeiter of stone."—(W. Henman in *British Architect*, 1887, p. 105).

1908*h*. For building purposes the great advantage of terra-cotta is the close and absolutely impervious character of the material. Whether the great advantage claimed for it as being impervious to the action of a London atmosphere, of the present day, is well founded or not, will have to be settled by the test of time, but theoretically it should stand better than any stone under the same conditions.

1908*i*. Another writer remarks as follows: "What are the special characteristics of architectural treatment which terra-cotta demands in order to produce a satisfactory architectural and artistic result with the capabilities and peculiar character of the material? There are two points: 1. The size of the pieces is limited, and the material, while incapable of the high finish and precision attainable in stone detail, and still more in marble, possesses, before it goes into the kiln, absolute plasticity; it can be modelled by the hand with great ease and rapidity, and with much variety. Large projections are unsuitable; they cannot be carried out in a pure terra-cotta style, or without assistance, open or concealed, from other materials. Nothing should be attempted in terra-cotta architecture which is not capable of being honestly executed in the material, without the aid of concealed supports and ties. 2. The designer has before him a material capable of endless variety of treatment, and the chief value of which consists in its artistic treatment. If a considerable amount of repeated ornament is required to be economically produced, it can be obtained by a mould more easily than in most materials; and this continuous ornament can be produced by hand with constantly varying detail. The architect or designer may, in fact, be the actual worker of the ornamentation. With this, if stoneware be used, may be a considerable variety of colour, which is not only indestructible, but is susceptible of being cleansed, an important point in the midst of a town atmosphere.

1908*j*. "The first really architectural use of terra-cotta was in the clay plains of North Italy, and it is from the productions of the architects of this district that much of the inspiration of the modern terra-cotta designer in architecture has been, or should be, drawn. The earlier specimens are of great simplicity, consisting of the simple moulded brick cornice in two or three projecting rolls one over the other. Later came a gradual elaboration of ornament, especially in cornices, in panels, and on the face of pilasters. At the Certosa, at Pavia, the richness is carried in some parts to its greatest possible extent, and is a good example of the constructive ornamental details, but the whole is too overloaded. On the other hand, in the Church of the Carmine, at Pavia, the ornament is for the most part confined to the cornices and horizontal strings, and is designed so as to bring out some of the best capabilities of the material. The cornice has a flat outline, and a slight projection as compared with its vertical measurement. The main divisions of a Classic cornice are kept in view, while in this is a reminiscence of corona, bedmould, and frieze; the effect which cannot be got by projection is sought by increased depth and by richness of surface ornament. The twisted rope-like string below what may be called the frieze, is easily carved out in a plastic material; it is easy to mould; the same may be said of the ornament above it. Other cornices may be found exhibiting a like treatment.

1908*k*. "The consideration of the difference which would have to be made in ornamental detail in transferring it from marble or stone to terra-cotta, or painted and glazed stoneware, suggests another influence in the nature of the material which must also affect the ornament executed. However well mixed and burned may be the clay, the shrinkage and twisting in the kiln render it impossible to trust terra-cotta to give the precise, clear, and sharp symmetry of, say, Greek detail. It may be supposed that the manufacturers of the North Italian artists devised the twists to, as it were, soften the resulting twist of their more immature material, as compared with the modern manufacture, and also in order to avoid the hard straight lines and attempts at symmetrical detail, and to impart such a degree of irregularity in line that accidental irregularities in the manufacture would be the less observable." The writer in the *Builder* goes on to design, and to explain the modifications he has made in, Greek details, to bring them within the proper scope of terra-cotta, and concludes:

1908*l*. "Another point in regard to the general treatment of the walling of terra-cotta buildings is that in many of the Cinque-Cento terra-cotta buildings there is an entire absence of any attempt to obtain a completely homogeneous wall surface. The surface is as varied and broken up in this respect as that of a brick building, thus rather proving again that it is the material for varied and picturesque effect rather than for symmetrical finish and neatness. It has an appearance of surface treatment about it, which is much more in harmony with the feeling of the Renaissance than of Gothic architecture, in which we look for the appearance of great mass and solidity, rather than of elegant surface ornament. This terra-cotta may offer to architects wishing to carry out a Classic type of design with great modifications, a material admirably suited to the conditions of modern city architecture." (*Builder*, 1880, vol. xxxix. p. 195, 230.)

1908*m*. Large and fine works of art, as busts, bassi-rilievi, ornament, &c., have to be *modelled* and *moulded* in the usual way by the artist or sculptor. He gradually forms the clay into a rough outline, hollow, in a cellular way, propping his model true until it is quite finished and dry and ready for burning. This is an original terra-cotta. The trouble is great, but is fully compensated by the result. No moulded copy presents such vigour, freshness, and grace. When, also, only one or two pieces are required, as in decoration, they are formed by hand-working on the clay itself, as in the case of sculpture above described. The more widely the knowledge of pottery is diffused, the more certain the architectural potter is to succeed in developing the use of argillaceous and vitreous substances, in the construction of monumental and sylvan works of art. It will be a new branch of work for the genius of the architect; it will improve and advance the study of modelling in all its ramifications; and it will give refinement and taste to the labours of the poorest brickmaker.

1908*n*. Cornices of great size have been made, and even portions of the shaft of a column 5 feet long. Terra-cotta steps have been advocated, but Messrs. Doulton have refused to make them; they have lately patented a tread (called the Sicilian tread) of great density, which may be used also as a nosing to stone or concrete steps. At South Kensington a flight of steps after two years' wear is still as perfect as when first fixed. Window sills, label mouldings, jambs, water tables, copings, sinks, fire hearths (with massive rounded edge to serve as a fender), stove backs, chimney shafts, &c., could be more elegantly and cheaply wrought in clay than in any other material.

1908*o*. Of late years terra-cotta has been used extensively for the facings and dressings of a building in the place of stone It is generally made of hollow blocks, formed with webs inside so as to give strength to the sides and keep the work true while drying, whereas, when required to bond with brickwork it must be at least 4½ inches thick. When extra strength is needed, these hollow spaces are filled with lime concrete, or Roman cement, as Portland cement is liable to swell and burst the terra-cotta. It is able to bear a very heavy crushing weight. A block of about 1 foot cube, without cross webs or filling, at 40 tons splintered at the edges; and at 100 tons it became generally broken, but not crushed, as on being tied with string it remained in shape.

1908*p*. The putting together of the material requires great care and consideration. The pieces may be flanged and rebated so as to hold together almost without the assistance of mortar. As the outer surface should be almost proof against any ordinary tools, alterations cannot be made as the work proceeds, and the design in detail must be matured before the work be commenced.

1908*q*. The *disadvantages* in the use of terra-cotta are neither numerous nor insuperable. Besides the difficulty of getting the blocks true, which is a matter mainly for the manufacturer, the architect has to design his work so as to be suitable to the material. The great difficulty is on the score of the extra time required to prepare the necessary drawings, one set for the builder, and another set made to the shrinkage scale for the manufacturer. These last are now often made by the manufacturer from the full-sized drawings supplied to him. Mr. Charles Barry writes: "Perhaps the most embarrassing of the disadvantages is the arrangement necessary to have the terra-cotta blocks made and ready on the ground before the rest of the work is begun, in order to work in where wanted as the bricklayers progress. At times this is found impossible, and annoying delays in the general work take place, for which clients are apt to blame their architect. The lesson, of course, to be learned from this is to carefully mature the design at the outset, instead of contenting ourselves with a mere sketch of what is intended, with the hope and intention of working in parts as time goes on and the work proceeds."

1908*r*. In good jobs it is recommended that the *fixing* should be done by or under the supervision of one or more persons experienced in the material, and the proper use of suitable cements—Portland cement will split a block in pieces—especially where most strength is required, as considerable additional strength may be gained, which is only acquired by practice. An expert will be more likely to make it work together for good line and fit, by setting and humouring, as the pieces are apt to be taken as they come; and this is especially necessary where small pieces are adopted for simplicity of execution, cheapness, and expedition; time is an object for large pieces to dry, burn, and cool gradually, all essential to good work, and to escape from twisting, hair cracks, &c.

1908*s*. Terra-cotta resists the *action of fire*. It is used as a protection to ironwork, iron columns, &c., and can be treated artistically. Heat which would destroy stone merely burns the dirt from this material, giving it the appearance of having just left the kiln. At a large fire at Messrs. Doulton's factory the stone sills of the windows and copings of the walls were destroyed, while the dressings of the windows, which were of their terra-cotta, were perfectly sound and looking all the brighter for the burning.

Colours in Terra-cotta.

1098*t*. One advantage of the material is the delightful random variety of tone of *colour* which is often to be obtained. The colour varies, giving an appearance of depth to the work and producing very pleasing effects, at times. This variety is generally produced by the flash of the fire. The natural colours are buff, red, and blue, more or less intensified by the amount of heat to which they are subjected. Other colours can be obtained by the admixture of foreign matter. The red terra-cotta of Ruabon is made from a natural red-coloured clay when burnt, very hard and non-porous, with a clean, smooth surface. The buff terra-cotta is a good and sound material, burns hard, and keeps its colour. The pink terra-cotta, a new colour, is made from pure clays, and is without any stain, very hard and durable. By a little additional cost and the operation of a second firing, a soft dull glaze can be put on all terra-cotta bricks, mouldings, and ornaments, so that façades executed in this way could be washed clean by water from a fire engine.

1908*u*. The aid of terra-cotta to polychromatic effect is capable of being developed in a very elaborate manner. Variety may be obtained in the *unglazed* ware by what is called "slipping," or mixing two clays of different tones together in water to produce a third or intermediate tone. In *glazed* terra-cotta the material can be painted in a great variety of colours, which are then fixed, and at the same time rendered more brilliant in effect. This ware is formed by throwing salt into the fire when the ware is at a white heat, which is decomposed in the form of vapour, the soda suspended in it incorporates itself with the surface of the ware, forming the glaze. Various mineral colours are used, and the main colour is influenced by the fuel: the blue colour of the ancient Rhenish productions is considered to be due to the use of woad. It has been stated (*Archæologia*, iii. 112, and *Proceedings*, xi.) that at Gatacre Old House, near Bridgenorth, "a glazing seems to have been applied to the stone of which the house is built, by some unknown process, after the building was finished, as it covered the joints as well as the stones."

1908*v*. The intense heat to which glazed ware is subjected, and the consequent difficulty of keeping its true shape, makes its use in this form very difficult. It is comparatively easy in all thrown ware, which, from its circular form, shrinks evenly in all its parts. The liability in all moulded work to warp and twist requires increasing care in all its preparatory stages. That it is not impossible may be ascertained from the salt-glazed stoneware in the vestibule of the "Palsgrave," opposite the Law Courts in the Strand. This greater risk seems to necessitate that "its use must be in small pieces, and in such places where absolute flatness of surface is not indispensable; but under these conditions it may be applied with admirable effect to heighten mouldings, or to panel terra-cotta pilasters, or as bases and capitals, especially as shafts to ornamental columns, and as bosses."

1908*w*. The paper read by the late J. M. Blashfield before the Northampton Architectural Society, Sept. 6, 1859, on *Ancient and Modern Pottery*; and that by Mr. James Doulton, read April, 1886, at Carpenters' Hall, on *Terra-cotta*, have also been freely quoted from in the above account.

Sect. III.

MASONRY.

1909. Masonry is the science of preparing and combining stones so as to tooth, indent, or lie on each other, and become masses of walling and arching for the purposes of building. The tools of the mason vary as the quality of the stone upon which they are to act. About the metropolis the value of stone is considerable; and it is accordingly cut into slips and scantlings by a saw moved horizontally backwards and forwards by a labourer. In those parts where stone is abundant it is divided into smaller scantlings by means of wedges. The principal tools of the mason are the *mallet* and *chisels*, the latter being formed of iron, except at the steel end, and the cutting edge being the vertical angle. The end of the chisel struck by the mallet is a small portion of a spherical surface, and projects on all sides beyond the adjoining part or hand-hold, which increases in magnitude towards the middle of the tool, to the entering or cutting edge. The other tools of the mason are a level, a plumb-rule, a square, a bevel, with straight and circular rules of divers sorts, for trying surfaces in the progressive states of the work.

1910. In London, the tools used to work the face of a stone are, successively, the *point*, the *inch tool*, the *boaster* (the operation of working with which is called *boasting*, as that with the point is called *pointing*), and the *broad tool.* The use of the point leaves the stone in narrow furrows, with rough ridges between them, which are cut away by the inch tool, and the whole made smooth by the boaster. The point is from $\frac{1}{8}$ to $\frac{3}{8}$ of an inch broad, the boaster is 2 inches wide, and the broad tool $3\frac{1}{2}$ inches at the cutting edge, which in use is always kept perpendicular to the same side of the stone. It performs two sorts of operations. Thus, imagine the impression made by the whole breadth of the tool at the cutting edge, to be called a cavity; in one operation, the successive cavities follow one another in the same straight line, until the breadth or length of the stone is exhausted; successive equidistant parallel lines are then repeated in the same manner, until the tool has passed over the whole surface. This operation produces a sort of fluted surface, and is called *stroking.* In the other operation, each successive cavity is repeated in new equidistant lines throughout the length or breadth of the stone; then a new series of cavities is repeated throughout the length and breadth of the stone; and thus until its whole length or breadth is gone through. This operation is called *tooling.* The tools for working the cylindrical and conical parts of mouldings are of all sizes, from $\frac{1}{8}$ of an inch upwards. Those for working convex mouldings are not less than half an inch broad, except the space be too confined to admit of such breadth.

1911. A stone is taken out of winding principally with points, and finished with the inch tool. In London, the squared stone used for facing buildings is usually stroked, tooled, or rubbed.

1912. In those parts of the country where the stone saved by the operation of sawing is not enough to compensate for the labour, the operation is altogether performed with the mallet and chisel.

1913. When stones, previous to the operation of hewing, are very unshapely, a *stone axe, jedding axe, scabbling-hammer,* or *cavil,* is used to bring the stone nearly to a shape; one end of the jedding axe is flat, and is used for knocking off the most protuberant angular parts, when less than right angles; the other end is pointed for reducing the different surfaces to nearly the intended form.

1914. In Scotland, besides the above described sorts of work, there are some other kinds, termed *droved, broached,* and *striped.* Droving is the same as that called random tooling in England, or boasting in London. The chisel for broaching is called a *punch,* and is the same as that called a point in England. Broached work is first droved and then broached, as the work cannot at once be regularly done with the punch. Striped work must also be first droved and then striped. If broaching is performed without droving, which is sometimes done it is never so regular, and the surface is full of inequalities. Of the three kinds of surfaces obtained, the droved is the cheapest.

1915. It is, however, to be observed, that the workmen will not take the same pains to drove the face of a stone which is to be afterwards broached, as in that of which the droving is to remain the final finish. When the surface of stone is required to be perfectly smooth, it is accomplished by rubbing with sand or gritstone, and it is called rubbed work.

1915*a*. Some useful practical remarks for obtaining the face to stone in mediæval work, is given in Denison's *Lectures on Church Building,* 1856, p. 216. "The mode of working mouldings depends a good deal upon the kind of stone used. In that from Steetly near Worksop, employed almost exclusively outside the new church at Doncaster, and in the Ancaster stone, used for pieces of window tracery and mullions too large for the blocks that can be got from Steetly, and in the Brodsworth stone, the mouldings are all completed with a *drag.* I do not use the word 'finished,' because that means going over the work to put a particular kind of surface upon it after it is really completed. On the other hand, the Crookhill stone, of which all the pillars and a few other parts are made, would utterly defy any such small tooth-comb work, as a drag; nothing under a chisel with a heavy hammer will touch it. Again, some stone from Huddlestone is too tough and cheese-like for dragging, and the mouldings in it are completed by shaving them with a chisel, something like wood carving. The effect of that is very good, because a chisel run along in that way will always make a rather undulating surface, though smooth enough to the touch, even to please the finger of a clerk of the works. In some real Norman arches, which had been covered with plaster for centuries, the mouldings showed that the drag or tool had never been allowed to make the marks directly across; generally they are oblique and sometimes parallel to the direction of the moulding. Worked in this way, the stones will be sure to show themselves distinctly, and the effect of the mortar staining the stones for a little distance from the joints, produces anything but a bad effect. Tuck-pointing, to rather rough masonry especially, *i.e.*, making prominent joints in mortar, with the edges cut quite straight and square, is another chance of spoiling work. After a few years this generally splits off," and the building may look at last as it should have done at first. The mortar should be finished within the face of the stone. The stone work at S. Alban's Abbey is described by Mr. Neale, as finished by the *axe* by the Normans; *chiselled* during the Transition period; *bolster tooled* during the Early English; *claw tooled* during the Decorated, and the mouldings *scraped*; while during the Perpendicular period it is *finely scraped.*

1915*b*. Grey granite, or moorstone as it is called in Cornwall, is got out in blocks by splitting it with a number of wedges applied to notches *pooled* in the surface of the stone, about four inches apart. The *pool holes* are sunk with the point of a *pick*, much in the same way as other hard quarry stones are split. The harder the moorstone the nearer it can be split to the scantling required. Generally speaking, granite has no planes of stratification, and it works or cleaves equally well in every direction; but in the porphyritic varieties there is a rough kind of arrangement of the crystals; and in gneiss there is a species of layer, formed by plates of the mica, which is plainly discernible. When brought to near the size required, it is first *scabbled* by a hammer with a cutting face $4\frac{1}{2}$ inches long by $1\frac{1}{2}$ inches wide, weighing 22 lbs.; then brought to a *picked face* with a pick or pointed hammer weighing 20 lbs., formed by two acute angled triangles, joined base to base by a parallelogram between them thus ; and if to be *finely wrought or fine picked*, it is further dressed with a similar pointed hammer, reducing the roughness to a minimun. The finer finish or *fine axed face* is produced by a hammer or axe with a sharp edge on both sides, weighing 9 lbs.; for *fine work* the "patent axe" is also used, which is a hammer formed of several parallel blades screwed together, capable of being taken to pieces when required to be sharpened. Polishing can then be done by machinery, the granite being rubbed by iron rubbers with fine sand and water, and finished with other materials.

1915*c*. Aberdeen red granite possesses the property common to all granites, that of a distinct plane of cleavage, which, though not perceptible to the eye, is at once recognisable under the hammer of the workman, and of course can be wrought with much greater precision and effect with the bed, than transversely to it. This bed bears no traceable relation to the natural joints of the rocks, which are indefinite in their directions; and still less so to their stratification. The grey granites are but slightly affected with cleavage, being capable of being *blocked* with the hammer with about equal facility in every direction. The local varieties of worked granite differ somewhat from those used in England, and are, I. *Hammer-blocked*, as in foundations, plinths, &c. II. *Scappled blocks*, squared with the heavy pick, as in docks and heavy engineering works. III. *Picked*, a better finish than No. II. IV. *Close picked*, the bed and arrises made fair, and the outer surfaces made as fine as the pick will make them; used in ashlar work, &c. V. *Single axed*, a finer finish than No. IV., and used in quoins, rebates, cornices, &c., in house building. And VI. *Fine axed*, the finest finish before polishing, given to dressed granite by means of the *patent axe*, used in the best work in house building, cemetery memorials, and as a finish to contrast with polished work.

WALLING.

1916. In stone walling the bedding joints are usually horizontal, and this should always, indeed, be so when the top of the wall is terminated horizontally. In building bridges, and in the masonry of fence walls upon inclined surfaces, the bedding joints may follow the general direction of the work.

1916*a*. Footings of stone walls should be built with stones as large as may be, squared and of equal thicknesses in the same course, and care should be had to place the broadest bed downwards. The vertical joints of an upper course are never to be allowed to fall over those below, that is, they must be made, as it is called, to *break joints*. If the walls of the superstructure be thin, the stones composing the foundations may be disposed so that their length may reach across each course from one side of the wall to the other. When the walls are thick, and there is difficulty in procuring stones long enough to reach across the foundations, every second stone in the course may be a whole stone in breadth, and each interval may consist of two stones of equal breadth, that is, placing header and stretcher alternately. If those stones cannot conveniently be had, from one side of the wall lay a header and stretcher alternately, and from the other side another series of stones in the same manner, so that the length of each header may be two thirds, and the breadth of each stretcher one third of the breadth of the wall, and so that the back of each header may come in contact with the back of an opposite stretcher, and the side of that header may come in contact with the side of the header adjoining the said stretcher. In foundations of some breadth, for which stones cannot be procured of a length equal to two thirds the breadth of the foundation, the works should be built so that the upright joints of any course may fall on the middle of the length of the stones in the course below, and so that the back of each stone in any course may fall on the solid of a stone or stones in the lower course.

1917. The foundation should consist of several courses, each decreasing in breadth as they rise by sets off on each side of 3 or 4 inches in ordinary cases. The number of courses is necessarily regulated by the weight of the wall and by the size of the stones whereof these foundations or footings are composed.

1918. Walls are most commonly built with an ashlar facing, and backed with brick or rubble-work. In London, where stone is dear, the backing is generally of brick-work, which does not occur in the north and other parts, where stone is cheap and common. Walls faced with ashlar, and backed with brick or uncoursed rubble, are liable to become convex on the outside from the greater number of joints, and, consequently, from the greater quantity of mortar placed in each joint, as the shrinking of the mortar will be in proportion to the quantity; and therefore such a wall is inferior to one wherein the facing and backing are of the same kind, and built with equal care, even supposing both sides to be of uncoursed rubble, than which there is no worse description of walling. Where a wall consists of an ashlar facing outside, and the inside is coursed rubble, the courses at the back should be as high as possible, and the beds should contain very little mortar. In Scotland, where there is abundance of stone, and where the ashlar faces are exceedingly well executed, they generally back with uncoursed rubble; in the north of England, where they are not quite so particular with their ashlar facings, they are much more particular in coursing the backings. Coursed rubble and brick backings admit of an easy introduction of bond timber. In good masonry, however, wooden bonds should not be continued in length; and they often weaken the masonry when used in great quantity, making the wall liable to bend where they are inserted. Indeed, it is better to introduce only such small pieces, and with the fibres of the wood perpendicular to the face of the wall, as are required for the fastenings of battens and dressings.

1919. In ashlar facing, the stones usually rise from 28 to 30 inches in length, 12 inches in height, and 8 or 9 inches in thickness. Although the upper and lower beds of an ashlar, as well as the vertical joints, should be at right angles to the face of the stone, and the face and vertical joints at right angles to the beds in an ashlar facing; yet, when the stones run nearly of the same thickness, it is of some advantage, in respect of bond, that the back of the stone be inclined to the face, and that all the backs thus inclined should run in the same direction; because a small degree of lap is thus obtained in the setting of the next course, whereas, if the backs are parallel to the front, no lap can take place when the stones run of an equal depth in the thickness of the wall. It is, moreover, advantageous to select the stones so that a thicker one and a thinner one may follow each other alternately. The disposition of the stones in the next superior course should follow the same order as in the inferior course, and every vertical joint should fall as nearly as possible in the middle of the stone below.

1920. In every course of ashlar facing in which the backing is brick or rubble, *bond*, or, as they are called in the country, *through* stones should be introduced, their number being proportioned to the length of the course; every one of which stones, if a superior course, should fall in the middle between every two like stones in the course below. And this disposition should be strictly attended to in all long courses. Some masons, in carrying up their work, to show that they have introduced a sufficient number of bond stones into their work, choose their bond stones of greater length than the thickness of the wall, and knock or cut off their ends afterwards. But this is a bad practice, as the wall is liable to be shaken by the force used in reducing, by chiselling or otherwise cutting away the projecting part, and sometimes with the chance even of splitting the bond stone itself.

1921. In piers, where the jambs are coursed with ashlar in front, every alternate jamb stone should go through the wall, with its bed perfectly level. If the jamb stones are of one entire height, as is often the case when architraves are wrought upon them, and also upon the lintel crowning them, of the stones at the ends of the courses of the pier which are to adjoin the architrave jamb, every alternate stone should be a bond stone; and if the piers be very narrow between the apertures, no other bond stones will be necessary in such short courses. When the piers are wide, the number of bond stones is to be proportioned to the space. Bond stones, too, must be particularly attended to in long courses above and below windows. They should have their sides parallel, and of course perpendicular to each other, and their horizontal dimension in the face of the work should never be less than the vertical one. The vertical joints, after receding about three quarters of an inch from the face of the work with a close joint, should widen gradually to the back, so as to form hollow wedge-like figures for the reception of mortar and *packing*. The adjoining stones should have their beds and vertical joints filled with oil-putty, from the face to about three-quarters of an inch inwards, and the remaining part of the beds with well-prepared mortar. Putty cement is very durable, and will remain prominent when many stones are in a state of dilapidation, through the action of the atmosphere upon them. The use of the oil-putty is at first disagreeable, from the oil spreading over the surface of the contiguous stones; but after a time this unpleasant look disappears, and the work seems as though of one piece.

1922. All the stones of an ashlar facing ought to be laid on their natural beds. From inattention to this circumstance, the stones often flush at the joints; and, indeed, such a position of the lamina much sooner admits the destructive action of the air to take place. Methods of building in cement and concrete blocks, are noticed in the previous section.

1922*a*. Rubble-work. A wall consisting of unhewn stone is called a *rubble* wall, whether or not mortar is used. This species of work is of two kinds, coursed and uncoursed. In the former, the stones are gauged and dressed by the hammer, and thrown into different heaps, each containing stones of the same thickness. The masonry is then laid in horizontal courses, but not always confined to the same thickness. The uncoursed rubble wall is formed by laying the stones in the wall as they come to hand, without gauging or sorting, being prepared only by knocking off the sharp angles with the thick end of the scabbling hammer.

1922*b*. Apparently, wherever there was any difficulty in obtaining stone, the mediæval builders employed the worst of all methods of construction in walling, viz., concrete or rubble-work between the two faces of squared stone. In the early period of mediæval art, flint or rough rubble, with "short and long work" to the quoins, seems to have been very general; this "short and long work" was also used in faced walls; in both cases the short work consists of stone upon its bed, and alternates with the long work or stone upright: the short work ought to serve as bond throughout the walls. In the 12th century the use of rubble in conjunction with worked stone became frequent. The chief defect, frequently considered one of the merits, of this system, consists in the omission of sufficient bond both in piers and walls; the occurrence of joints in angles is too frequent; in fact, any expedient seemed better than the trouble of making a back-joint.

1922*c*. Kentish Ragstone. This material, now so extensively employed for mediæval work in the metropolis and suburbs, is never used *internally*, as it *sweats*, that is, the condensed moisture from the atmosphere is not absorbed, and will show itself even through two coats of plastering. *Hassock stone*, however, which is the sandstone separating the beds of the ragstone, the sand being sufficiently agglutinated to allow of its being raised in blocks, must never be used *externally*. It is easily worked, and makes a good lining for ragstone walls, as it does not sweat. It should be roughly squared, for if not done, the crumbling nature of the stone would endanger the security of the work, should it be exposed to any unequal pressure: it must not be placed where it would be exposed to very great pressure, as in arches, jambs, &c. Hassock may be procured in London at from 6*s*. to 7*s*. per cord (3 feet cube), in roughly squared pieces; while rough rag is about 5*s*. per ton, and rag headers about 12*s*. 6*d*. per ton.

1922*d*. Sunk and moulded work in so hard a material is to be avoided, and so much wrought surface would cause decay. In using ragstone ashlar, it must be laid upon its natural bed, otherwise rapid decay will almost certainly follow, arising from the thinness of the strata, for blocks of a large size can seldom be entirely freed from hassock; and even what appears to the eye as blue stone, retains for a considerable distance inward the perishing nature of its enveloping crust. A block of ragstone, if the face be worked, will present in damp weather an appearance precisely similar to the heart and sap of timber. In the case of copings, &c., where one bed is exposed, the stone should be *skiffled* (or *knobbled*) as much as possible from the upper side, so as to expose only the soundest portion of the stone to the action of the atmosphere. In some situations, as mullions, door and window jambs, an unsightly appearance would be produced by too exact an attention to the beds of the stone, as the ashlar is generally too small to range with more than one course of headers. In these cases the old masons seem to have departed from their usual rule, and to have set the blocks on end, so as to embrace two or three courses; but as the depth of the block required to work an ordinary jamb or mullion is not very great, it is not difficult to get the whole thickness required out of the heart of the stone.

1922*e*. Stone of the smaller layings are generally worked into headers; it is common to work one side of the stone to a rough face with parallel sides, without paying much attention to the beds and joints, which often recede at an acute angle with the face, so as to bring the stones, when laid, to a closer joint. Such stones, however, must be properly pinned in behind, and carefully bonded with the work at back. Headers are generally knocked out to six, seven, eight, or nine inch gauge for the height; the length and tail being determined by the size of the stone: on the face they do not vary much from the square form. Formerly headers were set on their natural bed, therefore it is not unusual to find stones in an old wall entirely gone from this cause.

1922*f*. In the Whitelands bridge bed, a very free working stone of a bluish colour can be got 12 feet long with certainty, and the Horsebridge bed yields a good stone to a length of 15 feet. The white rag, the lowest of the beds in the quarry, tumbles to pieces on exposure to the air (Whichcord, *Kentish Ragstone*, 1846).

1922*g*. In its mechanical properties, ragstone possesses some of the qualities of granite, though in an inferior degree. In respect to resistance to pressure, it stands next to granite in the list of British stones; but when loaded for a transverse strain, the numerous vents to which even the best layings are liable, renders it untrustworthy for lintels, or in a suspended position, without much precaution. In the former case of lintels and architraves, three stones, arch jointed, gives the requisite security.

1922*h*. Whinstone, a material, in one form or another, found almost over all Scotland, makes a very durable arch for bridge work, when well built with good mortar, the stone being in its nature weather proof. In the neighbourhood of Edinburgh, whinstone arches have been erected since about 1770, the greatest span being about 60 feet. The Messrs.

Smith, of Darnick, stated, in the *Transactions* of the Institute of British Architects, that they had erected bridges with semi-elliptical arches of the spans of 51 feet, and of 62½ feet, of whinstone faced with hewn stone. A bridge, almost entirely of whinstone, having an arch 63½ feet span, the depth of the masonry being 2½ feet on the average, was erected in 1833; while another, 76 feet 4 inches span, at Falshope, was entirely of whinstone, with a rise of about 18 feet. It sunk about seven inches when the centre was struck, but no broken stone was observed. The depth of the arch, requiring three breadths of stone to make it up, was 3 feet; their average thickness was 3½ inches; but it varied from 1½ to 6 inches. The stones were laid as close as possible, and in crossing the bond the work was made firm, but the stones were not dressed straight upon the beds. Its cost was 360*l.* exclusive of the digging for the foundations.

1922*i.* The most annoying part in the building of rubble arches, is the slowness of the setting or drying of the mortar, as until the mortar is able to bear considerable resistance the arch is extremely supple, and easily bent out of its proper curve when the centre is struck. This bridge stood five weeks before that measure was considered advisable. Cement would perhaps be best for large rubble arches, and even if expensive, the whole cost would be cheaper than a bridge of hewn stone. With cement, almost any kind of stone, even the refuse of a slate quarry, might be worked into an arch of almost any extent.

1922*k.* Flintwork.—In the chalk districts, the houses of the fifteenth century are frequently faced with flints, cut and trimmed, and arranged with great skill and effect. One of the best examples is a house in St. Andrew's, at Norwich, next the cemetery, a fragment of the decorated period of Gothic architecture, in which the flint work is so delicately finished that a penknife can scarcely be inserted in the interstices.

1922*l.* As flint itself is practically imperishable, and as flintwork becomes, when perfectly set, a mass of concrete, it produces substantial work, if great care be taken in its manipulation. But flint walls frequently fail, by bulging while they are in course of construction, and splitting when they are old. On any sufficient natural cause, as the giving way of the foundation, they are riven into immense masses; hence a flint building gets out of repair less readily than a stone one, but if it suffer at all, it is very apt to become a complete ruin.

1922*m.* Flint walls intended for durability should not be less than two feet in thickness, built slowly and solidly, flushed up with stiff strong mortar compounded of quick-setting stone lime and coarse sharp sand free from loam. As flint is a non-absorbent, bricks and tiles are often worked into the middle of the walls to assist in the induration of the mortar; but for the sake of economy, lumps of hard chalk, pebbles, and flat-bedded stones are frequently used as the principal components of the *core* or middle of the wall. The work must be kept as dry as possible during its erection, as well as subsequently; frost is found soon to level the work while saturated with water.

1922*n.* Flint walls are strengthened by *lacing courses*, formed of bricks three or four courses deep, not generally showing outside. At Cambridge, Brandon, and elsewhere, they do show, and are used every two or three feet. The object is not only to get a continuous bond, but to bring the work to a level bed, and again start fair. When round flints are split, and the thicker portion is kept, as usual, at the face of the wall, driving rains are readily conducted by the inclination of the upper bed of each course to the middle of the wall, and by keeping it damp conduce to its decay; but as flints are seldom split at right angles to their axis, they can be so laid in the work as to be flush on the face as well as level, and the lower bed must be firmly pinned up with fragments. It is desirable that cavities for drainage, with exit holes at the plinth level, be formed in the middle of the wall by building in rods of wood or iron vertically, and drawing them up as the work progresses. The face is sometimes finished by inserting in the mortar joints *gailets*, or the sharp fractured bits of flint, when the work is called *galleted* or *garreted* (*Dictionary of Architecture*).

1922*o.* Amongst examples of a systematic parsimony of labour and material in mediæval art, may be noticed the characteristic *tables* or courses, where each projection is taken out of a separate course of stone or out of the smallest stone adjoining to it. The base (*fig.* 618.) and the capital (*fig.* 618*a.*) of a shaft are kept so small as to be got out of single blocks; the astragal belongs to the capital, and not, as in Roman work, to the shaft; the bell is in one stone, the abacus in another (*fig.* 618*d.*); each *order* of an arch is an independent range of stones; the hoodmould is self-existent; the sills are not dished, and the buttresses are toothed rather than bonded. In two cases, however, the use of large stones prevailed, viz., in shafts of the 13th century (in France, 1160–1230), which are long rods of stone 6, 4, or 3 inches in diameter and incapable of bearing any great weight, unless banded or bonded to the nearest wall or

Fig. 618.

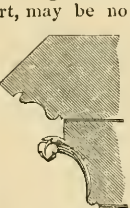

Fig. 618*a*.

pillar, and in the springing stones of vaulting, which are worked with level beds. (See par. 2002*f.*) The horizontal courses at the bottom of the arch are also seen in the construction of large horse-shoe arches. With the 13th century, also came the decided distinction between decoration and mere construction, which employed stone vertically, not only for shafts of columns, but for mullions and tracery of windows and dwarf walls, such tracery being cut out of slabs and confined by grooves or similar means.

1923. Where walls or insulated pillars of very small dimensions are to be carried up, every stone should be carefully bedded level, and be without concavity in the middle. If the beds should be concave, as soon as the superimposed weight comes to be borne by the pier or pillar, the joints will in all probability begin to flush; and it is, moreover, better, if it be possible, to make every course in the masonry of such a pier or pillar in one stone.

COLUMNS.

1924. When large columns are obtained in a single block, their effect, from that circumstance alone, is very striking; but as this is not very often to be accomplished, the next point is to have as few and as small joints as possible; and the different stones, moreover, ought to be selected with the view, as much as possible, of concealing the joints, by having the blocks as much of the same colour as possible. It will immediately, of course, occur to the reader that vertical joints in columns are inadmissible, though in many of the great edifices at Paris such do occur, much to their detriment.

1925. The stones for an intended column being procured, and the order in which they are to be placed upon one another having been determined, we must correctly ascertain the exact diameter for the two ends of each of them. To effect this, draw an elevation of the column proposed to its full size, divide it by lines parallel to the base into as many heights as the column is intended to contain stones, taking care that none of the heights exceed the lengths the stones will produce; the working of the stones to the diameters thus obtained then becomes easy. The ends of each stone must first be wrought so as to form exactly true and parallel planes. The two beds of a stone being thus formed, find their centres, and describe a circle on each of them; divide these circles into the same number of equal parts, which may, for example, amount to six or eight; draw lines across each end of the stone, so that they will pass through the centre and through the opposite divisions of the same end. The extremities of these lines are to regulate the progress of the chisel along the surface of the stone; and, therefore, when those of one end have been drawn, those of the other must be made in the same plane or opposite to them respectively. The cylindrical part of the stones must be wrought with the assistance of a straight-edge; but for the swell of a column, a diminishing rule, that is, one made concave to the line of the column, must be employed. This diminishing rule will also serve to plumb the stones in setting them. If it be made the whole length of the column, the heights into which the elevation of the column is divided should be marked upon it, so that it may be applied to give each stone its proper curvature. But as the use of a very long diminishing rule is inconvenient when the stones are in many and short lengths, rules or rods may be employed corresponding in length to the different height.

1925*a*. The method of setting the blocks or *frustra* by the ancients, was to *dish out* the beds to obtain a truly fine joint. In the Parthenon, an outer space of 7 inches in width all round the drum, was left a perfectly level and smooth bed for actual contact. The next space, of 1 foot in width, was very slightly tooled or scratched over. The next, 9 inches in width, was made still lower by being tooled over very roughly. The remaining portion round the centre was left smooth, but was made as low as the surface of the second space. A square hole, worked at the quarry, in the centre of the shaft, was filled with a cube of hard wood, in which was a hole to receive the half of a circular pin, also of wood, suggesting the idea that when the marble *frustra* were set, they were rubbed against each other. The first drum, at the temple of Hercules at Agrigentum, when placed on the stylobate, was turned round until it had been well ground down. (*Civil Engineer*, *&c.* vii. p. 241.) The practice of late years, for large columns, has been to place a plate of thin lead between the beds of stone, so as to secure an equal bearing and prevent the edges flushing, any space being filled in with putty or cement. At Paris, in many of the porticoes, the columns have very deep thin rusties (*fig.* 618*b*.), which would effectually prevent any broken edges from being observed. The effect is peculiar, especially in strong sunlight. The height of the face of the stone is ·385 of a metre; the height of the channel, including the rounded arrises, is ·40, and the depth of the channel is ·85.

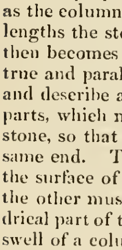

Fig. 618*b*.

1925*b*. Besides the usual mode of drawing a volute, described in par. 2576, we insert a method recommended by Mr. Gwilt for adoption. A general method of inscribing a spiral in a rectangular quadrilateral, A B C D:—Multiply the given height by the given breadth, and divide the product by the sum of the height and breadth. Then subtract the quotient from the height. The remainder is the radius of the first quarter revolution of the spiral: The formula is $h - \frac{h \times b}{h+b} = r$ (= BE, ba or Fa). Subtract the radius aF so found from the height BD and the remainder FD will be the radius of the second quarter of the revolution, and is to be set from F to b. The difference ab between a F and b F will form one side of the quadrilateral *abcd*. Subtract the radius Fb from the width CD and the remainder GC will give *bd* the other side of the quadrilateral *abcd* (which points will be the centres for the portions of the first revolution), and will be a figure similar to, or of the same proportions as, the given quadrilateral ABCD. Then dG will be the radius of the third quarter of the revolution and Hc the radius of the fourth quarter. In the quadrilateral or parallelogram *abcd*, draw the diagonals *ad*, *bc*, and draw bH, cutting the diagonal *ad* in *e*, then will *e* be a point for the formation on the diagonals of another parallelogram *efgh*, whose angles (as in that first made) will be the centres for the radii of the second revolution. By again drawing Hf to cut the diagonal *ad*, another parallelogram may be formed, and so on to bring out the spiral. X is the centre part to a larger scale (*Builder*, xviii. p. 364).

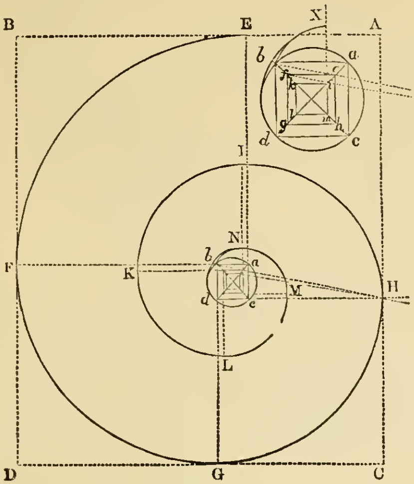

Fig. 618c.

1925*c*. From the nature of the formula it is evident that when $h : b$ is but by a trifle in a greater ratio than 1·61 : 1 the first radius will be greater than the breadth of the quadrilateral, and the spiral cannot be described within the figure. Also that when h and b are equal, the spiral vanishes, for the formula becomes $h - \frac{h^2}{2h}$ and the first radius is equal to half the side of the circumscribing square. Hence a circle is inscribed. Also that as the height and breadth approach equality the number of revolutions increases. In the diagram the height is taken at 27 equal parts and the breadth at 23 of such parts. Upon trial it will be found that the exact proportion of the height to the breadth to bring out a spiral within the given quadrilateral lies between 1·61 : 1 and 1·62 : 1.

1925*d*. When a *pier* was to stand upon the head of a pillar, the early mediæval builders avoided an error which their ancestors often committed. Instead of turning the arches and filling up the space at the springing until there was a clean base for the pier (*fig.* 618*d*.), they built some courses of the arch-stones in single blocks exceeding the width of the pillar. When these had risen so high that the base of the pier would not interfere with the

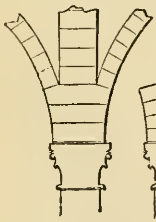

Fig. 618*d*.

Fig. 618*f*.

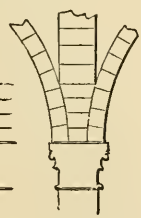

Fig. 618*e*.

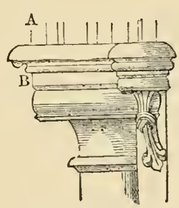

Fig. 618*g*. WESTMINSTER ABBEY.

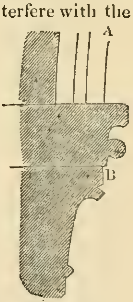

Fig. 618*h*.

arch-stones, these horizontal courses were discontinued (*fig.* 618*e*.). A modern folly (*fig.* 618*f*.) was unknown to them. A similar system dictates the construction of a corbelled foundation for any work standing free from the general thickness of the wall. In early pointed work the intrados of an arch (as A in *figs.* 618*g*. and 618*h*.) was plumb with the face of the square block B, forming part of the capital; and equally the front of a shaft over a capital is plumb with the same square block.

1925*e*. JOGGLING. Lintels or flat arches, stone architraves, chimney mantels, and such like, when formed of small stones, are secured by joggling the joints of adjacent stones so as to form a continuous beam, the strength depending upon the solidity of the abutments. The gauged arches formed of cut bricks and used as heads to openings, are similar in effect, but as they have neither joggles nor dowels, they are now sometimes assisted, especially in uncertain foundations, by placing under them a thin flat bar of wrought iron. Bartholomew, in his *Specifications*, 1840, gives some ancient specimens from Roman sepulchres, the three lower courses being prevented from sliding by a wedge-shaped joggle formed on the top bed of one stone, and a corresponding hole cut in the lower bed of the next stone, to receive it. *Fig.* 618*i.* is perhaps the earliest instance of a similar contrivance, and shows the oversailing portions (French *crossettes*). It is taken from

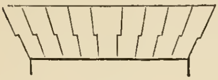

Fig. 618*i*.

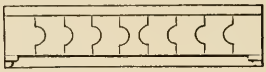

Fig. 618*k*.

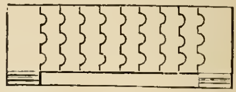

Fig. 618*l*.

Diocletian's palace at Spalato, a building often referred to as exhibiting the germs of several of the peculiar ornaments afterwards prevalent in the Romanesque and Norman styles of art (par. 198). The same principle is seen in a semicircular arch of eleven voussoirs in the lower story of the reputed tomb of Theodoric at Ravenna; in a chimney-piece at Conisborough Castle, Yorkshire; and at the gate of the Alhambra. Murphy's *Batalha*, gives, in plate 2, two instances of the same kind of construction. With double set-offs, an example is found in the upper part of Theodoric's tomb. *Fig.* 618*k.*, showing the introduction of tenons of a circular form, is the transom of the Norman west door-way of Rochester Cathedral. *Fig.* 618*l.* having three tenons to each stone, is from the mantel of a fireplace in Edlingham Castle, Northumberland.

1925*f.* Serlio, in his *Opere d'Architettura*, in Book iv. chap. v., shows two excellent modes for relieving the weight from a lintel over an opening, *figs.* 618*m.* and 618*n.* *Fig.* 618*o.* is the mode adopted by Mylne, in erecting Blackfriars Bridge, where each joggle consists of a cube foot of a hard stone. During the repairs of this structure in 1833, the decayed or broken stones were cut out, and new blocks inserted by the ingenious arrangement shown in *fig.* 618*p.* A represents the new block let in, in two parts. B is first fixed, having a hole cut to receive a plug C, which is placed in a hole in the half D; on this block being inserted in place, the plug C drops half its length into the hole in B and secures the portion D. Channels were also cut through the blocks, through which wires were placed attached to the plug to insure its sliding into its place. These were cemented up subsequently. In small works, copper plugs, or dowels would be more proper than the large blocks shown in *fig.* 618*o.*, as they require the removal of less of the substance of the arch stones as necessary for admitting joggles. Cubes, and dowels, of slate are now very much employed.

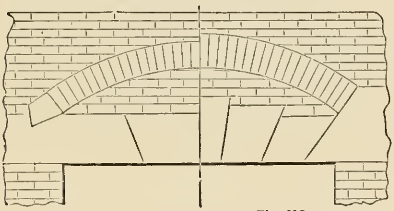

Fig. 618*m*. Fig. 618*n*.

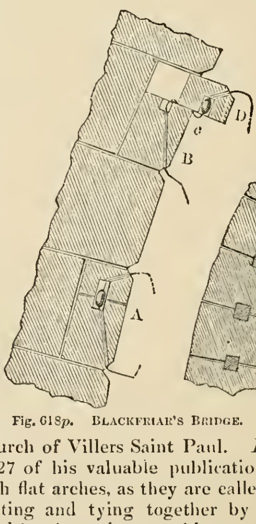
1925*g*. Another method much practised consists in joining, by an elbow to each voussoir, a portion of the neighbouring horizontal course of the work. This arrangement will be understood at once by reference to *figs.* 956 and 957; but, however good it may appear at first sight, it is liable to split at the junction of the horizontal portion with the radial parts, if any irregular settlement takes place. The rustic channels of arcades wrought in this form have, however, a good effect.

1925*h*. From Viollet le Duc, *Dictionnaire*, we obtain the use of the *crossettes* as exemplified in a chimneypiece (*fig.* 618*q.*). *Fig.* 618*r.* is the lintel to the door on the north side of the Church of St. Etienne at Beauvais; and *fig.* 618*s.* that of the Church of Villers Saint Paul. *Fig* 618*t.* shows the system described by Rondelet, in plate 27 of his valuable publication, for obtaining the requisite proportion of strength in such flat arches, as they are called. Whoever may be interested in the method of supporting and tying together by rods and bars, the stones of architraves, as formerly practised by the eminent architects of France, must be referred to the publications of Rondelet, Patte, D'Aviler, Blondel, and others of that period; in fact, the system is still introduced in the modern publications on construction, in the French school of architecture.



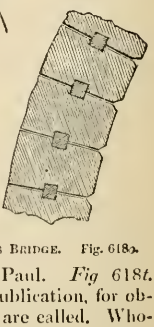


Fig. 618*p*. BLACKFRIAR'S BRIDGE. Fig. 618*o*.

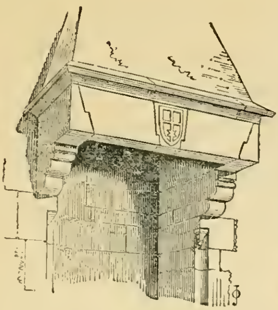

Fig. 618q.

1925i. To tie in ashlering to the brick wall, cramps are used, either of cast iron, wrought iron, copper, or bronze. The two latter are of course the best; the two former exfoliating by air and damp, and splitting the stone, unless perfectly secured. During the restorations at Cologne Cathedral, the cornice (above the 55 feet high windows) is 3 feet 7 inches high, and in order to connect the stones, iron hooks were put hot into the holes, which were then filled up and surrounded with asphalte. By this proceeding the iron is for ever preserved from oxidation; it has proved itself the best system, because the applications of mortar, gypsum, sulphur and lead, have all failed. On the exterior, bronze surrounded with lead has been used, which has hitherto proved satisfactory. Cramps are also now set in Portland cement.

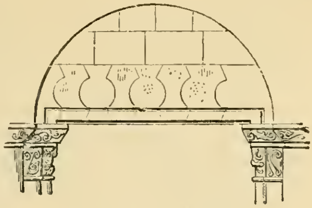

Fig. 618r.

Fig. 618s.

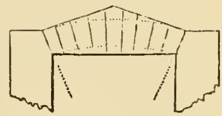

Fig. 618t.

STAIRS.

1926. Nothing to perplex will occur in carrying up stairs which are supported by a wall at both ends, because the inner ends of the steps may either terminate in a solid *newel*, or be tailed into a wall surrounding an open newel. Where elegance is not required, and where the newel does not exceed 2 feet 6 inches, the ends of the steps may be conveniently supported by a solid pillar; but when the newel is thicker, a thin wall surrounding the newel would be cheaper. In stairs to basement stories, where geometrical stairs are used above, the steps next to the newel are generally supported upon a dwarf wall.

1927. In *geometrical stairs*, the outer end of each step is fixed in the wall, and one of the edges of every step supported by the edge of the step below, and formed with *joggled* joints, so that no step can descend in the inclined direction of the plane nor in a vertical direction; the sally of every joint forms an exterior obtuse angle on the lower part of the upper step, called a back rebate, and that on the upper part of the lower step of course an interior one, and the joint formed of these sallies is called a *joggle*, which may be level from the face of the risers to about one inch within the joint. Thus the plane of the tread of each step is continued one inch within the surface of each riser; the lower part of the joint is a narrow surface, perpendicular to the inclined direction or soffit of the stair at the end next to the newel.

1928. With most sorts of stone the thickness of every step at the thinnest place need not exceed 2 inches for steps of 4 feet in length; that is, measuring from the interior angle of every step perpendicular to the rake. The thickness of steps at the interior angle should be proportioned to their length; but allowing that the thickness of the steps at each of the interior angles is sufficient at 2 inches, then will the thickness of them at the interior angles be half the number of inches that the length of the steps is in feet; for instance, a step 5 feet long would be $2\frac{1}{2}$ inches at that place.

1929. The stone platforms of geometrical stairs, that is, the *landings*, *half paces*, and *quarter paces*, are constructed of one or more stones, as they can be procured of sufficient size. When the platform consists of two or more stones, the first of them is laid on the last step that is set, and one end tailed in and wedged into the wall; the next stone is joggled or rebated into the one just set, and the end also fixed into the wall, as that and the preceding steps also are; and every stone in succession, till the platform is completed. When another flight of steps is required, the last or uppermost platform becomes the spring stone for the first step of it, whose joint is to be joggled, as well as that of each succeeding step, similarly to those of the first flight. The principle upon which stone geometrical stairs are constructed is, that every body must be supported by three points placed out of a straight line; and therefore, that if two edges of a body in different directions be secured to another body, the two bodies will be immoveable in respect to each other. This last case occurs in the geometrical staircase, one end of each stair stone being tailed into the wall so as to be incapable of tilting, and another edge resting either on the ground itself, or on the edge of the preceding stair stone or platform, as the case may be. The stones which form a platform are generally of the same thickness as those forming the steps.

ON THE SCIENTIFIC OPERATIONS OF STONE CUTTING.

1930. The operations by which the forms of stones are determined, so as to combine them properly in the various parts of an edifice, are founded on strictly geometrical principles, and require the greatest care and exactness in execution. It is only by a thorough knowledge of the nature of these operations that the master mason is able to cut and carve the parts which, when joined together, compose the graceful arch, the light tracery of the Gothic vault, or the graceful and magnificent dome. The method of simple walling, and its general principles, have been given in this book, chap. i. sect. x. In what follows we propose to confine ourselves, 1st, to the leading operations necessary to *set out* the simple arch or vault, and the groins formed by it; 2d, to the forms produced by vaults with plain and curved surfaces intersecting; 3d, and lastly, to dome vaulting; giving such examples as will so initiate the student that he may, we trust, have little, if any, difficulty in resolving any case that may occur, and reminding him that if he well understand the section already submitted to him on Descriptive Geometry, his labour will be much abridged, not only in what immediately follows, but in that section which treats hereafter on Carpentry.

1931. I. Of the Construction of Arches and simple Vaults, and the Groins formed by their Intersection. In arches and simple vaults we have to ascertain the exact form of the arch in all its parts, and the direction of its joints; both which points are dependent on the geometrical properties of the curve used for the arch.

1932. *To find the joints of a flat arch without using the centre of the circle of which the arch is a part.* Divide the arch AB (*fig.* 619.) into as many equal parts as there are intended to be arch stones, at the points 1, 2, 3, &c. From A, with any convenient radius, describe an arc at *a*, and from 2, with the same radius, describe another arc, crossing the first at *a*, and join *a*1; then 1 is the first joint from A. To find the joint

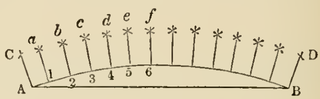

Fig. 619.

passing through 2; with the same radius as before, from the joints 1 and 3 as centres, describe arcs cutting each other at *b*, and draw 2*b*; then 2*b* is the second joint. In the same manner all the other joints between A and B will be found. To find the *skew backs*, or abutting joints AC and DB; with a radius equal to 1*a*, from the centre A describe an arc at C; from the centre 1, with the radius A*a*, describe an arc cutting the former at C, and draw the line AC, which will be the springing bed of the arch. In the same manner the joint BD may be found.

1933. The joints of any arch may be drawn with considerable accuracy by setting off at equal distances a point in the curve on each side of the place for the joint, and from these points, as centres, with any radius, arcs to intersect, through whose intersections lines being drawn, will give the directions of the joints.

1934. *To draw an elliptical arch to any two dimensions by circular arcs.* Draw the straight line AB (*fig.* 620.). Bisect AB in C by the perpendicular D*g*, make CA and CB each

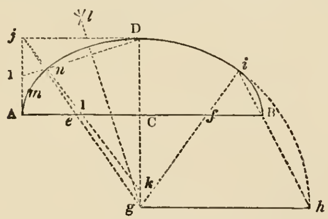

Fig. 620.

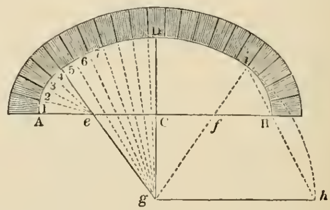

Fig. 621.

equal to half the span of the arch, and make CD equal to the height, and A*j* parallel and equal to CD. In C*g* make C*k* equal to CD. Divide A*j* and AC each into two equal parts. Through 1 in AC draw *kn*, and through 1 in A*j* draw 1D, cutting *kn* at *n*. Bisect *n*D by the perpendicular *lg*, and from *g* with the radius *gn* or *g*D describe the arc *n*D*ih*. Draw *gh* parallel to AB, and join *h*B, and produce *h*B to meet the arc *n*D*h* in *i*. Join *gi* cutting AB in *f* and make C*e* equal to C*f*. Join *ge*, and produce it to meet the arc *n*D*h* in *n*. From *f* with the radius *fi* describe the arc *i*B, and from *e* with the radius *e*A describe the arc A*mn*. Then A*m*D*i*B is the arch required.

1935. *An elliptical arch* ADB (*fig* 621.) *being given, to draw the joints for a given number* *of arch stones.* Find the centres *e, f, g* in the same manner as if the arch were to be drawn; join *ge* and produce it to meet the arch; also join *g, f* and produce it to meet the arc in *i*. Divide the elliptical curve ADB into as many equal parts as the number of arch stones. From the centre *e* draw lines through the points of division in the curve between A and where *ge* meets the curve, and from the centre *g* draw lines through all the intermediate points between *ge* and *gf*, and lastly draw lines from *f* through all the intermediate points between *i* and B, and the parts of the lines thus drawn on the outside of the curve will be the joints of the arch stones.

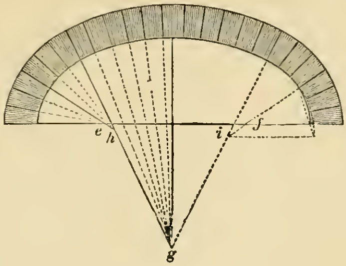

Fig. 622.

1936. In very large arches it will be desirable to find five centres, as in *fig.* 622., and these will be obtained by finding two intermediate points in each half of the curve instead of one; then bisecting each pair of adjacent points by a perpendicular, we shall have the centres *e, h, g, i, f*, to be used for drawing the joints in the same manner as in the preceding figure.

1937. The above methods are sufficient for ordinary purposes; but where strict accuracy is required, the following method is mathematically true. Suppose any joint, as *gk*, is required to be drawn (*fig.* 623.), and that the point D is the middle of the arch and the point C the middle of the springing line; then with the distance CA or CB, from the point D describe an arc at *e* and another at *f* to cut AB at *e* and *f*. Draw *eg* and *fg*; produce *eg* to *i* and *fg* to *h*, bisect *hgi* by the straight line *gk*, which will be the joint required. In the same manner, by drawing lines from *e* and *f* to each point of division, and bisecting the angle, lines for the other joints may be drawn.

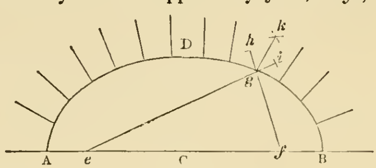

Fig. 623.

1938. *To draw a Gothic arch to any given dimensions* (*fig.* 624.). Draw the straight line

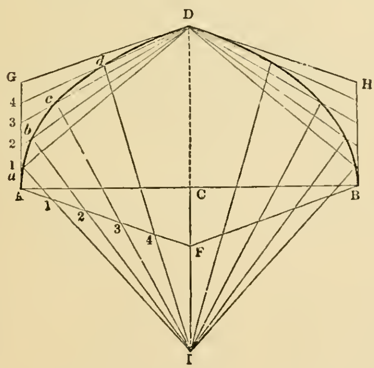

Fig. 624. (CI is made equal to BC.)

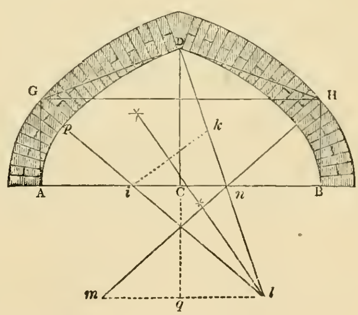

Fig. 625.

AB equal in length to the span of the arch. Bisect AB in C by the perpendicular DI, and draw AG and BH parallel to DI. Make CD equal to the height of the arch, and the angles CDG and CDH each equal to half the vertical angle; make CF equal to the difference between CD and AG and join FA and FB. Divide AG and AF each into the same number of equal parts, counting each from the point A. Through the points 1, 2, 3, 4 in AF draw I*a*, I*b*, Ic, I*d*, and through the points 1, 2, 3, 4 in AG draw 1D, 2D, 3D, 4D cutting I*a*, I*b*, Ic, I*d* at the points *a, b, c, d*, then through the points A*abcd*D draw a curve; which will be half of the Gothic arch required. (Other methods, *par.* 1943*a.*, *et seq.*)

1939. *To draw the joints of the arch stones of a Gothic arch* (*fig.* 625.). Having formed the angles CDG and CDH as before, make A*i* equal to AG and draw D*l* perpendicular to DG. In D*l* make D*k* equal to A*i* and join *ik*. Bisect *ik* by a perpendicular meeting D*l* in *l*. Produce *li* to *p*. Divide the curve into as many equal parts as the arch stones are to be in number. Then *i* will be the centre of the joints which pass through all the points between A and p, and l will be the centre for drawing the joints of the arch stones which pass through all the points between p and D.

1940. The reason for the foregoing rule is obvious; for the joints are merely made to radiate to the centres of the arcs of circles whereof the arches themselves are formed; as in subsections 1934, 1935, they were drawn to the centres of the approximating circles wherefrom the elliptical curves were struck.

1941. *To describe a parabolic curve for a pointed or Gothic arch by means of a series of lines touching the curve, the dimensions of the arch and the angles it forms at the crown being given.* Draw the straight line AB (*fig.* 626.) and draw CD perpendicular to AB. Make CD equal to the height of the arch, CA and CB each equal to half the span. Make the angles CDe and CDf each equal to half the vertical angle. Divide Ae and eD each into the same number of equal parts, and through the corresponding points of division draw lines which will form one half of the arch: the other half DB may be found in the same manner.

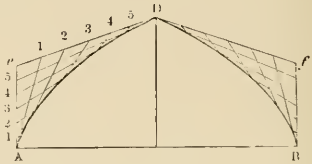

Fig. 626.

1942. *To draw the joints of the arch stones to the above sort of arch.* Draw the chords AD, DB for each half of the arch (*fig.* 627.); divide the arch into as many equal parts as there are to be arch stones. Let it now be required to draw a joint to any point h: bisect AD in k, and join eh cutting the curve in l. Draw hg parallel to Ak, cutting eh in g, and in el make li equal to lg. Join hi and draw hm perpendicular to hi. Then hm is the joint required. In the same manner all the remaining joints will be found.

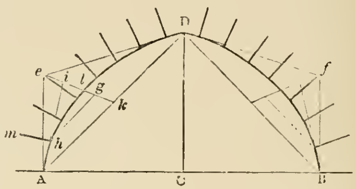

Fig. 627.

1943. *To describe a rampant pointed arch, whose span, perpendicular height, and the height of the ramp are given.* Draw the straight line AB (*fig.* 627.), and make AB equal to the span of the arch. Draw BC perpendicular to AB, and make BC equal to the height of the ramp. Bisect AC in D, and draw DE perpendicular to AB. Make DE equal to the height of the arch; draw Af and Cg parallel to DE, and make Af and Cg equal to about two thirds of DE. Join fE and Eg. Divide Af and fE each into the same number of equal parts, and through each two corresponding points of division draw a straight line. All the lines thus drawn will give one half of the curve. The other half may be drawn in the same manner. *To find the joints of the arch-stones to this sort of arch,* proceed as for a plain arch in the last example, as shown by *fig.* 629.

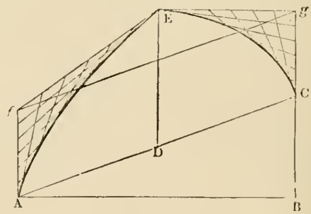

Fig. 628.

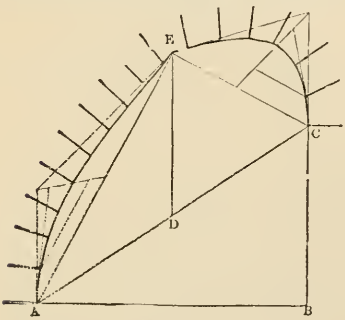

Fig. 629.

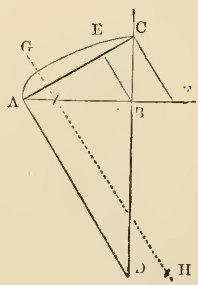

Fig. 629a.

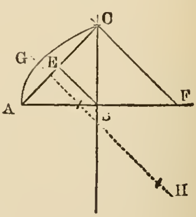

Fig. 629b.

1913*a*. Besides the rule given in *par.* 1938, *To draw a Gothic arch to any given dimensions,* the following plan has been put forward for finding the curves of arches and ribs. The fundamental rule that the curves should spring from the line of the impost has been abandoned by many; one centre was to be taken a little above this line, another a little below it, and so on. The following rule furnishes a principle which gives the centres of all these curves with perfect certainty and perfect harmony, at the same time furnishing what is a further requisite, an independent projection for each rib. The author insists that these curves were always elliptical. If the arch to be drawn be *less* in height than the half width, let AB, (*fig.* 629*a.*) be the half width; BC the height; join AC; draw lines from B and A perpendicular to AC, and the points E and D are those required. Then EC will be the smaller radius, and EC added to AD will be the longer radius. For arches whose height is *greater* than their half width (*fig.* 629*b.*), draw CF and BE perpendicular to AC, then EC will be the smaller radius; and EC added to CF will be the longer radius. The author of this theory is Thos. L'Aker, as read at the Liverpool Arch. Society, 16th October, 1850, and printed in the *Civil Engineer*, vol. xiii. p. 365. See *par.* 2002*d.*

1943*b.* Although the term *arc en tiers point* is still used in France for an arch enclosing an equilateral triangle, as it was in the time of De Lorme, that architect, in his work entitled *Nouvelles Inventions pour bien bastir*, published in 1578, showed that the *arc en tiers point* was obtained by division of the space into three equal portions, of which two gave the radius. The *arc en quatre points* was obtained by division into four, three of them giving the radius. This mediæval mode of determining some of the shapes of pointed arches, was noticed by Professor Willis in his elucidation of Wilars de Honecort's *Sketch-book*, 1859, p. 138–40. He is disposed to call the equilateral arch, the arch of two points; mentions arches of six points; and instances cases with a radius of five-sevenths and a radius of five-eighths, besides the occurrence of a centre placed to the extent of half the span outside the springing point. The same authority observes that the true method was forgotten soon after the disuse of mediæval art, as Viola Zanini, in his book *Della Architettura*, published 1629, defines the *terzo acuto* as the arch on an equilateral triangle, the *quarto acuto* as the arch on a square with the diameter for radius, and the *quinto acuto* on a pentagon: these last are respectively rather higher and lower than the true arch of four points. The term *point* is here used as meaning a division, and not a puncture.

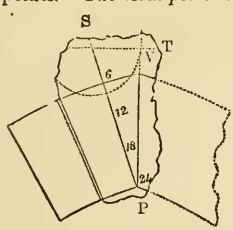

Fig. 629c.

1943*c.* The Professor has also explained, p. 141, that to know the extra length of a voussoir at the top of an arch of 2, 3, 4, or 5 points, the radius may be prolonged through the point P (*fig.* 629*c.*) of the arch to any extent S; then PS being divided into twenty-four parts, a line from S may be drawn parallel with the springing line to T, and respectively 12, 6, 8, or 9 of those parts in length; which will give a point V, so that PV will be the line of the central joint.

1943*d.* The construction of *ogee arches* is very simple; but as will presently be shown, the rule is open to judicious variation. The general principle is to draw the line of the nose Z, (*fig.* 629*d.*) of the hoodmould; to take a point upon that line; to draw from the springing a line through that point to the centre line, to accept the place where the centre line is cut as the height of the ogee, and to find in the usual manner the centre for the upper part of the ogee. The following directions are chiefly taken from Viollet le Duc, *Dict.*

1943*e.* *To draw an ogee arch of one point* (*fig.* 629*d.*). Bisect the span in D, draw the centre line CD, describe the arc AG, bisect AG in E, and through E from A draw a line cutting the centre line in H; through H draw FK parallel to the springing line, and through E from D draw a line cutting FK at M, which will be the centre for the upper part of the ogee arch. In some cases, as in the figures 629*e*, *f*, and *h*, the three points KMN form an equilateral triangle.

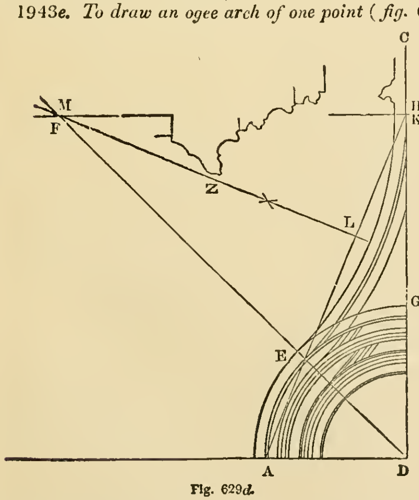

Fig. 629d.

1643*f.* *To draw an ogee arch of two points* (*fig.* 629*e.*). Bisect the span AB, draw the centre line, and describe the arcs AGB; then divide GB into five parts G1, &c., and proceed as before.

1943*g.* *To draw an ogee arch of three points* (*fig.* 629*f.*). Repeat the above operations, observing to divide the span AB into three parts, AE, EF, FB, and to divide GB into four parts, G1, &c. It will be observed that in *fig.* 629*g.* (from Pugin), AB is divided into three parts, and the centres E with F serve to describe the arcs on their own sides of the centre line; that the distances AI, II, and IB are equal, and that EH is equal to EI.

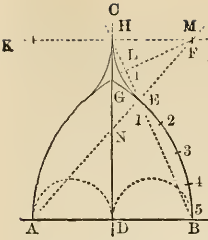

Fig. 629e.

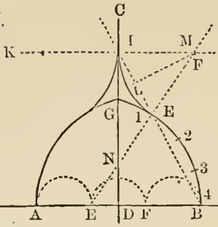

Fig. 629f.

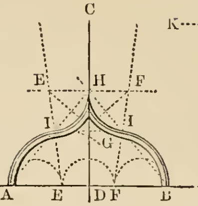

Fig. 629g.

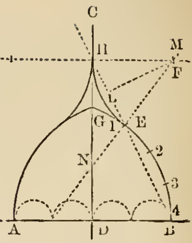

Fig. 629h.

1943*h*. *To draw an ogee arch of four points* (*fig.* 629*h*.). Bisect the span, draw the centre line, fix the four points, and describe the arcs AG, GB; then divide GB into *four* parts, and proceed as above indicated. But a difference is taught by an illustration adduced by Viollet le Duc, to show another feature of mediæval art. In *fig.* 629*i*. it will be observed that the arch GA is divided into *five* portions, and that the line AH is drawn through the second division. The line F2 produced, cuts the horizontal line JH in M; or 2H may be bisected, and a perpendicular obtained meets in the point M, for the ogee line 2H. A centre N has been assumed for the line RR; and also another centre, O, for the line PP, both lines being drawn each way from I; from which arrangement it results that the lines A2H, R1R, and P1P, are not parallel for their whole lengths. In some cases the line of work must be the centre of a fillet or of a boltel. It should be noticed that some very good decorated work of the middle of the 14th century, uses five-eighths of the space for the radius, and finds the centre of the ogee curve upon a line drawn from that central point of radius at an angle of 45° with the horizontal springing line.

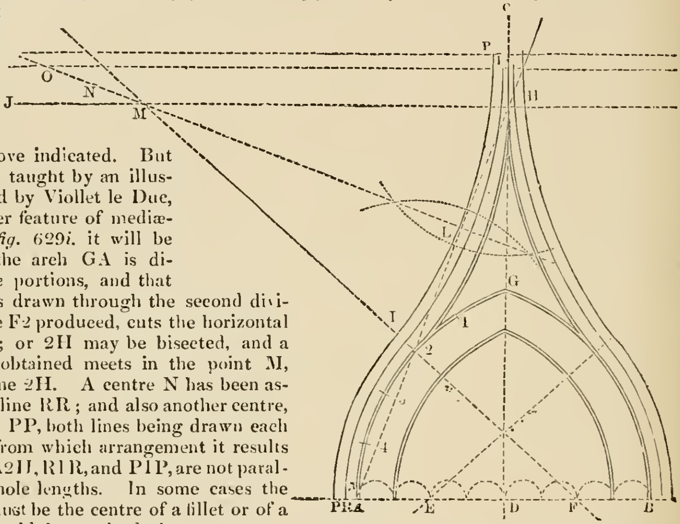

Fig. 629*i*.

1943*i*. *To draw a cusped ogee arch* (*fig.* 629*k*.). Proceed as above described for an arch of one point as far as the construction of the horizontal line JK. Then from the centre F through E draw a line, and thereon make IU equal to IS, being so much of IF as is intercepted by the centre line of the pointed arch; and then on the horizontal line JK make WH equal to IS: thus are obtained the two centres for the cusp. But Viollet le Duc appears to prefer another mode, which very slightly differs in result. He draws SI produced at an angle of 45° with the base line; on this he marks G′U, which is the half of a semicircle, equal to GA, fixing IU, and continuing the process as in the former method.

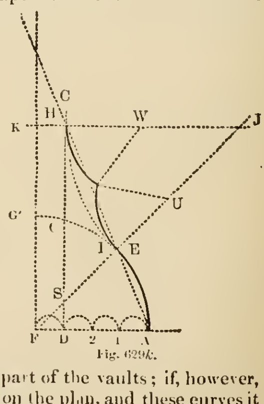

Fig. 629*k*.

1944. II. Of the Construction of intersecting Vaults or Groins. The forms of vaults may be so adapted to one another that the lines of intersection shall be in planes, and these planes the diagonals of the plan of the intersecting part of the vaults; if, however, they be not so adapted, the lines of intersection will be curved on the plan, and these curves it is necessary to ascertain in making both the moulds and the centerings for executing the work.

1945. *To determine the form of a vault to intersect with a given one in the plane of the diagonal, and also to find the diagonal rib for the centering.* Let the given vault be EIF (*fig.* 630.) and AC and BD the diagonals, crossing in *f*. Draw *f* I perpendicular to EF, cutting EF in *c*. In the arc IF take any number of points *ab*, and draw *ag*, *bh* parallel to I*f*, cutting EF in *d*, *e*, and the diagonal AC in *g*, *h*. Draw *fp*, *gq*, *hr* parallel to EF, cutting the base GH at *m*, *n*, *o*. Make *mp*, *nq*, *or*, each respectively equal to *c*I, *da*, *eb*. Draw *f*I′, *gk*, *hl*, perpendicular to AC, and make *f*I′, *gk*, *hl* respectively equal to *c*I, *da*, *eb*. Make

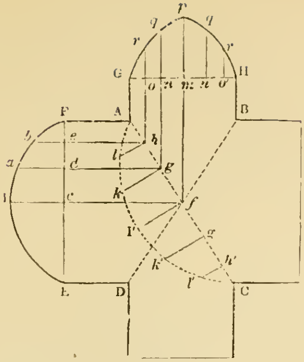

Fig. 630.

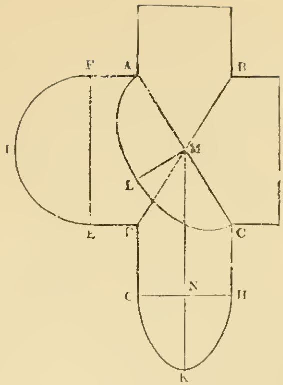

Fig. 631.

fg', *fh'* each respectively equal to *fg*, *fh*. Draw *g'k'*, *h'l'* parallel to *f*I'. Make *g'k'* equal to *gk*, *h l* equal to *hl*; also make *mn'*, *m'o'* each respectively equal to *mn*, *mo*. Draw the arcs *pqr*, *p'q'r*, as also I'*kl*, I'*k'l'*; then, through the points thus found, draw the curves upon their bases AC and GH, and that on GH is the form of the intersecting vaults, and that on AC is the form of the angle rib. If the form of the given arch be that of a semicircle EIF (*fig.* 631.), let ABCD be the angular points of the plan, AC and DB the diagonals, cutting each other at M. Draw MK parallel to GD, or CH cutting GH in N. Draw ML perpendicular to AC, and make ML equal to the radius of the semicircle. Then, with the transverse axis AC, and semi-conjugate axis ML, describe a semi-ellipse, which will be one of the angle ribs, as required. Also make NK equal to the said radius; then with the lesser axis and the semi-greater axis NK describe the semi-ellipse GKH, which is the form of the other vault.

1946. The same method applies in *fig.* 632., where the narrow opening is a semi-circle

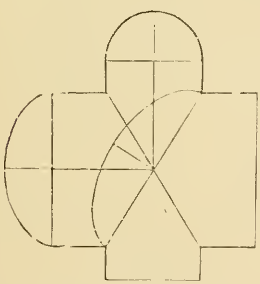

Fig. 632.

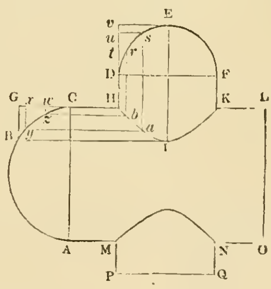

Fig. 633.

and the wide one, consequently, a semi-ellipse, having its minor axis vertical and its major axis horizontal.

1947. *When two circular-arched vaults of different heights intersect, to determine the plan of the arrisses in which the arches meet.* Let ABC (*fig.* 633.) be the arch of the main vault, and DEF that of the lesser vault; ACLO the plan of the main vault, and DPQF that of the lesser vault; and let the two vaults intersect each other at the points HKNM. Also, let E be the middle point of the lesser semi-circular arc DEF. Produce HD to *v*, and in the arch DE take any number of points *rs*, and draw *rb*, *sa*, EI parallel to DH. Draw *rt*, *su*, E*v* parallel to DF, cutting D*v* at the points *tuv*, and produce HC to G. In CG make C*w*, C*x*, CG respectively equal to D*t*, D*u*, D*v*, and draw *wz*, *xy*, GB parallel to AC, cutting the semi-circle ABC in the points *zy*B. From the points B*yz* draw BI, *ya*, *zb*, parallel to CL. Then through the points I*ab* draw a curve, which will be one half of the plan of the arris. The other half will be found in the same manner.

1948. The method of tracing the plan of the groins is the same (see *fig.* 634.) when the vaults intersect obliquely.

1949. *To find the plan of the intersections of two arches of the same height, and either of the same or different species.* Let the sections of the two arches be ABC and DEF (*fig.* 635.), the arcs AB, BC being equal to each other, and the arcs DE, EF equal to each other;

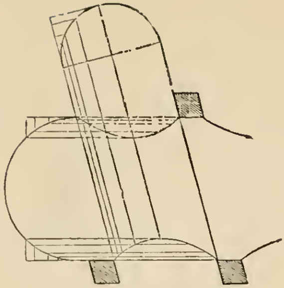

Fig. 634.

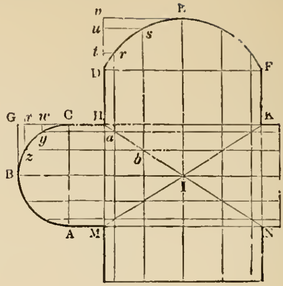

Fig. 635.

and let H, K, N, M be the points where the two arches intersect each other on the plan. Divide either of the arcs BC or DE into parts, equal or unequal; as, for example, in the arc DE take any number of points *r*, *s* at pleasure, and draw *ra*, *sb*, EI perpendicular to DF. Produce HD to *v*, and draw *rt*, *su*, E*v*, parallel to DF, cutting D*v* in *t*, *u*, *v*. Produce HC to G, and make C*w*, C*x* respectively equal to D*t*, D*u*; and as the arches are equal in height, CG will be equal to D*v*. Draw *wy*, *xz*, GB, parallel to AC, cutting the arc BC in the points *y*, *z*, and touching it in B. Draw *ya*, *zb* and BI parallel to HK, and through the points H*ab*I draw the curve H*ab*I, which will be half the plan of the groin as required. The other half IN and the other groin MK will be found in the same manner.

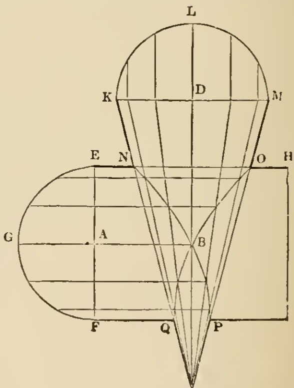

Fig. 636.

1950. *To find the plan of the groins produced by the intersection of a cylindric and a conic vault, the angle of position of the axis, the diameter of the cylinder, and the plan of the conic vault being given.* Let AB (*fig.* 636.) be the axis of the cylinder, CD that of the cone, C being the apex, and D the point through which the base passes. Through any point A in AB draw EF perpendicular to AB, and make AE and AF each equal to the radius of the cylinder, and draw EH and FI parallel to AB. Through D draw KM perpendicular to CD, and make DK and DM each equal to half the diameter of the cylinder. Join KC and MC, cutting EH and FI in the points N, O, P, Q. Divide the semicircles FGE and KLM into parts, whereof the corresponding ones are equal to one another. From the points of division in the semicircle EGF draw lines parallel to AB; and through the corresponding points in the semicircle KLM draw lines perpendicular to the diameter KM, cutting KM. From the points of section draw lines to the apex C of the cone, cutting the former drawn through the points in the semicircumference FGE. Through each set of corresponding points draw a curve, and the two curves will represent the arrisses of the groin on the plan. If in an octagonal ground vault the octagonal range be cylinders, and the cross vaults, which tend to the centre, diminish to a line of the height of the vault, the following construction applies: — Let EFGHI (*fig.* 637.) be the exterior side of the vault, which is both equilateral and equiangular, and let JKLMN be the line of the exterior surface of the inner wall; so that the lines EJ, FK, GL, HM, IN, which pass through every two corresponding angles, may tend to the centre O of the groin vault. Let the sections of the given ribs be PQR and STU, so that PR of the rib PQR may stand at right angles to the sides EF and JK and the side SU of the rib STU on the middle of the side FG. Divide the two bases PR and SU in the same proportion, and through the joints of division in SU draw lines from the centre O of the ground vault to meet the curve STU; and

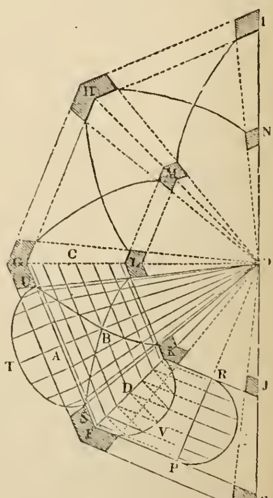

Fig. 637.

through the points of division in the base PR of the cross rib PQR draw lines parallel to EF, to terminate in the line FK, and in the semicircle PQR. From the points where these lines meet FK, draw perpendiculars on one side of FK, and make the heights of these perpendiculars respectively equal to the ordinates of the arc PQR; and through the ends of these perpendiculars draw a curve FVK, which will be the angle rib. From the points of meeting in the line FK draw lines parallel to FG, and through the points of division in SU draw lines to the centre O, intersecting the former lines drawn from the points of division in FK; through the corresponding points of intersection draw the curves SBL and KBU, which will form the plan of the angle.

1951. In single groins the centres are made for the widest avenue, and are covered over with boards (*fig.* 638.), so that the top of the boards may form the surface required for

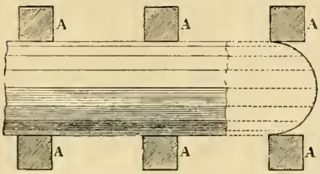

Fig. 638.

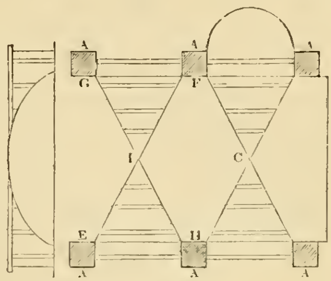

Fig. 639.

turning the arch upon the intersections; or the angles are found by the following practical method. The groins meet in the points I, C (*fig.* 639.), upon the boarding of the two groins. Place the straight edge of a board upon the point I, so as to range over the line GH on the plan Then set up another straight edge upon the point H, so as to be vertical, and the straight vertical edge will meet the horizontal edge; then apply a third straight edge to each of the other two straight edges, so that it may also come in contact with the boarding. After this draw a line along this third straight edge upon the boarding as far as may be found convenient; shift the moveable or third straight edge, and apply it in the same manner to another adjoining portion of the surface of the boarding. Proceed in the same manner until the whole line be completed on the surface. By this means, the necessity of laying down lines for the covering is avoided. The lines being thus drawn, ribs for the cross vaults are fixed on the top of the boarding; so that, making proper allowance for the thickness of the same, its surface, when fixed, may form the true surface of the other cross vault. The ribs fixed upon the boarding to form the cross vaults are called *jack ribs.*

1952. The mode of constructing the curves by lines is shown for a rectangular groin in *fig* 640., in which A is the plan, B the elevation. Here, to find the pliant moulds for forming the groins on the surface of the boarding, and working the arch-stones, describe a semicircle on one of its sides, and divide it into any convenient number of equal parts. Draw lines perpendicular to the base or diameter, the semicircle being supposed to be within the piers; the ordinates will cut the diagonals: but if it be laid down on the outside, the ordinates must be produced until they cut the diagonals. From the points where the ordinates cut the curve, draw lines parallel to the other side of the groin, and produce the side on which the diameter of the semicircle is placed, and extend the semicircular arc with its divisions upon any convenient part of the line thus produced. Through the points of division draw perpendiculars, so as to intersect with the former parallel lines; then through the points of intersection draw the curve, as shown at C, which will be the mould required.

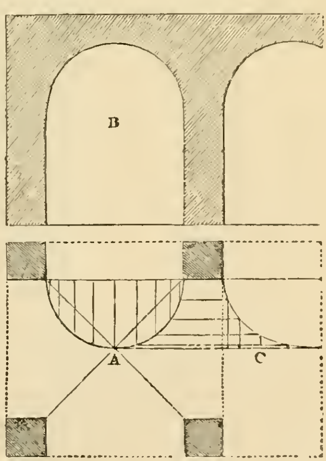

Fig. 640.

1953. Sometimes several vaults meet in one common centre, as in *fig.* 641., which exhibits the plan of an equiangular and equilateral groined vault, constructed of semicircular arches.

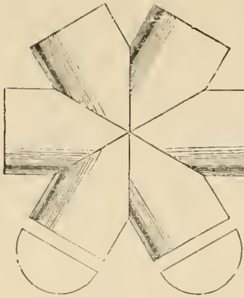

Fig. 641.

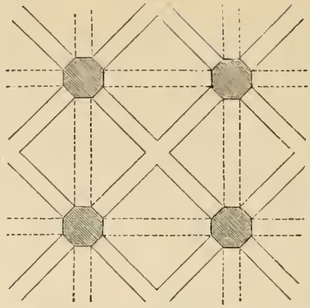

Fig. 642.

1954. Where the piers supporting groins (*fig.* 642.) are made octangular, the angles of the groins should be cut off or arched as ribs, by which they are rendered much stronger than when they are square. In stone groins, where the arch is cut off, there is no advantage in point of strength, and rather a defect in point of appearance, to the groined angles.

1955. Arches intersecting a coved ceiling are similar to groins. Such arches are called *lunettes*, and are generally practised for semicircular-headed windows piercing the coves in the ceiling: *fig.* 643. exhibits a plan and section of such arches.

1956. A dome is a solid, which may be conceived to be generated by the figure of the base diminishing as it rises, till it becomes a point at the summit; and when a dome has a polygonal base, the arches are plain arches, and the construction is similar to that of a groin. A domed ceiling of this kind upon a rectangular plan is shown in plan B (*fig.* 644.); the sections A A being elliptical in the top, and with lunette windows. C shows the geometrical construction.

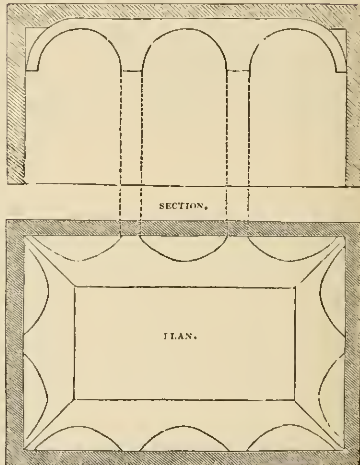

Fig. 643.

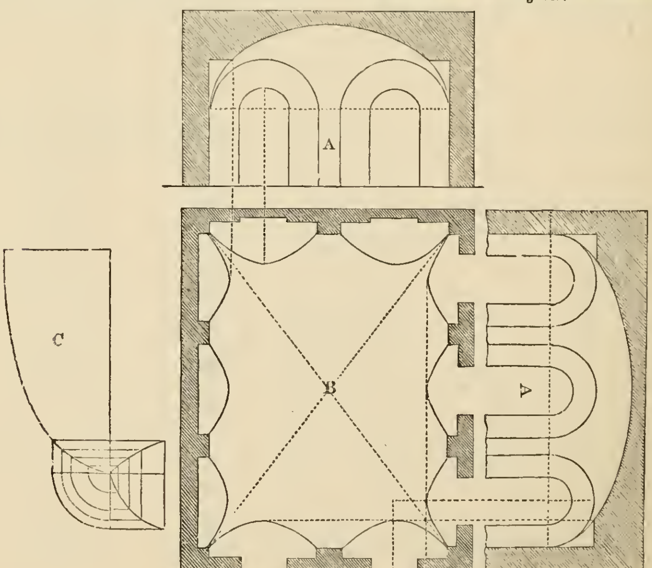

Fig. 644.

1957. *When arches intersect an inclined vault, and the projections of the arrisses cross each other at right angles, and the angle of elevation of one of the semicircular vertical ribs of the ascending avenue or opening is given to obtain the geometrical construction; so that the cross arches may be cylindrical surfaces.* Draw the straight line AB (*fig.* 645.) to represent the axis of the inclined vault, and draw CD perpendicular to AB. Produce CD to *e* and *h*; make AC and AD each equal to the radius which forms the edges of the ribs; draw *h*N parallel to AB, and make the angle N*ho* equal to the inclination of the axis represented by its plan AB. In the line *ho* take any point *p*, and draw *qr* parallel and *ps* perpendicular to *h*N. Make *ps* equal to AC or AD, and through *s* draw L*t* parallel to *ho*. Draw *pu* perpendicular to L*t*, cutting it in *u*. Produce *pu* to *v*. Set the circumference of the inclined vault from *u* to *v*, divided into the equal parts *u*, 1, 1, 2; 2, 3; 3*v*, at the points 1, 2, 3. Divide each of the quadrants *qs*, *sr*, into the same number of equal parts at the points 1, 2, 3, and through these points and in *uv* draw 1*a*, 2*b*, 3*c* parallel to *vt*, and through the points 1, 2, 3, in the curve *qs*, draw *i*L, 1*a*, 2*b*, 3*c*, parallel to *pu*. Through all the points

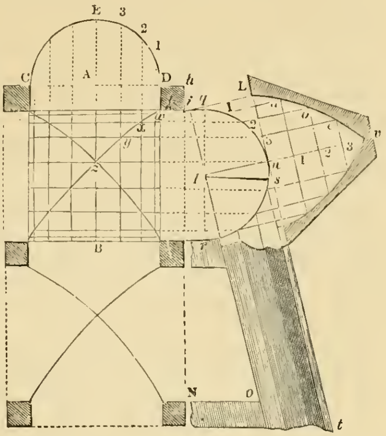

Fig. 645.

L, *a*, *b*, *c* draw the curve L*abcv*, and this will be the pliable mould for forming the angle or groin over the plan, and for working the arch stones. Draw D*k* parallel to A*z*. Let E divide the circumference CED into the two equal parts EC, ED; divide the arcs DE, EC into the same number of equal parts as *uv* at the points 1, 2, 3, and draw 1*u*, 2*x*, 3*y*, E*z*, parallel to AB; also through the points 1, 2, 3 in the quadrant *qu* draw *gk*, 1*w*, 2*x*, 3*y*, *vz*, perpendicular to *y*N; then through the points *k*, *w*, *x*, *y*, *z*, draw a curve, which will be the plan of the groin whereof the stretch-out is L*abcv*. In the same manner the other half of the plan will be found, as also the whole of the other parts.

1958. *The form of an arch crossing an inclined groined vault at right angles, and the plan of the diagonal ribs being given; to find the arch of the level vault.* Let AB, BC (*fig.* 646.) be the plan of the axis of the vaults. Through any point A in AB draw DF perpendicular to AB, and make AD and AF each equal to the horizontal breadth of the vault. Draw DG and FH parallel to AB; draw also any line LK parallel to AB, cutting BC in C, and make the angle KIL equal to the inclination of the axis represented by its plane AB. Make CM and CK equal to the breadth of the level vaults; draw KG and MN parallel to BC, and let MN cut DG in N, and FH in P. Draw the diagonals PG and NH. Produce GK to cut IL in L, and NM to cut IL in Q. In the curve DEF take any number of points *a*, *b*, *c*, and draw *ad*, *be*, *cf* parallel to AB, cutting DF in the points *p*, *q*, *r*, and the diagonal GP in *d*, *e*, *f*, and the diagonal HN in the points *d'*, *e'*, *f'*. Produce BA to E, draw *dl*, *em*, *fn*, B*o* parallel to BC, cutting QL in the points *g*, *h*, *i*, *k*; make *gl*, *hm*, *in*, *ko* equal respectively to *pa*, *qb*, *rc*, AE; then through the points *l*, *m*, *n*, *o*, draw the curve Q*o*L. Draw HR perpendicular to NH, and make HR equal to KL, and join NR; then will HR be the line of ramp for

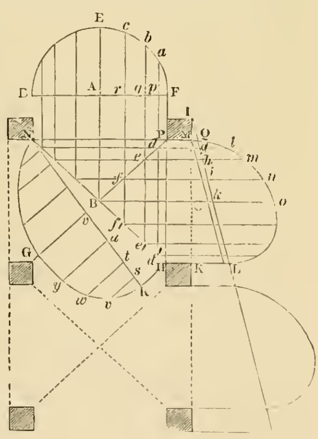

Fig. 646.

the diagonal rib over its plan HN. Perpendicular to HN, draw *d'v*, *e'w*, *f'y*, BG cutting the line of ramp RN in the points *s*, *t*, *u*, *v*. Make *sv*, *tw*, *uy*, *v*G respectively equal to *pa*, *qb*, *rc*, AE. Then through all the points *v*, *w*, *y* draw a curve, which will be the angle rib standing over HN, and which will also serve for the angle rib standing over GP. All the groined vaults continued in the same range may be constructed by the same moulds.

1959. *To make the working drawings for a semicircular arch with a straight face, and to describe the moulds for the voussoirs.* This simple case will serve as a rule for those following; hence the explanation should be perfectly understood, as all the other cases differ from it only according to the different kinds of arches to be constructed; such as the *bevelled arch*, that in a *battering* or *sloping wall*, and that on a *circular wall.*

1960. Draw two lines (*fig.* 647.) perpendicular to and crossing each other, as BA, GD. From the point E, as a centre, describe the sofite curve ACB, and the extrados or upper curve FGH. Divide each of these arcs into two equal parts, as the dotted arc *abc*. Draw LM parallel to AB, and make the distance A′ L equal to the thickness of the wall wherein the arch is to be constructed. Draw the outer and inner lines of the plan F′K, A L, B′M, HN parallel to CD. Divide the arc ACB into the proper number of equal parts for the arch stones or voussoirs, suppose five, by the joint lines 1, 2, 3, 4; from the point E draw the joints 1—5, 2—6, 3—7, 4—8; then from every point where the joints cut the arcs ACB, FGH, &c. draw the perpendiculars cutting the line KN, as 8*d*, *c*M, 4*f*, 7*g*, *hi*, 3*k*, 2*l*, *mn*, 6*o*, *p*, *a*L, and 5*s*. Divide the sofite of each voussoir A1, 1—2, 2—3, &c. into two equal parts *t*, *u*, *v*, *w*, from which also let fall the perpendiculars *t*Y, *u*X, *v*V, *w*T.

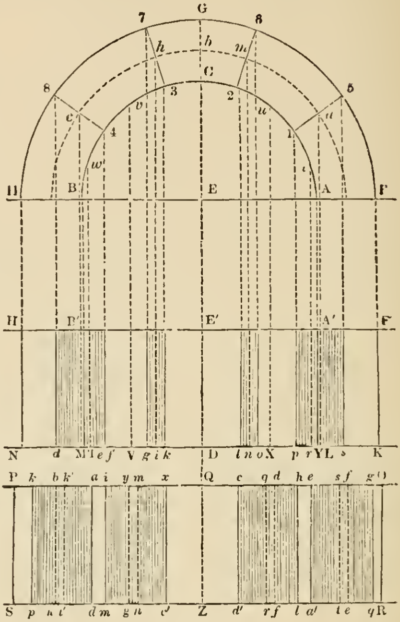

Fig. 647.

1961. *To draw the moulds of the sofite* below NK. Draw the line OP parallel to the line KN; prolong ED to Z and make the distance QZ equal to ED. Through Z draw RS parallel to OP, and on each side of QZ lay off the distances C3, 3*v*, *v*4, 4*w*, and *w*B respectively on Q*x*, *xy*, *ya*, *ab*, and *b*P. On the other side lay off C2, 2*u*, *u*1, 1*t* and *t*A on Q*c*, *cd*, *de*, *ef*, and *f*O. Through the points O, *e*, *c*, *x*, *a* let fall on RS the perpendiculars OR, *ea′*, *cd′*, *xc′*, *ad*, PS, and through the points *f*, *d*, *y*, *b* let fall the perpendiculars from the middle sheetings *fe′*, *df′*, *yg′*, *bh′*; the distances of the dark lines give the breadth of the sofite of each stone in the sofite curve.

1962. *To draw the moulds of the joints:* lay off the distance 1—5 on *eg*, *ch*, *xi*, *ak*, and through the points *ghin* draw the lines *gq*, *hl*, *im*, *kp*, parallel to QZ. To find the middle of the joint divide the distances *eg*, *ch*, *xi*, *an*, each into two equal parts, as in *k′*, *m′*, *g′*, *s*, through which draw the lines *k′l′*, *m′n′*, *q′r′*, *s t* parallel to QZ.

1963. The elevation is a section of a hollow cylinder, of which the concave or interior surface forms the intrados of the arch, and the convex or exterior surface the extrados, and of which the cutting plane of the section is perpendicular to the common axis of the cylinder.

1964. The angles of the stone are found from the angle which the arc of this section makes with any joint, and the curving of the sofite of the stone is found by a ruler or mould, the edge of which is made to the curve. The ends of the sofite are found by its developement.

1965. When the stones are shaped according to the moulds, and joined together in consecutive order, the whole mass, thus united, will form the solid arch as required.

1966. These separate operations being properly attended to, every difficulty will be removed, and no confusion will arise during the process, which can, in any degree, tend to perplex the delineator.

1967. *To find the bevels and moulds for the joints and sofites of an elliptical arch cutting obliquely through a straight wall, the joints radiating to the centre of the opening.* Draw the axis EN of the arch (*fig.* 648.), and therein take any point E, through which draw AB perpendicular to EN; make EA and EB each equal to half the space of the extrados or centre line of the arch; also make EC and ED each equal to half the span of the inner arch. Produce the diameter NE to G;

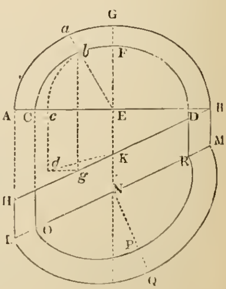

Fig. 648.

make EF equal to the height of the inner arch and EG equal to the height of the outer arch. On the major axis AB, and semi-minor axis EG, describe the semi-ellipsis AGB, which is the extrados of the arch. Also, on CD as the major axis, and EF the semi-minor axis, describe the semi-ellipsis CFD.

1968. Make the angle ABH equal to the angle which the wall makes with the right section of the arch, and let BH cut the axis in K. Draw ML at such a distance from BH that they may comprehend between them the thickness of the wall, and let ML cut the axis in N. The intrados of the arch on the one side of the wall is OPR, and the extrados is LQM; they are both ellipses respectively of the same height as the intrados and extrados of the right arch, but with the axes OR and LM.

1969. *To find the bevel of the angle of the arch stones corresponding to the joint ab tending to the centre* E. Describe the arc *bc* from E with the radius E*b* cutting AB in *c*. Draw *bg* parallel to EN cutting BH in *g*, and draw *cd* parallel, and *gd* perpendicular, to EN, and join K*d*: then EK*d* is the angle or bevel required (*fig.* 648.)

1970. The sofite of the arch is drawn according to the general principles of developement

1971. *To make the working drawings for an arch in a sloping wall, as, for instance, an arch in a terrace wall.* To draw the elevation; from any convenient point *o* in the line AB (*fig.* 649.), describe the arc of the intrados *a*P*f* and the arc of the extrados AQB: divide each of these arcs into odd numbers of equal parts (for the arch stones in this example five), and draw the joints *bg*, *ch*, *di*, *ek*. For the plan of the arc of the intrados draw AR perpendicular to AB, and draw the line of slope or *batter* AS. In the arc of the intrados take any number of points *bcd*, &c. and draw the lines *bb*, *cc*, intersecting AR in the points 1, 2, &c. and meeting the line of batter AS in the points *bc*. Draw CD parallel to AB, and at any convenient distance from it draw *aubvcw* perpendicular to CD, intersecting it in the points *e*, *l*, *m*, *n*, &c. Find the points *b'*, *c'*, *d* in the straight lines *bv*, *mw*, *nx*, such that the distance of those points from the line ED may be respectively equal to the intervals 1*b*, 1*c*, &c. between the perpendicular AR and the line of batter AS, and draw the curve *a' b' c' d' e' f'*, which will be the plan of the arc of the intrados. In the same manner the curve E*g h ik*D may be described; which being done, the plan of the arc of the extrados will be obtained.

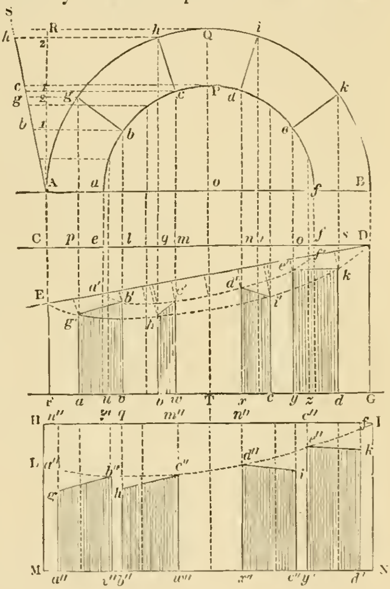

Fig. 649.

1972. *To find the moulds of the sofites and beds.* Draw any straight line HI in a separate place, and extend the arc of the intrados *abcdef* upon the line HI from H to I; divide it into the same number of parts that the arc *a*P*f* of the intrados is divided into (in this instance five), and mark the points of division *l'*, *m'*, *n'*, *c'*. Transfer the distances *ea'*, *lb'*, *mc'* between the line CD and the plan of the arc of the intrados, to the perpendiculars *n''a''*, *l''b''*, *m'c''*, *n''d''*, *c''e''*, and through the points *a''b''c''d''e''f''* draw a curve, which will be the developement of the arc of the intrados. Produce the lines *l''b''*, *m' c''*, *n''d''*, to *v''*, *w''*, *x''*, and transfer the distances *b v*, *c'w*, *d'x* from the plan to the sofite on the lines *b''v''*, *c'w''*, *d''x''*. Draw *ga'*, *hb'*, *ic''*, *kd''* perpendicular to HI; transfer the distances *g'a*, *h'b*, *i'c* from the plan to the sofite upon *ga''*, *hb''*, *ic''*, and join *a''v''*, *b''w''*, *x''c''*, which will complete the moulds of the joints.

1973. *To make the drawings for an oblique arch by an abridged method.* The following method is said to be abridged, because, by one very short operation the moulds of the sofites and joints are found within the plan of the arch ABDC (*fig.* 650.). Divide AB in E into two equal parts, and draw EF parallel to AG. From the point A draw AG perpendicular to AC; prolong DB to G; divide AC into two equal parts in the point H. From H, as a centre, describe the arc AFG, which divide into voussoirs, and draw the joints from the centre H. Draw lines from each sofite parallel to EF, and below the line CD; the moulds for the sofites are comprised between the parallels of the key, and those of the joints are traced on the sides of the plan, as follows: —

1974. *To find the moulds of the sofites.* Through the point Q draw QN parallel to GH. To find on RS the point N, through the point K draw KL also parallel to GH. To find on QT the point M, and on RS the point L, draw the front line of the second sofite

MN, and the front line of the first IL. The back of this sheeting sofite is found by the same operation below the plan. The mould of the key is formed by two lines RS, QT, and the front and back lines of the plan AB, CD; the two moulds of the sofites NMTS and LIXV serve to trace the two stones on each side, observing only that the lower arrisses of the sofite on the side AC become those of the top on the side BD; or that the under arriss of one side may be that on the other side by reversing the mould, which will have the same effect.

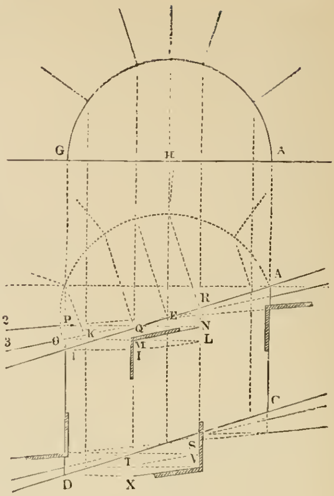

Fig. 650.

1975. *To find the moulds of the beds or joints.* Prolong NQ to meet DG, to find the point P, and through it and the point E draw the front of the second joint P2; prolong LM to GD to find O, through which and the point E draw the front of the joint O3. Proceed in the same manner to find the backs of the other joints, which are sufficient also to trace the stones by reversing them. It is not absolutely necessary to cut out the moulds of the sofites and joints, but the angles may be taken by bevels and applied to stones. The heads are prepared, as usual, with the moulds of the heads of the straight arc. It must be observed, that in this arch the face or front differs from a straight arch, being formed by different sections of a cylinder.

1976. *To find the moulds for an oblique arch, whereof the front slopes and the rear are perpendicular to the axis.* Let A′B′GH (*fig.* 651.) be the plan of the imposts. From the point *a*, as a centre, describe the arcs ACB, DRI, which divide into five or more equal parts for the arch stones. Draw the joint lines from the centre, and the perpendiculars from the joints below the line AB. From the summits of the perpendiculars, draw lines parallel to AB, to terminate in the perpendicular DF. From the point D, as a centre, describe arcs from the points which terminate in DF, to meet the line of slope DE in the points *m*, *l*, *k*, E. Draw the lines *mr*, *ls*, *kt*, EF parallel to AB, meeting the perpendicular DF in the points *rst*F; transfer the distances *rm*, *tk*, *u*P from *n* to *b′*, from *o* to *c′*, from *a′* to *s′*, and through the points A′*b′c′d′e′*B′ draw the curve. Find the extrados or outer line D*fghi* in a manner similar to that in which the inner curve has been found. Draw the points *b′f′*, *c′g′*, *d′h*, *e′i*. Prolong AH and BG to K and L, and draw the lines *b′b*, *c′c*, *d′d* parallel to AK.

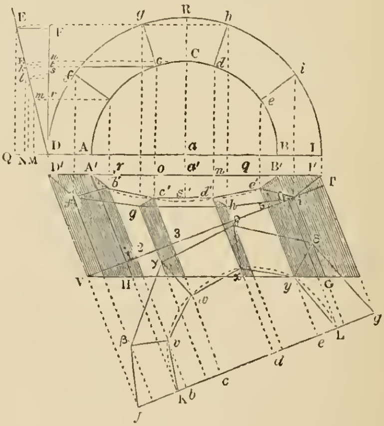

Fig. 651.

1977. *To make the straight arches.* Draw KL perpendicular to A′K, and produce KL to *f′* and *g′*. Transfer the distances between the points *m*, *l*, *k*, E, and the line QD to the ordinates of the lower arc from *b* to *v*, from *c* to *w*, from *d* to *x*, and from *e* to *y*, and draw the curve X*vwxy*L. Also find the outer curve in the same manner, and draw VT at right angles to AH.

1978. *To find the moulds of the sofites.* Draw the line WX (*fig.* 652.) in any convenient surface, and lay the breadths of sofite, not from the arc ABC as before, but from those of the right arc K*vwxy*L, that is, transfer the distance K*v*, *vw*, *wx*, *xy*, *y*L to the line WX upon W*a*, *ab*, *bc*, *cd*, and *d*X. Through the points W*abcd*X, draw the lines *dy*, *ei*, *fk*, *gl*, *hm*, *yz*, perpendicular to

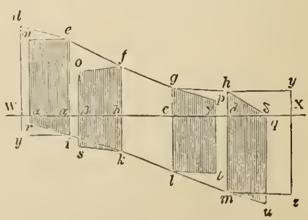

Fig. 652.

WX. Transfer the distances 1 A, $2b'$, $3c'$, $4d'$, $5e'$ upon the perpendiculars to WX: that is, from *a* to *e*, from *b* to *f*, from *c* to *g*, from *d* to *h*, and from X to *y*, and join *de*, *ef*, *fg*, *gh*, *hy*. In the same manner draw the line *yiklmz*, which will complete the sofites.

1979. *To find the moulds of the joints.* Transfer the distances $v\beta$, $w\gamma$, $x\delta$, $y\epsilon$, to the line XW from *a* to α, from *b* to β, from *c* to γ, and from *d* to δ, and through the points, $\alpha, \beta, \gamma, \delta$ draw the lines *nr*, *os*, *pt*, δu perpendicular to WX. Find the points *n*, *o*, *p*, *q*, as also, *r*, *s*, *t*, *u*, as in the preceding examples: then the moulds of the joints will be *eirn*, *fkso*, *ptlg*, $h\delta um$. It must be observed that the boundaries, or extrados and intrados, DRI, ACB of the ring of the arch, do not stand in a plane perpendicular to the plan, but are supposed to be the lines which are drawn on the wall itself; and this is the reason why arcs are described between the perpendiculars DF and the line of slope DE. It must also be observed, that the voussoirs of this arch must be cut by the moulds of the heads of the straight arch, and the moulds of the sofite must be applied on the voussoirs before the sofite is hollowed. Thus, let the first voussoir on the right hand be cut by the head mould on that face of the stone intended for the sofite; apply the first sofite mould, and its upper bed the first joint mould, and on its under bed the plan of the impost. Then cut the two heads according to these moulds, and hollow the sofite square to its arrisses, using for this purpose the curved bevel.

1980. *To find the moulds for executing a semicircular-headed arch in a mass of masonry, of which one of its faces is a battering plane upon an oblique plan, and the other opposite face a portion of a cylindric surface.* Describe the intrados and extrados of the elevation; draw the joints and describe the plan $a'b'c'd'e'f'$ of the intrados (*fig.* 653.), and the plan $Eg'h'i'k'D$ of the extrados. Draw BR perpendicular to AB, and draw BS', the portion of the cylindric surface. From the arc BS draw the plan $a'l'm'n'o'f'$ of the intrados upon the line TU, and the plan $Tp'q'r's'U$ of the extrados in the same manner from the arc BS, as the plan of the plane face was drawn from the line of slope AS.

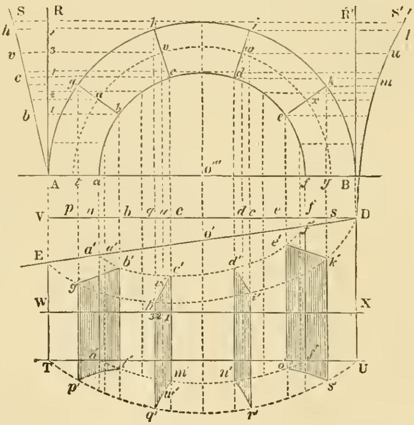

Fig. 653.

1981. *To find the plan of any joint*, as that for the line or joint *ch* in the elevation. Bisect *ch* in *v*, draw *cm'*, *vw'*, and *hq'* perpendicular to AB, intersecting the line VD in the points *quc*. From the points *cvh*, in the joint *ch*, draw *cc*, *vv*, *hh*, meeting the line AS in the points *cvh*, and intersecting the line AR in the points 1, 3, 2 by three intervals, 1*c*, 3*v*, 2*h*. Find the places *hvc* of the three points *hvc* on the elevation. In the same manner find the places $q'w'm'$ of the three corresponding points; then will $c'v'h'q'w'm'$ be the plan of the joint required. The plans of the other joints will be found in the same manner.

1982. *To find the joint mould itself.* Draw the line HI (*fig.* 654.) equal in length to the developement of the intrados, and let Hc be the developement of the arc *ac*; draw cm'' perpendicular to HI. Draw any line WX in the plan parallel to VD, intersecting the lines $c'm'$, $v'w'$, $h'q'$, in the points 1, 2, 3. Draw W X' in the developement or sofite parallel to HI, and at the same distance from HI that WX is from VD in the plan, and let WX intersect the line $c''m''$ in 1. Make the distances 1—2, 2—3 respectively equal to *cv*, *vh*, in the joint *ch* in the elevation, and through the points 1, 2, 3, just found,

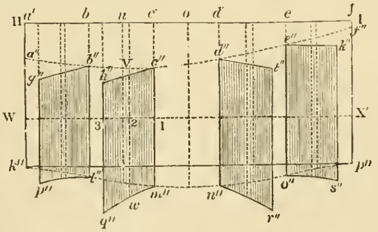

Fig. 654.

draw VW, $h''q''$, parallel to $C'm''$. From the plan transfer the distances $2v'$, $2w'$, $3h'$, $3q''$ to the sofite from 2 to V, and from 2 to W; also from $3h''$ and from 3 to *g* the points *crp'* will be in a straight line, because they correspond to the straight face of the wall, and the points m'', *w*, q'' will be in a curve, because they correspond to the cylindric surface. Draw, therefore, the straight line $c''h''$, and draw the curve line $m''wq''$, which will be a portion of an ellipsis, differing in its curvature but in a very small degree from that of a circle drawn through the same three points. However, if more exactness be required, we may find as many points in the joints of the surface of the wall and in the cylindric surface as we please; then *c''m''p''h''* is the joint required, which serves for the upper and under beds of the two stones that unite together in that joint.

1983. Find all the other joint moulds *b''l''p''g''*, *d''n''v''t''*, *e''o''s''k''*, in the same manner, and find the points *a''f''* in the developement. Through the points *a''b''c''d''e''f''* draw a curve line by hand, or by a ruler bent to the points, and this will be the front curve of the sofite. Find the points *k'p''* in the developement corresponding to the points *a'* and *f* on the plan, and through the points corresponding to the points *a* and *f* on the plan, and the points *k l''m''n''o''p''*, draw another curve, which will be the developement of the other side of the sofite. The developements of each of the parts of the sofite and of the two adjacent joint moulds give the three moulds for working one stone and the adjacent joints of the stone on each side of it. The angle which each of these joints makes with the sofite is found by making a bevel with one of its edges, circular for the intrados of the arc of the elevation, and the other to coincide with the joint line adjacent.

1984. *To find the moulds for executing a gateway in the quoin of a sloping wall.* Let ABCD (*fig.* 655.) be the plan of the angle in which the arch is to be constructed, whereof AB is the span. Draw the centre line EL, to which draw the perpendicular FG. Prolong the line CA to F, and DB to G; then from the point L, as a centre, describe the sofite FHG and its extrados. Divide these arcs into equal parts for the arch stones, and from the divisions let fall perpendiculars, and also from the middle of the sofites to EC, ED. From the summits of the perpendiculars draw lines parallel to FG terminated by the lines of slope Set off the slope at the different heights *a*1, *a*2, *a*3, *a*4 respectively at right angles to the lines on the plan, on *d*1, *b*2, *d*3, *b*4, K5; also on the opposite side lay *a*2, *a*4 on *d*2, *b*4; then on one side draw the curve A*bb*K, and on the other, to abridge the work, join B*b*, *bb*, *b*K. Again, for the outer curve, or extrados, set off *c*1, *c*2, *c*G on *di*, *d*2, N3. On both sides draw the curve M*dd*O on the one side, and to abridge the labour, draw the straight lines O*d*, *dd*, *d*N.

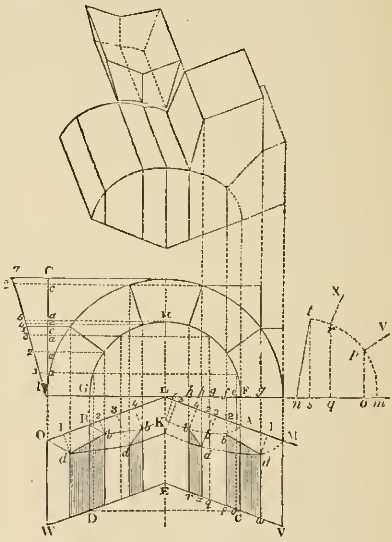

Fig. 655.

1985. *To find the moulds of the sofites.* Draw the line PQ (*fig.* 656.), on which lay the arc of the sofite FHG in the usual manner, making the points 1, 2, 3, which correspond to the points dividing such arc into equal parts; then on the lines of the sofite lay the distances FA, *fb*, *gb*, *hb*, LK, on PR, 1*k*, 2*l*, 3*m*, 4*m*, QS, and trace the front curve of the sofite R*klmn*S. Also repeat the same on the other side where there is only a straight line drawn from one sofite curve to another.

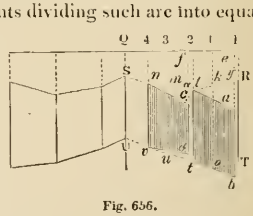

Fig. 656.

1986. *To find the back curve of the sofite.* Lay the distances *eo*, *fp*, *gq*, *kr*, LE on PT, 1*o*, 2*t*, 3*u*, 4*v*, QU, and trace the curve T*otuv*U.

1987. *To find the moulds of the beds or joints.* The sofite lines to which the beds belong are 2*t* and 4*v*. Draw the straight lines *eb*, *fd* parallel to QU, respectively distant from 2*t*, 4*v* by the breadth G1 of the joint, and let the lines *be*, *fd* meet PQ in *e* and *f*; make *ea* equal to *gd*, and *ab* equal to *dw*, and join *al*, *bt*; make *fc* equal to *hd*, and *cd* equal to *dx*, and join *nc*, *vd*. To trace the stones by moulds, prepare the voussoirs with the head of the moulds of the straight arch FHG. The sofite should be hollowed in each voussoir by its particular mould: the rest is done as usual; but it must be observed, that if the sofite moulds are made with straight lines in front and near the sofite, it must not be hollowed till the last. The voussoirs may be worked by bevels, preparing the stones by the plans ACVM, BDWO, as for common imposts. Although the arch in each front be not absolutely necessary here, we shall give the method of constructing it. Let the line *mn* be drawn apart, on which lay the distances L5, L4, L2, LA on the lines *ns*, *nq*, *no*, *nm* square to *mn*. Draw the perpendiculars *op*, *qr*, *st*, on which lay the heights of the joints of the straight arch taken on the line of slope; that is, lay 12, on *op*, 14 on *qr*, 15 on *st*, and draw the line nt, which is the slope. Then draw the curve $mprt$, and from the point n draw the joint lines pv and rX. The centre of this gate is represented (in the upper part of the diagram) with voussoirs, and the keystone placed behind to show the mitre of the centre. The sofite moulds serve for curving the ends of the stone where the intrados meets the surface of the two walls. It must, however, be observed, that, previous to the application of the sofite mould, the concave surface of the intrados must be formed by a mould with a convex edge, and then the sofite mould or moulds of developement must be bent into the hollow, so that the two parallel edges may coincide with the corresponding edges of the stone. The angles which the intrados makes with the joints are taken from the elevation of the face of the arch. This elevation is no more than a section of the arch perpendicular to the axis of the cylinder which forms the intrados.

1988. *To construct a semicircular-headed arch in a round tower or circular wall.* Let ABDC (*fig.* 657.) be the plan of the tower. Bisect the arc AB, and through the point of bisection draw EF parallel to the jamb line AC or BD. Through any point a in EF draw GH perpendicular to EF. Produce the lines CA and DB to meet GH in the points G, H, and GH will be bisected in a. From a, as a centre, and with the radius aG or aH, describe the semicircular arc GFH. Also describe the arc of the extrados and divide the arcs each into five equal parts, and let fall the perpendiculars of the joint lines, and those of the middles of the sofite curves to the inside circular line CED of the tower. Having extended the arcs of the intrados curve on the line IK, and having drawn the lines of the sofites and those in the middle of each sheet as before directed, lay off the distances between the right line GH and the circular outside line AbB, viz GA on IX and on KZ, cd on ef, Vg on hi, Sk on lm, Mn on op, ab on qr; then trace the front curve on the sofite XrZ. To find the rear curve, lay GC on IY, eC on eS, &c., by which the rear curve will be obtained.

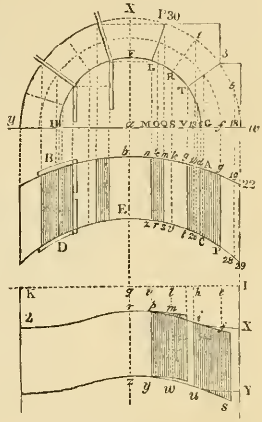

Fig. 657.

1989. We do not consider it necessary to pursue the construction of the moulds, the operations being very similar to those already given in the previous examples.

1990. *To find the moulds for an oblique semicircular arch in a circular tower.* The construction of this differs from the preceding only in the bevel or obliquity of the tower; hence it requires no particular description; only observing, that the bevel causes the mould to be longer on one side than on the other (see *fig.* 658.), as is evident from the plan; therefore the distances taken between the right line AB and the circular line of the tower CDE, being unequal, must be transposed each on its particular line of the mould and joint to which it corresponds in the sofite, that is, the distance AC must be laid on FG, BE on HI, and so of the rest. To work the stones, dress the beds, then apply the proper moulds and cut the head and tail circular as before. Trace the breadth of the sofite on the upper bed, then hollow the sofite, and cut the joints by the bevel.

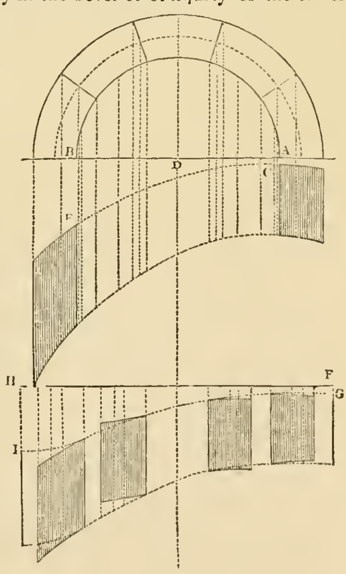

Fig. 658.

1991. *To construct an oblique arch in a round sloping tower intersecting a semicircular arch within it.* This is nearly the same as the two preceding cases. On one side draw the line of slope (*fig.* 659.) AB, and on the other the arc CD. Draw parallels from the divisions of the sofites and their middles, as in the figure, in order to cut the line of slope and arc. To work for the slope, set off all the retreats comprised between the perpendiculars AH and the line of slope AB on the perpendiculars of the sofite, square to the front line of the tower F 19 G, as follows: Transfer the retreat 9—10 on 19—20 by placing the compasses so that the line 19—20 would pass through the centre of the tower, and the point 20 fall on the centre of the gate O—75, and 7—8 on 17—18, and on 21—22 in the same manner (only terminated by the lines from the sofite instead of the centre line of the arch), set also 5—6 on 15—16, and on 23—24, 3—4 on 13—14 and on 25—26, and lastly 1—2 on 11—12 and on 27—28, and through these points trace the sofite 28—20—11. The extrados is found in like manner, and the middles of the joints 47, 49, 53; which done, draw the plan of the joints 14—47—35, 18—19—37, 22—51—39, and 26—53—41.

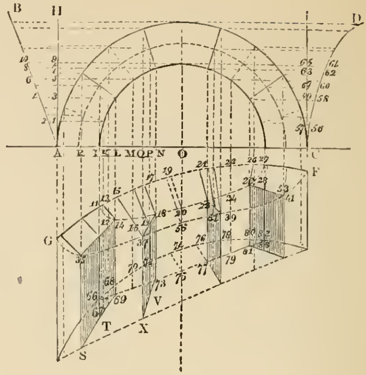

Fig. 659.

1992. *To find the curve of the plan which terminates the tails of the moulds.* Set the projections of the buttress of the semicircular arc at right angles to the inside line of the tower; viz. 64—65 on 74—75; 62—63 on 72—73 and on 76—77; 60—61 on 70—71, and on 78—79, 58—59 on 68—69. and on 80—81; 56—57 on 66—67 and on 82—83; then trace by hand the curve 83—75—66. The curves of the extrados and joints are found in the same manner.

1993. *To find the moulds of the sofite.* Draw the line of direction 94—84 (*fig.* 660.) as before, below which set off the distances I—11 or 84—85, K—12 on 86—87, L—14 on 88—89, M—16 on 90—91, N—18 on 92—93, O—20 on 94—95, and then trace the front of the sofite moulds 85—95—99. To find the rear, set I—66 on 84—33, K—67 on 86—36, L—69 on 88—100, M—71 on 90—98, N—73 on 92—97, O—75 on 94—96, and trace the rear curve of the mould 101—96—33.

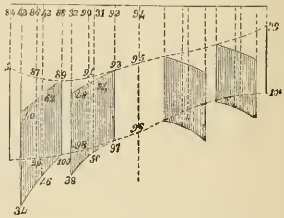

Fig. 660.

1994. *To find the moulds of the joints.* Transfer P—19 on 31—54, Q—37 on 32—48, I—47 on 42—52, R—35 on 43—40, and through these points trace the front joint or bed moulds 93—54—48, 89—92—40. To find the rear, make 31—50 equal to PV, 32—38 equal to QX, 42—46 equal to IT, and 43—34 equal to RS; which done, trace the curve lines 97—50—38 and 100—46—34. The two other joints are found by the same method. We do not consider it necessary further to multiply examples of the kind here given: the latter sort, especially, rarely occur in practice; and if they should, all that will be necessary to master the operations will be the application of a little thought and study.

1995. III. Of Dome Vaulting. In whatever direction a hemispherical dome is cut, the section A is always the same. B represents one half (see *fig.* 661.) of the same in the plane of projection. The construction is sometimes such that the plan is only a semicircle, as B, as in the termination of the choir of a church: in which case the French call it a *cul-de-four;* with us it is called a semi-dome.

1996. Through the extremities of the joints, and through the middle of each sofite of the section A, let fall on the line *ab*, perpendiculars, whereof all the distances *dc* from the centre *c* will be the radii of the arcs, which will serve for the developement of the sofites, of the joints, and for the construction of the arch stones. The method which follows, though it will not perhaps give the sofites and joints strictly accurate, will do so sufficiently for all practical purposes. Upon the developement C make SC equal to the arc MDGC, then set out to the right of the points of division the parts ST equal to *st* on the plan B; then raise through the points T upon the line SC perpendiculars equal

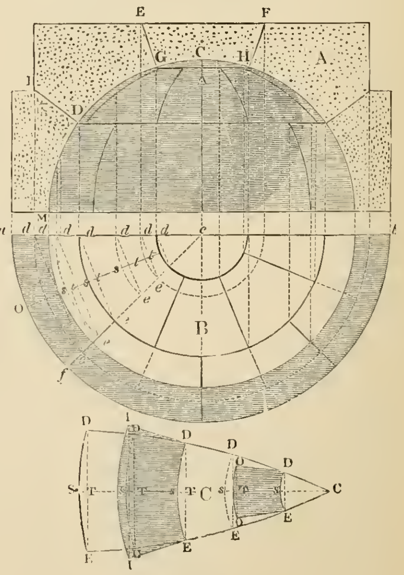

Fig. 661.

to the correspondents *e, t, d* of the plan B, and draw the curve ESD through the points so found.

1997. The sofites are terminated by four curves, whereas the joints have two right sides, as DI, EI, and DO, EO, and two curved sides, as II, DE, and OO, DE; the widths DI, DO of the joints are equal to DI, GE of the section; in one direction they are curved only one way, but as respects their sofites they are so in every way. The heights of the voussoirs are given by the section A, their bases on the plan B Thus G, I, in the voussoir next the keystone, being the most opposite points, the base of it on the plan will be comprised between the two arcs *dte*, which answer to the perpendiculars let fall from G and I. The base of the first voussoir, according to the first method, will be equal to the surface comprised between the arc *aof* and the arc *dse*, which answers to the perpendicular let fall from the point D.

1998. EF and GH are the diameters of the upper and lower bases of a truncated cone, whose lower surface is hollowed out spherically. After working the voussoirs, so as to make their bases such as we have just indicated, they must be worked to sofite moulds for giving them the hemispherical form of the section; after which the angles of the moulds are joined by arcs parallel to the arrisses of each stone, or by applying a general mould of the form of the section, that is, circular, of the radius of the dome.

1999. *For the pendentives formed in an hemispherical dome.* The piers D and E are supposed those of half the dome pierced by the pendentives. If we suppose the face or elevation B (*fig.* 662.) to make one quarter of a revolution about the point A, we obtain the elevations B and C. Through the points of division on the elevation C draw to the arc AD right lines perpendicular to CA. On the extremities of these lines upon CA, and from C, as centre, describe arcs in the plan F, by which the plan of the projection on F is obtained, whose intersections with the right lines drawn from B will give the joints and faces for the level beds. The lines HF, FE, ED are right lines. The spaces GAEF, FHIK are pieces of cylindrical vaulting, so that the only difficulty is in joining to each of their voussoirs their correspondent parts in ELMHFE.

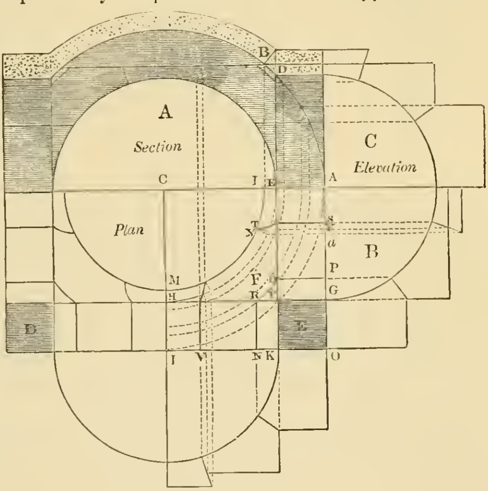

Fig. 662.

2000. The elevation B gives the height of the voussoirs; their bases, as seen in the preceding example, will be OPQRNO, GSTUVKFG. The length of the keystone will be XY, and *a*—A will be half its width.

2001. The part FQR is the plan of the springing stones of the pendentive in the elevation A. The remaining parts of the construction are sufficiently shown by the lines of the diagram, which will be understood by the student if he has previously made himself acquainted with the previous portions of this section.

2002. We should willingly have prolonged this part of our labours, if space had permitted us to do so without sacrificing other and important objects. If the subject be one in which more than the ordinary practice of the architect is called upon to put into execution, we refer him to Simonin, *Coupe des Pierres*, Paris, 1792, and Rondelet's *Art de Bâtir*, which we have used with much freedom, and in which many more interesting details will be found than we have thought it absolutely necessary here to introduce, though we believe we have left no important point in masonry untouched. We cannot close this section without paying our tribute of respect to the masons of this country, who are among the most intelligent of the operative builders employed in it. A very great portion of them are from the north of the island, and possess an astuteness and intelligence which far exceeds that of the other classes of artisans. We must not, however, altogether do this at the expense of those employed in carpentry, which will form the subject of our next section, among whom there will be found much skill and intelligence, when the architect takes the proper means of drawing it out; and we here advise him never to be ashamed of such means.

2002*a*. IV. Of Caissons in Cylindrical and Hemispherical Vaulting. — The method of setting out the *caissons* or sunken panels in cylindrical vaults and domes, is a process required almost in every building of importance, and imparts great beauty to the effect of the interior when properly introduced: it is, indeed, one of the elements in composing them, and must therefore be well understood before the student can succeed in developing his ideas.

2002*b*. In setting out the ribs of cylindrical vaulting, the vertical ones are supposed as falling on supports below the springing; but if such supports fall too wide apart, the caissons themselves will be too wide, and the space must be divided into a greater number; in which case, if practicable, an odd number is to be preferred, taking care that the caissons are not too much reduced in width. This, however, is only for the purpose of ascertaining roughly how many caissons may be used in the circuit of the vault; and it is to be remembered that they must be of an odd number, because a tier of caissons should always extend along the crown of the vault. *Fig.* 662*a*. is an example of a cylindrical vault wherein the

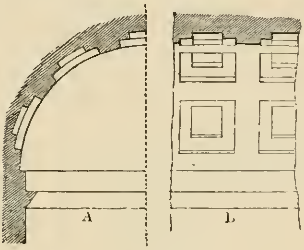

Fig. 662*a*.

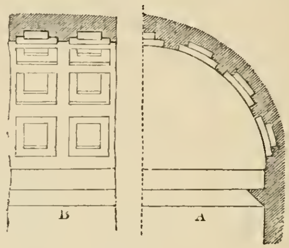

Fig. 662*b*.

number of caissons is five. A is one half of its transverse section, and B a small portion of the longitudinal section. The width of the ribs between the caissons is one third of them; hence, if the number of caissons, as in the example, be five, the arch must be divided into twenty-one parts, one of which parts will be the width of a rib, and three will be given to the width of a caisson. As we have just observed, a caisson is always placed in the centre; we shall therefore have the half-arch $= 1\frac{1}{2} + 1 + 3 + 1 + 3 + 1 = 10\frac{1}{2}$ and $10\frac{1}{2} \times 2 = 21$. The vertical lengths of the sides of the caissons thus found will regulate the horizontal lengths of their sides, inasmuch as they should be made square. If the caissons in the vault be seven in number, as in *fig.* 662*b*., the sofite or periphery must be then divided into twenty-nine parts; if their number be nine, into thirty-seven parts; and so on, increasing by eight each step in the progression. The caissons may be single or double sunk, or more, according to the richness required; their centres may be moreover decorated with *fleurons*, and their margins moulded with open enrichments. Where the apartment is very highly ornamented, the ribs themselves are sunk on their face, and decorated with frets, guilloches, and the like, as mentioned for ceilings in Book iii., c. i., s. xxiv. Durand, in his *Cours d'Architecture*, regulates the width of the caissons entirely by the interaxes of the columns of the building; but this practice is inconvenient, because the space may in reality be so great as to make the caissons extremely heavy, which is, in fact, the case in the examples he gives.

2002*c*. In the case of dome or hemispherical vaulting, the first point for consideration is the number of caissons in each horizontal tier of them; and the student must recollect that allowing, as before, one third of the width of a caisson as the width of a rib, the number of parts into which the horizontal periphery (whereof *e'e'* on the plan A is one quarter, and its projected representation at *ee* on the section B) is to be divided (*fig.* 662*c*.) must be multiples of 4, otherwise caissons will not fall centrally on the two axes of the plan. Thus,

A dome having 16 caissons in one horizontal tier must be divided into 64 parts.

—	20 ditto	-	-	-	-	-	80 ditto.
—	24 ditto	-	-	-	-	-	96 ditto.
—	28 ditto	-	-	-	-	-	112 ditto.
—	32 ditto	-	-	-	-	-	128 ditto.

and so on increasing by 16 for each term in the progression. In the figure, the number of caissons is sixteen. The semi-plan is divided into thirty two parts, three whereof are given to each caisson, and one and a half to each half-caisson on the horizontal axis of the plan. From the divisions thus obtained lines are carried up to the section *ab*, *ab*, *cd*, *cd*. As the projected representations of the great circles of a sphere are ellipses, if from *b*, *b*, *d*, *d*, we construct a series of semi-ellipses whose transverse diameters are equal to the semi-diameter of the sphere, and their conjugate axes determined from the points of intersection *b*, *b*, *d*, *d*, we shall have the vertical sides of the caissons. The next part of the process is to ascertain the ratio of diminution in the heights of the tiers of caissons as they rise towards the vertex, so that they may continue square in ascending. Upon a vertical line CC′, whose length is equal to the developed length of the line of dome *ef*, or in other words, whose length is equal to one quarter of the length of a great circle of the sphere, to the right and left of C set out at *g* and *g* the half width of the caisson obtained from the plan, and make *hg*, *hg* equal to one third of the caisson for the width of the ribs on each side. Draw lines to the vertex of the development from *hh* and *gg*. A diagonal *hi* being then drawn, the horizontal line *ik* will determine the lower edge of the next caisson upwards. Proceed in this way for the next from *l* and so on. The heights of the caissons thus obtained, being transferred to the section on the quadrant *ef*, will give the proportionate diminution thereon of the caissons as they rise. They are discontinued, and the dome is left plain, when they become so small as to lose their effect from below, and indeed they could not beyond a certain limit be executed.

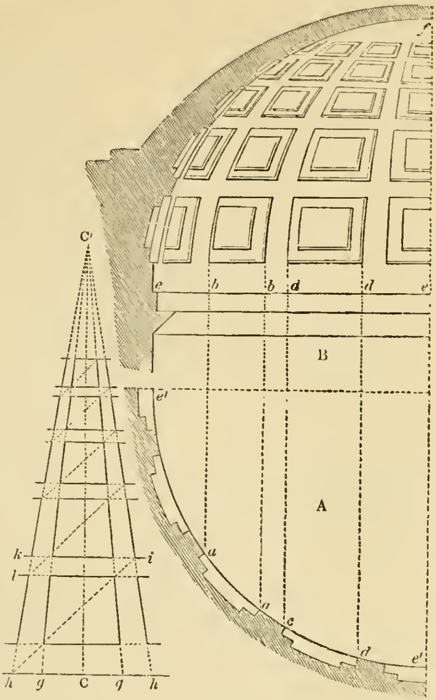

Fig. 662*e*.

2002*d*. V. Of Gothic Vaulting.—Professor Willis, in his valuable essay *On the Vaults of the Middle Ages*, printed in the Transactions of the Institute of British Architects, 1842, states that every rib should spring as a separate and independent arch, and that the elliptic curves produced by the method of obtaining the form by ordinates from those of the transverse ribs, are totally at variance with the characteristic forms of the Gothic style. De Lorme first taught this method, and others followed him, but it was never intended by them to be applied to Gothic rib-vaulting. This author shows (ch. viii.) that every rib is perfectly independent of the other in its curvature; each rib consists of a single arc of a circle whose centre is *upon the impost level*, and they cannot be therefore connected by projections. They all form pointed arches of different proportions, with the exception of the diagonal arch, which is very nearly a semicircle. "This," says Willis, "may have been the genuine French method, but in our English examples the centres are commonly placed without respect to the impost level, and the general forms of the vault are different from those which are produced in this manner." Dérand, writing later than De Lorme, says, "that in this style the ribs are always made arcs of circles, elliptical or other curves being inadmissible" (p. 177). Willis, later, however, allows certain ribs in a vault to be "semi four-centred arches," the others being arcs of circles. (See 1943*a*.)

2002*e*. "In the early stage of *rib-vaulting*," remarks Professor Willis, "the ribs consist of independent and separate voussoirs down to the level course from which they spring. The separate stones were roughly jointed at the back, instead of being each got out of a single stone, as in later structures. The back of these ribs is concentric with the soffite. The transverse rib of the north-east transept of Canterbury Cathedral consists of about one hundred richly-moulded stones, but the workmanship is exceedingly rude"

2002*f*. "The rough construction of the spandril, in the early instances, was followed at once by a more artificial structure, bespeaking a great advance in the art of masonry; and it remained with very slight change to the very latest period of rib-vaulting. This system is shown in *fig*. 662*d*. The junction of the solid mass L to N with the clearstory wall, is bounded by parallel vertical lines D, and this mass is always built of solid masonry bonded into the wall and forming part of it; the French name for this block of masonry is *tas de charge*. It is from the level of N that the real rib and panel work of the vault begins, for separate ribs are erected upon the surface of this solid, and connected by vaults of a light material. The decorative construction, however, of the vault, exhibits the rib and panel from the abacus L, upwards. The point N is commonly at about half the vertical height of the arch, and is not necessarily guided by the impost of any clear-story rib adjoining. M is the general position where the mouldings of the several ribs run clear of one another at the divergence of the ribs. The solid part LM is built of horizontal courses of masonry, generally each of a single stone and its level beds cut the curved mouldings obliquely in front."

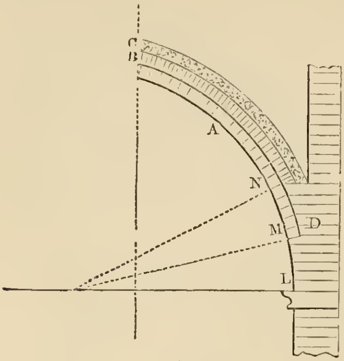

Fig. 662d.

2002g. Moller, *Memorials*, &c., translation 1836, p. 154, notices that, at Cologne, the lower part of the vaulting of the cathedral is formed by horizontal courses of stone projecting from the wall, consequently the actual span of the vaulting is proportionally diminished, while, on the other hand, the abutment is in the same degree strengthened. Still more deserving of attention is the manner in which the essential parts are so linked together as to be rendered incapable of thrusting or giving way, and therefore of necessity remaining in their original position. Price, in his work on *Salisbury Cathedral*, 1753, p. 25, quaintly remarks: "And here I beg leave to make a conjecture, that is, that all the springing stones of the vaultings were inserted into the walls at the time of their being erected, and so left till the whole church was roofed and covered in; and then being defended from rains, &c., they fixed their principal ribs and groins, and turned over the vaultings, as having the weight of the superstructure to act instead of a buttment."

2002h. "Above M," continues Professor Willis, "the ribs are each built separately of voussoirs, having their beds properly inclined to meet the axis of curvature of the rib, and these ribs are backed and united by solid masonry which connects them with the wall, and which, appearing between the rib, seems to be a portion of the light vaulting surface, really employed higher up. From the upper surface N, each rib A is still built as from M to N with voussoirs, but upon these ribs rests the light thin vault or panel-work."

2002i. "It is remarkable that the courses of the vaults are not laid level, but are in most cases made to incline downwards upon the diagonal rib. The reason for it is not easy to explain, but it is very common, especially in the earlier examples. These courses, in the transepts at Westminster Abbey, are of a light coloured stone, probably chalk, interrupted at regular intervals by a course of a darker stone; and the ridge, which has no rib, is also formed entirely of this darker stone, laid in a serrated manner. These dark courses are rather broader than the light ones, and there are four or five courses of the light between each of the dark. The surface of the panel between each rib is also made slightly concave or domical (probably to preserve the effect of being level, as seen from below it), and may therefore have been laid without any centreing, since each course would support itself. These peculiarities may all be found with some variations in other vaults of the same age."

2002k. "The architect of Leon cathedral," remarks Mr. Street in his work on *Gothic Architecture in Spain*, p. 110, "filled in the whole of the vaults with a very light tufa, obtained from the mountains to the north of Leon; so at least I was assured by the superintendent of the works at the cathedral. Some of the material I saw was no doubt tufa; but some of it seemed to me to be an exceedingly light kind of concrete. The vaulting of Salisbury Cathedral is similarly constructed. I do not know whether at Beauvais the same expedient was adopted to lessen the weight." Both at Beauvais and Leon the construction in every part was too light.

2092l. Over the vaults was *commonly* laid a thick irregular course of rubblework, which again is also often covered with a kind of concrete. The vaults of the western compartments of Westminster, and of the south transept and tower of Hereford, are left bare on the upper surface, and these vaults, instead of being built with small brick-like stones, are composed of long thin slabs. The ribs themselves are, in some later examples, formed of a few long bar-shaped voussoirs instead of the small and numerous pieces of the earlier examples. Thus, in the transept at Westminster, L to N consists of 13 or 14 stones; but at the west end of the nave of 6 only.

2002m. Price notices (p. 24) that at Salisbury, "The groins and principal ribs are of Chilmark stone, but the shell, or vaulting between them, is of hewn stone and chalk mixed, on top of which is laid a coat of mortar and rubble of a consistence, probably ground in a kind of mill, and poured on hot, while the lime was bubbling; because by this, the whole is so cemented together, as to become all of one entire substance. This composition is very remarkable, somewhat resembling the pumice-stone, being porous and light, by which it contributes prodigiously to the strength of the whole, and at the same time the least in weight of any contrivance that perhaps was ever used."

2002*n*. "The early moulded *ribs* are formed as *fig*. 662*f*. from St. Saviour's Church, Southwark, the vaulting or panel-work resting only on their backs; but the ribs of later date are rebated for the reception of this work, as shown in *fig*. 662*e*."

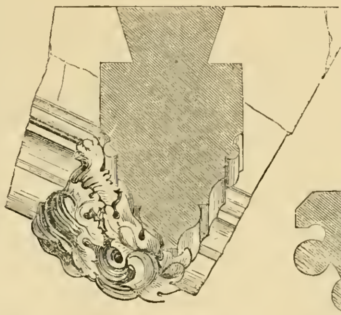

Fig. 662*f*.

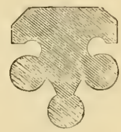

Fig. 662*e*.

2002*o*. As early as 1225–50, the square plans for vaults were superseded by oblong ones, which allowed the *cross-rib*, the *groin-rib*, and the *wall-rib* to arrive at nearly one level. In the new system the groin-ribs were portions of circles, and the cross-ribs were struck with the same radius; but these vaults were soon considered to be weak, and the cross-ribs were heightened while the groin-ribs were either stilted or (subsequently) sharper pointed.

2002*p*. As soon as mediæval builders admitted the principle that the strength of arch-stones, like that of beams, is more dependent on the depth than on the width, they reduced the width as much as they could in order not to require a large abacus to the capital. The next step was to resolve all thrusts upon that support into a force acting directly upon it; and consequently to endeavour to make the various pressures, which the pillar has to bear, combine in a point in a stone that should be fully as large in plan as the abacus, and perhaps rest upon others of the same character.

2002*q*. The operation of deciding the form and place of this stone is very simple after the size of the arch-stones has been determined. Supposing that the work is, as in a cloister, bounded by a wall, and without wall-ribs, there will only be a cross-rib and two groin-ribs to be heeded. A line AB (*fig*. 662*g*.) showing the face of the wall is to be cut in O by another line CD representing the centre of the cross-rib; and the plan of the arch-stones for that rib is to be projected by the aid of these lines. It gives at the wall a centre O, and in its length OE *on the central line* a radius with which a semicircle may be described (as shown by the dotted line); a couple of parallel lines, FG and HK, will now show the thickness of the cross-rib. To proceed with a groin rib, a line from O must be laid down at the correct angle made by the groin with the wall; and the plan of the groin-rib must be so projected that, with this line for an inside line, the front of the arch-stone shall touch the semicircle. A couple of parallel lines MN and PQ will now show the thickness of the groin-rib; and the plan of the abacus of the pillar may be designed, even so as to allow of wall-ribs if they should be intended.

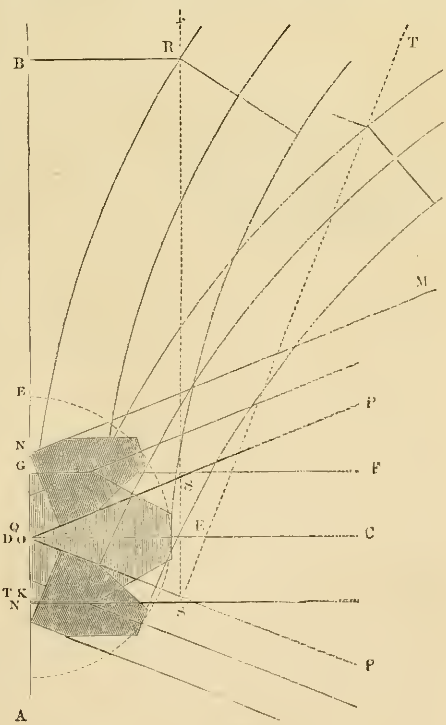

Fig. 662*g*.

2002*r*. The use of the semicircle is not an indispensable, but is a naturally convenient step, because the equal quantities so taken by it from all the spans of the ribs leaves undisturbed in general result all calculations founded upon lines drawn from mathematical points that are taken as centres in a plan made to a small scale; but the plans of the groin-ribs may be placed anywhere upon their respective centre-lines so long as the intersection or junction of the neighbouring lines of the widths of the ribs is secured at some point. This intersection is not an absolute necessity, but it is the means of reducing the size of the abacus; and the point of junction S is that beyond which (working from the wall) the two ribs will be distinct. Taking this point S as fixing a line for the springing, the elevations of the two arches are to be drawn on the intersecting lines; then lines SR and ST drawn perpendicular to the springings, will cut the extrados of each arch at points which decide the level of the top bed of the horizontal work. The mass of work between this bed and the capital will be divided into a convenient number of courses, and the plans of the beds thus fixed are easily drawn from the elevations of the arches; when it will be seen that, if the groin-ribs are less in depth than the cross-ribs, the former will give a good starting-place for the material which is to form the spandrils of the vaults. In a similar manner, the intersections of any number of ribs may be found, and the tertiary and secondary ribs may be successively suppressed in favour of the primary principal ones. Viollet le Duc, *Dictionnaire*, s.v. Construction, p. 96. Prof. Willis gives the following illustration (*fig.* 662*h.*) showing the method of setting out mouldings for vaulting, belonging to the perpendicular period; it is taken from one of the spandrils of a complex vault which formerly covered the extreme north-western compartment of the nave of Canterbury Cathedral, the lower storey of the so-called Lanfranc's tower. The number of ribs being seven required two stones in each of its upper courses at least: *fig.* 662*h.* being only a portion of the spandril, contains but four of them. It also shows that the stone had been scored, then rejected, and another set of lines drawn, and actually employed. AB, AC, are the rejected centres, and D a portion of the first outline. EF, EG, EH, and EI are the true lines drawn, each parallel to its own rib. The average thickness of the courses is about 10 inches.

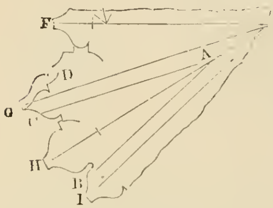

Fig. 662*h*.

2002*s*. The *key-stone* or *boss-stone* was adopted by the mediæval architects as a necessary appendage to groin-ribs, because the solidity of the vaulting depends greatly upon the pressure exerted by the key, which must consequently be heavier than any of the arch-stones; it will necessarily be an extremely large stone, allowing a great part of its mass to be cut away by the sculptor in order to diminish its apparent heaviness. This stone should generally be nearly circular in plan; for if the ribs diverge enough to leave any large space between them, a fracture is almost certain. In cases of such divergence, it is best to design the sculpture so that a mass may occupy the space This remark, of course, does not apply where there are only two groin-ribs meeting at right angles; but it governs the amount to which the groin-rib should be allowed to be worked in the key-stone. No part of the boss ought to be sunk within a horizontal line connecting the intrados of one rib with that of another; and it is generally desirable that, whether or not the ribs be back-jointed for the filling of the groining, as *fig.* 662*f.*, the key-stone should have a projection or tail sufficient to stand above the back of the filling. "Every boss-stone," says Professor Willis, "had its upper surface made horizontal, on which were drawn the lines from the axis of the boss in the direction of the respective ribs." The principles here indicated are illustrated in *fig.* 662*i.*

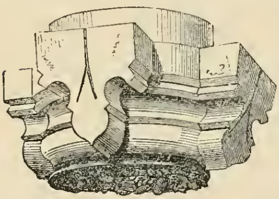

Fig. 662*i*.

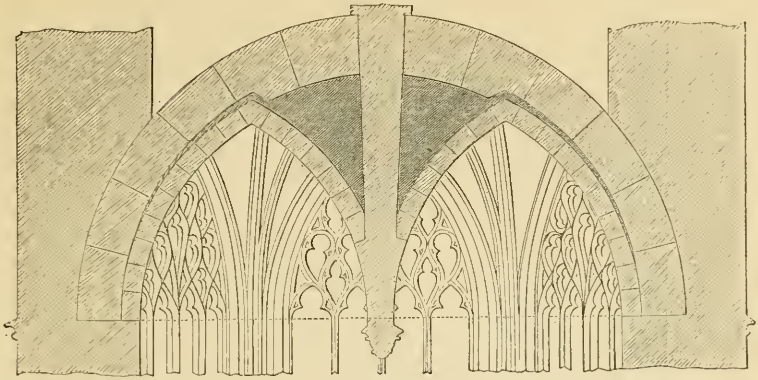
2002*t*. In the construction of groined vaulting it has been considered best to fix the key-stone on the centreing, before laying the arch-stones, for the sake of the guidance which it affords in the work; the inconveniences of working a boss in its place, and of setting it if already worked, were obviated in the 13th century by leaving its breast smooth, so that a wooden boss, carved at leisure, might be fastened to it with hooks. In the 15th century such a boss was not unfrequently of stone instead of wood

2002*u*. A striking feature of the Flamboyant style is the frequent use of *pendents* in the vaulted roofs of the period. These, however, are not confined to the Continent, for the Tudor period in this country exhibits many splendid instances of their employment, none, perhaps, more gorgeous, or more interesting as regards its construction, than the Chapel of Henry the Seventh. Some of the various examples that exist have been scientifically investigated by Professor Willis, in his paper *On the Construction of the Vaults of the Middle Ages*, already quoted; and we therefore now proceed merely to indicate the principles upon which the fairy-like system of not only suspending vast bosses from the ceiling was conducted, but that by which these bosses or pendents became in their turn the springers for supporting other vaults as in the beautiful little Lady Chapel at Caudebec in Normandy, and many other examples. A plan is given in the section on Principles of Proportion.

2002*v*. This chapel is hexagonal on plan, about 23 feet in span, or from side to side.

Fig. 662*k.* shows the mode by which, from the key-stone of an arch approaching a semicircular form, and suspended or elongated beyond its ordinary depth, support is given for the springing of the vaults of the different bays. On this practice Philibert De Lorme observes, " Les ouvriers ne font seulement une clef au droict de la croisée d'ogives, mais



See another section and] Fig. 662*k.* [plan, figs. 1322 and 1323.

aussi plusieurs quand ils veulent rendre plus riches leurs voûtes, comme aux clefs où s'assemblent les tiercerons et liernes, et lieux où ils ont mis quelquefois des rempants, qui vont d'une branche à l'autre, et tombent sur les clefs suspendues, les unes étant circulaires, les autres en façon de soufflet, avec des guymberges, mouchettes, claire-voyes, feuillages, crestes de choux et plusieurs bestions et animaux : qui étoient trouvés fort beaux du temps qu'on faisoit telles sortes de voûtes, pour lors appelées des ouvriers (ainsi que nous avons dict) voûtes à la mode françoise."

2002*w.* We have shown above the mode of suspending the pendent in a polygonal building. The *fig.* 662*l.*, by a little consideration, will explain the mode of suspending pendents not centrically situate, as in the case of the ceiling of Henry the Seventh's Chapel, whose date runs coincident with the Flamboyant period. The figure is a transverse section and plan of the vaulting of the building, in which one of the main arches, on which the whole construction depends, springs just below A, and reaches its summit at B. The voussoirs or arch-stones whereof it consists are marked in their order. The dotted interval from *a* to *b* is not to be considered as an interruption of the formation of the arch by the pendent, but may be supposed an imaginary line passing through it, or rather through the arch-stone or voussoir C, whose general form is marked by the bounding letters *c d e f b a* ; so that, in fact, the pendent is nothing more, as in the case of the Lady Chapel at Caudebec, than a voussoir, a large part whereof hangs down below the face of the vaulting. The voussoirs are out of blocks about 3 feet 6 inches deep ; but a considerable portion of the solid below the soffite of the arch is cut away to form the lobes of the cinquefoils. The arch D serves, by its connection with the walls, to stiffen and give weight to the arch where it would be most required, that is, towards the springing. The pendent or voussoir E, on the same block with C, being thus established in its place, serves at, or towards its foot, as a springer for the ribs of a fanwork tracery shown on the plan, whose ribs are, in fact, ribs of a dome, and in construction do not differ from it. Their section is shadowed somewhat lighter than the pendent voussoir. The fanwork round each affords the means of introducing another pendent at its meeting at F in the plan. (This pendent is shown at F in the two sections given in PRINCIPLES OF PROPORTION.) The *fan* vault is very properly distinguished by Prof. Willis from what he calls the *stellar* vault, which is formed of ribs that may be, and indeed frequently are, of different curvature, and the rays of the star of different lengths ; whereas the fan vault consists of ribs of the same curvature and height, and the summit of the fan is bounded (see the *fig.*) by a horizontal circular rib, instead of the ends of lozenges forming the points of the star. " The effect of the fan is that of a solid of revolution, upon whose surface panels are sunk : the effect of the star is that of a group of branching ribs." It is manifest that the constructive details of these two sorts of vaulting are vastly different. In the one, the dependence is upon ribs which support, by rebates on them, the filling-in panels ; while in the other the principle is similar to that of dome-vaulting. This will be immediately perceived by reference to the plan G, in which the courses are marked, as also in the part of the section marked H. The plan I shows the tracery of the soffite of the vault. The author above quoted observes, " The construction of these fan vaults is in all examples so nearly the same, that they seem to have proceeded from the same workshop ; and it is remarkable that, at least as far as I know, there are no

Continental examples of them; whereas, of the previous vaults, there are quite as many on the Continent as in England. In France, indeed, the lierne" (ribbed) " vaults are not

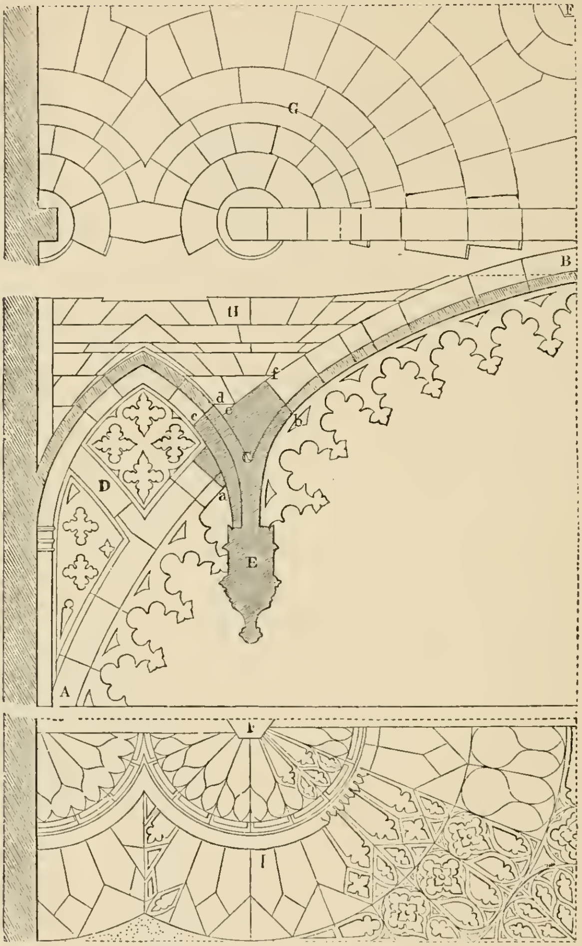


Fig. 662*l*. HENRY THE SEVENTH'S CHAPEL, WESTMINSTER.

very numerous; they are confined to small chapels, and their patterns are in general simple. But in Germany and in the Netherlands there is an abundance of them, distinguished, certainly, from ours by local peculiarities, but nevertheless of similar mechanical construction, and requiring the same geometrical methods."

2002*x*. The introduction of fan vaulting seems to have occurred in the beginning of the 15th century. The first instance wherein the span was considerable is the Dean's Chapel attached to the north-west transept of Canterbury Cathedral. In St. George's Chapel at Windsor, the aisle and central compartment only have fan vaults, the principal vault not being fanwork. The chief works of this kind, of known date (about 1500), are Henry the Seventh's Chapel at Westminster, King's College Chapel at Cambridge, the central tower of Canterbury, and Bath Abbey church. (See Principles of Proportion.) In the church of St. Etienne du Mont at Paris, we find a remarkable example of the style of the renaissance contending with the expiring flamboyant style. In short, the whole of the interior is a mass of interesting incongruities. The church is cruciform, and at the intersection of the cross is a pendent key-stone, most elaborately wrought, and more than 13 feet deep. It is obvious, in respect of these pendents, that there is no mechanical difference between their pendency and their being insistent, as lanterns are, on domes.

SECT. IIIA.

USE OF MARBLE.

2002*aa*. The Greek term "marble," to flash, gleam, sparkle, is well applied to the white marbles of the Greeks, which differed materially from those of Carrara, in Italy. The Greek and Roman marbles are noticed in the GLOSSARY. The Byzantine interiors exhibit fine examples of durable applied marble decoration, about one inch thick, showing no desire to appear anything different. The walls were covered with oblong panels in tiers of rich marbles opened out, framed with narrow white mouldings and bands of different colour, continuous horizontal lines of colour on white being introduced between these panels; the whole surmounted by a marble mosaic frieze, with a cornice displaying small, sharp, triangular shadows, as at Constantinople and St. Mark's at Venice. At Palermo the panels were framed with bands of mosaic work.

2002*bb*. The marble *pavements* of Greek temples were probably the earliest, and were usually of thick, large slabs. They perfected the tesselated mosaic pavements. The Romans gained the knowledge from them, became proficient, and used them throughout their extensive empire. Although under half an inch square, the mosaic is one inch thick, made to last. Some of the grandest pavements are the simplest, as those of the Basilica Julia at Rome, of Santa Sophia, and the one under the central dome of St. Mark's. That of the Basilica Julia has been lately discovered, and is very perfect in part. The plan is a rectangle of about two squares, the centre space being divided into three squares and four broad bands. The squares consist of large slabs of *Giallo antico*, with a broad border of *Pavonazzetto*, the bands being rectangular slabs of rich *Africano* and *Porta Santa*. The central slab is surrounded for about fifty feet with large slabs of Greek white marble.

2002*cc*. The *Opus Alexandrinum* pavements, as at St. Mark's and at Westminster Abbey, were usually composed of few colours—red and green porphyries with white *Palambino* for the mosaics, the bands being Greek white marble, and made out of old materials: a great variety of geometrical patterns. Some of the most beautiful examples are at Palermo. The Palambino was a limestone of pot-like texture. The great pavement in Siena Cathedral, one of the finest Italian Renaissance works, consists of pictorial subjects in dark green marble and mastic inserted into thick slabs of white marble. These have not worn well, and are kept covered. The filled-in lace-like patterns used as borders round the monuments at Sta Croce, at Florence, are in a better condition, the fillings being in smaller quantities. These fillings might be of lead set in a white ground, and would look well. *Black and white* marble pavements in squares were introduced about the time of Torregiano, and were largely used, as at King's College Chapel, Cambridge; the Beauchamp Chapel at Warwick; and in mansions generally. The white squares came from Italy, and the black from Belgium; and are still used in that country.

2002*dd*. The retiring grey marbles, as Petworth, Purbeck, or Frosterley, were used by the mediæval builders in England, and the colour was most useful in contrast with the stone. The altars and tombs of the Italian Renaissance were executed in white marble, with only one colour introduced for the columns, pilasters, frieze, pediment, and panels of the base. A variety of marble work of late date, seen at Palermo and Naples, consists of inlaid floral arabesque, of orange, red, and brown marbles, with black inserted into white. It is gaudy, being deficient in repose. Similar work is seen in the monuments at Agra, in India.

2002*ee*. English *Alabaster*, if selected free from earthy veins and used where wet would not run over it, though only for interior work, may be better than many stones, and it would keep its colour. Of all building materials it is about the least porous or absorbent. It has been used for monumental work from a very early period, and much delicate work has been executed in it. The inner arch moulding of the west doorway of Tutbury Church, carved into birds' beaks, of the Norman period, is in ordinary alabaster, and remains in good preservation. This material came into general use about the fourteenth century in Derbyshire, and extensively so during the Elizabethan period. Great Britain and Ireland (see MARBLE, 1681 *et seq.*) contain many varieties of well-known coloured marbles, little used, even at the present day.

2002*ff*. Memorial slabs of incised marble preceded brasses, and were far superior to them. The English Renaissance produced marble work in chimneypieces equal, if not superior to anything on the Continent. The designs and the marbles were equally good.

2002*gg*. The *Onyx* marbles of Algeria, Mexico, and California, of the same nature as Oriental alabaster, can be cut and ground thin enough for window purposes. At Tarragona Cathedral and at Orvieto are examples of orange-yellow Oriental alabaster. In the east windows of San Miniato are slabs of antique Pavonazzetto, with red-purple markings, nearly two inches thick (par. 615).

2002*hh*. *Carrara and Sicilian marbles* are used for steps and floors, wall linings, jambs, lintels, columns, capitals and bases, entablatures, altar rails, fonts, pulpits, sepulchral memorials, and many other purposes. If consistent *details* were used, it might probably be employed for public and other buildings (par. 1677*a*).

2002*ii* A new and beautiful white marble, called *Hegge marble*, from near Brönö, in Norway, is stated to be a pure calcium carbonate, hard, with a few small veins or spots, of nearly uniform whiteness, and taking a high polish. The price in London is about one half that of similar marbles. A green and a red marble are sent from Greece. *Verde Antico* and *Verde di Corsica* are composed of limestone, calcareous spar, serpentine, and asbestos.

2002*kk*. The British Museum, the South Kensington Museum, the University at Oxford, and the Geological Museum in Piccadilly all contain fine collections of coloured marbles, ancient and modern —some wrongly named. The most instructive collection is in the museum of the Louvre. (W. Brindley, *Marble: its uses as suggested by the past*, read December, 1886, at the Royal Institute of British Architects.)

Mouldings.

2002*ll*. A marble to stand exposure to the weather should be close, hard, and vitreous-looking. Plenty could be selected. The mouldings used in the palaces of the Cæsars and other important buildings in Rome were usually very simple, and mostly consisted of flat hollows and rounds, with small fillets produced out of a chamfer (fig. 662*m*.). They looked well, and cost less than many modern ones, which are designed forgetful of masons' methods of work. Mouldings needed to be drawn specially to suit the colour of the marble.

2002*mm*. Marble linings, whenever possible, should be fixed hollow at the back, and a few small places left open in the joints until the solid walls are dry; the hollow allowing the slab to keep warmer than the solid wall, thus avoiding condensation. Good well slaked lime mortar is the best for bedding. Cements are to be avoided. Plaster of Paris should be mixed with a little lime putty, to assist adhesion and prevent swelling. It must be remembered that marbles absorb water by capillary attraction, and are commonly permeable to gases. They absorb water from the mortar, which coming to the exterior surface becomes deposited at the mouths of the pores and gives the surface a brownish discolouration. If the interior surface be coated with asphaltum the discolouration will gradually disappear.

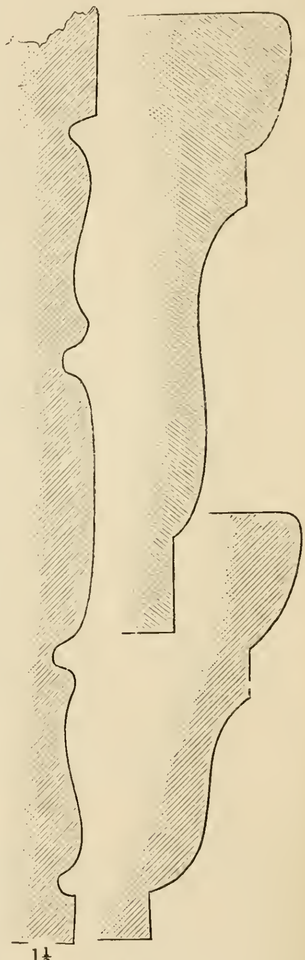

Fig. 662*m*.

Polishing.

2002*nn*. As to *polishing* marble: properly polished chimney pieces of foreign manufacture, and toilet tables, are rarely found, as acids are used to procure a rapid and cheap, though imperfect and fugitive, result. At the Carrara quarries the marble is first rubbed smooth with fine sand, then with pumice-stone, then with two or three stones of variable hardness, finishing off with lead, which gives the last and brightest polish. Water and friction do the work. (E. C. Robins.) Marble steps should never be polished, as if properly done they are very slippery and dangerous. In Belgium, only the face of the riser and rather more than half the nosing, stopping just where the foot pitches, is polished. This from below has the appearance of a completely polished stair, while at the same time there is no danger from slipping. (C. H. Brodie.) Polished marbles and stone rarely go well together in the same work; but some marbles—greys, reds, and cippolinos—look well dull-polished, and then would go better with stone. White marble as used by the Tuscan carvers was not polished.

These full-size illustrations (*fig.* 662*m*.) have been taken, by permission, from among the specimens of old marbles in the collection of Mr. W. Brindley.

SECT. IV.

CARPENTRY.

2003. Carpentry is the science of framing or letting into each other an assemblage of pieces of timber, as are those of a roof, floor, centre, &c. It is distinguished from joinery in being effected solely by the use of the *axe*, the *adze*, the *saw*, and the *chisel*, which are the carpenter's tools; whereas joinery requires the use of the *plane*. See 2102. *et seq.*

2004. Though necessarily of high antiquity, the very scanty information which Pliny and Vitruvius have left us on the subject would merely show that the science was known by the ancients. The roofs of Egypt present us with no more than flat coverings of massy stone; a pediment roof, therefore, would seem to have been among the first efforts of constructive carpentry; and upon the pitch which this, then and since, has received in different countries, we shall hereafter have to speak. The Greeks appear to have used carpentry in the construction of their floors and some other purposes; but in a country abounding with stone and marble, it is not likely that wood was much used in the interiors of their buildings, unless where lightness, as in doors, for instance, required its employment. With the Romans it was much more commonly used; and from all that can be gathered, we may consider them as the fathers of the science.

2005. Among the moderns it has been very successfully cultivated; and, with very few exceptions, we may almost assert that the works of Palladio, Serlio, De Lorme, Sir Christopher Wren, Perronet, and a few others, exhibit specimens which have scarcely been surpassed in later times, notwithstanding the scientific form it has assumed in the present age.

2006. To the mechanical principles of carpentry we have, in Chap. I. Sect X. of this book, directed the attention of the student; and to the section now under our pen we should have added the words *Descriptive* and *Practical* to *Carpentry*, but that much of what could have been said on that head has already been anticipated in the section on Descriptive Geometry. Hence, in what follows, that which comes under such predicament will be only given in particular cases, for the purpose of saving time and trouble to the reader in the application of its principles to them. We must, here, also remind the reader, that under the section BEAMS, &c., and TIMBER, have been described the different sorts of timber used for building purposes, their strengths, and the strains to which they are subject and which they are capable of resisting; and that therefore this section is confined simply to putting pieces of timber together, so as to form the assemblage of timbers under which we have commenced by defining the science. To do that properly requires great skill and much thought. Considerable waste, and consequent expense to the architect's employer, result from that ignorance which assigns to the scantlings of timber larger dimensions than are absolutely necessary for the office of each piece; insufficient scantlings will bring the architect into trouble and responsibility; and the improper connection of the pieces will be equally ruinous to his reputation. The principles of practical carpentry are, nevertheless, simple; and though to form new combinations and hazard bold and untried experiments in practice will require all the skill and science of a talented artist, the ordinary routine of carpentering is to be learnt by a little application and a due exercise of common sense.

2007. After these observations, we must introduce the student to the first operation which in practice may arise. It is not every where that timber can be obtained in sufficient lengths to stretch across the void he has to cover; and it will in such cases be necessary for him to know how one piece of timber may be so joined to another, for the purpose of lengthening it, that the two pieces, when joined, may be as nearly as possible equal in strength to one whole piece of timber of the same dimensions and length. This operation is of great service to the builder, and is technically called *scarfing*. To perform it, the joints are indented, and bolts are passed through the pieces within the length of the indents, such bolts being confined above and below by means of nuts and screws. In *fig.* 663. four ways are exhibited of accomplishing the object in question. A and B are the methods usually employed for joining together plates, lintels, and ties, in which bolts

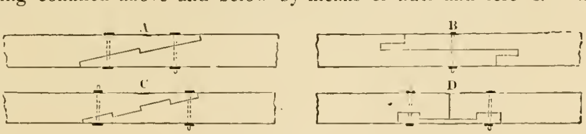

Fig. 663.

are rarely necessary; but if such a method is used for scarfing beams, bolts must be employed. The stronger forms, which only should be used for beams, shown in C and D, are not only in that respect such as should, on that account, be used for beams, but are executed without loss of length in the pieces of timber. The length of the joints of the scarfing may be increased at pleasure; the diagrams are merely given to show the mode of doing what was required. With fir, however, when bolts are used, about four times the depth of the timber is a usual length for a scarf. Scarfing requires great accuracy in execution; for if the indents do not bear equally, the greater part of the strength will be lost: hence it is improper to use very complicated forms for the indents.

2008. Pieces of timber are framed into and joined to one another, by the aid of *mortices* and *tenons*, and by iron straps and bolts; and on the proper placing of these depends the soundness of the work. If a piece of framing is to stand perpendicularly, as in the case of partitions, without pressure from either side, the mortice and tenon should be in the centre of the wood. But in the case of framing floors, in which the pressure is on the upper surface, and entirely on one side, the mortices and tenons ought to be nearest the side on which the pressure is, by which the timber will not be so much weakened; and hence it is the constant practice to cut the mortices and tenons as in *figs.* 664, 665. By the method shown in the last-named figure, the tenon obtains more strength from an additional bearing below, which is further increased by the inclined butment above, called a *tusk*.

Fig. 664.

Fig. 665.

2009. The method of framing wall plates together at an angle, for the reception of the hip rafter on the *dragon beam*, and the angle ties for retaining the wall plates in their places, is shown in *fig.* 666., wherein AB is the mortice cut for the tenon of the hip rafter

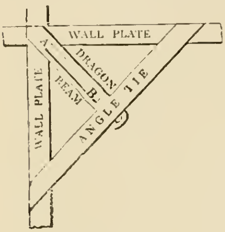

Fig. 666.

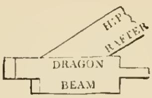

Fig. 667.

Fig. 668.

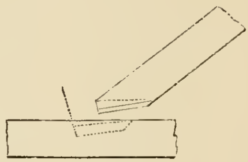

Fig. 669.

shown in *fig.* 667. *Fig.* 668. is one of the wall plates, showing the halving to receive the other plate, and the cutting necessary for dovetailing the angular tie. *Fig.* 669. shows the method of cutting the mortices and tenons of principal and hip rafters; another method being given in *fig* 670., and to be preferred where a greater resistance to thrust is sought, because by it a double *butting* is obtained on the tie beam. Inasmuch, however, as in this last case the beam is cut across the grain to receive the rafter, the part left standing to receive the heel of the rafter may be easily split away; to obviate which, the socket may be cut, as at A, parallel to the grain of the wood. *cd* is the iron strap for securing the rafter's foot to the tie beam, and keeping it in its place. A plan of the upper part of the tie beam is given at B, showing the socket and mortice of the section A in the last figure. C exhibits the mode in which a principal rafter is strapped to a tie-beam, with the *joggling*.

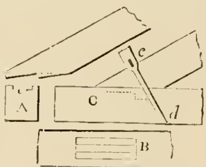

Fig. 670.

2010. The most approved method of forming butments (*fig.* 671.) for the *struts* or *braces*, *aa*, which are joggled into the king-post, is to make their ends, which act against the joggle, perpendicular to the sides of the brace; they will thus be kept firmly on their butments, and have no tendency to slide. C is a section of the king-post and tie beam, showing the mode of wedging and tightening the strap, with a single wedge, in order to draw the tie beam close to the king-post. D is a section of the same parts to a larger scale, and with the introduction of a double wedge, which is easier to drive than a single one, because there is less action upon the cross grain of the wood.

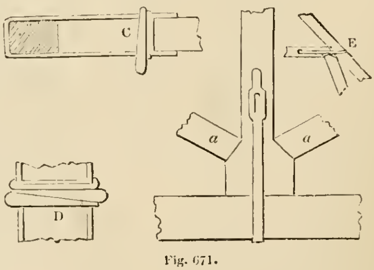

Fig. 671.

2011. Straps in carpentry should be sparingly used. Professor Robison has very properly observed, that "a skilful carpenter never employs many straps, considering them as auxiliaries foreign to his art." The most important uses of them are, that of suspending the tie beam to the king-post, and of securing the feet of the principal rafters to the tie beams in roofs.

2012. Bolts are sometimes used for the last-named office, with *washers* and heads and screw nuts, in which case the washers, nuts, and heads should be well painted, though even then they are liable to rust. Wherever the iron work used for securing a system of framing is exposed to the humidity of the atmosphere, it should be rendered durable by frequent painting. Price (*British Carpenter*, 1759) observes thus: "There is one particular that had liked to have escaped my notice, concerning the placing of iron straps on any truss, thereby meaning to help its strength, which is by turning the end square (as shown at E, *fig.* 671.). This method embraces the timber in such a manner, to make it like a dovetail, *which cannot draw from its place*; another observation is, to bolt on your straps with square bolts, for this reason: if you use a round bolt, it must follow the auger, and cannot be helped; by this helping the auger-hole, that is, taking off the corners of the wood, you may draw a strap exceeding close, and at the same time it embraces the grain of the wood in a much firmer manner than a round pin can possibly do." The example given by Price, however, for turning square the strap, is injurious to the rafter, which must be partially cut to admit of it.

FLOORS.

2013. The assemblage of timbers in a building, used for supporting the flooring boards and ceiling of a room, is, in carpentry, called *naked flooring*, whereof there are three different sorts, viz. *single flooring*, *double flooring*, and *double-framed flooring*. But before entering on the particulars of either of the sorts, we will make some general observations on the construction of floors, which require the architect's attention. First, the wall plates, that is, the timbers which lie on the walls to receive the ends of the girders or joists, should be sufficiently strong and of sufficient length to throw the weight upon the piers. Secondly, if it can be avoided, girders should not lie with their ends over openings, as doors or windows; but when they do, the strength of the wall plates must be increased. To avoid the occurrence in question, it was formerly very much the practice in this country, and indeed is still partially so, to lay girders obliquely across rooms, so as to avoid openings and chimneys, the latter whereof must indeed be always attended to. Thirdly. Wall plates and templets must be proportionately larger as their length and the weight of the floor increases. Their scantlings will, in this respect, vary to 4½ by 3 inches, up to 7½ by 5 inches. Fourthly. The timbers should always be kept rather higher, say half to three quarters of an inch higher, in the middle than at the sides of a room, when first framed, so that the natural shrinking and the settlement which occurs in all buildings, may not ultimately appear after the building is finished. Lastly, when the ends of joists or girders are supported by external walls whose height is great, the middles of such timbers ought not at first to rest upon any partition wall that does not rise higher than the floor, but a space should, says Vitruvius (lib. 7. c. 1.), be rather left between them, though, when all has settled, they may be brought to a bearing upon it. Neglect of this precaution will induce unequal settlements, and, besides causing the floor to be thrown out of a level, will most probably fracture the corners of the rooms below.

2014. Single Flooring is constructed with only one series of joists (as shown in *fig.* 672.). In this way of framing a floor, if a girder is used, it should be laid as nearly as possible over the centre of the apartment. A *single* floor containing the same quantity of timber as a double floor is much stronger; but the ceiling of the former is liable to crack, and cannot be got to so good a surface when finished. Hence, where the bearings are long, it is much better to use double flooring.

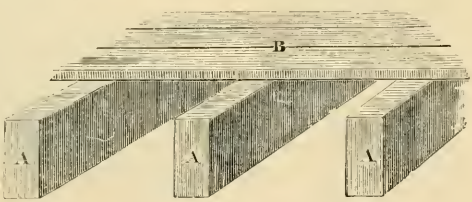

Fig. 672.

2015. The scantlings of fir joists for single flooring are exhibited in the subjoined table, and are founded on our own practice. The weight of a square varies from 11 to 18 cwt.

Length in Feet.	Width in Inches.	Depth in Inches.
6	2	6
8	2½	7
10	2½	7½
12	2½	8
14	2½	9
18	2½	12
20	3	12

These scantlings may be varied if wanted, according to the laws laid down in the section Beams, Pillars, &c.; 1622. *et seq.*

2016. In *fig.* 672. AAA are the joists, and B the floor boards. The laths for the ceiling are nailed to the under side of the joists AAA.

2017. In most floors, on account of the intervention of flues, chimney openings, and occasionally other causes, it will so happen that the ends of the joists cannot have a bearing on the wall. In such cases a piece of timber called a *trimmer* is framed into two of the nearest joists (then called *trimming joists*) that have a bearing on the wall. Into the trimmer, which is parallel to the wall, the ends of the joists thus intercepted from tailing into the wall are mortised. The operation is called *trimming*. The scantlings of trimmers and trimming joists may be the same as those hereafter given for binding joists; or if to the width of the common joists an eighth of an inch be added for each joist supported by the trimmer, the depth being the same, the scantling will generally be sufficient.

2018. When the bearing of a single joist floor exceeds 8 feet, a row of strutting pieces should be introduced between the joists, by which they will be prevented from horizontal twisting, and the floor will be stiffened. If the bearing be more than 12 feet, two rows of stiffening pieces or struts should be introduced, and so on for each increase of 4 feet in bearing. They should be put in, in continued rows, and be well fitted. Beyond a bearing of 15 feet it is not advisable to use single flooring, neither ought it in any case to be used where it is required to prevent the passage of sound.

2019. A *double floor* consists in its thickness of three tiers of timbers, which are called *binding joists* (these perform the office of girders), *bridging joists*, and *ceiling joists*. From an inspection of *fig.* 673. the construction will be easily understood. A A are the binding joists, which are the principal support of the floor on the upper side, whereon B B, the bridging joists are notched; which is the best method,

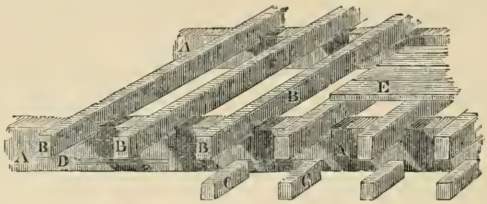

Fig. 673.

though sometimes they are framed between with *chased mortices*. The binders, of course, run from wall to wall; and as for carrying the floor, the bridging joists, as their name imports, are *bridged* on to them; so the lower tier of timbers, called the *ceiling joists*, are either notched to them, or are what is called *pulley mortised* into them; that is, a chase D is cut in the binder long enough to allow tenons of the ceiling joists C being obliquely introduced into them, and driven up to their places. The scantlings of timbers used in this method are the same as those for double-framed flooring of which, indeed, it is but a species.

2020. The *double-framed floor* differs only from the last-named by the binding joists, instead of going from wall to wall, being framed into large pieces of timber called *girders* (as shown in *fig.* 674.), wherein A is the girder, B a binding joist, C a bridging joist, D a ceiling joist, E the pulley mortice for the ceiling joist D, and F is the floor.

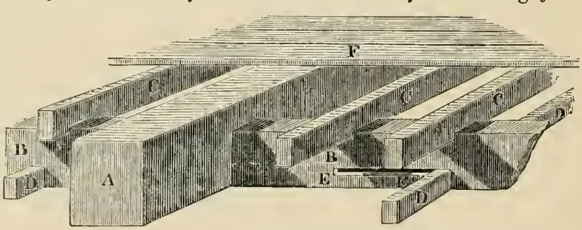

Fig. 674.

The great advantages of this sort of flooring are, that it prevents the passage of sound between the stories, and enables the architect to make a solid ceiling.

2021. As in a double-framed floor the girders are the chief supports, it is exceedingly important that they should be sound and free from shakes. The distances between one girder and another, or the wall, should not exceed 10 feet, and their scantlings as in the following table: —

Girders of the length of 10 feet	should be	9 inches deep,	7 inches wide.
12	—	10	8
14	—	11	9
16	—	12	10
18	—	12	11
20	—	13	11
22	—	14	12
24	—	15	12
26	—	16	12
28	—	16	13
30	—	16	14

2021*a*. Girders or beams whose bearing exceeds 24 feet are difficult to be procured of sufficient depth, in which case an expedient is put in requisition to strengthen a less depth. The principles it involves are explained under the head of roofs, namely, those of *trussing* them (2031, *et seq.*), an operation that converts the beam within its own thickness into a piece of framework, for the purpose of preventing the bending, or, as it is technically called, its *sagging*, which produces an injurious horizontal thrust on the walls. This operation is represented in *fig.* 675, in two different ways. No. III represents the plan.

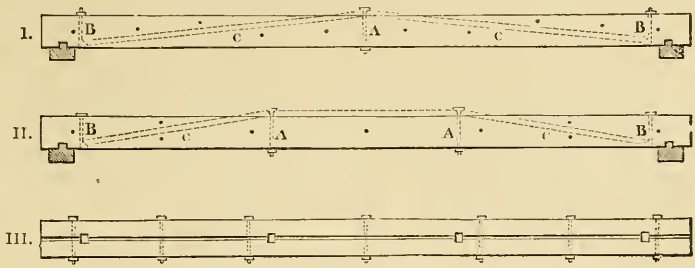

Fig. 675.

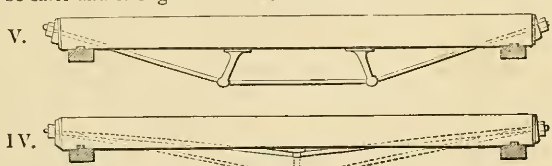
The beam is cut into two halves in the direction of its depth and length, between and into which the truss is inserted, as shown. It is better that the *truss posts* A, and *abutment pieces* B, should be of wrought iron; the *struts* C may be of oak, or some stiffer wood than the beam itself. In I. and II., the whole, or nearly the whole of the timber, is in a state of tension.

2021*b*. This operation is further developed by trussing the beam *below* itself, an arrangement considered to be safer and stronger than that above described. No. IV. has a wrought iron tension rod, with a stay in the centre, which takes the whole of the tension, whilst the timber is thrown entirely into compression. No. V. is the same with two stays. By these systems a beam, rafter, purlin, &c., which will barely support its own weight safely, may be made to carry a load of many tons without sensible deflection. The tension rod is useful in proportion to its distance from the beam (evidently within certain limits). If it be immediately under, or concealed *within* the under edge, it becomes nearly useless, especially in a cast iron beam with a wrought iron rod, where the beam is much less extensible than the rod. In such a case, the beam would break and fall before the rod has been brought into action. The respective size or sectional area of the rod and beam is regulated by the respective strength of the materials, as it is useless to apply a rod capable of sustaining double the tensile force that the beam can resist of crushing force, and *vice versâ*; it is merely adding weight (Warr, *Dynamics*, page 259.). The flitch girder is described in par. 1629*a*.



2021*c*. The resistance of beams of soft wood may be considerably increased by strengthening the centre of gravity. Du Hamel, *Force des Bois*, took twenty-four sticks, cut from young willows, of equal strength. Each stick was 3 feet (French) long, and 1½ inch square. Six of these broke in the middle with an average weight of 566·48 lbs. In two other pieces he made a cut *across it* ⅓ inch deep in the centre, and filled it out with a piece of oak; these broke with an average weight of 594·73 lbs. Two more were cut ½ inch deep, and treated in the same manner; they broke with 585 lbs. Five were cut ¾ inch deep, and broke with 572·78 lbs. All the trials showed that the piece of harder wood increased the strength of the beam.

2021*d*. Laves's girder is a simple and effective contrivance for strengthening a beam. The piece of timber having been cut nearly from end to end (*fig.* 675*a*.), is bound at each termination with an iron strap. Blocks are driven in the cut so as to separate the severed pieces to several inches distance in the middle of the length, thereby throwing

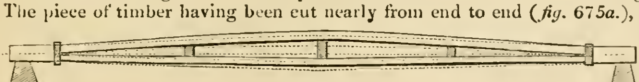


Fig. 675*a*.

the material farther above and below the neutral axis. A solid beam, 40 feet long, $9\frac{1}{4}$ inches deep, and $7\frac{1}{4}$ inches wide, deflected $5\frac{1}{4}$ inches with a load of 1,700 lbs. When a similar beam had been cut to 3·6 inches of each end, making the upper part 5 inches deep and the lower part $4\frac{1}{4}$ inches, and separated by blocks until the parts were as wide asunder as half the depth of the beam, the beam suffered a less deflection by $1\frac{3}{4}$ inch. A greater strength was obtained by separating the parts to the whole depth of the beam, when it deflected 3 inches less than the solid beam; and when separated to $1\frac{1}{2}$ times the depth, it deflected 4 inches less than the solid beam. The greatest strength is obtained by giving a section to the upper and lower parts proportional to the power of the material to resist tension and compression (*Civil Engineer* for 1840, page 161, being a paper read at the Institute of British Architects).

2021*e*. Floors are now largely made of fireproof materials, as referred to in the section Bricklayer. The introduction of rolled iron joists and girders has enabled the architect to construct his floors of larger span, by supporting the timber joists between them. By using riveted steel girders a saving is made in the cost of construction.

2022. We now return to the subject of binding joists, which ought not to be more than 6 feet apart. The depth, if necessary, for accommodating them to the thickness of the floor, may be varied from the following table by the rules given under section Beams, &c.

Binding joists of the length of

6 feet should be	6 inches deep,	4 inches wide.	14 feet should be	10 inches deep,	6 inches wide.
8 —	7 —	$4\frac{1}{2}$	16 —	11 —	$6\frac{1}{2}$
10 —	8 —	5	18 —	12 —	7
12 —	9 —	$5\frac{1}{2}$	20 —	13 —	$7\frac{1}{2}$

The scantlings of bridging joists are similar to those already given for single flooring. These, as well as ceiling joists, whose scantlings are subjoined, should not be more than 12 inches apart, and they require to be scarcely thicker than is necessary to bear the nails of the laths fixed to them, for which 2 inches is quite sufficient.

Ceiling joists of the length of

4 feet should be	$2\frac{1}{2}$ inches deep,	$1\frac{1}{2}$ inch wide.	10 feet should be	5 inches deep,	2 inches wide.
6 —	$3\frac{1}{2}$ —	$1\frac{1}{2}$	12 —	$5\frac{1}{2}$ —	$2\frac{1}{2}$
8 —	4 —	2			

The weight of a square of framed flooring with counter flooring varies from 22 to 36 cwt.

2023. Though, perhaps, more curious than useful, we should not perform our duty to the student, were we to omit a method of constructing floors with short timbers, where long ones are not to be procured. Suppose it be required to floor the room ABCD (*fig.* 676.)

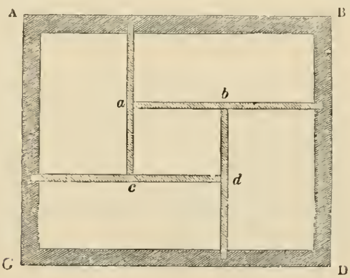

Fig. 676.

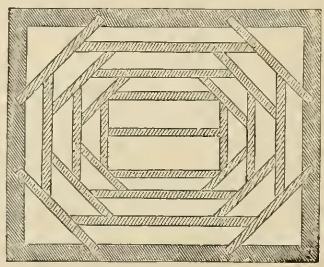

Fig. 677.

Let four joists, as in the figure, be mortised and tenoned at *abcd*, as there shown. Now it is evident that these joists will mutually support each other, for each is supported at one end by the wall, and at the other by the middle of the next joist. *Fig.* 677. shows another mode of accomplishing the same object; and many other forms would immediately suggest themselves to the experienced architect. The expedient is of ancient origin, inasmuch as our old master (so we delight to call him, notwithstanding the new lights that modern critics have found to guide them). Serlio, has described the expedient without any difference. In the fourth volume of Rondelet (*Art de Bâtir*), an author to whom we are under infinite obligations, is described a floor executed at Amsterdam for a room 60 feet square, of exceedingly singular construction, inasmuch as it is without joists at all. Each side of the room is provided with very strong wall plates, whose angles are secured with iron straps, and are rebated to receive the flooring, which consists of three thicknesses of $1\frac{1}{2}$ inch boards. Of these thicknesses, the first is laid diagonally across the opening, its ends resting on the rebates of the wall plates, and rising about $2\frac{1}{2}$ inches towards the centre of the room. The next (second) thickness is laid diagonally at right angles to the first thickness, and the two are well nailed together. In the third thickness, the boards are laid down parallel to one of the sides of the room, and form the upper side of the floor, being, however, well nailed to those below. The whole of them are *grooved* and *tongued* together, forming a solid floor 4½ inches thick. In this example is an instance well worthy the study of the architect, as respects a scientific connection of parts, and the great advantage of a well-disposed bond. The floor in question is, in fact, a thin plate, well supported round the edges, the strengths of the plates being directly as the squares of their thicknesses, equally strong to bear a weight in the middle, whatever their bearing; though if the load be uniformly distributed, the strength will be inversely as the area of the space.

2023*a*. The flooring of the Middle Ages, as used for upper rooms, were constructed with large square timbers resting on wood plates, which formed the cornice to the rooms; sometimes they had stone cornices under them. Occasionally the under sides of the joists were covered with boarding, and this was divided into panels by small ribs, with bosses at the intersections, carved with foliage, or with shields of arms, or other ornaments. An example of the 15th century exists at Wingham, in Kent; Parker, *Dom. Arch.* iii. 127. These were usually coloured in distemper. The ceiling of the nave and of the eastern part of St. Alban's Abbey church is a remarkable example of a fine flat *ceiling* of early date, as is also that in the tower of the church at St. Cross, in Hampshire, and that of the library, 15th century (and formerly in the chapel) of Merton College, Oxford. In England, in the 13th century, the ceilings (which were of wood) were frequently painted the same as on the wainscot, in green and gold, and were sometimes also decorated with historical subjects and with gilded bosses.

2023*b*. The joists that came upon a beam were placed upon it, and, being cut, were pinned into corresponding blocks. If the beam took two sets of joists, the blocks might be made long enough to connect the ends of the two sets. But by the 14th century the system of girders, binders, and joists was perfected; boarding one inch and a half thick, rebated on both edges, was laid with the wider face downward, and connected by rebated battens, fixed upon stop-moulded joists, and these were dovetailed for half their depth into moulded binders, that were dovetailed three-fifths of their depth into moulded girders, the backs of all being flush for the boarding, which received the mortar and tile floor.

2023*c*. Whether in oak or fir, this latter system was apparently never enriched with painting, but moulded and carved; indeed the inevitable towel decoration makes its appearance in panels formed by moulded strutting. These panels are let into rebates on the back of the struts and joists and binders, so as to leave a space between the panels and the flush floor, receiving the plaster or the tiles upon plastering. Another effective practice was to rebate the backs of the joists sufficiently deep to allow the apparent *ceiling* to consist of short pieces of board that were decorated on the two edges, laid close together, forming a pattern of circles, diamonds, foils, &c., cut in open work, with a ground formed by laying a plank over the whole length between the joists; over this came the finished one, or three coated floor. In the 15th and 16th centuries, pendentives hanging by keys to timber ceiling-joists, between binders, formed an entirely new arrangement of decoration, which rivalled in its complexity of drops and coffers the most elaborate works of Saracenic ceilings. In the time of Henry VIII., the ceilings were commonly of plaster, with a great variety of patterns stamped in them. The ceiling of the chapel of the Savoy Palace in the Strand is a rich example of panelling only.

2023*d*. Some of the timber houses built in Troyes at the commencement of the 15th century afford good specimens of the manner in which the construction of the floors was rendered ornamental. The studs of the framing carry the usual head-piece, which is moulded; and on this are notched down the ceiling joists, which have their ends cut as cantilevers: upon these rests a board, or plank, having its edge moulded, which is kept in place by the chantlates at the feet of the rafters. At other times the sill is separated from the joists; because they rest upon stanchions, upon which are planted brackets carrying the ends of the joists: between the ends, which are grooved, there is a piece of carved woodwork, so that the ends of the joists, in conjunction with a moulded plate resting upon them and receiving the tie beams or ceiling joists, form a sort of corbel-table. (*Fig.* 701*l.*)

2023*e*. Another method of forming a floor, with its ceiling, into decorated construction, is due to the 15th century. This consisted in cutting balks of timber diagonally and laying them with the angles downward close together. The ends were notched into the girders or binders, leaving flush backs. If not sightly enough, triangular fillets were put in between them; and the sharp angle might even be taken from off the arris or under edge of the balks. Floors were also composed of brick segment arches (the bricks being set herring-bone) between balks of timber laid with one corner upwards, so as to form a skew-back for the arches.

2023*f*. For these few remarks we are indebted to Viollet le Duc's admirable *Dictionnaire*. As the systems therein shown will scarcely be adopted in England in general practice, the student will do well to refer to the work should he require any illustrations. A very suggestive late example, richly moulded and carved, as it existed before 1843 at Fontainebleau, when it appears to have been reused and somewhat altered, is given in that work among many others.

2023*g*. *Timber groined ceilings* are to be met with in the choir and lady chapel at St. Albans'; in Warmington Church, Northamptonshire, of the Early English period; in the cloisters at Lincoln and Gloucester; in the towers at Exeter; in the lantern at Peterborough; the lantern at Ely, and the choir at Winchester, cathedrals; in the choir at Selby Abbey Church, Yorkshire; in the nave of Boston Church, Lincolnshire, where it unfortunately occupies 22 feet of height; the chapel of St. Mary's College, Winchester; and the entire roofing of York Minster. The vaults spring from stone-work carried up as high as required to free the ribs from the wall; there is no special mark of division at the point where the stonework ceased and the woodwork commenced. The boarding was let into a groove in the sides of the ribs, or laid on a rebate. The eastern part of the chancel of the 13th century church at Uffington, in Berkshire, is evidently groined or prepared for groining in this way, for whilst the walls and buttresses were insufficient to resist the thrust of a vault even filled in with chalk, the stone springers exist. "There seems to be no good reason," continues Mr. Street, from whose lecture on *Woodwork* we are quoting, "why this kind of ceiling should be condemned, as it has been by some writers, as though it were unreal, or in any way a sham. It is nothing of the kind, and no attempt was made to make the wood look like stone. The boarding was frequently feather-edged, and grooved and tongued, and thus obviously of wood. (*Fig.* 780*f.*) It may be introduced in buildings not calculated to resist the thrust of a stone vault; and it may be carried far up into the roof and above the top of the walls, which in stone vaults is always, within a little, the limits of internal height attainable."

PARTITIONS.

2024. The framework of timber used for dividing the internal parts of a house into rooms is called a *partition* or *quartered partition*. It is commonly lathed and plastered; when the spaces between the timbers or quarters are bricked up, it is called a *bricknogged partition*. The weight of a square of common partition is rarely less than from 13 to 18 cwt.; hence it becomes necessary to take care that partitions should not be set upon the floor, without taking due precaution to relieve it of the weight, either by struts, braces, or the formation of a truss in it. When a partition occurs in an upper story, under a strongly trussed roof, it may be often advantageously suspended from the roof, and its weight thus taken off from the floor below. If it have a solid bearing throughout its length, it requires nothing but struts between the quarters; but these are not absolutely required. The scantlings of the timbers of a quarter partition should vary according to the extent of bearing. Where that does not exceed 20 feet, 4 by 3 inches will be sufficient; and where it is as much as 40 feet, the quarters should not be under 6 by 4 inches, that is, supposing it to bear only its own weight. When it has to bear more, the scantling must, of course, be increased accordingly.

2025. *Fig.* 678. represents a design for a trussed partition, with a doorway in the centre

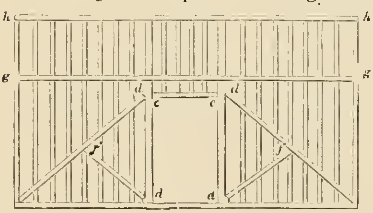

Fig. 678.

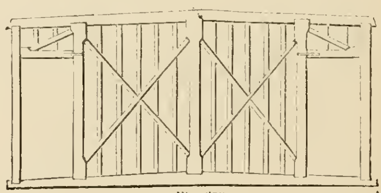

Fig. 679.

of it: in which *hh* is the head, and A A the sill; *dc*, *dc* the doorposts; *gg* the *intertie*, A*d*, A*d* the braces; *fd*, *fd* struts. *Fig.* 679. shows a method of trussing a partition in which the doors are at the sides. It is obvious that additional strength may also be gained, when wanted, by introducing a truss between the intertie and head of a partition. The angle of inclination of braces should be about 40° with the horizon.

CARRIAGE OF STAIRS.

2026. The framed timbers which support the steps of a staircase are called the *carriage*. They generally consist of two pieces inclined to the pitch of the stairs, called the *rough strings*. When geometrical stairs consist of two alternate flights with a half-pace between them, the carriage of the half-pace is constructed with a beam parallel to the risers of the steps, whose joists are framed into the beam for the support of the flooring. This beam is called the *apron piece*, and that which sustains the rough strings at the upper end is called the *pitching piece*. The joists of the half-pace are sometimes turned into the pitching piece, and sometimes bridge over it; but the steps of both flights are always supported by string pieces, as before. The upper ends of the string pieces at the landing rest upon an horizontal piece of timber, called, as above, an apron piece. The scantlings of the strings, of course, vary with the length of the inclined part. The depth given to joists of similar length will be more than sufficient.

ROOFS.

2027. The first obvious consideration in constructing a roof is the slope to be given to it, which depends on the climate against which it is to serve as a protection, and on the materials to be employed in covering it. In hot countries, rain more rarely falls than in temperate ones; but when it comes, it descends very abundantly, which, added to the temperature of the air, makes it unnecessary to give a great slope to the roof, from which the water immediately runs, and the air dries it almost at the instant of the rain's cessation. In cold countries the rain is more searching, the air is more impregnated with moisture, and snow often lies for a long time on a roof; circumstances which require a greater proportional slope to be given to it. Again, roofs covered with lead, zinc, or copper, do not require so great a slope as those covered with tiles or slates. (See ROOFING, in Glossary.)

2028. Though among architects there does not appear to have been any fixed principle by which the slope should be determined, we find that in different climates suitable slopes have been adopted for similar materials. Thus in the southern parts of Europe we find the roofs very flat; whilst as we proceed into its northern parts the roof acquires a very considerable elevation. We shall here transfer to our pages the notice of this subject in the *Encyclopedie Methodique*, which we consider extremely important and interesting, inasmuch as it shows that necessity was the parent of beauty in the inclination of the roofs of the ancients; and in the times of the middle ages it had some influence even in the production and developement of the lancet arch.

2029. The researches and observations made respecting the roofs of a great many ancient and modern buildings, situate in different countries, satisfy us that the slopes of roofs which have lasted best are always proportioned to the temperature of the climate. Before entering into the consideration of any law for determining the slope of a roof, it will be proper to comprehend the meaning of the word climate as here introduced, which we shall use in the same way as it is understood by geographers. According to them, the climates of the globe are comprised under belts or bands, of unequal size, parallel to the equator. Of them there are twenty-four between the equator and the polar circle, each of half an hour; that is, the length of the longest day of a place situated at the beginning of the climate is always shorter by half an hour than that of the place situated at the extremity of the same climate, or at the beginning of the succeeding one, proceeding from the equator towards the polar circle. This difference in the length of the day, caused by the greater or less obliquity of the tropic with the horizon, is one reason of the different degrees of temperature of countries corresponding to the different climates. We are not, however, to assume that the temperature will be exactly the same for all places under the same climate, since there are many circumstances which tend to make a place more or less damp, in which cases the slope of the roof should rather have a relation to a more northern spot. In the roofs of the Continent covered with the hollow tile, as in the south of France for instance, less slope is required than with the Roman tiles (see the word TILE in Glossary), which are in sections alternately flat and circular; and these, again, require less slope than the common plain tile or slate. From the observations that have been made, we find that the slope of roofs covered with hollow tile,  thus, of the south of France, should be after the rate of three degrees for every climate, beginning from the equator and proceeding northward, and that when the Roman tile is used, an addition of three degrees should be made to such inclination; an addition of six degrees, if covered with slates; and of eight degrees, if covered with plain tiles. According to this law, the table which will be presently subjoined has been constructed, and a comparison of it with ancient buildings gives a remarkable corroboration of its value. Thus, at Athens, situated about the middle of the sixth climate, the slope of a pediment would be about $16\frac{1}{2}°$; and that of the Parthenon is actually about 16°; that of the temple of Erectheus, $15\frac{1}{2}°$; of Theseus, 15°. In Rome, which is about one third of the way up the seventh climate, the Roman tile requires an inclination of 22°. The actual slope of the pediment of Septimius Severus is 23°; those of the temples of Concord and Mars Ultor, $23\frac{1}{2}°$; of Fortuna Virilis and the Pantheon, 24°; and, of more modern date, the slope of the roof of St. Paolo fuorì le murà was 23°.

2030. We shall now give the reader the table above mentioned. This ingenious theory is taken exception to by P. Waterhouse in his Essay on *Pediments*, &c., 1886.

“ There is no article,” says Ware in his *Body of Architecture*, “ in the whole compass of the architect’s employment that is more important or more worthy of a distinct consideration than the roof. The great caution is,” continues our author “ that the roof be neither too massy nor too slight. Both extremes are to be avoided, for in architecture every extreme is to be shunned, but of the two the overweight of roof is more to be regarded than too much slightness. This part is intended not only to cover the building, but to press upon the walls, and by that bearing to unite and hold all together. This it wil. not be massy enough to perform if too little timber be employed. so that the extreme is to be shunned. But in practice the great and common error is on the other side; and he will do the most acceptable service to his profession, who shall show how to retrench and execute the same roof with a smaller quantity of timber; he will by this take off an unnecessary load from the walls, and a large and useless expense to the owner."

2031. We shall now proceed to a popular view of the strains exerted by the timbers of roofs, referring the reader back to the section on Beams, Pillars, &c., for a more extended and scientific view of them. Suppose (*fig.* 680.), in the simplest form of roof, the rafters (shown by dotted lines) AB, CB to pitch upon the walls *Aa*, *Cc*. Let the rafters be supposed to be connected together at B as by a hinge, as also similarly connected with the walls at A and C. Now if the effective weight of the walls be not sufficient to resist the thrusts of the rafters, as respects the height, thickness, and situation of the centre of gravity of such walls, taken as solid masses and moveable on the points X and Y, it is manifest the rafters by their own gravity will descend, and the walls will spread and be thrown out of an upright, as in *ab* and *cd*. and the rafters will take the places shown in the figure. It has already been shown (par. 1622) that the horizontal thrust of a pair of rafters thus meeting each other. is proportional to the length of a line drawn perpendicularly from the rafter's foot until it intersects a vertical line drawn from its apex. As the roof therefore becomes flatter, the length of the perpendicular increases. Hence, if AB and BC be the rafters, and their weights be represented by their lengths, the weight or power of thrust exerted by the rafter AB in the direction of its length will be represented by BO, and the horizontal thrust by AO; AO being perpendicular to AB. To secure, then, the walls in their perpendicularity, which the thrust of the rafters tends to derange, a system of framing becomes necessary.

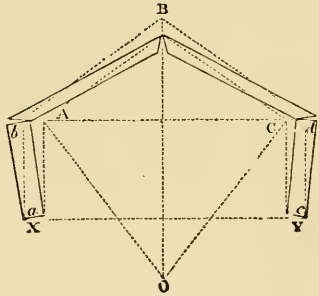

Fig. 680.

Thus, in *fig.* 681., a beam AC, which from the office it performs of tying or confining the feet of the rafters is called a *tie beam*, is introduced across the opening. and into this beam the rafters are framed. If the tie is introduced above the level of the walls, it is called a *collar beam*, as *ac*. It is manifest that these beams exert their power in the same way that a string would, that is, that the principal strain which they have to perform is in the direction of their length, and hence, that for such especial purpose, if they be prevented from *sagging* or bending, a small size or scantling will be sufficient, for we have already seen that the cohesive power of timber is very great in the direction of its length.

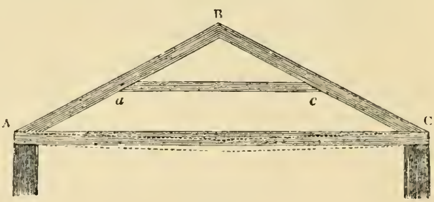

Fig. 681.

To take care that the tie beam thus introduced should be strained only in the direction for which it is used, we are now led to another expedient. The beam by its own gravity, especially in a large opening, would have a tendency to sag or bend in the middle, and the more so if its scantling be simply proportioned to its office of a tie. To prevent this a fresh tie is introduced called a *king-post* DB (*fig.* 682.), by which the beam is tied or slung up to the apex of the principal rafters; and this combination of a pair of rafters, a tie beam and a king-post, is called a *truss*, and is the most important of the assemblages which the carpenter produces. When the rafters are of such length that they would be liable of themselves to sag down, supports *aa* are introduced at the points where such failures would occur, and these supports are called *struts*, because their office is to strut up the rafter, which they should do as nearly as the case will admit in a direction perpendicular to the slope of the rafters.

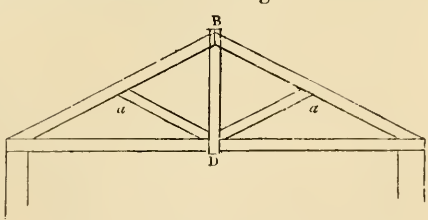

Fig. 682.

2032. It is clear that out of this last case a fresh system of trusses may arise as in *fig.* 683., for from those points procured by the struts against the rafters new rods may be slung for increasing the stiffness of the tie beam *ad infinitum* in theory, but not in practice, because the compressibility of the fibres of timber is considerable in lines perpendicular to their direction, and the contraction and expansion of metal places a limit to its use. This compression of timber deserves great attention on the part of the architect. We may lay down as a rule in respect to it that the more the weights or pressures act in the direction of the fibres, the less will be the compression.

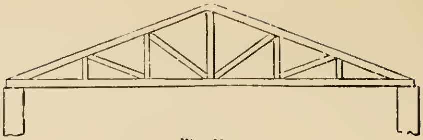

Fig. 683.

2033. To exemplify this, *fig.* 684. shows in No. 1. the principal rafters of a roof butting in an ordinary roof, against the shoulders AB, CD of the kingpost, whose fibres, being vertical, are compressed by the pressure against it, on each side of the rafters, whereby they approach each other, causing the whole figure of the roof to suffer a change. For by the action of compression and its consequence the kingpost must descend, and with it, consequently, the tie beam which is slung up to it. To remedy the inconvenience in roofs constructed of fir, the kingpost is often made of oak, which is less compressible, a practice which should be observed in all roofs of consequence. But cast iron kingposts are the best substitute where the expense can be justified. In No. 2. the end is accomplished much more economically by *housing* the rafters in the head of the kingpost at the angle in which the rafters meet, by which the fibres of the rafters butt against each other, bringing the compression nearer to that which takes place in a post according as the rafters are less inclined to each other, and the beam is then literally suspended from the vertical planes of the rafters at their junction.

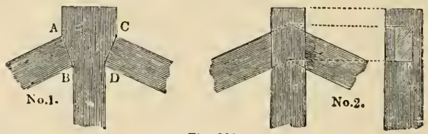

Fig. 681.

2034. When a roof (*fig.* 685.) is trussed by two upright suspending posts, which become necessary in increased spans, such posts, AB, CD, are called *queen-posts*, and the piece between them, BD, is called a *collar*, which acts as a *straining piece* to prevent the heads of the queen-posts moving out of their places towards each other. It will on mere inspection be seen that this roof has three points of support, B, E, and D; for by means of the struts AE, EC, a new suspending point is gained from E for sustaining the tie beam between the points A and C. It is also to be observed that the collar or straining piece BD performs in this assemblage an office exactly the reverse of that which it does in *fig.* 681.

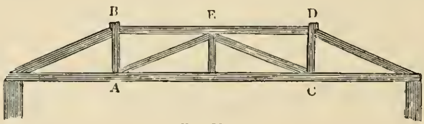

Fig. 685.

2035. The *Mansard* roof, so called from its inventor's name, and with us called a *Curb roof*, frequently used for the purpose of keeping down the height of a building, and at the same time of obtaining sleeping or other rooms in it, is shown in *figs.* 686 and 687. It may be considered as primarily consisting of four pieces of timber connected by hinges at the points ABCDE. If these be inverted, they will arrange themselves by their gravity in such a manner that when returned to their first position they remain in a state of equilibrium, which, however, in practice is but a tottering one, and requires additional expedients to prevent the whole assemblage thrusting out the walls; and, moreover, to prevent the upper rafters from acting by their thrust to displace the lower ones. To obtain these ends the first object is to introduce the tie AE; and, secondly, the tie BD. It is to be understood that means are to be used, when needed from their length, to prevent these beams from bending, similar to those already directed in the cases of simple trusses. *Fig.* 686 is an example selected from Krafft, (*Art. de la Charpente*, fol. 1805), having an arched ceiling to give additional height to

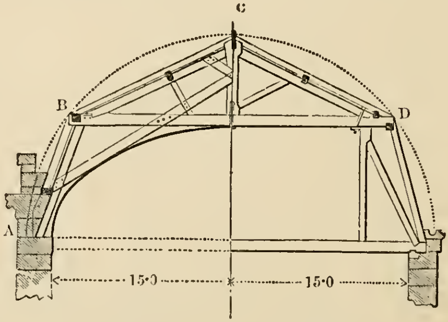

Fig 686. Fig 687.

some large or public room. This form of roof has been frequently adopted in the palaces of France and Germany. *Fig.* 687 is a king-post Mansard roof, affording a wide space over the tie beam available as an apartment. *Fig.* 698 is an example of the principles adopted for a much wider spanned roof.

2035*a*. We have thus far endeavoured to explain in the simplest way the conduct to be pursued for obtaining stability in the construction of a roof; but before we proceed to the scantlings of the timbers to be employed, the reader must be informed that the trusses to roofing, with whose nature he has now become acquainted, are placed only at certain intervals (which should not exceed 10 feet) apart, and are thus made to bear the *common rafters* and the weight of the covering, as well as to perform the office of suspending the tie beam by which the walls are kept together. Hence the rafters so framed in a truss are called principal rafters; and by the means of a *purline* A (*fig.* 688.), which lies horizontally throughout the roof's length on the principal rafters, they are made to bear all the superincumbent load. The purlines are in various ways made fast to the principal rafters, and upon it the common rafters are usually notched down. Their bearings are thus lessened, and less scantlings suffice for them. They are received at their feet on a piece of timber (B in the figure), which runs longitudinally along the sides of the building. This piece of timber is called a *pole plate*, from being the uppermost plate in a building; at their summits they abut against a *ridge piece* D. When a roof slopes each way, the space enclosed between the intersection of the slopes is called a hip (*fig.* 689.); and the longest rafters in it, which are those at the angles, are called *hip rafters*, and the shorter ones are named *jack rafters*, as A, A, A, &c.

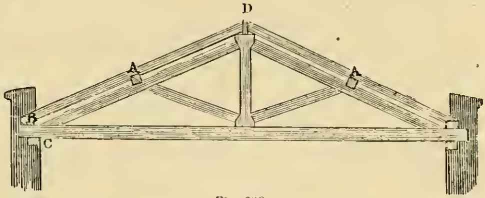

Fig. 688.

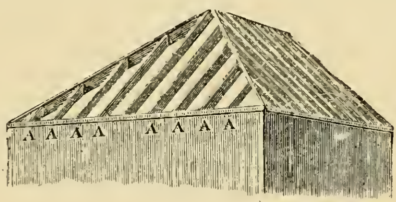

Fig. 689.

2036. We have, at the beginning of this section (2007.), observed, that the use made of bolts must be always in a direction as nearly as possible counter to the strain which the pieces exert; the method, therefore, of introducing them will, on due consideration, be sufficiently obvious.

Before proceeding to lay before the reader some few examples of roofs suitable to different spans, as well as of some of magnitude which have been executed, it may be as well to complete this portion of our labour, by giving some information on the scantlings of timber for roofing, in which a medium, founded on our own practice, is introduced between ignorant overloading, and fanciful theory.

2037. For roofs whose spans are between 20 and 30 feet, no more than a truss with a king-post and struts will be necessary, in which case the scantlings hereunder given will be sufficient.

For a span of 20 feet, the tie beam to be 9 in. by 4 in.; the king-post, 4 in. by 4 in., principal rafter, 4 in. by 4 in.; struts, 4 in. by 3 in.

For a span of 25 feet, the tie beam to be 10 in. by 5 in.; the king-posts, 5 in. by 5 in.; principal rafter, 5 in. by 4 in.; struts, 5 in. by 3 in.

For a span of 30 feet, the tie beam to be 11 in. by 6 in.; the king-post, 6 in. by 6 in., principal rafter, 6 in. by 4 in.; struts, 6 in. by 3 in.

2038. For roofs whose spans are between 30 and 45 feet, a truss with two queen-posts and struts will be required, and a straining piece between the queen-posts. Thus —

For a span of 35 feet, the tie beams to be 11 in. by 4 in.; queen-posts 4 in. by 4 in.; principals, 5 in. by 4 in.; straining piece, 7 in. by 4 in.; struts, 4 in. by 2 in.

For a span of 40 feet, the tie beams to be 12 in. by 5 in.; queen posts, 5 in. by 5 in.; principals, 5 in. by 5 in.; straining piece, 7 in. by 5 in.; struts, 5 in. by 2½ in.

For a span of 45 feet, the tie beams to be 13 in. by 6 in.; queen-posts, 6 in. by 6 in.; principals, 6 in. by 5 in.; straining piece, 7 in. by 6 in.; struts, 5 in. by 3 in.

2039. For roofs whose spans are between 45 and 60 feet. two queen-posts are required, and a straining piece between them; struts from the larger to the smaller queen-posts, and struts again from the latter.

For a span of 50 feet, tie beams, 13 in. by 8 in.; queen-posts, 8 in. by 8 in.; small queens, 8 in. by 4 in.; principals, 8 in. by 6 in.; straining piece, 9 in by 6 in.: struts, 5 in. by 3 in.

For a span of 55 feet, tie beams, 14 in. by 9 in.; queen-posts, 9 in. by 8 in.; small queens, 9 in. by 4 in.; principals, 8 in. by 7 in.; straining-piece, 10 in. by 6 in.; struts, $5\frac{1}{2}$ in. by 3 in.

For a span of 60 feet, tie beams, 15 in. by 10 in.; queen-posts, 10 in. by 8 in.; small queens, 10 in. by 4 in.; principals, 8 in. by 8 in.; straining piece, 11 in. by 6 in.; struts, 6 in. by 3 in.

2040. The scantlings of purlins are regulated principally by their bearing; and though we have subjoined scantlings for bearings of 12 feet, such should be avoided by not allowing the distances between the trusses to exceed 10 feet. Thus—for a bearing of 6 feet, the scantling should be 6 by 4; for 8 feet, 7 by 5; for 10 feet, 8 by 6; for 12 feet, 9 by 7.

For common rafters the scantlings are as follow; 12 feet should be the maximum of the bearing. For a bearing of 8 feet the scantling should be 4 by $2\frac{1}{2}$; for 10 feet, 5 by $2\frac{1}{2}$; for 12 feet, 6 by $2\frac{1}{2}$.

2040*a*. To determine the size of a rafter for a roof to support the covering of slate, the distance between the supports being 6 feet, and the weight of a superficial foot, including the stress of the wind, being 56 lbs.; the deflection not to exceed $\frac{1}{40}$th of an inch for each foot in length; the formula becomes:—56 lbs. × 6 feet = 336 lbs., and $\frac{336 \text{ lbs.} \times 40 \times 6^3}{E = 3072 \times 6} = 157\cdot5$, of which take $\frac{5}{8}$ths for uniform load = 98·44. If the breadth be made $2\frac{1}{2}$ inches, then $\frac{98\cdot44}{2\cdot5} = 39\cdot3$, and the cube root of 39·3 is 3·4 inches, the depth required. These are the rules given by Barlow (page 179), who, in the several editions of his work on *Strength of Materials*, put the "reduced tabular value" for Riga fir, E = 96, and 32 times E became 3072; and for English oak, E = 105. In the edition of 1851, this has been altered to E = 192, and 16 times E = 3072 also, for fir; or for oak E = 210. The reason of this change has been explained in Beams and Pillars, par. 1630*m*.

2040*b*. Another element in the calculation for timbers above-named, is the weights of the different materials used in covering buildings; these are stated to be as follows. (Flat fireproof roofs have been considered s.v. Bricklayer):—

A square of timbering for tiled and slated roof - -	5·5 to 6 5 lbs.		
,, boarding $\frac{3}{4}$ thick - - - - - - -	2·50 ,,		In lbs. per
,, ,, and sheet iron, 20 W.G. - - -	6·5 ,,		sq. ft.
,, pantiling about $7\frac{1}{2}$ cwts., also put at -	650 ,,	$\frac{2}{9}$	10
,, plain tiling ,, $14\frac{1}{2}$,, ,, -	1780 ,,	$\frac{2}{7}$	7 to 20
,, stone slating ,, — ,, ,, -	2380 ,,	$\frac{2}{7}$	
,, slating, a mean ,, $6\frac{1}{2}$,, ,, -	— ,,	-	5 to 11
,, ,, common ,, — ,, ,,	500 to 900 ,,	$\frac{1}{4}$	
,, ,, large ,, — ,, ,,	1120 ,,	$\frac{1}{3}$	
,, lead ,, 5 ,, ,,	700 ,,	$\frac{1}{48}$	6 or 7
,, zinc, 15 ounce ,, 1 ,, ,,	— ,,	$\frac{1}{48}$	1·25 to 1·63
,, copper ,, — ,, ,,	100 ,,	$\frac{1}{48}$	
,, sheet iron, 16 W.G., and laths - - - -	5 ,,		
,, ,, $\frac{1}{16}$ thick - - - - - -	3 ,,		
,, ,, corrugated - - - - - -	3·4 ,,		
,, ,, ,, and laths - - - -	5·5 ,,		
,, cast iron plates, $\frac{3}{8}$ thick - - - - -	15 ,,		
,, thatch about — ,, - - - - -	— ,,	$\frac{1}{2}$	6·50

The weights of iron roof coverings are given by G. S. Clarke, *Graphic Statics*, 1880, p. 137, from Unwin, *Wrought Iron Bridges and Roofs*. The column of fractions shows what the height of the roof, in parts of the span, is usually made. As the timbers employed are of course less in dimension as the weight decreases, it follows that a much less quantity of timber is requisite where the metals can be employed. On *flats* it will be necessary to consider the weight of the number of persons who may be probably standing on it at a time. The force of the wind has been considered in par. 1592*a*. When the rise or pitch is $\frac{1}{6}$th of the span, the angle formed is 18°25″; $\frac{1}{4}$ is 26°35″; $\frac{1}{3}$ is 33°42′; $\frac{1}{2}$ is 45°; $\frac{2}{3}$ is 53°; $\frac{3}{4}$ is 56°20″; when equilateral, 60°; a whole pitch is 63°30″.

2041. By a study of the roofs which follow as examples, the architect will be led to other expedients and modifications of the forms submitted to his notice, as circumstances may call forth his ingenuity and talents. We have, we trust, already said enough to lead him on. Where economy must be consulted, the roof shown in *fig.* 690 may be used; it is only fit for a small building, and the span of such a one should not exceed 25 feet. The left end of the collar beam exhibits what is called the *carpenter's boast*, but it partakes somewhat of the rule joint, being worked out to a centre. But in roofs above 25 feet span it is not well to omit the king-post and tie beam, though, if particular strains are to be provided

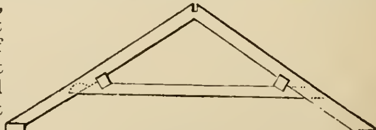

Fig. 690.

against, even in such small spans the struts should not be omitted, and the form shown in *fig.* 691. should be adopted, which will answer for spans at least up to 35 feet. In this and

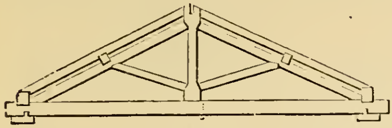

Fig. 691.

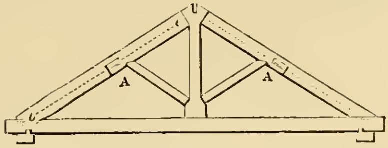

Fig. 692.

other cases of larger span, it is often desirable that the common rafters should not stand above the principals, and then the purlines are framed by mortices and tenons into the principals, as shown at A, *fig.* 692., wherein the line *bc* shows the underside of the common rafters notched on to the purlines. This is a usual practice in Gothic roofs.

2042. From 35 to 45 feet, the tie beam should be suspended from at least three points, or it will be unnecessarily heavy; and this suspension of the tie beam, so that it may be really a tie unsusceptible of alteration in form, is the true cause of this introduction of king and queen posts, as before explained. Indeed, as a general rule, it is well that the distance between such points of support for a tie beam should not exceed 13 to 15 feet, without expedients being used to prevent intermediate sagging. *Fig.* 693. is a queen-post roof of a span of 43 feet, over the railway workshops at Worcester, showing the introduction of skylights. The trusses are placed 15 feet apart. The principal rafters are 8 by 8; tie beam, 12 by 8; queen-post, 8 by 6; struts, 4½ by 4½; straining beam, 9 by 8; common rafters, 4½ by 2; purlines, in two flitches each (trussed with stirrup pieces and iron ties), 9 by 3. The tie beams are carried on iron shoes. *Fig.* 694. is a queen-post truss for a span of 50 feet, which leaves a considerable space free in the middle. The tie beam will probably be scarfed, which will be best made between *a* and *b*. The straining sill *c*, strapped to the tie beam, will add materially to its strength.

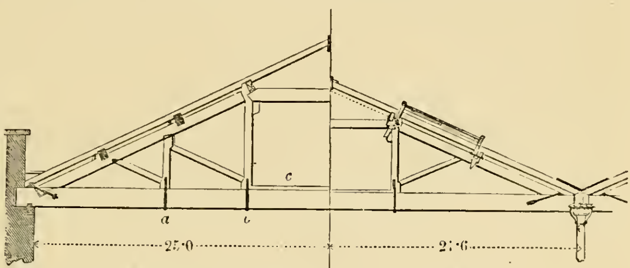

Fig. 694. Fig. 695.

2043. For spans above 60 feet we have not given scantlings of timber in the preceding tables; but such do not greatly increase beyond 60 feet with practicable spans, and enough has been already said to make the reader acquainted with that part of the subject. *Fig.* 695. is the truss of the parish church of Elgin, designed by A. Simpson, of Aberdeen. The trusses are placed 6 feet 6 inches from centre to centre. The tie beam is in two flitches, each 13 by 5½; principal rafters. 11 inches deep at lower end, 8 inches at top, and 6 inches thick; collar beam, 7 by 5½; king-post struts, 5 by 5½; struts, 5 by 4½; horizontal rafters, 4½ by 2½, placed 13 inches apart, and covered with inch grooved and tongued deal, and 7 lbs. lead. This is similar to the Italian system intimated in Specifications, par. 2285. The tie beams have cast iron shoes at each end, with abutments formed for the rafters, and secured with ⅞ inch diameter bolts with nuts and washers. The wrought iron suspending rods are inch square, and have abutment pieces for the rafters and struts.

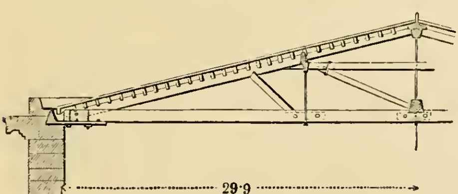

Fig. 695.

2043*a*. *Fig.* 695*a*. is the truss of a roof for a span of 45 ft., with cast iron shoes as abutments for the timbers acting as struts. The end of the tie beam has a cast iron shoe, which also takes the foot of the principal rafter. The sole plate of the shoe is prolonged inwards, to admit of its being secured by bolts to the tie beam. The head of the principal rafter *a*, and the end of the straining beam *a b*, are inserted into a cast iron socket, shown in detail in *fig.* A. The suspension rod passes through the solid part of the socket; it has a head at its upper end, and at its lower end it is screwed and secured by a nut. On the side of the socket is cast a rest, *c*, for the side of the purline. To avoid cutting the principal rafters, the other purline at B is also carried in a cast iron rest bolted to the rafter. The centre suspending rod passes through a cast iron socket, which serves as an abutment to the main struts. Similar abutments are provided for the lower end of the struts. *Fig.* 695*b.*

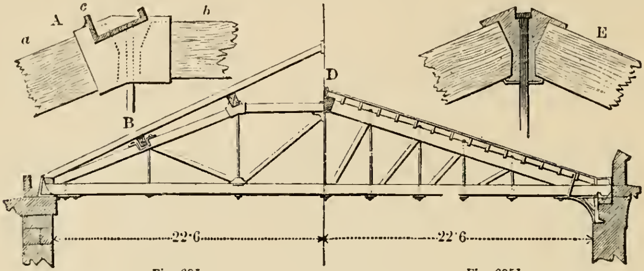

Fig. 695*a*. Fig. 695*b*.

for a span of 45 feet, has also wrought iron suspension rods. A roof of this description, 54 feet span and 212 feet long, is erected at the passengers shed of the Croydon railway station. The figure E is a section through a cast iron socket taking the heads of the principals, and through which passes a wrought iron king bolt, shown in position at D.

2044. In all the cases given, the roof is supposed to receive no support from any but the external walls, and the trusses to be in most cases not more than 10 feet apart.

2045. The reader who desires to become acquainted with other examples, is recommended to the works by Krafft, *Art de la Charpente*, and *Charpenterie*; Rondelet, *L'Art de Bâtir*, and its continuation by Blouet; Emy, *Art de la Charpenterie*; Tredgold, *Carpentry*; Newland, *Carpenter's and Joiner's Assistant*, to which work we are indebted for the above new examples and *The Doctrines of Carpentry Explained—of a Roof*, by Lieut.-Col. Waddington, in the Papers of the Corps of Royal Engineers, 1849, x. 71–152.

2046 *Fig.* 696. represents a roof designed by J. Gibbs. From the centres of columns the

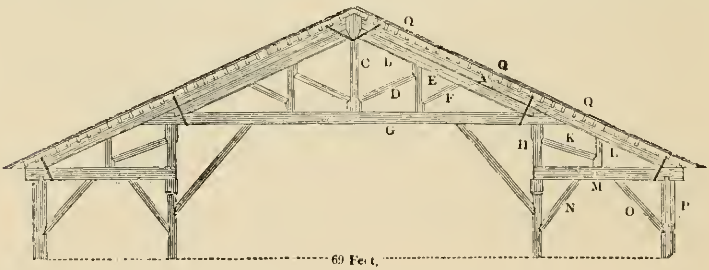

Fig. 696. ST. MARTIN'S-IN-THE-FIELDS, WESTMINSTER.

middle aisle is 39 ft. 11 in. The roof is well contrived and framed; but the timbers are stronger than they need have been. The scantlings are as follow:—A, principal rafter, 13 in. by 10 at bottom, and 11 in. by 10 at top; B, straining brace, 14 in. by 10 at bottom, and 11 in. by 10 at top; C, king-post, 9 in. by 9; D, strut, 7 in. by $7\frac{1}{2}$; E, queen-post, 8 in. by $9\frac{1}{2}$; F, strut, 7 in. by 7; G, tie-beam, 14 in. by $9\frac{1}{2}$; H, post over the column, 14 in. by $9\frac{1}{2}$: I, brace, 7 in. by 7; K, brace, 7 in. by 7; L, post. 8 in. by 9; M, hammer beam, 14 in. by $9\frac{1}{2}$; N, brace, 8 in. by 8; P, post in the wall; QQQ, purline rafters, 4 in. by 6.

2047. *Fig.* 697. is the section of a roof by James Stuart, about 1785. The span is 51 ft., and as a variation from the general forms of roofs, it is worth the student's attention. The

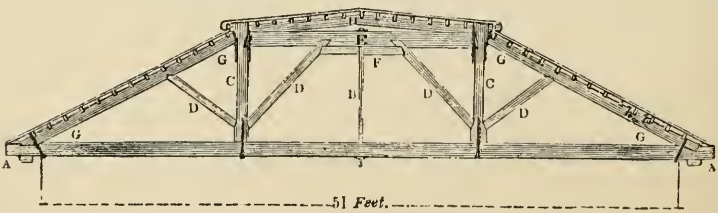

Fig. 697. GREENWICH HOSPITAL

scantling of the timbers are subjoined. The distance between the trusses is about 7 ft. All the joints are well secured with iron straps. AA, tie-beam, whose whole length is 57 ft., 51 ft. clear between the walls. 14 in. by 12 in.; B, an iron king-post, 2 in. square; CC, green posts, 9 in. by 12; DDDD, struts, 9 in. by 7; E, straining beam, 10 in. by 7; F, straining piece, 6 in. by 7; GG, GG, principal rafters, 10 in. by 7; *hhhh*, &c. purline rafters for boarding upon instead of rafters; H, a camber beam, supporting the platform.

2048. *Fig.* 698. exhibits the roof of the old Drury Lane Theatre, which was built in

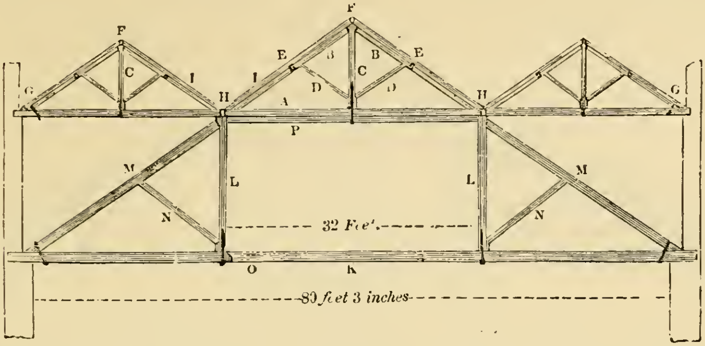

Fig. 698.

1793. It possesses great merit, from the simplicity of its composition and the accommodation afforded in the middle space for the carpenters and painters. By dividing the breadth of the building into three parts, the roof was kept low, and the scantlings much reduced in size. The span is 80 ft. 3½ in., the trusses were 15 ft. apart, and the whole length of the roof was 200 ft. It was destroyed by fire on the 24th of February, 1809. The scantlings of the timbers were as follow: — A, beams, 12 in. by 7; B, principal rafters, 7 in. thick; C, king-posts, 12 in. by 7; D, struts, 5 in. by 7; E, purlines, 9 in. by 5; F, ridge pieces, 1½ in. thick; G, pole plates, 5 in. by 5; H, gutter plates framed into beams, 12 in. by 6, I. common rafters, 5 in. and 4 in. by 2½; K, beams, 15 in. by 12; L, posts, 15 in. by 12. M, principal braces, 14 in. by 12; N, struts, 8 in. by 12; O, oak trusses to the middle bearing of beams, 5½ in. by 4½; P, straining beams, 12 in. by 12.

2049. The last example we shall present is of the method in which the external dome of St. Paul's is framed (*fig.* 699.). The internal dome A*a* is of brickwork, two bricks thick, having, at every five feet, as it rises, a course consisting of bricks eighteen inches long, which serves to bind the whole thickness together. This dome was turned upon a centre, which rested upon the projection at its springing, without any support from below, and was afterwards left for the use of the painter. It was banded together with iron at the springing. Exterior to the brick dome (which has indeed, nothing immediately to do with the subject) is a cone of brickwork BB*b*, 1 foot 6 inches in thickness, plastered and painted, part whereof is seen from the pavement under the cupola through the opening *a*. On this cone BB*b* is supported the timber work which carries the external dome, whose hammer beams CC, DD, EE, FF are tied into the corbels G, H, I, K with iron cramps, which are well bedded into the corbels with lead, and bolted to the hammer beams. The stairs which lead to the Golden Gallery on the top of the dome are carried between the trusses of the roof. The dome is boarded from the base upwards, hence the ribs are fixed horizontally at near distances to each other. The scantling of the curve rib of the truss is 10 in. by 11½ at the bottom, and 6 in. by 6 at the top. The sides of the dome are segments of circles, whose centres are not marked in the figure; and which, if continued, would meet at top, and form a pointed arch. Above the dome rises a lantern of Portland stone, about 21 feet in diameter, and 64 feet high, standing on the cone. The whole of this construction is manifest from the figure, which exhibits the inner and outer domes with the cone between them. The combination is altogether an admirable example of the mathematical skill and judgment of Sir C. Wren.

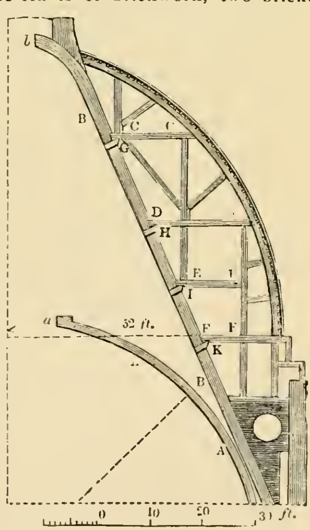

Fig. 699.

2050. The largest timber roof perhaps ever projected, was over a riding house at Moscow, in 1790, for Paul I. Emperor of Russia, the representation of which may be seen in Krafft, *Recueil de Charpente.* The span is 235 feet, and the slope with the horizon about 19°. The external dimensions of the building were 1920 feet long by 310 feet wide. It was lighted by a lantern at top, and had an interior gallery round the building for spectators. Cresy, in his *Civil Engineering*, states that this roof was never erected.

2051. We shall close this part of the section with a diagram (*fig.* 700.) of the roof of

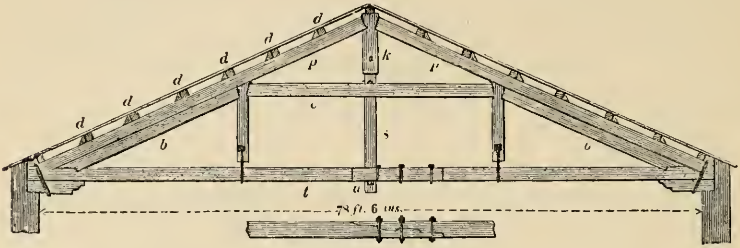

Fig. 700.

the basilica of S. Paolo fuori le mura, executed in the fifteenth century. The trusses are double, each consisting of two similar frames, nearly 15 inches apart, at intervals from each other of about 10 feet 6 inches. The principal rafters abut on a short-king post *k*. Between the trusses a piece of timber S is placed and sustained by a strong key of wood passing through it and the short king-posts. This piece sustains the beams by means of another strong key at *a*. The tie beams are in two lengths, and scarfed together, the scarf being held together by three iron straps. The scantlings of the timbers are as follow: beams *t*, $22\frac{1}{4}$ in. full by nearly 15 in.; principal rafters *p*, $21\frac{3}{4}$ in. by nearly 15 in.; auxiliary rafters *b*, full $13\frac{3}{4}$ in. by full $13\frac{1}{4}$ in.; straining beam *c*, near 15 in. by full $12\frac{3}{4}$ in.; purlines *d*, $8\frac{1}{2}$ in. square and 5 ft. 7 in. apart; common rafters, full $5\frac{1}{4}$ in. by $4\frac{1}{4}$ in., and $8\frac{1}{2}$ in. apart. The roof, which is constructed of fir, is nearly 78 ft. 6 in. span, and is covered with the Roman tile, the exact dimensions and form whereof will be found, under the head Tile, in the Glossary appended to this work. The roof is ingeniously and well contrived, and, with a different covering, would suit other climates. It was consumed by fire in the month of July, 1823. (275.)

Philibert Delorme, in his work entitled "*Nouvelles Inventions pour bien bâtir a petits Frais*," Paris, 1561, gives a mode of constructing domes without horizontal cross ties, when the springing of each rib is well secured at the foot. It is a very simple method, and of great use in domes, even of large diameter, the principle being that of making the several ribs in two or more thicknesses, which are cut to the curve in lengths not so great as to weaken the timber, and securing these well together by bolts or keys, and observing especially to *break* the joints of the several thicknesses. This method was adopted in the large Halle aux bleds at Paris, which was many years since destroyed by fire, and has been replaced by an iron-ribbed dome. The *fig.* 701. will explain the construction; and, if necessary, an iron hoop passed round at different heights will add much to the strength.

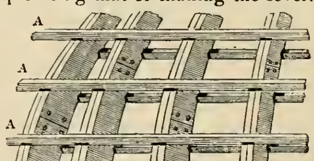

Fig. 701.

2052. The scantlings of the ribs, as given by Delorme, are as under: —

For domes of	24 feet diameter, the ribs to be	8 in. deep, and 1 in. thick.
	36 feet diameter,	—	10 in. deep, and $1\frac{1}{2}$ in. thick.
	60 feet diameter,	—	13 in. deep, and 2 in. thick.
	90 feet diameter,	—	13 in. deep, and $2\frac{1}{2}$ in. thick.
	108 feet diameter,	—	13 in. deep, and 3 in. thick.

For small spans of about 24 to 30 ft., the inch plank is about 4 ft. long by about 8 in. wide. The feet of the ribs are tenoned into the wall plates; the shoulders of the tenons being about one inch. The ties A, placed about 2 feet distant, are 4 in. by 1 in.; they are sometimes shown passing through the planks pinned with keys 1 in. thick and $1\frac{1}{2}$ in. wide, and of a length nearly the width of the plank; this method tends materially to weaken the ribs; that shown in the cut is a better mode. The wall plates, 10 or 12 inches wide and 8 or 9 inches thick, have mortices 2 inches wide, 3 inches deep and 6 inches long, sunk at 2 feet apart, to receive the ends of the ribs. In a roof where the span was 64 feet, the scantling was increased to 13 inches wide and $1\frac{1}{2}$ inches thick. The ties were alternately double and single, and were 3 inches by $1\frac{1}{2}$; and each rib was double tenoned into the wall plate. This system, with many modifications, was extensively adopted in the construction of the nave and side erections of the building for the Exhibition of 1862; and also for some of the passages, &c., of the Horticultural Society, where they still exist, and deserve examination. It is also adopted for temporary sheds of large spans.

2052*a*. This work by De Lorme deserves the study of every one that seeks to be an architect, though in these unfortunate days for the art the reward of study and reading is very doubtful.

2052*b*. Since the period of De Lorme, another system, arising out of it, has been extensively adopted for large buildings. Colonel Emy, having been called upon in 1819 to design a roof of 60 feet span, succeeded in composing one in which, while timbers of a greater length might be used, the necessary solidity, with the lightness and economy of the system of De Lorme, might be combined. This he carried out in 1825 and 1826. The workmanship is less than in De Lorme's roofs, as the wood is all in straight pieces, and is within the power of the ordinary carpenter. An arch is composed of a series of long and thin planks, laid flatways, the flexibility of which permits them to be easily and quickly bent without the aid of heat; and their rigidity, properly regulated, maintains the form given and destroys the thrust. *Fig.* 701*a* is a portion of the base of one arc, which will illustrate the system. The details are best learnt from Emy's own work, as it would require much space to do justice to them. The vertical pieces A are $7\frac{3}{4}$ inches thick, and placed about 4 inches from the wall. The three first radial pieces B are prolonged beyond the uprights, and enter recesses in the wall to steady the frames. The plates C, breaking joint well with one another, compose the arc, and are $1\frac{3}{8}$ inch thick, $5\frac{1}{10}$ inches broad, and about 40 feet long, bolted together, the bolts being driven tightly into accurately made holes, and are further firmly tied together by iron straps; the bolts are $\frac{7}{10}$ inch diameter, and about 2 feet 6 in. apart; the principal rafters are $5\frac{1}{4}$ in. thick; the trusses are placed 9 feet 10 in. apart.

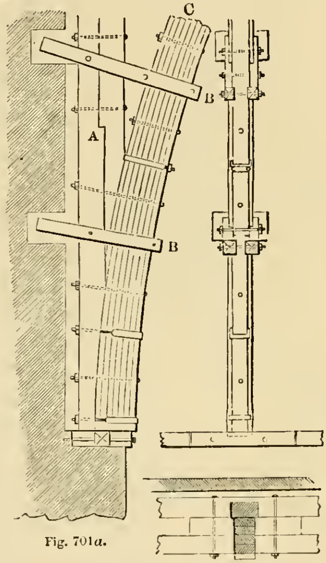

Fig. 701*a*.

2052*c*. Upon an experiment that was made by Emy to test the strength and thrust of this arch, he found it necessary to add a supplementary plate to a part of the extrados, and two plates to a part of the intrados. The following is the proportion of the number of plates and their width, which he adopted as a rule:—

			ft.	in.	
From the springing to radial (B) No. 1 - -	7	plates,	1	3	wide
From radial No. 1 to the tie placed between radials Nos. 6 and 7 - - - - -	8	,,	1	7	,,
From this tie to radial No. 6 - - -	6	,,	1	0	,,
From radial No. 9 to the king-post - -	5	,, nearly	0	11	,,

These supplementary plates were of oak, and of the same thickness as the others. These roofs are also given with sufficient detail in Newlands' work above-mentioned.

2052*d*. MEDIÆVAL ROOFS.—In the south of France the few Romanesque roofs did not differ from the common king-post roof, except in two points, viz., that the tie-beam and the king-post were stop-chamfered; and the strain of the purlines upon the principal rafter was counteracted by a nearly upright strut from the tie-beam. This system left the principal rafter with a false bearing, if the walls were not extremely thick in proportion to the width of the apartment which they enclosed. As a remedy, the late Romanesque builders tenoned the purline into the principals, and, moreover, laid it with its wider side to the rafters, in order that the backs of the common rafters should be flush with those of the principal rafters (similarly to *fig.* 692.). The next step was to put proper struts from the foot of the king-post. At the present day the purline is placed on edge for economy of material.

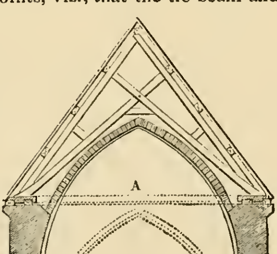

Fig. 701*b*.

2052*f*. In the north of France there was difficulty in roofing over the vaulting; either the main walls had to be carried as high as the ridge-rib, or else the frame of the roof had to be similar in principle to that shown in *fig.* 701*b*. Experience proved that the latter scheme resulted in letting the principal rafters draw the tenons of the braces and so destroy all idea of a tie connecting the two walls; hence the mediæval builders were obliged to raise the walls sufficiently high to allow the tie-beams to pass over the back of the ridge-rib, as would be the case at A. This was expensive, and, moreover, it was scarcely practicable where the walls were little thicker than was necessary for the backing to the formerets of the vaulting over the arches of windows. It is to these facts, rather than to any influence of climate, that may be attributed the adoption of the high-pitched roof, a system which required neither great width of footing nor large scantling of timber, for the purlines were discarded, and the weight was distributed among the rafters and trusses of each bay. The details of such a roof are simple. Two plates A (*fig.* 701c.) are placed with their widest sides on the wall, and are strutted between from the feet of the trusses to the centre of the bay. Upon these plates, tassels or short hammers B, are cocked down at intervals between the tie-beams, which are cocked down and dove-tailed, to take not only the feet of the common rafters, but also the nearly upright stud or ashlar rafter F, which serves to give a wider base to the principal and to the rafter. All these vertical pieces are double-tenoned and pinned into the other portions of the work.

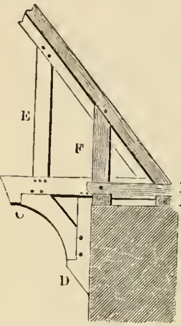

Fig. 701c.

2052*g*. The racking motion to which large roofs are liable, soon showed that this was not the manner in which to make them secure. The purlines had been discarded, but the need of their service remained, the necessity was obviated by erecting a sort of trussed partition under the ridge. If the king-post was *not* carried by the tie-beam, the whole roof depended upon the strength of the head of the king-post, into which the ridge was tenoned, and the manner in which it was connected with the ends of the principal rafters. It therefore appears to be more probable that the king-post was supposed to be carried by the tie-beam; indeed, examples occur of trussed partitions (*fig.* 701*d.*) to ridges, supported by king-posts A, which stand upon tie-beams that ride in queen-stirrups, B, where the stirrups are hung from the principal rafters at three-quarters of the height of the roof. Care has been given to this detail of the practice, because it seems to have been entirely mistaken by Viollet le Duc, *Dict.*: for example, the braces C, to the collars D, are supposed by him to exercise a favourable effect in preventing the flexure of the rafter outwards, whereas the fact would seem to be that the brace has to hold up the collar D and with it the stirrup B, and with them the tie-beam E, *for the collar is tenoned into the king-post and rafter.* That author defers dating the period of the perfection of mediæval carpentry (as well as of joinery) until the end of the 15th and the beginning of the 16th century.

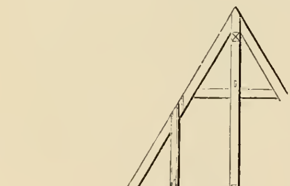

Fig. 701*d*. AT AUXERRE.

2052*h*. The framing of cradle roofs, with king-posts carried upon (*not carrying*, as Viollet le Duc supposes) the tie-beams, became a practice that in France was general from the latter part of the 12th until the end of the 16th century, and which continued the same peculiarities of construction that are above indicated. The distinction between the stirrup and the post is less easy in the truss shown in *fig.* 701*e.*, but still it must be reckoned as a post; this example from the *préfecture*, formerly the episcopal palace, at Auxerre, covers a hall which is 30 feet wide; the trusses are placed 13 feet apart from centre to centre. The scantlings are as follows: — King-posts, 5 by 5, and principal rafters $5\frac{1}{2}$ by $4\frac{3}{4}$; the common rafters, 5 by $4\frac{3}{4}$, are shown in *fig.* 701*f*, and are trussed in a different manner; they are placed nearly 2 feet apart. The roof appears to be boarded on the inside to the circular form.

2052*i*. Although Viollet le Duc is of opinion that the tie-beams to the fine cradle roof, 57 feet 3 inches span, constructed at the beginning of the 16th century, over the great hall of the *Palais de Justice*, at Rouen (*fig.* 247), have been cut away, it may not be unfair to suggest that the work might have stood as well if, in its construction, it had resembled the older and fine roof of the château at Sully-sur-Loire, which he so well illustrates, but which want of space prevents our also doing. The student has, perhaps, no cause for regret, as its construction can scarcely be recommended for imitation in the present day. It is about 36 feet span.

2052*k*. The absence of a ridge roll and the position of the ridge-piece in the majority of mediæval roofs deserve notice. As soon as the purlines were discarded, it seems that builders relied upon the king-post to carry a ridge-piece upon which rested the ends of the rafters; these were halved and spiked together above it. Excepting in a few cases the ridge-piece was rather a purline at the top of the roof than an abutment. Much of the bolt and strap work applied in the visible frames of roofs is not always the most judicious as regards the conversion of construction into decoration. For example, if it were calculated that a tie-beam would sag, instead of increasing its scantling, or of trussing it, the mediæval carpenter would very probably hang it up to his truss, as in *figs.* 701*g*. and 701*h*. At a later period (say the 14th century) with some spikes. *Fig.* 701*k*. illustrates the method of forming the junction of post, beam, and strut in a roof; and *fig.* 701*l*. that of beams and posts in the timber framing of houses.

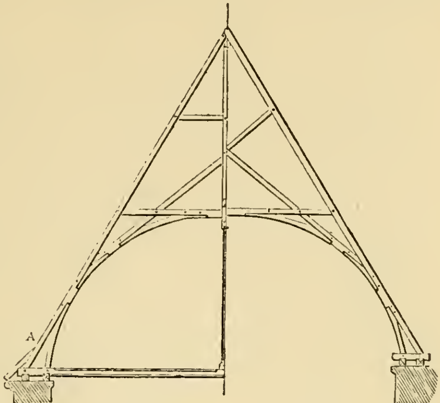

Fig. 701*e*. Fig. 701*f*.

2052*l*. It will be at once perceived, by *fig.* 701*c*., that the *hammer-beam* BB′ takes the place of the tie-beam, the middle part of which may have been cut away. The tinted portion shows the foot of the rafters in a cradle roof; and the lighter portion the position and form of the hammer-beam, the outer end of which is tenoned and pinned on to the wall

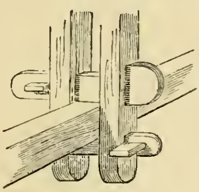

Fig. 701*g*.

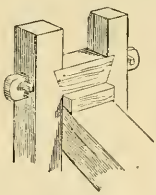

Fig. 701*h*.

Fig. 701*i*.

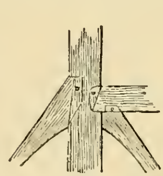

Fig. 701*k*.

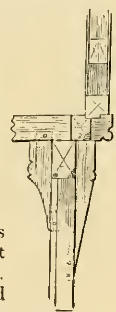

Fig. 701*l*.

plates A, and the inner end supported by a curved brace C, which starts from the bottom of the wall piece D, the whole being pinned together at the ends. Sometimes a corbel receives the foot of the wall piece and brace. Thus the whole length of the hammer beam may be said to have a solid bearing equal to supporting the roof rising above it, by the ashlar rafter or strut E, and at the same time forming a part of that structure. When the whole is put together securely, it has been considered almost impossible for hammer-beam roofs to spread, as from the stiffening action of the braces, it would require a very heavy force to push out the walls. But "the absence of that curved brace which distinguishes the Westminster example, makes these roofs much more likely to exert a thrust upon the walls, and, accordingly, it is notorious that in very many cases this has occurred. In the fine example at Croxton, the strain was so great as absolutely to break short off the perfectly sound heart of oak pins, nearly an inch in diameter, with which it was held together; and it is to be feared that many of the finest of these examples are similarly in a dangerous condition." So writes Mr. Street, in his *English Woodwork*, read at the Institute of British Architects in 1865, a paper which should not be neglected by the student. The principle of the construction of these roofs has perhaps not yet been satisfactorily elucidated.

2052*m*. The timber roofs in England may be divided into five classes: — I. Roofs with tie-beams; II. Roofs with trussed rafters, or single framed roofs; III. Roofs with braces with or without collars; IV. Roofs framed with hammer beams; and V. Aisle roofs. The first are more general and better treated in France. The others are more peculiar to England, in which country elaborate examples of these forms are to be found, especially on the hammer-beam system.

2052*n*. *Pitch.*—These roofs are for the most part acutely pitched, though this was by no means their invariable characteristic. An angle of 90° was perhaps the ordinary elevation of Norman roofs, and in the early English period, though generally acutely pointed, roofs are nevertheless found of an equilateral pitch or angle of 60°, though this is of rare occurrence. In this and the succeeding style, examples are found of so low a pitch as to equal the flattest specimens of the perpendicular period. The roof, of the decorated style, over the larger south aisle of St. Martin's Church, Leicester, has a span of 21 feet, with a rise of only 4 feet. (See *par.* 2040*b*.).

2052*o*. I. The *tie-beam* bears the whole weight of a low pitched roof. The roof over the south chapel of Kiddington Church, Oxfordshire, is of rather a steeper pitch than that at Leicester. The under side of the beam is well moulded, and is connected with the wall-pieces by moulded curved braces forming a very obtusely pointed arch; the purlines rest directly on the beam, and the ridge is supported on it by a post, and by short curved braces, the whole of the space above the tie-beam being filled up so as to give it the appearance of a solid triangular shaped beam. The naves of Raunds and of Higham Ferrers Churches, Northamptonshire, the latter of decorated date, and of Wimmington Church, Bedfordshire, present good and differing examples. The tie-beam is rarely left perfectly horizontal; the collar-beams and even the hammer-beams will be found to incline upwards. Tie-beams were sometimes employed quite independently of the other timbers, being simply laid across the building from wall to wall, notched down, and pinned to the wall plates. They were never entirely discarded. as they are to be met with in each of the four usually accepted divisions of the style. At Southfleet Church, Kent, the tie-beam is beautifully moulded; whereas, at Northfleet, it is left in almost its natural roughness, while the roof itself, which is one of the trussed rafter kind, is panelled, and has moulded ribs with carved bosses at the intersections.

2052*p*. An example of a strongly cambered tie-beam, with an ornamented king-post, is seen in Swardestone Church, Norfolk, and it is by no means uncommon in the counties of Kent and Sussex. The tie-beam of the roof over the aisle of North Walsham Church, Norfolk (*fig.* 701*m*.), passes through the nave wall, the end forming a corbel for the wall pieces of the nave roof. This roof also presents a practice which became almost universal in roofs of later date, viz., an intermediate truss between the tie-beams, in consequence of the extreme width between the main trusses, to support the ridge and purlines, by the adoption of double rafters on each side, strongly united and framed together, springing from a small hammer-beam over the apex of the arches. In roofs of high pitch, various endeavours were made to retain the arched shape in conjunction with the tie-beam. At Pulham Church, Norfolk, and Morton Church, Leicestershire, the beam divides the arch into two, with a bad result.

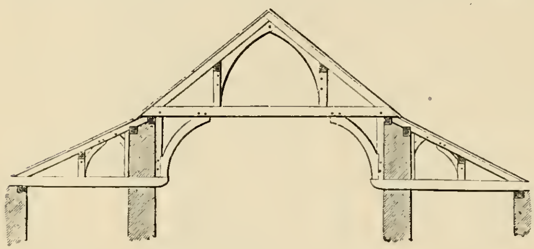

Fig. 701*m*. NORTH WALSHAM, NORFOLK.

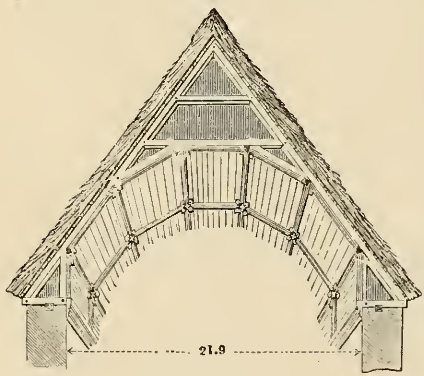

Fig. 701*n*. WIMBOTSHAM, NORFOLK.

2052*q*. II. *Single-framed roofs* sometimes have only diagonal braces connecting the rafters. These occur generally where the span is small, as over a porch. In wider spans, even without tie-beams, each pair of rafters was framed with a collar-beam, and was stiffened by braces crossing at times above the collar, and at others the braces being tenoned into its under side; when the latter was the case, a second collar was generally introduced above the first. Such roofs were very frequently boarded underneath, forming thus a polygonal barrel vault, and moulded ribs were applied, dividing the boarding into panels, with carved bosses at the intersections. The above details will be found combined in the examples of the decorated period from the nave of Wimbotsham Church, Norfolk (*fig.* 701*n*). The angle of the roof is 78°. The span is 21 feet 9 inches; the rafters and collars are $4\frac{1}{2}$ inches by 4 inches. The former are placed 1 foot 9 inches apart between the centres. The nave roof of Reedham Church, Norfolk, 31 feet span, is framed on the same principle. The hall at Sully-sur-Loire is a fine example.

2052*r*. III. Roofs constructed with *braces* may be divided into two classes: I. Those with collar-beams and braces; and II. Those without collar-beams. An example of the former is seen in the roof of the nave at Pulham Church (*fig.* 701*o*.), which is formed at an angle of 105°, with a span of 20 feet 5 inches. Wall pieces A, are used, pinned into the underside of the principal rafters, descending low down on the wall; the arched brace springs directly from this to the collar-beam, uniting them both with the principal. It is held that it would be impossible for this roof to spread until it had broken the curved braces. The various timbers are all effectively moulded. The principal rafters, 12 inches by 10 inches; common rafters, 6 inches by 3½ inches; collar-beam, 14 inches by 8½ inches; ridge piece, 8 inches by 8 inches; purline, 8 inches by 6½ inches; wall piece, 10 inches by 8½ inches. Width between centres of trusses, 6 feet 2 inches; and depth of cornice 3 feet 2 inches. Of class II. is the roof over the nave of Starston Church, Norfolk (*fig.* 701*p*). The angle formed is 100°. At the apex of the roof is a strut B, about 9 inches square, which hangs down 2 feet; its four sides are morticed, two to receive the ends of the braces where they are pinned, thus preventing the possibility of its dropping; and the other two on the opposite sides, to receive the arched ridge braces, as shown at C. This arrangement tends to prevent the roof either spreading outwards, or rocking from east to west. The span is 21 feet 10 in. The principal rafters are 10 in. by 9 in.; common rafters, 6 in. by 4 in.; wall piece, 10 in. by 7½ in.; purline, 6½ in. by 5½ in.; and cornice, 11 in. by 10 in.

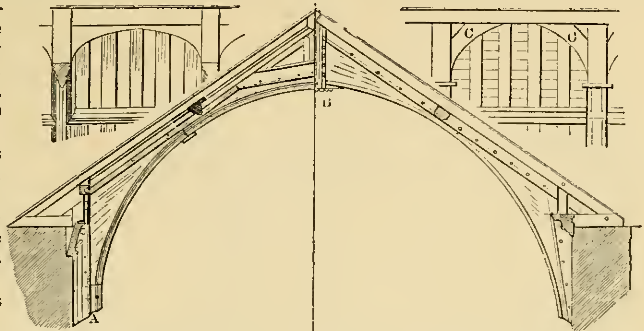

Fig 701*o*. PULHAM, NORFOLK. Fig. 701*p*. STARSTON, NORFOLK.

2052*s*. IV. *Hammer-beam roofs* are always double-framed roofs, the rafters being supported by a skeleton framing of purlines and ridge, resting on, or framed into, the principal trusses. Among the many varieties of this description of roof may be noticed:—(1) Those with collar-beams and no struts, the collars, principals, and hammer-beams being united with curved braces; (2) Those in which the collar-beam is omitted, the curved braces being carried up almost to the ridge, and framed at the apex of the arch into a strut, which receives also the upper ends of the principals; (3) Those with no collars or struts, the whole of the truss being connected together and stiffened with curved braces only; in this instance the arched braces are formed of three pieces of timber, one on either side of the roof, tenoned into the hammer-beam and principal, and reaching up as far as the purline, the centre piece forming the apex of the arch, being tenoned into each principal, itself acting as a brace, and to a certain extent as a collar beam; and (4) Those having hammer-beams, collars, and struts, connected together with curved braces. (See *par.* 2052*l.*)

2052*t*. An example of the first sort is the roof of Capel St. Mary's Church, Suffolk (*fig.* 701*q*.). The angle formed is 87°, and it is very seldom that a hammer-beam roof has a steeper pitch. The span is 18 feet 3 inches. The principal rafter is 10 inches by 8 inches; common rafter, 6 inches by 3 inches; hammer-beam, 10 inches by 8 inches; collar-beam, 10 inches by 8 inches; purlins, 6 inches by 5 inches; ridge piece, 6 inches by 6 inches. The trusses are 6 feet apart from centre to centre. The second sort is shown in *fig.* 701*r*., the nave roof of Trunch Church, Norfolk. The intermediate trusses are the same, except that instead of the long wall-piece and brace, the wall-piece is stopped at the crown of the arch of the clearstory window, and a very depressed brace connects it with the hammer-beam. The spandrils are filled in with perforated tracery. The span is 19 feet. The principal rafter is 10 inches by 9 inches; common rafter, 6 inches by 4 inches; hammer-beam, 10 inches by 10 inches; purline, 8 inches by 5 inches; ridge piece, 10 inches by 10 inches. The trusses are 5 feet 6 inches apart. The third sort is shown in *fig.* 701*s*., from the nave of Wymondham Church, Norfolk. The hammer-beams project rather more than a quarter the width of the nave, and are carved into figures; the intermediate trusses have also similar figures, but made subordinate to those of the main trusses. At the intersections of the purlines and ridge braces are large carved flowers standing out in bold relief. Of the

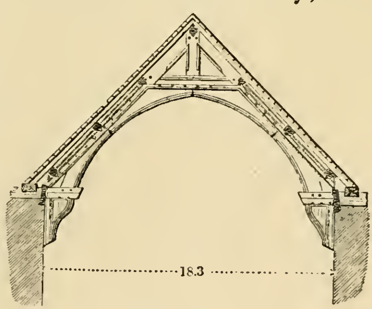

Fig. 701*q*. CAPEL ST. MARY, SUFFOLK.

fourth sort, the most noted examples are those of Westminster Hall, 68 feet span (*fig.* 196.); Hampton Court, 40 feet span; Eltham Palace, 36 feet 3 inches; Beddington Hall;

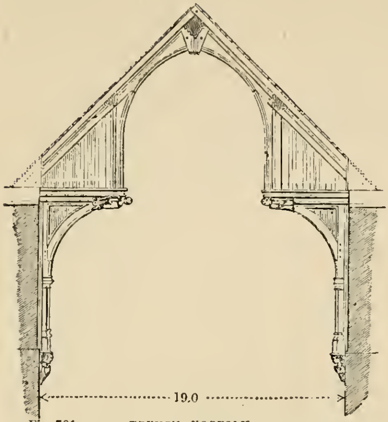

Fig. 701*r*. TRUNCH, NORFOLK.

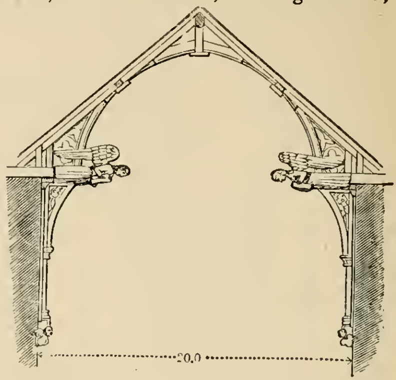

Fig. 701*s* WYMONDHAM, NORFOLK.

South Wraxhall, 19 feet 9 inches; Croydon, 37 feet 9 inches, &c. It will be well to notice, what is not usually known, or shown, in the sections of the Westminster roof, that the main purlines over the strut, are upheld with the collar-beam by an intermediate rafter of great strength. Mr. S. Smirke has observed (*Archæologia*, xxvi. page 417–18), that "this roof is the common collar-beam roof, and of extremely simple construction; the whole pressure is carried by the straight lines of the principal rafter, and (curved) brace, above alluded to, directly into the solid wall, where it *ought* to be." The examples of lesser importance, as regards span, are not all of the same elegance as that of Westminster, which, at the same time that it is the largest and best, is also the earliest (1397) of the series. Some examples present double hammer-beams, forming a sort of corbelling over up to the ridge or to the collar-beam. *Fig.* 701*t*., from Knapton Church, Norfolk, is 32 feet span, and is a fair specimen of such roofs. The wall is 2 feet 10 inches in thickness. For all these examples, we are indebted to the excellent publication by Brandon; *Mediæval Roofs*, to which work we must refer the reader for details of decoration and painting, as the above figures are only here introduced to show the principles of construction displayed in such roofs.

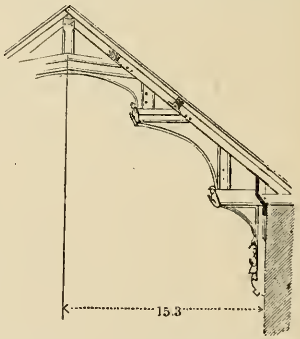

Fig. 701*t*. KNAPTON, NORFOLK.

2052*u*. In *fig.* 701*u*, we give the modern roof, of 31 feet 2 inches span, over the nave of Bickerstaffe Church, Yorkshire, designed by Sydney Smirke, R. A., as a good specimen of the adaptation of modern science to mediæval structures. The collar-beam is double, each 9 in. by 3 in., through which the king-post is tenoned and strapped. The purlines are 7 in. by 4 in.; the brace, 9 in. by 7 in.; and the corbels are 11 in. wide, being also tailed in 11 in.

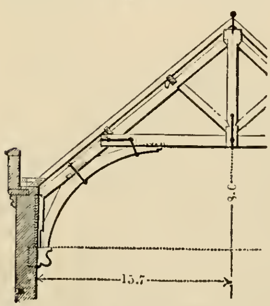

Fig. 701*u*. BICKERSTAFFE, YORKSHIRE.

2052*v*. V. *Aisle*, or *Lean-to, roofs*, may be described as usually consisting of strong timbers, answering the purpose of principal rafters, laid at each end on plates, the lower plate resting on the external wall, the upper one either supported on corbels projecting from the nave wall, or inserted therein. Wall-pieces are tenoned into the upper and lower extremities of the principals, and curved braces springing from the feet of these meet in the centre of the principal, forming a perfect arch, having the spandrils generally filled in with tracery. A purline is usually framed into the principal, and on this and the plates the common rafters are supported (see also *fig.* 701*o*.). In aisle roofs the whole of the timbers, even to the common rafters, were frequently found more richly moulded than those of the nave, possibly from being nearer the eye of the spectator.

2053. The following instructions relative to the lines necessary to be found in the framing of roofs are from Price's *British Carpenter*; and although published nearly 100 years, few be a plan to be inclosed with a hipped roof, whose height or slope is Cb. Divide the plan lengthwise into two equal parts by the line *ef*, which produce indefinitely at both ends. Make *ag* equal *ea*, and *dk* equal to *df*; and through *k* and *g*, parallel to *ab* or *cd*, draw lines indefinitely *mo*, *lp*. With the distance dc or Cc, either of which is equal to the length of the common rafters, set off *qe*, as also from *h* to *p*, from *i* to *o*, and from *f* to *n*; from *k* to *m*, and from *g* to *l*. Make *ts* equal to Cb, and *ab* equal to *ta*, which points join; then either aC or *as* represents the length of the hip rafter, and joining the several lines *aqb*, *bpoc*, *end*, and *dmla*, they will be the *skirts* of the roof.

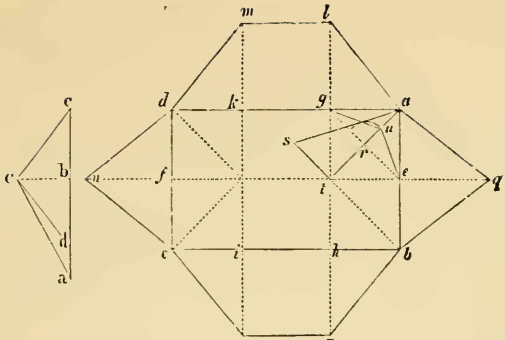

Fig. 702.

2054. To find the back of the hip. Join *ge*, and from *r* as a centre describe an arc touching the hip *as*, and cutting *at* in *u*. Then join *gu* and *ue*, and *gue* is the back of the hip rafter required.

2055. *Fig.* 703. represents, in *abcd*, the plan of a building whose sides are bevel to each other. Having drawn the central line *ef* indefinitely, bisect the angle *raq* by the line *ae*, meeting *ef* in *e*. From *e* make *eg* equal to *re*, and *rg* perpendicular to *ea*; then, if e a be made equal to *ea*, ra or *aq*, it will be the length of the hip rafter from the angle *a*. Through *e* and *f*, perpendicular to the sides *db*, *ca*, draw the lines *vp*, *mq* indefinitely; and from *a*, as a centre with the radius *aq*, describe an arc of a circle, cutting *mq* in *q*, and *cr* (perpendicular to *ba*) produced in *l*. By the same kind of operation *oc* will be found, as also the other parts of the skirts of the roof. The lines *nt*, *tfv*, and *vp* are introduced merely to show the trouble that occurs when the beams are laid bevel. The angle of the back of the hip rafter, *rwq*, is found as before, by means of *v* as a centre, and an arc of a circle touching *aq*. The backs of the other hips may be found in the same manner.

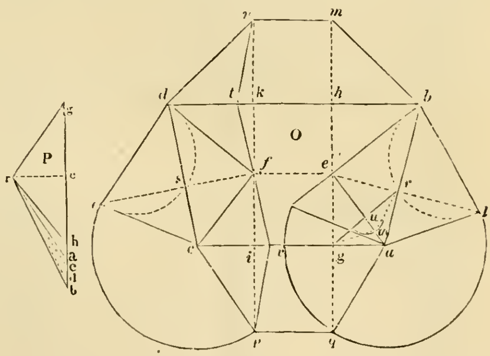

Fig. 703.

2056. *Fig.* 704., from Price's *Carpentry*, is the plan of a house with the method of placing the timbers for the roof with the upper part of the elevation above, which, after a perusal of the preceding pages, cannot fail of being understood. The plan F is to be prepared for a roof, either with hips and vallies, or with hips only. The open spaces at G and H are over the staircases: in case they cannot be lighted from the sides, they may be left to be finished at discretion. The chimney flues are shown at IKLMNO. Then, having laid down the places of the openings, place the timbers so as to lie on the piers, and as far as possible from the flues; and let them be so connected together as to embrace every part of the plan, and not liable to be separated by the weight and thrust of the roof. P is a trussed timber partition, to discharge the weight of the roof over a salon below.

2057. Q is the upper part of the front, and R a pediment, over the small break, whose height gives that of the blank pedestal or parapet S. Suppose T to represent one half of the roof coming to a point or ridge, so as to span the whole at once, "which," as Price truly observes, "was the good old way, as we are shown by Serlio, Palladio," &c., or suppose the roof to be as the other side U shows it, so as to have a flat or sky-light over the lobby F, its balustrade being W; or we may suppose X to represent the roof as spanning the whole at three times. If X be used, the valley and hip should be framed as at Y; if as T, the principal rafters must be framed as at Z, in order to bring part of the weight of the roof and covering on the partition walls. The remainder needs not further explanation.

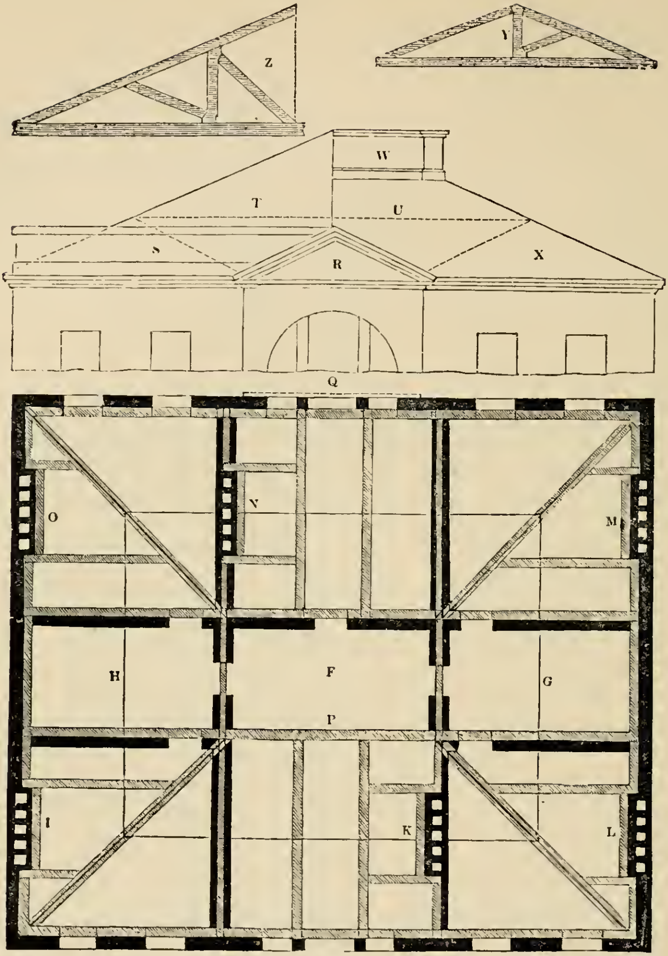

Fig. 704.

RIBS FOR GROINS, ETC.

2058. We shall now proceed to the method of forming the ribs for groined arches niches, &c. The method of finding the shape of these is the same, whether for sustaining plastering or supporting the boarding of centres for brick or stone work, except that, for plaster, the inner edge of the rib is cut to the form, and, in centering, the outer edge. Groins, as we have already seen, may be of equal or unequal height, and in either case the angle rib may be straight or curved; and these conditions produce the varieties we are about to consider.

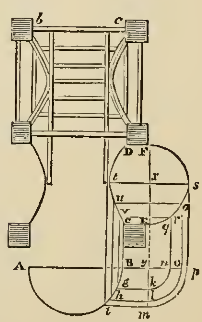

Fig. 705

2059. *To describe the parts of a groin where the arches are circular and of unequal height, commonly called* Welsh Groins. We here suppose the groin to be right-angled. Let AB (*fig.* 705.) be the width of the greater arch. Draw BD at right angles to AB, and in the straight line BD make CD equal to the width of the lesser arch. Draw DF and CE perpendicular to BD and EF parallel to BD. On AB describe the semicircle B*ghi*A, and on EF describe the semicircle E*qro*F. Produce AB to *p*, and FE to *m*, cutting A*p* in *y*. Through the centre *x* of the semicircle $EqrsF$ draw ts perpendicular to BD, cutting the circumference of the semicircle in s. Draw sp parallel to BD. From the centre y, with the distance yp, describe the quadrant pm. Draw mi parallel to AB, cutting the semicircle described upon AB in the point i. In the arc Bi take any number of intermediate points g, h, and through the points ghi draw it, hu, gv, parallel to BC. Also through the points ghi draw gk, hl, im parallel to AB, cutting FE produced in k and l. From the centre y describe the arcs ku, lo, cutting AB produced in mo. Draw nq, or, parallel to BD, cutting the lesser semicircular arc in the points q, r. Through the points q, r, s draw qv, ru, st parallel to AB; then through the points tuv draw the curve $tuvc$, which will be the plan of the intersection of the two cylinders. The other end of the figure exhibits the construction of the framing of carpentry, and the method in which the ribs are disposed.

2060. To describe the sides of a groin when the arches are of equal height and designed to meet in the plane of the diagonals. Let af and al (*fig.* 706.) be the axes of the two vaults, meeting each other in a, perpendicular to af. Draw AB cutting af in w, and perpendicular to al, draw BG cutting al in b. Make wA and wB each equal to half the width of the greatest vault, and make bB and bG each equal to half the width of the lesser vault. Draw AH and BE parallel to af, and draw BH and DF parallel to al, forming the parallelogram DEHF. Draw the diagonals HD, FE. On the base AB describe the curve $BcdefA$, according to the given height wf of the required form, which must serve to regulate the form of the other ribs. Through any points cde in the arc $BcdefA$ draw the straight lines cq, dr, es cutting the diagonal HD at q, r, s. Draw qh, ri, sk parallel to al cutting the chord BG at the points x, y, z, b. Make xh, yi, zk, bl each respectively equal to tc, ud, ve, wf, and through the points $Ghikl$ to B, draw the curve $GhiklB$. Draw qm, rn, so, ap perpendicular to HD. Make qm, rn, so, ap respectively equal to tc, ud, ve, wf, and through the points D, m, n, o, p, H draw a curve, which will be the angle rib of the groin to stand over HD; and if the groined vault be right-angled, all the diagonals will be equal, and consequently all the diagonal ribs may be made by a single mould.

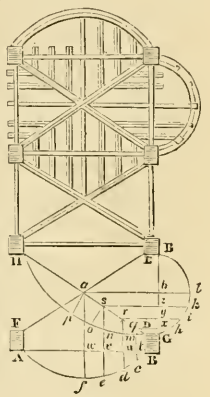

Fig. 706.

2061. The upper part of the above figure shows the method of placing the ribs in the construction of a groined ceiling for plaster. Every pair of opposite piers is spanned by a principal rib to fix the joists of the ceiling to.

2062. The preceding method is not always adopted, and another is sometimes employed in which the diagonal ribs are filled in with short ribs of the same curvature (see *fig.* 707.) as those of the arches over the piers.

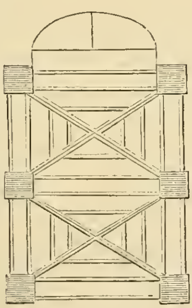

Fig. 707.

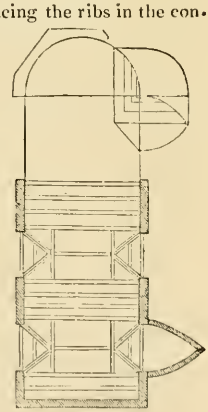

Fig. 708.

2063. The manner of finding the section of an aperture of a given height cutting a given arch at right angles of a greater height than the aperture is represented in *fig.* 708.

2064. When the angle ribs for a square dome are to be found, the process is the same as for a groin formed by equal arches crossing each other at right angles, the joints for the laths being inserted as in *fig.* 707.; but the general construction for the angle ribs of a polygonal dome of any number of sides is the same as to determine the angle rib for a cove, which will afterwards be given.

2065. When a circular-headed window is above the level of a plane gallery ceiling, in a church for example, the cylindrical form of the window is continued till it intersects the plane of the ceiling. To find the form of the *curb* or pieces of wood employed for completing the arris, let dp (*fig.* 709.) be the breadth of the window in the plane of the ceiling. Bisect dp in h, and draw $h4$ perpendicular to dp. Make $h4$ equal to the distance the curb extends from the wall. Produce $4h$ to B. Make

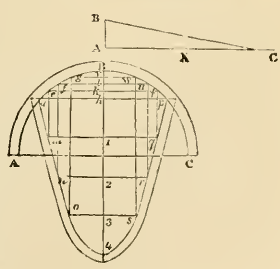

Fig. 709.

hB equal to the height of the window above the ceiling, and through the three points d, B, p describe the semicircle ABC for the head of the window. Divide hB into any number of equal parts, as 4 at the points k. l, v; and h4 into the same number of equal parts at the points 1, 2, 3. Through the points klv draw the lines et, fu, gw parallel to dp, and through the points 1, 2, 3 draw the lines mg, nr, os. Make 1m, 2n, 3o respectively equal to ke, lf, vg; as also 1q, 2r, 3s equal to kt, lu, vw; that is, equal to ke, lf, vg. Then through the points $dmno$4, and also through $pqrs$4, draw a curve which will form the curb required. In the section X of the figure, AC shows the ceiling line, whereof the length is equal to h4, and AB is the perpendicular height of the window; hence BC is the slope.

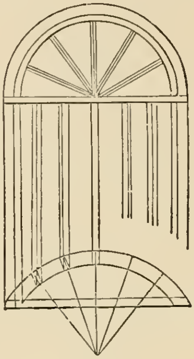

Fig. 710.

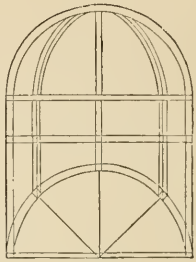

Fig. 711.

2066. The construction of a niche, which is a portion of a spherical surface, and stands on a plan formed by the segment of a circle, is simple enough; for the ribs of a niche are all of the same curvature as the plan, and fixed (*fig.* 710.) in planes passing through an axis corresponding to the centre of the sphere and perpendicular to the plane of the wall. If the plan of the niche be a semicircle (*fig.* 711.) the ribs may be disposed in vertical planes.

2067. In the construction of a niche where the ribs are disposed in planes perpendicular to the horizon or plan, and perpendicular to the face of the wall, if the niches be spherical all their ribs are sections of the sphere, and are portions of the circumferences of different circles. If we complete the whole circle of the plan (*fig.* 712.), and produce the plan of any rib to the opposite side of the circumference, we shall have the diameter of the circle for that rib, and, consequently, the radius to describe it.

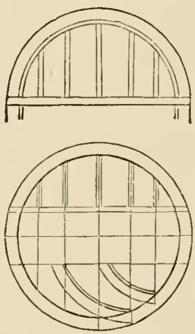

Fig. 712.

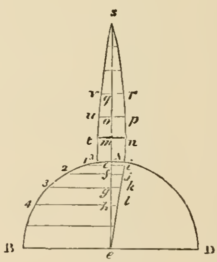

Fig. 713.

2068. *Of forming the boards to cover domes, groins, &c.* The principles of determining the developement of the surface of any regular solid have already been given in considerable detail. In this place we have to apply them practically to carpentry. The boards may be applied either in the form of gores or in portions of conic surfaces; the latter is generally the more economical method.

2069. *To describe a gore that shall be the form of a board for a dome circular on the plan.* Draw the plan of the dome ABD (*fig.* 713.), and its diameter BD and Ae a radius perpendicular thereto. If the sections of the dome about to be described be semicircular, then the curve of the vertical section will coincide with that of the plan. Let us suppose the quadrant AB to be half of the vertical section, which may be conceived to be raised on the line Ae as its base, so as to be in a vertical plane, then the arc AB will come into the surface of the dome. Make Ai equal to half the width of a board and join ei. Divide the arc AB into any number of equal parts, and through the points of division draw the lines 1i, 2j, 3k, 4l, cutting Ae in the points $efgh$ and ei in the points $ijkl$. Produce the line eA to s, and apply the arcs A1, 12, 23, 34 to Am, mo, oq in the straight line As. Through the points $mnoq$ draw the straight lines tn, up, vr, and make mn, op, qr, as also mt, ou, qv, respectively equal to ei, fj, gk; then through the points $inpr$ to s, and also through the points $xtuv$ to s, draw two curves from the points x and i so as to meet each other in s; and the curves thus drawn will include one of the gores of the dome, which will be a mould for drawing the boards for covering the surface.

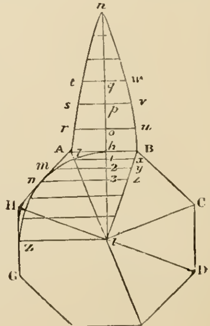

Fig. 714

2070. In polygonal domes the curves of the gore will bound the ends of the boards; as, for example, in the octagonal dome (*fig.* 714.), the plan being ABCDEFGH. Let *i* be the centre of the circle in which the octagon may be inscribed. Draw the half diagonal *i*A, *i*B, *i*C perpendicular to any side AB of the plan. Draw the straight line *ih*, cutting AB in *h*. Let *hlmZ* be the outline of one of the ribs of the dome, which is here supposed to be the quadrant of a circle. Divide the arc *hZ* into any number of equal parts from *h* at the points *lmn*, and through these points draw *lx*, *my*, *nz*, cutting B*i* at the points *xyz*, and *ih* at the points 1, 2, 3. Extend the arcs *hl*, *lm*, *mn*, on the line *hn*, from *h* to *o*, from *c* to *p*, from *p* to *q*, and through the points *opq* draw the straight lines *ru*, *sv*, *tw* perpendicular to *hn*. Make *ou*, *pv*, *qw*, as also *or*, *ps*, *qt*, respectively equal to 1*x*, 2*y*, 3*z*; then through the points A*rst* draw a curve, and through the points *uvw* draw another curve, meeting the former one in the point *n*. Thus will be formed the gore or covering of one side of the octagonal dome.

2071. When the plan of the base is a rectangle, as *fig.* 715., draw the plan ABCD and the diagonals AC and BD, cutting each other in E. Through E draw EI perpendicular to AB cutting AB in F, and through E draw EJ perpendicular to BC, cutting BC in G. Let the height of the dome be equal to half its breadth, and the section over the straight line EF a quadrant of a circle; then from the centre E describe the arc FH, its base being EF, and with the straight line EG as half the major axis of an ellipsis, and EF the minor axis, describe the quadrant GF of an ellipsis. Produce EF to I, and EG to J. Divide the arc of a quadrant FH from F into any number of equal parts, and extend the parts on the line FI to *klm*, through which draw the lines *kq*, *lr*, *ms*, &c. perpendicular to FI. Through the points 1, 2, 3, &c. draw *wt*, *xu*, *yv*, &c., cutting AE at *w*,*x*,*y*, and FE at *t*,*u*,*v*. Make *k'n'*, *l'o'*, *m'p'*, also *kq*, *lr*, *ms*, respectively equal to *tw*, *ux*, *vy*, and through the points *n'o'p'* draw a curve, also through the points *qrs* draw another curve meeting the former in I; then these two curves with the line AB will form the gore or boundary of the building of two sides of the dome. Also in the elliptical arc GF, take any number of points 1, 2, 3, and draw the lines 1*w'*, 2*x'*, 3*y'*, parallel to BC, cutting EC in the points *w'x'y'*, and GE in the points *t'*, *u'*, *v'*. Extend the arcs G1, 12, 23 from G*k'*, *k'l'*, *l'm'*, upon the straight line GJ, and through the points *k'l'm'* draw the lines *n'q'*, *o'r'*, *p's'*. Make *k'n'*, *l'o'*, *m'p'*, also *k'q'*, *l'r'*, *m's'* respectively equal to *t'w'*, *u'x'*, *v'y'*, and through the points B*n'o'p'* draw the curve BJ, and through the points C*q'r's'* draw the curve CJ; then BJC will be the gore required, to which the boards for the other two sides of the dome must be formed.

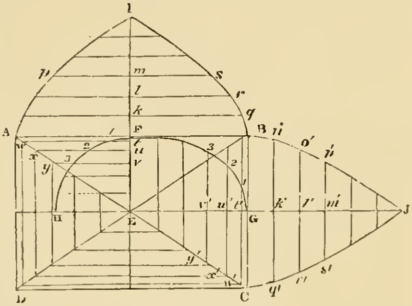

Fig. 715.

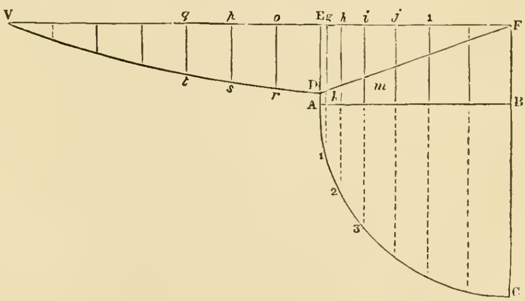

Fig. 716.

2072. A general method of describing the board or half gore of any polygonal or circular dome is shown in *fig.* 716. Let DE be half either of the breadth of a board or of one of the sides of a polygon, EF the perpendicular drawn from the centre. Draw the straight line AB parallel to EF, and draw EA and FB perpendicular to EF; then upon the base AB describe the rib AC of the vertical section of the dome. Divide the curve AC into the equidistant arcs A1, 12, 23, and through the points of division draw the lines 1*g*, 2*h*, 3*i* perpendicular to AB cutting EF at *ghi* and DF at *klm*. Produce FE to V and extend the arcs A1, 12, 23 upon the straight line EV from E successively to the points *opq*. Through the points *opq* draw the lines *or*, *ps*, *qt* parallel to ED. Make *or*, *ps*, *qt* respectively equal to *gk*, *hl*, *im*; then through the points *r s t* draw a curve, and DEV will be the half arc or half mould of the boarding.

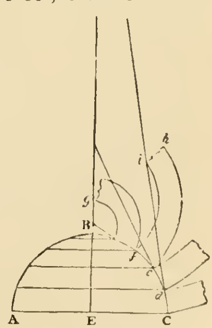

Fig. 717.

2073. *To cover a hemispherical dome by boards moulded to portions of conic surfaces.* Draw a vertical section of the dome ABC (*fig.* 717.) and divide the circumference into equal arcs C*d*, *de*, *ef*. Through the centre E draw EB perpendicular to AC. Draw the chords C*d*, *de*, *ef*, and produce all these chords till they meet the line EB, which they will produced in a convenient space; but those chords that are next to the bottom AC will require a distance too remote from AC; and for the present confining our attention to those chords which, when produced, would meet the line EB at a convenient distance from AC, let *ef* meet the axis EB produced in *g*, and from the point *g* as a centre with the distances *ge* and *gf* describe the arcs *eh* and *fi*. Then *efih* is the form of the board, so that its breadth is everywhere comprehended between the two concentric circles *eh* and *fi*, and when the boards are bent their edges fall on horizontal planes.

2074. We will here shortly repeat a method which has previously been given of describing an arc of a circle independent of its centre, as connected with this part of the subject, and useful in cutting out the boards of a dome where the centre is inaccessible or too distant for convenience. Let AB (*fig.* 718.) be the chord of the arc and CD its height in the middle. In this case AB will be bisected at C by the perpendicular CD. Draw the half chord AD, and perpendicular thereto draw AE, and through the point D draw EF parallel to AB; also draw AG and BH perpendicular to the chord AB cutting EF in the points G and H. Divide AC and ED each into the same number of equal parts, and draw lines through the corresponding points of division; these lines will converge, and if produced with the lines EA and FB, would all meet in one point. Divide AG into the same number of equal parts as the lines AC, ED, and from the points of division draw lines to the point D to intersect the former. A curve drawn through the points of intersection will form the arc of a circle. The other part DB is found in the same manner; and this is a convenient method, because any portion of a circle may be described within the width of a board.

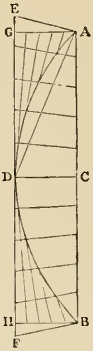

Fig. 718.

2075. To find the relation between the height and the chord of the arc. Let *abc*, &c. (*fig.* 719.) be the middle points of the boards in the arc, and from *a* draw a line parallel to the base to meet the opposite curve; also from these points draw lines to the opposite extremity of the base; then each parallel is the base, as *fa*, and the distances *eg* intersected between it, and the point where the oblique line from its extremity cuts the middle vertical is the height of the segment.

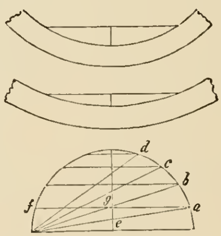

Fig. 719.

2076. It is, however, more convenient to describe the curvature of the board by a continued motion, which may be done as follows. Let AB (*fig.* 720.) be the chord of the arc. Bisect AB at C by the perpendicular CD, and make CD equal to the height of the segment. Draw DE parallel to AB, and make DE a little larger than AD; then form an instrument ADE with laths or slips of wood, and make it fast by a cross slip of wood GH. By moving the whole instrument, so that the two edges DA and DE may slide on two pins A and D, the angular point D of the instrument will describe the segment of a circle, and if the pin be taken out of A and put in the point B, the other portion DB of the segment ADB will be described in the same manner.

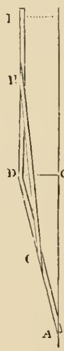

Fig. 720.

2077. The covering of an elliptical dome is formed by considering each part a portion of the surface of a cone. ABC (*fig.* 721.) is a vertical section through the greater axis of the base; the other vertical section through the axis at right angles being a semicircle; the joints of the boards therefore fall in the circumference of vertical circles.

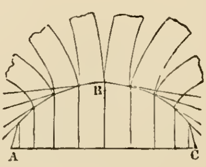

Fig. 721.

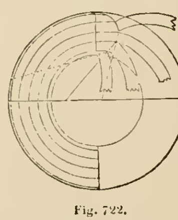

Fig. 722.

2078. In the same manner the covering of an annular vault whose section is semicircular is found, being on the same principles as now shown for a horizontal dome, which will be evident from an inspection of *fig.* 722.

BRACKETING.

2079. The pieces of wood which sustain the laths of cornices, coves, and the like, are called *brackets*, and they take in form the general outlines as nearly as possible of the forms to which they are to be finished.

2080. *A cornice bracket of any form being given, to make another similar one, or one that shall have the same proportions in all its parts.* Let ABCDEF (*fig.* 723.) be the given bracket. Draw lines from the angular points CDE, and let A*b* be the projection of the required bracket. The lines AC, AD, AE, being drawn, draw *bc* parallel to the edge BC, cutting AC in c; draw *cd* parallel to CD, cutting AD in *d*. Draw *de* parallel to DE, cutting AE in *e*, and draw *ef* parallel to EF, cutting AF in *f*. Then A*bcdef* is the bracket required.

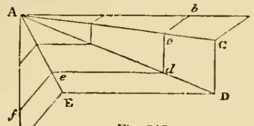

Fig. 723.

2081. *To form an angle bracket to support the plastering of a moulded cornice.* Let *fig.* 724. X be the plan of the bracket. Draw the straight line AE equal to the projection *ab* of the bracket on the plan X, and A*a* perpendicular to AE, to which make it equal. Join E*a*, and on AE describe the given form AFGHIKLE of the bracket which stands perpendicular to the line of concourse of the wall and the ceiling. From the angular points FGHIKL, draw the lines F*a*, G*b*, I*c*, H*c*, K*d*, L*d*, cutting AE in the points BCD, and *a*E in the points *a*, *b*, *c*, *d*. Draw *af*, *bg*, *ci*, *dk*, perpendicular to *a*E. Make *af*. *bg*. *ch*, *ci*, *dk*, *dl*, each respectively equal to AF, BG, CH, CI, DL, DK. Join *fg*, *gh*, *hi*, *ik*, *kl*, *l*E. Then *afghikl*E is the angle bracket required.

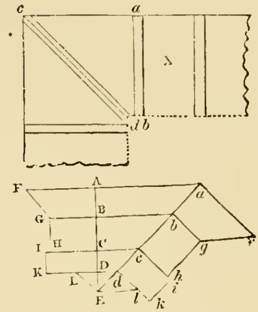

Fig. 724.

2082. An angle bracket for a cove (*fig.* 725.) may be described in exactly the same manner.

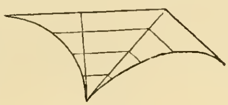

Fig. 725.

2083. When cove brackets have different projections, the method of describing the angle one is shown in *fig.* 726. Let AB, BC be the wall lines. Draw any line GD perpendicular to AB and HF perpendicular to BC. Make GD equal to the projection of the bracket from the wall represented by the line AB, and make HF equal to the projection of the bracket from the wall represented by BC. Then, as one of the brackets must be given, we shall suppose the bracket GAD described upon GD. Draw DE parallel to AB, and FE parallel to BC, and join BE. In the curve AD take any number of points Q, S, and draw QP, SR cutting GD in P, R and BE in *p*, *r*. From the points *p*, *r* draw the lines *pq*, *rs* parallel to BC, cutting HF in the points *p*, *r*. Draw *pq*, *rs* perpendicular to BE. Make *pq*, *rs* also *pq*, *rs* respectively equal to PQ, RS, &c. B*a* and HC equal to GA, then through the points *aqs*, &c. draw a curve which forms the bracket for the angle. Also through the points C, *q*, *s* draw another curve, and this will form the cove bracket.

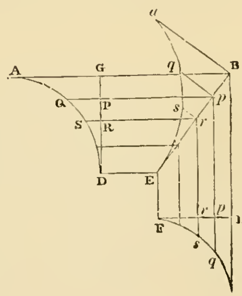

Fig. 726.

2084. The angle bracket of a cornice or cove may be formed by the method shown in X and Y (*fig.* 727.), whether the angle of the room or apartment be acute or obtuse, external or internal. Let ABC be the angle. Bisect it by the line BE. Draw GF perpendicular to BC, and make GF equal to the projection of the bracket, GC equal to its height, and FC the curve of the given bracket or rib. In the curve FC, take any number of points PQ, and parallel to BC draw the lines P*r*, Q*s*, cutting BE in the points *r*, *s*, and GF in the points R, S. Draw *rp*, *sq* perpendicular to BE, and make the ordinates *rp*, *sq* respectively equal to RP, SQ, and through all the points *pq*, draw a curve, which will be the bracket as required.

2085. When the angle is a right angle, it may be drawn as at *fig.* 728., which is an ornamental bracket for the string of a stair, and traced in the same manner as that on a right-angled triangle.

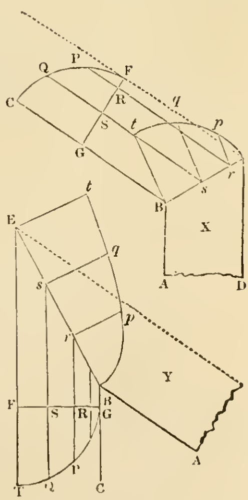

Fig. 727.

2086. In coved ceilings, the coves meeting at an angle are of different breadths, and the plan of the angle is a curve to construct the brackets. Let ABC (*fig.* 729.) represent the angle formed by the walls of the room, and let B*defg* be the plan of the bracket in the angle of a curvilinear form. Draw HM, and thereon describe the bracket HOPQ intended for that side, and in the curve HOQ take any number of points NOP, and draw the lines NR, OS, PT perpendicular to AB, cutting it in the points R, S, T. Let MQ be the height of the bracket, and draw QA perpendicular to BA, and through the points NOPQ draw the straight lines N*d*, O*e*, P*f*, cutting HM at IKLM. Draw *hm* perpendicular to BC. Make *hr*, *hs*, *ht*, *ha* respectively equal to HR, HS, HT, HA, and draw *rn*, *so*, *tp*, *aq* perpendicular to BC; also from the points *defg* draw the lines *dn*, *eo*, *fp*, *gq*, and through the points *hnopq* draw a curve, which will form the other bracket required.

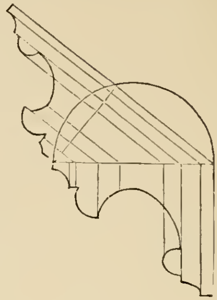

Fig. 728.

2087. Whether brackets occur in external or internal angles, the method of describing them is the same, and when the brackets from the two adjacent walls have the same projection, one of them must be given to find the angle bracket. When the brackets from these walls have unequal but given projections, then the form of one of the brackets must be given in form to find the angle bracket.

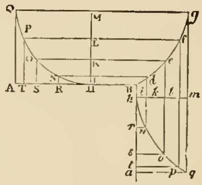

Fig. 729.

2088. *To form a bracket for a moulded cornice.* On the drawing of such cornice, draw straight lines, so as to leave sufficient thickness for the lath and plaster, which should in no case be less than three-fourths of an inch. Thus the general form of the bracketing will be obtained.

DOMES.

2089. We have, in a foregone page, mentioned a method of constructing domes with ribs in thicknesses. We here present to the reader two designs for dome-framing, wherein there is a cavity of framed work between the inner and outer domes; with moderate spans, however, simple framing is all that is required. *Fig.* 730. A is a design for a domical roof. B exhibits the method of framing the curb for it to stand upon, the section of the curb being shown upon *fig.* A. The design here given is nearly the same as that used for the dome of the Pantheon in Oxford Street, which was destroyed by fire. C is another design for a domical roof, which is narrow at the bottom part of the framing, for the purpose of gaining room within the dome.

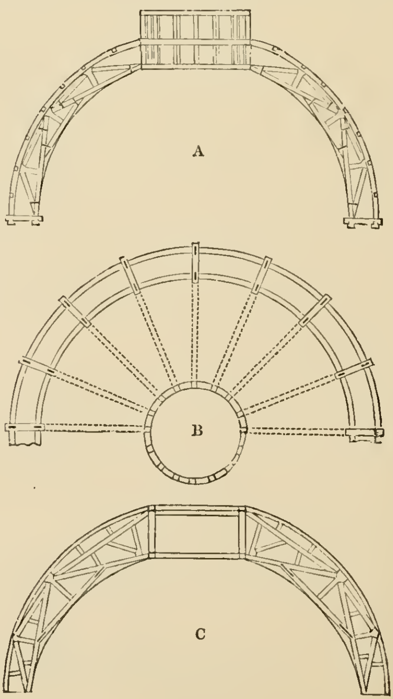

Fig. 730

PENDENTIVES.

2090. If a hemisphere, or other portion of a sphere, be intersected (*fig.* 731.) by

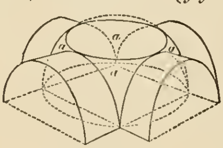

Fig. 731.

cylindrical or cylindroidal arches, vaults *aa* are formed, which are called *pendentives.* The termination of these at top will be a circle, whereon may be placed a dome, or an upright drum story, which, if necessary, may be terminated by a dome.

The reader will immediately perceive that many varieties may be formed. Our object here is merely to show how the carpenter is to proceed in making his *cradling*, as it is called, when pendentives are to be formed in wood.

2091. *To cove the ceiling of a square room with conical pendentives.* Let ABC (*fig.* 732.) be half the plan of the room, and DFE the half plan of the curb, at whose top the ribs are all fixed. The hyperbolical arches *agb*, *bhc* on each of the four sides are of equal height. The straight ribs *bf*, *ik*, *lm*, &c. are shown on the plan by FB, IK, LM, &c. The method of finding the hyperbolical curves *agb*, *bhc* will be explained in the following figure.

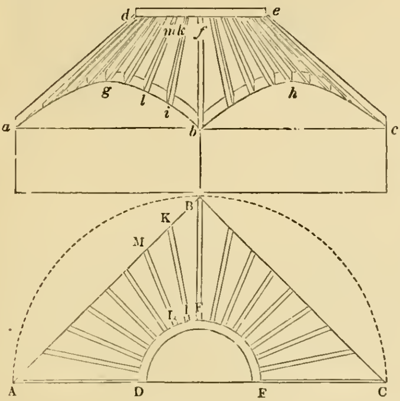

Fig. 732.

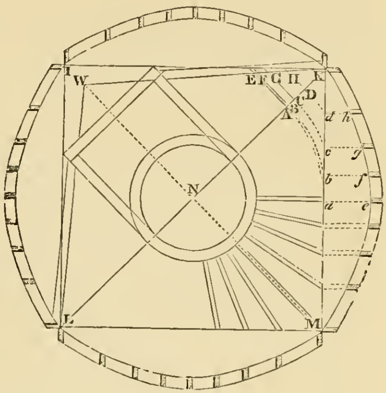

Fig. 733.

2092. *To find the springing lines of the preceding pendentives, the section in one of the vertical diagonal planes being given.* Bisect the diagonal LK (*fig.* 733.) at the point N by the perpendicular NW, which make equal to the height of the cone, and draw the sides LW and KW. Bisect the side MK of the square at *a*, and on N, with the radius N*a*, describe an arc *a*A, cutting the diagonal LK at A. Then take any points B, C, D, between A and K, and with the several radii NB, NC, ND, describe the arcs B*b*, C*c*, and D*d*, cutting KM at the points *d*, *c*, and *b*. From the points A, B, C, and D, draw AE, BF, CG, and DH perpendicular to the diagonal KL, cutting the side WK of the section of the cone at E, F, G, H. At the points *abcd* erect perpendiculars *ae*, *bf*, *cg*, and *dh* to the side ML, making each equal to their corresponding distances AE, BF, CG, and DH, which will be one half of the curve for that side from which the other may be traced. The dark parts show the feet of the ribs.

2093. *Fig.* 734. shows the method of coving a square room with spherical pendentives, which a few words will sufficiently describe. CD, DE are two sides of the plan; AFB is half the plan of the curb. In the elevation above is shown the method of fixing the ribs (which, in projection, are portions of ellipses) on two sides of the plan. *ab* is the elevation of the curb AFB; *cfd* and *dge* are ribs on each side of the plan supporting the vertical ribs that form the spherical surface, which vertical ribs support the curb *afb*. On *afb* may, if necessary, be placed a lantern or skylight; or, if light be not wanted, a flat ceiling or a dome may be placed. This pendentive is to be finished with plaster; hence the ribs must not be farther apart than about 12 inches.

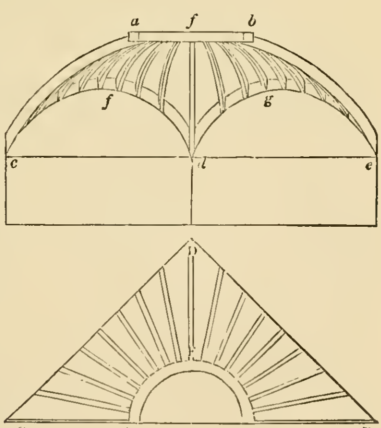

Fig. 734.

2094. For finding (*fig.* 735.) the intersection of the ribs of a spandrel dome, whose section is the segment of a circle, and whose plan is a square ABCD. Let DEFB be the section on the plane of the diagonal. First plan one quarter of the ribs, as at UC, TN, SL, RI, and QG, this last being parallel to DC or AB, the sides of the square; on V, with the radii VG, VI, VL, VN, and VC, describe the arcs GP*g*, I*ti*, L*ul*, N*vn*, &c. cutting the base DB of the angular rib in *g*, *i*, *l*, and *n*. Draw *gh*, *ik*, *lm*, and *no*, each perpendicular to DB, cutting the diagonal rib at *h*, *k*, *m*, and *o*. Then making the distances GH, IK, LM, and NO equal to the corresponding distances *gh*, *ik*, *lm*, and *no*, through the points H, K, M, O draw a curve which will be the under edge of that for the bottom of the ribs QG, RI, SL, TN, and UC, shown complete on each side of the square plan. If each of the circular segments on each side of the square plan be turned up at right angles to the plan ABCD, the ribs will then stand in their true position.

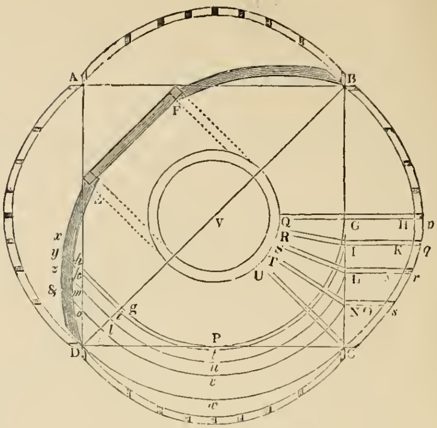

Fig. 735.

BRIDGES.

2095. We shall in this work confine ourselves to the simplest forms of timber bridges, which, as well as those of stone, will be found fully treated of in the *Encyclopædia of Engineering*, by Mr. Cresy, which forms one of the series. As they mostly depend on the principle of the truss, where the span is large, and this combination of timbers we have already explained; so in stone bridges the principle of construction of the arch is the chief matter for consideration, and to that a large portion of this work has been devoted; hence, on the part of the architect, we do not resign his pretension to employment in such works, for which, indeed, as respects design, his general education fits him better than that of the engineer.

2096. The bridge over the Brenta, near Bassano, by Palladio, is an example of a wooden bridge (*fig.* 736.), which is not only elegant as a composition, but one which is economical

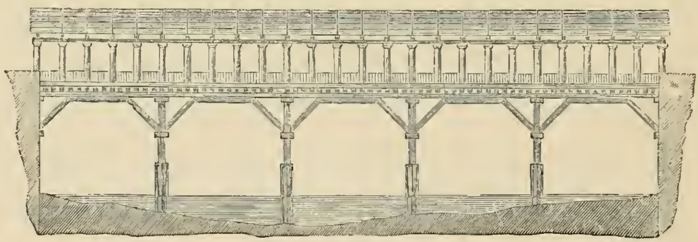

Fig. 736.

and might be employed with advantage where it is desirable that the piers should occupy a small space, and the river is not subject to great floods. The same great architect, in his celebrated *Treatise on Architecture*, has given several designs for timber bridges, the principles of whose construction have only been carried out further in many modern instances He was the earliest to adopt a species of construction by which numerous piers were rendered unnecessary, and thus to avoid the consequences of the shock of heavy bodies against the piers in the time of floods. Of this sort was the bridge he threw over the rapid torrent of the Cismone (*fig.* 737.) whose span was 108 feet.

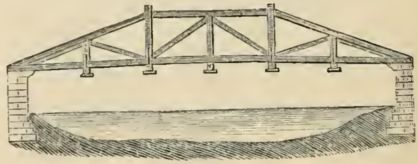

Fig. 737.

2097. Palladio has given a design for a timber bridge (*fig.* 738.) which is remarkable as having been the earliest that has come to our knowledge, wherein the arrangement is in what may be called framed voussoirs, like the arch stones of a bridge, a principle in later days carried out to a great extent, and with success, in iron as well as timber bridges.

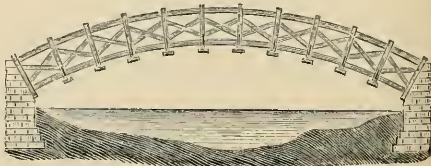

Fig. 738.

2098. We shall conclude our section on practical carpentry with a method of constructing timber bridges proposed by Price in his *Treatise on Carpentry*, and one not dissimilar in principle to the method of Philibert de Lorme, before mentioned. The bridge (*fig.* 739.) is supposed to consist of two principal ribs *ik*. The width of the place is spanned at once by an arch rising one sixth part of its extent. Its curve is divided into five parts, "which," says Price, "I purpose to be of good seasoned English oak plank, of 3 inches thick and 12 broad. Their joint or meeting tends to the centre of the arch. Within this rib is another, cut out of plank as before, of 3 inches thick and 9 broad, in such sort as to break the joints of the other. In each of these ribs are made four mortices, of 4 inches broad and 3 high, and in the middle of the said 9-inch plank. These mortices are best set out with a templet, on which the said mortices have been truly divided and adjusted. Lastly, put each principal rib up in its place, driving loose keys into some of the mortices to hold the said two thicknesses together; while other help is ready to drive in the joists, which should have a shoulder inward, and a mortice in them outward; through which keys being drove keep the whole together. On these joists lay your planks, gravel, &c.; so is your bridge compleat, and suitable to a river, &c. of 36 feet wide."

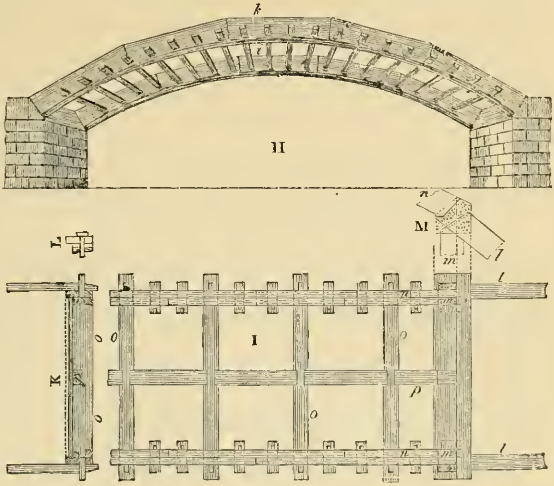

Fig. 739.

2099. "In case the river, &c. be 40 or 50 feet wide, the stuff should be larger and more particularly framed, as is shown in part of the plan enlarged, as I. These planks ought to be 4 inches thick and 16 wide; and the inner ones, that break the joints, 4 inches thick and 12 broad; in each of these are six mortices, four of which are 4 inches wide and 2 high; through these are drove keys which keep the ribs the better together; the other two mortices are 6 inches wide and 4 high; into these are framed the joists of 6 inches by 12; the tenons of these joists are morticed to receive the posts, which serve as keys, as shown in the section K, and the small keys as in L; all which inspection will explain. That of M is a method whereby to make a good butment in case the ground be not solid, and is by driving two piles perpendicularly and two sloping, the heads of both being cut off so as to be embraced by the sill or resting plate, which will appear by the pricked lines drawn from the plan I and the letters of reference." Price concludes: "All that I conceive necessary to be said further is, that the whole being performed without iron, it is therefore capable of being painted on every part, by which means the timber may be preserved; for though in some respects iron is indispensably necessary, yet, if in such cases where things are or may be often moved, the iron will rust and scale, so as that the parts will become loose in process of time, which, as I said before, if made of sound timber, will always keep tight and firm together. It may not be amiss to observe, that whereas some may imagine this arch of timber is liable to give way, when a weight comes on any particular part, and rise where there is no weight, such objectors may be satisfied that no part can yield or give way till the said six keys are broke short off at once, which no weight can possibly do."

Sect. V.

JOINERY.

2100. Joinery is that part of the science of architecture which consists in framing or *joining* together wood for the external and internal finishings of houses, such as the linings of walls and rough timbers, the putting together of doors, windows, stairs, and the like.

It requires, therefore, more accurate and nicer workmanship than carpentry, being of a decorative nature and near the eye. Hence the surfaces must be smooth and nicely wrought, and the joints must be made with great precision. The smoothing of the wood is called *planing*, and the wood used is called *stuff*, which consists of rectangular prisms roughly brought into shape by the saw, such prisms being called battens, boards, and planks, according to their breadth and thickness.

2101. We shall give but a succinct account of the joiner's tools; an acquaintance with their forms and uses being sooner learnt by mere inspection over a joiner's bench than by the most elaborate description.

TOOLS.

2102. The first is the *bench*, whose medium height is about 2 feet 8 inches, its length about 10 or 12 feet, and its width about 2 feet 6 inches. One side is provided with a vertical board, called the *side board*, pierced with holes ranged at different heights in diagonal directions, which admit of pins for holding up the object to be planed, which is supported at the other end of it by a *screw* and *screw check*, together called the *bench screw*, acting like a *vice*. The *planes* used by the joiner are the *jack plane*, which is used for taking off the roughest and most prominent parts of the stuff, and reducing it nearly to its intended form. Its *stock*, that is, the wooden part, is about 17 inches long, 3 inches high, and $3\frac{1}{2}$ inches broad. The *trying plane*, whose use is nearly the same as that last described, but used after it, the operation being performed with it by taking the shaving the whole length of the stuff, which is called *trying up*, whereas with the jack plane the workman stops at every arm's length. The *long plane*, which is used when a piece of stuff is to be tried up very straight. It is longer and broader than the trying plane, its length being 26 inches, its breadth $3\frac{5}{8}$ inches, and depth $3\frac{1}{8}$ inches. The *jointer*, which is still longer, being 2 feet 6 inches long, and is principally used for obtaining very straight edges, an operation commonly called *shooting*. With this the shaving is taken the whole length in finishing the joint or edge. The *smoothing plane*, which, as its name imports, is the last employed for giving the utmost degree of smoothness to the surface of the wood, and is chiefly used for cleaning off finished work. It is only $7\frac{1}{2}$ inches long, 3 inches broad, and $2\frac{3}{4}$ inches in depth. The foregoing are technically called *bench planes*.

2103. The *compass plane* which in size and shape is similar to the smoothing plane, except that its under surface or *sole* is convex, its use being to form a concave cylindrical surface. Compass planes are therefore of various sizes as occasion may require. The *forkstaff plane* resembles the smoothing plane in size and shape, except that the sole is part of a concave cylindric surface, whose axis is parallel to the length of the plane. The form is obviously connected with its application, and, like the last named, it is of course of various sizes. The *straight block* is employed for shooting short joints and mitres, instead of the jointer, which would be unwieldy: its length is 12 inches, its breadth $3\frac{1}{8}$ inches, and depth $2\frac{3}{4}$ inches.

2104. There is a species of planes called *rebate* planes, the first whereof is simply called the *rebate plane*, being, as its name imports, chiefly used for making rebates, which are receding planes formed for the reception of some other board or body, so that its edge may coincide with that side of the rebate next to the edge of the rebated piece. The length of the rebate plane is about $9\frac{1}{2}$ inches, its depth about $3\frac{1}{2}$ inches, and its thickness varies according to the width of the rebate to be made, say from $1\frac{3}{4}$ to $\frac{1}{2}$ inch. Rebate planes vary from bench planes in having no *tote* or handle rising out of the stock, and from their having no orifice for the discharge of the shavings, which are discharged on one side or other according to the use of the plane. Of the sinking rebating planes there are two sorts, the *moving fillister* and the *sash fillister*, whereof, referring the reader to the tool itself, a sight of which he can have no difficulty in procuring, the first is for sinking the edge of the stuff next to the workman, and the other for sinking the opposite edge, whence it is manifest that these planes have their cutting edges on the under side. Without enumerating many other sorts which are in use, we shall mention merely the *plough*, a plane used for sinking a cavity in a surface not close to the edge of it, so as to leave an excavation or hollow, consisting of three straight surfaces forming two internal right angles with each other, and the two vertical sides two external right angles with the upper surface of the stuff. The channel thus cut is called a *groove*, and the operation is called *grooving* or *plowing*. This species will vary according to the width from the edge; but it is generally about $7\frac{3}{8}$ inches long, $3\frac{5}{8}$ inches deep.

2105. *Moulding planes* are for forming mouldings, which, of course, will vary according to the designs of the architect. They are generally about $9\frac{3}{8}$ inches long, and $3\frac{3}{8}$ inches deep. When mouldings are very complex, they are generally wrought by hand; but when a plane is formed for them they are said to be *stuck*, and the operation is called *sticking*.

2106. The *bead plane* is used very frequently in joinery, its use being for sticking mouldings whose section is semicircular; when the bead is stuck on the edge of a piece of stuff to form a semi-cylindric surface to the whole thickness, the edge is said to be beaded or rounded. When a bead is stuck so that it does not on the section merely fall in with its square returns, but leaves a space , thus, between the junctions at the sides, it is said to be *quirked*. The beads or planes vary from very small sizes up to the $\frac{3}{4}$ inch and $\frac{7}{8}$ bead. They may however be larger, and are sometimes stuck double and triple. The *snipebill plane* is one for forming the *quirk*, whereof we have spoken; but we do not think a detailed description of it necessary, more than we do of those which are made for striking *hollows* and *rounds*.

2107. The *stock and bit* is the next tool to be mentioned. Its use is for boring wood, and the iron, which varies as the size of the bore required, is made in a curve on its edge of contrary flexure so as to discharge the wood taken out. It fits into what is called the stock, which has a double curved arm working on spindles, the end opposite to the bit being pressed by the body, whose weight against the whole instrument is the power whereby the operation is performed. The bit is also called a *pin*, or *gouge bit*. It is an important tool, and much used. (See Auger in *Glossary*.)

2108. *Countersinks* are bits for widening the upper part of a hole in wood or iron for the head of a screw or pin, and are formed with a conical head. *Rimers* are bits for widening holes, and are of pyramidal form whose vertical angle is about $3\frac{1}{2}$ degrees. The hole is first pierced by means of a drill or punch, and the rimer then cuts or scrapes off the interior surface of the hole, as it sinks downwards, by pressing on the head of the stock. According to the metal on which they are to be used they are differently formed.

2109. The *taper shell bit* is conical both within and without. Its horizontal section is a crescent, the cutting edge being the meeting of the interior and exterior conic surfaces. Its use is for widening holes in wood. Besides the above bits, there are some which are provided with a screw-driver for sinking small screws into wood with more rapidity than the unassisted hand will accomplish.

2110. The *brad awl*, the smallest boring tool, the *gimlet*, and the *screw driver*, are so well known, that it would be waste of space to do more than mention them, the commonest of instruments in the science of construction.

2111. The variety of *chisels* is great. They are well known to be edge tools for cutting wood by pressure on it, or by percussion with a mallet on its handle. The *firmer chisel* is a tool used by the carpenter as well as the joiner for cutting away superfluous wood by thin chips. Those are best which are made of cast steel. If much superfluous wood is to be cut away, a strong chisel, with an iron back and steel face, is first used with the aid of the mallet, and then a slighter one with a very fine edge. The first is the *firmer* first mentioned, and the last is called a *paring chisel*, in the use whereof the force employed is from the shoulder or hand.

2112. The *mortice chisel*, whose use is for cutting out rectangular prismatic cavities in stuff is made of considerable strength. The cavity it so cuts out is called a *mortice*, and the piece which fits into it a *tenon*, whence the name of the tool. This chisel is one acted on only by the percussion of the mallet.

2113. The *gouge* is used for cutting concave forms in stuff. It is, in fact, a chisel whose iron is convex.

2114. The *drawing knife* is an oblique-ended chisel, or old knife, for drawing in the ends of tenons by making a deep incision with the sharp edge, guided by that of the tongue of a square, for which purpose a small part is cut out in the form of a triangular prism. The use of this excavation is to enter the saw and keep it close to the shoulder, and thus make the end of the rail quite smooth, for by this means the saw will not get out of its course.

2115. There are many species of the *saw*, which is a thin plate of steel, whose edge is indented with teeth for cutting by reciprocally changing the direction of its motion. The varieties are — the *ripping saw*, which is used for dividing or splitting wood in the direction of the fibres; its teeth are large, the measure being usually to the number of eight in 3 inches, such teeth standing perpendicularly to the line which ranges with the points: the length of the *plate* or *blade* of this saw is about 28 inches. The *half ripper* is used also for dividing wood in the direction of the fibres: the plate of this saw is as long as of that last described, but it has only three teeth in an inch. The *hand saw*, whose plate is 26 inches long, contains fifteen teeth in 4 inches; it is used for cross cutting, as in the direction of the fibres; for which purposes the teeth recline more than in the two former saws. The *panel saw* has about six teeth in an inch, the length of its plate being the same as the last; but in this and the hand saw thinner than in the ripping saw: it is used for cutting very thin wood, either with or across the fibres. The *tenon saw* is most used for cutting wood transverse to the fibres, as the shoulders of tenons. The plate of a tenon saw is from 14 to 19 inches long, having eight to ten teeth in an inch. This saw not being intended to cut through the whole breadth of the wood, and the plate being too thin to make a straight kerf, or to keep it from buckling, it has a thick piece of iron fixed on the edge opposite to the teeth, called the back. From the opening for the fingers through the handle of this and the foregoing saws being enclosed all round, it is called a double handle. The *sash saw* is used for forming the tenons of sashes ; its plate is 11 inches in length, having about thirteen teeth to the inch. It is sometimes backed with iron, but more frequently with brass. The *dovetail saw* is used for cutting the dovetails of drawers and the like ; its plate is backed with brass, it contains fifteen teeth in about one inch, and is about 9 inches long. The handles of this and the last saw are only single. The *compass saw*, for cutting wood into curved surfaces, is narrow, thicker on the cutting edge as the teeth have no set, and is without a back ; the plate, near the handle, is about an inch broad, and about a quarter of an inch at the other extremity, having about five teeth to the inch ; the handle is single. The *keyhole*, or *turning saw*, in its plate resembles the compass saw, but the handle is long, and perforated from end to end for inserting the plate at any distance within the handle ; there is a *pad* in the lower part of the handle, through which is inserted a screw for fastening the plate therein. As its name implies, it is used for turning out quick curves, as keyholes, and is therefore frequently called a keyhole saw.

2116. The teeth of all saws, except turning and keyhole saws, are bent alternately on the contrary sides of the plate, so that all the teeth on the same side are alike bent throughout the length of the plate, for the purposes of clearing the sides of the cut made in the wood by it. The saw is a tool of great importance in every case where wood is to be divided, for by its means it can be divided into slips or scantlings with no more waste than a small slice of the wood, whose breadth is equal to the depth of the piece to be cut through, and the thickness of it equal to no more than the distance of the teeth between their extreme points on the alternate sides of the saw measured on a line perpendicular to them ; whereas, by any other means, such as the axe for instance, large pieces of timber could only be reduced in size by cutting away the superfluous stuff, which would be no less a waste of labour than of the material used ; and even then it would have to be reduced to a plane surface.

2117. Joiners use the *hatchet*, which is a small axe, for cutting away the superfluous wood from the edge of a piece of stuff when the part to be cut away is too small to be sawed.

2118. The *square* consists of two rectangular prismatic pieces of wood, or one of wood, and the other, which is the thinnest, of metal, fixed together, each at one of their extremities, so as to form a right angle both internally and externally ; the interior right angle is therefore called the inner square, and the exterior one the outer square. Squares are, for different applications, made of different dimensions. Some are employed in trying up wood, and some for setting out work ; the former is called a trying square, and the latter a setting out square. To prove a square it is only necessary to reverse the blade after having drawn a line on the surface to which it is applied : if the line of the blade on reversal do not coincide with that first drawn, the square is incorrect.

2119. The *bevel* consists, like the square, of a blade and handle ; but the tongue is moveable on a joint, so that it may be set to any angle. When it is required to try up many pieces of stuff to a particular angle, an immoveable bevel ought to be made for the purpose ; for unless very great care be taken in laying down the moveable bevel, it will be likely to shift.

2120. The *gauge* is an instrument used for drawing or marking a line on a piece of stuff to a width parallel to the edge. It consists generally of a square piece with a mortice in it, through which runs a sliding bar at right angles, called the stem, furnished with a sharp point or tooth at one extremity, projecting a little from the surface ; so that when the side of the gauge next to the end which has the point is applied upon the vertical surface of the wood, with the toothed side of the stem upon the horizontal surface, and pushed and drawn alternately by the workman from and towards him, the tooth makes an incision from the surface into the wood at a parallel distance from the upper edge of the vertical side on the right hand. This line marks precisely the intersection of the plane which divides the superfluous stuff from that which is to be used. When it is required to cut a mortice in a piece of wood, the gauge has two teeth in it, and is called a *mortice gauge*, one tooth being stationary at the end of the stem, and the other moveable in a mortice between the fixed tooth and the head ; so that the distances of the teeth from each other, and of each from the head, may be set at pleasure, as the thickness of the tenon may require.

2121. The *side hook* is a rectangular prismatic piece of wood, with a projecting knob at the ends of its opposite sides. The use of the side hook is to hold a board fast, its fibres being in the direction of the length of the bench, while the workman is cutting across the fibres with a saw or grooving plane, or in *traversing* the wood, which is planing it in a direction perpendicular to the fibres.

2122. The *mitre box* consists of three boards, two, called the sides, being fixed at right angles to a third, called the bottom. The bottom and top of the sides are all parallel ; the sides of equal height, and cut with a saw in two directions of straight surfaces at right angles to each other and to the bottom, forming an angle of 45 degrees with the sides. The mitre box is used for cutting a piece of tried up stuff to an angle of 45 degrees with two of its surfaces; or at least to one of the arrisses, and perpendicular to the other two sides, or at least to one of them, obliquely to the fibres.

2123. The *straight edge* is a slip of wood made perfectly straight on the edge, in order to make other edges straight, or to plane the face of a board straight. It is made of different lengths, according to the required magnitude of the work. Its use is obvious, as its application will show whether there is a coincidence between the straight edge and the surface to which it is applied. When joiners wish to ascertain whether the whole surface of a piece of wood lies in the same plane, they use two slips, each straightened on one edge, with the opposite edge parallel, and both pieces of the same breadth between the parallel edges; whence each piece has two straight edges or two parallel planes. To find, therefore, whether a board is twisted, one of the slips is placed across one end and the other across the other end of the board, with one of the straight edges of each upon the surface. The joiner then looks in a longitudinal direction over the upper edges of the two slips, until his eye and the said two edges are in one plane; or otherwise the intersection of the plane passing through the eye and the upper edge of the nearest slip will intersect the upper edge of the farthest slip. If it happen as in the former case, the ends of the wood under the slips are in the same plane; but should it happen as in the latter, they are not. In the last case, the surface is said to *wind*; and when the surface is so reduced as for every two lines to be in one plane, it is said to be *out of winding*, which is the same as to say it is a perfect plane. From the use of these slips, they are denominated *winding sticks.*

2124. The *mitre square*, an instrument so called because it bisects the right angle or mitres the square, is an immoveable bevel, for the purpose of striking an angle of 45 degrees with one side or edge of a piece of stuff upon the adjoining side or edge of the said piece of stuff. It consists of a broad thin board, let or tongued into a piece on the edge called the fence or handle, which projects equally on each side of the blade, whereof one of the edges is made to contain an angle of 45 degrees with the nearest edge of the handle, or of that in which the blade is inserted. The inside of the handle is called the guide. The handle may be about an inch thick, 2 inches broad; the blade about $\frac{3}{16}$ to $\frac{1}{4}$ of an inch thick, and about 7 or eight inches broad. The *arris* of a piece of stuff is the edge formed by two planes.

MACHINERY.

2124*a*. In many of the operations of the joiner, where numerous copies of the same thing have to be produced, accuracy is ensured by introducing the principle of the *guide*, either to direct the tool over the work, or the work over the tool. The *mitre box*, *shoot blocks*, and the various kinds of *fences* and *stops*, are examples. The principle of the *guide* is also applied to simple sawing and planing, and to grooving, tonguing, morticing, tenoning, and shaping. The *circular saw* was introduced about the end of the last century into England, and attempts to construct a *planing machine* were made about 1776 and 1791 (G. L. Molesworth, *On the Conversion of Wood by Machinery*, read at the Institute of Civil Engineers, November 17, 1857). When Sir S. Bentham was in Russia previous to 1790, he had made considerable progress in contriving machinery for shaping wood, such as all the parts of a highly finished sash window; another for preparing all the parts of a wheel, so that the joiner or wheelwright in that case had only to put the several pieces together. In 1802 Bramah patented machinery for producing straight, parallel, and curvilinear surfaces on wood. In 1807 Brunel's famous block machinery was set in motion in Portsmouth dockyard. Thomson's machinery for sawing, gauging, grooving, and tonguing floor boards was in operation in 1826; and, in 1827, Muir of Glasgow patented a machine for working floor boards, which has since served as a model for others. This machine has approached perfection in that of MacDowall of Johnstone. A rack circular saw bench, for round or square timber, quickly converts a log or balk into square timber.

2124*b*. For the ordinary workshop, where the trade is limited and much varied, the simpler American machines are more suitable. The *saw bench* occupies little space and can be applied in plain and bevel sawing, and ripping, mitring, tenoning, rebating, &c. It is only 3 feet 2 inches long, 2 feet 2 inches wide, and 3 feet $6\frac{1}{2}$ inches high; the saw is 8 inches in diameter and makes $15\frac{1}{2}$ revolutions for each turn of the handle. A crank may be acted on by a treadle when the stuff is thin, but in ordinary cases the machine requires two operators. We cannot satisfactorily describe the details, without illustrations, of the many operations which this handy bench aids in performing with accuracy and dispatch. In Furness's patent wood working machine for planing, moulding, morticing, sawing, squaring, tenoning, boring, rebating, and grooving, the stuff is operated upon by cutters, held by horizontal arms fixed to a vertical shaft, in which it resembles the Bramah's machine of 1802, but it is much simpler and less expensive. Worssam's "general joiner" for the same purposes will, it is said, with a 2 horse-power, do the work of at least fifteen skilled joiners. Perin's patent French *band saw blades* are made from $\frac{1}{16}$th of an inch to 8 inches in width and up to 50 feet in length.

2124*c*. In machines with revolving cutters the general opinion is, that the greater the speed of the cutting tool the better will be the quality of the work. The practical limit, however, appears to be between 2,500 and 3,500 revolutions per minute. A higher velocity heats the bearings, destroys the balance, and causes injurious vibrations. To produce a good result the travel of the work should be very slow relatively to the travel of the cutters. In some of the planing machines the cutters revolve with a velocity of 7,000 feet per minute, while the work advances at the rate of only 30 feet, but as a general rule the work travels about $\frac{1}{20}$th of an inch for each stroke of the cutters. To withstand this high velocity the framing of the machine requires to be perfectly constructed, the bearings made of a hard alloy, and precautions taken for obviating the wear of them. Newlands' work gives illustrations and detailed descriptions of some of the machinery.

2124*d*. Mention must be made of Jordan's patent wood and stone carving machine, invented about 1843, and worked by Pratt in 1845 to 1850 on a large scale. It roughed out the material according to the design, leaving but little labour to be received from the hands of the carver. Moulded work has also been obtained by applying red-hot iron moulds to the wood, and so charring off the superfluous wood. This system is probably cheap, but the work is flat and spiritless. Carved panels for doors, consisting of a thin veneer of wood on a layer of pulp, the whole pressed in moulds, is put forward by the Decorative Wood Company, and has a good appearance.

2124*e*. The introduction from New York, Sweden, and other places, of prepared flooring, ready-made doors and machine worked mouldings, out of well seasoned pine, is of great advantage for cheap houses in the neighbourhood of large centres of population.

2125. In joiners' work executed during the 13th, 14th, and 15th centuries, the wood has neither warped, split, nor shrunk in the tenons and at other joints. This excellence is ascribed to the practice of seasoning the wood for at least six years after it was sawn, by first leaving it in damp places or even in water, and then stacking it in open piles under cover, when it was often turned and sometimes smoked; after such treatment the wood, when worked, has a tendency to acquire the appearance of Florentine bronze.

2125*a*. As very old timber is likely to show shakes and to be worm-eaten, the mediæval joiners felled oak from two to three hundred years old; i.e, timber which, at a yard from the ground, measured from 66 or 72 to 120 or 126 inches in girt without the albumen, and commenced its conversion by marking it with one diameter crossing another at right angles. The cuts on these lines having been made, the quarters were sawn in various ways, regard being had, as much as possible, to the texture of the wood. An unseasoned log of oak splits as shown at A, *fig.* 739*a*. because the inner concentric circles are harder and more compact than the outer ones; therefore the latter, being the most extensive in surface as well as the most porous, contain a greater quantity of moisture, and shrink more than the inner ones in drying, thus causing splits or shakes leading to the centre. If timber be converted without regard to this result of dryness, the stuff will not only split, but will be so affected by changes of weather as to twist. If the cuts be made in lines converging, or even tending to the centre, the stuff may shrink in width but will neither split nor warp. Although oak is formed like other exogenous trees by a succession of layers, these are united and solidified in this particular wood by the medullary rays which form a sort of natural dowel.

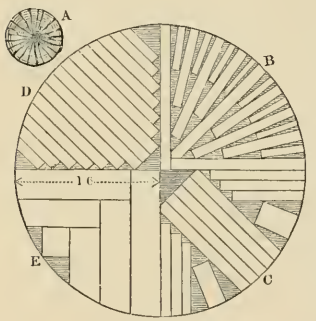

Fig. 739*a*.

2125*b*. The best method of converting oak for the use of the joiner is shown at B, *fig.* 739*a*., in which there is no waste, as the triangular portions form feather-edged laths for tiling and other purposes. The next best method is that at C; that at D is inferior; but the most economical method, where thickness is required, as for planks or for moulded work, is that marked E. The resemblance to a watered silk, which is sometimes called the feather, or flower, or curl, or pattern, of wainscot, is due to the medullary rays, which show most when the saw follows the chink-grain as in B; in C and D the silky appearance does not exist, as most of the rays are cut across; very slight examination will show which course has been followed, especially in the case of the quarter-grain stuff produced by the method E. It is probable that the cross-cuts will follow the line of a layer, called the felt-grain, in the plan marked B, which is that adopted in Holland on timber furnished in great part from Champagne (whence, simply, the superiority of Dutch wainscot), and in all cases of split oak for lathing and for park paling. (Viollet-le-Duc).

2125*c*. The wood principally used for joinery is of three sorts, pine, and white and yellow deal; the two first for panelling, and the last for framing. Of late years much American wood has been used, both for panels and frames. It works easily, is soft, free from knots, but more liable to warp than white deal. But joinery is not of course limited to the use of a particular sort of wood. When the exporter cuts a log, the first thing done is to get one good deal or more for the London market; the residue is then converted to supply other markets. Many deals 3 inches thick are sent to France, perhaps as large a proportion as those of 2 inch and $1\frac{1}{4}$ inch, but they are not of so good a description as those sent to London. France is the great mart for all deals that will not suit the London market. The following are the modes which have been and are at present practised to obtain deals for both markets. In 739*b*. (the mode practised until the French market improved), are obtained an English deal, A, 9 in. by 3 in., and two battens, B, 7 in. by $2\frac{1}{2}$ in., making 62 feet superficial. In 739*c*., the old mode of cutting, gave two English deals, C, 9 in. by $2\frac{1}{2}$ in., and two English battens, D, 7 in. by $2\frac{1}{2}$ in., making 80 feet superficial. In 739*d*., the present mode of cutting, gives two English deals, E, 9 in. by 3 in., and two French deals, F, 9 in. by $1\frac{1}{4}$ in., making $76\frac{1}{4}$ feet superficial. This communication has been obligingly furnished by Mr. T. A. Britton, as obtained at the Docks.

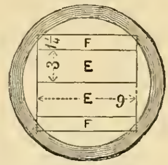

Fig. 739*d*.

2125*d*. *Glue* is a material extensively used in joinery; see Glossary.

MOULDINGS.

2126. When the edge of a piece of wood is reduced to a cylindrical form, it is said to be *rounded*, which is the simplest kind of moulded work. (*Fig.* 740.) When a portion of the arris is made semicylindrical, so that the surface of the cylindrical part is flush both with the face and the edge of the wood, with a groove or sinking made in the face only, the cylindrical part is called a bead, and the sinking a quirk; the whole combination (*fig.* 741.) being called a *quirked bead*.

2127. If a quirk is also formed on the other or returning face, so as to make the rounded part at the angle three fourths of a cylinder, the moulding (see *fig.* 742.) is called a *bead and double quirk*.

Fig. 740.

Fig. 741.

Fig. 742.

Fig. 743.

Fig. 744.

Fig. 745.

2128. If two semicylindrical mouldings both rise from a plane parallel to the face, and one comes close to the edge of the piece and the other has a quirk on the further side, and its surface flush with the face of the wood, as in *fig.* 743., the combination is called a *double bead* or *double bead and quirk*, wherein the bead next to the edge of the stuff is much smaller than the other.

2129. Mouldings are usually separated from one another, and often terminated by two narrow planes at right angles (*fig.* 744.) to each other: these are called *fillets*, and show two sides of a rectangular prism. The different pieces of the combination of mouldings are called *members*. A semicylindrical moulding, rising from a plane parallel to the face, and terminated on the edge by a fillet (*fig.* 745.), is called a *torus*. In the figure there are two semicylindrical mouldings, whence that is called a *double torus*. The reader must observe that the distinction between torus mouldings and beads in joinery is, that the outer edge of the former always terminates with a fillet, whether the torus be single or double; whereas a bead never has a fillet on the outer edge. A repetition of equal semicylindrical mouldings, springing from a plane or cylindrical surface, is called *reeds*. In joinery, the , *cima recta*, and , *cima reversa*, are called respectively the *ogee* and *ogee reverse*. The ovolo , so named from its egg-like form, and the *quarter round*, the fourth part of a cylindrical surface, are the remaining of the principal mouldings used in joinery. When the margin of any framing terminates on the edges next to the panel, with one or more mouldings, which both advance before and retire from the face of the framing to the panelling, the mouldings thus introduced are called *bolection mouldings*. Their combination is shown further on. (See *fig.* 759.) Greek, Roman, and Italian mouldings are also shown in 2531. and 2532.; and mediæval mouldings are treated in Practice of Architecture.

DOORS.

2130. We shall now more particularly address ourselves to the subject of doors and their mouldings. The most inferior sort of door used in building is the *common ledged door*, in which five or six or seven vertical boards are held together usually by three horizontal pieces called ledges, to which the vertical ones are nailed. Sometimes there is an outer framing, consisting of the top rail and the two outside stiles, but still having ledges as before; these are called *framed and ledged doors.* A door, properly made, is formed by framing and fitting pieces of stuff together of the same thickness; those which are horizontal (*fig.* 746.) AAAA being called *rail* and those which are vertical BBBB being called *stiles.* These form a skeleton into which *panels,* usually of a less thickness, are fitted. And this, indeed, is the general practice in all systems of framed joinery. In

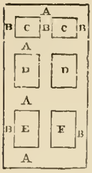

Fig. 746

doors, the upper rails are called *top rails*; the next in descending, *frieze rails*; the next, which are usually wider than the two first, are called the *lock* or *middle rails*; and the lowest, from their situation, are called *bottom rails.* The stiles on the flanks are called *outside stiles,* and those in the middle are called *middle stiles.* The panels are also named from their situations on the door; thus CC, being the uppermost, are called *frieze panels*; the next DD are called *middle panels,* and EE *bottom panels.* The rails and stiles are wedged together, being previously morticed and tenoned into each other. The student should, however, to obtain a clear comprehension of the method adopted, see a door put together at the bench. The varieties and forms of doors are dependent upon the will of the architect, from whom the design of the whole emanates; it will be, therefore, here sufficient to mention the three sorts, viz. the *common door,* just described; the *jib door,* which is made with the same finishings and appearance as the room in which it is placed, so as not to have the appearance of a door; and, lastly, *folding doors,* which open from the centre of the doorway, and are used for making a wider communication between two apartments than a common door will permit, or, in other words, to lay two rooms into one.

2130*a*. A patent *safety and escape door,* applicable for all positions, has been produced to supply the demand of the authorities that all doors in public buildings be made to open outwards. This invention consists of a door within a door, one opening inward, the other outward; the inner door being so constructed that on a rush it yields to the pressure. Sufficient fittings are provided to afford security as well. Messrs Chubb have produced a door, having a superimposed spring panel on the inside of the door, in which the lock is embedded. While a smart knock, or even a slight pressure, on this panel causes the double doors to fly open outward, it is impossible to open the door from the outside without a key.

2131. Though the panelling of framed work is generally sunk witnin the face of the framing, it is for outside work sometimes made flush. In the best flush work, the panels are surrounded with a bead formed on the edge of the framing, and the work is called *bead and flush.* In the commoner kind of flush framing, the bead is run only on the two edges of the panel in the direction of the fibres, and is called *bead and butt.*

2132. The different denominations of framed doors, according to their mouldings and panels and framed work in general, are shown in section of panel and frame. *Fig.* 747. represents the commonest door; it is technically described, first mentioning the number

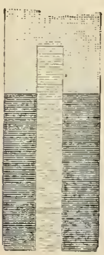

Fig. 747.

Fig. 748.

Fig. 749.

Fig. 750.

Fig. 751.

of panels intended in it, as a *door square and flat panel both sides.* The number of panels will not be repeated in the following explanations of the figures. (See Specifications.)

2134. *Fig.* 748. represents the rail and panel of a door, with a quirked ovolo and a fillet on one side, but having no mouldings on the other. The panel flat on both sides, it is described as a *door with quirked ovolo, fillet and flat with square back.*

2135. *Fig.* 749. only differs from the last in having a bead instead of a fillet, and is described as *quirked ovolo, bead and flat panel with square back.*

2136. *Fig.* 750., with an additional fillet on the framing, is described as *quirked ovolo, bead fillet and flat panel with square back.* The back, in the foregoing and following cases, is described as square, because of its having no mouldings on the framing, and of the panel being a straight surface on one side of the door.

2137. In *fig.* 751. the framing is formed with a quirked ogee, and a quirked bead on one side and square on the other, the surface of the panel being straight on both sides, and the door is described as *quirked ogee, quirked bead and flat panel with square back.*

2138. *Fig.* 752. only differs from the last in the bead being raised above the lower part of the ogee and a fillet It is described as *quirked ogee, cocked bead and flat panel with square back.*

2139. *Fig.* 753. is described as a door with *cove, cocked bead, flat panel and square back.*

Fig. 752.

Fig. 753.

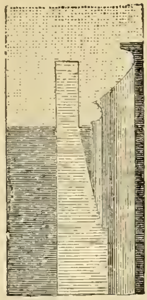

Fig. 754.

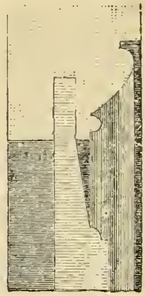

Fig. 755.

2140 *Fig.* 754. is a combination by which much strength is imparted to the door, and it is therefore much used for external doors. It is, however, often used in the interior of houses, and is described, *quirked ovolo, bead fillet and raised panel on front and square back.* It is from the raising of the panel that the additional strength is acquired.

2141. *Fig.* 755. resembles the last in general appearance, the difference being in the ovolo on the raised panel. It is described, *quirked ovolo, bead and raised panel, with ovolo on the raised panel and square back.* When an external door has raised panels, they are always placed towards the exterior.

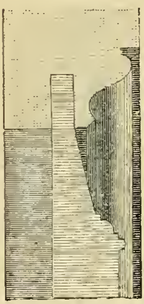

Fig. 756.

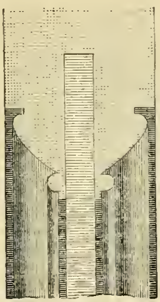

Fig. 757.

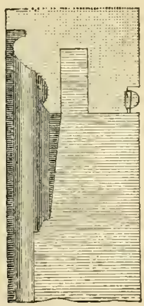

Fig. 758.

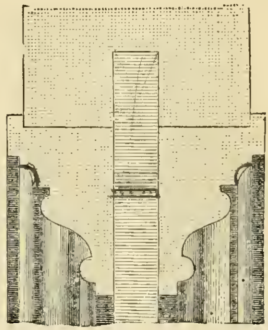

Fig. 759.

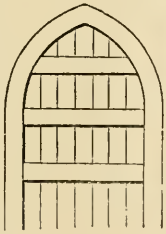
2142. In *fig.* 756. there are more mouldings than in the last on the raised panel. It is described, *quirked ogee, raised panel with ovolo and fillet on the rising and astragal on the flat of panel in front and square back.*

2143. *Fig.* 757. is described, *quirked ovolo, bead fillet and flat panel on both sides.* This description of doors is used where a handsome appearance is to be equally preserved on both sides of the door, as between rooms, or between halls or principal passages and rooms.

2144. *Fig.* 758. is a combination used, as all bead butt and bead flush work is, where strength is required. The form here given is described, *bead and flush front and quirked ogee, raised panel with ovolo on the rising, grooved on flat panel on back.*

2145. The series of mouldings are, as we have before mentioned, called *bolection* mouldings (*fig.* 759.), and are laid in after the door is framed square and put together. They project beyond the framing on each side. When bradded on through the sides of the quirks, the heads of the brads will be entirely concealed; but it is to be observed that, in driving the brads, they must not be directed towards the panels, but into the solid of the framing. The form of these bolection mouldings is of course varied according to the pleasure of the architect.



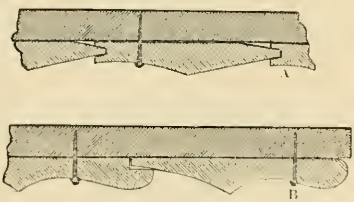


Fig. 759a.

2145*a*. *Mediæval Doors*, of a simple sort, were formed of planks placed upright, grooved or feather-tongued at the edges, and generally secured together by plain band-hinges, or more or less ornamented, or with scroll work. These planks are further nailed to a skeleton framing. *Fig.* 759*a.* gives a sketch of the back of the door at Bidborough Church, Kent, with its planking at A; and B is a section of the same at Staplehurst Church, Kent; the place for the nails is only indicated. These examples were supplied to the *Dictionary of Architecture* by Professor Lewis. Larger doors were made up of frames and rails, strutted or braced, on the same principle as the modern ledged doors and coach-house gates. Viollet le Duc's *Dictionnaire* has many examples of this mode of framing, all the timbers being stop-chamfered, and the planks bolted through the braces.

2145*b.* The head of a door enriched with panelling; the door, with the planks carved with panelling, running ornament, and niches with figures; an early English door, with two foliated band hinges; of the same period with three hinges; of the decorated period, the panelled and enriched headed door at Holbeach Church, Lincolnshire, of which the construction (a framing of square panels, A A) is shown in *fig.* 759*b.*, rising from a plain plank $14\frac{1}{2}$ inches high; with other examples, are all given in Brandon, *Analysis*, etc. together with one of the perpendicular period, wherein the face has panelled planks, and square panel framing at back.

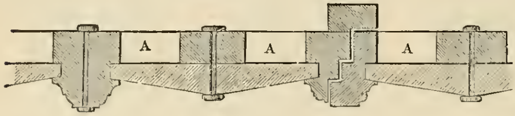

Fig. 759*b.*

2145*c.* The framework is sometimes placed externally and ornamented, as in *fig.* 759*c.*, from the west door of the Church of San Pietro; and *fig.* 759*d.*, from a door in a courtyard opposite that of Sta. Maria Antica, both at Verona. The sizes are $9\frac{1}{2}$ inches and 12 inches respectively, from centre to centre of panels. These cuts are taken from the plates of the *Dictionary.* The very elaborate moulded and carved door from the Norman portion (12th century) of the Palazzo Reale, at Palermo, is given in the illustrations of the *Dictionary of Architecture*, from careful measurements by the late J. M. Lockyer. In the doors of cedar or deal, but covered with paint, at the chapels of St. Martin and St. Giles at Notre Dame le Puy (cir. 1043–53.), the subjects, inscriptions, and borders are all obtained simply by sinking the ground 8-16ths of an inch. Gates of the same description are said to exist in the churches of Chamalières and Lavoûte-Chilhac in the same district. The wood doors, having iron plates beaten up into a pattern secured with large brass nails, at Huesca Cathedral, date about 1400-1405, the era of the erection of the west entrance. (*Street.*)

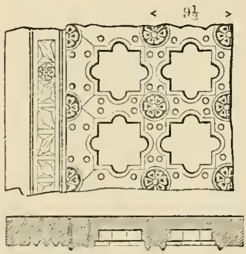

Fig. 759c.

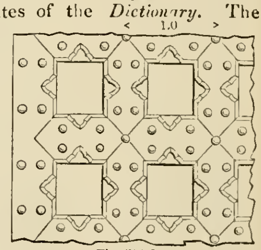

Fig 759*d.*

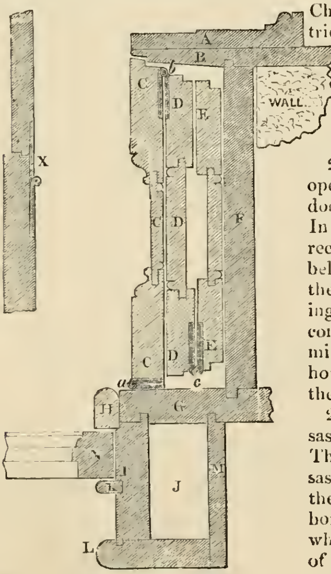

SHUTTERS.

2146. *Shutters*, which are the doors of window openings, are framed upon the same principles as doors themselves; but their backs are very often flush. In the better sort of buildings they are folded into recesses called *boxings*, whereof we shall give a figure below as an example of the ordinary method; but as the extent and different forms of windows vary, the ingenuity of the architect will be often required to contrive his shutters within a very small space. Into minutiæ we cannot enter in a work of this nature; however, in all their shapes, they are dependent on the leading principles given.

2147. *Fig.* 760. is a plan of the shutters, architrave, sash-frame, and part of the sash of common shutters. The cavity which forms the *boxing* into which the sashes fold is formed by the ground B (upon which the architrave A is nailed), the *back lining* F of the boxing, and the *inside lining* G of the sash-frame, whereof H is the *inside bead.* L is the *outside lining* of the sash-frame, M the *back lining* of it, and K the *parting bead*, so called from parting the upper and lower sash. The vacant space J, between the pulley piece I and M, is a cavity which contains the weights for balancing the sashes; N shows the plan of one of them. The shutters, when stretched out in their different folds, are supposed to cover one half of the window, another series being supposed to be placed on the other side of it. The *front shutter* CCC is hung by hinges at *a* to the inside lining G of the sash-frame. The inner shutters DDD and EE are called the *back flaps*, the former of which is hinged on to the front shutter at *b*, and the latter is hinged on to DDD at *c*. It will be immediately seen that these three will thus altogether turn upon the hinges at *a*, and cover, in one straight line, from both sides, the whole of the light of the window. When the boxes are scanty, the hinge, called a *back flap hinge*, may be placed as shown in X attached to the figure.

2148. In ordinary cases, this example will sufficiently exhibit the method to be adopted. When it is not applicable, the architect must apply himself to the work *pro re natâ*, in which, with very little attention, he will not find insurmountable difficulty.

2148*a*. The *boxings* of a window are further described in the Glossary and Addendum. Besides the *lifting shutters* commonly used in houses of a lower rate, which in their construction is simply a repetition of the sash-frame, we must notice briefly the many *revolving shutters* for inside and outside purposes, whether of iron, steel, or wood, laths. The latter were first made at Ipswich, some twenty years since, and were wound up and down by a winch and upright rod working a toothed wheel. They were soon afterwards made of iron, also worked by machinery. Within the last few years, their great convenience has led to many improvements, and the greater use of wood; instead of machinery, counterbalance weights were introduced. Later, they were "constructed of laths of wood rebated together, having numerous mortices, through which pass a series of tempered steel bands, causing the shutter to be *self-coiling*." Iron laths were also used. Lately, they "are made of steel, in one sheet, without either chains, links or rivets, or pins; the steel being corrugated transversely gives them the appearance of laths, and enables them to be coiled into a small space." We avail ourselves of some illustrations issued by Clark and Co., showing the adaptability of this shutter to various places, as windows, shops, doors, fireplaces, &c. *Fig.* 760*a*. shows the head and foot of an ordinary house window. At A, it is fitted with the shutter inside, and to pull down. At B, it is fitted also inside, and to lift up, the coil being placed in a boxing forming a step *on* the floor. When the position of the joists admit of so doing, the coil may be placed *in* the flooring, as at C; and occasionally it may be more convenient to place it even *under* the ceiling, at D. *Fig.* 760*b*. is the plan of a window frame, showing the groove, *a*, for the shutter, which is 1 inch deep by ⅞ths wide.

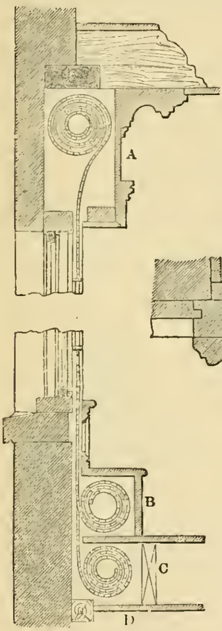

Fig. 760*a*.

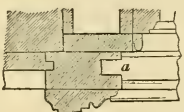

Fig. 760*b*.

2148*b*. A great improvement in securing the common shop shutters without a shutter-bar is one of the early inventions introduced by Jennings; these *shutter shoes* are so much advertised with illustrations that further notice of them herein is needless.

HINGEING.

2149. A very essential consideration in the neatness and beauty of joiners' work, is the formation of the joints on which are placed the hinges of doors and shutters. They ought to be so continued as to preserve the uniformity of the door or shutter on both sides, and as much as possible to be close enough to exclude a rush of air between the edges of the bodies to be hinged together, which, in this cold climate, is essential. In these joints, both angles of one of the bodies is usually beaded, to conceal the open space, which would otherwise be seen; and for preserving the appearance of the work, the hinges are made of such a curvature towards the eye, as to seem, when painted, a part of the bead itself on that side where the knuckle is placed, so that when hung the whole may appear to be one bead.

2150. The section of a door style, and part of the *hanging style* at the joint, are represented in A and B (*fig.* 761.), wherein the centre of the bead on each side is in the line of the straight part of the joint from the opposite side. In this figure, C is the centre of the bead, AG part of the joint in a line with its edge. Joining AC, draw AB perpendicular thereto. The other part BH is perpendicular to EF, which

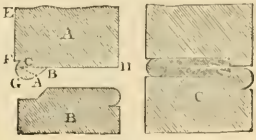

Fig. 761.

is the face of the door or hanging style. This is a joint suitable for many purposes, and may be made with common hinges. If crooked, it will assist in excluding the current of air, a point of no mean importance.

2151. In *fig.* 762. A and B exhibit a plane joint, beaded similarly on both sides. In this case, the plane of the joint is a tangent to the cylindrical surfaces of the two beads; and as the margin on each side is alike, no check to the rush of cold air is afforded. The hinge, moreover, is such that it cannot be made in the usual manner, but must be formed as at C.

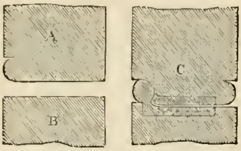

Fig. 762.

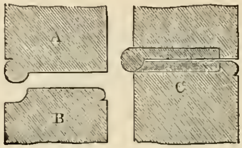

Fig. 763.

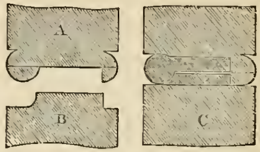

Fig. 764.

2152. *Fig.* 763. A and B represent a hinging wherein the plane of the joint from one side is directed to the axis of the bead on the other. The principle in it is the same as that in *fig.* 761., and it may therefore be hinged with common hinges, as shown in C, in which the two parts are conjoined. The methods shown in this and *fig.* 761. are useful in cases wherein a part of the margin is concealed on one side of the door.

2153. *Fig.* 764. A and B exhibit the beads of similar size on each side, and exactly opposite to each other, the joint being broken by indenting a part terminated by a plane directed to the axis of the two opposite beads. The hinges are required merely of the common form, the arrangement is strong, and the apartment rendered comfortable by their use. In C the parts are shown as hinged together.

2154. In *fig.* 765. the beads are on both sides, but not on the same piece, as in the last figure. The appearance is uniform, but the bead, which projects the whole of its thickness, is weakened. The junction is seen in the representation at C.

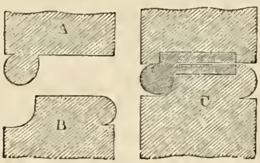

Fig. 765.

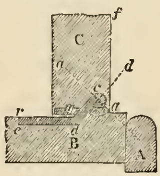

Fig. 766.

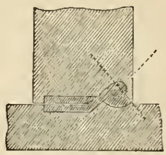

Fig. 767.

2155. *Fig.* 766. is a method that has been adopted for concealing the hinges of shutters. A is the inner bead of the sash-frame, B the inside lining, C the style of the shutter. For the form of the joint, let *af* be the face of the shutter, perpendicular to *ar* the face of the inside lining. Let the angle *f a r* be bisected by the straight line *aa*, and in the centre take *c*. Draw *dd* perpendicular to *aa*, cutting it in *c*, which is the centre of the hinge. From *c*, as a centre, describe the arc *am*, which must be hollowed out from the inside lining of the sash through the height of the shutter. In order to make room for the opening and shutting of the hinge, the internal right angle of the shutter must be cut out of its edge to the breadth of the hinges. The *toils* of the hinge are here for the purpose of strengthening them, represented of different lengths.

2156. In *fig.* 767. the hinges, which are for a door, are concealed, as the door allows it in the thickness of the wood, the ends of the hinges being of equal lengths.

2157. *Fig.* 768. shows the common method of hingeing shutters, a mode wherein the whole thickness of the hinge is let into the thickness of the shutter, the inside lining being assumed as too thin to afford sufficient hold for the screws employed to fasten them.

2158. *Fig.* 769. exhibits the hanging of a door with the centres concealed. Let *ad* be the side of the jamb in contact with the edge of the door; bisect it in *b*, and draw *bc* perpendicular to *ad*, make *bc* equal to *ba* or *bd*, and join *ac* and *cd*; from *c*, as a centre, describe the arc *acd*, which will show the portion to be hollowed out of the jamb. The centres are fixed to the upper and under parts of the door, and the former is to be so constructed as to allow its being taken out of the socket to unhang the door when required.

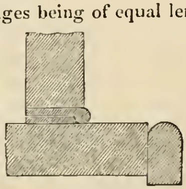

Fig. 768.

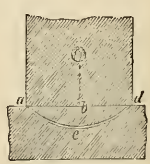

Fig. 769.

2159. Shutters are usually hung in the way represented in *fig.* 770., wherein the centre of the knuckle of the hinge is exactly opposite to the perpendicular part of the rebate. The dotted lines exhibit the flap when folded back.

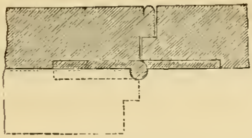

Fig. 770.

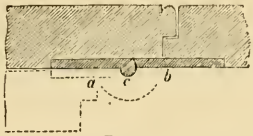

Fig. 771.

2160. When the axis of the knuckle cannot be disposed so as to fall opposite to the joint, the hinge is to be placed as shown in *fig.* 771. Thus, *ab* being the distance of the edge of the flap from that of the shutter, bisect it in *c*, which will be the point opposite whereto the centre of the hinge is to be placed. This arrangement is necessary, both when the shutters are not square at the ends, and when the boxing is restricted in space; the principle being to place the centre of the knuckle of the hinge at half the distance of the edge of the flap from the rebate on the edge of the shutter. In *fig.* 772. the two parts are shown hinged together.

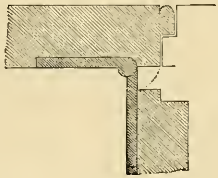

Fig. 772.

2161. When a door has attached to it any projection, and, when open, it is requisite to bring it parallel to its place when shut, the knuckle of the hinge (*fig.* 773.) must project at least as far as the projection in question. An inspection of the diagram, wherein the dotted lines show the situation of the door when folded back, will sufficiently convey the mode of conducting this expedient.

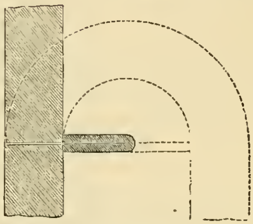

Fig. 773.

2162. *Fig.* 774. is the representation of what is called a *rule joint*, which is used when the piece to be hung is not required to open to more than a right angle. In this case, the centre of the hinge is necessarily in the centre of the arc. In *fig.* 775. the expedient shows the method turned to a right angle.

2163. The various methods of hingeing to suit every possible case would occupy a very large space, were we to enter into them; and even after exhausting all the cases that we may have imagined, others would arise to which no example given might be applicable; we therefore leave this portion of the subject of joinery, under an impression that the principles have been sufficiently developed to enable the student to pursue from them the application to any case that he may be called upon to put in practice.

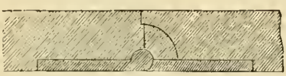

Fig. 774.

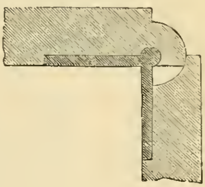

Fig. 775.

SASH-FRAMES AND SASHES.

2164. In *fig.* 760. the connection between the shutters and sash-frame has been fully explained; we may now, therefore, proceed to the detail of a common sash-frame with its sashes, supposing them to be hung so as to be balanced by weights, suspended by sash-lines running over pulleys, capable of balancing those of the sashes themselves. On the case of *French sashes*, which open like doors, we do not think it necessary to dilate. *They* are, in fact, nothing more than glazed doors; and the principal object for attainment in their construction, is to prevent the rain from penetrating into the apartments they serve, as well where they meet in the middle as at their sills, which is a subject requiring much care and attention.

2165. In *fig.* 776. is shown the construction of a sash-frame, and the method of putting together the several parts, wherein R is the elevation of the frame, of which ABCD is the outer edge. The thinner lines at EF, GH, FG, are grooves whose distances from the edges of the sash-frame LM and KI are equal to the depth of the boxing, together with three-eighths of an inch more that is allowed for margin between the face of the shutter, when, in the boxing, and the edges ML and KI of the sash-frame next to the bead. S is a horizontal section of the sides, whereon is shown also the plan of the sill. T is a vertical section of the sill and top, in which is shown the elevation of the pully style *m* and *n*, and the pullies let into the pully piece. U is the horizontal section of the sides, showing also a plan of the head of the sash-frame. V the elevation of the outer side of the sash-frame; the outside lining being removed for the purpose of showing the work within the sash-frame. In this *fg* is the *parting strip* fastened by a pin; *ed* one of the weights connected to the sash by means of a line going over the pulley *c*, the other end being fixed to the edge of the sash.

The weight *de* is made equal to one half the weight of the sash. W is the head of the sash-frame before put together, and X shows the edge of W. Y is the edge of the bottom, exhibiting the manner of putting the styles in it, and Z is the plan of Y. *Fig.* 777., Nos. 1. and 2., are sections of the sills of sash-frames, with sections of the under rail of the sash, showing the best method of constructing them, in order to prevent rain from driving under the sash-rail. In each of these, A is the section of the bottom rail, B a section of the bead tongued into the sill, C a section of the sill. *Fig.* 778. exhibits sections of the meeting rails of the upper and lower sashes, with side elevations of the upright bars; C is the rebate for the glass, D a square, E and F an astragal and hollow moulding, G a fillet. The smaller letters mark the same parts of the under sash. *Fig.* 779. is the section of an upright bar with the plans of two horizontal bars, showing the *franking* or manner in which they are put together to keep the upright bars as strong as possible. The thickness of the tenon in

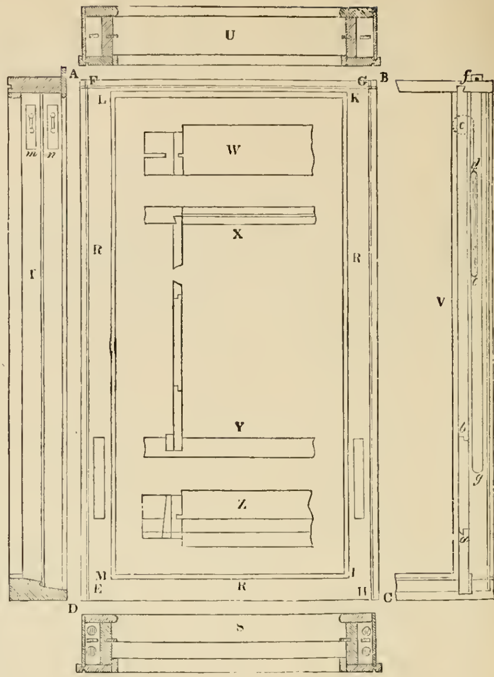

Fig. 776.

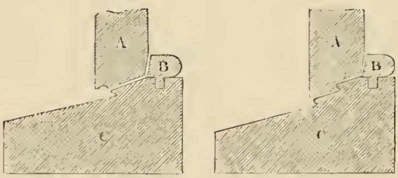

Fig 777.

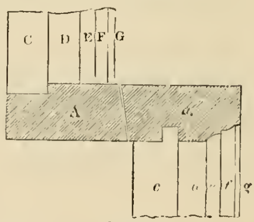

Fig. 778.

general is about one sixteenth of an inch to the edge of the hollow of the astragal, and close to the rebate on the other side. *hh* is a dowel to keep the horizontal bars still firmer together. In this diagram the letters refer to the same parts as in the preceding figure; and it is also to be observed, that no rebate is made for the glass on the inside meeting rail, a groove being made to answer that purpose. *Fig.* 780. exhibits four sections of sash bars. But their forms, as in the case of mouldings, generally depends on the taste of the architect.

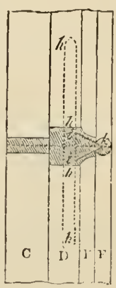

Fig. 779.

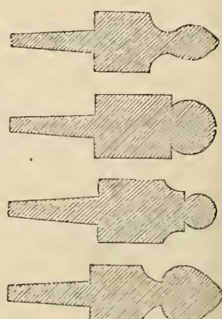

Fig. 780.

2165*a*. Several patents have been taken out, of late years, for hanging sashes so that they may be removed from the frames for cleaning or repairing without taking down the inside beads, an operation which always results in at least damaging them in a few years. They are not always satisfactory. Gurman's *sash pocket and fittings*, and Gribbons' *sash mountings*, were introduced about 1858. Other inventions have been made for hanging them so that the upper and lower sashes shall open with the same action. William M'Adam's "Imperishable material applied to sash and other pulleys, economical sash weights, and improved methods of hanging windows," comprises a material for pulleys of vitrified stoneware, proof against the action of the weather.

For window weights he substitutes a cheap material manufactured out of various kinds of refuse; and suggests an improvement in the mode of hanging windows whereby one weight can be made to answer the same purposes as two applied in the usual way. R. Adams has a patent anti-accident reversible and sliding window, for cleaning, ventilation, &c., whereby the outside of the sashes can be safely revolved, or reclined into the room for cleaning, &c., thus removing all danger to the cleaner. *Meakin* has a new patent standard sliding sash, for cleaning. For sash lines, see par. 2260.

2165*b*. The *French casement window*, or *sash door* as it is called when it opens down to the ground, is a feature commonly introduced even in English town houses. Its most ordinary form for small apertures is that of two leaves opening inwards or outwards, meeting in the centre of the opening; one leaf being secured to the frame by a bolt at top and bottom, and the other, when closed, is fastened to the first by a handle, fixed on the second leaf and turning over a staple fixed on the first. When the casement is high, this second leaf may require a bolt also at top and bottom to prevent the wind bending it (when inwards), and so admitting cold air and wet. When placed towards an exposed quarter and subject to driving rains, it becomes necessary to take extra precautions to prevent the wet being blown through the joints at the bottom and the sides. To effect this object, the stiles, rails, and frames are beaded and sunk in various manners; some are shown in *figs.* 780*a*. and 780*b*., sills and bottom rails. For the latter, a *water bar* is now much used.

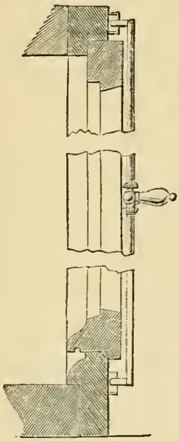

Fig. 780*a*.

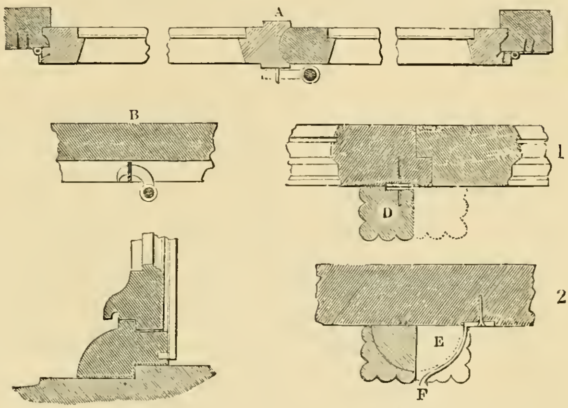

Fig. 780*b*. Fig. 780*c*.

2165*c*. The next improvement is perhaps that of affixing to the leaf which is first opened an upright bar, which turns, and on being closed, fits against the other leaf, and by a hook at top and bottom effectually fastens both leaves. A similar method is shown in *fig.* 780*c*., adopted at Pisa, as given in the *Papers* of the Royal Engineers, x. 187. The upright square reeded bar D, is moved to or from the sash, as the window is required to be opened or shut; the top and bottom of the bar being rounded, as shown at E, so as to slide into two segmental plates F, secured to the sill and lintel. 1 is a plan of the two casements, and 2 a plan of the head and sill.

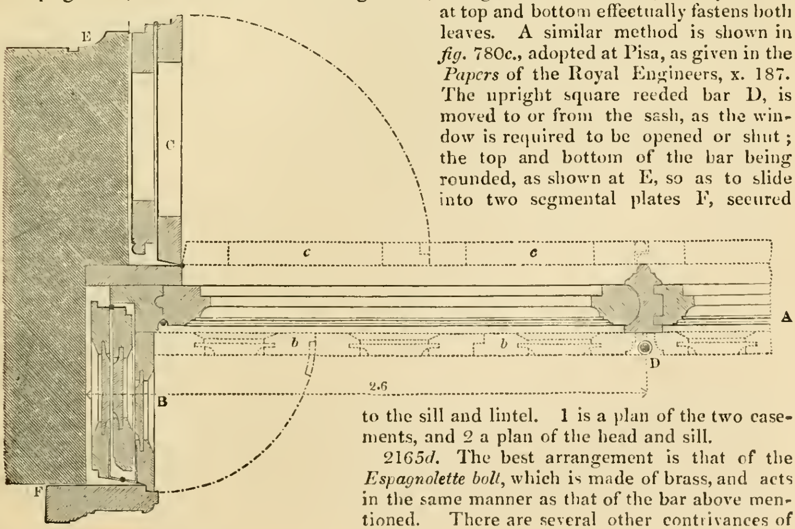

Fig. 780*d*.

2165*d*. The best arrangement is that of the *Espagnolette bolt*, which is made of brass, and acts in the same manner as that of the bar above mentioned. There are several other contrivances of a similar kind to effect the object, but the above are those in most general use. There is also a late invention for forming the bolt into a plate, and setting it in a groove in the *edge* of the meeting stile, a corresponding groove being formed in the other stile to receive its half of the plate when moved forward by the handle in closing the casement. This, at the same time, forms a weather bar. (See *par.* 2259.)

2165*e*. The *fig.* 780*a.* is a section of an ordinary arrangement in France for a casement. A is the plan, taken across the middle of the height, near the handle; and B the plan of the hooks at top and bottom of the rod, working into a staple fixed in the head and in the sill, with the movement of the rod by its handle. The round and hollow joint in the middle of the casement necessitates the two leaves being closed together and pressed into the frame when shutting the leaves, thus securing all the joints from admitting air or water.

2165*f*. *Fig.* 780*d.* is a plan of the elaborate but usual French casement, as lately put up to the stone-fronted houses in the Rue de la Victoire, at Paris. It is given by Daly, in the *Revue Generale de l'Architecture* of 1858. A shows the casements when shut; B the shutters closed in the boxings; and *b b* the shutters when opened out. C the *persiennes* or outside blinds shut against the stone reveals; the ordinary mode is for them to shut on the face of the wall, which spoils the architecture of the façade; *c c* the same when closed; D the espagnolette bolt; E the outside architrave; and F the inside architrave.

GROUNDS.

2166. *Grounds* are formed of pieces of wood forming skeleton frames, and attached to walls, around windows, doors, or other openings, for the facility of fixing architraves or other mouldings upon them. For doorways the front and back grounds were connected by a third, specified as *dovetailed backing.* They are disused in common work, the grounds being the wrought woodwork carrying the mouldings, forming a single or double faced architrave, and having the jamb space filled by a single or a double rebated and beaded jamb lining. The grounds served as screeds for the plastering, for which purpose the edge was chamfered, rebated, or grooved. Grounds or *narrow grounds* were those to which the bases and surbases of rooms were fastened; slips of wood now receive the skirtings of rooms. All these appliances were secured to *wood bricks*, which themselves have given way to plugs or wedges. Wright and Co's patent improved *fixing blocks* for linings to walls, and floors, are substitutes for wood as a fixing. They take and retain nails equal to wood; they do not shrink, split, or decay, or become loose; whilst the crushing weight is fully equal to good average brick or stone. They are built into reveals as bricks, without destroying the bond. When required for skirtings, for boarding, and such like, the brick is made $\frac{3}{4}$ inch wider, offering for the plastering a better key than that obtained when using the wood ground. They are useful also in other cases. In all cases the *grounds* ought to be fixed vertical on the face and edge, and be fixed firm and solid in every part; for otherwise the inside work cannot be well finished, as in plastered rooms the plaster is worked to them.

2167. In fixing window grounds, the sash-frame must be first carefully placed so as to stand perfectly vertical; and then the face of the ground must stand quite parallel to the face of the sash-frame, and project about three quarters of an inch from the face of the naked brickwork, so as to leave a sufficient space for the thickness of the plaster. The edge of the ground should be in the same plane with the edge of the sash-frame, or, as the workmen term it, "out of winding." The edge of the architrave, when finished, in ordinary cases, will stand about three-eighths of an inch within the inner edge of the sash-frame, so that a perpendicular line down to the middle of the grounds would stand exactly opposite to a perpendicular line down to the middle of the sash-frame.

FLOORS OR FLOOR BOARDS.

2168. In the laying of floors, the first care to be taken is that they be perfectly level, which, owing to the nature of the materials whereof they are constructed, is a difficult task. The chief sorts of floors may be divided into those which are *folded*, that is, when the boards are laid in divisions, whose side vertical joints are not continuous, but in bays of three, four, five, or more boards in a bay or fold; and those which are *straight joint*, in which the side joints of the boards are continuous throughout their direction.

As soon as the windows are fixed, the floors of a building may be laid. The boards are to be placed on their best face, and put to season till the sap is quite exhausted, when they may be planed smooth, and their edges shot and squared. The opposite edges are brought to a breadth by drawing a line on the face parallel to the other edge with a flooring guage, after which the common guage is used to bring them to a thickness, and they are rebated down on the back to the lines drawn by the guage.

2169. The next operation is, to try the joints, which, if not level, must be brought so, either by *furring up* if they be hollow, or by adzing down if they are convex, the former being more generally the case.

2170. The boards used for flooring are battens, or deals of greater breadth, whose qualities are of three sorts. The best is that free from knots, shakes, sapwood, or cross-grained stuff, selected so as to match well with one another. The second best is free of shakes and sapwood, and in it only small sound knots are permitted. The third, or most common sort, are such as are left after taking away the best and second best.

2171. The joints of flooring-boards are either quite square, ploughed and tongued, rebated, or dowelled; and in fixing them they are nailed on one or both edges, when the joints are plain and square without dowels. When they are dowelled, they may be nailed on one or both sides; but in the best dowelled work the outer edge only is nailed, by driving the brad through the edge of the board obliquely, without piercing its surface. which, when the work is cleaned off, appears without blemish.

2172. In laying the floor-boards, they are sometimes laid one after the other, or one is first laid, then the fourth, at an interval of something less than the united breadth of the second and third together. The two intermediate boards are then laid in their places with one edge on the edge of the first board and the other upon that of the fourth board, the two middle edges resting against each other, rising to a ridge at the joint. In order to force these boards into their places, two or three workmen jump upon the ridge till they have brought the under sides of the boards close to the joints; they are then fixed in their places with brads. This method is that first mentioned under this head, and in it the boards are said to be folded. We have here mentioned only two boards, but four boards are most commonly folded at a time, and the mode is always resorted to when a suspicion exists that the boards are not sufficiently seasoned, or they are known not to be so. The headings of these folds are either square, splayed, or ploughed and tongued. If a heading occurs in the length of the floor, it should be invariably made to fall over a joist, and one heading should not meet another.

2173. In dowelled floors, the dowels should be placed over the middle of the interjoist rather than over the joists, so that the edge of one board may be prevented from passing that of the other. When the boards are only bradded upon one edge, the brads are concealed by driving them in a slanting direction through the outer edge of every successive board, without piercing the upper surface. In adzing the under sides of floor-boards over each joist, great care should be taken to chip away the stuff straight, and also to avoid taking away more of the stuff than is necessary, in which case the soundness of the floor will not be compromised.

2173*a*. The practice of joining the edges of *boards* by means of rebates, or of tongued grooves, does not appear to have existed before the 15th century. Previously to that period, the use of ledges dovetailed to the whole or part of their depth into chases, of dovetailed wooden cramps, or of wood or iron pins or dowels, was general. In the cathedral at Messina the boarding under the tiling is in two thicknesses that cross each other; and, in the cradle roofs, it was usual to groove and tongue the wainscoting, and also to cover those joints with moulded fillets, as shown in the examples in *fig.* 780*e*. The thickness of this wainscoting, which was oak split, not sawn, was only three-eighths of an inch (barely more or less), and it was frequently put together in the manner shown in *fig.* 780*f*.

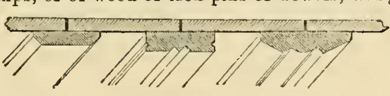

Fig. 780e.

Fig. 780f.

2173*b*. The nailing of floors is not satisfactory in appearance. S. Putney has designed the *Pavodilos* solid wood flooring to remedy the disadvantages of an ordinary nailed floor, and to obviate the necessity for a parquet floor over it. By a mode of interlocking throughout the sides of each board, a perfectly smooth, air-tight, and dust-proof surface is obtained, free from nail holes and indentations (*fig.* 780*g*). This floor is laid upon the joists direct, and edge-nailed to it in the shoulder. Another method is adopted by

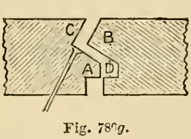

Fig. 780*g*.

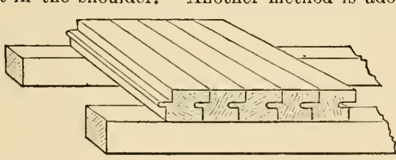

Fig. 780*h*.

S. Jennings, the boards being solid, rabbeted, and tongued, and edge-nailed, forming dust-proof joints, with a fair surface (*fig.* 780*h*).

2173*c*. *Woodblock flooring.* A warm, solid, durable, non-slippery floor, free from foul air, vermin, and damp, being laid on a concrete bed, is that invented about 1856 by Mr. W. White, F.R.I.B.A., and called *woodblock flooring.* It consists of oblong blocks, placed diagonally on concrete, being prepared from first or second yellow deals, which are Burnetized and seasoned. This invention has produced other systems. *W. Duffy's* patent immoveable acme, being pinned at the end and sides. *Lowe's* improved system, the blocks being secured to the bed of concrete by a composition. *S. Jennings's* prepared paraffined flooring, which has been laid in several large hospitals and infirmaries, for which places it appears well suited, as also in houses. *Geary's* patent premier system, wherein the blocks are keyed down and cannot get loose. In *Geary and Walker's* improved patent Invincible system, each block forming the flooring is firmly keyed to the substructure by means of metal keys dovetailed into the under side of the blocks; the other end of the keys being embedded in a matrix, acting not only as a damp-proof course and against dry rot, but also as a floating to the concrete foundation in place of the usual cement surface. Another is *Nightingale and Co.'s* bevelled principle of woodblock flooring. *Ebner's* patent hydrofuge floor is formed of, first, a cement bed in which are set small iron channels; second, a bed of mastic which runs into the channels and into grooves formed in the bottom of the wood blocks or parquet; it is considered to be a fireproof, damp-proof, noiseless, and warm floor.

2173*d*. It is stated that in Western Australia both the woods called Jarrah and Karri are used for paving, and from exhaustive tests it is considered that Karri is the superior wood for most purposes, and paving in particular. This refers to paving for roadways, a subject of high importance, and upon which opinions are much divided. It, however, does not come within the province of the joiner, and scarcely within the scope of this work. The engineer to the Corporation of the City of London reported (1888) that about forty years since many of the principal thoroughfares of the City were paved with wood, . . . most of which proved unsatisfactory; in 1853 only eight streets remained so paved. Since 1873 (December) the granite in nearly the whole of the main thoroughfares in the City has been replaced by either asphalte or wood, but mainly asphalte. Of the latter there are now 23,579 lineal yards, or about 13 miles; and of the former, 10,898 lineal yards, or about 6 miles. The parishes in the metropolis differ in their opinions, some entirely condemning wood for asphalte, others using wood only, and one, at least, keeping to granite as cheapest in all ways.

2173*e*. *Parquetry, &c.* Floors of principal rooms of the better class of houses are now being finished with parquetry. It is composed of different pieces of some four or five coloured and hard woods, arranged in regular geometrical figures, for the whole of a room, corridor, or gallery; or applied as borders round carpets, to treads and risers of stairs and landings; and even as dadoes, panellings, friezes, &c. Parquetry is kept clean by sweeping and periodical waxing. It is usually made *solid*, one inch thick, grooved, tongued, and keyed at the back and corners. When the woods are applied only as a veneer, they are liable to warp and separate by heat. *Turpin's* thin parquet floor is $\frac{5}{16}$ in. thick, prepared on deal back laminations to wear equal to inch solid parquet; it can be used for veneering an old existing deal floor, and is susceptible of removal at pleasure.

2173*f*. *Wood carpet* parquetry is three-eighths of an inch thick, firmly nailed down with small barbed wire brads on to the top of the old floor; it is stated to be of a durable nature and texture, bearing constant traffic. It may likewise be used for wainscotings, and walls and ceilings. Ebner's parquetry is attached firmly to basement floors without any under flooring, as above explained. "Wood tapestry (Howard's patent) for covering walls, ceilings, and other surfaces with real wood at a less cost than painting and graining," dates from about 1865.

2173*g*. *Marquetry*, or the inlaying of coloured woods, became very general at the latter end of the 16th century. Oak was inlaid with ebony ornaments in the panels and stiles of wainscoting; and the framing of doors, windows, and shutters was sometimes made of dark-coloured woods, the panels being of light colours, inlaid with ornaments, profiles of heads, &c. This process is applied greatly to furniture, where it is imitated by paint. A new method has been introduced, of applying a printed pattern to the prepared wood, as in the Tunbridge ware, and then varnishing it as usual. "Ornamental pyrographic woodwork," for panels and in cabinet work, being a process for burning-in ornament upon wood, is now in operation.

FRAMING.

2174. In *fig.* 781. are shown several methods for framing angles in dadoes, skirtings, troughs, and other objects, whereof A exhibits the method of mitring a dado on exterior angles in an apartment. In fixing this together, brads may be driven from each side. B is a method of framing used for troughs or other rectangular wooden vessels. C is a method of putting a dado or skirting together at any interior angle of a room. This mode is also employed for water-trunks, or troughs. In D is shown the manner of fixing and finishing two pieces of framing together, with a bead at their meeting, by which the joint is concealed. It is used only in common finishings. In those of a better sort the angle is kept entire, and only a three-eighth bead used at the joint. It is of great importance in all joiner's work to preserve the sharpness of the angles of the work, and many prefer to employ the method shown in F, without any bead at the joint. In this the joint is made as close as possible, and is well glued together. If additional strength be required, blockings may be glued in the interior angle, which will make it quite firm. The method. by a simple mitre at E, is not so good as at A, because it has no abutment.

2175. When it is required to glue up large work, those edges which are to receive the glue should be well warmed at a fire, and then, while warm, and the glue as hot as possible, they should be united, inasmuch as glue never holds well when it is chilled or cold.

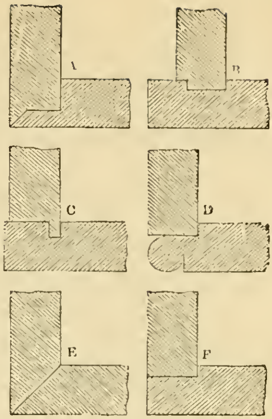

Fig. 781.

2175*a*. In studying mediæval *framing*, much attention should be given to the modes in which the junction of pieces was effected ; there are two which are chiefly important. The first is a characteristic in the work of the carpenter as well as of the joiner, viz., the shoulder, either solid or applied (*figs.* 701*k*. and 701*l*.). In the first case, it is not economical of material, which was a great point of consideration ; and therefore it is rarely seen except on short pieces, such as the posts of doorways : but as an applied means of strength it is almost as common in good work as a corbel in masonry. The second is the use of the mortice and tenon with trenails ; and the extreme care which was given to this part of the work is scarcely to be expected in these days of speed and cheapness. It may be predicted that no truly mediæval work will now be ever reproduced except in the fancy-work of the cabinet-maker and the smith.

2175*b*. Another peculiarity is the use of stops to all chamfers and mouldings at points of junction of framing : it is not until the last phase of pointed art, that the stop of the moulding of a stile is worked in the rail, or that the corner of a panel is rounded : it is only in the dawn of the renaissance that the *four-panel quirk ogee front and square back* can be portion of a specification for a door ; for a mitre-joint is eminently not a feature of mediæval joinery. The juxtaposition, even accidentally. of two stop-chamfered edges, suggests a means of enriching work, whether in open or close panels. The avoidance of work against the grain, and of large hollows, is also mentioned as a characteristic of joiner's work in pointed art; but this disappears in the course of the 15th century. The mediæval joiner, depending sometimes upon halving his work together, more frequently thought time less valuable than material, and did not repent a profusion of morticing and tenoning, to which he added the trouble of fastening with wooden trenails or iron pins. As large an amount of rebating and of grooving, however, was done in framing by the joiner as could be expected by those who were accustomed to the back-jointed and the grooved work of the mason.

2175*c*. Perhaps the most defective part of the joinery of the middle ages is that which consisted in planting one thickness upon another. The contrivances in glueing and dovetailing were not of themselves sufficient ; and recourse was obliged to be had to nails. The absence of screws and nails, except where nail heads could be made decoration, is another characteristic of mediæval joinery. It was not until the beginning of the 14th century that the transition from planted work to panel work can be said to have appeared in any strength. At the end of that century, an architect might have specified a door as *nine-panelled, beaded three edges, chamfered bottom, and raised panel both sides* ; but his beads would have been stuck in the solid, and not applied : during the whole of the 14th century planted work was commonly introduced, as in screens, closets, and shutters, where perhaps a sham buttress serves to conceal the wide joint made by the work in consequence of the inaccurate finish of the hingeing. A curious method, which must have been laborious before the introduction of the plane, of attaching the planted work, consisted in running in the ground a chase wide enough to take the whole breadth of the planted stuff, and then to run a couple of grooves in that chase ; of course the back of the planted stuff had to be worked to match, with two tongues to enter the grooves.

2175*d*. The size of the materials was restricted. Three inch stuff for the thickness of rails and stiles, with a not much wider face ; inch and a half stuff for mouldings to be planted ; panels not more than eight inches wide, and three-quarters of an inch thick ; may be quoted as usual dimensions for joiner's work. The observance of this restriction constitutes an essential characteristic of mediæval work.

STAIRS.

2176. *Stairs* and their *handrails* are among the most important objects of the joiner's skill. The choice of situation, sufficiency of light, and easy ascent, are matters for the exercise of the architect's best talent.

2177. There are some leading principles which are common to all staircases, of whatsoever materials they may be constructed. Thus it is a maxim that a broad step should be of less height than one which is narrower; and the reason is sufficiently obvious, because in striding, what a man loses in breadth he can more easily apply in raising himself by his feet. Now, as in common practice it is found that the convenient rise of a step 12 inches in width is $5\frac{1}{2}$ inches, it may be assumed as some guide for the regulation of other dimensions. Thus $12 \times 5\frac{1}{2} = 66$, which would be a constant numerator for the proportion. Suppose, for instance, a step 10 inches in breadth, then $\frac{66}{10} = 6\frac{3}{5}$ inches would be the height; and this agrees very nearly with the common practice. The breadth of steps in the commonest staircase may be taken at 10 inches at a medium. In the best staircases the breadth of the step should not be less than 12 inches, neither should it be more than 18 inches. (See 2814.)

2178. Having adjusted the proportions of the steps, the next consideration is to ascertain the number of risers which will be necessary to pass from one floor to another. If the height divided by the rise of each step should not give an exact number of risers, it is better to add one rather than diminish the number.

2178*a*. An easy mode of proportioning steps and risers may be obtained by the annexed method. Set down two sets of numbers, each in arithmetical progression; the first set showing the width of the steps, ascending by inches, the other showing the height of the riser, descending by half-inches. It will readily be seen that each of these steps and risers are such as may suitably pair together. (Newland, *Carpenter's and Joiner's Assistant*, 1860, p. 197.) It is seldom, however, that the proportion of the step and riser is exactly a matter of choice—the space allotted to the stairs usually determines this proportion; but the above will be found a useful standard. In first-class buildings the number of steps is considered in the plan, which it is the business of the architect to arrange in accordance with the style of the edifice.

Treads. inches.	Risers. inches.
5	9
6	$8\frac{1}{2}$
7	8
8	$7\frac{1}{2}$
9	7
10	$6\frac{1}{2}$
11	6
12	$5\frac{1}{2}$
13	5
14	$4\frac{1}{2}$

2179. The width of the better sorts of staircases should not be less than 4 feet, to allow of two persons freely passing each other; but the want of space in town houses often obliges the architect to submit to less in what is called the *going* of the stair.

2180. The parts of every step in a staircase are one parallel to the horizon, which is called the *tread* of the step, terminated on the edge by a moulded or rounded *nosing*, and the other perpendicular to the horizon, which is called the *riser* of the step. Where great traffic exists, the treads of stairs wear down at the nosing. This is often protected by a brass edging, and by lining it with lead. Hawksley's *patent treads* have come largely into use, not only at railway stations, but in warehouses and other buildings where there is much traffic on the stairs and landings.

2180*a*. A curious instance of economy of material is given in *fig.* 781*a*., which shows the mode of getting six steps out of round timber 30 inches in diameter, being a saving of about ten per cent. upon the attempt to cut up square timber. Such solid steps were housed into the carriage; A showing the under side of it in relation to the step B. In straight flights the system of carrying solid newels from bottom to top of the staircase is one which has since been repeated successfully in iron construction. The ingenuity of the mediæval joiner in this subject is seen best treated in Viollet le Duc's dictionary. (See *par.* 2185.)

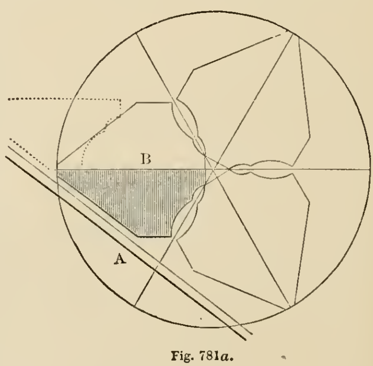

Fig. 781*a*.

2181. Stairs have many varieties of structure, dependent on the character, situation, and destination of the building. We shall now, therefore, describe the method of carrying up *dog-legged*, *bracket*, and *geometrical stairs*.

2182. A Dog-legged Staircase is one which has no opening or well-hole, and in which the rail and balusters of the progressive and returning flights fall in the same vertical planes. The steps in it are fixed to strings, newel, and carriages, the ends of the steps of the inferior kind terminating only upon the side of the string without any housing. Y and Z in *fig.* 782, are the plan and elevation of a staircase of this kind; AB is the lower newel whereof the part BC is turned. On the plan, *a* is the seat of this newel. DE and FG in Y are the lower and upper string boards framed into newels, KL is a joist framed into the trimmer I. The lines on the plan represent the faces of the steps in the elevation without which is as follows: — In the upper ramp, for example, produce the top of the rail HM to P; draw MN vertical, and produce the straight part ON of the pitch of the rail to meet it in N, making NO equal to NM. Draw OP at a right angle to ON. From P, as a centre, describe the arc MO, and then the other contrary curve, which will complete the ramp required. The *story rod* RS is in the fixing of all staircases a necessary instrument; for in fixing the steps and other work by a common measuring rule, bit by bit, the chances are that an excess or defect will occur, to make the staircase faulty; which cannot be the case if the story rod is applied to every riser, and such riser be regulated thereby.

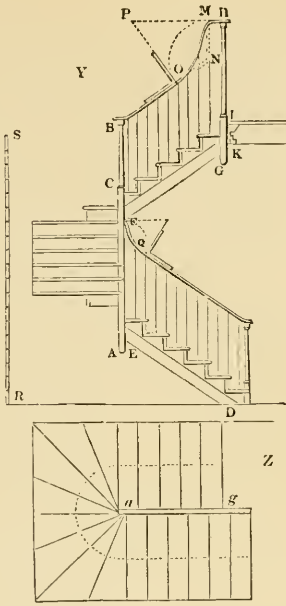

Fig. 782.

2183. A Bracket Staircase is one which has an opening or well, with strings and newels, and is supported by landings and carriages. The *brackets* are mitred to the end of each riser, and fixed to the string board, which is usually moulded like an architrave. In this sort of staircase the same methods are to be observed in respect of dimensions and laying off the plan and section as in a dog-legged staircase. Nothing is to be done without the story rod just described, which must be constantly applied in making and setting up the stairs. The method of forming the ramps and knees has been touched upon in the preceding article, and the few particulars we intend to give respecting scrolls and handrailing will be reserved for a subsequent page. In bracket stairs the internal angle of the steps is open to the end, and not closed by the string, as in common dog-legged stairs; the neatness also of the workmanship is as much attended to as in geometrical stairs. The balusters should be nicely dovetailed into the ends of the steps by twos, and the face of each front baluster is to be in a plane with the front face of the riser, and all the balusters being equally divided, the face of the middle one must of course stand in the middle of the face of the riser of the preceding step. The treads and risers are previously all glued up and blocked together, and when put in their places the under side of the step is nailed or screwed into the under edge of the riser, and then rough bracketed to the strings, as in a dog-legged staircase, in which the pitching pieces and rough strings are similar.

2184. A Geometrical Staircase is one whose opening is down its centre, or, as it is called, an open newel, in which each step is supported by one end being fixed in the wall or partition, the other end of every step in the ascent having an auxiliary support from that immediately below it, beginning from the lowest one, which, of course, rests on the floor. The steps of a geometrical staircase should, when fixed, have a light and clean appearance, and, for strength's sake, the treads and risers, when placed in position, should not be less than $1\frac{1}{8}$ inch thick, supposing the going of the stair or length of the step to be 4 feet. For every 6 inches in length of the step an eighth of an inch should be added. The risers should be dovetailed into the cover, and in putting up the steps, the treads are screwed up from below to the under edges of the risers. The holes for sinking the heads of the screws ought to be bored with a centre bit and fitted closely in with wood well matched, so that the screws may be entirely concealed, and appear as a uniform surface without blemish. Brackets are mitred to the risers and the nosings are continued round; but this practice induces an apparent defect, from the brackets, instead of giving support, being themselves unsupported, and actually depending on the steps, being indeed of no other use than merely tying together the risers and treads of the internal angles of the steps; and from the internal angles being hollow, except at the ends, which terminate by the wall at one extremity, and by the bracket at the other, there is an appearance of incomplete finish. The cavetto or hollow is carried all round the front of the slip, returned at the end, and again at the end of the bracket, thence along the inside of it, and then along the internal angle at the back of the riser.

2185. The ancient mode, however, was the best, in which the wooden was an imitation of the method of constructing geometrical stairs in stone, which will be found under Masonry, in the previous Section III.; that is to say, the making of the steps themselves solid, and in section of the form of a bracket throughout their length. This is a more expensive method, but it is a solid and good one, and is still practised on the Continent, especially in France. (See also par. 2180*a*.)

2186. In *fig.* 783. X is the plan and Y the elevation, or rather section, of a geometrical staircase. AB in X is what is called the *cur-tail step* (curved like the tail of a cur dog) which must be the first step fixed. CCC are the *flyers* supported from below by rough carriages, and partly from the string board DHEF in Y. The ends next the wall are sometimes housed into a notch board, and the steps then are made of thick wood and no carriages used. GGG are *winders* fixed to bearers and pitching pieces, when carriages are used to support the flyers. The winders are sometimes made of strong stuff firmly wedged into the wall, the steps screwed together, and the other ends of the steps fixed to the string DEHF. In all cases of wooden geometrical stairs their strength may be greatly augmented by a flat bar of wrought iron coinciding with the under side and screwed to the string immediately below the steps. HIK in Y is the wall line of the sofite of the winding part of the stairs, and LMN part of the rail supported by two balusters upon every step. Where the space of the going of the stairs is confined, the French have long since introduced, as in *fig.* 784., the practice of placing the balusters outside the steps, which affords more room for persons ascending and descending.

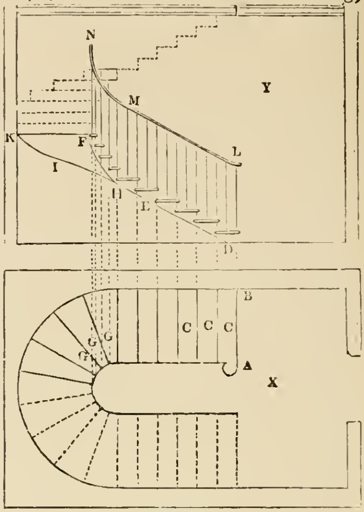

Fig. 783.

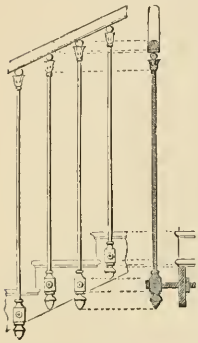

Fig. 784.

HANDRAILS AND CUR-TAIL STEP.

2187. The upper part of the fence formed by capping the balusters of stairs is called the *handrail*, whose use, as its name imports, is for a support to the hand in the ascent and descent of stairs. The hand, for support to the body, should glide easily over it without any strain, whence it is evident, that to be properly formed, it must necessarily follow the general line of the steps, and be quite smooth and free from inequalities. It must be obvious to the reader who has thus far followed us throughout the different previous portions of our labours, that the chief principle of handrailing will be dependent on the methods of finding sections of cylinders, cylindroids, or prisms, according to three given points in or out of the surface, or, in other words, the section made by a plane through three given points in space. The cylinder, cylindroid, and prism are hollow, and of the same thickness as the breadth of the rail, or the horizontal dimension of its section; and their bases, their planes or projections on the floor. Thus is formed the handrail of a staircase of a portion of a cylinder, cylindroid, or prism whose base is the plane of the stair, for over this the handrail must stand, and is therefore contained between the vertical surface of the cylinder, cylindroid, or prism. As the handrail is prepared in portions each whereof stands over a quadrant of the circle, ellipse, or prism of the base which forms the plane, such a portion may be supposed to be contained between two parallel planes, so that the portion of the handrail may be thus supposed to be contained between the cylindrical, cylindroidal, or prismatic surfaces and the two parallel planes. The parts to be joined together for forming the rail must be so prepared that in their place all the sections made by a vertical plane passing through the imaginary solid may be rectangular: this is denominated *squaring the rail*, and is all that can be done by geometrical rules. But handrails not being usually made of these portions of hollow cylinders or cylindroids, but of plank or thicknesses of wood, our attention is naturally drawn to the consideration of the mode in which portions of them may be formed from planks of sufficient thickness. The faces of the planks being planes, they may be supposed to be contained between two parallel planes, that is, the two faces of the plank. Such figures, therefore, are to be drawn on the sides of the plank as to leave the surfaces formed between the opposite figures, portions of the cylindrical, cylindroidal, or other surfaces required, when the superfluous parts are cut away. A mould made in the form of these figures, which is no more than a section of them, is called the *face mould*.

2188. The vertical, cylindrical, or cylindroidal surfaces being adjusted, the upper and lower surfaces must be next formed: and this is accomplished by bending another mould round the cylindrical or cylindroidal surfaces, generally to the convex side, and drawing lines on the surface round the edge of such mould. The superfluous wood is then cut away from top to bottom, so that if the piece were set in its place, and a straight-edge applied on the surfaces so formed, and parallel to the horizon directed to the axis of the well-hole, it would coincide with the surface. The mould so applied on the convex side for forming the top and bottom of the piece, is called the *falling mould*. For the purpose of finding these moulds it is necessary to lay down the plan of the steps and rail; next, the falling mould, which is regulated by the heights of the steps; and lastly, the face mould, which is regulated by the falling mould, and furnishes the three heights alluded to.

2189. *Fig.* 785. exhibits two of the most usual forms of handrails. The upper part, A and B of the figure, are sections of the rail and mitre cap of a dog-legged staircase. Vertical lines are let fall from the section of the rail A, to the mitre in B; from thence, in arcs of circles, to the straight line passing through the centre of the cap at right angles to the former straight lines; then perpendiculars are set off and made equal in length to those in A. A curve being traced through the points gives the form of the cap. C is called a *toad's back rail*, and is used for a superior description of staircases.

2190. *Fig.* 786. shows the method of drawing the scroll for terminating the handrail at the bottom of a geometrical staircase. Let A B be the given breadth; draw A E perpendicular to A B, and divide it into eleven equal parts, and make A E equal to one of them. Join B E, bisect A B in C and B E in F. Make C D equal to C F and draw D G perpendicular to A B. From F, with the radius F E or F B, describe an arc cutting D G at G. Draw G H perpendicular to B E cutting B E at O. Draw the diagonals D O K and I O L perpendicular to D O K. Draw I K parallel to B A; K L parallel to I D, and so on to meet the diagonals. From D as a centre, with the distance D B, describe the arc B G. From I as a centre, with the distance I G, describe the arc G E. From K as a centre, with the distance K E, describe the arc E H. From L as a centre, with the distance L H, describe the arc H P. Proceed in the same manner and complete the remaining three quarters, which will finish the outside of the scroll. Make B R equal to the breadth of the rail; namely, about two inches and a quarter. Then with the centre D and distance

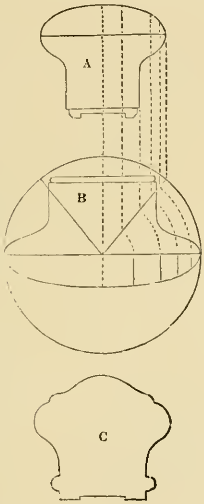

Fig. 785.

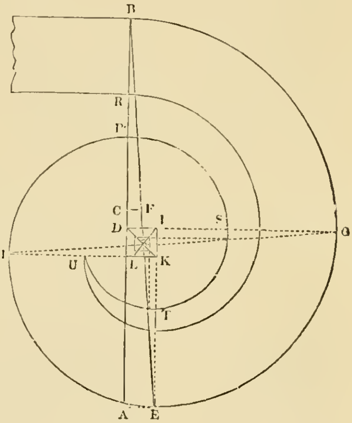

Fig. 786.

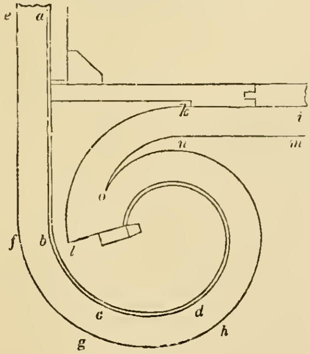

Fig. 787.

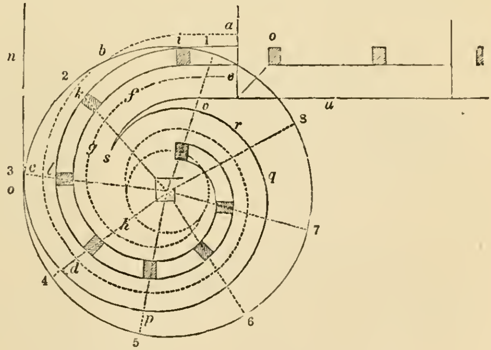

Fig. 788.

DR describe the arc RS, with the centre I and distance IS describe the arc ST, and with the centre K and distance KT describe the arc TU, and the scroll will be completed.

2191. *Fig.* 787. gives the construction of the cur-tail step, or that which lies under the scroll, *abcd* is the veneer that covers the riser; *efgh*, the nosing of the cover or horizontal part of the step; *ikl* the face of the string board, and *mno* the projection of the nosing.

2192. In *fig.* 788 is shown the cover board for the cur-tail step, *abcd* and *efgh* in dotted lines represent the plan of the scroll; *opqrs*, the nosing of the cur-tail step; *t*, *u*, *v*, *s*, the nosings and ends of the risers. The circle 1, 2, 3, &c. is described from the centre of the scroll, and divided into equal parts equal to the distances of the balusters from centre to centre, and lines are drawn to the centre of the scroll in order to ascertain the middle of the balusters, by giving a regular gradation to the spaces. The whole of the spiral lines in this and the previous figure are drawn from the same centres as the scroll.

BENCHES.

2192*a*. "It must be confessed," says Denison, in his *Lectures on Church Building*, 1856, page 242, "that our ancestors did not offer much temptation to people to come to church by the comforts they provided for them when they got there. Nothing, indeed, can be better for sitting in than some of the old stalls, such as those in King's College Chapel, where the back has a slope of one to four; but most of the common old church seats are frightfully uncomfortable—the back of the seat ought to be inclined, especially when it rises as high as the shoulders. It is not of so much consequence when the seat backs are low, but even in them it is better to have a little inclination, about one in eight; and above all things, the top rail ought *not* to project. The seats ought never to be less than 13 inches wide with a sloping back, or 14 inches with an upright one, and they will be all the better if they are an inch or two more. Nothing under 2 feet 10 inches at the very least will allow proper room for sitting, standing, and kneeling, especially if there are any divisions under the seats to prevent people from kicking their neighbours' hats, or appropriating their bassocks. Where it is necessary to save room in every possible way, it is not a bad plan to make the division under the seat only come down to 3 or 4 inches from the floor; and never in any case ought there to be (what there often is) a thick rail or bar of wood lying along the floor and taking off an inch or more from the space for the feet. The book boards are best not sloping, which is of no use, but flat and narrow, just wide enough to lay a book upon shut, and to put the arms upon in kneeling. As regards the difficulty of finding a good place and proper height for the pulpit and reading desk, I know of no better advice to give upon the subject than to try various places before you finally fix upon any one, unless the construction of the church is such that there is one place marked out by nature (as we may say) as the proper one."

2192*b*. Examples of benches and bench ends are represented in so many publications that it is deemed unnecessary to give any illustration. Some cappings to benches, and edges to divisions, are shown in the section Wood Mouldings in Book III. Those shown in Brandon's *Analysis*, and Bury's *Woodwork*, give the following dimensions:—

Name of Church.	Height.	Width.	Seat.	Opening.	
Comberton, Cambridge - -	2. 9	3. 4	1. 0	1. 6

The rules of the Incorporated Society for Promoting the Building of Churches state, that "the distance from the back of one seat to that of the next must depend in great measure on the height of the backs. Where the funds and space will admit, convenience will be best consulted by adopting a clear width of 3 feet; but a width of not less than 2 feet 8 inches from centre to centre will be allowed if the back of the seat is not more than 2 feet 8 inches in height. If a greater height be adopted, the distance from back to back must be increased one inch at least for every additional inch in height; but under no circumstances must it exceed 3 feet. There must not be any projecting capping on the top of the backs. Facilities for kneeling in all cases to be provided. The width of the seat boards for adults to be not less than 13 inches. 20 inches in length must be allowed for each adult, and 14 inches for a child. Children's seats must be at least 26 inches from back to front, and must have backs." Her Majesty's Commissioners for building new churches allow 20 inches by 34 inches for each sitting; free seats 20 inches by 27 inches, and 14 inches for children. Benches for free sittings are to be 3 feet, 4 feet 6 inches, or 6 feet long. The allowance made for each sitting in St. Paul's Cathedral is, as nearly as possible, 20 inches by 33 inches. From 4 to 5 square feet of floor is not too much space to be calculated for each person, allowing for gangways, communion table, &c.

2192c. Cloisters, porches, canopies, over-doors, stall-work, lych-gates, windows, staircases, bell-wheels and carriages, luffer or louvre boards, fencing, screens, pulpits, desks, lecterns, chests, tables, *cum multis aliis*, are amongst the many other productions of the joiner, being far too numerous to be described in detail herein.

FORMATION OF BODIES BY JOINING THEM WITH GLUE.

2193. The way in which bodies are glued up together for different purposes will be given below, and with them will close this section.

2194. *Fig.* 789. shows at A a section of two boards glued up edge to edge. At B the face of the same is seen. C shows the section of two boards glued edge to edge, each piece being grooved, and a *tongue* inserted at their junction. By similar means a board may be increased to any width, be the pieces whereof it is composed ever so narrow. D shows two boards fixed at right angles, the edge of one being glued on the side of the other. A block for the purpose of strengthening the joint is fitted and glued to the interior side.

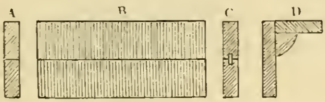

Fig. 789

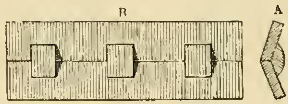

Fig. 790.

2195. *Fig.* 790. A is a section of two boards to be joined at an oblique angle. They are mitred and glued together with a block at the angle. B shows the inner sides of the boards so fixed. It is by repeating this operation that columns are glued up.

2196. *Fig.* 791. A is the section of an architrave. The moulding is usually, if not always, glued to the board; the vertical line therefore, showing the extreme boundary of the moulded part, is the section of the piece to be glued, B is the face of the architrave, C and D a section and front of it before it is moulded, E a section of it with the button and nail to show the way in which the two parts are glued together, and F shows the back of the architrave with the buttons which are used for the purpose of bringing the two surfaces to be glued together in contact, till after they are set and fully held together, being knocked off when the glue has become hard, and then the moulding shown at A and B is stuck.

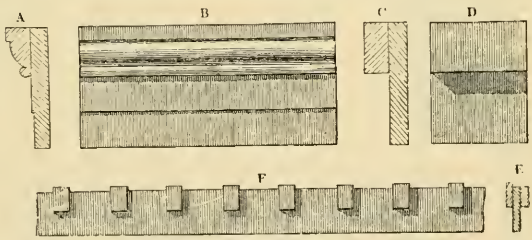

Fig. 791.

2197. *Fig.* 792. exhibits the method of gluing up a solid niche in wood where A is the elevation. The work is performed in the same way as if it were stone or brick, except that the joints are all parallel to the plane of the base, because of the difficulty of making a joint with curved surfaces, which would necessarily be the case if they all tended to the centre of the sphere. B and C are the two bottom courses, where the vertical joints are made to break, as seen in the elevation A.

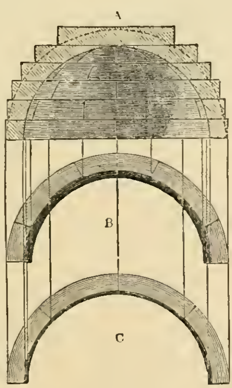

Fig. 792.

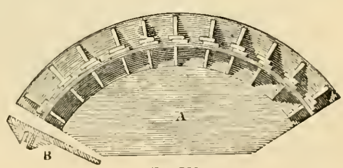

Fig. 793.

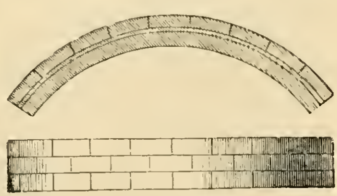

Fig. 794.

2198. In *fig.* 793. is exhibited the mode in which veneers are glued together for the purpose of forming cylindrical surfaces. Brackets, with their faces upwards are nailed to a board. Their ends are perpendicular, and a cavity is left between them sufficient to receive the veneers and wedges. In A the thin part in the form of an arc shows the veneers as in the state of glueing, the wedges being on the convex side. B is a section of the board and bracket. The work when putting together should be dry and warm, and the glue should be hot. When this last has set hard, the wedges must be slackened, and the veneers, which now form a solid, taken out.

2199. *Fig.* 794. is a strong method of forming a concave surface by laying the veneer upon a cylinder, and backing it with blocks in the form of bricks, which are glued to the convex side of the veneers and to each other. The fibres of the blocks are to be as nearly as possible parallel to the fibres of the veneers. A is the section of the cylinder veneer and blocks, and B shows the convex side of the blocks.

2200. *Fig.* 795. is another mode of glueing veneers together with cross pieces screwed to a cylinder, the veneers being placed between the former and the latter.

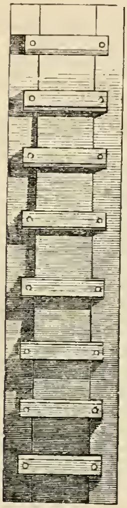

Fig. 795.

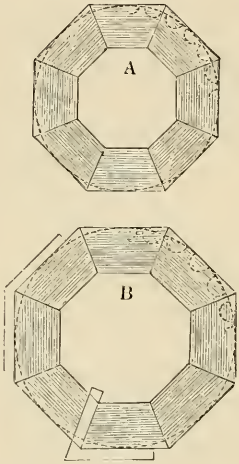

Fig. 796.

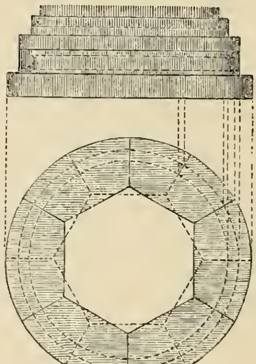

Fig. 797.

2201. In *fig.* 796. is shown the method of glueing up columns in pieces, which here are eight in number, each being glued to the other after the manner of *fig.* 790. The workman should be careful to keep the joints out of the flutes, when the columns are to be fluted, by which the substance will be more likely to prevent the joints giving way. A is a section of the column at top, and B at the bottom. After glueing together, the octagons and mitres should be correctly laid down for the true formation of the joints. In B are shown two bevels, one for trying the mitres, and the other for trying the work when put together.

2202. *Fig.* 797. is the mode of glueing up the base of a column. It is formed in three courses, the pieces in each of which are made to break joint over one another. The horizontal joints of the courses must be so adjusted as to fall at the junction of two mouldings, forming a re-entering angle. After the glue is set quite hard, the rough base is sent to the turner, by whom it is reduced into the required profile. The fibres of the wood should lie horizontally, in which direction the work

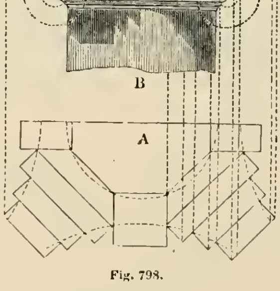

Fig. 798.

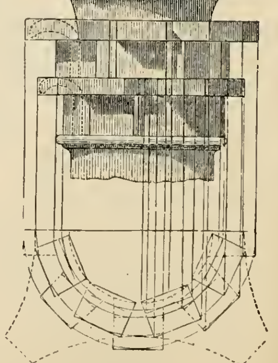

Fig. 799

will stand much better than when they are vertical. A is the plan of the base inverted, and B is the elevation.

2203. The formation of a modern Ionic capital is given in *fig.* 798., wherein A is the plan inverted, showing the method of placing the blocks; and B is the elevation.

2204. *Fig.* 799. is the method of glueing up for the leaves of the Corinthian capital, A is the plan inverted, and B is the elevation. The abacus is glued up in the same manner as in the preceding example.

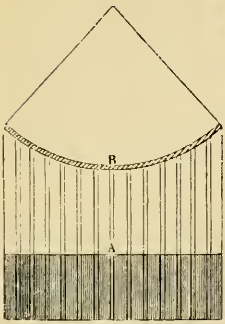

Fig. 800.

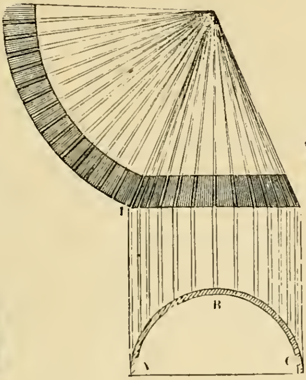

Fig. 801.

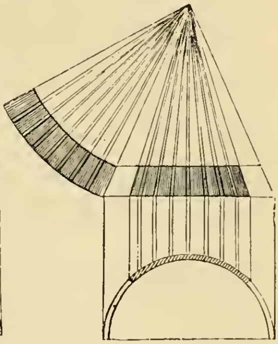

Fig. 802.

2205. *Fig.* 800. exhibits the mode of forming a cylindrical surface without veneers, by means of equidistant parallel grooves, A is the elevation, and B the plan.

2206. *Fig.* 801. exhibits the method of covering a conic body. It is, in fact, no more than covering the frustum of a cone, and is accomplished by two concentric arcs terminated at the ends by the radii. The radius of the one arc is the whole slant side of the cone, that of the other is the slant side of the part cut off. In this case, the grooves are directed to the centre, and filled in with slips of wood glued as before. The plan is shown by the circle ABC. The arc HI must be equal to the circumference ABC.

2207. *Fig.* 802. shows the same thing for a smaller segment.

2208. *Fig.* 803. shows the manner of glueing up a globe or sphere by the same method. A is the face of the piece; B the edge showing the depth of the grooves; C shows the mould for forming the piece to the true curvature; and D the faces of two pieces put together.

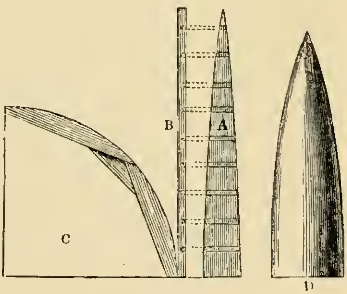

Fig. 803.

Sect. VI.

SLATING.

2209. An account of the materials used by the slater has been detailed in Chap. II. Sect. IX. The tools used by this artificer are the *scantle*, which is a gauge by which slates are regulated to their proper length; the *trowel*; the *hammer*; the *zax*, an instrument for cutting the slates; a small *handpick*; and a *hod* and a *board* for mortar. The *zax* is an instrument made of tempered iron, about 16 inches long and 2 inches wide, like a large knife bent a little at one end, with a wooden handle at the other, and having a projecting piece of iron on its back, drawn to a sharp point, to make holes in the slates for the nails, the other side being used to chip and cut the slates to their required size, as when brought from the quarry they are not sufficiently square and cleaned for the slater's use. The places for the nail holes are marked usually on the slate where they have to be punched, with a gauge, and then the iron of the *zax* is struck through the slate. Each slate has two holes; large slates require three. A better mode of obtaining the place for the holes is to mark a plank with two small pieces of wood across it, at the distance required; the position is thus shown at once.

2210. Slating is laid in inclined courses, beginning from the eaves and working upwards, the courses nearest the ridge of the roof being less in width than those below. The *lap* of one slate over another is called its *bond*, and it is the distance between the nail of the under slate and the lower end of the upper slate. The *bed* of a slate is its under side, and the upper side is called its *back*. The part of each course which is exposed to the weather is called its *gauge, bare*, or *margin*. The slates are nailed to close or open boarding, lying on the back of the rafters, with nails, which should be of copper or zinc If iron nails are used they should be well painted. The operation of cutting or paring the side and bottom edges of the slates is called *trimming* them; but the head of the slate is never cut. In that part the holes were formerly pierced by which the nails pass to the boarding. This boarding (or *sarking*, as it is called in the north of Great Britain) is usually $\frac{3}{4}$ inch to $1\frac{1}{4}$ inches thick, rough, of equal thickness, and well secured to the common rafters. A good practice obtains of bedding slates in mortar, on boarding, which gives them a sound bearing, especially if the roof will have to stand much wear from persons passing along the gutters, or over the ridge, for repairs or other purposes.

2210*a*. Another method of forming a roof, as lately employed by some architects, consists in slating on boards fixed to purlin-rafters, without any common rafters, as shown in *figs.* 695*a*. and 697. The purlins are placed somewhat closer than when rafters are used; the boards are $1\frac{1}{4}$ inches thick, usually placed diagonally. It makes very sound work, and saves height, where that may be an object. Another method, as noticed in par. 2285*a*., is to nail the boarding on to common rafters laid as purlins, as shown in *figs.* 695 and 696.

2210*b*. The common method of slating is to nail the slates to laths or battens, as in tiling, but a house so done is more liable to be affected with the various changes from heat to cold than by the other system. These laths are cut to boards of 20, 25, 30 or 36. Thus a board 12 × 9 × 3, cut 3 deep and 4 flat, equals 1 board 20. If cut 4 deep and 4 flat, equals 1 board 25. If cut 4 deep and 5 flat, equals 1 board 30. If cut 5 deep and 5 flat, equals 1 board 36. Slating laid on battens, at places on the sea coast, and as usual in work in Ireland, is either wholly "rendered" with lime and hair on the under side, or only the under edges and laths are thus secured. Without this precaution the slates rattle, and the driving winds get under them, tending to strip the roofs. Rendering properly done, lasts as long as the slates exist in a perfect state.

2210*c*. Open or ventilated slating, which is nearly equally as waterproof as the usual method of slating, will save one third of the quantity per square.

2210*d*. *Felt.* Slate is also laid on *felt*, on $\frac{3}{4}$-inch boarding. Croggon's patent *asphalte roofing felt* is impervious to rain, snow, and frost, and is a non-conductor. From its anti-corrosive properties, it is of service when placed between iron and wood and between metals. It is manufactured of any required length, by 32 inches wide. There is some risk of dry rot occurring, however, by using it thus; the better plan is to lay the felt on boards, and then to batten for the slates over the felt, so as to leave an air space between the felt and the slates. Its general weight is about 42 lbs. per square. Patent asphaltic roofing felt is about $\frac{3}{16}$ in. thick; slaters' or sarking felt is about $\frac{1}{8}$ in. thick, as is also inodorous felt. Fibrous asphalte or foundation felt is suggested for preventing damp rising when placed above the footings of a wall; but it has some disadvantages. Non-conducting dry hair felt, in sheets 34 inches by 20 inches, is also obtainable in long lengths.

Roofing felt is specially prepared for hot climates. *Non-conducting felt* is formed entirely of hair, and is used for covering boilers. steam pipes, &c., for the purpose of preventing the radiation of heat. When applied to boilers, a cement of 2 parts of white lead, 1½ parts of red lead, 4 parts of whiting, is mixed with boiled linseed oil; after being spread over the felt, the whole is patted down on the boiler, and in a short time the felt firmly adheres. No cement is needed for steam-pipes, the felt being wrapped round and secured by twine. Sheets of this felt are made 32 inches by 20 inches; and of the following weights:—No. 1, 16 oz.; No. 2, 24 oz.; No. 3, 32 oz.; No 4, 40 oz.; No. 5, 48 oz. This dry hair or inodorous felt is also useful for deadening sound, by cutting it into 2 or 2½ inch strips, and laying it on the joists under the floor boards; also as lining to walls and floors; and for lining iron houses to equalise the temperature.

2210*e*. Felt is also applied for forming roofs of temporary buildings. It has been suggested for permanent buildings, but to that employment of it we must withhold our approval. The rafters may be about 2 inches by 1¼ inches, placed 20 to 24 inches apart, laid at a pitch of 2 or 3 inches to the foot, and covered with ½-inch boarding. The felt is to be stretched tight, overlapping 1 inch at the joints, nailed with two-penny fine clout nails, first heated and cooled in grease, about 1½ inches apart; copper nails are preferable. The whole roof is then to have a good coating of hot coal tar and lime, in the proportion of 2 gallons of the former to 6 pounds of the latter, well boiled together, put on with a common tar mop, and while it is soft some coarse sharp sand sifted over it. The gutters are made of two folds, cemented together with the boiling mixture. The coating to the roof must be renewed every fourth or fifth year, according to the climate. The felt is found to last better, if it be not made to adhere by any mixture to the boarding.

2210*f*. Felt for sheds, or occasional purposes, may be put up without boarding; the rafters in this case would not exceed 3 inches by 1¼ inches, placed at a distance of 30 inches apart. To prevent the felt bagging, battens, or slighter rafters, of about 2 inches by 1 inch, are placed between the others. To such roofs the felt must be laid from eaves to eaves, nailing through the overlap into the main rafter. The pitch of this roof should be about 6 inches to the foot. The "ventilated" slating will bear an economical contrast, provided the smaller size of slates be used, and is more durable.

2210*g*. Another modern material for roofing is *Willesden paper and canvas*. Two-ply paper is used for underlining slates, tiles, leaky roofs; for interior lining; fixing against damp walls, under floors, and for interior decorations. It is waterproof, and does not smell. 100 square feet of it equals 16¼ lbs. The 1-ply paper is used for underlining, fixing against damp walls, waterproof wrapping, packing, stencil paper, &c. The *canvas* is water-repellant and rot-proof. The *scrim* is waterproof, and useful for shading greenhouses, ferneries, &c., and for fixing to damp walls to protect ornamental wall-papers.

2210*h*. Slating is sometimes laid lozengewise, but it is much less durable than when laid in the usual method. It is introduced for the sake of ornamental effect. The ends of the slates are also rounded, or cut angleways to a point, or the angles only cut off; or, if the slates be of a small size, they are set angleways over courses with square ends. These are all shown in an excellent article in Viollet-le-Duc's *Dictionnaire*, s.v. Ardoise. Slating is also made to have a decorative effect by forming zigzag patterns with red coloured slates among blue slates; or a few courses of the one above a larger number of the other.

2210*i*. James Wyatt, R.A., arranged a system for forming roofs with slate slabs without boarding or battens. In this the slates were all reduced to widths equal to the distance between centre and centre of the rafters. On the backs of these last they are screwed by two or three strong inch-and-half screws at each of their ends. Over the junctions of the slates, on the backs of the rafters, fillets of slates about two and a half or three inches wide, bedded in putty, are screwed down, to prevent the entrance of rain. The handsome regular appearance of this sort of slating gained it at first much celebrity; but it was soon abandoned, on account of the disorder it is liable to sustain from the slightest partial settlement of the building, as well as from the constant dislodgment of the putty, upon which greatly depended its being impervious to rain.

2211. Subjoined is a succinct account of the different sorts of slates brought to the London market, and enumerated in the order of their goodness and value.

2211*a*. *Westmoreland slates*. These are from 3 feet 6 inches to 1 foot in length, and from 2 feet 6 inches to 1 foot in breadth. They should be nailed with not less than six-penny and eight-penny copper or zinc nails (iron nails should never be used); and a ton in weight of sized slates will usually cover about two squares and a quarter. The weight of the coarsest Westmoreland is to that of common tiling as 36 to 54.

2211*b*. *Welsh rags* are next in goodness, and are nearly of the same sizes as those last mentioned; but a ton of these will cover only from one square and a quarter to one square and three-quarters. Permanent green, Eureka unfading green, Whitland Abbey green, Westmoreland green, best blue Bangor, best red Bangor, Eureka red, Old vein Portmadoc, are among those now supplied.

2211*c*. Table of the Names and usual Sizes of Slates,

with the squares a thousand (1200) will cover according to their size, and the gauge at which they are laid, as stated in various works.

Name.	Size. Inches.	Cover about Squares.	Cover about Squares.	Weight per 1200. Cwts. 1st quality.	Weight per 1200. Cwts. 2nd quality.
Queens - - -	32, 34, 36 × 16, 17, 18				
Princesses - - - -	30 × 15	16¾	- -	115

* Denotes best Welsh roofing sizes.

During last century, when building works were executed with more regard to durability, a thousand duchesses were said to cover 9 squares; countesses, 6 squares; ladies, 3 squares; and doubles, 2 to 2¼ squares.

2211*d*. Slates are now split so thin, that in specifications it is desirable to state the weight per square of the slating required. The scientific journals noticed (1865) that at the Rhiwboyfdir Slate Company's quarries, sheets of slate 8 feet long and $\frac{1}{32}$nd part of an inch were obtained, the width being generally 16 inches. The grain must, of course, be very fine to permit of so thin a cleavage.

2211*e*. The strength of slate 1 inch thick is considered equal to that of Portland stone 5 inches thick. A foot superficial weighs from 11¼ to 14 lbs. Slates of the usual thickness will not bear much heat before cracking: the thicker the slate the more readily does it crack with heat; and they will fly at once if cold water be poured suddenly upon them when in a heated state.

2211*f*. The *Tavistock slates* were sold by the thousand of ten hundred, which quantity covered about three squares and forty feet.

2211*g*. *Horsham slate*, obtained in Sussex, is a limestone, and is found to have no limit to its durability; but being very heavy, proper preparation is needed for it, as timbers of much greater scantling than usual are required.

2211*h*. *French slates*, formerly used in London to some extent, are very light, and must therefore only be used on boards; otherwise the wind would act upon them. In France they are bedded in plaster on the boarding.

2211*i*. The ridge, hips, and valleys of a slated roof were formerly always covered with lead. The valleys are still usually so formed, but slate has been introduced for the two former. The pieces require to be cut truly square, screwed to the boarding, and the joints and heads secured with putty or white lead. For hips and ridges, *slate roll ribbing* is often employed (*fig*. 803*a*.). Shorter slates, A, are first nailed to each side of the ridge-piece, C, or of the hip rafter, to form the saddle, and then the slate roll B is put on and secured by screws through the top. This roll is made also with rebated joints, but it is obviated by the roll b eaking joint with the saddle. The roll, as shown in the figure, is sometimes attached to one side of the saddle, which must be made according to the pitch of the roof. The 3-inch diameter roll has a 7-inch width of saddle, or wing, on each side; the $2\frac{1}{2}$-inch a 6-inch; and the 2-inch a $5\frac{1}{2}$-inch saddle. There are 175, 225, and 320 feet in a ton of the ribbing; and 400, 560, and 700 feet of the ribbing.

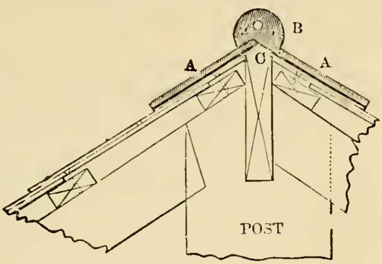

Fig. 803*a*.

2211*k*. The edges of the slates next a wall, either at the head or sides of a roof, have to be protected. This, in the best work, is effected by lead flashings (*par*. 2214.). In the former case, it is laid on the head of the slate for about 5 to 7 inches, and then turned up against the wall for about the same height, and secured by holdfasts; it may also be either turned over into a course of bricks, and the brickwork continued up, or the turned up edge is protected by a lapping of lead inserted in the brickwork. This lapping, in commoner work, is replaced by cement. At the edge of the roof against a wall, lead is likewise placed in a similar manner; but as the lapping cannot be laid in a straight joint, it is cut in a zigzag form, called "stepping," to each course of bricks. Of late years this lead flashing is entirely replaced by filleting of lime and hair plaster; of gauged stuff, being lime and cement mixed; or of cement and sand. But as these materials crack and fall away in a few years, the filleting has to be looked to periodically or whenever damp makes its appearance. Zinc also takes its place, but is not so effective, as it is more difficult to dress it to the surface of the slates.

2211*l*. In exposed situations, where filleting cannot be trusted, and lead is too expensive, various contrivances have been made for preventing the entrance of wet. One of these consists in forming a small gutter between two rafters, lining it with lead, turning one side of the lead under the slates, and turning up the other side against the wall, and cementing over it. Another good method is to cement a row of tiles against the wall above the slates, and when dry to cover the tiles and wall with cement, tucking it well into all the crevices.

2211*m*. The mediæval method of easing the line of tiling at the foot of the framing deserves some notice; thus, as shown in *fig*. 701*e*., it appears that the use of chantlates, A, frees the tie-beams, tassels, and other timber, except plates, from all contact with the masonry; and. as a matter of course, from any consequent tendency to rot. This method seems more advantageous than that of beam-filling, which is altogether prevalent at the present time, in order to keep out draughts, but it requires care in closing the work. Tiling has been already described in the section Bricklaying.

2211*n*. In many churches with open roofs, the solid rafters, without any under panelling or boarding, may be seen covered with rough slabs of boarding, having large fissures through which the lead is visible. Great inconvenience is often felt in roofs so constructed, during the autumn and winter months, when, upon sudden alteration of temperature, condensation takes place under the lead, and the drops of water fall in almost a shower. This defect has been the cause for ceiling many open roofs. A space of two inches left between the inner boarding and the outer covering has been found to be sufficient to obviate this discomfort. Felt (*par*. 2210*d*.) is also sometimes used, to assist in remedying the evil.

2211*o*. In Pembrokeshire, slate is used for everything. For posts and rails of the same scantling as if for wood. The walls of buildings are of square blocks, rough casted. A range of stabling might be erected of rough blocks, with the door and window-frames of worked slate. A prejudice exists against the use of squared blocks without plastering them, on the ground that they admit damp. It was found that if there was the smallest perforation in the slate, or if, as was often the case from the want of absorption, the joints were not perfectly close, the damp is driven through. The defect, might, perhaps, be obviated by laying every block with the b d slightly inclining outwards.

2211p. *Slabs of slate*, sawn, self-faced, and planed are now extensively manufactured at all the large quarries. They are usually in $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{2}$, and 3 inch thicknesses. A quarter of an inch is required for each face planed from the rough, and they are sanded in addition afterwards. The best quality Bangor slabs can be obtained in sizes varying from 4 to 6 feet long, or from 2 to 3 feet wide; and from 6 to 8 feet long, or from 3 to 3 feet 6 inches wide. The second quality slabs, quarry planed, are under 6 feet long or 3 feet wide.

2211q. The purposes for which slate slabs are now used are multifarious. Amongst them are: cisterns (Plumbery) from $\frac{3}{4}$ inch to 2 inches thick; sinks of inch slate, 4 inches deep inside, either bolted together as cisterns, or with flush ends, planed both sides, and screwed; troughs; filters; baths, 2 feet wide, 2 feet high, 4 feet 9 inches at bottom and 5 feet 9 inches at top, all outside dimensions, of plain slate, sanded inside, or enamelled self-colour inside, or enamelled Siena marble inside, and so on; urinal back and divisions, plain or enamelled, fitted with angular earthenware basins, flat back basin, hollow back cradle basin, square basin, or with slate apron only; linings to damp walls; panels of doors; table tops; billiard tables; shelving to dairies and pantries; fittings for wine bins, with permanent or with movable shelves and ledges; steps; and landings.

2211r. *Enamelled slate.*—Slate, as just shown, has a surface of paint put upon it, for utility as well as appearance. This can be either plain, or marbles and granites can be represented to great perfection. Several coats of paint are applied, and polished, and dried in a kiln at a great heat. The Kingston Enamelled Slate Company base their reputation on all their enamel work being imperishable. First, the slate has to be finely surfaced to receive the body colour, after which it is placed in a proper stove and burnt or baked in three times, the process being repeated each time, and rubbed down with pumice between each, then a coat of enamel is placed thereon; finally, it is subjected to a high polish obtained by hand friction. It is claimed that by this process a near resemblance to marble and granite is gained; that the depth of body of enamel procured renders it imperishable; and that it has an extremely high polish of the surface when finished. Cheap work is not lasting.

2211s. Thatching is an admirable covering for securing warmth in winter, and coolness in summer; but it is subject to injury by birds, and to risk from fire. It was much used for churches in Norfolk and Suffolk (*fig.* 701*n.*). The thatcher requires a common *stable fork*, to toss up the straw together before being made into bundles; a *thatcher's fork*, to carry the straw from the heap up to the roof; a *thatcher's rake*, to comb down the straw straight and smooth; a *knife*, or *eaves' knife*, to cut and trim the straw to a straight line; a *knife* to point the twigs; a half *glove* of leather, to protect the hand when driving in the smaller twigs or *spars*; a long flat *needle*; a pair of leathern *gaiters* to come up above the knees, used when kneeling on the rafters; and a *gritstone* to sharpen the knives. Wheat straw lasts from 15 to 20 years; and oat straw about 8 years. Reed thatching, as done in the West of England, is the truss after the ears have been *cut off*, leaving the clean, sound pipe straw, of which a thickness of 3 inches is laid on the common thatching with *spars* only. The materials required are straw or reeds, laths, nails, withes and rods. A load of straw, laid on about 12 to 16 inches in thickness, will do a square and a half; a bundle of oak laths, $1\frac{1}{4}$ inches wide, and from $\frac{1}{4}$ to $\frac{3}{8}$ths thick, nailed about 8 inches apart, 1 square; a hundred of withes, 3 squares; a pound of rope yarn, 1 square; 100 of rods, 3 squares; and $2\frac{1}{2}$ hundred of nails, 1 square. The fish-house at Meare, Somersetshire, of about the middle of the 14th century, still retains its thatched roof. Probably thatched roofs were ornamented by a species of cresting, for in some parts of the country the withes or willow twigs that bind the thatch are sometimes arranged on the tops of ricks and cottages in an interlacing manner, terminating with a spike with a rudely formed cock. Viollet-le-Duc alludes to the custom of forming the ridge in mud, in which plants and grasses were inserted to prevent the earth being dissolved and washed away by the rain.

Sect. VII.

PLUMBERY.

2212. The plumber has but few working tools, for the facility with which the metal in which he works is wrought does not render a variety necessary. The principal are—a heavy iron *hammer*, with a short but thick handle. Two or three different sized wooden *mallets*, and a *dressing and flatting tool*, which is made of beech wood, usually about 18 inches long and 2½ inches square, planed smooth on one side, and rounded on the other or upper side. It is tapered and rounded at one of its ends for convenient grasping by the workman. Its use is to stretch and flatten the sheet lead, and dress it into the shape required for the various purposes whereto it is to be applied, by the use of its flat and round sides as wanted. The *jack and trying planes* similar to those used by carpenters, for planing straight the edges of their sheet lead when a regular and correct line is requisite. They also use a line and roller called a *chalk line*, for lining out the lead into different widths. Their cutting tools are *chisels* and *gouges*, of different sizes, and *cutting knives*. The latter are for cutting the sheet lead into strips and pieces to the division marked by the chalk line. They use also *files* of different sizes for making cistern heads to pipes, for pumpwork, &c. For the purposes of soldering, they have a variety of different sized *grozing irons*, which are commonly about 12 inches long, tapered at both ends, the handle end being turned quite round to allow of its being held firmly in the hand whilst in use. The opposite end is spherical, or more usually spindle-shaped, and proportioned to the different situations for which they are required. The *grozing iron* is heated to redness when in use. The *iron ladles* are of three or four sizes, and used for the purpose of melting lead or solder. The plumber's *measuring rule* is 2 feet long, in three parts, each of 8 inches. Two of the legs are of box-wood, and the third of steel, which is attached to one of the box legs by a pivot whereon it turns, and shuts into the other legs in a groove. The steel leg is useful for passing into places which the plumber has to examine, into which anything thicker would not easily enter, and it is often used also for removing oxide or other extraneous matter from the surface of the heated metal. The plumber moreover is provided with *centre bits* of all sizes, and a stock to work them in, for perforating lead or wood where pipes are to be inserted, as well as with *compasses*, for striking out circular portions of lead. *Scales and weights* are also in constant requisition, as nothing done by the plumber is chargeable till the lead is weighed.

2213. The method most commonly adopted in laying *sheet lead* for terraces or flats, is to place it on a surface as even as possible, either of boarding or plastering. If boards are employed, they should be sufficiently thick to prevent warping or twisting, which, if it occur soon, causes the lead to crack or to become unsightly. As sheets of lead are not more than about 6 feet in width, when the area to be covered with them is large, joints become necessary, which are contrived in various ways to prevent the wet from penetrating. To do this, the best method is that of forming *rolls*, which are pieces of wood about 2 inches square extending in the direction of the joint, planed and rounded on their upper side. These being fastened under the joints of the lead between the edges of the two sheets which meet together, one is dressed up over the roll on the inside, and the other over both of them on the outside, whereby all entry of the water is prevented. No fastening is required other than the adherence of the lead by close hammering together and down on the flat: indeed, any fastening would be injurious, as by it the lead would not have free play in its expansion and contraction from heat and cold. When rolls are used, the rule should be specially enforced of turning the open sides or laps from the south-west, west, or south, wherever practicable, so as to ensure the lap from being forced up by the wind, and thereby the water consequently blown in. If *rolls* are not employed, which from their projection are in some cases found inconvenient, *seams* are substituted for them; but they are by no means equal to the roll either for neatness or security. They are formed by merely bending up the two edges of the lead, and then over one another, and then dressing them down close to the flat throughout their length. Though some solder the joints, it is a bad practice, and no good plumber will do it, for the same reason as that just given in respect of fastenings in flats. A lead *flat*, as well as a gutter, should be laid with a fall to keep it dry. A quarter of an inch in a foot is sufficient inclination for lead, if the sheets be 20 feet long, so that in this case they will be 5 inches at one end higher than at the other. This *giving a current*, as it is called, is usually provided for by the carpenter previous to laying the lead.

2214. Round the extreme edges of flats and gutters where lead is used, are fixed pieces of milled lead which are called *flashings*. When the lead work is bounded by a wall of brick or stone work, the flashings are passed on one edge into and between a joint of the work, and the edges of the flat or gutter being bent up, the other edge of the flashing is dressed over it. If there be no joint into which the flashing can be inserted, it is fastened on that side with wall hooks (*par.* 2211*k.*). *Drips* in flats and gutters are used when the length of the gutter or flat is greater than the length of the sheet of lead, or sometimes for convenience, or to avoid joining lead by soldering it. Some architects place them every 6 or 8 feet, which however good in a box or parallel gutter, it raises an ordinary gutter too much, and causes great width of lead at the head. They are formed by raising one part above another, and dressing the lead round, as has been described for rolls. No sheet should be laid in greater length than 10 or 12 feet without a *drip*, to allow of expansion and contraction. Small *cisterns* are often sunk in gutters to collect the water before passing off into the head of the down pipe. The cistern has usually over it a perforated lead *rose*, to prevent dirt, leaves, &c. passing down with the water.

2215. The work of the plumber is estimated by its weight and the time employed in fixing it.

2215*a*. The thickness of sheet lead varies from 5 to 12 lbs. in weight to the superficial foot, and is used in covering large buildings, in flats or slopes, for gutters, the hips, ridges, and valleys of roofs, the lining of cisterns, &c. Thus 7lb. lead is commonly used for roofs, flats, and gutters; it is the least thickness in which *bossing* can be properly done. 8lb lead is a better quality for all these purposes. 6lb. lead is used for hips and ridges; this is the thinnest quality for such purposes. 5lb. lead is used for flashings. It is said that 16lb. lead was used on the earlier mediæval churches. The following thicknesses, obtained from Hurst, *Surveyors' Handbook,* may be compared with the Birmingham Wire Gauge given in *par.* 2254, Sect. x.

Table I. of the Thickness and Weight of Lead, per Superficial Foot.

Thickness - - - or Decimal of an Inch -	$\frac{1}{16}$ ·0625	$\frac{1}{8}$ ·125	$\frac{3}{16}$ ·1875	$\frac{1}{4}$ ·25	$\frac{5}{16}$ ·3125	$\frac{3}{8}$ ·375	$\frac{7}{16}$ ·4375	$\frac{1}{2}$ ·5
Pounds - - - -	3·708	7·417	11·125	14·833	18·542	22·250	25·958	29·667
Thickness - - - or Decimal of an Inch -	$\frac{9}{16}$ ·5625	$\frac{5}{8}$ ·625	$\frac{11}{16}$ ·6875	$\frac{3}{4}$ ·75	$\frac{13}{16}$ ·8125	$\frac{7}{8}$ ·875	$\frac{15}{16}$ ·9375	Inch. 1·0
Pounds - - - -	33·375	37·083	40·792	44·500	48·208	51·917	55·625	59·333

Table II. of the Weight and Thickness of Lead, per Foot Superficial.

Weight in Pounds.	Thickness in inches.	Weight in Pounds.	Thickness in inches.	Weight in Pounds.	Thickness in inches.
1	0·017	6	0·101	11	0·186
2	0·034	7	0·118	12	0·203
3	0·051	8	0·135		
4	0·068	9	0·152		
5	0·0 5	10	0·169		

2215*b*. Lead is generally cast about 7 feet wide and about 33 feet in length, but its width and length depend upon the margin which is cut off after casting, as the scum, &c., is driven to those parts. This may reduce it about 6 inches in width and 18 to 24 inches in length. Lead is now cast to the above-named weights, and also "bare," according to the directions of the contractor. The architect, to do justice to his employer, should carefully ascertain for himself the weight and size of the sheet of lead from which the piece is cut. It is usually marked or painted upon it. A small piece is not a true test either for weight or gauge, and the edge is sometimes cut on a bias. The best direction is that it should weigh over the weight specified.

2216. A hundred weight of sheet lead will usually cover on a platform, roof, gutter, &c. at 4 lbs. = 28 ft.; 5 lbs. = 22 ft. 5 ins.; 6 lbs = 18 ft. 8 ins.; 7 lbs = 16 ft.; 8 lbs. = 14 ft.; 9 lbs = 12 ft. 6 ins.; and 12 lbs. = 9 ft. Old lead weighed for recasting has generally a deduction made of 6 lbs. per cwt. for waste, &c.

2217. Lead is used to fasten iron cramps, posts, and bars into masonry by filling up the cavities between them. Sheets of thin lead are sometimes placed between the drums of columns (par. 1925*a*.), as well as in the bed joints of wrought stone arches, to distribute the pressure between the stones. Lead work treated ornamentally for ridges, and hips of roofs, knobs, vanes, &c., as during the mediæval period, is superseded in the present day by cast and wrought iron, and by zinc work. (*Builder*, 1856, p. 410.) The skill of the plumber is brought to action in, among other things, eaves and other gutters, flashings and valleys, hips to flats or platforms, hatches, windows, and domes; also rain-water pipes, waste and soil pipes, water-closets, baths, cisterns for hot and cold water, basins or lavatories, cabinet stands, sinks, urinals, pumps, the hydraulic ram, syphon and other traps, &c. Many of these will be found treated herein, and more in detail in Buchan, *Plumbing*, 8vo., 1876. This section includes many articles which should perhaps have come under Bricklayer and Founder, but would have caused repetition.

WATER SUPPLY.

2218. Water is obtained by various means. The aqueducts of the Romans have been previously described. In England, the chief means of supply, according to locality, is (1) by pumps from springs and wells; (2) by water companies; and (3) by the hydraulic ram.

2218*a*. Modern sanitation has put down surface wells in towns and cities. It has been found that the quantity of saline and organic matter in two gallons of water from certain wells in London ranged from 26·63 grains to 129·73; while that of the New River water had but 17·16 grains. Solid matter in these wells ranged from 50 to 100 grains, and some to 130. As most of these waters were bright and sparkling, and had a cool and agreeable taste, they were much sought after for drinking purposes; but the coolness and briskness are dangerous, for they are both derived from organic decay. According to Dr. Letheby, the dead and decomposing matters accumulated in the soil are partially changed by a wonderful power of oxidation, and thus converted into carbonic acid and nitre. This, although frequently drunk without any apparent injury to health, yet the products of such corruption admitted into the human body must cause insidious mischief, while, if the impurities of the soil pass unchanged into the water, quick and certain injury must result.

2218*b*. As the plumber finds and fixes the *pumps* for the supply of water to a dwelling in some localities, a description of the three sorts commonly used, namely, the *lifting*, the *common*, and the *force pump*, will be here given.

2218*c*. *Fig*. 804. is a diagram of a *lifting pump*. ABCD is a short cylinder submerged in the well or other reservoir, whence the water is to be raised. In this cylinder a valve is placed at *x*, above which the pipe or tube CE is carried upwards as high as is requisite for the delivery of the water. In the cylinder AD a water-tight piston, *cd*, moves vertically, being worked by rod or framework, *m*, *n*; to this piston is fixed a valve at *v*, opening upwards. On the descent of the piston the pressure against the water opens the valve *v*, and the cylinder between the two valves is filled with the water. When the piston is then raised, the water between the valves being pressed upwards against the valve *x*, opens it, and is driven into the tube CE, from which, on the renewed descent of the piston, its return is intercepted by the valve *x*. The water follows the piston in its ascent by the hydrostatic pressure of the water on the reservoir outside the cylinder; and on the next descent of the piston the water will again pass through the valve *v*, and will be driven through the valve *x* on its next ascent. In raising the piston a force is required sufficient to support the entire column of water from the valve *v* to the surface of the water in the tube CE. To estimate this, the weight of a column of water is taken, whose base is equal to the area of a section of the piston, and whose height is equal to that of the surface of the water above the valve *v* in the tube CE. Hence, after each stroke of the pump, the pressure on the piston and the force necessary to raise it will be increased by the weight of a column of water whose base is the horizontal section of the piston, and its height equal to the increase which the elevation of the column in CE receives from the water driven through the valve *x*. WW is the level of the water in the well.

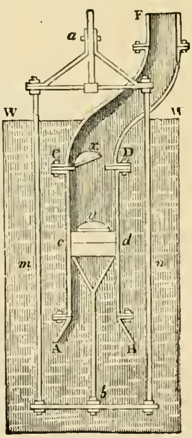

Fig. 804.

2218*d*. The common household pump, or, as it is usually called, *suction pump* (*fig*. 805.), is nothing more than a large syringe connected with a tube whose lower extremity is plunged in the well from which the water is to be raised into the cistern MN, and delivered by its gravity at the nozzle *e*. The tube SO is called a *suction pipe*; its end in the well is at O, which, for the purpose of preventing the ascent of solid impurities, that might choke the pipe and impede its action, is pierced with holes like a strainer. At the upper end of this suction pipe is placed the valve *x* in the flange CD, opening upwards. At this place the tube is connected with another, BC, which acts as a great syringe, and in which works a piston cd, worked by the piston rod ab, having a valve at v, also opening upwards. The piston is worked alternately upwards and downwards in common pumps by a lever called the *brake*, but it may be worked in many ways. In the figure, W is the level of the water. At the commencement of pumping, as soon as the syringe ABCD exhausts the air by the upward and downward action of the piston cd, the pressure of the air in SO being diminished and rendered less than that on the surface, the water in the well will rise in SO by the atmospheric pressure. The valve x should on no account be more than 28 feet above the level of the water in the well. The cistern MN at the top is placed for the purpose of affording an unintermittent discharge of the water by holding more than the whole accumulation of water, which is contrived to be greater than the spout or nozzle will discharge.

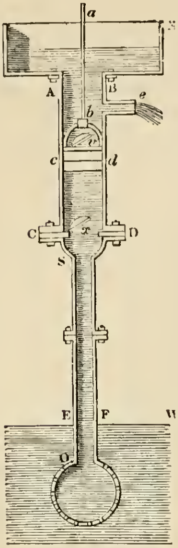

Fig. 805.

2218*e*. The *forcing pump* (*fig.* 805*a*.) is a combination of the common suction and lifting pumps. CEFD is a suction pipe descending into the well, and at its top is the valve V, opening upwards. The pump barrel, ABCD, has a solid piston cd, whose rod is ab, without any valve. From the side of the barrel, just above the suction valve V, a curved pipe proceeds, communicating with an upright cylinder or force pipe, GH, carried to such height as the water is intended to be raised. At the bottom of this cylinder is placed the valve V′, opening upwards. At the commencement of working, the suction pipe CDEF and the chamber between the piston and valves are filled with air. When the piston descends to the valve V, the air enclosed in the latter chamber becomes condensed, and opening, therefore, the valve V′, a part of it escapes through it. On raising the piston the air below it becomes partially exhausted, and that in the suction pipe, opening the valve V by its greater pressure, expands into the upper chamber. A part of this is expelled when the piston next descends, by means of the valve V′. This action is similar to that of an air pump or exhausting syringe. When by the repetition of this action the air is sufficiently exhausted, the atmospheric pressure upon the water in the well causes the water to rise therefrom through the suction pipe and the valve V, into the chamber between the piston and the valves. When the piston next descends it presses on the surface of the water, and the valve V closing prevents the return of the water into the suction pipe, while the pressure of the piston, being transmitted by the water to the valve V′, opens it, and as the piston descends, the water passes into the force pipe GH, and so on. By repeating the action the quantity of water in the force pipe increases, receiving equal additions at each descent of the piston. This force pipe may be perpendicular, oblique, or horizontal; for in each case the water will be propelled through it. A column of water suspended 34 feet in height in the force pipe will press on the base of the piston with a force of about 15 lbs. for each square inch; and the pressure at other heights will be proportional to this. Thus the force necessary to urge the piston downwards may always be calculated. The valve V′ is closed in drawing up the piston, and it then relieves the piston from the weight of the incumbent column. If the valve V is opened, the piston is subject to the same pressure as in the suction pump (*fig.* 805.), and this is equal to the weight of a column of water raised above the level of the water in the well. When the height of the force pipe is equal to the length of the suction pipe, the piston will be pressed upwards and downwards with equal forces; but when the height of the force pipe is greater or less than the length of the suction pipe, the downward pressure must be greater or less, in the same proportion, than the force which draws the piston up.

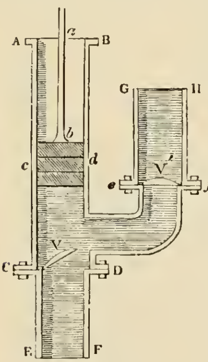

Fig. 805*a*.

2218*f*. The supply of water by the force pipe through the valve V′ is evidently intermittent, being suspended during the ascent of the piston; hence the flow from the point of discharge will be subject to the same intermission if means be not taken to counteract such effect. A cistern at the top of the force pipe, as already shown for the suction pump, would answer the purpose; but it is found more convenient to use an apparatus called an *air vessel* (*fig.* 805*b*.), in which immediately above the valve V′ a short tube communicates with a strong close vessel MN, of sufficient capacity, through the top whereof the force pipe GH passes, and descends to near the bottom. When the pump is in action the water is forced into this air vessel MN, and when its surface, as at *ww*, rises above the mouth H of the force pipe, the air in the vessel MN is confined above the water; and as the water is gradually forced in, the air, being compressed, acts with increased elastic force on the surface of the water. This pressure forces a column of water up the pipe HG, and maintains it at an elevation proportional to the elastic force of the condensed air. When the air in the vessel MN is reduced to half its original bulk, it will act on the surface of the water *ww* with double the atmospheric pressure; meanwhile, the water in the force pipe being subject to merely once the atmospheric pressure, there is an unresisted force upwards equal to the atmospheric pressure which sustains the column of water in the tube, and a column 34 feet high will thus be sustained. If the air is reduced to one-third of its original bulk, the height of the column sustained will be 68 feet, and so on. If the force pipe G were made to terminate in a ball pierced with small holes, so as to form a *jet d'eau*, the elastic pressure of the air on the surface would cause the water to spout from the holes.

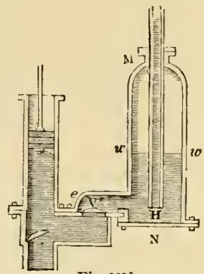

Fig. 805*b*.

2218*g*. In the formation of all pumps the parts should be nicely fitted, and as air-tight as possible, otherwise, in using them, much of the power employed will be lost. All expedients which tend to this great desideratum are of value. The joint CD, *figs.* 805 and 805*a*, is especially liable to leak if not well fitted. The variety of pumps now made is very great, although they are all formed on the principles first explained. The architect had best select the manufacturer, and learn of him the make and powers of the article required for the proposed purpose. Nearly one hundred varieties are shown in Messrs. Tylor and Sons' Illustrated Catalogue for 1885, 14th edition. They consist of a pumping apparatus for public thoroughfares, with cast iron cased well-engine frames, with fly wheel and with one or two handles; pillar well-engine frame and single or double cranks; the same with wheel and pinion to decrease labour; rotary action, fixed on plank; horse wheel frame, for horse power, and others applied to steam power; pumps for artesian wells; lift-pump; vibrating standard lift-pump; and rotary action lift-pump, all on planks, &c.

2218*h*. The *Pulsometer* is a patent pump, of great service for foundation and sinking work of all kinds, and for general pumping work; skilled attention is stated not to be required, and it will pump thick gritty water. Norton's *Abyssinian* and artesian tube wells and pumps are of much service for large and pure water supplies from shallow or deep sources; they are also called *driven tube wells*.

2218*i*. The Aqueous Works and Diamond Rock Boring Company, Limited, by their method of using black diamonds (or carbonate), are able to bore through hard strata, such as granite; they drive a tube for a well say 25 feet deep; or to a depth say of 1144 feet, having a bore hole $9\frac{1}{4}$ inch diameter; or in the case of minerals even to a depth of 1906 feet, as at Battle in Sussex.

2218*k*. As to water supplied by *a company*, it will only be needful to refer to the quantity, and to the two systems: I. the ordinary pressure; and II. the non-intermittent or constant supply. A Parliamentary return issued about Midsummer, 1866, states that the New River Company supply was equal to 209·5 gallons per house per day; or, taking each tenement to hold five persons, it was equal to 41·9 gallons per individual per day. The *daily* supply of water to the metropolis in 1865 by all the companies was nearly 93 millions of gallons, or at the rate of rather more than 200 gallons per house, or over 30 gallons per head. In 1887 the metropolis was supplied by eight companies. The East London supplies a population of 1,180,000 persons; the New River Company, 1,125,000; the Southwark and Vauxhall, 800,000; the Lambeth, West Middlesex, Grand Junction, and Kent, 500,000 each; and the Chelsea, 260,000. The daily total supplied is 179,600,000 gallons, for a population of 5,3·0,000, being an average of rather over 33 gallons per head, and ranging over 725,912 houses.

2218*l*. It may be useful to note that the non-intermittent system, or constant supply, has been adopted at Manchester, Nottingham, Derby, Durham, Leeds, Dundee, Glasgow, Ipswich, Chatham near Rochester, Wolverhampton, Bristol, &c.; the two last are described in Cresy's *Encyclopædia of Civil Engineering*. At all these places the result appears to be satisfactory in every way, both to the water companies and to the consumers. At Hitchin the average daily consumption was 235 gallons per house; at Croydon, at one time 500; Whitehaven, 250, or 50 per person; York about 200; Exeter, 120; while at Bristol, Rugby, Sandgate, and Barnard Castle, the waste was so great the supply became inadequate. Nottingham had only 20 gallons per person, and Durham 20 to 25. In America, New York has 90 gallons per person; Boston not less than 55. In 1884 it was stated that, taking the daily consumption of water in London at 29 gallons per head, in Paris it was less, while at Berlin it was but 20. At Detroit, Michigan, it was 100; while at Chicago and Washington it was 119 and 155 gallons respectively.

2219. The third mode of obtaining a supply of water is by the *hydraulic ram.* It is more available in the country on account of the noise caused by the continual clicking of the valve. It is a simple self-acting machine for raising water into a cistern or tank, where a fall of water can be secured from a stream, or other source. Once set in motion, it will continue to work as long as it is supplied with water, or until the wearing of the iron valve disables it. A fall of only 5 feet to the ram will enable it to supply a tank 60 feet higher than the source and 2,000 yards distant. Much of our present information on the subject of supply of water was known to the Romans, and is carefully described by Vitruvius in Book VIII. of his work.

Water Closets.

2220. It is unnecessary to describe at length the machinery of a *water closet.* The principle on which the usual apparatus is formed is that of a head of water in a cistern placed above it, which by means of a lever attached to a valve in the cistern allows a body of water to rush down and wash the basin, whose valve, or pan, is opened for the discharge of the soil at the same moment that the water is let down from the cistern (par. 2223*a.* describes the cistern). Bramah's patent was among the first; Underhay's among the latest, which does away with wires and cranks, the supply pipe being constantly filled with water. The student will obtain by the inspection of a closet a far better notion than words or diagrams will convey. The apparatus of a water closet has also been made self-acting, either by opening the door of the closet, or by lifting or depressing the seat of the apparatus. For the more modern *flush* closets it is generally necessary to pull a chain, which allows a certain quantity of water to flow from the cistern by a valve, or from a water-waste preventer (par. 2223*f.*), into the pan, and so wash out the foul water.

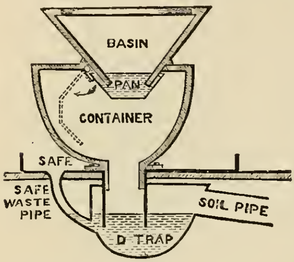

Fig. 806.

2220*a.* Notwithstanding the many forms of water closet apparatus, nearly all of them may be classed under four heads. I. The old *pan* apparatus (Fig. 806.), where the water is retained in a pan, which is discharged on drawing up a handle, into and through a "container," and thence by a short pipe into a trap, called from its shape a D trap. This form was considered to be so objectionable from the occasional deposit in the container, that under par. 69 of the Bye-laws as to New Streets and Buildings, issued by the Local Government Board, "he shall not construct or fix under such pan, basin, or receptacle, any container or any other similar fitting;" and "he shall not construct or fix in or in connection with the water closet apparatus any trap of the kind known as a D trap." The "Banner system" has introduced an ordinary pan closet improved, and also a patent closet with a pan, both without traps.

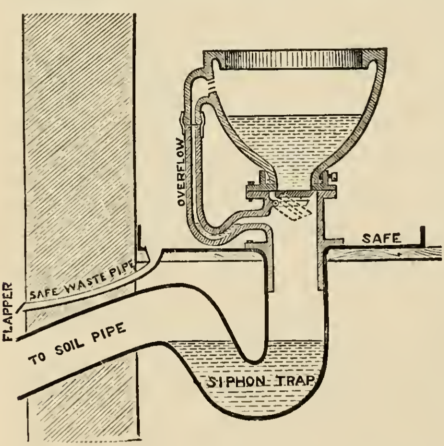

Fig. 806*a.*

2220*b.* II. The *valve* apparatus (*fig.* 806*a.*), is now generally fixed in the houses of the better classes. On lifting the handle a valve or flap is let down into the pipe, when the soil descends through it at once into a syphon trap. The water is, however, only kept in the basin by the closeness of the fit of the valve and its seating, or bottom of the basin. Any slight corrosion, grit, hair, soapy slops, or paper, not washed through, causes the valve to fail to close properly; the water then escapes, the basin is left in a state unfit for use, and smells arise which the valve is intended to prevent. Hayward Tyler and Co. make valve closets with copper bellows or brass regulators. Adams's improved elastic valve closet, with brass or bellows regulator. Warner's patent valve closets. Stidder's improved valve closet, with patent overflow trap and ventilating junction combined; also his patent *Siamese* trapless closet; and his patent London side outlet valve closet. Banner's *Nestor, Elastic, Simplex, Safety,* and *Twin basin* valve closets. Buchan's (Edinburgh) patent sanitary closet, "whereby no sewer smell can pass into the room, even when the handle is pulled up. When the closet valve is lifted, the water falls in full volume direct into the soil pipe, pressing all the gas before it, and causing a syphonage that sends the whole contents in one body to the drain. There being no trap under the valve, the soil pipes are scoured and kept clean."

2220*c*. III. This class comprises the *hopper* water closet, or flushing basin (*fig.* 806*b*), which is simply a basin or pan finished with a syphon trap at the bottom, without any further apparatus than that which admits the water to flush or wash it out. These pans require the addition of a pail or two of water poured down occasionally to help the clearing of dirt and paper. They are popular for servants' closets and for cottage and common use, but require occasional cleaning out. One of the most simple pans is that called by Messrs. Doulton the *enamelled stoneware closet pan, figure* D, which, with pan and syphon trap complete, is sold at 3*s*. 9*d*. each. This class includes Adams's hopper pattern closet, with flushing apparatus; Warner's patent cottage basin and trap; Stidder's household closet; and others.

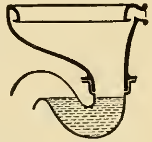

Fig. 806*b*.

2220*d*. IV. includes a series of more modern contrivances, invented for the purpose of obviating certain defects in the others. They are called the *wash-out* basin or closet (*fig.* 806*c*.); but many still retain the chief defect in the carrying down of the discharge into another receptacle, or trap, below, or at the side, only partially out of sight, and not always with a sufficient flushing power each time it is used, especially where only a small "preventer" is allowed. Among the many patents of these closet pans, are Bostell's Excelsior; Woodward's Excelsior; Winn's complete sanitary closet; Twyford's National; Sharpe's patent pan basin; Winn's free flushing basin and trap; Woodward and Rowley's wash-out closet; Adams's wash-out pattern closet, with flushing apparatus; Stidder's Torrent water closet; Banner's patent wash-out closet (*fig.* 806*c*.), &c.

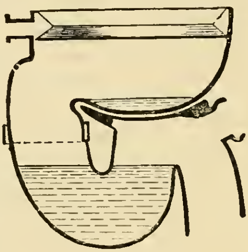

Fig. 806*c*.

2220*e*. *The Merits and Demerits of Various Kinds of Water Closets in General Use*, by D. Emptage, is printed in the *Sanitary Record* of October 15, 1883, p. 187. The figures above of these closets are obtained from Dr. Corfield's *Laws of Health*, 8vo., 1887.

2220*f*. A protest has been often made against the continuation of the general mode of fitting up a water closet with a seat, lid, and riser, or enclosure, which too often proves to be all fair without but foul within. Probably not one of them when taken down but would disclose a state of things, as regards cleanliness, as foul as any drain; especially so, when the closet has been used for disposing of bedroom slops in contravention of all orders. The lead safe gathers the overflow which will occur, as the servant cannot hold up the handle at the same time as she empties the pail; and unless it has a fall to the waste pipe (if there be one), it lies there to dry up and annoy the house with the foul smell. Often this waste pipe passes into the trap or into the soil pipe, making matters worse. Hence the admirable arrangement put forward by Doulton and Co., in the Lambeth *Combination closet*, which has the basin and trap made in one piece of stoneware decorated, so that the customary riser is unnecessary; it stands on a finished wood or tiled floor; the seat being made to lift up, it forms a slop sink. The *Desideratum closet*; Gildea's closet, are others. Twyford's special water closet basins, which comprise the *Unitas*, the *National* patent *side* outlet closet and trap; while the *Alliance front* outlet closet and trap is a variation of the former one. The *Crown* sanitary closet basin and trap is a cheap and simple apparatus. The Farnley sanitary closets comprise the *Trinal, Universal, National,* and *Simplex*, each in one piece, with or without trap and ventilator. Warner's improved London open water closets, combining in an elegant form a water closet, slop sink, and urinal, well trapped above the floor line. Shanks's patent *Tubal* and *Citizen* water closet with hinged seat, &c. Shanks and Co.'s patent system of combined closets and cisterns, where the closet is in one piece of enamelled stoneware, having a very large inlet horn made with the closet. On it is seated a single or double valve cistern, having a correspondingly large outlet valve, which from its size gives a flush compensating for the lack of the usual height, and washes out and replenishes the basin fully. Banner's *Holborn* combination water closet. All these require an inch-and-a-quarter pipe from the cistern, or two gallon syphon cistern or water-waste preventer, for flushing purposes.

TRAPS.

2220*g*. Traps to *water closet* pans consist of the old-fashioned and now condemned trap (*fig.* 806*d*.), with its dip pipe near one side of it; the trap; and the or syphon trap. These two last are now generally used. Hellyer makes a patent cast lead V dip trap, or "anti-D" trap as it was termed, of about 8 lb. sheet lead. It is as self-cleansing as all syphons, and leaves no corners for lodgment of dirt. This has an air pipe on the top of the "out-go" portion of the trap, which may be a useful addition.

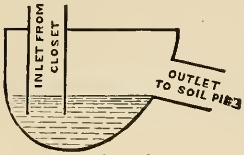

Fig. 806*d*.

2220*h*. The traps themselves must be ventilated to prevent syphonage; they may be unsealed by the momentum of any discharge passing through the trap itself, and by the passage of a considerable quantity of water through a pipe with which the trap is connected. The passage of this water causes a momentary vacuum, by means of which the water is sucked out of the trap.

2220*i*. The question has been raised, why should the water closet be trapped if the soil pipe be kept ventilated and trapped? There must always be some portion of the refuse matter adhering to the inside of the pipe, even if there be good and constant flushing; hence the advisability of trapping it.

2220*j*. The importance of good *stench traps to drains* is not to be overrated. The usual iron *bell trap*, as supplied to a sink, or let into a pavement, is sufficient as long as the bell remains perfect. Tye and Andrews manufacture a good new patent *sink trap*; Cottam has also a cast iron trap or "effluvium interceptor." Beard and Dent have patented a *cast lead pipe trap* of 2 and 4 inches diameter, and claim for it that it is of pure and solid lead, without solder or seam of any kind; as clear inside and out as any pipe made by hydraulic pressure; of a perfectly regular substance throughout; and that, being composed of one metal, it is not subject to expansion, nor liable to be affected by the gases, which tend to destroy the ordinary trap. Jennings's "Du Bois" drawn *lead traps* and bends are made by hydraulic pressure, in the same manner as ordinary lead pipes, from $1\frac{1}{4}$ to $4\frac{1}{2}$ inches diameter; the inside becomes accessible for cleaning by a screw tap at the bottom of the bend. All these traps only continue effective as long as water remains either in the cup or at the syphon bend, a fact which is either not known to, or forgotten by, very many housekeepers, who complain of the bad smells from the drains in summer time, or after some days of dry weather. Many of such syphons are now manufactured for various purposes in glazed stoneware, which are readily cleaned. Stiff has several "sewer air excluding traps," as the *Interceptor trap*, and the *Weaver ventilating* trap. *Buchan's* patent stoneware *drain* trap is one of the most useful of the sort. He adopted first a trap with a slope down into the syphon, but found that a fall was better; hence the *fig.* 806*e*., having a fall of 2 inches for a 4 inch trap, $2\frac{1}{2}$ inches for 6 inches fully, and 4 inches for 9 inches fully. Doulton and Co.'s safety sanitary trap (Henman's patent, 1885) is for connecting a water closet pan with the soil pipe; no untrapped joint within a building. Adams's special disconnecting traps. Smeaton, Son and Co.'s interceptor trap. Banner's main drain traps, as the *Excello*, and the *Cerus*. Bolding's air shaft or disconnecting trap, with inlet at top and inlet for easy access to drain for clearing stoppages; his soil pipe intercepting trap; and his "disconnector" for 6-inch and 4-inch stoneware drains. Davies's disconnecting receiver and trap for house drains is stated to give: 1. Thorough disconnection from the sewer. 2. Thorough ventilation of drains. 3. Simplicity in planning house drains. 4. Easy access to drains and traps in case of stoppage. 5. Convenience of fixing in any position, irrespective of sewer. 6. A barrier against rats coming up from the sewer. It is made by J. C. Edwards, of Ruabon.

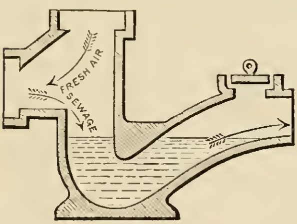

Fig. 806*e*.

2220*k*. *Gully traps*, for taking off water from yards and from rain-water pipes, are provided of stoneware as well as of iron. Such as Bolding and Son's *simplex* gully trap, for various purposes; salt glazed and galvanized iron grates, square and round, some with raking inlets. Bellman's patent *gully* receives and disconnects one rain-water pipe and three waste pipes; it avoids splashing, ventilates the pipes and drain, forms a gully or drain from a yard or path, and is easy of access for cleaning out; the ordinary or trap can be used with it, and placed at any angle to meet the drain. Adams's patent street gully and yard traps. Banner's gully trap.

2220*l*. A *scouring trap* is a late invention; it appears to possess some advantages in affording a good scouring wash-out and dip to the drain. Davies's receiver, &c., above described, is for a somewhat similar purpose.

2220*m*. When drain traps are left for some time they should be flushed out and left full of fresh water, into which should be placed some ordinary calcium chloride, a by-product of a chemical process, and very cheap. This is exceedingly hydroscopic, having a great affinity for water. Thus the traps would remain full of water for any length of time. (Prof. Babcock of Cornell University, U.S.A.)

2220*n*. A *grease trap* to catch the melted fat, &c., from the kitchen sinks, is considered a desirable addition, as it tends to prevent the grease from passing into and stopping the drain. There are several varieties, chiefly of stoneware. Those readily cleaned out by hand are perhaps the best; buckets, used in some, can scarcely be considered satisfactory. Emptying the usual grease trap is one of those many works in connection with a household that almost amounts to emptying a cesspool, as it is usually left and becomes foul; this trap is to be avoided if possible. It is recommended to be ventilated (*fig.* 807*c*.). The best of the number is the patent of Mr. Farrow, the first one introduced as a special fixture. Hellyer's, Buchan's, Stiff's, Doulton's, with others, are to be procured. One has been devised by Mr. J. Honeyman, architect, consisting of a shallow box encased with cold water, and covered with a movable grating resting about half an inch or more below the level to which the water would rise. The cold water would be frequently replaced from the service to the sink. The greasy water would adhere to the sides, and be forced up through the grating for removal, and the box, being in sight, would be cleaned out as required. Smeaton, Son & Co.'s grease trap; Adams's grease trap only; and his combination grease trap and flush tank; Durrans' patent glazed stoneware gully and fat trap, by J. C. Edwards of Ruabon, is a cast iron box dropping into the water, and removable for cleansing purposes, giving free access to the drain pipe.

2220*o*. The self-cleaning *Trough closet*, as Adams's patent, is largely used in schools, factories, barracks, workhouses, and other such institutions where a number of persons are collected or employed. It is automatic, having a Field's self-acting flushing cistern. About five or more closets, or stalls, are formed over the stoneware trough that communicates with the drain. The trough is also made of iron, and is also arranged to be discharged on land and disposed of by irrigation. These troughs require occasional inspection and good water supply.

2220*p*. Reference has been made (pars. 1887*b*. and 1888*h*.) to flushing requirements. To these may be added, Adams's patent automatic flush tank, "giving an instant start with drop by drop supply"; his patent improved automatic flushing syphon; his syphon cistern for closet, urinal, &c.; his flushing valves and penstocks for drains and sewers; Stidder's patent syphon water flusher; Doulton and Co.'s automatic flush tank; and others by Jennings and Co.

2221. *Urinals* are made of slate for public use, of various forms and arrangements. A water supply from a self-acting flushing cistern, holding from 10 to 20 gallons, arranged for a discharge according to use; about every quarter of an hour is considered sufficient to free a much frequented urinal from all nuisance. Sometimes water is turned on for a time at several hours of the day. White pottery urinals for private use are of all varieties and shapes. The overflow pipe supplied to some is not always a desirable addition. Doulton and Co.'s improved urinal and lavatory; Adams's patent lavatory ranges for schools, &c.; and urinal and closet erections. Jenning's urinal erections for two or more persons. Stidder's school lavatory and slop sink, as used in the London and other Board schools. Mounted lavatories for domestic use, by Warner and other manufacturers above mentioned.

2222. The use of *Earth closets* as one of the safeguards against smells from sewers has made no headway for large populations, and is beset with practical difficulties. In the Midland and Lancashire towns the *pail* or *tub* system has been much more largely introduced as a substitute for the water closet, and it has, from a landlord's point of view, many attractions. The first cost, as compared with that of a water closet, is small, and the landlord is, in most towns, relieved afterwards of all future cost and maintenance. Whereas in the case of water closets in cottage property there is undoubtedly great difficulty in keeping them in good working order, especially during frosts. There are, however, many objections to the pail system, especially that it appears to be a costly appendage to the water-carriage system, inasmuch as the remaining liquid refuse has still to be dealt with by the modern systems of precipitation or irrigation, at practically the same cost as would have been the case if the water-carriage system had been adopted in its entirety by the municipal authorities.

2222*a*. The deposits are at once deodorised by a small quantity of coal ashes or earth, which absorbs the ammonia and other fertilising properties, for removal to the garden or field. It may be considered more serviceable where there is a deficient water supply or a want of proper drainage, and in country, rather than in town, localities. *Moule's* patent was the first invented. *Morrell's* patent cinder sifting ash closet, and *Heap's* patent dry closet, are other inventions. The earth may, with proper drying, be used over and over again for years. Ashes, fine and dry, may be used, to obtain which there is the modern automatic cinder sifter. They are not considered preferable to the water-carriage system, where obtainable.

Tanks and Filters.

2222*b*. Having obtained the source of a water-supply, a *tank* for a collection for a farm, or a *cistern* for the supply of a house, are requisite. The former may also be required to retain the rain water from the wood, lead, or zinc gutters of the buildings; water from copper gutters is poisonous. The *tank* is usually formed of brick or stone built in cement, and cemented inside, and when of a small size it is domed over, with a man-hole for access. If of large size, iron girders supporting slate or stone slabs will form a flat covering to it. These should be well jointed to prevent dirt falling in. Pain ing the cement with a solution of silicate of potash is said to prevent the soft rain water becoming hard in a new tank. Such a system as the following would be found very serviceable on many farms having clay lands.

2222*c*. In Venice, the rain water is collected from the roofs and led into the court-yard, where it undergoes a regular system of filtration before it reaches the tank, whence it is raised by buckets. The construction to effect this consists of—I. A water-tight enclosure. II. A well of dry brickwork in the centre of, III. A wall of sand, filling up the remainder of the enclosure round the well, and serving partially as a reservoir, and partially as a filter; care being taken that no water enters the well but what passes through the sand. The system is shown in the *Allgemeine Bauzeitung* for 1836, pl. 556; and in the *Transactions* of the Institute of British Architects, 1842, p. 187.

2222*d*. Another and more simple method is described in the *Building News*, 1862, p. 127. A large hole is dug about 9 feet deep; the sides are supported by an oaken framework of a square truncated pyramid, the wide base being turned upward. A coating of compact clay, 1 foot thick, is applied on the frame with great care, to stop the progress of the roots of plants, as also to prevent the pressure of the water. A large circular stone, partly hollowed out like the bottom of a kettle, is placed therein with the cavity upwards, and on this as a foundation a cylinder of well baked bricks is constructed, having no insterstices except a number of holes in the bottom row. The large vacant space left between the sides of the pyramid and the cylinder is filled with well scoured sea sand. At the four corners of the pyramid a stone trough is placed, covered with a stone lid pierced with holes; they communicate with each other by means of a small channel made of bricks resting on the sand, and the whole is then paved over. The rain water is led from the roof to these four sink stones, and, penetrating into the sand through the channels, filters down and passes into the filter itself by the small holes left in the bottom row of bricks. These cisterns get filled about five times a year, and the distribution of water is at the rate of about 312 gallons per head.

2222*e*. The average annual rainfall is 31 inches. Where rain water has to be depended upon, a *separator* has been invented by Roberts, which "prevents the first portion of the rainfall passing into the storage tank. It cants and stores the water when the roof has been washed by the first rain."

2222*f*. The Rivers Pollution Commissioners put the several waters derived from various sources in the following order, having regard to their hardness:—I. Rain water (softest). II. Upland surface water. III. Surface water from cultivated land. IV. Polluted river water. V. Spring water. VI. Deep well water. VII. Shallow well water (hardest). They consider water at or below six degrees of hardness to be soft, and above that number of degrees to be hard.

2222*g*. *Filters* are used for purifying water for towns, or purposes for which large quantities are required. They are usually formed in England of several layers of sand and gravel, gradually increasing in the volume of its particles in descending; and in the lowest course of gravel perforated tiles are laid, through which the water flows into the reservoirs. The water is supplied on the top, so as to stand at a depth of from 4 to 6 feet over the sand and other filtering media. At the Lambeth Water Works these media consist of: I. A layer of sand 3 feet thick. II. A layer of clean sea-shells 6 inches thick. III. Fine gravel 6 inches thick. IV. Coarser gravel 6 inches thick. V. Very coarse screened and washed ballast 6 inches thick; and VI. Pierced tiles covering the drains. At the Southwark Water Works the filtering media are rather thicker. At Hull the sand is 2 feet thick, and the gravel 16 inches thick. At York the sand is 4 feet thick, and the gravel 4 feet thick. At Paisley the sand is 2 feet thick, and the gravel only 6 inches; but the upper part of the sand is mixed with animal charcoal. Local conditions must regulate the proportion of these materials, for the thickness of the sand must be increased according to the impurity of the water. When the water is at all turbid, it is advisable to make settling reservoirs by the side of the filtering basins, to collect the impurities in the first instance. The usual yield of filtered water from a basin established under the preceding conditions, is about 80 to 100 gallons per foot superficial per day.

2222*h*. Dr. Clarke's approved process for softening water is stated to be by adding an equal quantity of lime in solution to the pure lime of the bicarbonate contained in the water. The solution of lime combines with one-half of the carbonic acid and forms chalk, at the same time reducing the bicarbonate to chalk also. Chalk being insoluble, settles to the bottom. The Consumers' Economic Water Softening and Purifying Company (Limited) has been formed for the use of Atkins's patents, to adopt the recommendations of the Royal Commission on the Pollution of Rivers; and though several towns of small or moderate size had carried out those recommendations by adopting one or other of the systems then available, it was considered impracticable for any large town to do so. At the Southampton Water Works, the largest works of this sort are now (1888) completed and many other towns are contemplating the introduction of the system.

2222*i*. In some places both the chemical and mechanical impurities may be eliminated from water by dividing the tank by a cross wall of a filtering stone. Such a stone will filter about 60 gallons per foot superficial per day. Chemically, this could be effected by causing the water to pass through a diaphragm or cross wall, composed of two slabs of filtering stone, placed at a small distance from one another, and filled in with animal charcoal or with magnetic oxide of iron. The latter material appears to be the best for such water as is collected from roofs, because it parts with its oxygen with great rapidity to the rain water, and is susceptible of rapid revivification; it is also cheaper than charcoal. A double wall thus formed ought to pass 100 gallons per foot superficial per day. A few drops of permanganate of potash, put into water tasting and smelling of decaying organic matter, will render it in a few minutes clear and sweet. A small quantity of alum tends to render water very pure, by freeing it from matters held in suspension. Ransome's patent siliceous stone is the best material of the kind ordinarily obtainable in England. Filters of porous sandstone, as made at Halifax, are recommended as effective and durable. A paper on the subject of filtration, read at the Institute of British Architects, 1850–51, by Mr. G. R. Burnell, and given in the *Builder*, ix. 404, deserves attention. Household filters, whether for occasional use or for a system of domestic filtration of water as it flows from the cistern, is now often a subject of consideration for a tenant and landlord. Among these are Lipscombe's; Maignen's patent *Filtre Rapide*, with his patent process for softening water by means of the patent *Anti-calcaire*; the patent *Porous Carbon* Company's material; Halliday's patent high-pressure self-cleansing filter, which can be attached to the main or supply pipe; the *Chamberland-Pasteur* filter; *Compound charcoal* filter; Atkins's patent cistern filter, a pure charcoal block filter; the *Queen*, which can be fixed to any tap; the patent Moulded carbon block and loose charcoal thorough self-cleansing rapid water filter; the Grant revolving ball water filter, also attached to the tap on a main or service pipe, and is rapid and self-cleaning; and others.

Cistern and Supply for daily use.

2223. The amount of water used varies very much in different communities, but where the allowance is scanty disease of various kinds is encouraged by the absence of attention to the cleanliness of persons and of things, the want of sufficient water to flush the drains, &c. About 10 gallons a head per day are required for domestic purposes, including bathing, and about as much more for flushing purposes; the average amount required for trade purposes is generally roughly put down at an average of 20 to 30 gallons a head per day. Many towns have a less supply. Where there are large public baths, or manufactories requiring much water, or even a large number of animals, 30 gallons or more are required. Rome had probably from about 170 gallons to 300 gallons per head per day, but authorities vary. An imperial gallon per man per day appears to be the allowance on board a vessel. In stables, each horse should be provided with 16 gallons, four of which is consumed with his food. Each four-wheeled carriage takes about 16 gallons. Each two-wheeled carriage about 9 gallons. To wash a paved court or passage, a gallon of water may be provided for each superficial yard. The available rainfall from roofs in England is estimated at 18 inches per annum; and if the source of supply be only rainfall, a tank capable of holding 4 months' collection should be provided. (Hurst, *Surveyors' Handbook*.) One cube foot of cistern will hold nearly $6\frac{1}{4}$ gallons of water; and a cube foot of water weighs 62·321 lbs.; a gallon weighs 10 lbs.; a cylinder inch, ·02842 lbs.; and a cylinder foot, 49·1 lbs.; 35 cubic feet of water equal 1 ton. The supply for each man, woman, and child in a house is reckoned at 15 gallons per day, though it is considered no one really uses much more than 6 gallons; or about 12 gallons, as calculated by Sir W. Clay, by a family in London.

2223*a*. The *cistern* for a house was originally placed outside, and made entirely of lead, the front of it being frequently decorated with devices, either cast with it, or secured by *paleing*, i.e., the soldering on of embossed figures. Lead cisterns are still in use, but they are cased with wood, and placed were most wanted for the supply. No cistern should be put where the sun can act upon it, as vegetation in the water sometimes ensues. (1785*a*).

2223*b*. A cistern is usually made of $1\frac{1}{4}$ or 2 inch memel fir, lined with 6 lb. lead. A cover should always be provided. This metal lining is now much superseded by one of zinc, on account of the deleterious effects arising by the action of pure water on the lead; but zinc can only be trusted as a temporary resource. Slate is a better material for all collections of water or other liquids in general use. Care must be taken that a porous quality be not supplied; and it should not be placed where mild damp air will meet it and condense on its cold surface, and so run down in drops. As it is very unyielding to the expansion of ice, its position in the house in that respect is an important consideration, and in case the joints become leaky from that or any other cause. Cisterns are supplied with water by a main service or feed pipe sufficiently large to allow of its filling during the time the water is turned on. The flow of water is regulated by a *ball cock.* The water supply to each bath, water closet, &c., is suggested to be controlled by a stopcock of a bore equal to the pipe. Ball cocks to be supplied with a stop cock to each, in case of repair. The cistern to have a proper standing waste for cleansing purposes only, as well as the ordinary half or three-quarter warning pipe, which must be provided, according to some water companies' rules. The *fig.* 615*k.* shows a system of water supply, where *c* is the cistern in the roof Z, which is often placed over, but quite separated from, the water closet A. *m*, water pipe, cased; *y*, slop sink, having a tap from the main *n*. X, flushing tank; the cistern *c*, in B, also supplies the syphon flushing cistern in the servants' water closet *d*. The dotted line *o* shows the line of water pipe from the cistern *c* in the garden, supplying the kitchen boiler.

2223*c*. The cistern to supply a water closet should properly be distinct from that for domestic purposes; and when the former is placed in a confined spot, necessitating smallness of dimensions, one of an upright form is essential to provide the head of water for flushing the basin, *Fig.* 806*f.* shows an apparatus fitted to a lead cistern for supplying water to the pan. A, the ball valve pulled down by the wire B, and thus lifting, by the wire C, the valve D, which admits the water into the lead service-box E, soldered into the bottom, F, of the cistern. The air-pipe G lets out the air from the box forced into it by the pressure of the water rushing through the down pipe H. A waste pipe for emptying the cistern, or for carrying off the surplus water when being over filled, must always be provided. When a cistern supplies the house, a service pipe is required from it, the outlet having a *rose.* For a slate cistern, a brass flange (*fig.* 807.), fitted with screws and nuts, is soldered to the lead service-box, and then secured to the slate. A "round closet valve with union, fly-nut," and air-pipe (*fig.* 807*a.*) is occasionally used in lieu of the above contrivances; or a spindle valve with union, fly-nut and air-pipe.

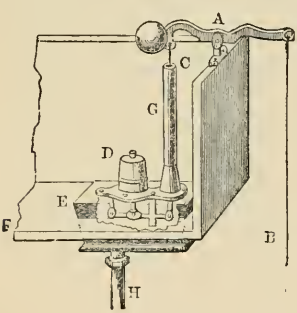

Fig. 806*f*.

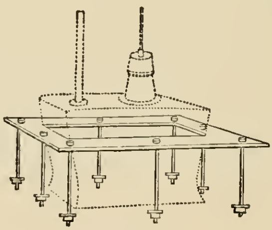

Fig. 807.

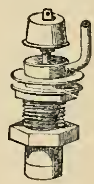

Fig. 807*a*.

2223*d*. Iron tanks and cisterns made of plate iron riveted, plain or galvanized, are formed to any shape or size; as also of a small size in stoneware. A question has arisen as to zinc and zinc-coated iron for cisterns. Soft water, such as rain water, dissolves zinc more easily than hard water. Water containing carbonic acid is specially able to dissolve it. The French Government have prohibited the use of galvanized iron tanks on board men-of-war. Professor Heaton analysed spring water, with a further analysis after it had passed through half a mile of galvanized iron pipe, and found it had taken up 6·41 grains of zinc carbonate per gallon. Dr. Venable states that where spring water passed through 200 yards of such pipes it took up 4·29 grains of zinc carbonate per gallon (John Smeaton). To stop leaks in iron cisterns, mix litharge and red lead; if to dry quickly, gold size mixed with boiled linseed oil. Extra hard carriage varnish is useful for inside purposes only, well rubbed into the crack.

2223*e*. With the constant supply system, now being generally introduced, service cisterns are said to be unnecessary; but it will be advisable to have one, and especially near any office requiring a good supply of water, as the service is occasionally cut off for two or three days during repairs or cleaning of the mains. Some lower-class houses are said to have a 6-inch zinc-lined trough instead of the usual cistern; hence frequent stoppage of drains occur from want of flushing power, as depth of water is essential for it.

Water-waste Preventer.

2223*f*. In some towns the water company insists upon a small cistern being placed in the water closet, or to a urinal, to prevent waste of water, as it is stated. There are various patents, worked by a syphon or other action. They are each regulated for a supply or flush of about a couple of gallons of water at a time. Such are Purnell's syphon; Winn's *Acme*; the *Peckham* (No. 2) improved pneumatic syphon cistern for fixing in a cistern, has no valves, rubbers, washers, &c., the action is noiseless, and the connection is by an air pipe of $\frac{1}{16}$ inch bore, worked by a push knob; the *Invicta*; the *Peerless*; the *Syphon*; the *Double valve*; the *York*; Trott's patent; Crapper's syphon; Bolding and Son's syphon, their *Simplex* after-flush, which is not syphon action, is a simple apparatus; the registered *double syphon*; Tylor and Sons' improved patent model *waste-not* cistern valve, for fixing in a cistern under water; Smeaton's new water-waste preventing valve; Humpherson's syphon cistern; Bean's direct-acting valveless cistern; Bostell's cistern. Most of the patents are noisy in action, and all are of questionable utility for the purpose, often getting out of order and wasting water rather than preserving it, besides preventing that useful flush of water which aids in keeping the drains clear.

Pipes.

.2223*g*. The *pipes* used for the purposes of building are proportioned to their uses. Those, for instance, called *soil pipes*, for carrying away the soil from a water closet, or those for conveying water from roofs, called *rain-water pipes*, and those occasionally from sinks, are, of course, of larger diameter than those called *service pipes*, which are merely, as their name implies, for laying on water to a house, those of somewhat larger diameter being called *main service* or *supply pipes*: the service pass from the mains to the cistern.

2223*h*. From the cisterns *pipes* are required to convey the water to the several places it is destined to supply. Those of lead are either cast round or soldered. In casting, a mould is made of brass, wherein down the middle a core of iron is loosely supported, at such a distance from the mould all round as is equal to the contemplated thickness of the pipe. When this is set the core is removed, and the cylinder opened so as to withdraw the pipe, which is much thicker than is needed, and must be lengthened, while its substance is reduced, by *drawing* it through a succession of holes in steel plates, diminishing gradually in diameter, similarly to the method employed in drawing iron rods. This machinery became gradually improved in its construction, so that it was of rare occurrence to meet with an imperfect pipe. Lately the manufacture of lead pipes has been further improved by casting them under hydraulic power. A quantity of lead is placed in a box, and forced through the mould at a certain rate, which gives the metal time to cool, so that it is pressed out gradually in a complete state, and wound round a wheel ready for use, its length being made within the limits of carriage. When pipes are made by soldering, a core of wood is provided, round which the sheet lead is rolled, and the edges are brought together and joined with *solder*. A solid drawn lead pipe with a distinct inside lining of block tin $\frac{1}{16}$th of an inch thick was made, but it was found expensive, and the labour involved in fixing it prevented its ready adoption; also a solid drawn square or rectangular fall pipe; both by Hanson, Dale & Co., of Huddersfield. Hellyer has made a square drawn lead pipe for outside of houses. Glass lined pipes are later. Glass pipes for conveying distilled water are used in laboratories.

2223*i*. Concussion in water pipes is caused by the weight of water being shut off and stopped in its flow while turning off the end tap suddenly. If it be turned slowly this does not take place. The noise may be obviated by continuing the pipe (or a smaller one) over the tap, and inserting the end into the pipe. Either the water rebounds into the supply or the curved piece of pipe contains air, which serves as a buffer. The same arrangement answers for gas pipes where the last jet sometimes has a quivering flame; or the pipe (in either case) can be carried into another pipe near to it, so as to obtain a circuit.

Soil Pipes.

2223*k*. The most important point in connection with the water closet is the *soil pipe*. Great care is necessary in fixing it. It should be hung on *tacks* of lead at least one pound heavier than that from which the pipe is made, at least nine inches long, to take three courses of bricks, and three tacks to each ten feet length of soil pipe. Often in the course of three or four years the soil pipes start crawling down, owing to the fixings being scamped. It should not be nailed too closely. Pipes from *slop sinks* are often branched into the soil pipe, and require the same treatment, also care to prevent syphonage. Its trap should be as close to the fixture as possible, so as to avoid a length of pipe, which might become foul on the near side of the trap, and so become a nuisance of itself. Banner's soil pipe traps are either for the soil pipe at the end, or the soil pipe in the centre, each trap having a fresh air or rain-water pipe inlet, and an inspection hole. Doulton and Co. manufacture vertical soil pipes, or patent safety house drainage pipes,

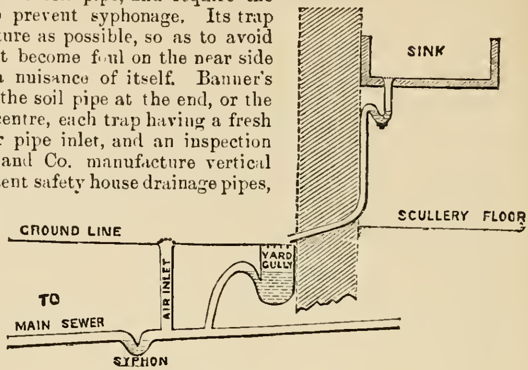

Fig. 807*b*.

being incorrodible, with junction pieces, fastened to the walls by ornamental iron bands, readily adapting themselves to any settlement of the brickwork; and are made in lengths of 3 feet, and of 4 in. and 6 in. diameter.

2223*l*. The wastes from a bath, a lavatory, a pantry, or a wash-up sink (as partly shown in *fig.* 807*b*.), require special treatment. The discharge from a sink should be under the grating of an intercepting trap, not upon it, as is sometimes done. Under the fixture, and as near to it as possible, should be a syphon trap of good construction, soldered, if to a sink, with only a taper piece to take its grating or washer. The waste from a bath, &c., is sometimes carried through the wall into the open head of a rain-water pipe, or other contrivance, and so to a grating, the end being left open; a syphon trap under the fixture is useful, though not often put. A 2 or $2\frac{1}{2}$ inch lead pipe may not be found too large. *Safes* are provided under the old water closet apparatus, and under a bath, for which 4 lb. lead is enough. The waste pipes from these should also be carried outside, the end provided with a mica or brass flap valve to prevent an in-draught.

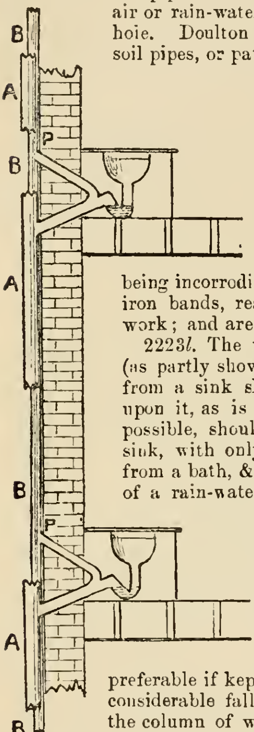

Fig. 807*c*.

2223*m*. The fresh air inlet pipe is considered by many as preferable if kept smaller than the ventilating pipe. The soil pipe, if it have considerable fall, must have a provision made for the partial vacuum which the column of water in descending tends to create, causing syphonage of the traps. This pipe being open at the top is not sufficient to remedy the evil; a separate vertical ventilating pipe is the only effectual remedy, into which, from all the horizontal branches, are secured ventilating branches. This vertical pipe may be about 3 inches in diameter, with 2 inch or $2\frac{1}{2}$ inch branches at least, carried from the soil pipe into the other vertical pipe. The fig. 807*c*. shows how the trap under a water closet may be ventilated, where closets are placed one above another to prevent syphonage. A is the soil pipe; B the ventilating pipe, or ventilating pipe from the grease or other trap; and P, ventilating pipe from branch pipe to soil pipe. The separate air shaft to the Ʊ trap might perhaps be better dispensed with by carrying the small pipe through the wall to the open air, and using a mica valve; thus fresh air would be constantly brought in. Mica valves are considered by some to decay. (E. T. Hall.)

2223*n*. *Solder* is a mixture of two parts of lead with one part of tin. In soldering, portions of the lead must first be scraped, and when finished they are then done over with a black paint. This solder is used also for tin plates and zinc work. There is a new process for connecting lead pipes without solder, called a cold metal double cone mechanical lead pipe joint. By means of a small piece of a double coned full-bore tube, assisted by a tubular hexagonal-headed screw and nut, the joint is firmly and securely made, and easily taken apart when required. A new system of jointing, which is readily applicable to every kind of joint required for lead pipes, is adopted at Manchester, whereby the joints are not merely soldered, but welded. A lining pipe is used somewhat similar to the above mentioned process. A clean bore is obtained, no lodgment of solder inside, and a sightly external finish instead of the ugly bulb by the common method. Stidder patents a closet arm joint with india-rubber cones.

2223*p*. *Earthenware pipes*, like iron mains, are employed underground. At the beginning of this century, machinery was invented for forming *stone* pipes, which were used for some time, but did not supersede those in use formed of timber. Near Lincoln have been found circular earthenware tiles, 6 inches diameter and 22 inches long, set in a thick casing of cement, so as to exclude air entirely, and to strengthen and protect the piping, which conveyed the water for about a mile and a half. It is always necessary to have some outlets for letting off the air which accumulates in any length of such tubing. When water is first allowed to enter a long length of new piping, a quantity of very fine sand or dust should be put into it to fill up any cracks or spaces left in the joints. This is also recommended to be done for new iron boilers, iron water tanks, &c., as it tends to make the joints watertight. A well-made stoneware pipe of 4 inches diameter will bear a pressure of from 75 to 100 lbs. per square inch.

2223*q*. *Iron water pipes* for the service of a house are objectionable in case of their bursting in winter, but this is remedied by placing a stop-cock at the entrance of the pipe into a house, to shut off the supply for repairs, or in anticipation of a frost. Some wrought iron pipes are lined and coated with hydraulic mortar; others are *enamelled* in the interior. These latter have been found, both for gas and water purposes, absolutely incorrodible; in the former case preventing the great loss from leakage, and in the latter case conveying the water in perfect purity. For a high service hot water supply, a galvanized wrought iron hot water cistern, with man hole screwed down, is supplied. It is usually 2 feet 6 inches long, 2 feet wide, and 18 inches deep. Cast iron pipes are naturally very porous; so much so, that water when very forcibly compressed, as by an hydraulic machine, will make its way through the thick cast iron cylinder in a sort of perspiration on the external surface. Oxidation, to a certain extent, will close the pores of the metal, and prevent this escape of water or of gas; and it is recommended that all new gas pipes be proved with a solution of sal ammoniac, which being forced into the body of the metal effectually oxidises it, and to a great extent cures the evil. Patent welded wrought iron tubes and fittings, and malleable iron fittings, are made for gas, or low pressure steam, and cast iron pipes for water, of from $\frac{1}{8}$ to 4 inch bores: such pipes are also made for high pressure steam or water, and proved to a pressure of 200 lbs. per square inch. The ordinary gas pipe is proved to 75 lbs. on the square inch.

2223*r*. *Gutta Percha.* On account of the injurious effects of water on lead cisterns and piping, this material has been recommended as a substitute for it in both cases, since its general introduction about 1849. But it is uncertain whether the material can be guaranteed as a lining; and some soils appear to affect it when buried underground. It is also attacked by a fungus. Experiments made at the Birmingham Water Works, on the strength of gutta percha, showed, that tubes made $\frac{3}{4}$ inch diameter and $\frac{1}{8}$ inch thick, attached to the iron main, and subjected for two months to a pressure of 200 feet head of water, were not in the slightest degree deteriorated. They were afterwards subjected to a proof of 337 lbs. per square inch. The material being slightly elastic, the tubes expanded, but recovered their former size on the pressure being withdrawn. At Stirling, $1\frac{1}{2}$ inch tubing bore a pressure of about 450 feet, without the slightest injury, whilst the same pressure upon strong leather hose scattered the rivets in all directions. A *vulcanised fibre* is a new substitute for leather, rubber, gutta percha, &c., for packing hot or cold water taps, valves, washers, &c.

2223*s*. Pipes to cisterns are supplied with ball cocks and valves, both round way and square way, of various forms and sizes, too numerous to be here described. The "Brockley" patent ball valve, of Wood Brothers of Brockley, is an improvement consisting of the usual ball turning on a pivot fixed to the screw. "The spherical form of the seating, and the cup into which it works, have been designed to prevent the collection of grit. The rubber envelope at the end of the seating fitting into the opening through which the water flows is specially made, and is durable as there is no cutting edge to destroy it; they only require to be stretched on." For sinks, or the usual supply taps, bib-cocks having a "T key," or a "spanner" or other key, are required; these are of different makes, and often produce a recoil. "Screw-downs" or "valves" are used where the high pressure system is adopted, the "T key" then screws down the valve. A "stop-cock" or "valve" is used to shut off the water in a length of pipe, as the service from the main pipe, as above noticed, and likewise for reducing the pressure of the water on the "screw-down" valves in a constant service. This system is described in Cresy, *Encyclopædia*, pages 1655–57. Stidder's patent hydraulic ball valve is intended to resist the highest possible pressure; the greater the pressure the more secure from leakage.

2223*t*. *Lavatories* are fitted up with an apparatus for supplying the basin with hot and cold water, and for taking off the waste. *Baths* are supplied from a boiler either placed at the back of a kitchen range, or set in the fireplace of the bath room, or of an adjoining chamber. They are also heated by a gas boiler called "Geiser," or other name, fixed close to or on the bath, having a flow and return pipe; or by ranges of lights under the bath itself. A five-feet bath is said to be heated to 100° in half an hour by gas, at a small cost. A bath generally contains about 60 gallons of water, and requires about 20 gallons of boiling water to heat it. Ewart's lightning geyser gives a hot bath in five minutes. Shanks's new instantaneous gas water heater. Doulton and Co.'s Lambeth patent water heater.

2223*u*. The bath itself is sometimes formed of marble, cast iron enamelled, opalized glass, glazed earthenware, and glazed porcelain tiles (Rufford's), the weight of which is 7 cwt. The Farnley porcelain bath, of fireclay and enamelled, is reduced in weight to $4\frac{1}{2}$ cwt.; they are made of four shapes, from 60 inches to 74 inches in length. Zinc, lead, copper, galvanized iron, and slate all require a coating of light-coloured paint, so as to render easily apparent any want of purity of the water. A patent stamped tinned *steel* bath is designed to obviate the disadvantages of cast iron; it does not chill the water, and is light and durable. If not painted, all metal baths require considerable friction to appear clean. The difficulty of making a bath with joints that shall not leak is self-evident. Tylor's pattern-book gives several descriptions of their baths (par. 2228*a*.). Shanks and Co. have approved baths and fittings.

2223*v*. With water raised to a high level great power is gained for various purposes, domestic and otherwise. The *hydraulic lift*, lately introduced into banks and hotels, is the saving of much trouble and time. The general details for hotels were described by J. Whichcord, in a paper read at the Institute of British Architects, in 1864. Waygood and Co. are manufacturers of the more modern lifts, cranes, and hoisting machinery of all descriptions by hydraulic and hand power. The American Elevator Company are makers of the "Standard" hydraulic elevators fixed in various public edifices, hotels, &c. A small lift, to be worked by hand, is readily arranged for raising a scuttle of coals, or other package, from the bottom to the top of a building. Other manufacturers are Clark, Bunnett and Co.; the Hydraulic Engineering Company, Limited (of Chester); Goddard and Stewart; S. Chatwood, 1878, balanced hydraulic lifts; and Attwood and Co.'s lifts and hoists for goods and passengers, worked by gas, steam, hydraulic, or hand: makers of the A B C self-sustaining lift for houses, clubs, &c. Water applied to a turbine is capable of producing a small motive power, useful for organ blowing, turning a fan to effect ventilation, and other such purposes, without wasting the water so employed.

2223*w*. It will be useful to note the *non-compressibility of water*. It is often necessary, before re-melting cast iron, to reduce the large masses into smaller pieces. This by the ordinary method is both troublesome and difficult. A simple and ingenious mode of producing the required fracture has been recently employed in France. It consists in drilling a hole in the mass of cast iron for about one-third of its thickness, and filling the hole with water, then closing it with a steel plug, fitting very accurately, and letting the ram of a pile-driver fall on the plug. The first blow separates the cast iron into two pieces.

COPPER

2224. Many of the uses to which copper is put have already been noticed in the paragraphs 1787 to 1791. The nave of Chartres Cathedral was roofed in 1836–41 with iron ribs covered with copper plates; in 1853 the latter had so much oxidised as to require removal. It is said that if strips of the best zinc, about 8 inches by 2 inches, be screwed on each course of copper, galvanic action would prevent the oxidation of the latter material. Iron cramps encased and brazed in copper, or gun-metal cramps, in lieu of iron merely, the exfoliation of which bursts and demolishes stonework, is a precaution now generally adopted in good work. In the Indies, copper gutters decay after twenty years' use, not lasting longer than shingles, the heat and moisture of the climate converting the metal into red oxide of copper; iron nails decay there very fast from the same cause.

2224*a*. Table I. of Thickness of Copper Sheets

Number of wire gauge	1	2	3	4	5	6	7	8	9	10
Weight of one foot super. in pounds	14·5	13 9	12 75	11·6	10·1	9·4	8·7	7 9	7·2	6 5

Molesworth.

No. 1 is equal to $\frac{5}{16}$ths of an inch thick; No. 4 = $\frac{1}{4}$; No. 7 = $\frac{3}{16}$; No. 11 = $\frac{1}{8}$; No. 16 = $\frac{1}{16}$; and No. 22 = $\frac{1}{32}$. Nos. 22 to 28, or 18 to 12 ounces per foot superficial, were used formerly for gutters. As the plates of copper are made of a uniform size, 4 feet long by 2 feet wide, the weight determines the thickness: thus, 70 lb. plates are $\frac{3}{16}$ths thick; $46\frac{1}{2}$ lbs. = $\frac{1}{8}$; 23 lbs. = $\frac{1}{16}$; $11\frac{1}{2}$ lbs. = $\frac{1}{32}$; 6 lbs. = $\frac{1}{64}$ of an inch.

2224*b*. Table II. of the Weight of a lineal Foot of Round and Square Copper, in Pounds.

Weight	26·016	28·906	31·797	34·688	37·578	40·469	43·359	46·250

2224*d*. Solder for copper, iron, and brass, is composed of an alloy of zinc and copper; for pewter an alloy of tin, lead, and bismuth. *Copper* is a metal too soft to use very much in decoration, but it goes well with brass, in inlay, incrustation, or bands. A tinned copper bowl where the ground is cut away and the pattern left is a good example of work.

2224*e*. *Wetterstedt's patent metal* should be laid by a good plumber. The flats are formed with rolls and drips similar in every respect to lead, but the latter should be formed with a gradual descent. The rolls need not be more than 1 to $1\frac{1}{4}$ inch diameter, tapered at the ends, and brought close up to the edge of the drip. Circular and sloping roofs may be laid either with rolls or welts, the ends of the sheets being joined by a welt or overlap of 6 inches. The metal should be laid free, and nails avoided as much as possible, but if used they should be of wrought copper. Soldering is to be avoided, but to secure the metal as against an upright face, a solder dot over a screw is the best means to adopt.

2224*f*. *Muntz's metal* is used as a coating for iron vessels under water; to prevent galvanic action a band of vitreous sheathing is attached for some distance below and above the water line. This sheathing consists of small plates of iron covered with a preparation of glass, and is intended to be an anti-fouling as well as a protective agent.

ZINC.

2224*g*. The common sheets in general use are 12, 14, 16, 18, and 20 ounces to the foot superficial; and as 18 thicknesses of 16 ounces to the foot are half an inch thick, the following show the thicknesses of the different weights:—

Plates or sheets of 10	ounces to the foot are	0·01736	inch thick.	
12	—	0·02083	„	
14	—	0·02430	„	
16	—	0·02777	„	= $\frac{1}{36}$ of an inch.
18	—	0·03125	„	
20	—	0·03472	„	

It is employed for water-cisterns and baths, rain-water pipes—in short, for almost all purposes where lead has been hitherto employed. Latterly it has been formed into sash-bars for skylights and ornamental sashes; for which purposes, strength excepted, it is superior to iron, as not being liable to rust, and loosen the putty and glass. It is, in every respect, equal to copper, and not more than one-third the cost of it. The discovery of the electro process was said to have introduced the application of zinc to cast and wrought iron, so as to prevent its oxidation or rust, but such has not been the case (see galvanized and zinked Iron).

2224*h*. About 1861, the Vieille Montagne Zinc Mining Company took steps to improve the mode of laying zinc roofs, and to prevent the use of thin gauges of sheet zinc, which are unfit for the purpose. This Company recommend that for roofs and flats on boards no gauge thinner than No. 13 be used: a medium thickness, No. 14, for roofs, flats, and gutters; for best work and for roofs without boards, Nos 15 or 16. The Company is preparing thicker zinc, Nos. 17 and 18, principally for gutters. Steel cut gauges notched for roofing numbers only, are supplied whereby to test the thickness. The weight of No. 13 gauge is 19 oz. 10 drs.; No. 14 is 21 oz. 13 drs; No. 15 is 24 oz.; and No. 16 is 26 oz 3 drs., per square foot.

2224*i*. Good zinc, properly laid, has been proved by long experience in France, Belgium, Germany, and Italy, to be a secure, durable, and economical covering. No detrimental effects from any particular climate are to be feared, so that care be taken to adopt the proper mode of laying, and to select the proper gauges, of the best quality of zinc. Even good zinc badly laid will prove a failure. Screws or embossed holes on the surface of good zinc work are not required. As the prescribed mode for laying zinc, illustrated by diagrams, can be obtained on application to the agents of Devaux's Vieille Montagne Zinc Company, and to the agents for the supply of the Improved roofing zinc, we do not consider it necessary to describe it here in detail.

2224*k*. *Stamped ornamental zinc*, for dormers, Mansard roofs, vanes, finials, moulding, and enrichments, has been used on the Continent for many years with good effect. In London it is hardly known, but has been employed lately at the Charing Cross Hotel; at the Langham Hotel; and at No. 114 Piccadilly. The steeple of Ripple Church, Kent; the Victoria Railway Station, Pimlico; and many other public and private buildings throughout the kingdom, now show the employment of this useful material.

2224*l*. *Perforated zinc* for various sizes of perforations or in patterns, is extensively employed in filling up squares in sashes, or panels in partitions, to assist ventilation by breaking the force of the current of air.

Zinc has been noticed in paragraphs 1792 to 1797.

BRASS.

2224*m*. ***Brass*** is a metal which has been adopted very widely in the last thirty years, in art progress, for the decoration of public buildings, churches, and houses. The feeling of softness, which the special smoothness and polish of brass calls for in design, requires much study; the rounded contours, with great delicacy in the curves, and fine detail, some of it almost imperceptible, is what the skilled turner knows how to give to the work. Candlesticks, chandeliers, dishes, fire-irons, fenders, dogs, balustrades in screens to choirs and chapels, as in Belgium and Holland (the last having a very rich and beautiful effect); fonts, desk rails, lecterns, sepulchral brasses, arrangements for lighting, are among the many purposes for which this material is employed. Inferior brass turns nearly black by the smoke of towns and chemical vapours, but good brass only requires moderate care to keep it looking well.

TABLE OF THE WEIGHT OF A SUPERFICIAL FOOT OF A PLATE OF BRASS, IN POUNDS.
(Molesworth, *Formulæ.*)

This material has been described in paragraph 1790.

Sect. VIII.

GLAZING.

2225. Glazing, or the business of the glazier, consists in fitting glass in sashes, frames, and casements, either in putty or lead. It may be classed under the heads of SASHWORK, LEADWORK, and FRETWORK. Glass, as a material, has been already described in Chap. II. Sect. XII. of this book.

2226. The tools necessary for SASHWORK are—a *diamond*, polished to a cutting point, and set in brass in an iron socket, to receive a wooden handle, by which it is held in a cutting direction. The top of the handle goes between the root of the forefinger and middle finger, and the under part between the point of the forefinger and thumb. In general, there is a notch on the side of the socket, which should be held next the lath. Some diamonds have more *cuts* than one. Plough diamonds have a square nut on the end of the socket next the glass, which, on running the nut square on the side of the lath, keeps it in the cutting direction. Glass benders have their plough diamonds without long handles, as they cannot make use of a lath in cutting, but direct them by the point of their middle finger. The *ranging lath* should be long enough to extend beyond the boundary of the table of glass. *Ranging* of glass is the cutting it in breadths, and is best done by one uninterrupted cut from one end to the other. A *short lath* is used for stripping the square to suit the rebate of the sash, as in ranging they are generally cut full. A *square*, for the more accurate cutting at the right angles from the range. The carpenter's *chisel* is used in paring away some of the rebate of the sash when the glass does not lie so flat as to allow a proper breadth for front putty. The *glazing knife* is used for laying in the putty on the rebates, for bedding in the glass, and finishing the front putty. A *bradding hammer* is made with a head in the form of a small parallelopiped, with a socket for the handle, using it at an obtuse angle from the middle of one of its sides. The square edges of the head drive the brads in a horizontal direction, and with this tool there is less liability to accident than with any other. Some use the basil of the chisel for the purpose. *Brass points* are considered the best for bradding; *small cut brads* are also used. All new works should be bradded, to prevent the glass being moved out of its bed. The *duster* is a large brush for brushing the putties, and taking the oil from the glass. The *sash tool* is used wet, for taking the oil from the inside after the back putties are cleared off. The *hacking knife* is for cleaning out the old putty from the rebates where squares are to be stopped in. The use of the *glazier's rule* needs no explanation: it is 2 feet long, doubling in four different pieces.

2226*a*. The *putty* in which the glazier beds the glass is of four sorts. *Soft putty*, which is composed of flour, whiting, and raw linseed oil; *hard putty*, composed of whiting and boiled linseed oil; *harder putty*, the same ingredients as the last, with the addition of a small quantity of turpentine for more quickly drying it; *hardest putty*, composed of oil, red or white lead, and sand. The first of these putties is the most durable, because it forms an oleaginous coat on the surface, but it requires a long time for drying. The hard sorts are apt to crack if not soon well painted, and the hardest of them renders it difficult to replace a pane when broken; hence it is altogether unfit for hothouse and greenhouse work. Probably the best manner of fixing glass and glazed frames in stone mullions is with a mixture of Bath stone dust and linseed oil, made up similarly to putty. Its elasticity allows of any slight settlement if the work be new, and it is more of a waterproof cement than Portland, as it is not nearly so liable to crack: that cement, without a large proportion of sand, will almost invariably burst glass or stone after a few months; and it also stains freestones, Corsham Down stone especially, giving it the appearance of having been burnt. (*Builder*, 1864, p. 796.)

2226*b*. To remove glass from old sashes, a mixture of 3 parts of American potash with 1 part of unslaked lime, laid on both sides with a stick, and allowed to remain for twenty-four hours, will soften the putty enough to cut out easily. This mixture will also take off paint, and even tar.

2226*c*. Many systems of glazing large roofs have been introduced of late years, each supposed to be an improvement upon the other, and recommended by the designers for billiard-rooms, picture-galleries, dining-rooms, concert-halls, yards, large span roofs, &c.

Braby's *patent glazing*; glass set free, allowing expansion and contraction, and precluding breakage.

Brown's *patent system* of glass and iron roofing. No putty, zinc, galvanised iron, cast-iron, india-rubber, felt, asbestos, or other perishable material.

Causley's system of *glazing without putty*, 1881.

Crewe's *dry* glazing; simple and cheap.
Drummond's patent *roof-glazing*; sash-bars in iron, steel, zinc, or wood.
Grover & Co.'s *simplex* glazing. No iron, zinc, or putty. Lead strips on wood-bars, &c.
Helliwell's patent *perfection* system of imperishable glass roofing. No putty used.
Jeffrey's patent *system of glazing*, guaranteed air and water tight.
Johnson Brothers & Co.'s patent *imperishable* glazing.
Mackenzie's patents, by the British *Patent Glazing* Company (Limited). No zinc used; a lead cushion over an iron bar.
Mellowes and Darby's *eclipse* glazing; tin-lead bar, V section.
Rendle's *Acme* glazing.
Rendle & Burrow's *indestructible* glazing. Wood sash-bar, the glass covered on it by a wood capping.
Shelley's patent *standard* system of glazing, using glass up to 10 feet in length, with his patent bars placed two feet apart.
The *Pennycook* patent universal system of glazing without putty.
Each system must be examined for its peculiarity.

2226*d*. The Transparent *Wire Wove* Roofing Company (Limited) has manufactured a substitute for glass, made in sheets 10 ft. by 4 ft., at $6\frac{1}{2}d.$ per foot. Much is said in favour of it, and for many purposes it may work in usefully as a temporary material.

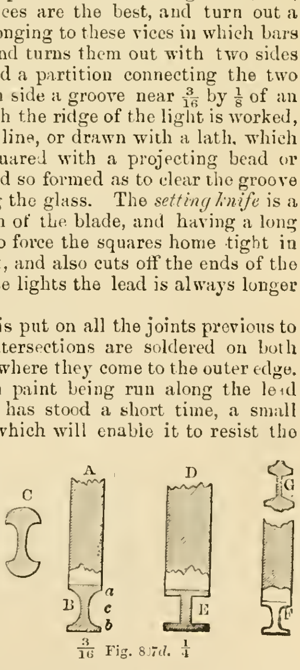
2226*e*. The diminution of light by passing through various sorts of glass has been given thus: British polished plate, 13 per cent.; rough cast plate, 30; rolled fluted plate, 4 flutes to the inch, 53; 32 oz. sheet, 22; common window glass, about 10; ground glass, from 30 to 60; opal globes, from 50 to 60; green, purple, and ruby glass, 82 to 89; and porcelain transparency, over $97\frac{1}{2}$. Light decreases in the ratio of the square of its distance from its sources.

2227. Leadwork for fixed lights is used in ecclesiastical buildings, often in inferior offices, and frequently in country buildings. Frames made with crossbars receive these lights, which are fastened to *saddle bars*. Where openings are wanted, a casement is introduced of wood or iron. Sometimes a sliding frame is used, particularly for house windows. Plain, painted, and stained lead lights have of late years been largely introduced in the so-called "Queen Anne" designs, and adapted for blind or transom, fanlight, door panel, or window.

2228. The *glazier's vice* is for preparing the leaden slips called *cames* with grooves, &c., to fit them for the reception of glass. The German vices are the best, and turn out a variety of lead in different sizes. There are *moulds* belonging to these vices in which bars of lead are cast; in this form the mill receives them, and turns them out with two sides parallel to each other, and about $\frac{3}{8}$ of an inch broad, and a partition connecting the two sides together, about $\frac{1}{8}$ of an inch wide, forming on each side a groove near $\frac{3}{16}$ by $\frac{1}{8}$ of an inch, and 6 feet long. The *setting board* is that on which the ridge of the light is worked, and divided into squares, and struck out with a chalk line, or drawn with a lath, which serve to guide the workman. One side and end is squared with a projecting bead or fillet. The *latterkin* is a piece of hard wood pointed, and so formed as to clear the groove of the lead, and widen it, for the more readily receiving the glass. The *setting knife* is a blade with a round end, loaded with lead at the bottom of the blade, and having a long square handle. The square end of the handle serves to force the squares home tight in the lead; being loaded with lead, it is of greater weight, and also cuts off the ends of the lead with greater ease, as in the course of working these lights the lead is always longer than is necessary till trimmed.

2229. The resin box contains powdered resin, which is put on all the joints previous to soldering. *Clips* are for holding the irons. All the intersections are soldered on both sides except the outside joints of the outer side, that is, where they come to the outer edge. These lights should be cemented, which is done by thin paint being run along the lead bars, and the chasm filled with dry whiting. After it has stood a short time, a small quantity of dry red or white lead is dusted over it, which will enable it to resist the weather well.

2229*a*. Fretwork is the ornamental part of lead-light work, and consists in working ground or stained glass into different patterns and devices, as may be seen in the old stained glass windows. The leads used until the middle of the seventeenth century are nearly of one uniform width, and are much narrower in the *leaf* than the common modern leads. That this was the case, can be proved not only by the existence of the original leads themselves, but more satisfactorily perhaps by the black lines drawn upon the glass, with which the glass painters were accustomed sometimes to produce the effect of leads without unnecessarily cutting



$\frac{3}{16}$ Fig. 837*d*. $\frac{1}{4}$

the glass. A in *fig.* 807*d.* represents an ancient lead of the usual width; B its section, consisting of the *leaf, a* and *b*, and the *core c.* C is the section of a German lead of the early part of the 14th century. D is a piece of modern *fret lead* of the ordinary width, and which is now considered (1847) as being very narrow; and E its section. The process of compressing the lead between rollers to the proper dimension makes them more rigid than the old leads. It is the practice at the present day to surround each *glazing panel* with a *broad lead*, that is, a lead three-quarters of an inch broad in the leaf, to strengthen the work (page 27.). Leads somewhat narrower than these were very extensively employed. An entire window at Stowting Church, Kent, probably of the early part of the reign of Edward IV., was leaded with leads as F. The other lead, G, is of the early part of the reign of Henry VI., and is from Mells Church, Somersetshire, where similar lead is commonly used. This mode of strengthening the lead without increasing its width was not confined to the decorated period. Both these specimens had all the appearance of being cast in a mould. One of the faces in each is narrower than the others; these were placed outside, and the difference probably arose from decomposition of the metal. A still narrower lead may be occasionally met with in heraldry and other minute mosaic work of the 15th and 16th centuries. It is hardly necessary to observe that the greater the number of leads employed, the weaker individually may they be made (page 259–61.). The width of the leads must be proportionate to that of the lines usually painted on the glass, for the leaden outlines will easily be detected if they are much stronger than the painted ones. The effect of the increased width of modern leads, E, although so trifling, is very perceptible.

2229*b.* *Saddle bars* in ancient windows will be found to be usually placed from 8 to 9 inches apart, which seems to be the most agreeable distance, though one of 6 inches does not appear too little in some cases. The great object is to avoid, as much as possible, causing the light to appear as if it were divided into a number of square compartments, by making the height too nearly the width of the glass. Amongst the advantages resulting from the use of saddle bars at short intervals, is the opportunity it affords the glazier of carrying a horizontal lead across the light immediately in front of each saddle bar, the opacity of which hides the lead. This method of concealing lead work was carried to such perfection during the first half of the 16th century, that a person ignorant of it would find it difficult to conceive how some of the works of that period were constructed.

2229*c.* *Iron standards* or *stancheons*, in ancient windows put through the saddle bars, should be retained in pattern windows, which they improve, and do not appear to be out of place in picture windows whenever they do not happen to pass immediately behind the head of the principal figure. They seem also on the whole to improve the effect of the architecture from without. (Winston, *Inquiry into Style in Glass Painting*, 8vo. 1847.)

2229*d.* It is stated that at Cologne Cathedral the glass is strong; the different pieces are joined together with lead, and soldered with tin, both inside and outside, which gives the whole great strength. The panes are fastened upon iron frames, which are again fastened upon rods. In the interior the panes are screwed upon iron bars, half an inch thick, which are let into the masonry.

2230. In London a large portion of the glazier's business consists in cleaning windows.

2231. *Glazed partitions* formed of wood, or of iron frames with the lower panels filled in with slate, are now very usual in warehouses, banks, and counting-houses. If sound be desired not to pass through such fittings, they must be glazed with extra thick glass; but double sheets or squares, placed about half an inch or more apart, and carefully puttied, is best. This method will also conduce to the warmth of the room. Double windows to the fronts of houses are common fittings to effect both the above purposes.

2231*a.* Glass has been introduced for a variety of building purposes. Thus, Lloyd and Summerfield's patent crystal *window bars*, for windows, shop fronts, and cases, are not uncommon. They are fitted with arched heads and spandrils of glass, having patterns, silvered or gilt, on a coloured ground. Glass *tiles* and *slates* are a useful auxiliary to a roof where a small modicum of light is required. Lockhead's *perforated glass ventilator* can either be set in the sash, or fixed outside of it in a frame for the whole width of the opening, air being admitted by moving the sash. For the like purpose are such inventions as Moore's louvre ventilators in a sash pane; Boyle's draughtless window ventilators, being a fine gauze of wire set in a pane of glass, and used with or without a glass cover; and the circular glass "revolving" ventilator. Glass *balusters* and *handrails*; pilasters for chimneypieces; door handles, knobs, and plates; mirror frames; trays for dairies; cut crystal and opal letters; Pratt's patent process of gilding by precipitation (1886), are among other useful inventions in this material. See Pavement Lights, par 2225*l*.

2231*b.* *Coloured or stained glass.* We can only here name the varieties. There are three modes of colouring glass: I. Pot metal glass, in which the colour is mixed up with the molten mass. II Flashed, covered, or coated glass, formed by uniting a thin layer of coloured glass with another layer, either of a different colour or colourless. III. Painted glass, the white substance being painted on, and then the colour or pigment burnt in. The colouring materials are in all cases metallic substances. Such are the methods by which all coloured glass windows are produced.

2231*c*. For ornamental purposes, besides *coloured* glass, glass may have a *ground* surface, which is obtained by grinding it with a stone, or by the use of fluoric acid. *Embossed glass*, which permits the application of devices, according to the fancy of the designer or intention of the manufacturer, is effected by covering the square of glass with a varnish, except where the device is intended. An acid is then poured on which eats away the uncovered glass for a small depth. The varnish is then cleaned off, and the general surface is ground as usual. Its imitation is obtained by covering the plate with a varnish, a lace or stencil pattern placed on it, then dusted over with a colouring matter in the state of fine powder, and the plate thus treated sufficiently heated to vitrify and fix the dusted varnish to the glass. Messrs. Chance, and other manufacturers, sell various enamelled stencilled patterns, as *white enamelled, enamelled and flocked, embossed repeated pattern, stained enamelled*, and *double etched glass, self shadowed glass, patent polychromatic glass, printed glass, stamped in colours*, and many other kinds, all which are better seen at the factories than described.

2231*d*. The compressive strength of glass, that is, its resistance to a force tending to crush it, is about 12¼ tons per square inch. This is nearly equal to one quarter the strength of cast iron. Glass has three times the specific gravity of iron. In the form of bars, a favourable shape for developing a highly tensile strength, one ton per square inch of area is the highest amount to be assumed for it.

2231*e*. MOSAIC WORK. This durable manner of decoration in glass, requires a short notice. The *Roman mosaic* is composed of pieces of enamelled glass, thus rendered opaque, sometimes called *smalto* and sometimes *paste*, made of all kinds of colours and of every different hue For large pictures they take the form of small cakes. For small works they are produced as threads, varying in thickness from that of a piece of string to the finest cotton thread. The *Venetian mosaic* pictures are formed of pieces of very irregular shapes and sizes, of all colours and tones of colours; the ground tint almost invariably prevailing is gold. The manner of execution is always large and coarse, and rarely approaches any neatness of joint or regularity of bedding. *Opus Grecanicum* consists in the insertion, into grooves cut in white marble to a depth of about half an inch, of small cubes of these coloured and gilded *smalto*, and in the arrangement of these forms in such *geometrical combination* as to compose the most elaborate patterns. It was customary to combine the bands of this mosaic work with large slabs of Serpentine, Porphyry, Pavonazzetto, and other valuable marbles and to use it in the decoration of ambones, cancelli, &c.; its use externally was comparatively rare. The hexagon, triangle, square, and octagon, form the usual bases of most of the specimens of this ingenious art to be found in Italy. Patterns of accumulating intricacy are seen at Palermo, and at Monreale. Illustrations in colour are given in the useful work on *Mosaics*, by M. D. Wyatt.

2231*f*. *Coloured enamels* are made of a vitreous *paste* (or glass), to this are added other mineral substances, which, when properly prepared and fused together, impart to the paste its density and extreme hardness, and also its colour; the better the manufacture, the more satisfactory the appearance and the greater the durability of the mosaic work. In an imperfect manufacture, the mosaic is liable to be injured by damp, smoke, and all atmospheric changes; when well produced, they can be made to give precisely the same effect as the painting.

2231*g*. *Gold and silver enamels* were introduced: these are made of the precious metals, but in such thin sheets that their use is comparatively inexpensive. The process is a difficult one, for, to produce true gold and silver enamels, great knowledge and experience are necessary. On a ground of thick glass or enamel, according as it is desired to render the gold enamel transparent or opaque, or to impart to it a warm or variegated colour, there is laid a leaf of gold or silver, which is attached principally by the action of fire; then a film of the purest glass is spread over it, and this may either be perfectly colourless or of any tint that may be required. When well manufactured, these thin layers, after being fused, become perfectly united with each other, and form a homogeneous body, and the metal is for ever protected against all possibility of injury from any cause except actual violence.

2231*h*. Stevens has produced a new kind of glass mosaic, executed at about one third the price of the ancient manufacture of this kind. The glass is stained or gilt, and the method is adapted for many purposes. Messrs. Rust are working in gold, silver, and enamel mosaics of their own invention; and Dr. Salviati employs his "indestructible system of Venetian enamel-mosaic, in works, in a comparatively inexpensive and expeditious manner." At the Wolsey tomb-house, at Windsor, the entire ceiling, consisting of 2,100 feet, was decorated in the space of ten months, including the time of the transit of the mosaics from Venice; and was executed, with the scaffolding, at the price of 4,725*l*. It was also employed at St. Paul's Cathedral, for the figure of the prophet Isaiah, covering 250 feet, which was executed and fixed in two months, at the price of 600*l*. (Lecture read at Leeds, by A. Salviati, 1865.)

2231*i*. The cements used are of three sorts. The first, for large tesseræ in forming floors, is composed of pitch, mixed with a black earth. The second, for stones of a middling dimension, is made of tufa and oil. The third, for the more delicate mosaics of pieces of glass, is made of white of lime, pounded bricks, gum andragan, and the white of eggs. The ancients are said to have used 1 part of slaked lime and 3 parts of pounded marble, made up with water and white of egg. But as this is considered to harden too quickly, a mixture of 1 part of slaked lime, and 3 parts of powdered travertine stone, mixed up with linseed oil, and kept stirred every day, is used, adding oil as it dries. The mass is ready sooner in warm weather than in cold, varying from 20 to 30 days, when it is like a smooth ointment. For the larger works, Keene's, Portland, or other similar cements might be used.

Sect. IX.

PLASTERING.

2232. In the finishing of our dwellings, the decoration owes much of its effect to the labours of the plasterer: it is in his department to lay the ceilings, and to give, by means of plaster, a smooth coat to the walls, so as to hide the irregularities left by the bricklayer and mason, and make them sightly and agreeable. He also, in the better sort of buildings, furnishes plain and decorated mouldings for the cornices and ceilings; and in the external parts, where stone is expensive or not to be procured, covers the exterior walls with stucco or other composition imitative of stone.

2233. The plasterer's tools are—a *spade* or *shovel* of the usual description; a *rake* with two or three prongs bent downwards from the line of the handle, for mixing the hair and mortar together; *stopping* and *picking out tools*; rules called *straight edges*; *wood models*; and *trowels* of two sorts and various sizes, namely, the *laying and smoothing tools*, consisting of flat pieces of hardened iron, about 10 inches long, and 2½ inches wide, very thin, and ground to a semicircular shape at one end, but square at the other. Near the square end on the back of the plate a small iron rod is rivetted, with two legs, whereof one is fixed to the plate, and a round wooden handle is adapted to the other. All the first coats of plastering are laid on with this tool, as is also the last, or *setting*, as it is technically called. The other sorts of trowels are of three or more sizes, and are used for *gauging* the *fine stuff* and plaster for cornices, mouldings, &c. The length of these trowels is, the largest about 7 inches in length on the plate, and the smallest 2 or 3 inches: they are of polished steel, converging gradually to a point, with handles of mahogany adapted to the heel or broad end with a deep brass ferrule.

2234. The stopping and picking out tools are of polished steel, of various sizes, about 7 or 8 inches long and half an inch broad, flattened at both ends, and somewhat rounded. They are used for modelling and finishing mitres and returns to cornices, as also for filling up and finishing ornaments at their joinings. There is also used a small instrument, which is a piece of thin fir 6 or 7 inches square, called a *hawk*, with a handle vertical to it, for holding small quantities of plaster.

2235. The composition used by the plasterer is a groundwork of lime and hair, on which, for the finish, a coating of finer material is laid. The sorts of it are various; as, for instance, white lime and hair mortar on bare walls; the same on laths as for partitions and plain ceilings; for renewing the insides of walls; roughcasting on laths; plastering on brickwork with finishing mortar, in imitation of stone work, and the like upon laths. For cornices and the decorations of mouldings, the material is plaster of Paris, one which facilitates the giving by casts the required form and finish to the superior parts of his work. The plasterer uses it also for mixing with lime and hair, where the work is required to dry and set hard in a short time. For inside work, the lime and hair, or *course stuff*, is prepared, like common mortar, with sand; but in the mixing, hair of the bullock, obtained from the tanners' yards, is added to it, and worked in with the rake, so as to distribute it over the mass as equally as possible.

2236. What is called *fine stuff* is made of pure lime, slaked with a small quantity of water, and afterwards, without the addition of any other material, saturated with water, and in a semi-fluid state placed in a tub to remain until the water has evaporated. In some cases, for better binding the work, a small quantity of hair is worked into the composition. For interior work, the fine stuff is mixed with one part of very fine washed sand to three parts of fine stuff, and is then used for *trowelled* or *bastard stucco*, which makes a proper surface for receiving painting.

2237. What is called *gauge stuff* is composed of fine stuff and plaster of Paris, in proportions according to the rapidity with which the work is wanted to be finished. About four-fifths of fine stuff to one of the last is sufficient, if time can be allowed for the setting. This composition is chiefly used for cornices and mouldings, run with a wooden mould. We may here mention that it is of the utmost importance, in plasterers' work, that the lime should be most thoroughly slaked, or the consequence will be blisters thrown out upon the work after it is finished. Many plasterers keep their stuffs a considerable period before they are wanted to be used in the building, by which the chance of blistering is much lessened.

2238. When a wall is to be plastered, it is called *rendering;* in other cases the first operation, as in ceilings, partitions, &c., is *lathing*, nailing the laths to the joists, quarters, or battens. If the laths are oaken, wrought iron nails must be used for nailing them, but cast iron nails may be employed if the laths are of fir. The lath is made in three and four foot lengths, and, according to its thickness, is called *single*, something less than a quarter of an inch thick, *lath and half*, or *double*. The first is the thinnest and cheapest, the second is about one-third thicker than the single lath, and the double lath is twice the thickness. When the plasterer laths ceilings, both lengths of laths should be used, by which, in nailing, he will have the opportunity of breaking the joints, which will not only help in improving the general *key*, (or plastering insinuated behind the lath, which spreads there beyond the distance that the laths are apart,) but will strengthen the ceiling generally. The thinnest laths may be used in partitions, because in a vertical position the strain of the plaster upon them is not so great; but for ceilings the strongest laths should be employed. In lathing, the ends of the laths should not be lapped upon each other where they terminate upon a quarter or batten, which is often done to save a row of nails and the trouble of cutting them, for such a practice leaves only a quarter of an inch for the thickness of the plaster; and if the laths are very crooked, which is frequently the case, sufficient space will not be left to straighten the plaster. (2246*b.*)

2239. After lathing, the next operation is *laying*, more commonly called *plastering*. It is the first coat on laths, when the plaster has two coats or set work, and is not scratched with the scratcher, but the surface is roughed by sweeping it with a broom. On brickwork it is also the first coat, and is called rendering. The mere laying or rendering is the most economical sort of plastering, and does for inferior rooms or cottages.

2240. What is called *pricking up* is the first coat of three-coat work upon laths. The material used for it is coarse stuff, being only the preparation for a more perfect kind of work. After the coat is laid on, it is scored in diagonal directions with a *scratcher* (the end of a lath), to give it a key or tie for the coat that is to follow it.

2241. *Lath layed* or *plastered and set* is only two-coat work, as mentioned under laying, the setting being the guage or mixture of putty and plaster, or, in common work, of fine stuff, with which, when very dry, a little sand is used; and here it may be as well to mention, that *setting* may be either a second coat upon laying or rendering, or a third coat upon *floating*, which will be hereafter described. The term finishing is applied to the third coat when of stucco, but setting for paper. The setting is spread with the smoothing trowel, which the workman uses with his right hand, while in his left he uses a large flat-formed brush of hog's bristles. As he lays on the putty or set with the trowel, he draws the brush, full of water, backwards and forwards over its surface, thus producing a tolerably fair face for the work.

2242. Work which consists of three coats is called *floated:* it takes its name from an instrument called a *float*, which is an implement or rule moved in every direction on the plaster while it is soft, for giving a perfectly plane surface to the second coat of work. Floats are of three sorts: the *hand float*, which is a short rule, that a man by himself may use; the *quirk float*, which is used on or in angles; and the *Derby*, which is of such a length as to require two men to use it. Previous to floating, which is, in fact, the operation of making the surface of the work a perfect plane, such surface is subdivided in several bays, which are formed by vertical styles of plastering, (three, four, five, or even ten feet apart,) formed with great accuracy by means of the plumb rule, all in the same plane. These styles are called *screeds*, and being carefully set out to the coat that is applied between them, the plaster or floating laid on between them is brought to the proper surface by working the float up and down on the screeds, so as to bring the surface all to the same plane, which operation is termed *filling out*, and is applicable as well to ceilings as to walls. This branch of plastering requires the best sort of workmen, and great care in the execution.

2243. *Bastard stucco* is of three coats, the first whereof is roughing in or rendering, the second is floating, as in trowelled stucco, which will be next described; but the finishing coat contains a small quantity of hair or white sand. This work is not hand-floated, and the trowelling is done with less labour than what is denominated trowelled stucco.

2244. *Trowelled stucco*, which is the best sort of plastering for the reception of paint, is formed on a floated coat of work, and such floating should be as dry as possible before the stucco is applied. In the last process, the plasterer uses the hand float, which is made of a piece of half-inch deal, about nine inches long and three inches wide, planed smooth, with its lower edges a little rounded off, and having a handle on the upper surface. The ground to be stuccoed being made as smooth as possible, the stucco is spread upon it to the extent of four or five feet square, and, moistening it continually with a brush as he proceeds, the workman trowels its surface with the float, alternately sprinkling and rubbing the face of the stucco, till the whole is reduced to a fine even surface. Thus, by small portions at a time, he proceeds till the whole is completed. The water applied to it has the effect of hardening the face of the stucco, which, when finished, becomes as smooth as glass.

2245. From what has been said, the reader will perceive that mere laying or plastering on laths, or rendering on walls, is the most common kind of work, and consists of one coat only; that adding to this a setting coat, it is brought to a better surface, and is two-coat work; and that three-coat work undergoes the intermediate process of floating, between the rendering or pricking up and the setting.

2245*a*. This plain plastered surface has received an improvement in a method of stamping or incising it, while wet, the invention, in 1857, of Mr. Benj. Ferrey, architect. "It is well known that the external rough-casting on old timber houses was stamped or wrought in small devices, known by the term *pargetting*; but it never assumed the importance of extensive wall decorations. The plan now proposed is to impress the common stucco with geometrical or other forms, and applied according to taste, either under string courses, around arches, in spandrils, soffites, or in large masses of diapering; and texts may be imprinted on the plaster instead of being simply painted on the walls. If colour be desired, it can be effected by mixing the desired colour with the coat forming the groundwork, then by laying the stencilled pattern against it, and filling in the solid portions of the device with the ordinary stucco or plaster." The process does not pretend to do more than enliven wall surfaces, but for this purpose it is very effective. Whippingham Church, in the Isle of Wight, is decorated in this manner, with devices in different colours.

2246. Ceilings are *set* in two different ways; the best work is where the setting coat is composed of plaster and lime putty, commonly called *gauge stuff* (2237). Common ceilings are formed with plaster without hair, as in the finishing coat for walls set for paper. The deflection of $\frac{1}{40}$th of an inch for each foot in length is not injurious to ceilings; indeed, the usual allowance for settlement is about twice that quantity. Ceilings have been found to settle about four times as much without causing cracks, and have been raised back again without injury. (Barlow, p. 179.)

2246*a*. In Dublin, the designations in plasterers' work are different to those we have named above. Work to ceilings is described as "Lath scratched, floated, and coated, while to walls it is described as "scratched, floated, and coated" *Skimming*, to plasterers work, is a very thin coat of white (i.e. lime) put on float work to smoothen it, and to leave a clean face; *coated* is the term for better work of the same character.

2246*b*. Hitchin's *fireproof plaster* appeared about 1877; it is valued for its simplicity, economy, and facility in working. The fibrous slab plastering is always dry and ready for fixing. The slabs on a wire base protect ceilings, walls, and woodwork from fire. Casings on wire base protect iron and wood girders, columns and such like. Pugging slabs are used for prevention of sound. Wilkinson and Co's *fibrous plaster slabs* are intended for lining walls and ceilings, and for fixing under slating; also to partitions and under floor-boards for deadening sound.

2246*c*. Johnson's patent *rolled fireproof wire lathing* is now occasionally used as a substitute for wood laths. It is a foundation for fire-resisting plaster. His *woven wire and iron fireproof partition wall* is intended to supersede the ordinary stud and brick partitions, and is applicable to roofs. *Metal laths*, of thin sheet iron, by Edwards's patent, are for use in fire-resisting ceilings, partitions, and doors. *Wirework*, in place of *lathing*, for forming ceilings and other plaster surfaces, patented in 1841 by L. Leconte, had been previously adopted in the building of the Pantechnicon, near Belgrave Square.

2246*d*. Nickson and Waddingham have patented a *slate ground for plaster*, by using, instead of laths, those slates which do not turn out in the quarries sufficiently wide for sized roofing slates; an immense number of them being necessarily thrown aside daily, although of the best quality. The slates are fixed $\frac{1}{4}$ in. apart; the plaster to be $\frac{3}{4}$ in. thick, of well haired stuff, which keys itself between the slates; they run from 12 to 7 in. long and upwards. The system was worked about 1862 at Manchester

2247. *Pugging* is plaster laid on boards, fitted in between the joists of a floor to prevent the passage of sound between two stories, and is executed with a coarse stuff made of lime and hay chopped into lengths of about 2 inches. *Silicate cotton* or *slag wool*, nailed in slabs to the under side of the joists of a floor, or against the studs of a partition, acts as a non-conductor of heat or cold; it is also fireproof, sound-proof, vermin-proof, and frost-proof. One ton of it, one inch thick, covers 1,800 square feet. This material is now greatly used; also for protecting exposed iron work. *Asbestos* millboard is another material greatly employed for lining partitions, to deaden sound passing through; as well as for fireproof purposes.

2248. The following materials are required for 100 yards of render set; viz. $1\frac{1}{2}$ hundred of lime, 1 double load of river sand, and 4 bushels of hair; for the labour, 1 plasterer 3 days, 1 labourer 3 days, 1 boy 3 days; and upon this, 20 per cent. profit is usually allowed. For 130 yards of lath plaster and set—1 load of laths, 10,000 nails, $2\frac{1}{2}$ hundred of lime, $1\frac{1}{2}$ double load of river sand, 7 bushels of hair; for the labour, 1 plasterer

6 days, 1 labourer 6 days, 1 boy 6 days; and upon this, as before, 20 per cent. is usually allowed.

	inch	$\frac{7}{8}$	$\frac{3}{4}$in.	$\frac{5}{8}$	$\frac{1}{2}$in.
1 bushel of Portland or Roman cement will cover, yards super.	$1\frac{1}{7}$	$1\frac{3}{4}$	$1\frac{1}{2}$	$2\frac{1}{2}$	$2\frac{1}{4}$
1 ditto, and 1 of sand - - - -	$2\frac{1}{4}$	$2\frac{3}{4}$	3	4	$4\frac{1}{2}$
1 ditto, and 2 ditto - - - - -	$3\frac{1}{3}$	$4\frac{1}{4}$	$4\frac{1}{2}$	6	$6\frac{3}{4}$
1 ditto, and 3 ditto - - - - -	$4\frac{1}{2}$	$5\frac{1}{2}$	6	8	9
1 cwt. of mastic and 1 gallon of oil - - -			$1\frac{1}{2}$		$2\frac{1}{2}$

1 cubic yard of chalk lime, 2 yards of sand, and 3 bushels of hair, will cover 75 yards of render set on brickwork; 70 yards on lath; or 65 yards plaster; or render two coats and set on brick; and 60 yards on lath. Floated work requires about the same as two coats and set. A bundle of laths and 500 nails will cover about $4\frac{1}{2}$ yards superficial. Two hundred laths, 4 feet long, are required for a square. A bundle of laths contains 500 feet nominally.

2249. In the country, for the exterior coating of dwellings and outbuildings, a species of plastering is used called *roughcast* It is cheaper than stucco or Roman cement, and therefore suitable to such purposes. In the process of executing it, the wall is first pricked up with a coat of lime and hair, on which, when tolerably well set, a second coat is laid on of the same materials as the first, but as smooth as possible. As fast as the workman finishes this surface, another follows him with a pailful of the roughcast, with which he bespatters the new plastering, so that the whole dries together. The roughcast is a composition of small gravel, finely washed, to free it from all earthy particles, and mixed with pure lime and water in a state of semi-fluid consistency. It is thrown from the pail upon the wall, with a wooden float, about 5 or 6 inches long, and as many wide, formed of half-inch deal, and fitted with a round deal handle. With this tool, while the plasterer throws on the roughcast with his right hand, in his left he holds a common whitewasher's brush dipped in the roughcast, with which he brushes and colours the mortar and the roughcast already spread, to give them, when finished, an uniform colour and appearance.

2249*a*. *Gypsum* or *plaster of Paris* is largely used in France for the construction of walls, both internally and externally, as well as for rendering them afterwards. We adopt the following method of working it, as explained by G. R. Burnell: "The coarser kinds of plaster are used for rendering; the finer qualities for ceilings, cornices, and decorative works. For walls, the plaster must be gauged stiff for the first coats, and more fluid for the setting coat. For cornices worked out in the solid, the core is made of stiffly gauged plaster, which is floated with finer material, and lastly finished off with plaster laid on by hand, about the consistence of cream. Practice only can ascertain the precise degree of stiffness to be given, as every burning yields a different quality of plaster. When walls are to be rendered, they require to be first jointed, and then wetted with a broom. The surface is then covered with a coat of thinly gauged stuff, laid on with a broom, or at least worked with a trowel in such a manner as to leave sufficient hold for the next coat. This is gauged stiff, and is laid on with a trowel; it is floated with a rule, but the face is finished with a hand trowel; the surfaces, however, are never so even, or the angles so square and true, as in the usual plasterers' work adopted in England. The ceilings are lathed about 3 to $3\frac{1}{2}$ inches from centre to centre, and the plaster poured in from above on to a sort of flat centering, leaving about an inch for the thickness of plaster; the ceiling coat is added after the centering is removed. The better descriptions are made with laths 4 inches from centre to centre, the space between ceiling and floor filled up with light work, and the under and upper surfaces rendered to receive the ceiling and tiles."

2249*b*. With gypsum, only about $\frac{3}{8}$ths of the evaporation arises as from ordinary plastering. A series of experiments made in 1850, proved that the cost of ordinary works need not exceed in any sensible proportion, if at all, those usually called "render set;" and that they are strictly the same as "render float and set." A room was begun and finished in thirty hours, whilst a common lime and hair rendering coat would have required, properly speaking, about a month. French plaster must never be used in any position where moisture is likely to affect it for any length of time. It is very hygrometric, and soon decays if kept moist. If it be used as mortar, as in brick-nogged partitions, to be covered over immediately, a space for its expansion must be allowed. In France, a small space is left between the wall and partitions; this is filled in by the plastering coat. The same observation applies to floors with plaster pugging, and even to cornices with a large body of that material, the mitres and returns being executed some time after the straight mouldings.

2250. In forming the coves and cornices which are applied below the ceilings of rooms, it is of the greatest importance to make them as light as possible, for the plaster whereof they are formed is heavy, and ought not to depend merely on its adhesion to the vertical and horizontal surfaces to which it is attached. Hence, when cornices run of large dimensions, bracketing, as has already been described in the section Joinery (2079, *et seq.*), must be provided, of the general form of the cornice or cove, or other work, and on this the plastering is to be formed. On this, when roughed out, the work is run with wooden moulds, having zinc or copper edges, so as to give the general outline of the cornice. If enrichments are used in it, they are cast in plaster of Paris, and afterwards fixed with that material in the spaces left for them to occupy. These enrichments are previously modelled, and from the model a matrix is formed, as for all other plaster casting. Great nicety is required in all the operations relative to the moulding and fixing of cornices, and most especially that the ornaments be firmly fixed by screws or other means, that they may not be detached from their places by partial settlements of the building, and cause accidents to the occupiers of the rooms where they are used.

2250*a*. *Selenitic lime* was the invention, about 1856, of General Scott, R.E., who observed that limestone capable of conversion by burning into a hydraulic lime, might be able to furnish a good cement by simply allowing a small portion of sulphuric acid gas to pass into the kiln during the burning of the lime. The process, since about 1870, is explained as consisting of carefully mixing with the water used in the preparation of the mortar a small quantity of plaster of Paris or gypsum, or green vitriol. The lime may then be ground in an ordinary mortar-mill with the mixture into a creamy paste for three or four minutes; the sand, burnt clay, or other ingredients may then be added, and the whole thoroughly ground for ten minutes or more. The lime is a good buff in colour. With double the usual quantity of sand the tensile strength of the mortar is increased fourfold. It sets rapidly and well, and as "stuff" in plastering it effects a considerable saving in time over that usually made from lime. "Selenitic mortar saves half the lime, is four times as strong, and sets in a quarter of the time of common mortar."

2250*b*. A *rendering plaster*, for superseding the use of lime and hair mortar in the plastering of walls and ceilings, has been brought forward by A. G. Barham, of Bridgwater. It is stated to be very tough and strong, not liable to crack or swell, and is applied without hair, direct to brick walls or lathwork. The surface dries and hardens rapidly, and it can be painted or papered at once, as there is nothing in the plaster to injure either of the processes. When dry it is of itself a good grey in colour. For outside stucco it is also stated to be a safe material, and is likewise free from vegetation and colouring.

2250*c*. *Adamant cement* has last year (1887) been introduced into this country, at Birmingham, from Syracuse, New York, by a company. It is a wall plaster and cement, and is manufactured in three qualities, No. 1, 2, and Chromolith. The two first are used as for ordinary plastering, and the third in place of the superior Parian cement, at a less cost. As all the bright mineral and vegetable pigments can be used with it, floorings, mosaics, and mantels are produced; also tiles, marble slabs, terra-cotta, and other articles of a similar character. It is very hard; costs but little more than lime plaster; the room plastered one day can be used the next; is easily applied, even to iron lath or wire work; is impervious to wind or weather; smooth to work over for painting, absorbs but little oil, the colours do not change, requires no sizing, and from a sanitary point of view is of great value. It is also considered to have fireproof qualities.

2250*d*. Stucco is a species of plastering which is sometimes subsequently worked to resemble marble. There are two sorts of *stucco*, those made of limes, and those made of plaster. The former are often classed under the name of cements, but their disagreeable colour prevents their being used for ornamental decoration. They serve, however, to form the foundations for the better class whenever humidity is to be feared. The latter are generally made of lime, mixed with calcareous powder, chalk, plaster, and other substances, in such a manner as to obtain in a short time a solid surface, which may be coloured, painted, and polished with such perfection as to allow of its being used instead of more expensive materials.

2250*e*. The Italians usually execute their stuccoes in three coats. The first is very coarse, to form the rendering. The second is much finer, and contains a larger proportion of lime, bringing the work up to a very even close grain. The last is made of rich lime, which has been slaked and run through a very fine sieve; it is allowed to stand from four to five months, in order that every particle may be reduced to a hydrate. If the lime cannot be kept for so great a length of time, the slaking may be assisted by beating it up very frequently. When great perfection is required, pounded white Carrara marble is mingled with it; gypsum and alabaster are used for enclosed situations. Colours are obtained by mixing with the lime such metallic oxides, &c., as the case may require. The excellence of the work consists in the care with which the effects of the natural marbles are imitated.

2250*f*. When plaster is used instead of lime, it is gauged with lukewarm water, in which size or gum has been dissolved, so as to fill up the pores, to give more consistency, and to render it susceptible of receiving a better polish. Any colours used should be previously dissolved in the size water. When the whole of the stucco is perfectly dry, the surface is then rubbed with grit stone and polished up with rubbers, much in the same way as real marble. The thickness of a coat of stucco varies from one-sixth to one-eighth of an inch.

2250*g*. *Stucco work*, as it is called, and as executed daily in Ireland for outside work, consists of their *roche lime*, slaked for three or four months previously, as above described, mixed with sand, and worked up with the trowel. It stands the weather as perfectly as Roman cement. The term is also given to the interior moulded and cast work.

2250*h*. There are practically five mortars now in use. 1. Ordinary grey stone lime mortar; 2. The same selenised; 3. Lias lime mortar; 4. The same selenised; and 5. Portland cement mortar. The four last take a rapid set. If after a few days set they become expanded and disintegrated by frost, it is doubtful if, when thawed, they will reassume a pasty condition and set again. The first develops heat in slaking, and can be used hot, and will therefore take longer to freeze, but then as it sets slower it remains longer open to the attack of frost. The building journals in the first month of 1888 printed a communication from Norway explaining how bricklaying was done there in frosty weather. It has been suggested by Mr J. Woodley that, after all, the secret lies in 'dry slaking' the lime, and following it up in small quantities at a time, thus keeping up a continuous supply of mortar in a hot state. This method is to lay out a portion of unslaked lime, and to sprinkle upon it just so much, and no more, water as is sufficient to set the action called 'slaking' in motion: it is not to be run; then to add the stipulated proportion of sand, which should be spread over the lime in such a manner as to effectually prevent the escape of the generated heat and steam. Ordinarily, this should be repeated again and again until the whole consignment of lime is absorbed in one heap, which should be sheltered from the weather, and when required for use passed through the usual 'sand-screen' or sieve to remove the core. But if desired to be used warm, it can be slaked and made up in small quantities as required; hence hot mortar. In winter time the bricks should be protected from excessive saturation by rain or snow; in summer time it is difficult to get them wetted at all by the builder.

2250*i*. The plastering of a house has occasionally to be dried artificially. Ligny's patent drying process is used: 1. For damp walls and plaster in new houses, so that they may be papered, painted, and occupied as quickly as possible without risk to health, and that at a cost of from thirty shillings a room, according to degree of dampness: 2. For old buildings and basements where the damp arises from contact with wet soil; also for drying thin walls much exposed to the weather and through which wet penetrates.

2250*k*. *Scagliola* work is an imitation of real marble. Its manufacture has generally been assumed as a mystery. It is a species of plaster or stucco invented at Carpi, in the state of Modena, by Guido Sassi, between 1600 and 1649. It is sometimes called *mischia*, from the mixture of colours introduced in it. It was not, however, till the middle of the eighteenth century that the art of making scagliola was brought to perfection. The following is the method of making columns and pilasters:—A wooden cradle, composed of thin strips of deal or other wood, is made to represent the column designed, but about 2½ inches less in diameter than the shaft is intended to be when finished. This cradle is lathed round, as for common plastering, and then covered with a pricking-up coat of lime and hair. When this is quite dry, the scagliola artist commences his operations, and, by imitating the rarest and most precious marbles, produces a work which cannot be, except by fracture or sound, discovered to be counterfeit. The purest gypsum which can be obtained is broken into small pieces, and calcined. As soon as the largest fragments lose their brilliancy, the fire is withdrawn; the calcined powder is passed through a very fine sieve, and mixed up with a solution of Flanders glue, isinglass, etc. In this solution the colours are diffused that are required to be imitated in the marble; but if the work is to be of various colours, each colour is separately prepared, and they are afterwards mingled and combined nearly in the same manner that a painter mixes the primitive colours on his palette to compose his different tints. When the powdered gypsum is prepared and mingled for the work, it is laid on the shaft of the column or other surface over the pricked-up coat of lime and hair, and it is then *floated* with proper moulds of wood, the artist during the *floating* using the colours necessary for the imitation, by which means they become mingled and incorporated with the surface. The process of polishing follows; and this is done by rubbing the surface with pumice-stone in one of his hands, while with the other he cleans it with a wet stone. It is then polished with tripoli and charcoal and fine and soft linen; and after going over it with a piece of felt dipped in a mixture of oil and tripoli, he finishes with application of pure oil. Scagliola work is so easily put up in a building, and requires so small an amount of time and expense for renovation and repair, compared with repainting and varnishing, that those who are induced to go to the expense of plastering the walls with mastic, to be ready for immediate painting, marbling, and high polishing, might be justified in expending a further sum and adopt scagliola at once. For the walls of the staircase in the building formerly called Crockford's Club House, St. James's Street, the scagliola was prepared upon slabs of slate half an inch thick, sawn on the surface with cuts about one-eighth of an inch deep, to form a key for the plaster groundwork. When the slabs were fit for polishing they were secured with battens fixed to the wall The scagliola to the staircases at the Reform Club House is worked upon the walls; they are richly panelled, moulded and inlaid. The fluted columns, in the same building, to the gallery and skylight of the saloon are done upon stone. The three-quarter columns in the drawing and coffee rooms were cast in three lengths, and each backed with tiles bedded in coarse plaster. Some black and gold columns, worked in Keene's cement on stone, and two twisted columns in plaster, are placed in Wilton Church, Wiltshire. When Parian cement is used, the groundwork is formed of wet cement of the coarse quality, the veneer being of the same thickness as common scagliola; but one half of the quantity of colours will produce the same depth of colouring as in the common scagliola. For polishing, the same process is to be followed as for walls, as described in par. 2251*i*.

2250*l*. Scagliola *floors* exist at Sion House, Isleworth; at the entrance hall at the Athenæum Club House, London; and at Crewe Hall, Cheshire. Many other examples of the employment of scagliola work will be found named in an excellent article in the *Builder* for 1863, p. 840, one of the best on the subject; and another in February 1845. A very inferior imitation of scagliola is too often to be seen.

2250*m*. A material has been lately prepared at the Patent Marble Works, for similar purposes. It is manufactured in slabs from $\frac{3}{4}$ to 1 inch thick, of any size, for lining, and for moulded work. The prices are stated to be under those of enamelled slate. *Marezzo marble*, made of cement, has been introduced since 1868. The entrance hall at the Society of Arts, London, has been lined with it.

2251. In the present time, the use of ornaments made of *carton-pierre*, a species of *papier maché*, has been reintroduced for cornices, flowers, and other decorations. The basis of it is paper reduced to a pulp, which, having other ingredients mixed with it, is pressed into moulds, and thus ornaments are formed of it. They have not all the delicacy of the plaster cast, and there is the want of that nicety which a good cornice workman in plaster exhibits; but their lightness, and the security with which they can be fixed with screws, render them often preferable to plaster ornaments. The "Critic" newspaper in 1863 stated that in Bergen, in Prussia, there is a church capable of holding 1,000 persons, constructed entirely, statues and all, of papier maché. Probably, however, the material is that used to a very great extent in Norway and Sweden for forming the roofs of houses, and said to be incombustible. It appears to be in many respects similar to the *Fibrous slab*. the manufacture of which, by Bielefeld, was discontinued a few years since, after much success; though the dust penetrated through it, showing the marks of the joists. as in plaster work. The ceiling of the reading room at the British Museum was lined with it. Another material, superseding *carton-pierre* and papier maché, is Desachy's *Fibrous plaster*, which is formed of a thin coat of plaster of Paris, run upon a backing of coarse canvas. It is of great lightness, not inflammable, and is ready to be painted immediately after it is made. It is adapted for the speedy and economical production of any coffered or circular work; and for wagon-headed ceilings, as but little bracketing is necessary, it being fixed to the joists direct; for fluted or ornamented columns, panelled dadoes, &c., for the lining of walls and ceilings, and for all purposes of ornamental plaster work. Mr. Owen Jones has extensively used this material for his interior decorations. (2246*b*.)

CEMENTS.

2251*a*. We have already adverted to the cements used in plastering. Roman, Blue Lias, and Portland cements are the principal ones for the outside coating of buildings, and the process of laying them on is so similar to that of other plasterers' work, that it will not be necessary to say much respecting them. The best mode, perhaps, of using these natural cements is to employ them purely in works under water, or where a great crushing weight is to be brought upon them at once. For foundations in damp situations, where rapidity of execution is desired, the mixture may be 2 parts of sand to 3 of cement; and also for cornices or coatings exposed to the weather. For upright faces, the proportion is of 3 parts of sand to 1 of cement. Care must be taken that no fissures are formed such as will admit water, as the action of frost will destroy it. The brickwork in mortar, to be covered, should be thoroughly dry, or the expansion of the water will throw off the cement; the brickwork itself must, however, be wetted before a coat is applied. to prevent the absorption of the moisture before the coat sets, or it will not harden. With slow setting cements, it is too often the custom to allow the filling out, and even plain faces, to become partially set, when the adhesion of the next quantity will be found imperfect and unsound. All work requires to be finished off at once for a good result. Dirty sand causes the cement to be crumbly. Cement once set, or even partially so, should not be worked up in a fresh mixture, or it will form rotten work. Like lime in the setting coat in plastering, cement fa ings and mouldings are not so liable to show fire-cracks on the face if a small quantity of sand be mixed up with it.

2251*b*. In using *Portland cement*, plasterers should use thicker screeds, and finish their work in one coat with the screed-rule, instead of working all the water used in gauging to the surface with the hand-float and trowel, spoiling the thinner coat whilst they lay it on. This cement has an advantage over others, that it can, with good management, be worked in winter, while other cements cannot be so used without great risk of the frost injuring them before they are dry. More cement added to make a coat set quicker, causes it to crack and burst. This cement is best when used of a uniform thickness of $\frac{3}{4}$ths of an inch, any dubbing out being done with pieces of brick and Roman cement. A proportion of Portland cement mixed in the usual plastering coat affords a quicker drying material for finishing with Portland or with Martin's cement. The coarse quality of Martin's cement may take the place of plaster, and all the delays consequent on its use.

2251*c*. Lime putty should never be put in the finishing coat of Portland cement; it is done to make the cement fat, and to save labour in trowelling the face up to a smooth surface; the lime takes weeks to get hard, the cement takes days only, hence the two cannot agree. Labour to the cement and clean washed sand is all that is required.

2251*d*. For *interior* embellishments, the cements known as Martin's, Keene's, and Parian, are largely adopted. *Martin's cement* is manufactured in three qualities, coarse fine, and superfine. The coarse quality presents a whitish speckled surface, and is supplied in red, light red, and grey, colours. The fine is whiter; the superfine is a cream colour. It is said to cover 20 per cent more surface, at half an inch in thickness, at a less cost than an equal quantity of any other cement for internal use, and to be 35 per cent. cheaper than such cements. For walls, 1 part of coarse cement is used with $1\frac{1}{2}$ of clean dry sharp sand, for the under coat of half an inch thick, finished with $\frac{1}{8}$ inch thick of pure cement. It is of a fireproof character, and preserves to some extent the building from damp: the cement is supposed to continue to indurate with age, and therefore to be very durable. When adopted for floors, skirtings, and other finishings, whether plain or ornamental, in lieu of wood, the cost is stated to be less than similar work executed in that material, while in appearance it is very much superior, as it takes a fine polish. It can be painted upon within twenty hours after having been worked on old brickwork, and in twelve hours when on lathed work; but all three qualities are as well without paint. Plaster of Paris must not be mixed with it, or Roman or Portland cement used as an undercoat.

2251*e*. *Keene's cement* is said to show on its face the lines of any woodwork which it may be carried across. If required, it can be painted upon in twenty-four hours after the coat on old brickwork is completed. Skirtings, flooring, and internal stucco are worked in this material, on account of its superior hardness. This cement will mix with any of the metallic oxides, &c., to produce a coloured cement.

2251*f*. *Parian cement* (Keating's patent), for internal stucco, has been used throughout the Westminster palace. It does not effloresce, takes paint or paper in forty-eight hours, and makes a very hard and beautiful scagliola. It sets in four or five hours. It must not be treated as common plastering, by being hand-floated up with water, as for all purposes as little water as possible is to be used with it. This material must not come in contact with green lime, or with limewater in any of the operations. On *brickwork*, it is first floated about $\frac{1}{2}$ in. thick, with equal parts of clean washed sharp sand, and the surface slightly dragged. The next day a setting coat, $\frac{3}{16}$ in. thick, of net cement, may be worked, laid down with a beech float and slightly trowelled. If intended to be painted or papered, the first coat of paint should be applied from twenty to twenty-four hours after. The paint is to be mixed, for the first coat, only one-fourth oil and three-fourths turpentine, and with a very small portion of red lead and gold size. The succeeding coats of paint are to be mixed in the usual manner. On *lathing*, the laths may be closer than usual; the first coat of equal parts of clean washed sharp sand and cement, broomed while soft, and floated the next day with cement as before; the setting coat to be followed up next day, and finished as described for brickwork. The three coats will be $\frac{3}{4}$ in. in thickness.

2251*g*. *Damp walls* require a first coat of Portland cement $\frac{3}{4}$ in. thick; when dry, a coat of $\frac{1}{4}$ part of Parian cement mixed with $\frac{3}{4}$ part of washed sand, gauged very stiff, rubbed in hard, and dragged before it sets. When hard, a floating coat without sand is to be applied; to be set as before on the following day, and painted on the succeeding morning, without fail.

2251*h*. For *floors*, the cement mixed with $\frac{1}{4}$ part of Bath stone dust, $\frac{3}{8}$ in. thick, is to be laid on a solid bottom of Portland concrete, in one body $\frac{3}{4}$ in. thick. On *common plastering*, where the ordinary time is allowed for finishing the works, the plaster is to be laid fair, and dragged and left to dry; the cement to be mixed with an equal part of washed sharp sand and floated $\frac{1}{2}$ in. thick. The next day a thin coat of cement having $\frac{1}{6}$ of sand is laid down and trowelled as before. If required to be *papered*, it must first have two coats of paint. In patching, when required to be painted or distempered on immediately, the edge of the old plastering is to have first a coat of paint.

2251*i*. For *polished work* on walls, the floating coat is mixed with equal parts of sharp sand and cement. The setting coat is $\frac{1}{4}$ in. in thickness, of fine net cement, rubbed down with grit stones and water; the grit is to be then well washed off, and when the water is gone, a stopping of fine cement mixed up stiff in a pan is to be applied and well rubbed in. This is then to be scraped off with a wood scraper, and the stopping repeated until a proper face is obtained, leaving a scum on the face to be taken off by the next grinding, which should be done with finer grit stones. The stopping is to be repeated and finally finished with snake stone, putty powder, and clean cloths. Three or four weeks' time is required before a good polish can be obtained, it being essential that each successive stopping of fine cement should be allowed several days to harden before the surface is again scraped.

2251*k*. For *casting* work, the cement is to be mixed stiff and dubbed in the moulds with a brush, and then left until thoroughly set. Such are the instructions for all these several processes issued by Messrs. Francis, the manufacturers of this cement, which was applied to the walls of the wards, corridors, and staircases of Middlesex Hospital, in 1849, from its non-absorbing qualities.

2251*l*. A very good specimen of plain decorative work is to be seen in the booking-office of the London, Chatham, and Dover Railway Company, at the Victoria Station. The walls, piers, &c., were executed in this cement, then painted in flat tints, and varnished and polished several times.

2251*m*. Cement *floors* may be made in an economical manner, by first forming a bed of concrete to prevent damp rising, then placing on it a coat $1\frac{1}{2}$ in. thick of Atkinson's cement, mixed with three of clean fine sand; or in Roman cement; or in Portland cement, with four of sand, floated in by a rule on screeds, care being taken to prevent the joints setting. If the cement set slow, it may be trowelled down while soft, but not when it is setting, or the face will be injured. If the cement sets very quick, a rough key is to be formed, and then covered with fine mortar $\frac{1}{8}$ in. thick, trowelling it gently before it begins to set. If rising damps be not anticipated, the floor may be first paved with clean hard brickbats in lieu of concrete, and covered an inch thick with good cement.

2251*n*. Portland cement floors have answered perfectly in several instances, but it is an uncertain material; therefore, where the floors were not to be covered, or where a slight defect was of consequence, it has been considered better to use other cements, such as Keene's, as employed at the Metropolitan Convalescent Asylum, Walton-on-Thames. A good floor for common purposes is made of a concrete formed of 6 parts of clean gravel to 1 of ground lias lime: this is generally impervious to damp and vermin.

2251*o*. The *bituminous cements* are used for paving, and for covering the extrados of arches to prevent the percolation of water through them. In all new constructions, there are always movements which crack the coatings executed in limes and natural cements, which are also subject to unequal shrinkage, producing crevices; and from these united causes, it is very rare to find such coatings impermeable. The bituminous cements are more elastic; it may happen that small crevices, so to speak, solder themselves, and if any serious repairs are required they are much easier to be executed than in those works executed with limes. When asphalte is to be used, it is placed in a quantity of nearly boiling *mineral pitch* to secure its melting. Colonel Emy found the following proportions as the best for the asphalte of Gaugeac, and it may be taken for the others of this class of cements, when used as a coating for arches: —

$2\frac{1}{8}$ pints (wine measure) of pure mineral pitch.
11 lbs. avoirdupois of bitumen or asphalte.
17 pints of powdered stone dust, wood ashes, or minion.

It is advisable to lay this mixture upon a bed of concrete or mortar; and as much as possible in slabs of 2 feet 6 inches to 3 feet in width. It should be evenly spread and compressed with a trowel, well rubbed, and reduced to a uniform close surface. When all the bubbles have been expelled, a fine sand is sprinkled over the surface, and worked in with the trowel, observing never to fill the crevices formed by the air-bubbles with sand, but only with asphalte. The thickness for coating any arches is not more than from three fifths to half-an-inch. The quantity of cement thus employed to cover a yard square is about $4\frac{1}{2}$ lbs.

2252. It is scarcely within the branch of the plasterer's practice, but as we shall have no other place for adverting to it, we may as well here mention what are called "composition" ornaments, seldom used in cornices, but principally for the decoration of chimney-glasses, frames, and to woodwork generally. The composition is very strong when dry, of a brownish colour, consisting of about 2 pounds of powdered whiting, 1 pound of glue in solution, and half a pound of linseed oil mixed together in a copper, heated and stirred with a spatula till the whole is incorporated. After heating it is laid upon a stone covered with powdered whiting, and beaten to a tough and firm consistence, when it is laid by for use, covered with wet cloths to keep it fresh. This composition is then put into moulds and pressed. Later inventions have nearly caused its disuse in architectural decoration.

Sect. X.

SMITHERY AND IRONMONGERY.

2253. Smithery is the art of uniting several lumps of iron into one lump or mass, and forming them into any desired shape. The operations necessary for this are primarily performed in the forge, and on the anvil with the hammer; but for finishing, many other implements and tools are necessary. These, however, we do not think useful to particularise, a course we have pursued in the other trades, because the expedients introduced by the engineer and machinist have of late years, except in rough work, superseded many of them. It is now, for instance, easier to plane iron to a perfect surface than it was a few years ago to file or hammer to what was then always an imperfect one. Formerly a man would be occupied as many minutes in drilling a hole as by machines it now takes seconds to perform.

2254. We have, in a previous section, given all the particulars relating to the produce of the metal from the ore; in this section we propose little more than to enumerate the different objects which the smith and ironmonger furnish in the construction of buildings; and introductory to that it will be convenient to subjoin tables of the weights of round and bar iron, and also of the weights of 1 foot of close hammered bar iron of different thicknesses; remembering that a cube foot of close hammered iron weighs about 495 lbs., of common wrought iron about 480 lbs., and of cast iron 450 lbs., whence may be derived the weight of other solids whose cubic contents are known.

2254*a*. Bolts are now often made with square heads, so that these being let into the timber, the stem cannot turn while the nut is being screwed up. Machinery has been brought to bear for the manufacture of bolts, rivets, spikes, and other like articles; "the motions are so arranged that no attention is required beyond entering the bars into the feed rolls and cleaning the pieces of the ends of the iron out of the dies."

TABLE SHOWING THE WEIGHT OF *close-hammered* FLAT BAR IRON, FROM ONE INCH WIDE AND AN EIGHTH OF AN INCH THICK TO TWELVE INCHES WIDE AND ONE INCH THICK.

Inches, and their Parts in breadth.	Thickness in Parts of an Inch, and Weight in Pounds avoirdupois.

If of Cast Iron.								
12	4·835	9·664	14·500	19·336	24·172	29·000	33·836	38·672

2255. For the carcase of a building the articles furnished by the SMITH are, wrought iron *columns with caps and bases* for the support of great superincumbent weights. *Wrought iron columns* were used in England as early as 1860 by Sir W. Fairbairn, together with wrought iron girders, and brick arches for fireproof work. When columns are beyond a certain length in proportion to their diameter they fail by bending, and not by crushing; also wrought iron is much stronger to resist tension than cast iron; and as it is an undoubted fact that connections can be made to wrought iron much better than to cast, we have here a combination of advantages where long columns have to be used which cannot but be appreciated. The use of *steel* for constructional purposes is increasing rapidly, as it is so much more reliable than iron. Messrs. Lindsay roll many sections of steel which can very easily be formed into columns by riveting. A column made of a series of steel troughs, 16 inches diameter externally, would bear a safe load of 115 tons if 30 feet long, and the weight would be 74 lbs. per foot only. A *cast iron* column 16 inches in diameter, 30 feet long, with 1½ inches of metal, would (roughly) in weight be 220 lbs. per foot run, and safe load 100 tons (J. Slater). Combination columns of *steel* can be made to 6 feet diameter; these, having a central concrete filling and outer ring of bricks in cement, can be designed to sustain a load up to 2,000 tons. They are made from 13 inches to 48 inches in diameter, and are stated to be not more expensive than cast iron columns, and far superior. Cast iron *columns* and *stanchions* were preferred both for economy and stiffness, as was also that material for *girders*, *beams*, *joists*, and *bressummers*, until the introduction of *plate iron* and *rolled iron* (all which have been treated in previous sections). Iron columns can be rendered *fireproof* by encasing them with fireclay blocks, grooved and secured by iron plates with claws, which fit on the rivet heads. For round columns a metal band is brought round the column, hooked together, and dropped into the groove of the blocks. In either case a heavy bed of mortar is next applied, and then another course of blocks is bedded over the band or plate. Then it is finished with Keene's or Parian cement, making a good surface for decoration. *Cast, blister, shear, and spring steel; charcoal sheets and plates; boiler, tank, and flitch plates; galvanized and tinned sheets; chequered floor plates, buckled plates; flat bars up to 10 in. wide, round bars up to 8 in. diameter, square bars up to 5 in.; angle, T, and trough irons.* Ties of all descriptions, straps, bolts, nuts and screws, plates, washers, and the like, employed in connecting pieces of framing where the strain is greater than the mere fibres of the wood will resist. *Half-round, bevelled, oval, octagon, hexagon, moulding, and fancy irons, hoop iron, wall nails, and sash irons;* shoes for piles, when that mode of obtaining a foundation is adopted; sanitary appliances in iron; *manhole covers* for access to sewers and drains. The Kent disconnecting trap and cover hinged to manholes for outside a building, and air-tight cover for inside a building. *Cramps* for holding blocks of stone together; but those of cast iron are better, as less likely to be subject to oxidation, while those of copper or gun-metal are still better. *Area gratings* and *window bars* for securing openings, now generally superseded for those of cast iron, especially when of an ornamental character, as are *balusters* and *railings* for stairs and balconies. Ornamental fancy *panels*. *Rain-water pipes* in 6 feet lengths, 2 to 6 in. in diameter, with their cistern heads, offsets, shoes, branch pieces, elbows, sockets, and bent pieces, and ornamental. *Square rain-water pipes*, 2½ in. square, 3 in. by 2½ in., 3 in. square, 3½ in. by 3 in., 4½ in. by 3½ in., 3½ in. by 4½ in., 4 in. by 3½ in., 4 in. by 3 in., 4½ in. by 3 in., 4 in. square, and 5 in. by 4½ in., with branch pieces, shoes, ears, &c. *Rain-water gutters* of all shapes and sizes, plain and moulded; patent spout irons or brackets, with a screw pin to hold the spout to the clip; *roof gutters* between slopes, square, angular, and square and angular. Grayson's *perfection* down spouts; where the pipe is simply hung on the nails and projects an inch from the wall, it has a T-neck socket for sliding to wall joints, and for sliding out any broken middle lengths for removal without removing others or drawing the nails. This separate patent hanger can be bolted to the ear of any other maker's pipes; when bolted they project 1½ inches, so as to be painted all round. Pavement gutters, air or bench traps, scrapers, and coal-plates, the which last have lately been brought out Burnet's self-fastening; Stiddle's self-locking; also one self-fastening put forward by a company. Hyatt's glazed coal-plates, with many, if not all, of the articles required for *stable fittings*, either plain, enamelled, or galvanized, as advertised by Varnell; Cottam and Hallen; the St. Pancras Iron Work Company; Musgrave of Belfast; and others. *Pavement lights*, or Hayward's patent "semi-prism," are extensively used for lighting basements, cellars, and underground apartments, giving a brilliant result. Hayward's small round lights. The former differs greatly from the prismatic or single bull's-eyes. T. Hyatt's patent ornamental tile and glass lights for pavements, semi-prism gratings to light basements, &c., stall-board lights, &c.; the former have a neat appearance, and afford a better foothold than glass alone. There are also Haddon's patent prism and Hatfield's patent prism pavement. *Circular iron staircases* with the bent riser, and spandrel, in one, and adaptable where the space is confined, or to pass from one story to another only; and among other things, *chimney bars* to relieve the weight of brickwork over a chimney opening. In kitchens and rooms where a large opening is required, and two bars may not be sufficiently strong, a wrought or cast iron *[illegible]* is necessary. The Metropolitan Building Act requires that under certain cases the trimmers of a chimney must be bolted in by an iron bar or bars, turned up and down at the ends, and built into the jambs for at least 4½ in. on each side.

[illegible]. The advantage of now being able to procure wrought iron *flitches* of a good length and depth has obviated the necessity of *welding* two or more lengths together by the sledge hammer, which has not a sufficient impetus to reach the very core of the metal, and thus the joint became weaker than the remainder of the flitch or bar. In late experiments were made in Paris on the effect of welding by hydraulic pressure; two bars, each 1½ in. square, were thus welded together with great ease, and the machine was stopped when the part welded was brought down to the thickness of the bar. After cooling, the welded part was cut through, and the inside was found perfectly compact.

[illegible]. *Boiler plate* is made of rolled or wrought iron. They are termed *sheets* when under ¼ inch in thickness; *plates* from a ¼ inch to 2 inches thick; and *slabs* when more than 2 inches thick. They are named according to the quality of the iron, or the locality where they are manufactured. The sizes of those most in use are from 4 feet to 8 feet long, 2 feet to 4 feet wide, and from ⅛ to ⅝ of an inch in thickness. Fine charcoal bevelled galvanized flat sheet iron is imported for roofing purposes, instead of zinc or lead. It can be bent and hammered without cracking.

[illegible]. *Corrugated iron* is sheet iron which has been rolled into the form of a series of waves. It is in that state frequently used for a covering for temporary purposes, between joists to carry concrete, &c.; and for fencing, the corrugation giving a thin sheet great capability for carrying a heavy weight, or for stiffening framework. The flutes are generally about 3½ or 4 inches from centre to centre. Sheets of Nos. 16, 18 and 20 wire gauge are made from 6 feet by 2 feet, to 8 feet by 3 feet; and of Nos. 22, 24, and 26, from 6 feet by 2 feet, to 7 feet by 2 feet 6 inches. In calculating the measure for fixed roofing, add $\frac{1}{10}$ to the weight per square for lapping. The sheets should overlap each other about 6 inches, and be double riveted at the joints. About 3 lbs. of rivets are required for a square of roofing. In roofs, the iron sheets are best used in a curved form.

2155d. *Wrought iron casements* are still introduced into buildings. This has given rise to several improvements upon the old method of manufacture for making them wind and water tight. Those now generally advertised are:—patent *wrought iron windows*, by the General Iron Foundry Company (Limited); Burt and Potts' patent *wrought iron water-tight window and frame*; Gibbons and White's *wrought iron weather-tight casements and frames* for stone mullions; and casements for wood mullions as designed by Mr. G. Devey, architect. All these are fitted with *casement stays and fastenings*. Connected with this purpose are Smith's (of Princes Street, Leicester Square) "patent weather-tight water-bar," for French casements, formed in the sill; and one of another make, by a manufacturer of the same name (formerly of Queen Street, Oxford Street). In connection with this subject is the use of iron bars and casements for forming the lights in rear of warehouses and offices in crowded localities, for the purpose of obtaining as much space and light as possible, at the same time so as not to interfere with neighbours' lights. A useful example, designed by Mr. Basset Keeling, architect, is given in the *Builder*, 1861, vol. xxxix. 721, from which the following cuts forming part of the illustrations are here given. Fig. 807a. is a section of the lower part of the vertical framing and sill. Fig. 807b. is a section of one of the upright bars, showing hinge of casement. Fig. 807c. is a section of the other bars and of the side of casement. Fig. 807e. is a section of the horizontal bar on the curved head from the vertical to the head. Fig. 807f. shows the thrust of the curved head against a wrought iron girder carrying a wall above. The letters B show the iron framing; C the iron casement; G the glass; W the inside beaded wood framing.

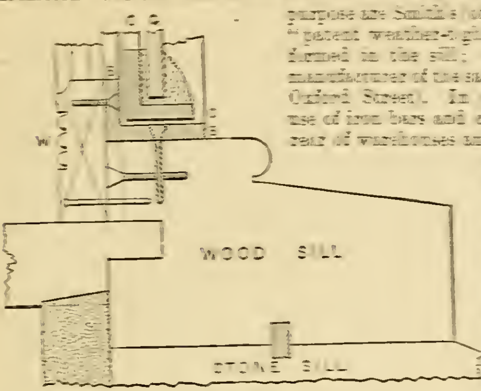

Fig. 807a.

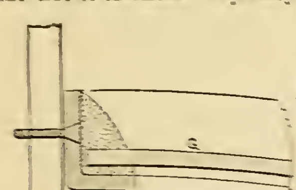

Fig. 807f.

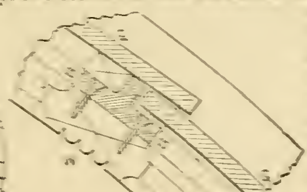

Fig. 807e.

2155e. *Fire-proof iron doors* are made to shut in a rebate as required under the Metropolitan Building Act, or are made sliding; or sliding as carried out by Messrs. Hobbs, Hart and Co. on their new patent clutch rebate principle. A door on each side of the party wall is usually required; and for warehouse purposes in London they are specified to be made folding, and to be not larger than a definite size. The usual dimensions, outside of frames, of fire-proof wrought iron doors and frames, may be usefully inserted here:—5 ft. 9 in. high by 2 ft. 8 in. wide; 6 ft. by 2 ft. 4 in.; 6 ft. 2 in. by 2 ft. 6 in.; 6 ft. 6 in. by 2 ft. 6 in.; 6 ft. 9 in. by 2 ft. 9 in.; and 6 ft. 4 in. by 3 ft.

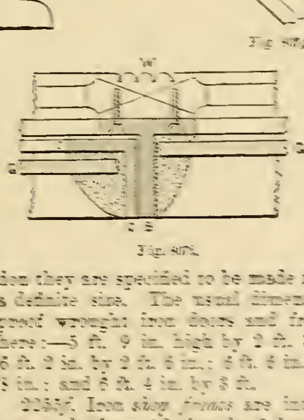

Fig. 807c.

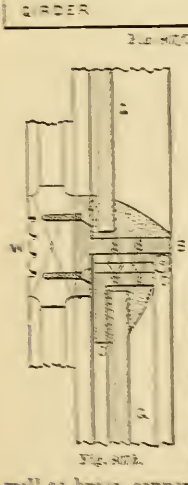

Fig. 807b.

2155f. Iron *shop fronts* are introduced in many towns. They are made from 12 feet by 6 feet to 14 feet by 10 feet, generally at one shilling per superficial foot. "Whole brass" and "half brass" sash bars, of nearly every form and size, are manufactured, as well as brass, copper, and zinc beads. Metal "stall-board plates" hardly come within our province, except to notice them. With this subject is connected the varieties of *revolving shutters* in iron, wood, or steel, and with or without machinery; and made to lift up, or down, or to move sideways. A revolving safety shutter in one sheet of steel is probably the last invention; it requires no machinery. Where the old method of putting up shutters exists, Jennings's *shop-shutter shoes* secure them as they are each put up, without the necessity of any shutter bar.

2255*g*. Wrought iron *wine bins*, and new registered iron bins, adapted for small quantities of wine, placed in a closet in a sitting or other room, and with or without doors, will be found a useful addition in small houses.

ORNAMENTAL METAL WORK.

2255*h*. The ornamental portion of SMITH'S work has been largely introduced, of late years especially, in wrought iron shaped by hand into various devices and patterns, more especially according to the several periods of mediæval architecture. The taste is chiefly developed in gates, railings, altar and staircase standards, screens, grilles and gratings, tombs, hinge fronts, the band finishing either in a fleur de lis or trident, reaching to about three-fourths of the width of the door, and of ⅜ths iron; or in some scrollwork, which curls and scrolls over the entire face of the door; shutter hinges, common door hinges; gable crosses, terminals, vanes, and hipknobs; ridge crestings; drop handles with plates, closing rings and plates; lock plates and escutcheons, knockers, keys, latches and bolts, bell pulls, levers and plate pulls; umbrella stands; scrapers; fenders and fire-irons; dog-grates; lecterns and book rests; candlesticks. gas, lamp, and candle pendants and brackets, desk lights, and standards; coronæ lucis, lanterns, and pillars. It is almost unnecessary to add that many of these articles are to be had in polished brass, and that many of them are imitated in cast iron. Wrought and cast iron, as in panelled work to gates, are sometimes employed together, the wrought parts enclosing the panels.

2255*i*. As iron has now neither the tenacity nor the ductility which it gained by the old process of being repeatedly forged, the modern smith can scarcely hope to emulate the fine works which were produced in mediæval times, unless the iron be made for the purpose. It is not easy to repeat the mediæval operations of slotting a bar, so as to get the eyes at equal distances, without a machine; or of fastening hot (or, as in later times, cold) clips; or of cutting slits into a bar from the edge, and then curling the splintered parts; yet these were common work for the smith in the 12th century. It is equally difficult to produce the twisted work which was easy to the mediæval smith, whose chief care in the 13th and 14th centuries was bestowed in welding, stamping, and chiselling; the file was scarcely ever used. In welding he was careful to fire the two parts separately, getting the upper one to a white heat, the lower part to a red heat, and hammering the joint lightly at first, but harder as the iron grew colder. He disguised the uneven state of the upper part by punching on it separate dots, or else close ones, forming a sort of incised line.

2255*j*. In very large specimens of ancient work, some parts are additions entirely welded, others are additions confined at the ends by bands, which are welded across the groundwork. To imitate work of the 13th century, such as a grille, requires a drawing at full size, and a matrix for each leaf or bud, with an anvil cut to each section which a bar or a band is to assume; this last seems, with regard to the bar, to have been overlooked by M. Viollet-le-Duc. Then, when a bar has been rounded (if needful), and the end stamped, the curl is given, and the smith has a stalk with a foot. Two of these must be applied to the drawing to have the point of junction marked, and the feet are to be welded together. If the sprigs then made are to be combined into branches, the larger stem is to be prepared; and, if moulded on the face, this was passed between the hammer and the cut anvil by a process equivalent to rolling the bar. After the sprigs are welded with the branch, the poverty of the joint is perhaps to be masked; usually the mask was a moulded band, to which an ornament, e.g. a cup of foliage, was sometimes added; but frequently the band was superseded by a stamped button. After the feet of the branches are welded to the trunk or main stem, bands are laid over the junction, are welded, and are finished with the chisel. The whole has to be riveted to the framework. The size and weight of the pieces at the last times of welding were difficulties that were partly obviated after 1250 by omitting the welded bands.

2255*k*. These operations were superseded by the introduction of sheet iron, in England before 1300, in Germany before 1400, and in France soon afterwards, which was cut and bossed to a remarkable extent, sometimes stamped, and frequently welded, but later was riveted. In work of the 15th century the bars are neither stamped nor chased, and the sheets are riveted instead of being welded; but later they are either planted or housed. Finally, the mediæval smith returned to the slots, mortises, and short bars of the earlier periods, and used clips which were closed cold with rivets of soft iron.

2255*l*. The use of metal work in decoration, both as fixed in buildings, and in useful movable articles, is most ancient; the use of *bronze* is recorded extensively in Greece and Rome. The metal so used has been mostly lost to us. Except gold, this is the most enduring metal, and is susceptible of the finest work which the modeller can bestow upon it, and the chaser can enlarge on it. Its tenacity, too, enables cast work to have thick and thin places, such as cast iron, and to some extent cast brass, will not allow without cracking. The statue of Colleoni at Venice, by Verocchio, is a fine example, together with its band of bronze ornament round the pedestal. The gates and enclosure of the tomb of Henry VII.'s chapel in Westminster Abbey should be studied for the art as well as for their curious construction. Bronze is a metal which is beautiful if left in its own golden tone, and in changing from this tone it never becomes ugly. It can be gilt. and will take various patinas, the green, brown, and black; and when used with marble of contrasting colours, produces effects which cannot be had so well in any other way. J. S. Gardner, *Monumental Use of Bronze*, in Journals of February and March, 1888, which describes the *cire perdue* process of casting.

2255*m*. *Wrought iron* has special qualities of strength, tenacity, durability, and relative cheapness. It has lately come more and more into use. Hinges, screens, railings, grilles, knockers, door handles, dogs, fenders, fittings for lights, fire irons.

2255*n*. *Polished iron* is to be seen, but is not generally suitable for use in this damp climate, but the fine grey polish it takes is very harmonious with rooms richly furnished.

2255*o*. *Steel* was much used in the latter part of the 18th century; it has rather a cold and severe tone, but where it can be kept clean it may be used with excellent effect.

2255*p*. For external work, black or painted wrought iron must be used. The present manufacture of iron is not favourable to durability; the old mode of smelting by charcoal made a finer, close and ductile iron, and less liable to rust; and perhaps the atmosphere in the great cities and towns is not favourable to the duration of wrought iron work. For fine work the best iron should be used, especially when the work is intricate and needs many welds. The French work of Louis XIV.'s time is very stately, rich, and well balanced in design, with firm leading lines and graceful foliage and garlands. In Louis XV.'s time the curves became bolder and looser, as in all art of that time, as in the eight screens in the Grand Place at Nancy. In Louis XVI.'s time the work became elegant and rather stiff. Soon after, fine ironwork died out. The German work is comparatively clumsy, and the endless scrolls with sprays going out at strange tangents, and passing through the scrolls in gratuitously difficult ways, the scrolls ending in flowers of the shape of cocoons, and with antennæ springing from them, so as to remind one of great insects, are not very beautiful, if clever from the ironworker's point of view. In later times ironwork throughout Europe seems to have been greatly affected by the French taste of the time. In England, the very noble work of Huntington Shaw, now at the South Kensington Museum, having been removed from Hampton Court Palace, is different from any other work, though it has its points of resemblance with French ironwork. This and the gates and grilles in St. Paul's Cathedral are some of the best ironwork in England. The construction is good, and the ornament is so applied as to enrich the construction without hiding it, and to make a good composition of open and solid work, well contrasted and varied in the screens almost infinitely. There is a largeness of style in these screens and in the St. Paul's work, probably impressed upon it by Sir C. Wren. The later work at the Adelphi has a very good contrast of free and rigid lines.

2255*q*. There is no reason why the men now living should not do work as good as the old men did. There is still skill, patience, and dexterity in the country, and English work from the 12th to the 18th century can be well compared with work of other countries, so we need not be ashamed to compare that of the 19th century. The design must be suitable to the material. (H. Longden.)

2255*r*. The chief articles furnished by the IRONMONGER are for the joiner's use, and, except in particular cases, are kept in store by that tradesman for immediate supply.

2257. They consist in *screws* made in brass, copper and iron, whose common sizes are from three-quarters of an inch up to 4 inches in length. They are sold by the dozen. *Self-boring wood screws*, the thread being made at a particular angle, are supplied in lengths of $\frac{1}{2}$, $\frac{5}{8}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, and 4 inches.

2257*a*. *Nails* are now both wrought, cut, and cast, and made of iron, copper, and zinc. They are called by a variety of names, according to their special uses. The principal are here enumerated. *Back nails*, whose shanks are flat so as to hold fast but not open the wood. *Clamp nails* are for fastening clamps. *Clasp nails*, or *brads*, are those with flatted heads, so that they may clasp the wood. They also render the wood smooth, so as to admit of a plane going over it. The sorts of most common use in building are known by the names of *ten-penny*, *twenty-penny*, and *two-shilling nails*. *Clench nails* are such as are used by boat and barge builders, sometimes with boves or nuts, but often without. They are made with clasp heads for fine work, or with the head beat flat on two sides. *Clout nails*, used for nailing clouts on axle-trees, are flat-headed, and iron-work is usually nailed on with them. *Deck nails*, for fastening decks in ships and floors nailed with planks. *Dog* or *jobent nails*, for fastening the hinges of doors, &c. *Flat points* are of two sorts, *long* and *short*; the former much used in shipping, and useful where it is necessary to hold fast and draw without requiring to be clenched; the latter are furnished with points to drive into hard wood. *Lead nails*, used for nailing lead, leather, and canvas to hard wood, are the same as clout nails dipped in lead or solder. *Port nails*, for nailing hinges to the ports of ships. *Ribbing nails*, used for fastening the ribbing to keep the ribs of ships in their place while the ship is building. *Rose nails* are drawn square in the shank. *Rother nails*, chiefly used for fastening rother irons to ships. *Scupper nails*, much in use for fastening leather and canvas to wood. *Sharp nails*, much used in the West Indies, and made with sharp points and flat shanks. *Sheathing nails*, for fastening sheathing boards to ships; their length is usually three times the thickness of the board. *Square nails* are of the same shape as sharp nails; chiefly used for hard wood. *Brads* are long and slender nails without heads, used for thin deal work to avoid splitting. To these may be added *tacks*, the smallest sort of which serve to fasten paper to wood; the *middling* for medium work; and the *larger size*, which are much used by upholsterers. These are known by the name of *white tacks*, *two-penny*, *three-penny*, and *four-penny tacks*. *Cut nails* are now much used.

2257*b*. Nails of Crown quality comprise "cut clasp of inch, $1\frac{1}{2}$, 2, $2\frac{1}{2}$, and 3 to 6 inches long. Floor brads of $2\frac{1}{4}$ and $2\frac{1}{2}$ inches long. Cut lath of $\frac{7}{8}$ and 1 inch. Joiners' brads of 1, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, and 2 inches. Steel flat point rose for clenching, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{4}$, $2\frac{1}{2}$, $2\frac{3}{4}$, and 3 to 4 inches long. Cordes' patent rose, flat points, $1\frac{1}{4}$, $1\frac{1}{2}$, $1\frac{3}{4}$, 2, $2\frac{1}{2}$, and 3 to 6 inches long. Slate nails, $1\frac{1}{4}$ or $1\frac{1}{2}$ inches, of zinc, wire, malleable, galvanized." *Spikes* of 5, 6, and 7 inch lengths. See GLOSSARY, ADHESION.

2257*c*. WEIGHT OF FLOORING BRADS PER 1,000 (RARELY EXCEEDING 900 NAILS).

Wrought.		Patent Cut.		Thickness of floors.
Length.	Weight.	Length.	Weight.	
2 inch.	8 lb.	2 inch.	8 lb.	$\frac{3}{4}$ inch.
$2\frac{1}{4}$ „	10 „	$2\frac{1}{4}$ „	10 „	Inch.
$2\frac{1}{2}$ „	12 „	$2\frac{1}{2}$ „	12 „	Inch.
$2\frac{3}{4}$ „	16 „	$2\frac{3}{4}$ „	15 „	$1\frac{1}{4}$ inch.
3 „	20 „	3 „	18 „	$1\frac{1}{2}$ „

2257*d*. *Tacks* are tinned over; and all nails can be galvanized to prevent their rusting. Nails for ornamental purposes, and likewise screws, are made with *brass heads*, and the latter also with *gilt heads*.

2258. *Butt hinges*, whose name is probably derived from butting close surface to surface when closed, are used for hanging doors and shutters, and made of wrought and cast iron and brass, the former varying in size from $1\frac{1}{4}$ to 4 inches in length; the latter from 1 inch to 4 inches. These, as well as all other hinges, are in size necessarily proportioned to the magnitude and consequent weight of the shutters or doors they are to carry; and it is to be observed that, for the well-hanging of a door or shutter, the size of the hinge should be rather on the outside of enough than under the mark. There is a species of hinge used for doors called the *rising joint hinge*, a contrivance in which the pivot, having on it a short portion of a spiral thread, and the part to which the door is fixed having a correspondent mass, the door in opening rises, and clears the carpet or other impediment usually placed on the floor. The *projecting brass butt* is used when the shutter or door is required to clear some projection, and thus, when opened, to lie completely back in a plane parallel to its direction when shut. All hinges are sold by the pair, including the necessary screws.

2258*a*. Besides these hinges there are *cross garnets*, whose form is like the letter ⊢ sidewise. These are only used on the commonest external doors, and are made from 10 to 12 inches, varying in their dimensions by differences of two inches. H *hinges* are of the shape of the letter H, showing their form as well as the origin of their name; and in their sizes range from 4 to 12 inches by differences of an inch. HL *hinges* (H and L conjoined), whose form is implied by their name, and whose sizes are from 4 to 14 inches, proceed by inches. *Parliament hinges* are to allow a shutter to open back upon a wall, and are made of cast and wrought iron, from 3½ to 5 inches, proceeding in size by half inches.

2258*b*. Redmund's patent hinges consist of, iron rising butts; or in brass with moulded burnished knuckles and concealed joints; iron and brass projecting butts with moulded burnished knuckles, flaps, and concealed joints, in three sizes of proportional strength, from 1¼ to 4½ inches projection; *pew hinges*, in iron and brass, projecting 1, 1½, and 2 inches. Rising *spring hinges* in iron; and not rising spring hinges, in brass, iron, and patent malleable iron, and of single and double action; these are made flush, the knuckle being made to suit the bead of the architrave; rising swing hinges, which rise and act each way; gate hinges of many descriptions, &c.

2258*c*. Collinge's patent spherical hinges run from 2 to 6 inches, in plain brass, ornamental brass, and cast iron. The gate or strap hinge, from 1 foot 6 inches to 3 feet 6 inches, in steps of 3 inches. Improved gate springs, with hardened joints. Spring hinges, and also to open both ways, are made light, strong, and extra strong, for 1½, 2, 2¼, and 2½ inch doors, in iron and brass.

2258*d*. Among other useful hinges are swing centres, double action, to open both ways, known as Smith's patent, Redmund's and Gerish's, chiefly for 2 and 2½ inch doors. Hart's iron rod door springs, from 15 to 42 inches, called No. 1, No. 2, No. 3 and No. 4 qualities, also brass mounted. Circular door springs. Rising and not rising door back springs; spiral door springs; and patent climax door springs for single and double action doors, must also be noted for closing doors.

2259. *Rough rod bolts* are those in which there is no continued barrel for the bolt, and are for the most common service. Their sizes begin with a length of 3 inches, and proceed by inches up to a length of 10 inches; such, at least, are their common sizes. *Bright rod bolts* run of the same sizes as the last; and, as the name indicates, the bolt is polished and finished, so as to make them a better fastening, as far as appearance is con-concerned. The *spring plate bolt* is contrived with a spring to keep the bolt up to its work, but one which so soon gets out of order that we wonder it is now manufactured or used. It is made of lengths from 3 to 8 inches, by variations of an inch in size. *Barrelled bolts* are those in which the whole length of the bolt is enclosed in a continued cylindrical barrel, and are superior to all others in use, as well as the most finished in their appearance. The common sizes are from 6 to 12 inches, varying by steps of an inch. All the bolts above mentioned are sold per piece by the ironmonger, as are those called *flush bolts*, a name given to such as are let into the surface to which they are applied, so as to stand flush with it. They are mostly made of brass, and are of two different thicknesses, viz. half and three-quarter inch. Their lengths vary from 2½ to 12 inches, and occasionally, as circumstances may require, as in book-case doors and French sashes, to a greater length. But for French casements, what is called the *Espagnolette bolt*, a contrivance whose origin is French, though much improved in its manufacture here, is now more generally in use. Smith's *patent weather-tight casement fastenings for French windows*, consist of a plate formed in the edge of one door, which when shut is forced half its width into a groove in the other door. This acts in lieu of the Espagnolette bolt above mentioned. Smith's patent *water bar* for casements opening outwards has been mentioned in pars. 2165*b*. and 2255*d*. Jackson's patent *mortise bolt* appears to be a late improvement upon the round or the flush bolt. Elliott's patent *perfect simplex* metal weather bar is adapted for all sorts of casements and doors opening inwards. It is made in zinc, brass, and iron.

2260. *Pulleys*, for hanging sashes and shutters, are made of iron and of brass, and with brass sheaves and brass axles. Their sizes are from one inch and a half to two inches and a half in diameter. M'Adam's pulleys for window sashes, of porcelain or vitreous material, are considered to be exempt from damp and rust through which cords may become rotten. He adds to them a method of hanging double sashes with a single weight on each side of the window. Johnson's patent axle pulley for sashes, whereby the wheel, axle, and bushes can be removed for oiling and cleaning; the two last being covered in, are protected from dust and damp; and the wheels cannot get fixed as in ordinary pulleys. Adams' patent reversible and sliding window, by which the glass can be cleaned from the inside. Solid-frame oilable sash pulleys. Austin's imperial patent sash and blind lines are made of flax in four qualities, and his new imperial patent flax sash line for heavy weights. Patent braided sash line with a twisted copper wire centre, known as the "patent golden eagle sash line." A common description is made from jute, but it is very inferior to flax. Henry's patent sash line fastener is easily fitted and the cord readily adjusted. Newall's patent *copper wire cord* and *wire strand* are extensively used for window sash line, hothouses, lightning conductors, picture cord, clock cord, tent ropes, clothes lines, &c; the advantages, as reported, being that they are cheaper, much more durable, equally flexible, and one-sixth part the bulk. Newall's patent improved *iron wire rope* we do not detail.

TABLE I. OF NEWALL'S COPPER CORDS.

Number	0	1	1¼	1½	1¾	2	3	4	5	6	7	8	9	10
Diameter, inch	$\frac{3}{8}$					$\frac{1}{7}$	$\frac{1}{8}$	$\frac{1}{10}$						
	Lightning Conductor.		For Window Sash Line, Hothouse, &c.							Picture Cord, &c.				
Breaking strain, lbs.	1200		960	690	480	300	180	125	45	90	120	128	130	300
Working load, in lbs.	336		224	168	112	75	45	31	11	22	30	32	50	80

Brass axle pulleys and hothouse pulleys are supplied to suit.

TABLE II. OF IRON CORDS—GALVANIZED AND PLAIN.

Number	1	1¼	1½	1¾	2	3	4
Breaking strain, in pounds	2520	1920	1380	960	600	360	250
Working load, in pounds	672	448	326	224	150	90	60

Wire strand, 4 and 6 wire, of No. 3, 4, 5, 6, and 7 qualities; galvanized and ungalvanized.

2261. The varieties of *locks*, their contrivances for security, and their construction, are so many, that to describe them minutely would require almost a work of itself. All that the architect has to deal with, for common purposes in building, we shall mention. For fastening places where particular security is requisite, as strong closets for plate or cash, some of the patented locks should be used, and we must leave this matter for inquiry in the hands of the architect. Every patentee says his invention is the best. We nevertheless believe, notwithstanding the boasts of all the inventors, that no lock has appeared which an expert locksmith acquainted with its construction will not be able to pick. The locks in common use are *stock locks*, whose box is usually of wood, and whose sizes vary from 7 to 10 inches. *Dead locks*, whose sizes are from 4 to 7 inches, and so called from the key shooting the bolt home *dead*, without a spring. *Cupboard locks*, of 3, 3½, and 4 inches in size. *Iron rim locks*, whose box or case is made of iron, and which are fitted on to one of the sides of a door, and whose sizes are from 6 to 8 inches. Of those made of the last-named size, there are some, as also of 9 inches, which are used for external doors, called *iron rim drawback locks*. For the doors of all well-finished apartments *mortise locks* are used. These take their name from being mortised into the thickness of the door, and being thus hidden. Gerish's patent cylindrical mortise lock, Barron's patent locks, Bramah's patent locks, Hodges' patent lock furniture, Kaye's patent automatic lock and door opener, or *push and pull* lock, and Chubb's patent locks. Hobbs's patent locks "are made for all purposes, from the smallest cabinet to the largest fortress gate." Hill's patent *reversible rim lock* has four "hands" in one lock, doing away with the necessity of considering which way the door is to open. Tucker's new patent flush bolt spring lock, self-locking dead lock, and railway carriage flush bolt spring lock; they lock themselves when closing or closed. Biggs' patent tubular reversible mortise lock; the machine-made lock, 6 inches long and one inch diameter; the foreplate and striking plate are 3 inch by 1 inch, with rounded ends. To these either plain or fancy *furniture*, that is, *knobs* and *escutcheons*, are affixed. Longbottom's patent adjustable lock furniture, simple and reliable.

2261*a*. Pitt's patent *self-adjusting spindle*, with his new patent *mount and spindle*, and Ager's patent *adjusting spindle*, all command a large sale. They are all fitted with knobs and plates, from china, plain white and buff, to gold lines, gold bands, flowers, &c., and in hard woods, as ebony, maple, satin, rose, mahogany, wainscot, and walnut; the knobs in many shapes: also with plain and fancy brass, brass and china combined, and buffalo horn furniture. Also with glass furniture, crystal and amber of varying shapes and cutting, with green, black, and opal cut octagons. Above and below them *finger plates* are generally directed to be fixed, to prevent the door being soiled in the places where it is mostly caught.

2262. The different sorts of latches in use are the *thumb latch*, which receives its name from the thumb being placed on the lever to raise its latch; the *Norfolk-latch*, which is sunk, and requires a pressure on the lever to raise the latch; the *Suffolk-latch*; the four-inch *bow latch*, with brass knobs; the brass *pulpit latch*; the *mortise latch*; and Gothic latches.

2262*a*. Wishaw's registered improved "telekouphonon," for *speaking pipes*, consists of a whistle mouth-piece of ivory, wood, or metal, with an indicator attached to point out from which one or two or more tubes the whistle proceeds. These pipes are now arranged for one or more mouthpieces. Electric bells are named in the next section. The ordinary crank system of *bell hanging* is noticed in SPECIFICATIONS, 2292.

2263. Besides the articles already mentioned, the ironmonger furnishes *holdfasts*, *wall-hooks*, *door springs* of various sorts, *door chains and barrels* of brass and iron, *thumbscrews*, *shutter fastenings*, *shutter bars*, *sash fastenings*, of which there are now many varieties against burglary, adjustable silent *door springs*, brass *turn buckles*, *closet knobs*, brass *flush rings*, iron *drawer handles*, brass flush *draw handles*, *brass rollers*, *bars with latchets*, *shelf brackets*, *sash weights*, with numerous other articles.

2263*a*. Bolts, straps, and other exposed iron work are preserved from the action of moisture on them by the following mixture:—To two quarts of boiling oil add half a pound of litharge, putting in small quantities at a time, and cautiously. Let it simmer over the fire two or three hours; then strain it, and add a quarter of a pound of finely-pounded resin and a pound of white lead, keeping it at a gentle heat till the whole is well incorporated. It is to be used hot. A composition of oil and resin and finely levigated brick-dust is found useful in preserving iron from rust. It is to be mixed, and used as a paint of the usual consistence (see par. 1779*c*. *et seq.*). Wrought iron ornamental work exposed to the weather has been cased with copper and gilt, as much for decoration as for preservation. The surface of iron may be decorated and highly vitrified, the colours being burnt in. Thus the iron can be shaped to elaborate designs and artistically treated; being easily cleaned, it is a permanent material for walls, ceilings, and other parts of a building. See the Barff-Power process, &c. for protection of iron, 1780*c*.

2263*b*. Mr. T. Fletcher, of Warrington, has lately (1887), by the use of compressed oxygen and coal gas, with a ½-in. gas supply, brazed a joint of a 2-in. wrought iron pipe in about one minute. He then tried welding, a process not possible with ordinary coal gas and air, and found that a good weld was obtained on an iron wire ⅛ in. diam., with a very small blowpipe, having an air jet about $\frac{1}{32}$ diam. Larger articles, as boiler plates, he thinks could be done perfectly with little trouble and no handling. By this process he fused a large hole in a plate ¼ in. thick wrought iron by an apparatus which could be carried up a ladder by one man.

GAS FITTER.

2264. The work of this artizan may be placed under the head of this section, although his trade is now kept distinct. Gas is required by the Companies' Acts of Parliament to have a lighting power of 16 sperm candles when consumed at the rate of 5 cubic feet per hour. As regards purity, the gas must be entirely free from sulphuretted hydrogen, and the maximum quantities of sulphur and ammonia allowed are fixed from time to time for London by the gas referees (1885). The *pressure* of gas usually during the day varies from 1½ inches to about 3 inches at night. This causes the burners to flare and hiss. To regulate this pressure various contrivances have been invented. Carnaby's is for the turning off of any number of lights by working the handle of a dial in the master's room or office. The Stott, Tice, Oakley, and other gas economisers are automatic, having valves that rise and fall according as the pressure is larger or smaller; they are said to save from 20 to 40 per cent. of gas without diminution of light. A ready plan of regulating the supply is to put the tap to the meter at such a point, by trial, as will supply the lights in ordinary use. In large establishments this has been done by a man, specially instructed, who alters it according to the lighting up or putting out of the lights. A great saving has been thus effected. The various formulæ for calculating the velocity and the pressure of effluent gas are to be found in CLEGG, *Treatise on Gas Lighting*. The most economical working pressure is equivalent to the weight of a column of water on the outlet, of about 1 inch. The formula for calculating the quantity discharged is $q = 1350d^2 \sqrt{\frac{hd}{sl}}$; in which q = the quantity sought in cubic feet per hour; d, the diameter of the pipe; h, the working pressure in inches; l, the length of the pipe in yards; and s, the specific gravity of the gas compared with atmospheric air as unity.

TABLE OF THE DELIVERY PER HOUR THROUGH PIPES OF THE DIAMETERS NAMED.

Size. diam.	Thickness.	Length.	Weight.			Delivery.	Size. diam.	Thickness.	Length.	Weight.			Delivery.
ins.						cubic ft.	ins.	inch.	feet.	cwt.	qr.	lbs.	cubic ft.
½	wrought iron.					90	5	13-32nds	9	1	3	24	12,500
⅝						160	6	7-16ths	9	2	2	2	18,000
¾						250	7	15-32nds	9	3	0	14	24,500
⅞						380	8	1-half	9	3	3	5	32,000
1	inch.	feet.	cwt.	qr.	lbs.	500	9	17-32nds	9	4	2	2	40,500
2	5-16ths	6	0	1	24	2,000	10	9-16ths	9	5	1	6	50,000
3	11-32nds	6	1	0	3	4,500	12	5-8ths	9	7	0	5	72,000
4	3-8ths	9	1	1	24	8,000							

For cost of laying, see Lockwood's *Price Book*, 1887, art. Gas Fitter.

2264*a*. The main distribution of gas is effected through cast iron pipes with sockets and spigot ends, whenever the diameter exceeds 2 inches. Wrought iron welded tubing for gas is made from 3 in. diameter, $1\frac{1}{2}$ in., and then down by each $\frac{1}{4}$ in. to $\frac{1}{2}$ in., then $\frac{3}{8}$, $\frac{1}{4}$, and $\frac{1}{8}$ in. diameter, in lengths of from 4 to 12 feet, from 2 to 4 feet, and shorter pieces under 2 feet; together with all their connecting pieces, cocks, taps, screws, &c. A $\frac{1}{4}$ inch pipe is used for 2 lights, $\frac{3}{8}$ inch for 6, $\frac{1}{2}$ inch for 12, $\frac{3}{4}$ inch for 25, 1 inch for 50, $1\frac{1}{4}$ inches for 70, $1\frac{1}{2}$ inches for 120, and 2 inches for 200 lights. In the details of house fittings, wrought iron pipes are used when the diameter is, and exceeds, half an inch; $\frac{3}{4}$ in. is the least size recommended to be used, even for supplying upper rooms. For pipes of small diameters, and for abrupt bends, block tin and composition pipes are fixed. For occasional use, flexible pipes are employed, such as those made of gutta-percha, caoutchouc, with or without a wire coil inside, and caoutchouc coated with varnish. This last is the safest of the flexible pipes; the other, though safer when used with a wire core, is not impermeable to gas, though a coat of linseed oil may render it so. The first-named is not only permeable, but causes an unpleasant smell, and is liable to contraction at any junctions with metal work, allowing of the escape of gas. There has lately been patented one formed of two layers of rubber, with pure soft tinfoil, vulcanised, between; perfectly gas-tight under any pressure and free from smell, and very flexible. The braided or cloth-covered tube has not come into general use. Brass pipes are generally used for the gasalier.

2264*b*. Under no circumstances whatever should either iron or composition pipes be let into the plastering, as is too constantly done, or into solid brick or stone work; for the salts in the latter are liable to affect the pipes in a serious manner, and the contraction and expansion of their materials may injure the joints; whilst it must always be difficult to trace a leakage. When placed in a partition, any gas escaping fills all the spaces between the studs, and between the joists of the floors, so that when it comes in contact with a light the whole ignites, and the force of the explosion may cause the entire destruction of the house. The police regulations of Paris require that gas-pipes in houses should be visible throughout their length, excepting when they traverse floors, partitions, &c., when the pipe conveying the gas is required to be enclosed in a larger one, projecting beyond the floor or partition, so as to ensure ventilation round it. Copper pipes should never be used, on account of the action of the gas on the metal. Gas pipes should be laid with a slight fall, on account of the condensation of the gas, and a draw-off tap is required to empty it. Gas by itself will no more explode than air, and on issuing into the air it will, if at once ignited, burn quietly, as at a gas burner. When gas is previously mixed with air, the mixture, on ignition, explodes with terrific force.

2264*c*. The form of *burner* which yields the best economical results is the argand; the bat's-wing is the next best; and the fish-tail the worst. A number of small burners dispersed will give a better light than collections of them. The argand burner, with 15 holes, will burn about $5\frac{1}{2}$ to 8 feet per hour, according to the pressure; ordinary street lamps, having the bat's-wing, burn 3 to 8 feet per hour, and are usually contracted for at the rate of $5\frac{1}{2}$ feet. Bronner's burners afford a steady light, and each is made to consume as many feet per hour as may be required. The number of new burners have been much increased. Bray's have a large sale; Sugg's are of various sorts for private use and in public thoroughfares and edifices. His burners for public lamps affording 20 candle-power consume 5 cubic feet per hour; 35 candles, 8 feet; 50 candles, 12 feet; and 60 candles, 15 feet. The former are two burners, and the latter three burners. The Heron's *duplex* has two small burners impinging upon one another and so affording a clearer light. 34 of Bray's burners burnt 230 feet of gas, 34 of the duplex for one hour burnt 167. Hart's economising burner dates from about 1859. Peeble's needle governor burners save 20 to 40 per cent. of gas. Many of these lights are now supplied with "non-corrosive" burners made of soapstone. One of the latest inventions (1887) is *Welsbach's* system of the incandescent light; it consists of a prepared "mantle" placed over a Bunsen burner. It is stated that it doubles the illuminating power of the gas; gives a steady, brilliant light; and saves 50 to 70 per cent. of gas; there is greatly diminished heat, no dirt, and no smoke; the light rivals the electric light. Another is the *Clamond* incandescent gas light, supplied by the Æolus Company; each gives a 40 candle-power light on a consumption of 6 feet of gas per hour. The Chandler patent regenerative gas light has no burner, the gas issuing from a free, open pipe. By the action of the air supply and the shape of the burner opening the flame assumes the form of an incandescent sphere, like a ball of fire, brilliant and white. It is adapted for burning 2 to 60 cubic feet per hour. A matchless self-lighting gas burner is in use. It is stated that 60 gas burners produce 2 gallons of water per hour by the combustion, hence part of the damage caused to the walls, works of art, &c.

2264*d*. The ordinary lights are stated to require 4 cubic feet of gas per hour, but this is much too large; $2\frac{1}{2}$ and 3 will be found to give sufficient light if the burner is fairly near the person; the high lights of a gasalier are either inefficient or wasteful for reading or working purposes, and often affect the eyesight.

2264*e*. For lighting large rooms the solar or *sun-light* arrangement is agreeable, and it is fitted to promote the ventilation of the room. It is very costly, not only in its first establishment, partly from the necessity of securing the burners and pipes from setting fire to the surrounding timbers, but also in the subsequent consumption of gas. In rooms of moderate height, the heat to the occupants is objectionable. The *Wenham* lamp is somewhat similar, but having a globe under, is better adapted to a small room. Benham's (formerly Rickett's) ventilating lamps are also fixtures. The reflecting and ventilating *Clapton light* is economical in gas and suitable for public places. The patent *Albo-carbon* light is said to save 30 to 50 per cent. of gas, by the gas passing through a white composition, which, on being melted by the heat obtained from the burner, gives off a vapour which is taken up by the gas, thus giving increased brilliancy to the light.

2264*f*. As illustrations of the mode of *lighting* public buildings may be cited: I. The concert room at Liverpool, designed and executed by Mr. A. King; it is effected principally by carrying a pipe in the cove of the ceiling, which pipe is pierced with numerous holes for fish-tail burners. II. St. James's Hall, London, and the great hall of the Reform Club, which are admirable illustrations of the use of the stellar and of the solar lights. III. The new theatre du Chatelet, at Paris, where the lighting is effected by 1,300 burners placed above a vault of ground glass, and under a large enamelled reflector; the glass vault forms, in fact, the ceiling of the body of the house, so that the burners themselves are entirely hid. This arrangement was also employed for a few years at the picture gallery in Suffolk Street, London. And IV. The various passages and rooms of the Houses of Parliament, which are lighted and ventilated under Faraday's principle.

2264*g*. TABLE OF COMPARISON OF LIGHT-PRODUCING MATERIALS, by Dr. M. Tidy, in *Handbook of Modern Chemistry*.

Light-producing Material equal to 12 standard Sperm Candles, each burning 120 Grains per Hour.	Cubic Feet Oxygen Consumed.	Cubic Feet Air Consumed.	Cubic Feet Carbonic Acid Produced.	Cubic Feet Air Vitiated.	Heat=lbs. of Water raised 10 deg. Fahr.
Cannel Gas - -	3·30	16·50	2·01	217·50	195·0
Common Gas - -	5·45	17·25	3 21	348·25	278·6
Sperm Oil - -	4·75	23·75	3·33	356·75	233·5
Benzole - - -	4·46	22·30	3·54	376·30	232 6
Paraffin - - -	6·81	34·05	4·50	484·05	361·9
Sperm Candles - -	7·57	37·85	5·77	614·85	351·7
Wax - - -	8·41	42·05	5·90	632·25	383·1
Tallow - - -	12·00	60·00	8·73	933·00	505·4
Electric Light - -	None	None	None	None	13·8

A table, prepared by Mr. V. B. Lewes, showing the amount of oxygen removed, the carbonic acid gas and water vapour generated, by various illuminants to give a light equal to 32 candle-power, is printed in the *Proceedings* of the Royal Institute of British Architects, for April 12, 1888.

2264*h*. A notice was issued in January, 1862, from the London Fire Engine Establishment, stating that, "It appears absolutely necessary that some steps should be taken to caution owners of property, particularly in large wharves and warehouses, as to the position and protection of the dangerous gas lights. These remarks may not be considered unnecessary when it is remembered that in many of the most valuable buildings in the metropolis movable gas brackets are placed within 20 inches of the ceiling without the slightest protection whatever. It may be laid down as a rule that the jet on the outer arm of the bracket should never be less than 36 inches from the ceiling over it, and that it should be protected on the top by a hanging shade, and on the sides by stops on the swivel joints, which should prevent the brackets moving beyond a safe distance. Attention might, perhaps, also be called to the very common and dangerous practice of nailing tin or iron on the adjoining timbers. This has long proved to be no protection, and it has the disadvantage of allowing the timber to be charred completely through before it is known." In some places gas lights are used within 15 inches of the ceiling, and when the glass shade has been broken and not replaced, the heat has been known to ignite the floor timbers over the plastering.

2264*i*. It will not be necessary here to do more than mention the use of gas in the kitchen for boiling water, or for baking and roasting (the apparatus for each, or for such purposes, are now supplied in London by the gas companies at a rent); the baths heated by gas, so readily adaptable in places where a coal stove cannot be used; or the several gas stoves for warming buildings and rooms, &c. See 2279*c*.

2264*j*. The urgency of efficient *ventilation* when gas is burnt in a room habitually is a subject of immediate importance. It is principally to the neglect of this precaution that the bulk of the injurious effects said to attend the use of gas may indeed be attributed.

In the case of libraries, the destruction of book-bindings may be assigned more justly to the heat than to the chemical action of the products of combustion. No doubt the bisulphide of carbon, which is present in even the most carefully purified gases, must give rise to the formation of minute quantities of sulphurous acid: and this, in its turn, must be destructive to some descriptions of leather—especially Russian (as noticed in the *Builder*, vi. 89), but a rapid removal of the products of combustion would almost entirely obviate this effect. It seems, however, that the excessive dryness and the heat of the air in the upper part of rooms where gas is burnt may occasion the injury quite as much as the chemical reactions supposed to take place; the books which suffer most being always those placed above the level of the lamps. Under any circumstances, ventilation should take place close to the plane of the ceilings. Even when provision is made for ventilation over gas burners, a stratum of heated air is often allowed to stagnate over the openings, close under the line of the ceiling; and the area of the openings is rarely sufficient to allow the escape of the decomposed gases. Again, if any sulphurous acid should be produced, it will be found also to tarnish the colours of tapestry and hangings, and to turn imitation gold; hence none but the best leaf-gold should be employed in rooms where gas is burnt. The injury caused by the use of such gas as is supplied in London, Paris, Bruxelles, &c., is very small compared with the brilliance of the light; and the gas of Liverpool, Edinburgh, Manchester, and some other places having, bulk for bulk, a higher illuminating power than that of London, is even less injurious. Mr. Spencer has reported that the quantity of gas leaking from London gas pipes is not less than 9 per cent, or between six and seven million cubic feet per annum, which causes the stinking black earth of the London street subsoil. No such leakage occurs at Liverpool or Manchester, where the joints of the pipes are bored, turned, and fitted to each other, like ground stoppers in glass bottles; whereas in London the pipes are jointed with tow and lead, so that after expansion and contraction in summer and winter the perfection of the joints is destroyed. The gas then, acting upon the subsoil, forms sulphuretted carbon, which corrodes not only the gas pipes, but the water mains also, and converts them in ten years almost entirely into a sort of plumbago, although in pure London subsoil they last a century.

ELECTRIC APPLIANCES.

2264*k*. For the important subject of *Lightning Conductors*, reference should be made to R. Anderson, *Their History, Nature, and Mode of Application*, of which the third edition, revised, rearranged, and enlarged, was published in 1887: "The numerous accidents to buildings fitted with conductors sufficiently indicate the indispensable necessity for occasional inspection. The chief causes that detract from their efficacy are original defects of capacity, conductivity, and fitting, faulty earth connections, accidental injury and mechanical derangements, oxidation of joints and of earth contacts, and alterations in the conductive capacity of the ground in consequence of improved drainage." The efficiency of a conductor is in proportion to the sectional area of the metal. Tapes are made $\frac{1}{10}$th of an inch thick, being inch, $1\frac{1}{2}$ inches, and 2 inches wide; $\frac{1}{12}$th of an inch thick, being $\frac{5}{8}$ths of an inch wide; $\frac{1}{8}$th of an inch thick, being $\frac{3}{4}$ths of an inch, inch, and $1\frac{1}{2}$ inches wide. The conductors should not be less than $\frac{1}{8}$th of an inch thick and $\frac{3}{4}$ths of an inch wide, weighing 6 oz. per foot, as recommended by the Lightning Rod Conference, 1882. The upper terminal should be in the form of a sharp point, or a cluster of sharp points. As this point may become blunted, an alloy of 835 parts silver and 165 parts of copper is therefore used for it, at Paris. The earth termination should be taken some depth, and into moist ground or water, and have a large area of contact. When this is not to be obtained, a copper plate at least 9 feet square should be carefully riveted to the end of the tape and be buried in a well, packed with cinders or coke. Professor Fleming has pointed out that the ultimate safety of a conductor lies in the proper periodical testing of the earth connection of the conductor.

2264*l*. Electricity for lighting purposes can be obtained by chemical action, as by an arrangement of a voltaic battery, and the combination of cells is termed a "primary battery." A steady light is stated to be maintained at a cost not much in excess of that from a "dynamo" machine. Such a battery may suffice for a small country house, but a large number of lamps will require a battery of great bulk; hence it is more economical to produce electricity mechanically, by converting the energy of the prime motor into electric force by the use of the dynamo machine. This motive power is obtained by steam, water, or gas, according to circumstances. The engine house would contain the dynamos for generating the electric current. The current is then taken to a "switch board," which is a simple apparatus on which all connections are made with suitable arrangements, so that either one or more machines can be made to deliver into the same conductor. On this board is an instrument for measuring the strength of the current, so fixed that it can be read by the attendant by turning the handle of a switch. From this board the mains go towards the lamps, starting as a cable, which ramifies into smaller mains and branches until each incandescent lamp is reached. It is of supreme importance in electric lighting that the current should always be uniform at all times in each individual part of the work, and be unaffected by changes in other parts. The compound shunt machine has been devised to effect this arrangement.

2264*m*. A source of danger to property is in the mains and branch wires conducting the current to the lamps; they must be of sufficient proportion, and of a material whose resistance is uniform. Copper wire is used because it can be obtained in a purer state than any other available metal, and next to silver it is the best conductor of electricity. Great attention is required to the connectors and joints, and the connections made with binding screws; besides causing resistance in the circuit, bad contact between a wire and a terminal will produce heat. A faulty junction may also upset the calculations made for the current to be taken by an otherwise efficient cable; solder alone must not be relied upon, as it may become softened by the current; it must be mechanically perfect. A "short circuit" is the current taking the shorter path, where, having no work to do, it causes fire. The only preventive is a "cut out" or a "safety fuse," described as "a piece of easily fusible metal, which would be melted if the current attains any undue magnitude, and would thus cause the circuit to be broken." From arc lights pieces of incandescent carbon are apt to drop; more fires have occurred from this cause than any other. Electricity, having no smell to betray a leak, shows when it is escaping by the diminished appearance of the lights, caused by the diversion of the system.

2264*n*. Even if the cost of electric lighting be higher than that of a private gas supply, the extra cost of it for those rooms where the preservation of works of art, books, and decorations has to be considered would be amply returned. The property of not vitiating or heating the air will be the salient one which, when fully appreciated, must banish gas and oil from the houses of those who consider sanitary excellence the principal feature of a beautiful house. (K. Hedges, in *Transactions* of Royal Institute of British Architects, 1883–4, p. 143). The Electric Lighting Act was passed August 18, 1882. The Maxim-Weston Electric Company (Limited) supply (Nov. 1887) the new "Watt" system of lighting. They claim that they can now obtain six arc lamps of 150 candle-power in place of one, as heretofore, from one electrical horse-power. The Pilsen-Joel arc lamp is of 1,000 to 10,000 candle-power; the incandescence or glow lamps are of 5, 10, 16, 20, 30, to 100 candle-power, for lighting rooms, &c. To popularise the electric light is the only way to make it pay—it must be cheap and efficient. By cheapness is to be understood, either a small first cost and a correspondingly small cost for maintenance, as in the case of a battery placed in the house, or a moderate charge for the supply of the current, as in the case of a central distributing station. The lamps must be adaptable to the present gas fittings, and the cost of the light must be but little, if at all, in excess of that of the gas of the district. Though the advantages of this light are great in a hygienic and domestic point of view, the public would, in the main, continue to use the present methods of illumination rather than adopt any new system which entailed extra cost, however satisfied they might be that positive advantages were to be gained by it. (P. F. Mersey, *On Primary Batteries*, Nov. 1887.) The Phœnix Fire Office rules for fixing, &c., an installation are those now generally required to be carried out by the fire offices.

2264*o*. Although electricity has not ousted gas from the field, as it was at one time thought it would do, it has yet made more progress than many people imagine, and no architect would design a public hall without fitting it with incandescent lamps. These do not give off as much heat as gas, nor do they contaminate the atmosphere. The insertion of "storage batteries" as a sort of buffer between the machine and the lights, and as a means of avoiding the risk of a break-down of the engine, has done much to render electric lighting more generally available; and considerable improvements have been made in these "storage batteries" during the last few years. The battery of the Union Electrical Power Light Company, of fifteen cells, will run twelve ten-candle incandescent lamps, and occupies a few feet only. A small primary battery and lamp combined is invented, so that an electric lamp can be placed on the table; this can be recharged by simply pouring into the cell containing the plates the necessary liquid. These lamps will run for about three hours—say a dinner time.

2264*p*. A method of electric lighting for small areas, where the trouble and expense of fixing up and working engines and dynamos constitute a serious objection, has been introduced by Messrs. Woodhouse and Rawson, in which no machinery is required. The whole apparatus is contained in a space of some 5 feet by 6 feet, by 8 feet in height, with a perfect absence of smell, noise, or dirt. The light is generated by an "Upward" battery. The cost for the equipment of an installation to run eleven lamps (10 candle-power each) for two hours, or six for four hours, is 56*l.*; while fifteen lights for three hours, or eight for six hours, is 84*l.*, and so on. The *House to House Electric Light* Supply Co. is taking active steps to promote this means of illumination.

2264*q*. There is a new *electric gas lighting* system, by which gas is lighted, turned on, and extinguished at any distance by simply pressing a button, as in ordinary electric bells; and at the same time the battery may be used for ringing electric bells.

2264*r*. *Bells*. The principle, as applied to all the different methods of construction, is that the completion of the circuit of the electric current rings the bell, the medium of communication from the distant points being wire of various descriptions, carefully insulated. The mechanism is confined to the *push* (the reverse of the crank system, which has the *pull*) and to the bell itself, which is struck by a hammer attached to a small and light magnet. The wires are fixed. One bell will answer the purpose for any number of rooms. The battery whence the electric power is supplied is, for an ordinary house, a small six-cell battery, about twelve inches long, nine inches wide, and six inches deep. The positive poles of the six cells are all connected with each other, and also the negative poles, each to brass knobs on the outside of the box. From the positive pole of the battery a wire passes, which is connected with each room, and from each room a wire passes to the *indicator*. This is a tablet with openings, upon which are inscribed numbers for, or names of, the rooms. The *push*, a light ivory knob, completes the electric circle; on being set in action by it, the current travels through the wire to the indicator, and then by the movement of a balanced magnet the number or name appears, and by a light magnet attached to a spring it rings the bell, which can be made to ring until the magnet is released by the hand, or a button, which also returns the name or number to its place. The wires are insulated by gutta-percha or india-rubber and coils of cotton or silk, which, if exposed, can be made of a colour to match the paper or paint of the room. The bell pushes and other furniture can be carried out in any decorative character.

2264*s*. The electric bell system can be adopted for protection against thieves and fire. For the former, every external door and window may be connected with a battery so that, when the circle is complete, the opening of the door or window will ring the bell. In the daytime a switch is used to disconnect the communication, so that the doors and windows may be opened without ringing the alarum. For the latter, or fire, a thermometer, hermetically sealed, into which a platinum wire is fixed, is regulated to any point indicating danger, say 100° of heat, and connected with the battery. Should the mercury rise to that point, the contact of it with the platinum completes the circuit, the bell rings and sounds the alarum. For the sick bed, the invalid has only to give a slight pressure to a knob at the end of a silk cord, laid close to the pillow, instead of having to overcome the stiffness and weight of the old crank and wire system.

2264*t*. Moseley's patent electric bells are fixed on the system of the battery not being in use when the bell is not ringing.

2264*v*. The best time to commence fixing the bells is stated to be when the first coat of plaster is laid on the walls, and before the floor boards are nailed down. The joints and connections between the compo tubing and the bells should be carefully soldered, and the iron wall boxes fixed flush with the finished wall, with the screw holes in front perfectly vertical. The fixings required are press buttons or pushes, lever action pulls, or bell ropes, for rooms used in the day. Bed-head pulls, flexible cords, or pushes, for the bedrooms. Pull-out pulls or pushes for front door or entrances. The tubing is $\frac{1}{8}$-inch bore composition, let into the plaster, &c., and protected therein by wood, or by larger zinc bell tubing. The pulls may be either the "sunk" pattern, or the "raised" pattern, which is fixed on the face of a wall or partition.

We can only here refer to the later invention of the "telephone."

Sect. XI.

FOUNDERY.

2265. The very general use of cast iron by the architect induces us to give a succinct account of the common operations of foundery, or the art of casting metal into different forms. To gain a proper knowledge of the operations, the student should attend a few castings at the foundery itself, which will be more useful to him than all the description we could detail of it; however, we give a few particulars not noticed in the previous section on Iron. Some of the articles cast are noticed in par. 2255*k*.

2265*a*. Those manufacturers who will attend to the good quality of the irons they sell can generally command their own price. Thus, the Low Moor and the Bowling bar irons continue in possession of the market at nominally high prices, whilst the ordinary irons are hardly saleable at remunerative ones. The Welsh iron, known as the SC brands, or the Staffordshire mitre iron, are of at least equal quality to the above, and there are others as good.

2265*b*. Staffordshire, Shropshire, and Derbyshire afford the best irons for castings. The Scotch iron is much esteemed for hollow wares, and has a beautifully smooth surface, which may be noticed in the stoves and other articles cast by the Carron Company. The Welsh pig iron is principally used for conversion into bar iron. Almost all irons are improved by admixture with others, and therefore, where superior castings are required, they should not be run direct from the smelting furnace, but the metal should be remelted in a cupola furnace, which gives the opportunity of suiting the quality of the iron to its intended use. Thus, for delicate ornamental work a soft and very fluid iron will be required, whilst for girders and castings exposed to cross strain the metal will require to be harder and more tenacious. For bed plates and castings, which have merely to sustain a compressing force, the chief point to be attended to is the hardness of the metal. Various mixtures of different qualities of iron have been recommended as materials for large castings (see Fairbairn's *Application of Iron, &c.* 65). Most engineers are agreed in considering that the best course for an engineer to take, in order to obtain iron of a certain strength for a proposed structure, is not to specify to the founder any particular mixture, but to specify a certain minimum strength which the iron should exert when tested by experiment.

2265*c*. As noticed in a previous chapter, the ores are smelted by cold and hot air blasts. The latter iron makes very fine castings, but is deficient in tenacity, and requires great care in its application to the purposes of machinery, and for girder castings, by employing it as second runnings from the cupola, and mixing third-class pig iron with the first. On account of some defects in it, hot blast iron should be excluded from all such works as girder bridges, machinery castings, &c., and from the preparation of bar iron where great strength in the metal is required. It appears that there are no means of detecting hot or cold blast irons in pig castings. Whenever great strength is required, air furnaces instead of cupolas should be used, and where it is not connected with too great an expense, loam instead of green sand should be used for moulding.

2265*d*. TABLE OF THE WEIGHT OF CAST IRON PER FOOT SUPERFICIAL. (Hurst.)
The weight of a cubic foot is put at 456 lbs. and 460 lbs.

Thickness in inches -	$\frac{1}{16}$	$\frac{1}{8}$	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{5}{16}$	$\frac{3}{8}$	$\frac{7}{16}$	$\frac{1}{2}$
Weight in pounds -	2·34	4·68	7·03	9·37	11·72	14·06	16·40	18·75
Thickness in inches -	$\frac{9}{16}$	$\frac{5}{8}$	$\frac{11}{16}$	$\frac{3}{4}$	$\frac{13}{16}$	$\frac{7}{8}$	$\frac{15}{16}$	1
Weight in pounds -	21·09	23·44	25·78	28·12	30·47	32·81	35·16	37·50

2265*e*. Collinson's Mansfield moulding sand has a wide reputation among the modellers of the finest brass and iron castings, arising, no doubt, partly from its exquisite fineness of grain, but more particularly from its clay-like adhesiveness and plaster quality, combined with a total freedom from any coarse or gritty particles. It is found under a deep deposit of coarse sand, ordinarily known as building sand, and within a short distance of the well-known white and red Mansfield stone quarries, in Nottinghamshire. The Isle of Wight sands are also used for the purpose. The sand usually employed in casting is of a soft yellow and clammy nature, over which, in the mould, charcoal is strewed. Upon the sand properly prepared, the wood or metal models of what is intended to be cast are applied to the mould, and pressed so as to leave their impression upon the sand. Canals are provided for the metal, when melted, to run through. After the frame is finished, the patterns are taken out by loosening them all round, that the sand may not give way. The other half of the mould is then worked with the same patterns, in a similar frame, but having pins which, entering into holes that correspond to it in the other, cause the two cavities of the pattern exactly to fall on each other. The frame thus moulded comes now under the care of the melter, who prepares it for the reception of the metal.

2265*f*. In making patterns for cast iron, an allowance is always made of about one-eighth of an inch per foot for the contraction of the metal in cooling. And it may be also requisite that the patterns should be slightly bevelled, that they may be drawn out of the sand without injuring the impression; for this purpose, $\frac{1}{16}$ of an inch in 6 inches is sufficient.

2265*g*. All castings should be kept as nearly as possible of the same bulk, in order that the cooling may take place equably. It is of importance to prevent air-bubbles in castings, and the more time there is allowed for cooling the better, because, when rapidly cooled, the iron does not become so tough as when gradually cooled. It is important in any casting to have the metal as uniform as possible, and not of different sorts, for different sorts will shrink differently, and thus will be caused an unequal tension among the parts of the metal, which will impair its strength; and, beyond this, an unevenness is produced by such mixture on the surface of the casting, for different sorts can never be perfectly blended together.

2265*h*. Castings should show on the outer surface a smooth, clear, and continuous skin, with regular faces and sharp angles. When broken, the surface of fracture should be of a light bluish-grey colour, and close-grained texture, with considerable metallic lustre; both colour and texture should be uniform, except that near the skin the colour may be somewhat lighter and the grain closer; if the fractured surface is mottled, either with patches of darker or lighter iron, or with crystalline patches, the casting will be unsafe; and it will be still more unsafe if it contains air-bubbles. The iron should be soft enough to be slightly indented by a blow of a hammer on an edge of a casting. Castings are tested for air-bubbles by ringing them with a hammer all over the surface. Iron becomes more compact and sound by being cast under pressure; and hence cannon, pipes, columns, &c., are stronger when cast in a vertical than in a horizontal position, and stronger still when provided with a *head* or additional length, whose weight serves to compress the mass of iron in the mould below it. The air-bubbles ascend and collect in the head, which is broken off when the casting is cool. Care should be taken not to cut or remove the skin of a piece of cast iron at those points where the stress is intense. The most certain test of the goodness of a piece of cast iron is by striking the edge with a hammer: if a slight impression be made it denotes some degree of malleability, the iron is of a good quality, provided it be uniform; if fragments fly off, and no sensible indentation be made, the iron will be hard and brittle. The difference between good and bad iron is shown mainly by the breaking; good iron breaks like a piece of good fir timber; bad iron will break like a carrot, it snaps in two.

2265*i*. *Malleable cast iron* is made by embedding the castings to be made malleable in the powder of red hæmatite. They are then raised to a bright red heat, which occupies about twenty-four hours, maintained at that heat for a period varying from three to five days, according to the size of the casting, and allowed to cool, which occupies about twenty-four hours more. The oxygen of the hæmatite extracts part of the carbon from the cast iron, which is thus converted into a sort of soft steel: and its tenacity, according to experiments by Messrs. A. More and Son, becomes more than 48,000 lbs. per square inch. (Rankine.) *Steel* is noticed in Book II. Chap. II.

2265*k*. For resisting fire, as in fireplaces, good strong cast iron is the best material. The quality of breadth of design can be got by cast work better than by wrought work, and each requires its own system of design. The street railing or screen to All Saints' Church, Margaret Street, is considered a good specimen. It can be covered with fine delicate ornamentation, as done by Mr. Philip Webb. The backs of old fireplaces are generally fine specimens of cast work. There are also cast iron fire-dogs.

2266. The foundery of statues, which is among the most difficult of its branches, belongs exclusively to the sculptor, and is usually carried on in bronze. The execution of the bronze castings, made by the firm of Barbedienne of Paris, is attributed mainly, after the skill of the modeller, to the fineness of the sand, which can only be obtained at Fontenay-aux-Roses, in France. When new it is yellow in colour, but on account of its cost it is mixed in well-ascertained proportions with the old sand, which has become black, the mixture forming a good combination for the mould; other sands are considered to have two much silex in them, whereas the Fontenay sand has exactly the proportion necessary for the fineness of the work.

TESTING AND MACHINERY.

2266*a*. Ironmasters are, to some extent, averse to testing. A writer has been advised to exhibit his knowledge of the subject by simply specifying "best merchantable iron," and if from inspection it was not found to be good it could be tested. Testing is about the only means at the disposal of an engineer to obtain really what he wants. *Work tests* mean, tapping plates with a hammer to ascertain if they are solid, in which case each tap will produce a ringing sound; also breaking the corner off a plate here and there, of course before the plates are "worked"; and examining the punchings from the iron, for the purpose of forming some idea of its quality. Those from Low Moor and some of the Staffordshire brands will stand the punch without the slightest sign of cracking, whilst hard, brittle iron will break up in all directions on the convex side of the punching. Good ordinary iron, such as ought to be used in girder work, will only show slight cracks, all running with the fibre of the iron. (C. G. Smith, *Wrought Iron Girder Work*, 1877.)

2266*b*. Granting that it is advisable to carry out tests, and that these tests should be realities and not mere forms, it is certainly advisable that some method of testing should be substituted for the present plan of testing girders whole. At present, a certain percentage of the rolled joists or other girders for a building are specified to be tested up to loads equivalent to those given in "Shaw's Tables," which correspond to a maximum stress of 6 tons per square inch in the material, and should return to their original forms without permanent set; and this deflection test is the only one carried out. But it is not easy to measure a small permanent deflection, say $\frac{1}{10}$ of an inch, with certainty on a 30-foot joist with such means as are commonly used in the yard, and so it cannot be very rigidly enforced under ordinary circumstances. But it affords no clue to the properties of the material used. It would be much more satisfactory, and probably not more expensive or troublesome, if the tests specified were made more like those adopted by the Registry societies. The temper test, for the architect's purpose, might be omitted. The ultimate extension test is an indication—a rough indication—of the difficulty of the metal; we ought to know the maximum extension before the material begins to give way locally. This, however, is somewhat more difficult to measure. It would be sufficient to specify that one out of, say, every ten joists or angles should be supplied 18 inches more than the ordered length, the extra piece cut off, and two strips cut from it (one from the web, and one from the flange in the case of the joist) tested for tenacity and extension. The limits fixed might be, according to circumstances, either 28 to 32 tons tenacity per square inch, and 20 per cent. extension in 10 inches; or 38 to 42 tons tenacity and 12 per cent. extension. The tests are made by preference at the manufacturer's yard, in the presence of the inspector, doubtful or special cases being sent to some independent testing machine. In cases of large orders not less than 2 per cent. of the number of plates, &c., have to be tested in this way. (*A. B. W. Kennedy.*)

2266*c*. To test a stanchion, or other cast iron work, especially if painted, it should be examined carefully all over by a good-sized hammer, having a sharp point at one end, such as a scaffolder's axe. Ply the point or edge of the hammer to any scaly-looking or white spots, and follow it on. Some founders are clever at filling up faults with a soft metal, and the defects are generally on the face that lies uppermost in the mould. One fault may be found that would jeopardise the stability of a building. To test the same for strength can only be done by a scientific apparatus now provided at many establishments for the purpose.

2266*d*. *Testing Stone.* The weight necessary to crush a stone varies with the state of cohesion and hardness of the particles composing it. (See par. 1500 *et seq.*) The full particulars of the quarry and bed of each stone tested should be stated. It is almost useless to experiment upon cubes of one inch, as was necessarily done before the powerful machines of the present day were invented; 4-inch or 6-inch cubes are the least sizes, especially where large shells appear. Much care and skill are also requisite in the manner of testing. The cubes should all be carefully dressed by rubbing down the faces, which should be strictly parallel, perhaps made so in a steel frame. They should all be placed on or against their natural bed. The Bath stones tested by Messrs Poole are stated to have been placed between parallel iron plates, and the pressure communicated to the cubes, having a sheet of lead at the top and bottom, and between the upper or movable plate and the upper lead plate was a conical heap of fine sand, which was carefully pressed by the upper plate, so as to ensure an equal pressure on every particle of the upper and lower beds of the stone. Sometimes the stone is bedded with pieces of pine, from $\frac{1}{4}$ to $\frac{1}{2}$ inch thick. Leather has likewise been used (*Builder*, 1886, p. 561); also mill-board. Prof. Henry (of the American Association of Science, 1855) experimented on blocks of $1\frac{1}{2}$-inch cube between thin plates of lead. It was found that while one of these cubes would sustain 30,000 lbs., it would sustain 60,000 lbs. without the lead plates. When the blocks were rendered perfectly parallel by a machine, the marble chosen for the Capitol, from a quarry at Lee, Massachusetts, would sustain about 25,000 lbs. to the square inch. Barlow states that the crushing strength of Portland stone ranges from about 1,384 lbs. to 4,000 lbs. per square inch; the Institute experiments give 2,576 lbs. for 2-inch cubes, 4,099 lbs. for 4-inch cubes, and 4,300 lbs. for 6-inch cubes, proving the advantage of testing large sizes. Rennie gives 3,729 lbs., followed by Molesworth; while Hurst gives 2,022 lbs.

2266*e*. *Testing cement* has been described in par. 1864*e*. The machines commonly used are those by Mr. Adie and Mr. Michele (*Builder*, xlviii. p. 283); by the former, briquettes of $1\frac{1}{2}$ inch square can be tested. Reid and Bailey's is described in *Builder*, 1877, xxxv. p. 1015; Arnold's in *Builder* for October 22, 1887, p. 579.

2266*f*. The *hydraulic press* is generally used for testing. This is a closed vessel, with its upper surface level, completely filled with water; two openings are made in it, which are replaced by pistons of areas 1 and 10 square inches. If a weight of 1 lb. be placed on the smaller piston, a pressure of 1 lb. will be felt everywhere in the interior of the fluid, and the pressure on the larger piston will be 10 lbs. Thus a force of 1 lb. acting on the area 1 square inch, produces a pressure of 10 lbs. on the area 10 square inches.

2266*g*. Messrs. W. H. Bailey & Co., of Salford, manufacture testing machines, as Thurston's for torsion; Bramah's hydraulic, for cement, tensile, crushing and transverse, and for yarn and oil; testers for tensile, torsion, and compression, and other purposes, as paper, wire, cloth, &c.; also test pumps for steam boilers, kitchen boilers, high pressure, gas fittings, water works, &c.; Professor Thurston's patent testers for materials of construction; and Tangye's patent hydraulic boiler prover. There are many well-known American testing machines.

The following persons and institutions have set up testing machinery for public use or for instruction:—

2266*h*. *D. Kirkaldy*, established 1866, for testing and experimenting on the strength of various kinds of metals and their alloys, stones, artificial stones, bricks, concretes, cements, timbers, &c. The powerful machinery is adapted for any kind of strain—namely, pulling, crushing, thrusting, bending, twisting, shearing, punching, bulging, and buckling, from 10 lbs. to 1,000,000 lbs. To entire manufactured articles, and timbers of full size, any amount of proof strain desired can be applied, or their ultimate breaking strength can be ascertained. The delicacy and accuracy of the machine is proved by its ability to test cement, canvas, and wire up to the greatest strains required for practical purposes. The capabilities for sizes are as follows:—Pulling stress, any length up to 300 inches. Crushing stress, any length up to 250 inches for columns, &c. For testing bricks, six of a sort are required for average results. For stones, three or four 6-inch cubes, accurately ground; concrete, usually 12-inch cubes. For cement, half a bushel is required, and it is suitably made up at the works for testing under pulling or thrusting stress. Bending stress, any span up to 300 inches. For comparing the strengths of full-sized timber or iron joists, 10 feet span is recommended as a good standard. The fine museums at Messrs. Kirkaldy's works are open to architects and others taking an interest in the subject; and the results of the many experiments on full-sized work of every variety of material used in building or engineering operations, since January, 1866, will be seen. An apparatus of simple construction is engraved in his *Results—into the Comparative Tensile Strength, &c., of Wrought Iron and Steel*, 8vo. 1862.

2266*i*. *King's College, Strand.* The plant for mechanical testing consists of two machines. One is a Kirkaldy machine, 23 feet long, taking test pieces up to 4 feet in length; it exerts a strain of 50,000 lbs., and is constructed to make tensile, transverse, compression, and torsion tests. The other is a Thurston automatic recording machine. A description of the first machine is given in *Engineer*, October 5 and 12, 1883.

2266*j*. *City of London and Guilds Central Institution*, South Kensington. The machine is a 100-tons machine, and will take in ordinary tension specimens up to 4 feet 6 inches in length. It will take in 6 feet 6 inches in specimens with eyes. It has compression and transverse shackles and autographic diagram apparatus. It takes in about 3 feet specimens for compression, but will be altered for 4 feet. The *Engineer*, July 25, 1884, shows a nearly similar one. Prof. W. C. Unwin, *Machines for Testing Materials, especially Iron and Steel*, in *Journal* of the Society of Arts, July 8, 1887. Also, *The Testing of Materials of Construction*, 8vo., 1888.

2266*k*. *W. Harry Stanger* has opened a chemical laboratory and testing works at Broadway, Westminster. There is a 50-ton machine by Buckton & Co. (Limited), with Wickstead's patent apparatus for measuring and autographically recording stresses in tension, deflection, compression, and torsion, from $\frac{1}{100}$th of a ton up to 50 tons. Also other machines and apparatus for various purposes.

2266*l*. *Messrs. Shaw, Head & Co.*, Queen's Wharf, Bankside, have a testing machine for girders. It is shown and described in *Builder*, 1869, xxvii. 1020.

Sect. XII.

PAINTING, GILDING, PAPER-HANGING, DECORATING, ETC.

2267. Painting is the art of covering the surfaces of wood, iron, and other materials with a mucilaginous substance, which, acquiring hardness by exposure to the air, protects the material to which it is applied from the effects of the weather. House painting was described by the editor at the Institute of British Architects, *Transactions*, Nov. 1857.

2268. The requisite tools of the painter are—*brushes of hog's bristles*, of various sizes suitable to the work; a *scraping or pallet knife*; *earthen pots* to hold the colours; a *tin can* for turpentine; a *grinding stone and muller*, &c. The stone should be hard and close-grained, about 18 inches in diameter, and of sufficient weight to keep it steady. The knots, especially of fir, in painting new work, will destroy its good effect if they be not first properly *killed*, as the painters term it. The best way of effecting this is by laying upon those knots which retain any turpentine a considerable substance of lime immediately after it is slaked. This is done with a stopping knife, and the process dries and burns out the turpentine which the knots contain. When the lime has remained on about four and twenty hours, it is to be scraped off, and the knots must be painted over with what is called *size knotting*, a composition of red and white lead ground very fine with water on a stone, and mixed with strong double glue size, and used warm. If doubts exist of their still remaining unkilled, they may be then painted over with red and white lead ground very fine in linseed oil, and mixed with a portion of that oil, taking care to rub them down with sand paper each time after covering them, when dry; so that they may not appear more raised than the other parts. When the knotting is completed, the *priming colour* is laid on. The priming colour is composed of white and a little red lead mixed thin with linseed oil. One pound of it will cover from 18 to 20 yards. When the primer is quite dry, if the work is intended to be finished white, mix white lead and a very small portion of red with linseed oil, adding a little quantity of spirits of turpentine for second colouring the work. Of this second primer, one pound will cover about 10 to 12 square yards. The work should now remain for some days to harden; and before laying on the third coat it should be rubbed down with fine sand paper, and stopped with oil putty wherever it may be necessary. If the knots still show through, they should be covered with silver leaf, laid on with japanned gold size. The third coat is white lead mixed with linseed oil and turpentine in equal portions, and a pound will cover about 8 square yards. If the work is not to be finished white, the other requisite colour will of course be mixed with the white lead, as in the case of four coats being used. When the work is to be finished with four coats, the finishing coat should be of good old white lead as the basis, thinned with bleached linseed oil and spirits of turpentine; one of oil to two of turpentine. If the work is to be finished *dead white*, the very best old lead must be used, and thinned entirely with spirits of turpentine.

2269. When stucco is to be painted, it will require one more coat than wood-work; the last coat being mixed, if the work is as usually executed, with half spirits of turpentine and half oil, for the reception of the finishing coat of all turpentine or *flatting*. If the work be not flatted, the finishing coat should be with one part oil and two of turpentine. It would be impossible to enter into the details which are to be observed in painting walls of fancy colours; all that can be said on this point in instruction to the architect is, that when fancy colours, as they are called, which in these days a painter construes as anything but white and a tinge of ochre or umber, each coat must incline, as it is laid on, more and more to the colour which the work is intended to bear when finished.

2270. In repainting old work, it should be well rubbed down with dry pumice stone, and then carefully dusted off, and when requisite, the cracks and openings must be well stopped with oil putty. After this, a mixture of white with a very small portion of red lead, with equal parts of oil and turpentine, is used to paint the work, which the painters technically call second colouring old work. After this, the work being dry, a mixture of old white lead, adding a small portion of blue black in a medium of half bleached oil and half turpentine, is used for finishing, or, if flatting be intended, the former preparation will be suitable for receiving dead white or any fancy colour. The same process will serve for stuccoed walls, observing that, if more coats be required, the mixture of half oil and half turpentine is proper. To remove old paint, see 2275.

2271. In respect to outside work, the use of turpentine is to be avoided, for turpentine is more susceptible of water than oil, and thence not so well calculated to preserve work exposed to the weather. Oil, however, having from its nature a natural tendency to discolour white, that is necessarily finished with a portion of half oil and half turpentine; but in dark colours this is not necessary, and in such cases, boiled oil, with a little turpentine, is the best, or indeed boiled oil only.

2271*a*. When linseed oil is clarified and cleansed by means of sulphuric acid, much of the cohesion in the vegetable property of the oil is destroyed, preventing its forming that perfect pellicle which it invariably does upon exposure to the atmosphere during drying. White lead should be ground with linseed oil in its pure state; this oil is now largely adulterated with oils of resin and pine, as those oils are very much cheaper. Oils are thus clarified that the lead, when ground, may appear at once as white as possible; whereas, if ground in pure linseed oil which has had the refuse cast down by means of ivory black or powdered litharge, it will at first have a yellow tinge, which is only to be got rid of by time; and hence arises the value of old ground white lead. (*Builder*, xiv.).

2271*b*. The blackness which in the winter frequently shows itself upon exterior painted work probably arises from the outer skin of the oil having been rendered porous by the sulphuric acid, and the foul, or hydrogen, gas readily fastens itself to the unprotected lead, for which it has an affinity, and hence results the mottled appearance of such work.

2271*c*. The best linseed oil is obtained from good Baltic and Bombay linseed. crushed. Mineral turpentine is sometimes used as an adulteration of that article; the paint made with it dries, and then softens, becoming sticky even under a coat of sugar of lead and varnish. Woodwork prepared with bad linseed oil for being stained, prevents the varnish from drying: good size is all that is required. To distinguish the good and bad qualities, states a writer in the *Builder*, xxi. p. 919, pure vegetable turpentine, upon exposure to the air, always loses in bulk by evaporation, but gains in weight by absorption of oxygen, which makes it more binding in its properties. This peculiarity none of the mineral substitutes possess; on the contrary, the mineral is so extremely volatile that, upon exposure, the spirit all flies off, leaving the oil without anything to assist it to harden, and of course increases the evil of the bad oil, instead of counteracting it. The use of varnish in white lead work cannot be sufficiently reprehended, on account of the ultimate defect of the work.

2271*d*. Nut oil has been stated to be more durable, and to stand the weather much longer than any other oil in paint.

2272. White lead, which is the principal basis of all stone colours, is carbonate of lead, generally containing hydrated oxide of lead, which is sometimes combined in the proportion of one atom of hydrated oxide to two of carbonate of lead. It is usually made either by precipitation, as when carbonic acid or a carbonate is used to decompose a soluble salt, or a subsalt of lead; or by exposing plates of cast lead to the joint action of the vapour of acetic acid air and carbonic acid. It is by the latter process only that the resulting carbonate of lead is obtained of that degree of density, opacity, and perfect freedom from crystalline texture which fits it for paint. The last, called the Dutch process, was introduced into England about 1780. White lead is often largely adulterated with sulphate of baryta, which may be detected by insolubility in dilute nitric acid, whereas pure white lead is entirely dissolved by it. Fine lead is now made from *slag lead*, which is treated with nitrate of soda, thus oxidising all impurities except copper. The same effect is accomplished by calcining the lead in an improving furnace, especially when the lead contains much antimony. The copper is next removed by a process not yet published, and finally the lead is crystallised by Pattinson's process. The resulting metal is remarkable for its fine crystalline surface and bold columnar fracture. Lead containing even only $2\frac{1}{4}$ ounces of copper per ton communicates a pink tint to the corrosions of white lead, which it is important to remove.

2272*a*. The ill effects on the constitution of persons engaged both in the manufacture and use of the article have recently (since the publication of the first edition of this work) induced the French chemists to find some less deleterious substitute for it, and M. de Ruolz has discovered two substances which fulfil the required conditions—viz., combination with oil, good colour, property of concealing, &c. The first is an arsenical compound (product) hitherto little known, which M. de Ruolz does not describe, because, although inoffensive, it may be made, by very simple chemical reaction, to retake its poisonous qualities, and be employed criminally. The second, which he considers well adapted for use, is the oxide of antimony, and possesses the following properties: its colour is a very pure white, rivalling the finest silver white; it is very easily ground, and forms with oil an unctuous and cohesive mixture, comparatively with the white lead of Holland as 46 to 22; mixed with other paints it gives much clearer and softer tones than white lead. It may be obtained directly from the natural sulphuret of antimony, and at one third of the cost of ordinary white paint. (See *Literary Gazette*, Nov. 25, 1843.) If the finishing colour is white, nothing but white lead should be employed.

2272*b*. A new process of making white lead is that of H. J. B. and H. B. Condy, who claim the following advantages: I. White lead of the finest colour and body can be made within seven days, instead of four to five months, as required by the ordinary process. II. Old lead or any description of metallic lead can be used, all impurities being removed by their process, instead of buying "refined pig lead" for the ordinary process. III. The present uncertainty in composition is corrected by the new process, which is identical time after time; the covering properties are better. IV. The colour is preserved in impure atmosphere. V. The absence of danger to workpeople, since nearly all the operations are effected by machinery, instead of being handled at each stage in the ordinary mode.

2272*c*. The other metallic white paint used is Hubbuck's patent *zinc white*, known for its intense whiteness, its resistance to sulphurous and other deteriorating causes, and its harmless qualities to the painter and the inmates of the house under decoration. It is requisite that the oil used should be as white as possible, that the brushes and pots should not have been used for white lead, or else have been cleaned with spirits; and that driers and colours with a lead basis should not be mixed with it. *Zinc white* possesses less body than white lead, and great care is requisite that the colour when ground in oil is of sufficient consistence to be laid on a flat surface without showing through; for in that state any oil in excess will form a slight glutinous coating on the surface, retaining every particle of dust brought in contact with it, until it has evaporated. Proper drying oils will cause zinc white to dry as quickly as the other colour. With these precautions, a few trials will enable any painter who is willing to work zinc white to overcome the difficulties which appear at first to condemn the invention. It is asserted that in consequence of the great durability of the colour of this material, a house painted with it may be washed for a succession of three, four. or even five years; and that after each successive washing the surface will be found as clear and bright as when fresh painted. The effect, in appearance, of this paint is perhaps better when it is applied as a finish to a coat of pure white lead; generally it looks better on new work than on old, as some specimens prove that it was then apt to turn black. An American discovery consists in subjecting the oxide of zinc, in its dry state, to the combined action of friction and pressure, by which means its bulk is greatly reduced, and it is enabled to be ground with a reduced quantity of oil, while a greater body is given to the paint. Hubbuck states that 2 cwt. of his paint, with 6 gallons of oil, covers as much surface as 3 cwt. of white lead and 12 gallons of oil; and that it is cheaper also than white lead.

2272*d*. Lead colours are formed by a mixture of white lead with lamp black; all colours, however, that are called *fancy colours* have white lead for their basis, chocolates, black, brown, and wainscot only excepted. The *fancy colours* are drabs, French greys, peach blossom, lilac, light greens, patent greens, blues, vermilion, lake, &c.

2273. There is a process used by painters termed *clear-coleing*, which is executed with white lead ground in water, and mixed with size. This is used instead of a coat of paint;

but it has not sufficient body usefully to answer the end for which it is usually employed. It prevents the oil paint sinking into the wood; it scales off, and in damp situations its colour almost immediately changes. The only occasions wherein it is useful are where the work is greasy and smoky, in which the use of it prepares better for the reception of paint. It should, however, never be employed upon joiner's work or cornices to ceilings, where much enrichment is found; for, of all things, it destroys the sharpness and beauty of the ornaments. Painters are very fond of using it; but their endeavours to persuade the architect should always be resisted, except in cases of absolute necessity, namely, that in which a fair appearance cannot otherwise be given to the work. The old work should be well cleaned and dried, and then the mixture above stated applied. For finishing, the white lead is mixed in half linseed oil and half turpentine, and used as stiff as possible; blue black, or some colour, and a little drier, are requisite.

2273*a*. Various prepared paints are employed. One of the oldest is Carson's *Anticorrosion paint*, used for out-door work only, such as farm buildings, implements, fencing, &c., all kinds of iron work, brick, stone, compo, &c. It is stated to be lower in price, and to last twice as long as the best white lead. The powder, in which state it is supplied, is composed of ground glass bottles, scoriæ from lead works, burnt oyster shells, and the required matter for the colour that may be chosen. 112 lbs. of this paint requires 7 gallons of raw linseed oil and 1 gallon of turpentine; to be mixed over-night; 2 coats are required on paint, 3 on new work; 3 or 4 on brick, compo, &c.; everything to be well scraped first, and the paint rubbed in well. It is thus more laborious to put on than common paint; it wears out the brushes in a very short time, and as it lasts so long, painters will seldom use it. The appearance of a surface painted with it is rough, resembling that of unrubbed cast iron or freestone. It will blunt the edges of carpenters' tools when being sawn or cut through.

2273*b*. *Oxide of iron paint*, of various colours, is a ferruginous paint, for iron and wood, made at Matlock. Messrs. Peacock and Buchan have successfully applied their *improved coating composition* to many iron vessels and life boats, for many years, and it is found to preserve the plates, keep the iron cleaner, and to stand the sea air and salt water much better than most, if not all, other paints. The *Pure Carbon paint* protects iron from rust, and is valuable for all outside work. When *tar* is used as a paint, about a pint of spirits of turpentine is put to a gallon of tar as driers, or a larger quantity if it be required to dry quickly. The addition of yellow ochre will change the black to several shades of brown.

2273*c*. The *Bideford and mineral black paint* has been exclusively used in H. M. dockyards, &c., for the last forty years. "Its superiority is observable in the preservation of wood, iron, and canvas; it covers the work well, dries quick and hard, is more durable, and does not blister like other blacks, and has a body inferior only to white lead." The *Torbay iron paints*, made at Brixham, in Devonshire, have been much used in dockyards, &c., for coating materials under water, or in a position to be affected by damp. Their peculiar characteristics are, great covering properties, 62 lbs. effectually coating as large a surface as 112 lbs. of lead paint; economy, durability, protection of iron from corrosion, arresting oxidation at any stage, and resistance to sulphurous and other gases. (Hunt, *Handbook*, 1862. *Builder*, xx. 527.)

2273*d*. The *Iron minium paint*, by A. de Cartier, manufactured at Auderghem, near Bruxelles, is a pure oxide of iron mixed with about one-fourth its weight of siliceous clay, and not containing any acids. It is now extensively used in this and other countries for painting the ironwork of ships, gas-holders, &c., superseding red lead and other pigments for such purposes. It is said to be solid, durable, cheap, and, above all, to preserve iron from oxidation, and of hardening wood. It is a dark brown in colour, but mixes easily with other colours, such as black, yellow, green, &c. To test its purity, it is said to be sufficient to dilute it with a small quantity of water, spreading it on paper, when, if pure, the edges of the paper will preserve the special tint of the iron minium. If a change of tint is perceived, an adulteration has been effected.

2273*e*. Warner's *Silicate of iron paint* is sold prepared in genuine boiled linseed oil, of a great variety of colours, for painting iron work. It is said to stand extreme heat and damp, and not to be affected by the strongest acid, sea-water, sulphuretted hydrogen, or ammonia; and to be equally well adapted for iron or wood. It adheres so tenaciously, that sheet iron may be bent until it breaks, without the paint coming off. The powder, when boiled up with tar, is a very cheap preservative for iron or wood.

2273*f*. When visiting Paris in 1860, the present editor was much struck with the appearance of the margins of the stairs at the hotel. On examination, they proved to be covered with a thickish coat of a hard compound, having rather a glossy surface, and somewhat of a light orange tinge. A water-closet which had been out of order on one morning was not only repaired, but the seat and riser, the floor, and the wall to a height of three feet, covered with this mixture, and ready for use by the next day. The tiled floor of the manuscript room at the library of St. Généviève, which had been covered with the same mixture, was then in various stages of obliteration according to the traffic. The attendant there spoke very highly in favour of its cleanliness. It is believed to be composed of 10 lbs. of purified yellow wax, 10 lbs. of linseed oil, 8 lbs. of spirits of turpentine, and 5 lbs. of common resin. The wax is dissolved separately in the linseed oil, and the resin in the spirits of turpentine by heat, and are subsequently intimately mixed, when they form a pasty compound. In this condition it is used as priming, being nearly colourless after application. Pigments ground up in oil in the usual way are added in the proportion of one-third of the vehicle, and then spirits of turpentine added in quantity sufficient to produce the desired amount of liquidity. So soon as the turpentine has evaporated, the coat of paint will support rubbing, if not too hard, without damage, but it takes some time to become *completely* hard. It is put on in one coat, without apparently any of the smell or inconveniences attending the ordinary process of painting.

2273*g*. Among the modern inventions the following are noticed. *Albissima* paint, which is brilliant and pure, non-poisonous, without smell, and unchanged by gases. The Sanitary Paint Company manufactures non-poisonous silicate and other hygienic paints and colours for all purposes. The Silicate Paint Company manufactures the patent Charlton white, for use in place of white lead, zinc, &c., and other materials. Price's *chez-lui* is a hard drying enamel for metals. The *granitic* paint and the silicate *zopissa* composition is stated to be a cure for damp walls. Morse's "perfect oil paint" is put forward for inside and outside work, old and new; and as damp-proof and weather-proof. *Magnetic oxide of iron* paints of all colours; a cure for damp walls.

2273*h*. Paint done upon recently set Portland cement will not stand. The work must be finished in Portland cement compo, and faced with at least half an inch of Keene's cement or, better still, Martin's cement, followed at once with paint having plenty of boiled oil in it; the paint must be put on before the cement is thoroughly set, or the face becomes greasy and will not take the paint. In ordinary work, the stucco or cement must be dry, which may take six or twelve months to effect, or the paint will go in blisters, and colours will fly. Pure red lead and good boiled oil should always be the first or priming coat.

2273*i*. The Indestructible Paint Company protected in 1880 the obelisk called Cleopatra's Needle, fixed on the Thames Embankment, with Browning's patent preservative solution, which appears to have prevented the stone absorbing damp. (See also Preservation of Stone.)

2273*j*. *Fireproof paints*. These are modern inventions. Astrop's patent *Cyanite* is stated to be non-poisonous; a colourless or coloured priming for paint or varnish, or alone as a staining for wood. It is greatly recommended for painting timber as well as for textile fabrics, to resist the action of fire. (*Builder*, Sept. 15, 1883.) The *Asbestos* paint does not contain any oil, and wood coated with it has resisted fire. Griffith's *Pyrodene* paints and liquids were used in 1887, in the Royal Jubilee Exhibition buildings at Old Trafford, near Manchester, under the recommendation of Professor Watson Smith. Sir Samuel Blane's fireproof paint has been used at the new theatre in the Strand, built, 1887, for Edward Terry.

Distemper.

2274. The use of *distemper* is older than that of oil and varnish. *Whitewashing* is a kind of distemper, especially when size is used with it. Common distemper colour for walls is Spanish white, or *whiting*, broken into water, to which is added strong size whilst warm, and then allowed to cool, when it should appear a thin jelly; two coats are generally necessary. The old work should be first washed by a brush with water. This process in old publications is called, "painting in water colours." It is much used for ceilings, and always requires two, and sometimes three, coats, to give it a uniform appearance. It is not generally known that walls which have been distempered cannot afterwards be *limewhited*, in consequence of the lime when laid on whiting turning yellow; oil colours, however, can be applied, and then whitelead is used as the vehicle. Papered rooms coloured in this manner, especially over flock papers, look well, as the raised pattern can be seen through the coats of colour. Rooms may be distempered and dry again in a day, with little dirt. When wood is covered with distemper, it is liable to swell with the damp. Rooms that are to be afterwards *varnished* are prepared in two ways: I. By applying the intended distemper colour, and then covering it with as many coats of varnish, coloured or uncoloured, as may be required; but if the wood be not dry, the colour becomes hardened and flakes off. II. The colour is ground and mixed up with varnish, which produces a better result. If the last coat of varnish be applied colourless, it then forms a glazing to the under tints, and its brilliancy will be greater. The use of size here, again, produces a considerable saving of varnish. For new plaster work a coating of size is desirable.

2274*a*. Morse's patent *Calcarium* distemper, or washable non-poisonous water colours in cold water, does not require to be washed off previous to re-doing; colours for inside or outside work, but not on outside painted walls; white for ceilings. It will not rub off; is stated to be one-fourth the cost of lead paint; that one hundredweight will twice cover 200 to 300 square yards of inside work, and from 100 to 200 square yards of outside work.

2274*b*. Mander Brothers' non-poisonous colours for distemper. They recommend one pound of first-rate glue to be dissolved in water over the fire, adding more water to make a bucketful of size of about $2\frac{1}{4}$ gallons. A preparative coat, made of whiting slacked in cold water, adding the proper proportion of colour; then reduce four ounces of soft soap in a little warmed size, and mix thoroughly in the colour, adding it to each bucketful of stuff. Then thin down the whole with jelly size until it is fit for use. This coat should be made much thinner (with size) than the finishing coat, and it should be laid on evenly with a flat brush and allowed to dry. For the finishing coat, make the colour as for the preparative coat, but with rather less size and more colour, and omit the soft soap. The walls should always be properly dry before being coloured, unless made with Parian cement, otherwise they will not dry of a uniform colour. Manders supply about one hundred fine colours for various purposes.

2274*c*. *Duresco* is a new washable distemper.

2274*d*. *Distemper* and *fresco painting* are subjects we do not to treat in this section, as they would come under "Decorative Painting," a higher branch of artistic skill.

2275. Some colours dry badly, black especially, and in damp weather they require a *drier*, as it is called, which may be made from equal parts of copperas and litharge, ground very fine, and added according to circumstances. Drying oil is made as follows:—To 1 gallon of linseed oil put 1 lb. of red lead, 1 lb. of umber, and 1 lb. of litharge, and boil them together for two or three hours. Great care must be taken that the oil does not boil over, on account of the danger to which the premises would be thereby exposed. Thus, in a pot capable of holding fifteen gallons it would not be prudent to boil more than one-third of that quantity. To remove old paint, varnish, &c., the *Electric* paint remover, as well as the *Egyptian clay*, are said to be very efficacious. The Wellington automatic *torch* for burning off paint, and for plumbers' work, as soldering, is a useful instrument.

2275*a*. Painter's *putty* is made of whiting and linseed oil, well beaten together.

Imitations.

2276. *Graining* (or *combing*, as it is termed in some late specifications) and *marbling*, or the imitation of real woods and marbles, is done by the painter. *Mahogany grained* in 1798 is the earliest notice the writer on the subject in the Architectural Publication Society's *Dictionary* had found; *grained wainscot* appeared in 1815. Imitation *wainscot* is obtained by giving the painted work a coat *in oil* of a brownish tone, the colour being thicker than usual; this is then scratched over by combs of bone, with blunt points, and of various degrees of coarseness, leaving the ground visible. The cross white veins or *champs* are next taken out with the corners of a piece of soft leather doubled up. The next process, which in cheap work is omitted or carelessly done, is *over veining*; this is effected with a wide flat brush, the hairs of which are long and slender, dipped in transparent colour, when the hairs stick together in a sort of lock; the cross veins of the woods are dexterously imitated with this tool, and show the other veins below. Other expedients have been made to imitate knots, veins, mottles, &c., of various woods. The little dark spots with a lighter shade round them in maple wood are imitated by dexterous touches with the tips of the fingers on the wet pigment. Almost every other wood, as well as wainscot, is imitated in distemper, for which small beer and water, mixed with Vandyke brown and burnt sienna, according to the tint required, is found to be sufficiently glutinous without the aid of size, to prevent it smearing during the application of the coat of copal varnish which follows soon afterwards. Graining operations are always done after the wood has been painted; in best work, indeed, the coats are thicker than usual, to afford a good ground for the combing. Taken with the subsequent varnishing, grained work is considered to be more lasting than painted work. Certain tools have been invented for performing this work; the grain has been imitated by machinery; and grained papers have been printed from the grain of the wood itself. To save the delay consequent on painting and all its annoyances, the editor of this edition explained, in 1857 8, his system of graining on the wood itself, whereby only a preparatory sizing is necessary; the result is that scarcely any smell of paint is perceived; a greater brilliancy in effect is attained; and the woodwork may be left to dry until the last moment.

2276*a*. *Marbling* is painting on a prepared painted surface, an imitation of the material as exact as the talent of the painter will admit, and requires no detailed explanation.

2276*b*. *Varnishing*, a subsequent operation to both of the above processes, requires much care and the use of good material, the best copal varnish, to bring out the colours of the work. Many qualities of varnish are manufactured, as:—finest copal, for imitation woods, &c.; copal oak, for grained interior work; mahogany varnish, being darker in colour; fine hard-drying oak varnish, drying in about 8 hours, and used for seats in churches, &c.; dark hard drying oak varnish, used after deal has been stained; paper varnish, for paperhangings, &c. Where expense is not an object, two or three coats are applied, especially to marbling, each coat being well rubbed down to obtain an even surface and a high degree of polish. To restore the gloss of varnished graining, of marbling, or of varnished paper, the whole must be well cleaned, then sized afresh, and revarnished. But the original colour of the work can never be fully reproduced, as the varnish darkens by time. Brunswick black varnish, a quick drying jet black, is used for grates, iron work, &c. Copal cabinet varnish, and a white, and a brown, hard varnish, and French polish, are used for cabinet-makers' work. A water flatting varnish renders paperhangings washable without imparting a gloss. These varnishes are all as made by Mander Brothers, Wolverhampton.

2276c. To clean varnished work, soap and water applied carefully with a sponge, and the use of warm woollen cloths to dry the work, is very efficacious. The steps of wooden staircases, painted, grained, and varnished, last a very long time, and neither dust nor dirt adhere so easily to such work as to paint. Real woods, especially wainscot, are prepared for receiving coats of varnish, by being first sized to prevent the rise of the grain which ensues when the slightest quantity of water touches it. When to be polished, they are well smudged over a short time previously with Russian tallow. A preparation called *Lethicium* is said to remove paint from wood in twenty minutes, doing away with the necessity for burning it off. A *hypo-nitro kali* has been introduced for the same purpose.

2276d. *Sand paper*, *glass paper*, *emery paper*, and *emery cloth*, of various degrees of fineness, are employed to rub down work to a surface. It is made by the pulverised material being placed in fine sieves, and by a gentle motion distributing it by hand over the paper or cloth prepared for its reception.

2276e. *Stains*, as substitutes for paint, the tints resembling oak, mahogany, rosewood, walnut, and satinwood, cause the natural grain of the deal on which they are applied to appear. The wood is then sized and varnished; their durability is stated to be at least three times that of paint in interior work, and only at half the cost. This is Stephen's preparation. Naylor's *stain* is said not to require sizing, and to stand exposure to the weather. Swinburn's *Transparent staining and anti-dry-rot fluids* are chemically prepared, and show the natural grain and feathery appearance of the wood. When sized and the proper varnish used, they are said not to fade or blister by exposure to the weather.

2276f. *Mander* Brothers supply permanent wood stains in dry powder, which are instantly soluble in boiling water and perfectly fast in daylight; they are provided in boxes of 1 oz., 2 oz., 4 oz., 8 oz., and 16 oz. A pale copal varnish, or a dark hard-drying oak varnish, should follow in two coats, put on in a warmish room, free from dust. *Kallkolith* is a new patent priming and stain; it is considered to be best used as a first coat of paint to wood, to impart durability to all oil colours, and that the paint does not blister. It is very useful to prepare walls for paperhangings.

2277. In the outside work and stairs, the process of *sanding* is frequently adopted. It is performed with fine sand thrown on the last coat of paint while wet. Cement work is generally *coloured* with its own cement mixed up with water. Roman cement, or black cement, as it is sometimes called, must have a wash or two; and while Portland cement is declared not to require any colouring, certain it is that in London not many years pass over before its dirty look urges a colouring or painting process. The process of painting the artificial cements, such as Parian, &c., is noticed in pars. 2251*f*, and 2273*h*.

Gilding.

2277a. *Gilding* is of two kinds, burnished, and mat or dead, gilding. The former is seldom used in architectural decoration. The latter is done in oil-size on woodwork; in water-size on plastering. The gold leaf of various thicknesses, but generally about $\frac{1}{28200}$ of an inch, is called "single," "double," and "thirds," and of tints, is furnished in books of 25 leaves, each leaf being $3\frac{1}{8}$ by 3 inches, or in the book 18 inches and $\frac{6}{8}$ of an inch superficial, covering about 1 foot of plain work. It should not be too thin nor have too much alloy. Gilding on metal is effected by first giving it a coat of paint or some other substance to prevent oxidation. Gold, absolutely pure and of extra thickness, was applied to the ironwork of the great tower at Westminster; and double gold leaf, pure, was used in the reading room of the British Museum. It has been stated, that if just before commencing to gild, each leaf of the book be *slightly* rubbed over with wax, sufficient only to cause the adhesion of the gold, that gilding in the open air, even in windy weather, may be done without the loss of a leaf, as the stickiness of the gold-size will overcome that of the wax, and no part be blown away, as is generally the case.

2277b. A *gold paint*, patented by H. Bessemer, is now much used, which, by the highly improved manufacture of bronze powder, is greatly reduced in price in England, although very much is still purchased from the German dealers. As an impalpable metallic powder, its application to plaster, wood, &c., is effected by using a camel's hair brush, which is dipped into a little of the powder and rubbed up in a small portion of transparent gummy varnish, by which it adheres to the surface. For all outdoor works it requires to be varnished over for better preservation.

Paperhanging.

2277*c*. With painting is often connected the practice of paperhanging by the same artificer. The various sorts of paper used for lining walls may be described as follows: Block printed by hand, a process now seldom done. Machine printed, of great variety. Flocks, the pattern being formed by a wool ground to a fine powder and fixed to the paper by a sticky oil. Raised flocks; patent embossed flocks; imitation leather, of which the new *Coriacene* is an example. Woollams and Co. were the original makers of *non-arsenical* papers. They are also manufacturers of patent embossed flock papers, embossed imitation leather paper, and raised flock papers for painting over. Arsenical green in printed papers is considered injurious to health, from its flaking off in light particles, and floating in the air, when it is taken into the lungs while breathing. This colour may be at once detected by placing a few drops of ammonia on it, whereby the green will be changed into a deep blue.

2277*d*. The methods of manufacturing marble, granite, and wainscot wall papers, is well described in the *Builder* for 1865, p. 912, and which need not be here entered upon.

2277*e*. It may be mentioned that papers are printed 12 yards in length, such a length being called a *piece*, and 1 foot 8 inches wide; hence 1 yard in length contains 5 feet superficial; therefore, any number of superficial feet divided by 60 (the length 36 × 1 ft. 8 ins.) will give the number of pieces wanted for the work; 1 piece in 7 or 8 is allowed for cutting and waste to common papers, and any odd yards are allowed as a piece. French papers contain about $4\frac{1}{2}$ yards superficial per piece, being of various widths. In best papers this allowance for waste is not enough. Borders are 12 yards or 36 feet in each length, each being technically *a dozen*. A ream of printed paper of 20 quires of 24 sheets to the quire, is equal to 28 pieces of paper, or each piece contains 17 sheets. Satin papers should be hung over a *lining paper*. The paperhanger has to provide and hang materials required for covering damp walls.

2277*f*. Walls of rooms should *always be stripped* before the new paper be put up, a process usually attempted to be shirked, even when charged in the estimate. In bad common plasterer's work the setting coat often comes off in parts with the paper and has to be repaired. The walls are commonly prepared for papering by a coat of *clearcole*, or similar material, and for better work by rubbing down, &c.

2277*g*. Paperhangers' paste is made of flour, a little alum, and single size.

2277*h*. *Tectorium* is stated to be a sanitary decoration for walls; it is a fine textured calico painted, with the patterns printed thereon. The dado filling is made in 22, 27, 30, 36, and 45 inches widths. The filling 22 inches wide is either in plain oil colours, or colours varnished, so that it can be washed with soap and water. The material is applied in the usual way as a paper; it checks the inroads of damp into a room. *Lincrusta-Walton*, formerly known as *Muralis*, the Sunbury wall decoration, is impermeable to moisture, and has other advantages. *Muraline* is one among the many *washable* papers. A *Sanitary* paper is made of non-absorbent materials, and being printed under a great pressure, the colouring is pressed into, and thoroughly incorporated with, the fibre of the paper. These papers are well adapted for sick rooms, and can be washed with cold water. The *Duro-textile* is of this character, and is made 24 inches wide. W. Cooke & Co.'s *golden lustre silk paper hangings* are stated to be free from all impurities.

Other Decorative Appliances and Processes.

2277*i*. *Distemper* and *Fresco painting*. *Sgraffito*, an ancient Italian process for external and internal plaster work. *Pargetry*, or modelling in wet plaster, as carried out in the half-timbered buildings of the 16th and 17th centuries. *Modelled fibrous plaster work*, for ceilings, &c. *Marble mosaic floors*. *Tile paving*. Artistic joinery in dados, doors, panelling, &c, in all woods. Chimneypieces in marble and wood. Real wood veneering in lieu of painting and paperhanging. Xylatechnigraphy, a new and permanent process for decorating woodwork in lieu of painting or graining. Badeke's compressed *wood pulp*. *Stained glass* and leaded lights. Embossed and painted modern *leather*, and Spanish leather, for walls, screens, &c. *Tapestry*, imitation painted or printed, for wall hangings, stuffs for curtains, furniture coverings, &c. *Pyrographic* woodwork (par. 2173*g*.). *Marquetry* (par. 2173*g*.). Colour decoration, applied to walls, continually fails. Mr. Heaton has invented *Cloisonné mosaic*, a material that will take colours on the principle of cloisonné work, which could be applied in panels 6 feet by 3 feet. It is a metal lining, filled in with a coloured material, and washable.

Sect. XIII.

VENTILATION OF BUILDINGS.

2278. Though this and the following section can scarcely be said to come legitimately under the heading of this chapter, the subjects are so intimately connected with each of the sections, and have been referred to occasionally in their description; and as, moreover, the architect is expected to make himself fully acquainted with these subjects, this place, then, appears to be suitable for the consideration of them.

2278*a*. Whether ventilation be left to chance, or whether any special apparatus be erected for the purpose, foul or vitiated air must be got rid of; while fresh air, adapted to the purposes of respiration, must be admitted in sufficient quantity, that is, at the rate of about 4 cubic feet per minute for each individual in the apartment. The force or impetus of the incoming air ought slightly to compress the air of the room and assist the efflux of the vitiated air; and this, in its turn, ought to be so heated as to have a certain amount of ascensional power. Mechanical means are sometimes necessary to expel or withdraw the air, such as fanners, bellows, pumps, &c.; but for general purposes it is more convenient, as well as economical, to trust to the natural method of getting rid of vitiated air; that is, by making certain ventilating tubes or openings at the highest point of the room, towards which the hot air tends to flow.

2278*b*. Some authors have divided artificial ventilation into two branches, called *plenum* and *vacuum*. By the first, fresh air is forced into the interior of a building, and the vitiated air is allowed to escape by openings contrived for the purpose. By the second, vitiated air is drawn out of the building, and fresh air finds an entrance through channels adapted to the purpose.

2278*c*. As the velocity of a falling body in a second of time is known to be eight times the square root of the height of the descent, in decimals of a foot, so the velocity of discharge per second, through vent tubes or chimneys, may be briefly stated as equal to eight times the square root of the difference in height of any two columns of air, in decimals of a foot. This number, reduced one-fourth for friction, and the remainder multiplied by 60, will give the true velocity of efflux per minute. The area of the tube in feet or decimals of a foot, multiplied by this last number, will give the number of cubic feet of air discharged per minute. The height of a column of heated air must be calculated from the floor of the room to the top of the tube where it discharges into the open air. Where several vent tubes are employed, they must all be of the same vertical height, or the highest vent will prevent the efficient action of the lower ones, so that there might be a smaller discharge through two tubes than through one only.

2278*d*. When several openings are made above the level of the floor of a room, the highest one may be the only one capable of acting as an abduction tube, the other lower openings often serving as induction tubes, discharging cold air into the room instead of taking it out, and, in doing so, it may lower the temperature of the hot vitiated air and prevent it from escaping, thus not only causing the bad air to be breathed over again, but filling the room with unpleasant draughts. But if the highest abduction tube be too small to carry off the requisite quantity of hot air, the tube next below it in elevation at any part of the room will act as an abduction tube. If the lower openings (to be provided with sliding valves) for the admission of fresh air be too small in proportion to those for the escape of hot air, a current of cold air will descend through one part of the hot air tube, and the hot air will ascend through another part of the same tube. In order that ventilating tubes or openings may be effective, the lower opening for the admission of fresh air must be at least as large as the upper ones, and larger if possible. Tredgold recommended that the lower should be about double the area of the upper openings, and be so subdivided as to break the current. (Tomlinson, *Warming and Ventilation, &c.*, 1850.)

2278*e*. It must be noted that all noxious gases do not rise, and therefore that in a few exceptional cases ventilation must be effected at the floor level. Taking atmospheric air at 60° Fahr., and under a pressure equal to 30 inches of mercury as 1,000, then hydrogen gas equals 6,926; nitrogenous miasma, about 975; olefiant gas, 978; sulphuretted hydrogen gas, 1,178; carbonic oxide, 957; and sulphurous acid, when anhydrous, 3,000. On the contrary, carburetted hydrogen gas, or marsh miasma, is as light as 555; and common coal gas ranges between 514 and 420. Thus above or below the temperature of 60° the conditions of the diffusion of gases vary in a marked manner, and it is on this account that the foul air of sewers, &c., exercises a more extended action laterally in hot weather, when it is able to diffuse itself more easily through an attenuated atmosphere, than in cold weather, when the greater density of the atmosphere, and the comparatively higher temperature of the gases given off from the receptacles mentioned, enable the foul air to rise vertically with greater ease than to spread laterally. In a room, the carbonic acid emitted by the lights and by the breath of its occupants being of greater specific gravity than atmospheric air, would, at the ordinary temperature of the air, tend to accumulate in its lower strata; but the temperature of the products of respiration and of combustion is usually so much in excess of that of the air, that they are enabled to rise through it, and to accumulate in the upper portions of the enclosed room until some change in their temperature takes place. The foul state of the air in the lower portions of a public building on the day following a crowded meeting may be due to the change of temperature during the night, and the retention, by closed doors and windows, of the air so rendered impure. In 1865 General Morin read a paper to the Paris Academy of Sciences, again urging as a fundamental principle the exploded practice of drawing off vitiated air from the stratum nearest the floor, pure air being admitted near to the ceiling.

2278*f*. Our limited space will not permit us to do more than very briefly notice the chief principal methods of ventilation; the application of any one of them must be left to the ingenuity of the architect. He will find that all public buildings, and even all private houses, from the highest to the lowest class, must be spontaneously ventilated, for if any trouble be entailed, it will be neglected. The means for ventilation must be cheap, easily procurable, always in place, self-acting, and not liable to get out of order. Such an invention is the Arnott ventilator, when placed as close to the ceiling as practicable, forming a direct communication between the room and the chimney. The chimney has been made the means of securing a ventilation by a separate and rarified air channel. Thus, besides a mere channel left in the wall adjoining a flue, Doulton's patent combined smoke and air flues, of terra-cotta, for 12, 10, and 8-inch chimneys, are effective. Boyd's patent flue plates are similar in principle. Chowne's patent air-syphon, consisting of an inverted syphon tube, acts upon the principle of the air moving up the longer leg, and of entering and descending in the shorter leg, without the necessity for the application of artificial heat to the longer leg. This, however, does not appear to be always proved in practice, for whether the current in the longer leg be ascending or descending, depends chiefly upon differences of temperature within and without a building; but as the brickwork of chimneys often gets heated by the vicinity of the kitchen flue, or even by the sun shining upon it during the day, an ascending current is more likely to be sustained than a descending one, since brickwork will retain its heat for some hours.

2278*g*. The system adopted by Dr. Reid, at the House of Commons, was that of admitting air into a chamber underground, where it was (and is still) purified by being washed while passing through a stream of water, and then through canvas, whereby other impurities are extracted. It then rises to the floor of the apartment, which is pierced with many thousand holes, and passing through them is then further distributed by means of a hair-cloth, ascending towards the ceiling at about the rate of one foot per minute. This air is, in cold weather, warmed below; and in warm weather it is cooled with ice. The object is to keep the air in all seasons at a uniform temperature of 64°. The air is often cooler in the House than that outside it. From the ceiling it is carried rapidly away along a tunnel to feed the great furnace which creates this current of ventilation. The complaint is made that it carries with it from the floor the fine dust brought in by the members' feet, which, being inhaled, sometimes affects those in the House. The method adopted by Dr. Reid to warm and ventilate St. George's Hall, at Liverpool, is detailed in the *Civil Engineer* for 1864, page 136. The system employed from 1736 to about 1817 at the old House of Commons, which was effectively ventilated, was by a fan placed over it for *extracting* the heated air, its rate of working being dependent upon an attendant, who received his directions from a person within the House. The common revolving windguard placed at the top of a chimney to induce a suction, whereby the smoke may be drawn out, is of the same system; as is also Howarth's patent revolving Archimedean screw ventilator. One of the latest systems of effecting the regularity of working such fans or screws is by the aid of the high service water supply; a flow of water impinging upon the blades of a wheel turns the extracting fan, and the water is conveyed to a lower reservoir, to be used for domestic or other purposes.

2278*h*. The opposite system, that of air being forced into apartments by mechanical means, such as the fan driven by steam power, is practised with great success at the Reform Club House, the General Post Office, and many other buildings, public and private, and especially in factories. The fan is regulated to a velocity of between 80 and 100 feet per second. Dr. Van Hecke's system of warming and ventilating, as arranged at the new French hospitals, is effected by means of a $3\frac{1}{2}$ horse-power engine, working a fan, which drives the external air through long subterraneous channels into four warming apparatuses, whence it ascends into flues, which conduct it into all the wards, passing through regulating air gratings in the walls. In each ward are two or more escape flues carrying the vitiated air above the roofs.

2278*i*. The *Blackman air propeller*, for ventilating, cooling, and drying, has given good results. One of 14 inches diameter, revolving 1,000 to 1,500 revolutions per minute, moved 1,500 to 2,500 cubic feet of air per minute. One of 24 inches diameter, revolving 500 to 900 per minute, moved 3,000 to 6,000 cubic feet of air. Another of 48 inches diameter, revolving 300 to 600 per minute, moved 13,500 to 30,000 cubic feet of air per minute.

2278*k*. The *Boyle system* of ventilation of workhouses and hospitals (1882), by self-acting air pump ventilator (perfected Oct. 1887) and the air inlet brackets, is used at St. George's Hospital for the extraction of the foul air and admission of fresh air, which is effected without draught, and is put forth as "the simplest, cheapest, and most efficient system of ventilation that is at present in existence."

2278*l*. Another system prevails to some extent. The ventilation is combined with the method of warming, be it a church or other room devoted to a public purpose. This is effected by means of flues for extracting the air in the building being connected with the furnace of the apparatus. Such is the principle adopted by Messrs. Haden and Co., of Trowbridge. It has been in practice with success at the Royal Polytechnic Institution, London, for ventilating the large theatre since its erection in 1838. After the fire is once lighted, all its communications with the outer air are closed, and that of the extracting flue opened, which then supplies the fire with air brought down from the upper part of the theatre. Fresh air is admitted to the theatre only through the ordinary doors and openings.

2278*m*. As regards ventilation by windows, or the natural method, as it is called, as no system of making a sash working upon a horizontal axis, such as French casements, can wisely dispense with stay-bars, even when made to open and shut by means of a wheel and axle, our attention may be confined to lights hung on pulleys, or on hinges, or on centres. The first of these three classes is the common lifting sash. Wind-boards at top and bottom to prevent the effects of direct currents have been suggested; and machinery has been fitted to open both sashes simultaneously, so as to ensure the desired circulation of air through apertures at pleasure, or that shall not be altered without a key. This improvement has lately been successfully managed by the "patent counter-balance rack slips," which also do away with the use of lines, pulleys, and weights. In double windows, however, as in the lavatories at Middlesex Hospital, a roller has been placed between the two pairs of sashes, which move reciprocally, like the double bucket action; so that when the inner top sash is lowered the outer bottom one is raised, and the reverse; and the extension of this idea to the lights of water closets has been advocated. It has also been suggested that, in the usual windows, the horns of the upper sash styles should appear above the top rail, so that the window could never be tightly shut; but the benefit from this plan is confined to periods at which the window is not closed by shutters or by roller-blinds. The same objection applies to the use of such perforated glass and other contrivances as are mentioned in *par.* 2231*a*. It is stated that no draught is felt by the use of these inventions, as the air passing through the perforations is diffused equally and imperceptibly. We must notice that it will be found that the air is always passing into the apartment, and that when the wind blows towards the glass, the extra supply of air sent in is undoubtedly felt by the occupants, but sometimes not appreciated by them. Another method consists in the admittance of air either by a space left between the top bead (the horns, as before, stopping the sash from going home) and the head of the opening, or by such a space over the outer bead, to communicate with the box formed by the inside lining and the architrave or other dressing, the latter being either pierced with holes or detached slightly from its grounds. Another method much practised is to make the inside bead to the lower sash of a greater height than usual, say about two inches; thus when the sash is raised a little and clears the meeting bar, fresh air will be admitted at the meeting bar and *not* admitted at the lower part. Old sashes may be so treated; even a bar of wood about three inches high, lined with baize, its length being the width between the sash reveals, can be put on the sill when the sash is raised, and the sash shut down upon it. This admits fresh air at the meeting bar sufficient to ventilate the room without draught.

2278*n*. Of the second class is the common hopper to a window, framed with or without side lights. In this are included all greenhouse sashes that are hung from the top, which may be made to open simultaneously by means of ratcheted stay-bars dropping into toothed wheels fixed on a continuous axis, worked by a wheel against an endless screw. When double windows are used, as in very cold climates, or when it is desirable to shut out noises, the upper portions of them should be made to open by the action of opening the inner window. This scheme has been adopted in the hospital of the Wieden suburb, and also in the Imperial stables, at Vienna, with success; its action is not described, but the outer window is presumed to be fixed, the heads of it forming a hopper, which is opened or shut by lowering or raising the inner window.

2278*o*. To the third class belong nearly all the modern English patents for window ventilation, which consist of one or more planes working like a jalousie lath upon a horizontal axis. Of the two principal adaptions of the system to an entire window, Hurwood's, shown in *fig.* 808*a.*, and worked by an endless screw, is the simplest; there is another arrangement of this kind by Mackrory, where the action is similar to that of a carriage window; the sash runs in a groove, and being turned by means of a toothed pivot working against an endless screw, it can be kept at any desired height. The method indicated by *fig.* 808., adopted at Middlesex Hospital, seems more simple and more economical. By turning the handle to the points in the plans A, B, and C, the glazed louvres are simultaneously opened or shut to those limits.

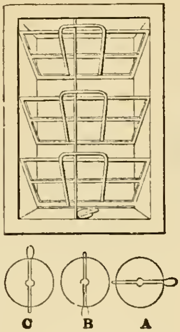

Fig. 808.

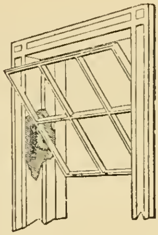

Fig. 808*a.*

2278*p.* Ventilation is effected on the principle of the extracting valve, as advocated by Dr. Arnott, which is a plate of metal hinged to the lower edge of a metal box next to the room, and on the other open to its chimney. The draught of the flue tends to carry away the air of the room, when the current is upward; should it be downward, a silk or mica flap is driven against the plate, tending to prevent the ingress of smoke. However useful this contrivance may be, its result in cubical consumption of air is necessarily small. A cowl with vertical, or horizontal, or slanting jalousied sides has also been employed, with or without an Archimedean screw, at the top of a flue, to exhaust the air of a room. The simplest means of the admission of air to a room is a hole in front of which, on the inside, should be a board inclined to throw up the current of fresh air, as *fig.* 808*b.* Another well known invention is *Sheringham's* inlet ventilator. An opening is made in an external wall for the introduction of air, and a metal box inserted, which is a sort of hopper, having at its mouth a valve, so hung as to direct the current of air towards the ceiling, whereby no draught is felt by the occupants of the apartment. Somewhat similar is Hart's ventilator, the face being of perforated zinc. Such articles are also made with a box to contain charcoal as a purifier of the air before it is admitted. Looker's patent ventilator, consisting of a tubular piece of pottery fixed in the wall, into which on the inside is placed another tube, perforated all round with small holes, the inner end being closed altogether. This second tube is pushed in or out, according to the quantity of air required.

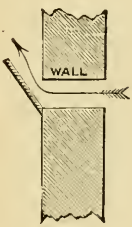

Fig. 808*b.*

2278*q.* Amongst the earliest of other and later systems is Watson's double-current ventilator, consisting of a tube divided by a diaphragm, and rising from the ceiling to the external air; it was intended that the air should circulate, as shown in *fig.* 808*c.*, by an ascending and a descending current. It has been said that this result only occurs in rooms that are perfectly closed, and that the two tubes generally serve as exhausters; but our own experience is more favourable to the effective working of this invention. Somewhat similar to this is *fig.* 808*d.*, called the Shaftesbury ventilator, which appears to have been applied in small tenements with success, probably for the very reason that the rooms in such cases are generally kept as close as possible; for it has been necessary to conceal the opening at the ceiling by an ornamental rose, and to put at G an air grate with large openings. At times,

Fig. 808*c.*

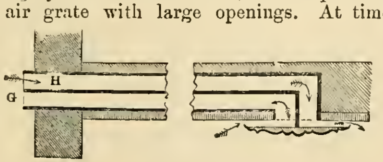

Fig. 808*d.*

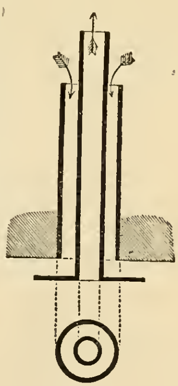

Fig. 808*e.*

however, the rush of cold air is very great through this tube into the room; to remedy this, the end G may be connected with a horizontal tube or box about 3 feet long, and somewhat larger than the tube H; each end of this box is open, but filled with very fine wire gauze; the result then has generally proved satisfactory. A modification of the preceding invention is adopted by McKinnel. Two concentric tubes are so fixed that the inner one is longer than its envelope. This apparatus, shown in *fig.* 808e., nearly answers its purpose, according to certain authorities, and certainly gives, in some cases, a result that would be satisfactory if its regularity were not affected by atmospheric influences. The openings require to be covered, so as to prevent the admission of rain. A square turret, diagonally divided, as shown in *fig.* 808*f.*, is known as Muir's ventilator. The inventor calculates upon utilising the slightest current of air, as he supposes that when it arrives at one of the sides it will enter, descend, and force an equal quantity of foul air to discharge itself at the other sides. The report of MM. Blondel and Ser upon the London Hospitals in 1862, states broadly that none of these methods gives a satisfactory solution of the question.

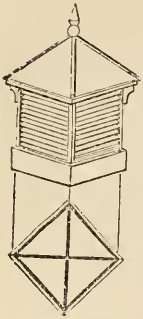

Fig. 808*f*.

2278*r*. *Honeyman's diaphragm* ventilator, 1886, is prepared for use for open timber roofs and for ceiled apartments. Air pressing in on one side shuts a valve on the windward side of a middle diaphragm, passes through an orifice in it, creating an upward current in an air trunk, which draws out the foul air in the room through other valves on the lee side. When there is no wind, the valves on both sides of the diaphragm open freely for the exit of the heated air.

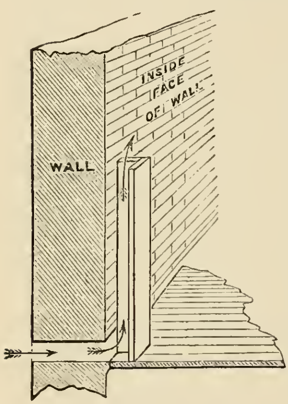

Fig. 808*g*.

2278*s*. The system of Mr. Tobin (of Leeds) for providing access of fresh air into a room is now extensively used, and sometimes under other names. It was promulgated by him about 1874, and although the principle is of an earlier date, it is to his endeavours that it has become recognised as a most valuable auxiliary. The principle is that of a *tube* carried up from the floor against the inside of an external wall to a height of about 7 feet. *Fig.* 808*g*. shows a section of the tube on this principle, from Dr. Corfield's *Laws of Health*, p. 41. The bottom of the tube is made to communicate with the outer air and the top is left open. This tube may be made of planed deal or metal. The top is by some manufacturers covered by a piece of coarsely perforated zinc to prevent articles dropping down the tube. Others put in a coarse canvas bag to filter the air as it passes through into the room. A regulating valve is also sometimes provided, but this is best avoided, as when once shut it is not always opened again. A "deflecting shield" is often added to the top to prevent the wall decorations from being marked by the dust often in the air passing in. *Inlet brackets* are also made, which are short tubes placed high up, but their efficacy may be doubted. They are also called "vertical tubes" and "air inlets" by some manufacturers. E. H. Shorland, of Manchester, claims to have used "vertical pipes for ventilation" long before they were introduced by Tobin. The opening on the outside of the wall should be protected by a grating: a patent automatic *air washer*, for washing the air by a spray, is adapted by some to this system, as also the introduction of gas lights for warming the air.

Table of Cubic Feet of Air Discharged per Minute through a Ventilator, having an Area of One Square Foot. (Hood.)

Height of Ventilator, in Feet.	Difference between Temperature in Room and the External Air, in Degrees.					
	5	10	15	20	25	30
10	116	164	200	235	260	284
15	142	202	245	284	318	324
20	164	232	285	330	368	404
25	184	260	318	368	410	450
30	201	284	347	403	450	493
35	218	306	367	456	486	531
40	235	329	403	465	518	570
45	248	348	427	493	551	605
50	260	367	450	518	579	635

The openings for the inlet of fresh air must be smaller than those for the escape of the heated air, otherwise there will probably be a descending current of cold air in the same tube with the ascending current of hot air. It is now proved that all inlets should admit the air in an upward direction.

2278*t*. The *Æolus waterspray* ventilator is patented to supply a constant circulation of pure air entirely under control. It is adapted for all public edifices, as well as houses, stables, &c., and for use in hot climates. Ice can be used to cool the fresh air, and a gas furnace can be attached to warm it. The air passing through the apparatus is cleansed from dust and all impurities. The consumption of water is stated to be small, and the total cost of ventilating and warming a large apartment for nine hours does not exceed sixpence. The company has also an *exhaust* roof ventilator, a waterproof *downcast shaft* ship ventilator, an automatic invisible roof ventilator, a chimney cowl, and a ventilating stove.

2278*u*. F. H. Smith, patentee of the automatic *syphonic aspirator* system of ventilation, which produces ventilation without draught by supplying air to the room by ducts at the floor level. The exit for the vitiated air is placed in the ceiling, and consists of two tubes, a large and a small one, parallel to each other, between the floor joists. In the case of top rooms the two tubes may be concentrical. The larger tube carries off the foul air, while the smaller one forms an induction tube for cold air, its outer extremity being open to the outer air, the inner one opening under the rim of the foul air tube. The principle was applied to the hot "island room" of the fountains of 1884 Exhibition, reducing the temperature from 110° to about 70°. The *Eon* ventilators, extractor, and chimney cowl are stated to be the cheapest and most effective used with the *eon* inlet. The *Acme* system of ventilation (Liverpool) is an exhaust and blower type, dependent on mechanical action for its motive power. The action of the ventilator produces a partial vacuum at each stroke, and with the graduated pipes fresh air is brought into rooms without draughts, and may be warmed as it enters. The system has been applied at the new County Sessions Courts, at the Town Hall and Council Chamber, and at the Conservative Club, all at Liverpool. Its application at the former building is described, with an illustration, in the *British Architect* of December 2, 1887. Westmorland's patent improved *automatic ventilator* combines an iron breast trimmer and fireproof hearth bearer (1885), to carry the air from a ceiling up into a smoke flue. The ventilating and warming arrangements of the new portion of Eton College (1888, A. W. Blomfield, architect) have been carried out by J. Weeks & Co., by air passing over hot water coils, and the foul air carried off by ducts at the ceiling of the passages to a shaft having a series of gas jets to secure an updraught.

2278*v*. Where gas lights are much used in apartments or buildings, it is desirable to carry off the products of combustion and heated air by a tube placed over the light, whereby its heat assists the escape of the impure air. An ordinary gas-burner is calculated to vitiate, to the same degree, three times the quantity of air that a man does in the same time. This plan was first effected by Professor Faraday. The improved ventilating sun-burner, with its self-acting valve for preventing a down draught, as manufactured by Strode and Co.; Rickets's ventilating globe-light; and others, all tend to produce the desired result.

Table of Quantity of Air Required per Hour to make up for Vitiated Air by Forms of Artificial Illumination.

Illuminator.	Consumption of Illuminating Material per Hour.	Air Required.
Gas jet - - - - - -	$4\frac{1}{2}$ cubic feet	750 cubic feet
Gas jet - - - - - -	$5\frac{1}{4}$,,	830 ,,
Tallow candle - - - -	$\frac{3}{8}$ of an ounce	124 ,,
Wax candle - - - - -	$\frac{3}{4}$,,	257 ,,
Oil lamp - - - - - -	$\frac{4}{5}$,,	276 ,,
Petroleum lamp, slit burner - -	$1\frac{1}{4}$ ounce	502 ,,
,, round burner -	$1\frac{3}{4}$,,	544 ,,

2278*w*. The Commissioners for Barracks and Hospitals, in their *Report*, 1855, p. 65, &c., state that for such establishments the different systems adopted in the Parisian hospitals appear to be too expensive and too complicated. Those which they approve consist of induction, and of flues for exhaustion, each of two sorts. *Induction.*—I. Openings with an air-brick in the face of the wall, and a wooden hopper near the ceiling, placed at an angle of 45°, covered with zinc pierced with holes from $\frac{1}{6}$ to $\frac{1}{8}$ inch in diameter. A plate of zinc or galvanized iron, hung at the bottom and worked by a string, regulates at pleasure the admission of air, the size of the opening being calculated at an inch square for each 60 cubic feet of space in the room, where there is not a special provision for fresh air to pass round the stove; when there is such provision, the size for the opening may be one half less. II. Openings with an air-brick in the face of the wall, and a trunk or tube leading the air to a case behind the stove, so that warm air may rise in a tube to a luffer-boarded opening at the ceiling, the size of the tube being calculated at an inch square for each 100 cubic feet of space in the room.

2278x. *Exhaustion.*—I. Flues of the warming apparatus extract the bottom layers of air in the room. The experiments made between 4.30 and 6.30 A.M. in April, 1858, showed that the volume of air extracted was on the average 9,000 to 10.000 cubic feet by each flue, the rapidity being at the rate of 5 to $5\frac{1}{2}$ feet; by which numbers the section of the flue would be 0·446 English feet. II. Tubes from the ceiling to the roof, the size of the opening being calculated at an inch square for each 50 cubic feet for an upper story, and for each 55 cubic feet for the story below it, and for each 60 cubic feet for the lower story. The rapidity of the current is regulated by the difference between the internal and external air, by currents, &c. When the temperatures are equal the current is feeble, when the reverse occurs it is strong. The volume extracted (under the above conditions) was 8,500 to 9,000 cubic feet, the rapidity being at the rate of 3 to $3\frac{1}{2}$ feet. So that the greatest effect by the combined systems only takes 8,000 to 10,000 cubic feet by each flue on the average, and this irregular result is sometimes annulled; moreover, the currents may reverse the action of the flues, and enter by the exhausting tubes.

2278*y*. *Other systems.*—In the new buildings at Guy's Hospital, as also at the Lunatic Asylum at Derby, Sylvester's method was carried out. Here the air arrives by a large inducting flue, capped by a cowl which utilises the action of currents of wind; the air passes underground in contact with hot-water pipes, rises in flues, and enters the room at the ceiling; it escapes by exhaustion holes in the skirting of the opposite walls, and rises to the roof by flues continued by plate iron tubes to an exhausting flue, which surrounds the smoke flue of the warming apparatus. The inventor calculated for about 4,000 cubic feet per bed per hour, and stated that in the winter about 4,300 had been obtained generally, but that once about 2,200 only were gained.

2278*z*. The methods of ventilation adopted in France are required to produce effects absolutely free from perceptible currents of air. The report produced by MM. Blondel and Ser, before noticed, mention Duvoir-Leblanc's system, in one portion of the hospital Lariboisière, as drawing away about 2,500 cubic feet per bed per hour, half of which is supplied by the doors and windows; and the method of MM. Thomas and Laurens, which gives 3,200 cube feet per bed per hour, and is not found always sufficient to remove every trace of odour. They consider that Dr. Van Hecke's system, used at the Baujon and Necker hospitals, leaves much to be desired. They require 3,500 cubic feet per bed per hour; and perceive that in order to obtain anything like such a result, recourse has necessarily been had to large exhausting flues, or to mechanical means, such as the fan.

Table of Air Required per Hour for Each Person.

Prepared by Herr von Fragstein of Berlin (*Builder*, xliv. 1883, 56).

	cubic feet.		cubic feet.
Drawing rooms - -	700 to 1,000	Sick rooms, epidemic diseases - - - -	5,300
School rooms and libraries	450 to 500	Theatres - - -	1,400 to 1,750
Sick rooms, ordinary -	2,100 to 2,500	Assembly rooms - -	1,050 to 2,100
Sick rooms, wounded and confined	3,500		

Each person is considered, in England, to require from 3 to 5 cubic feet of air per minute, equal to 180 to 300 cubic feet per hour. At Finsbury Technical College about 11 cubic feet of air per minute is provided in the class rooms, and 50 cubic feet per minute in the chemical laboratories and draught closets.

Sect. XIV.

WARMING OF BUILDINGS.

2279. Heat, as required in architectural structures, results from raising the temperature of the air by means of various contrivances so arranged as to take advantage of the laws which govern the transmission of heat. A body capable of affording heat gives out caloric by two methods; these are *radiation* and *conduction*. Radiation is diffused through the air at an immense velocity without materially raising its temperature, but immediately warming solid bodies exposed to its influence, which in turn give out the acquired heat slowly; the redder the fire, the warmer is the radiant heat. When the air in a large apartment is to be raised in temperature, the method of heating by contact is employed; this is effected by volumes of air coming in contact with a heated surface, and, becoming raised in temperature, are put in motion, and communicate the heat they receive to surrounding bodies.

2279*a*. In order to obtain full advantage of heating surfaces, their area must be proportioned to the cubic feet of air required to be warmed. A small surface, if raised to a very great temperature, will heat a large quantity of air if means are taken to pass it rapidly from contact with the heated surface. It is better, in all respects, to have a large surface maintained at a mild temperature with a gradual change of air. In general, if the temperature of the heated body is above that of boiling water, i.e. 212°, the air in contact is rendered unhealthy. Ventilation very greatly assists the endeavours to warm successfully a room or building.

2279*b*. The method of warming classed under radiation and conduction may be further arranged under the following heads:—I. *Open fires*, including grates and stove grates of every sort, having ordinary flues or chimneys; this is warming by radiation. Warming by conduction is effected by, II. *Close fires*, as furnaces, cokles, &c., and the Cabin, Arnott, Vesta, Gill, Chunk, Dumpy, Nott or American, laundry or ironing, caloric, ventilating, &c. stoves; and by *Gas*, as the atmopyre, asbestos, calorifere, cylinder, and gas heating apparatus; having metal or brick flues continued some distance from them for the purpose of heating. III. *Hot water* on the *low* temperature system, with pipes about 3 or 4 inches in diameter. IV. *Hot water* on the *high* temperature system, with pipes about 1 inch in diameter. And V. *Steam*, both on the high and low pressure systems.

2279*c*. The principle of erecting one chimney to serve for all the fire-places of a house is liable to very unsatisfactory results, unless such a system be carried out as that exhibited at Osmaston Manor, near Derby, by its architect, H. J. Stevens, and described at the Institute of British Architects in 1851. All the rooms in Fair Oak House, Isle of Wight, are warmed by means of one shaft in the middle of the house, heated by a large open fire in the basement. Around this shaft is a thin enclosing case of brickwork, in cement, leaving a space between to receive the cool air, which is then warmed by the heated shaft, and is admitted into the several apartments through perforated cornices, the supply being regulated by a valve. Obstacles presented themselves which rendered it necessary to adopt the cornice and not the floor as the place for the admission of the warm air. The arrangements are stated to have met with a decided success; the plan and details are given in *Builder*, 1860, p. 329. In a series of small dwellings where the one shaft system was tried, its complete failure necessitated the new formation of all the fireplaces and flues.

2279*d*. I. It scarcely enters within the province of this work to describe the best form for an open *grate*. The point has been taken up of late years by manufacturers, and very many excellent forms adopted. The result is that iron at the back and sides has been greatly discarded, and fire-lumps substituted, whereby greater heat is thrown out with the same quantity of fuel. The *fire-lump grates* for cottages, bedrooms, schools, &c., have had a large sale. But it has also been found that too large a surface of the fire-lump tends to consume the coal too quickly, consequently it is now chiefly confined to the back of the grate. A length of bar equal to about 1 inch for each foot of length of room, and the height of the front half an inch for each foot of breadth of the room, are dimensions found to produce good proportions for average purposes. The depth of the part in which the fuel is placed has been greatly decreased, about 9 inches being ordinarily sufficient at the bottom, and enlarging upwards at the back, so as to present a good heating surface in the front, and at the top, of the fuel. The height that the lowest bar should be from the hearth is a matter of greater uncertainty; we advocate that it should be as near to 12 inches as possible, in preference to the 6 inches which the grates are now usually made. We have had grates raised from the latter to the former height with greatly increased results. Advantage has been taken of the fire-clay stoves, since the period of their invention by Count Rumford, to combine the back and sides with air flues of the same material, which, becoming heated, impart their heat to the cold air supplied from the outside, admitting warm fresh air to the apartment. These stoves were first adopted by Cundy. Numerous forms of *slow-combustion grates* have been introduced of late years. The *Carron*, *Musgrave's*, and Barnard, Bishop & Co.'s *Norwich* stove, are among many others of that description. *The registered Economiser grate and fire-brick back*, manufactured by Nelson and Sons, of Leeds, on the principles advocated by T. P. Teale, in *Economy of Coal in House Fires*, has a door to the ash-pit to close the draught; the sides and back of the fire are of fire-brick, while *above* the fire the back slopes forward and over it to near the mantel, when it again slopes back to the back of the chimney; all this being in firebrick and channelled where above the fire. It is considered to give perfect combustion of fuel, with complete radiation and projection of the heat produced, the form of back ensuring the greatest possible consumption of smoke. It can be readily fixed by any bricklayer. The *Marlborough grate* (Garland's patent), with adjustable canopy acting in place of a register door, fire-brick sides and back on the same principle with Economiser; when the fire is not used, the canopy can be let down to shut up the flue opening, like a register. Radiation of heat has been materially assisted by Sylvester's arrangement of the ends of the fire bars projecting into the room forming a hot hearth; and also by Joyce. Dr. Arnott's smoke-consuming grate, and the application of a solid bottom to a grate, producing "the Builder's fire," are points of consideration for the householder rather than for the architect. The *Galton* ventilating air stove is largely used in hospitals and infirmaries. The *Manchester grate*, manufactured by E. H. Shorland, of Manchester, for houses, schools, hospitals, asylums, &c., is used by the Bank of England at its branch establishments. It is called a patent first class smoke consuming and warm air generating grate. Heat is not only given off by radiation, but warm air can be supplied to rooms above or adjoining the one in which the grate is fixed; in 1882 it was stated to possess nearly 80 per cent. more heat-giving properties, and to be nearly 100 per cent. better as a smoke consuming grate, than others tested at the time. The *Wharncliffe* patent warm air ventilating grate. *Grundy's* patent warm air ventilating fire grate, in which the heating surface is stated to be greater than any other. Reeve, Ratcliffe & Co.'s *Cosy grate* is the only open fireplace in which the products of combustion are filtered through a red-hot wasteless purifier, and therefore is a smoke consuming economical grate.

2279*e*. II. The varieties of close stoves are very numerous, but the principle upon which they depend for their efficiency is in all cases nearly the same. This may be stated to be the heating of metal plates by the combustion of fuel in actual contact with them. The quantity of heating surface in the room wherein the stove is placed can be materially increased, and nearly the full effects of the heated products from the fuel obtained, by lengthening the smoke flue; but the longer the flue the less is the draught of the fire, which is further lessened by its becoming choked with soot; thus a 3-inch pipe attached to a small stove, burning coal and in constant use, has been found so completely filled up with soot in the course of a week that a stick half an inch in diameter could scarcely be passed through the hole left in the centre. The now common American cooking-stoves are on this principle. The principle of the Arnott stove is that of consuming the peculiar fuel recommended for its use very slowly, and the detention of the heat in the stove. The addition of a descending flue to some of these stoves is an advantage when it is desired to place the stove in the middle of a shop or warehouse. Franklin's calorifere, or the vase stove, having a descending flue, was formerly much used. When this system has been adapted to flues carried under a stone floor (after the Chinese fashion), it has been found to warm most efficiently an office and principal staircase with a mere handful of fire, at a cost of about 30*s*., while by another apparatus the cost was 18*l*. (Beaumont, *Hints for preventing Damage by Fire*, 1835.) This is an elaboration of the common method of warming greenhouses by the brick or smoke flue, through which the smoke and flame travels from the furnace. A fire-clay casing for the fuel is also combined with some of them. Haden's apparatus has been mentioned (par. 2278*f*.) for warming large buildings; and equally efficient is that by Grundy, which is also much used for churches and large buildings. The *Tortoise* stove is a late production for a small room.

Gas stoves are of various sorts. There are many of iron make, which render the air unwholesome. *Wessel's* patent heat disseminator (about 1850), made of copper, has proved of value even in rooms kept closed. Ritchie & Co.'s *Lux-calor* new patent apparatus for heating and ventilating large buildings by gas, requires no flue, and has no smoke nor smell; the principal parts are made of copper. It was much used in the Bank of England. S. Clark & Co.'s patent *Syphon* stove is a condensing gas heating, similar in principle.

2279*f*. The high temperature stoves, such as the cokles, the Strutt or Belper stove, the Sylvester's, and others, all used for warming extensive spaces, consist of large metal plates or surfaces of brick or stone, heated in or by a furnace or fire, the air to be warmed being caused to impinge upon or pass between them, and then carried along in tubes to the several rooms or floors where the heat is required. The hot air pipe furnace is used for the same purposes, whereby the flame and smoke passes along the *inside* of the tubes. In Davison and Symington's furnace for obtaining heated currents of air for manufacturing purposes, the cold or fresh air is driven by a fan at a great velocity through the pipes, which are placed in contact with the flames. Any cessation of the blower may be expected to cause material injury to the pipes.

2279*g*. A writer explaining the common American system of warming houses by hot air, says that the whole comfort of the result depends upon *how* the atmospheric air is heated. The various plans are effected by a furnace, from the dome of which pipes are coiled and twisted about so as to gain the utmost possible radiating surface, and the air is brought in contact with them as it passes through the chamber. To get cheaply a great amount of heat, the castings are made very thin, the air chambers and hot air pipes small; whereby the result is, that a hot desiccated poisonous air is discharged into the room, injurious to the lungs, and causing headaches. Where the air chamber, however, is large, the furnace very wide and shallow, and its dome high, with the radiating surface largely extended, and the external cold air shaft spacious, this mode of heating is excellent. No apparatus of its kind ever surpassed the old Boston furnace, first invented by Chilson, and since so greatly improved by his successor in New York. In the "Boynton furnace," as it is called, the shaft bringing in the cold air is very large, frequently 4 feet wide and 2 feet or more deep, and the air chamber and tin pipes therefrom are also of considerable size. In the air-chamber a small jet of water is kept playing to restore the natural moisture to the air. Anthracite coal is used, a ton of which, for an ordinary house, would be a sufficient supply for nearly three weeks. No other fires, except that of the kitchen range, is usually seen in houses possessing this apparatus. (*Builder*, xxiii. 582.)

The heating of houses by warm air, and the substitution of gas for general heating and cooking purposes, advocated by a method adopted by Mr. A. E. Fletcher, was considered in the *Journals* of Jan. 1888. A brick chamber in the basement contains a stove in which coke is burnt; air is brought in from the outside, and then conveyed by means of pipes to the entrance-hall and ground-floor rooms, thus warming the whole house, with the result of a considerable economy of fuel. Then asbestos gas fires were used in the rooms, and gas cooking ranges in the kitchen, with great avantages of less dust, cleaning grates, lighting fires, &c. This is not all new (see par. 2279*g*). Many persons have for years found the advantage of the hall and staircase being warmed, if not carried to too great a heat, but only as an auxiliary to open fires, and the upper floor kept ventilated. Gas fires are not to be depended upon as successful. Gas cooking stoves are useful in many cases, but much depends on the domestic even then.

2279*h*. III. The circulation of hot water in pipes is caused by the unequal density of the fluid, arising from the difference of temperature in the ascending and descending columns of water connected with the heating reservoir; and its velocity is governed by the height of the columns; Bramah, in appendix to Tredgold, *Heating*. A boiler (the "conical" boiler is considered the best form by some manufacturers, while others prefer the "saddle-back") heats the water, which, as it becomes warmed, rises and passes out through the flow pipes; these are laid at a very slight inclination, to assist the current. When the water has arrived at its furthest extent, it enters what are termed the return pipes, on its way back to the boiler, which it enters at the lowest part, to be re-heated, to rise, flow, and return as long as a fire is kept up. A rough calculation has been made that for every 50 feet of 4-inch pipe 1 square foot of boiler surface is required. The self supplying cistern and its expansion box must be placed somewhat above the highest level at which the hot water is desired to rise, yet not so high that the pressure in the pipes will affect their joints. It should be covered, and have a pipe to allow the vapour or steam produced by over-heating to escape into the external atmosphere. With this, the low temperature system, the heat of 212°, or that of boiling water, cannot be exceeded. Jeffrey's patent *Radiator*, for hot water or steam, in single or double loops or coils, is ornamental.

2279*i*. IV. The high temperature system was introduced by Perkins, and is frequently called by his name. Water is placed in a coil and range of piping of small diameter, hermetically closed, so as to prevent all communication with the external atmosphere. A coil, being at least one-sixth of the whole piping, is heated by the action of the fire in immediate contact with it, by which means the temperature of the water in it can be raised easily to 300° or 400°; but then the same objection applies to the air warmed by pipes so heated as to that from high temperature stoves. As water expands with heat, allowance has to be made by the addition, at the highest point, of a larger tube to receive the surplus, which varies from 10 to 12 feet per cent.; one-tenth of the space of piping may thus be allowed for expansion. After the pipes are fixed, they are very carefully filled with water, so as to expel all air, through a filling tube situated at the bottom of the expansion tube, and when sufficiently full they are hermetically closed. The danger to be chiefly apprehended from this apparatus is that, if leakage takes place, the loss of water causes red-hot vapour to be formed, with the possibility of setting fire to any wood to which it may be attached. There is now no doubt but that wood, subjected to a constant current of greatly heated air, becomes very liable to combustion.

2279*k*. When heating surfaces of great extent are required to be obtained by the application of hot water or of steam, Walker's system will probably be found to be the most effectual yet introduced. It must be sufficient here to describe it as consisting of a number of small iron blocks, each block having square perforations passing through it for the current of air from the top to the bottom, of very thin metal. The blocks are enclosed in a corresponding perforated iron box, leaving 1 inch for water or steam all round each block, which heats the metal forming the blocks By this very compact arrangement 160 feet of heating surface may be obtained in a box measuring not more than 2 feet cube.

2279*l*. The rules for finding the area of hot water pipes for any sized apartment are in all respects essentially the same as will be given for steam, excepting the mean temperature of the pipes: for steam-pipes 200° is given; but 140° to 150° may be taken as that of low temperature hot-water pipes. From data obtained by Hood, *Practical Treatise*, 3rd edit., 1850, it appears that water in a pipe of 4 inches diameter loses ·851 of a degree of heat per minute, when the excess of its temperature over that of the surrounding air is 125°; and also that, under the same condition, one foot of such a pipe will heat 222 cubic feet of air one degree in the same time; whence he deduces the following rule:—Multiply 125 by the difference between the maximum proposed temperature of the room and that of the external air, and divide this product by the difference between the temperature of the pipes and that proposed for the room; then the quotient is to be multiplied by the number of cubic feet of air to be warmed per minute; and the product, divided by 222, will give the number of feet, in length of pipe of 4 inches diameter, required to produce the same effect; this length is to be multiplied by 1·33 or by 2, for equivalent lengths of pipes respectively 3 and 2 inches in diameter.

2279*m*. In making arrangements for heating by *steam*, we need not describe the construction of the furnace and boiler, or of the chimney, matters which are perhaps better arranged by the engineer fitting up the apparatus, as steam for warming purposes is rarely adopted except where waste steam can be brought into use, as in factories and workshops using steam power. The thicker the metal of the pipes the better for greenhouses and such like places; for buildings, the thinner the better, consistent with strength; say about $\frac{3}{8}$ths of an inch in thickness. Provision must be made for the expansion of pipes, both for steam and water, of about one-eighth of an inch for every 10 feet of length. The pipes should be placed near the floor, and as close as possible to the apertures for the admission of fresh air. The pipes should be laid with an inclination to the boiler, so that condensed water from the steam shall be returned to it; and they should be carried at once to the highest part of the building and descend to the lowest.

2279*n*. To form some idea of the requisite area of piping for any desired buildings, the quantity of cubic feet of air required per minute must first be ascertained. In order to ascertain this, attention must be given to the loss of heat by ventilation, and the direct influence of cold external walls, glass windows, &c. From the first cause there will be a loss of heat proportioned to the quantity of the air withdrawn per minute: if 4 cubic feet are supplied to each individual per minute, then "there will be for each individual 4 cubic feet of air conveying off a quantity of heat equal to the difference between the heat of the external air and that of the room." Thus, if the heat of the room be 70° and that of the external air 50°, then the withdrawal of 4 cubic feet of air per minute must lead off a quantity of heat equal to the differences between 70° and 50°, or 20°. From the second cause there will also be a loss, as heat is transmitted very quickly through glass; the quantity of air cooled in a given time being simply proportional to the surface of the glass exposed to the external air, and, consequently, will be constant, whatever variation of temperature may take place. The rule given by Tredgold, § 67, is as follows:—"If the area of the surface of glass be multiplied by 1·5, the product will be the number of cubic feet of air per minute which will be cooled from the temperature of the room to that of the external air;" and to this loss will also be added that arising from each door and window (independently of occasionally opening and shutting the former); this was calculated by the same author, § 65, to be equivalent to 11 cubic feet per minute, the difference of temperature between the internal and external atmosphere being 60°.

2279*o*. From a combination of these circumstances, assisted by various experiments, Tredgold, § 68, deduced the following rule:—If the number of people the room is intended to contain be multiplied by 4 (or the quantity of air allowed per minute), and added to 11 times the number of external windows and doors (as 11 cubic feet of air is passed through each per minute on an average), added to $1\frac{1}{2}$ times the area in feet of the glass exposed to the external air, the sum obtained will be the quantity, in cubic feet, to be warmed per minute. The next operation is to find the area or surface of piping which will warm this quantity of air. The mean temperature of a steam pipe at the ordinary pressure is 200°. The temperature of the air supplying ventilation is to be known at the extreme case of cold, which for the day may be taken at 30°, but for the night may be assumed in this country at zero of Fahrenheit's thermometer; the temperature to be maintained at the same season of cold is also to be settled. Then, Tredgold, § 44, gives the following rule:—Multiply the cubic feet per minute of air to be heated, to supply the ventilation and loss of heat, by the difference between the temperature the room is to be kept at and that of the external air, in degrees of the thermometer, and divide the product by 2·1 times the difference between 200 and the temperature of the room. This quotient will give the quantity of surface of cast iron steam pipe that will be sufficient to maintain the room at the required temperature. According to Dr. Arnott, 1 foot of superficies of heating surface is required for every 6 feet of glass; the same for every 120 feet of wall, roof, and ceiling; and an equivalent quantity for every 6 cubic feet of air withdrawn from the apartment by ventilation per minute. (Tomlinson, p. 124.)

2279*p*. "The Metropolitan Building Act, 1855," requires that:—I. The floor under every oven or stove used for the purpose of trade or manufacture, and the floor around the same for the space of 18 inches, shall be formed of materials of an incombustible and non-conducting nature; II. No pipe for conveying smoke, heated air, steam, or hot water, shall be fixed against any building on the face next to any street, alley, mews, or public way; (III. A pipe for conveying hot water, or steam, at low pressures is now *not* required to be kept clear of combustible materials); IV. No pipe for conveying hot water shall be placed nearer than *three* inches to any combustible material; and V. No pipe for conveying smoke or other products of combustion shall be fixed nearer than *nine* inches to any combustible material; with a penalty not exceeding 20*l*. for non-compliance.

SECT. XV.

SPECIFICATIONS.

2280. The importance of an accurate specification or description of the materials and work to be used and performed in the execution of a building, is almost as great as the preparation of the designs for it. The frequent cost of works above the estimated sum, and its freedom from extra charges on winding up the accounts, will mainly depend on the clearness, fulness, and accuracy of the specifications; though it is but justice to the architect to state that extras arise almost as often from the caprice or change of mind of his employer during the progress of the work, as from the neglect of the architect in making the specification. A specification should be made in all cases of new designs, additions, or alterations in reference to designs, which, the more they are given in working drawings by the architect, the better will it be for his employer, no less than for the artificer.

2280*a*. When the drawings have been brought to suit the client's tastes and requirements, the architect commences to prepare the working plans and details. Before these are completed, he should take up the specification. The primary and main object of a specification, is to give, fully and clearly, all necessary and useful written explanations and instructions for the execution of the work, and for making due preparations for the effecting of a definite and clear bargain between the person or company accepting an offer and the contractor offering to execute the work.

2280*b*. To write out a document fulfilling all these requirements, going into every particular, and describing fully and accurately each different part of the work, must naturally cause a lengthened document. But a line must be drawn between running to an almost absurd length and being too brief. The former may occasionally cause the specification to be neglected, as the builder or his foreman has seldom the time to refer often to it. The rotation of the various paragraphs is a very important matter. It was formerly, and is now, much the custom to divide the specification into trades, which system arose when separate contracts were taken for different branches of the work; but at the present day, when it is so general to have one contractor to carry out the entire work, it has occasionally been attempted to write a specification in a form more quickly and easily consulted than by referring to paragraphs in several trades respecting some one single portion of the work.

2280*c*. Some architects have written the main portion of the details on the drawings themselves, detaching them from the general and specific work, particulars, and conditions; but the drawings are not always at hand to refer to, if there be no "office" on the building.

2280*d*. In many large towns it has become the custom to relegate this important part of an architect's business, especially of a young one, to a "quantity surveyor." By doing this, he loses that grasp of construction and of details which the preparation of a specification, as of quantities, so greatly helps. The man who originally draws the working plans can with much greater facility write out the specification for the execution of the same than the man who, so to say, has first to learn his lesson. It should bear the impress of the artistic feelings of the designer, which the quantity surveyor can never give it. Each item is usually taken separately, and should be clearly described; simple language should be used, without abbreviations; all such words as proper, properly, sufficient, with others, should be avoided; involved sentences, bad punctuation, and faulty grammar should not appear, and each sentence should bear but one meaning; but, regarding the haste with which specifications have to be drawn up, these are sometimes unavoidable. Sketches made in the margin, of difficult bits of construction, as well as of ornamental details, may be copiously used, especially if the detail drawings are not fully prepared.

2280*e*. Specifications are now usually lithographed, which saves much trouble and risk in examining each copy that may be required.

2280*f*. It is advisable that the agreement with the artificer or contractor should be drawn up by the client's solicitor, who, no doubt, will seek the assistance of the architect.

2280*g*. It is impossible to frame a set of directions which shall be applicable in all cases of buildings. Something like a list or skeleton of the component parts of buildings are given in the following pages, from which the architect may select such as are suitable to the particular case whereon he may be engaged. This is not carried into the repairs and alterations of houses, because, with difference of application, the same system can be carried forward in such cases without difficulty. Chapter III., USE OF MATERIALS, OR PRACTICAL BUILDING, may be consulted for many other details.

2280*h*. The following pages have been rewritten, condensed, and added to as necessary. A large amount of information as to the manner in which materials are used and put together is contained therein. There are several books on the subject, one of which, Pewtner's *Comprehensive Specifier*, 8vo. 1870, should be on the student's shelf.

2280*i*. Among the Acts of Parliament, &c., to which the attention of the architect and of the builder has to be directed, are the following. Towns and several other places, and the London parishes, &c., have their own local Acts and bye-laws.

Metropolitan Building Act, 1855, 18 & 19 Vict., c. 122. Amendment, 1860, 23 & 24 Vict., c. 52. Amendment, 1869, 32 & 33 Vict., c. 82.

Metropolis Management Act, 1855, c. 120. Amendment, 1862.

Metropolis Management and Building Acts Amendment Act, 1878, 41 & 42 Vict., c. 32. Amendment Act, 1882, 45 Vict, c. 14.

Metropolitan Board of Works, Bye-Laws, after 1878.

Public Health Act. 1875, c. 55.

Knight's Annotated Model Bye-Laws of the Local Government Board, 8vo., 1883, is useful.

GENERALLY.

2280*k*. The contractor to supply all requisites; to provide all materials, new and of the best quality; to execute and complete in the best and most workmanlike manner all the works set forth in the specification and drawings, to the satisfaction of the architect; to give notices to, and pay fees and charges of all local authorities and officers, as district surveyor, paving board, for hoarding, water, gas, and such like (the rights as to advertising on hoardings to be reserved, or not to be allowed as on some estates, and as to the gravel and sand that may be found on the site); to provide a watchman; to insure from fire in the names of the builder and the client; to provide and maintain on the site an office for the clerk of the works, furnished, and for the custody of the drawings and papers; to afford access for the architect, his representative, clerk of the works, and the client, to the premises; to remove all dirt and rubbish; to sweep out and scour all floors, and clean all glass, and to deliver up the building and premises in a satisfactory state at the conclusion of the works, or at a specified time (it is not very clear when a house is "completed"); as to the use and possession of the documents, and of making copies; to keep on the building a foreman of the works; to carry on the works, and to complete the same; as to unfit workmanship and materials, and works not in accordance with the directions; as to day bills; all disputes to be settled by the architect, or arbitrator agreed to before signing the contract; sum to be allowed for contingent works; as to sureties, time of payments, &c. Besides the above, it would be well to refer to the "Heads of Conditions of Builders' Contracts," sanctioned by the Royal Institute of British Architects, 1882.

EXCAVATOR.

2281. To *take down* any old buildings and impediments that may be on the site of the new works. If any old materials are to be used again, he is to clean, sort, and stack them for re-using in such parts of the premises as may be directed. The rubbish, as well from these as from any superfluous earth that may come out of the basement and foundations, if not wanted for any purposes, he is to cart away, either wholly, or to such part of the premises as he may be directed, as well as all rubbish that may accumulate in executing the works. To *reserve* any clay dug out, and to thoroughly burn it with small coal into ballast, as directed.

To *strip* the surface soil to a certain depth. To *dig out* for basement story (where one is to be), for the foundations, areas, drains, floors, and all other works requisite. To beat down to a solid consistence the ground forming the beds of the trenches for receiving the foundations and walls, and after they are in, he is to fill in and ram down the ground; to level, and to do such other rough groundwork as may be necessary for forming the sectional ground lines shown upon the drawings. To prepare for concrete in foundations. To cover over the ground under paved or tiled floors (except where the tiles are laid on joists) with broken bricks well rammed and grouted with liquid mortar. This layer is to be made of sufficient thickness to receive 6 inches of concrete, which is to be properly rammed and covered with a layer of 2 inches of fine concrete, finished with a level surface. In basements no earth is to be left nearer than 9 inches to any floor or other timbers, such cavities being by the specification to be filled in with dry lime core. If water cannot be supplied by any public company, a *well* may have to be provided, as in next section. To leave the ground free from all useless soil or materials.

Roadway and Paths. Remove the top soil from the intended lines of the roads; spread over the site a stratum of coarse stone ballast, or of brick rubbish, 12 inches deep; cover the same with coarse gravel, spread, beaten, and rolled down until hard and solid, forming the width with a curve to each side, and rising . . . inches in the middle. The *Paths* to have a stratum of coarse stone ballast (or burnt brick ballast where such is to be obtained), or of brick rubbish, 4 inches deep; cover the same with 3 inches of fine red gravel, well beaten down and rolled over until solid, and to be formed to a curve rising . . . inches in the centre.

2281*a*. EXCAVATOR.

To *bale out or pump out* and remove all soil and water which may be necessary for laying the foundations, whether arising from springs, drains, cesspools, rain, or otherwise, and to be answerable for all accidental damage that may occur whilst the foundations and walls are carrying up; as also, when buildings adjoin, for all damage that may occur to neighbouring buildings.

BRICKLAYER.

2282. The *brickwork* is to be executed with the very best hard well-burnt grey stocks (or kiln-burnt red stock bricks, or such others as may be directed), to be laid in flat joints, and so that every four courses shall not exceed $11\frac{1}{2}$ inches in height.

When better bricks are used for *facing* external walls, they are to be specified (as best marle stocks, second marle stocks, Suffolk white bricks, as the case may be), in which case it must be specified that no headers of the facing are to be cut off, except where absolutely necessary to form good bond. Fronts so faced are to be either carried up with a neat flat parallel ruled joint, or to be afterwards tuck-joint pointed if a finished face is wanted, though the latter is not altogether a sound practice. In old work the joints have to be raked out, the brickwork washed, stained, and tuck-joint pointed. No place or samile bricks to be allowed in any part of the work.

The *mortar* is to be compounded of well-burnt stone lime and sharp clean grit or drift sand (if the work be of importance), to be ground in a pug-mill, or otherwise to be well tempered and beaten with wooden beaters, and to be in the proportion of one heaped bushel of lime to two of sand. (The use of sea sand is sometimes to be avoided; and road scrapings, unless very well washed and screened.)

When the earth foundations are bad, *concrete* should be provided; it is to be formed in the proportion of six parts of Thames or other unscreened clean ballast, and one part of fresh-burnt Dorking (or other) *stone* lime, beaten to powder on the premises, and unslaked. They are to be thoroughly mixed in small quantities at a time, the lime at mixing being slaked with as small a quantity of water as possible. The concrete, after mixing, is sometimes stated to be dropped from a stage, but this is a bad practice. The thickness may vary from 4 feet to 18 inches in height, according to the quality of the earth or soil, and the width about six inches on each side wider than the wall.

Damp course. The brick or stone walls and partitions to be covered with a continuous layer of asphalte at least $\frac{1}{4}$ inch thick, poured on while hot, at above the level of the outside ground as finished. A continuous layer of 5 lb. milled lead has been used. Taylor's patent vitrified stoneware, of 1, $1\frac{1}{2}$, or 3 inches thick. A course of Bangor slates in cement 3 inches lower than the general level of the ground floor (and where else as needed). See *par.* 1886*b*, *et seq.* for methods of obviating the rise of damp.

English bond is preferred by many to Flemish bond; for good work, the brickwork should be specified to be flushed up at every course with mortar. No bats to be allowed except for closures; and for sound work every fourth course to be *grouted* with liquid mortar, and in the foundations every course, or at least every second course. The walls, chimneys, their shafts, piers, and other works, to be carried up of the height and thicknesses and in the manner shown and figured on the several plans and drawings, together with all brickwork requisite for the completion of the house. When the work is within a district under bye-laws of a local board, and not required to be of special solidity, it will be well to describe that the thicknesses of the walls, their heights above the roofs, and other matters, shall be conformable to the regulations.

Work to appear without a stone or plaster facing requires *rubbed* and *gauged arches* for all the external openings in the principal fronts, of 9 inches in depth (or more according to their span), accurately cut, and set closely in front, in back, and on their sofites. To the other openings the arches will be plain arches, closely set; those which appear externally to be tuck-pointed on their outside faces. Over all lintels, in external walls, should be provided uncut accurately formed arches.

When *fascias* are formed of brick, their projections must be named; also all cornices formed by arrangements of bricks; but a drawing should, for the latter, appear on the drawing or specification.

Any *moulded bricks* are to be carefully made in accordance with the detail drawings, and to be trimmed up before they are placed in the kiln. They are to be made a little thicker than the other bricks, so that the beds and joints may be rubbed true before they are laid; they are to be set in fine mortar, and (before the scaffolding is struck), they are to be rasped, rubbed with gritstone, and the arrises to be made as straight and true as stonework.

2282*a*. Bricklayer.

Work into the exterior and interior faces of the walls (if required), crosses, diapers, zigzags, or other patterns; and form bands, string-courses, &c., with white, black, red, or other bricks, as shown on the elevations, &c. The red and black bricks are to be laid in blue-black or other mortar, or the joints to be raked out and pointed with the same.

Shafts of *chimneys* carried up above the roof, out of the common way, must be referred to drawings; otherwise what relates to them and their flues is described as follows:—*Turn, parget*, with cow-dung mortar (or point the inside of all flues with a flat mortar joint), and *core* the chimney flues, and finish the shafts with salient courses 6 inches (or more) in height, with *double plaintile creesing* thereto; for each flue provide and fix a large-sized chimney-pot (of cement, plain or moulded; or of earthenware, or ornamented, as may be necessary); the upper courses of the shafts above the creesing to be laid in cement.

Parapets not coped with stone or cement are finished with double plaintile creesing, and a brick on edge on top, or as shown on drawing, all laid usually in cement.

Where weather is to be provided against, as in upper courses and elsewhere, the laying in cement must be described.

Turn *trimmers* of 4-inch brickwork to all the fire-places for receiving the stone, marble, or cement hearths throughout the building, except where, as in basement stories, the hearths lie on fender walls, or on the ground.

Tile-arch or flat. The . . . . to be covered with 3 courses of plain tiles set in cement, the tiles to be first well soaked in water.

To basement stories, or the story on the ground, describe *piers* 9 inches square, or continued walls 9 inches thick, to carry the sleepers whereon the joists of the floor or the courses of paving stone are to lie; the cavity, if small, may be filled with dry lime core. Where the piers or sleeper walls are high, arches may be formed in them to save material, afford ventilation, and sometimes access throughout the cavity.

Build 9 inch *sleeper walls* to support ends of joists of wood floors abutting upon paved floors (as in a church), and build half-brick honeycomb sleeper walls on one brick footings, 4 feet apart, under all wood floors in basement, or on ground floor when not excavated under.

Foundations to piers of arches to be in brickwork of hard bricks, laid in cement, and every course throughout the foundations to be well grouted.

Bed in mortar all *bond timber*, wall or other plates, lintels, wood, bricks, templets, stone, or other work connected with the brickwork. All the door and window frames to be bedded in and pointed round with lime and hair mortar. Execute all requisite beam-filling.

When the building is *faced with stone*, or stone dressings are used; to the above must be added—back up and fill in solid with brickwork all the stone work and iron work that is set in the brickwork.

If *cornices*, *fascias*, &c., are to be run in cement, then—prepare and fix brickwork, and such Yorkshire stone slabs and other materials as may be necessary for forming the several external cornices, pediments, strings, sills, and dressings to openings, in cement, as shown on the drawings.

Brick *relieving arches* that are visible are to be formed of three or four courses of red and black bricks, alternately or otherwise, as shown, or as the architect may hereafter direct.

Turn arches in cement (if wanted) for carrying entrance or other steps. Provide all brickwork for stone steps. Turn vaults of brickwork (describe thickness not less than 9 inches) over the intended cellars, according to the drawing, and properly cut all groins of intersections. The spandrels to be filled in with solid brickwork up to the level of the internal crown of the vaulting, the whole grouted with liquid mortar. When the centering is struck, the sofites of the vaultings are to be evenly and fairly cleaned off, and pointed.

Construct round the building a *dry drain* or area, as shown on the drawings. Ram down the ground at the back thereof as the work is carried up, and provide such stays of stone, slate, or iron wall-ties from the building as may be necessary for maintaining such wall in its place, and as will not carry the damp to the main wall. Such dry area may probably require a drain if the soil be very wet.

Drains for draining the premises, as shown on the plans, to fall into a main sewer (or cesspool, as the case may be). The principal drains to be 1 ft. 6 in. and the smaller ones 12 inch, 9 inch, 6 inch, and 4 inch diameter, as the case may require, of glazed socketed stoneware pipes (state manufacturer), at depths as figured on the drawings. Provide all necessary bends and junctions. All the pipes to be jointed in cement, and the drains to be properly connected with the sewer (or cess-

2282*b*. Bricklayer.

pool). The outlet of the drain to have a galvanized iron flap to shut flush all round. The feet of all rain-water and waste pipes are to be brought on to the grating of a syphon trap, or to be let into it under the grating, as may be preferred. The lead soil pipes to be carried into syphon traps. The main drain is to be ventilated by a lead pipe carried up above the roof and clear of all openings and chimneys; and at or near its connection with the sewer should be placed an "interceptor" with a syphon trap, for the purpose of readily cleaning out the drain if it become stopped. This chamber should also be ventilated in like manner to prevent foul air ascending the drain.

When foul water cannot be carried off to a public sewer or running stream, *cesspools* must be formed to receive it, and made water-tight, if possible, or allow absorption by the earth. They are usually 3 feet 6 inches to 5 feet clear diameter, circular on plan, steened round with hard stocks, in half a brick thick, laid dry till within 18 inches of the top, which 18 inches are to be laid in cement. If the water-closets be far apart, each may have to be provided with a cesspool, and apart from the building. Cesspools (and also wells) are sometimes domed over in brickwork, with an eye or opening for access, a circular stone being let into the opening; or the cesspool be covered with a Yorkshire stone slab.

Wells, when above 6 feet in diameter, to be steened one brick thick; and when less than that size, in half a brick, laid flat, paved at bottom, and domed over as for cesspool.

Execute walls for carrying the columns of the *portico* as shown on the plan, all piers or cross walls for receiving the landings, and brickwork to receive the steps. If the portico be of large size, describe discharging arches above the architrave in the space over intercolumniations, and from return columns to main walls. If a pediment, back up with brickwork behind the tympanum of pediment quite up to under side of raking cornice of pediment.

For *fence walls*, their footings, thicknesses, heights, and lengths are to be mentioned, and of what bricks they are to be built. If anything peculiar in their form, a drawing should be given.

Bricknogged partitions are described as with grey stock bricks laid flat in mortar, or on edge, filled in between the timber quarters, ties, &c.

Strong closets for plate or deeds require a description of thickness of walls and brick arch and paving, and usually 4-inch walls brought up for holding the requisite number of slate or iron shelves. A fireproof (and perhaps burglar-proof) door may be required to be named; and if the room be large, an inner grated door may be useful. The same of *wine cellars*, whose bin walls and slate shelving must be mentioned.

When the building is to be *heated* with hot air or hot water, then:—build furnace room where shown on plan, with flues as necessary; or, build channels for hot water pipes under floors; the channels to be 2 feet high by 12 inches wide in the clear, resting upon 3 inches of concrete and a double course of Bangor duchess slates to form channel floors; the sides to be half a brick thick in mortar.

Paving with bricks is described to be either of stocks, paving bricks, malm paviors, or clinkers, which may be laid flat, or on edge, in sand, mortar, or cement, and either straight-coursed or herring-bone. *Paving with tiles* is usually in mortar; the tiles either 6, 8, 10 or 12 inches square.

All splays, *ramps*, *and chases* to be cut where wanted; the two former to be rubbed where necessary, and the latter to be pargetted.

Brick ovens (one 10 feet wide and 8 feet 6 inches deep will bake twelve bushels of bread, and one 8 feet wide and 7 feet deep will bake eight bushels, and so in proportion) are to be constructed with Welsh lumps or fire-bricks for fire-place, domed over, and hooped with iron hoops. The bricklayer is to provide the bars, plate door, bar to the archway of door, and other ironwork, and to carry up a proper flue from the fire. This is often a separate trade.

An *Iron oven*, capable of baking two bushels of bread, to be set in proper brickwork.

Coppers and stewing stoves to be set neatly in brickwork, the latter in gauged brickwork with tile top, and flues carried up therefrom. Set the kitchen range (or kitchener) according to its requirements; and set all fire-grates at back and sides well backed up with brickwork in cement, and cemented at top to prevent soot getting down behind the grate.

Columns to porticoes, or *fronts*, which are to be coated with cement must be described of such diameters as the drawings require, with entablature, &c., as the case may be, carried up in cement.

For *stables*, besides what may be applicable from the foregoing directions, two *air-flues* are to be constructed to each stall and loose box, 9 inches square, and carried

2282*c*. Bricklayer.

up over the racks within the thickness of the brickwork, communicating at their tops with the external air, and secured from the penetration of the rain.

Dung-pit walls, whose dimensions depend on the size of the stables.

Dust-bin, to contain 30 feet cube, to be of half-brick walls in cement. The deal top, and cover hinged with water-joint hinges. and with deal slides and door in front, to be provided by the carpenter. Morrell's patent cinder-sifting ash closet is adapted for outdoor use. The "galvanized iron dust-bin," which is easily emptied in towns, has much superseded the old wood or brick dust-bin, with its inconveniences and smells. They are non-absorbent, and are made 24 × 20 × 37 ins. high at back; also 27 × 20 × 37; also 30 × 20 × 37 (see also 1907*d*). *Dust shoots* are now used in artizans' dwellings; one is so arranged as to prevent the passage of foul odours into the building should the hopper be left open.

In cases of *underpinning*, the bricklayer is to cut all holes for the needles, and to remove the old work, and to bring up the new work in cement on concrete foundation; and, finally, drive in the cast iron wedges for bringing the work to a solid bearing.

Hollow walls for exposed situations. The external walls above the plinth line are to be built with a hollow cavity in the middle of about 3 inches, having courses of bonders or through stones not more than 1 foot apart in height, and of various widths, but never more than 2 feet 6 inches apart. At the level of the top of the plinth a course of thick slates. or of thin stones, is to be worked on the walls, closely bedded in strong mortar under all the voids or flues thus formed, and a small aperture, 9 inches by 6 inches, is to be made for the admission of air and to carry off any moisture that may have been driven in; openings into each of these flues are also to be made between the joists of the different floors for ventilation. Other methods of building such walls are described in Chap. III. Sect. II. *par.* 1902*c*.

Fence wall. The site to be enclosed with a 9-inch stock brick wall in mortar, . . . feet high, with brick footings 6 inches high, with two $2\frac{1}{2}$-inch set-offs on each side of the wall, laid on concrete 9 inches thick and 2 feet 6 inches wide, the bottom being . . . feet below the finished surface of the ground. The top of the wall to have a brick on edge course set in cement (or other coping, to be specified).

Provide (according to the extent of the job) a certain number of *rods of brickwork*, at a price per rod to be named, for such extras as may be ordered in writing by the architect; if the whole or any part thereof should not be wanted, a deduction to be made on settling the accounts.

To build all the walls level, except otherwise directed; to be answerable for all damage that may occur to the work, by settlements or otherwise, during the time of building, and to rebuild or make good the same as the architect shall direct; and, further, to perform all such jobbing work as shall be necessary for completely finishing the building. To provide good sound and sufficient *scaffolding*, which is to remain for, and to be altered for, the mason, carpenter, and other artificers that may have occasion to use the same. A specimen brick of every description, splayed, moulded, for facing, &c., to be submitted to the architect for his approval before the commencement of the work.

SLATER.

2283. To cover the *roofs* with the best strong Westmoreland, best Bangor, Tavistock, or other slate and size to be named, each securely fixed with two best strong copper nails. To be properly bonded, especially at the eaves and heading courses, with slates cut to keep the bond uniform; the bands and diapers to be formed of Carnarvon or Westmoreland green, or other coloured slates; or courses to be laid of slates cut to a notched pattern. No slates to be laid lengthwise. A little latitude may be allowed as to the exact size of the slate to be used. By specifying sizes, other than Countesses and Duchesses, there would frequently be less delay and less expense in covering.

If *roofs* are covered with tiles, either *pan* or *plain*, the description for the former will be either laid dry, or bedded in lime or hair, or pointed outside or inside, or on both sides; or if glazed pantiling, to be so described, laid to a 10-inch gauge on stout fir laths, with hip, ridge, and valley tiles, filleting, cutting to splays, beam filling, painted T nails, hip hooks, &c. *Plain tiling* is described to be of good sound tiles, laid to a close gauge on heart of oak double laths, combined with ornamental tiles, to form patterns, as shown; every tile to be pegged with a good English-oak peg, and laid in mortar to a 3-inch lap. The hip and ridge tiles to be set in cement, with T nails dipped in melted hot pitch, in all the joints. Strong, similarly pitched, wrought iron hip hooks. Filletings of cement, with strong cast

2283*a*. Slater.

iron nails for forming a key driven into the walls or other brickwork at intervals close enough to secure the same. Cover the *ridges* with socketed roll Staffordshire ridge tiles set in cement; the tiles to be grooved for cresting (if any). Cover the *hips* with proper lapping hip tiles or rolled hip tiles. Provide ornamental *tile cresting* (if any), and fix same on ridges where shown on elevations.

Fillets (other than lead flashing) against the brickwork, where requisite, of gauged stuff or cement, formed on nails driven at intervals to form a hold. Fillets of brick or stone may be built up with the wall, level or raking; and if they should be preferred, they must be described in the bricklayer's or mason's works.

If the slating be required to be rendered air-tight, it must be described to be pointed on the inside with lime and hair mortar; but this pointing, from the expansion and contraction arising from heat and cold, may soon fall out. The slater to be answerable for twelve months for his work.

All the slating is to be rendered up perfect on completing the building, and all jobbing work to be performed that may become necessary as the work is carried on.

Provide slates to form damp-proof course in walls; and for the bottoms of hot water pipe channels (if any).

Slate slabs are now much used for sinks, cisterns, steps, skirtings, sills, covering to bay windows, mouldings, doorsteps, linings, chimney-pieces, trusses, lavatories, nosing to steps, &c.; they must be described.

MASON.

2284. The *stone* to be used in a building generally depends of course on the place where it is to be built, unless, without regard to expense, the employer determines on the use of any particular sort. Chap. II. Section II. furnishes the means of describing the best of its sort. In London, Portland stone is most used. Granite or other hard stone is used where great strains and pressures occur, or where use and wear, and the action of the weather, indicate its employment.

Having described the sort of stone selected to be of the best quality, free from all vents, shakes, &c., the next direction is, that it shall be throughout laid in the direction of its natural bed in the quarry; and if the whole building is of stone, many of the following particulars will be unnecessary. Where the building is only faced with stone, then the . . . fronts (describing them) are to be faced with Portland (or other) stone, ashlaring in courses to fall in with the courses of brickwork; the stretchers of such ashlaring being $4\frac{1}{2}$ inches deep and the headers 9 inches, with bond stones running through the whole thickness of the wall in the proportion of $\frac{1}{16}$ of the face, to be introduced where the piers allow. No quoins to show a thickness of less than 12 inches. The whole to be cramped with gunmetal cramps, the mason finding the same and properly running them with lead.

Where the building is of *brick with stone dressings*, then—To provide and set a Portland stone (or other stone or granite) plinth all round (or part, as the case may be) the building, . . . feet . . . inches high and $8\frac{1}{2}$ thick, in stones not less than 3 feet in length, the vertical joints to be cramped with T cramps not less than 12 inches long. Describe whether joints are to be close or channelled, and whether ashlar is to be rusticked (rockworked). To provide and fix at the angles of the building, as shown upon the drawings, solid quoins of Portland (or other) stone [describe whether close, chamfered, or channelled joints, and whether rusticked] of the length and height shown.

Kentish Rag. The Kentish rag to be of the best quality, from the quarries at Boughton, sound and free from hassock, laid in random courses, galleted and pointed with dark mortar. A sufficient number of bond stones to be built in, one through stone (at least) to each yard superficial.

Bath Stone. To be the best Bath stone from Sumsion's, Pictor's, or Randall and Saunders's Combe Down quarries (no Farleigh Down stone to be used), to be laid on its natural bed in all cases, and cleaned off when set. All plinths, bases, and other work for a height of 4 feet above the ground level to be of Box Ground stone.

Random walling of local stone. The stone for the walls generally is to be brought from . . . (state the quarry), that for the foundations (unless brickwork is used for them) to be of large size; all those in the visible surface of the walls are to be carefully hammered, scabbled, or sawn (as the quality of the stone and nature of the work may require). All stone used in the main walls of the building to be of good scantling, and no very thin stone will be allowed in any part.

Walls with concrete cores. The external face to be built up in courses of hammered, scabbled, or sawn stone. The internal face to be built up in sawn (or other) ashlars, or in rough brickwork, in English bond, or rubble if it is to be plastered. The

2281a. Mason.

body of the walls to be filled in with strong concrete, composed of 1 part of ground stone lime and 5 parts of clean sharp gravel, filling in interstices. At every 2 feet 6 inches in height a double course of bricks is to be set in mortar, and at every 8 feet 6 inches in height a bonding through stone, from 10 inches to 1 foot 3 inches deep, is to be fixed. Small stone chippings may be mixed with the gravel forming the concrete.

Regularity in the *quoin stones* is not desired, but they may be worked and set in any reasonable scantling so as best to bond in, and harmonise with, the intermediate rubble. The upper beds of the stones to be laid with a slight inclination outwards, and as close as their nature will allow. Every precaution is to be taken to avoid risk of the settling of the work from imperfect beds and open joints. The work is to be carried up regularly all round the building. In the case of a church with a tower, the walls of the latter are to be specified to be built up very slowly and without being bonded into those of the church, but are to have slip joints or chases worked in them for forming the connection; this is in all cases to be so free as to allow for the settlement of the masonry without injury to the work in the church walls; with this exception, no part of any wall is at any time to be raised more than three feet higher than another, during the progress of the works.

The walls of the *tower* of a church are to built quite solid, and inverted arches are to be turned under all the large apertures therein. All flat headed apertures are to be covered with York (or other) lintels, of thickness proportionate to the width of the opening.

A *cornice and blocking course*, scantling . . . by . . . , moulded, to be provided according to the drawings, the bed to be such that the weight of each block of stone in the projecting part shall not be equal to that on the bed by one-fourth of its cubic contents. The same to be executed according to the drawings; to have proper sunk water joints, and to be channelled and plugged with lead at all the joints.

String-courses to be . . . inches by . . . inches, throated and bevelled on the upper face, and the joints plugged with lead.

Blocking course, as shown on the drawings, . . . inches high, . . . thick on the bed, and . . . on the top, plugged with lead at all the joints, with solid block at the quoins, returned at least 24 inches.

The *quoins*, jambs, *string-courses*, hoodmoulds, buttress weatherings, copings, and dressings generally, to be strictly worked according to detail drawings, and to be dragged, chopped, tooled, or rubbed (according to the quality of the stone) so as to be truly worked in every particular.

All the *tracery* and *mouldings* to be set out full size, and cut and set to the right jointing, as approved by the architect or the clerk of the works.

Face the walls of . . . with Minton's glazed (or other) tiles, value . . . per yard superficial, to be secured with cramps of stout copper wire inserted in holes in edges of the tiles.

All the *paving tiles* to be of the best quality, free from blemishes; to be set in Roman cement, and to have all cement removed from their face after the work is finished; the edges of the tiles to be rubbed, where necessary, to ensure neatness, and care is to be taken that the tiles are not injured by the workmen after they are laid.

The *base mouldings* of the tower, jambs, and arches of the windows and doors throughout the building, and whatsoever parts are tinted . . . upon the elevations, are to be of tooled or dragged masonry.

The *plinths*, eaves, string courses, and the labels over the windows and doors, are to be of Ketton (or other suitable) stone, finished with a dragged or tooled face.

The *coping of the gables* to be of Bramley Fall (or other stone that is not porous), worked as shown, and the apices of the (here enumerate which) gables to be surmounted by crosses worked in Ketton or other stone, according to drawing, set with copper dowels.

Balustrades to be provided of the heights and sizes shown on the drawings. The balusters to be wrought out of one stone, allowing at least one inch of joggle at their ends into the plinth and impost. All the vertical joints to be well plugged with lead; the imposts to be cramped with cast iron (or bell metal), and the whole to be securely fixed. The half balusters to be worked out of the same block of stone as their adjoining pedestal.

Columns and pilasters, with their pedestals, capitals, bases, plinths, &c., and entablature, to be fixed as shown on the drawings. The columns and pilasters to be monoliths, or not to be in courses of more than . . . blocks of stone. The architraves to be joggled from those resting on the columns or pilasters themselves, and these as well as the frieze and cornice to break joint over the architrave. The architraves, if blocks of stone can be supplied large enough, to be in one block from

2284*b*. Mason.

centre to centre of column, with return architraves in like manner. The whole of the entablature (as well as the pediment, if any) to be executed with all requisite joggles and cramps (and if a pediment, the apex to be in one stone). The pilasters (if any) to be bonded not less than . . . inches into the wall, against which they are placed in every other course. The sofites of the portico to be, as shown on the plan and sections, formed into panels and ornamented. Provide and let into the top of the architrave good and sufficient chain bars, with stubs on the other side for letting into every stone composing the architrave.

The *caps and bases* to piers to be in large stones. The caps and bases to dwarf shafts (if any), and the corbels under wall pieces or other roof timbers, to be well pinned into walls, and sunk and dowelled to receive shafts or timbers.

If a *portico* is shown, to provide and fix of solid . . . stone . . . steps round the portico, scantling . . . by . . . , properly back-jointed and worked all over; and within the portico to provide and fix a complete landing of stone, at least 4 inches thick (or less, if a small portico), in slabs, as shown. The joints of the steps and landings are to be joggled and run with lead. If the *portico* be very large, it is not necessary to make the frieze solid, but concealed arches should be turned in the space from column to column to support the superincumbent weight of the cornice and pediment. If the columns are fluted, it must be mentioned. When a *pediment*, the tympanum may be described to be faced with ashlaring.

To construct and fix *dressings and sills* to the external windows and doors, as shown on the drawings, with all such throated, sunk, moulded, carved, rebated, and other work as may be necessary.

To describe *sills* generally:—

Sills to . . . windows of . . . stone, $9\frac{1}{2}$ by 6 inches. To . . . windows moulded and of . . . stone, 14 by 8 inches. To . . . windows of Aberdeen granite, finely tooled, 14 by 9 inches. To . . . windows of . . . stone, 9 by 5 inches. All sills are to be properly sunk, weathered, and throated, and at each end to be 4 inches longer than the opening.

The *tower and spire* to be carefully carried out in accordance with detailed drawings. The spire to spring from squinch arches or from the solid broaches (or as the case may be), and gradually reduced towards the top, each stone to be wrought and cut to its through bed and inclination of its plane, the parts (as shown) to be in solid ashlar and carefully tailed and bonded. The bands, mouldings, cornices, strings, &c., to be worked as shown, and continued round; the storm lights to be formed with solid sills, heads, &c.; the vane to drop through the finial and to be securely fixed. The windows of the tower and the storm lights of the spire to be grooved for louvres of wood or slates (or to be filled in with thin slabs of stone with ornamental piercings).

Turn *relieving arches* over all arches of nave, chancel, &c., formed of different coloured stones, arranged as directed, and form bands, diapers, crosses, &c., of same where shown. The stones for parti-coloured work to be Pennant, Caen, Temple Quiting, Red Forest of Dean, Silver Grey Forest of Dean, Red Mansfield, Whinstone, or Blue Warwickshire stone (or local stone, if of suitable colour).

Provide *shafts* where shown of Derbyshire, Devonshire, Purbeck, or other marble, or of alabaster, serpentine, Aberdeen or Peterhead granite (or other material as may be selected), to be well polished, and to be sunk, dowelled, and secured into caps and bases. Shafts in angles of doorways (if any) to be of any suitable dark stone (if necessary) to contrast with the jamb.

All *ornaments*, carving, enrichment of capitals, of columns and pilasters, and of such as may be shown in the entablature, is to be executed in an artist-like good style. Models from the working drawings are to be made at the contractor's expense, and the whole to be executed to the satisfaction of the architect. The Order may, however, be described if the working drawings are not sufficiently made out.

Plinths and base mouldings to the portico, as shown on the drawings, to be worked out of (describe stone) . . . stone of . . . by . . . scantling.

Finish the *chimney shafts* with mouldings as shown in the drawings, or with sunk moulded and throated copings, . . . inches wide and . . . inches thick.

Damp course. All the walls to have Yorkshire stone 3 inches thick and 4 inches on each side wider than the several lowest footings, in slabs of one length across the width of the footing. This was an old custom.

Balconies to a house:—A balcony landing of Portland stone, . . . inches thick, moulded on the edges and the pieces carefully joggled together, and run with lead, to be provided with holes cut therein for the iron railing. The said balcony is to be tailed into the wall, and securely pinned up.

Steps to the doorways must be described as to scantlings. All external steps should be weathered.

2284c. MASON.

For a *back staircase*, carry up and construct a staircase from the basement to the principal floor, with solid Yorkshire quarry steps 13 inches wide and $6\frac{1}{2}$ inches high, properly back-jointed and pinned into the brickwork; cut holes for the iron balustrades. N.B. This sort of staircase of Portland will serve also for back stairs of upper flights. That from the basement may also be made of granite street curb, 12 by 7 or 8 inches. A staircase may, for cheapness, be made of Yorkshire stone paving 3 inches thick, wrought with fair tooled edges, and securely pinned into the brickwork.

Principal stairs to be of Portland stone (as may be), to extend from principal to . . . floor, with steps and square (or semicircular, as may be) landings, entirely of solid stone, tailed 9 inches into the brickwork, with moulded nosings and returned nosings, and also at the back. The sofites to be moulded to the shapes of the ends of the steps. The landings to be 6 inches thick, with moulded nosings and joggled joints, run with lead, to be inserted at least 4 inches in the walls, but such as tail into the walls, as steps, must go at least 9 inches into the walls. When the under sides of the steps of the geometrical staircase are not moulded, the nosings are returned so as to fall beyond the upright line of the succeeding tread; in this case the sofite or string is plain wrought.

The steps to the *sanctuary and chancel* of a church to be of rubbed Portland, Red Mansfield, Robin Hood, Craigleith, or other hard stone, or of marble, in lengths of not less than 10 feet, very carefully set and bedded, pinned, joggle jointed, and run and plugged with lead, and back-jointed to receive tile paving.

Pave the entrance hall and principal staircase, together with (any passage, &c.), with the best . . . marble, and border according to the pattern drawn. The back staircase (and such other parts as require it) to be paved with Portland stone 2 inches thick, laid in squares, and with a border 8 inches square.

Where *story posts* are used in a front, it is well to place along the front two pieces of parallel square Aberdeen or other good granite *curb*, 12 inches by 9 inches, cut out to receive the bases of the columns and story posts.

Pave the *scullery*, larder, pantry, passages, lobbies (and other such places as may require mention), with rubbed Yorkshire stone $2\frac{1}{2}$ inches thick, laid in regular courses with close rubbed joints.

Pave the bottom of the *air drain* with Yorkshire paving.

Yards may be paved with $2\frac{1}{2}$-inch Yorkshire paving, or such other as the place affords, as in common use. The same to basement stories.

Pave (if a church) the entrance passage, porches, &c., where coloured on plan, with Minton's (or other) encaustic tiles, one third (or more or less) being figured, combined with chocolate and black tiles, value . . . per yard superficial, manufacturers' prices. Pave the chancel (usually with richer tiles) with tiles value . . . per yard superficial.

The *tiled floor* (when laid on joists): Spike fillets to joists at 3 inches below their upper surfaces; fill in between the same with inch rough boarding. The vacuity to be filled up with pugging of concrete flush with the upper surface, finished with a layer inch thick of Roman cement smoothly floated to receive the tiles.

Dairy to be paved with . . . stone (or marble) in regular courses, . . . inches thick. Provide a shelf or dresser round the said dairy of veined marble (or slate) 1 inch thick, and a skirting round it 6 inches high. The dresser to go into the wall 1 inch, and to be supported on veined marble piers 4 inches square.

To fit up the *wine cellar* with bins, as per drawing, with 2-inch Yorkshire stone shelves (some prefer slate), fairly tooled, supported on half-brick uprights, all set in cement. A cellular hexagonal brick has been patented by King and Smith, of Weedon, to be used to form the wall of a vault; each is hollow and open at the inner extremity, so that each brick becomes the receptacle for a bottle. They are made of three different sizes.

To provide and fix a *warm bath* of veined marble; rendered waterproof by being properly set in Dutch tarras, and plugged and cramped with copper at the joints, with all requisite finishing. A marble step round two sides of the bath. Cut all holes necessary for laying on the water. A bath, if a fixture, may be similarly made of slate, which is of course much cheaper.

Where *iron girders* are used, describe . . . . pieces of granite street curb, or 3-in. Yorkshire stone, as corbels or plates, each . . . . long and . . . . wide, to receive the ends of the iron girders.

Where *chimneys* project without support from below, corbels must be described proportioned to the weight they have to carry. The best *corbel*, however, is the gradual projection of the work by inverted steps, which, if there be height to hide them, should always be the mode of execution.

2284*d*. MASON.

Cellar doorways should have in each of them three pieces of Portland or other such stone 18 in. wide, 18 in. long, and 9 in. high, cut out to receive the hinges and also the rim of the lock.

The commonest *chimney-pieces* that can be described are of $1\frac{1}{4}$-inch Bath stone, jambs, mantels, and shelves, 6 inches wide; with slabs of 2-inch Portland stone, 20 inches wide, and 6 inches or a foot wider on each side than the width of the opening. Those of butler's and housekeeper's rooms would be of a better quality.

A *kitchen chimney* is described as jambs and mantel (in one piece) of 2-inch Portland stone 10 (or 12) inches wide, with a slab of $2\frac{1}{2}$-inch rubbed Yorkshire stone, if used with a wood floor; but sometimes the whole width of that side of the kitchen is paved.

Where *marble chimney-pieces* are to be placed, they are described to be provided of a given value of such marble as may be determined, or working drawings and workmanship may be referred to. It must always be provided in the specification that the slabs are included, and that the price is, or is not, to include the carriage and fixing. Marble, wood, and iron chimney-pieces, with grates, fenders, tile borders and hearths, &c. *en suite*.

All *fire-places* should have back hearths of $2\frac{1}{2}$-inch rubbed Yorkshire stone. Front hearths of stone, or of Portland cement, or of marble.

Sinks of rubbed Portland or other stone, 7 inches thick (describing the size required), sunk $3\frac{1}{2}$ ins. deep, with holes cut for the grating and socket-pipe, and fixed with all requisite brick or stone bearers or supports, complete. A sink of earthenware is now to be obtained. An improved patent combined sink and wash-up tub is specially adapted for kitchens, sculleries, cottages, artizans' dwellings, &c. It is made of galvanized or enamelled iron. Housemaids' slop sinks in earthenware or in plain or enamelled slate are made, to suit any position.

Sink stones to drains to be provided where shown on the plan.

Flint work. Flint walling is of the following descriptions:—Rough, or as the flints are dug; random, or broken without any regard to regularity; split, so that they are true on the face and oval in form; or, split and squared, by which neat and square work is produced. The walling is to be built in the soundest manner with . . . . flints (state which of the four descriptions is to be used), laid in mortar compounded of quick-setting stone lime and coarse sharp sand, free from loam; bricks, tiles, pebbles, &c., may be bedded in the centre or core of the wall. The long flints to be selected and laid as through stones, and the string-courses, &c., to be laid entirely through the thickness of the wall, so as to give additional bond. The work to be kept as dry as possible during the construction, to be protected by boards in wet weather, and to be covered in as soon as possible after completion. No grouting to be used. If the walling is faced with half-flints, care is to be taken in laying them to keep their upper surfaces as level as possible, to prevent rain driving into the centre of the wall; firmly pin up the lower bed with fragments.

The *joints* of the masonry generally are to be where exhibited on the drawings, and the work is to be left perfectly cleaned off, all necessary joggles, joints, rebates, moulded, sunk, weathered and throated works, grooves, chases, holes, back joints, and fair edges, that may be necessary in any part of the work, and all jobbing, though not particularly mentioned under the several heads, is to be performed that may be requisite for the execution of the building, and all the work is to be well cleaned off before delivering it up. The whole of the work is to be warranted perfect, and any damage that may occur to it by reason of frost or settlement within two years after the completion of the building is to be repaired, under the architect's direction, at the sole expense of the contractor.

All *mortar* is to be of the same quality as that described in the bricklayer's work.

All *cramps* to be of copper; iron cramps not to be allowed (see *par.* 2286). Lead joggles, and slab slate dowels set in cement, to be inserted in the joints where directed. The contractor is to provide *lead* to run the cramps and joints.

In *stables*, granite should be provided to receive the heel-posts if cast iron be not employed, and at the piers of gates, hinge and spur stones, the latter, of granite, if to be had, should be described. The caps and bases of the last can be noted only with reference to the drawings of them. The *paving of stables* and their courts is described thus: Prepare the ground for paving (stating where) with good and sufficient hard materials, and pave it with Aberdeen granite paving, properly dressed and sorted, 8 inches deep and 5 inches wide at the top and bottom thereof. The whole to be laid with good currents upon a layer 4 inches at least in thickness of good rough gravel, the joints of the surface to be run with stone lime and river sand grouting. It is to be well rammed, and the contractor is to relay, at his own

2284c. Mason.
expense, all such parts as may sink within eighteen months of the work being completed.

To provide and fix under the contract . . . . cubic feet of . . . . stone, including plain work and setting thereto, also . . . . superficial feet of 2½-inch Yorkshire paving, laid in regular courses; and in case the whole or any part of either or both should not be wanted, the quantity not used or directed shall be deducted from the amount of the consideration of the contract after the rate of . . . . per foot of cubic stone and . . . . per foot superficial for the Yorkshire paving, including the workmanship and fixing thereof.

Where the work is within the metropolitan district, or within a town, a sufficient *hoarding* must be erected for enclosing the premises during the execution of the works, which is to be removed and carried away when they are complete. So, also, all *shoring* is to be provided, if the works be alterations, or the adjoining buildings may be injured by carrying them into effect. The shoring is to be performed in a safe, scientific, and workmanlike manner, of the several fronts, floors, or otherwise, as the case may be.

For a stone building:—To provide, fix, maintain, alter as occasion may require, and finally remove, the necessary double square fir *framed scaffolding*, travelling cranes and other implements, and utensils and plant necessary for the performance of the whole of the works; and perform all the requisite sawing, lifting, hoisting, setting, and other labour that may be necessary for the carrying out of the whole of the works.

Carpenter and Joiner.

2285. To provide all materials requisite for completion of the buildings. The oak is to be of English growth and perfectly sound; the timber is to be of the best Dantzic, Riga, or Memel yellow fir. No American, Swedish, or Scotch fir to be used in any part of the building. All the floors and joiner's work are, except where otherwise directed, to be of the best yellow Christiana deals. The timbers and deals are to be cut square, entirely free from sapwood, shakes, large knots, black outsides, and all other defects. If any part or parts of the joiner's work should shrink or fly within . . . . months from the finishing and fixing the same, the contractor is to take down, make good, and refix the same, together with all works that may be affected thereby, at his own expense.

Provide and fix . . . . cubic feet of Baltic yellow fir timber, with all labour thereto, beyond the quantity necessary for the work herein described, to be used in such additional works as may be directed by the architect; and if the whole or any part thereof should not be ordered, the same shall be deducted from the amount of the consideration of the contract, after the rate of . . . . per foot cube. All additional fir, if any should be ordered, is to be taken at the like price of . . . . per foot cube.

No *joists*, rafters, or quarters are in any case, unless particularly so directed, to be more than 12 inches clear distance from one another.

Provide and fix, ease, and strike all *centering* and turning pieces for the vaults, arches, trimmers, and other works. Provide all temporary *shores* that may be necessary. Provide and fix all necessary *templets*, linings, blocks, stops, casings, beads, springing fillets, angle staffs, grounds, linings, backings, furrings, cappings, and other finishings incident to carpenter's and joiner's works, together with all necessary grooving, rebating, framing, tonguing, housing, beading, mitring, framing, and other workmanship necessary for completing the works.

Provide *casing* for all the stone dressings, to secure and protect the same from injury during the execution of the works; any accident arising from neglect in this respect is to be made good at the expense of the carpenter.

Bond timber, 4 inches by 2½ inches all around the walls, except where intercepted by the chimneys, to be lapped together, where joints occur, at least 6 inches, and to be properly spiked together. One tier is generally enough for basement story. Two tiers in the other floors, unless very lofty. One tier in the upper story. These are now dispensed with, hoop iron bond being used, and party walls may be so bonded, if thought proper, for a greater security against fire.

All *wood*, or patent, *bricks* to which the finishings are to be fixed.

All *lintels*, and filling in lintels necessary to the several openings; each to be 4 inches high, of the width of the brickwork, and 16 inches longer than the opening. Two small lintels will do if the width of the sofite be considerable, and arches, as directed in the bricklayer's work be turned.

For ground or, rather, basement floors, walls are brought up for receiving *oak sleepers* 5 by 3 inches, on which fir joists 4½ by 2½ are generally the scantlings employed

2285a. CARPENTER AND JOINER.

For other floors.—Wall plates, 6 inches by 4 inches; girders; joists according to the kind of floor; trimmers and trimming joists; all which, with their requisite scantlings, will be found in Practical Carpentry. (2013 *et seq.*)

Cradling to the girders and such parts as may be necessary to form panels and coffers on the under side for the ceiling, if such be practised. State if the girders are to be trussed. Cock down all girders on the wall plates. Pin bridging joists to binders with $\frac{3}{4}$-inch oak pins.

Wall plates to roofs should be at least 6 inches by 6 inches. The different timbers of the several sorts of roofs are described in Practical Carpentry, and scantlings given. (2027, *et seq.*) Ceiling joists to be described. Hips and ridges rounded for lead ought to be 10 inches by 2 inches.

The *trusses of roofs* are to be framed as shown, and of timbers of the scantlings respectively figured (or as here specified). They are to be mortised, tenoned, arched, notched, moulded, chamfered, and stopped, as shown on the detail drawings; and to be bolted and strapped with wrought iron straps, forged with ornamental ends; all bolts to have washers and nuts, notched as shown.

The *curved ribs* (if any) to be put together in (three) thicknesses, so as to break joint, to be wrought all over, and the joints to be tongued. These (three) thicknesses are to be screwed close together with long screws, and bolted with $\frac{1}{2}$-inch bolts between each joint. The centre thickness to be tenoned into the timbers on which it abuts. Tongue a bold 3-inch bead to underside of same.

The *hammer-beams* (if any) are to be cogged down upon the wall plates, and framed to the ribs, and bolted, as shown. The principals are to be notched and tenoned to the hammer-beams, and well spiked to ribs, and tenoned together and pinned at top. The collars (if any) are to be firmly tenoned into and spiked to principals. The purlins are to be notched down and housed into the principals on each side, and spiked. The king-post, or queen-posts, are to be framed in the usual manner.

All the *timbers* of the roofs exposed to view are to be wrought, and the angles moulded, or chamfered, or stop chamfered.

All *roofs* (if exposed to view) to be *boarded* above the rafters with $\frac{7}{8}$-inch wrought matched V jointed boarding, laid diagonally, and securely nailed to rafters and covered with (asphalted) felt (or specify, to lath on the top of rafters and plaster between the same). Lay battens 3 inches by 1 inch over the boarding or laths, on the back of every rafter, and on the battens lay 3 inch by 1 inch slating battens (or double oak tiling laths if the roof be tiled), fixed to a proper gauge for the sized slates required.

Where *close boarding* is used, it should not be less than $\frac{3}{4}$ to an inch thick. If battens for slating, they should be $2\frac{1}{2}$ inches wide; the first should be nailed with eightpenny nails. Provide lear boards. On many accounts the Italian method of laying the rafters horizontally as so many purlins is to be preferred. For the boarding not lying lengthwise towards the gable, any wet that may find its way on to it from defective slates or lead, is not apt to lodge against and rot the edges.

Flats.—Wall plates usually 6 by 6. Trimmers and trimming joists against chimneys, and where skylights occur. $1\frac{1}{2}$-inch yellow deal boarding, listed, free from sapwood, laid with a current of $1\frac{1}{2}$ inch to 10 feet lineal, with $2\frac{1}{2}$ drips to heading joints, of lead rolls to longitudinal joints, and inch yellow deal risers not less than 4 inches wide next the gutter.

Gutters to the roof, or roofs, are to be as shown on the plan, with inch yellow deal bottoms on strong fir bearers, and laid with a current of $1\frac{1}{2}$ inches to every 10 feet; $2\frac{1}{2}$ rebated drips, and at the sides to have $\frac{3}{4}$-inch deal lear boards, 9 inches wide. Gutter boards are rarely more than $1\frac{1}{4}$ inches thick. *Gutter plates*, if any, to be described, but they should never be used without support from below.

Trim for *trap doors*, size as shown, if any, leading to the inside of the roof Dormers thereto on to roof, with all necessary framing.

Cheeks, doors, beaded stops and linings, and ironmongery. Boarding for slating or lead to top and cheeks, as the case may be.

Dormers may be similarly described for windows in the roof.

Quartered partitions, where shown on the plan, with heads and sills 4 inches by 4 inches. Ties above the doors 4 inches by 5 inches. Posts 4 inches by $3\frac{1}{2}$ inches. Braces or struts 3 inches square. Quarters 4 inches by 2 inches, and three tiers of interties, 1 inch by $2\frac{1}{2}$ inches. In cases where partitions are to be trussed for carrying either their own or some additional weight, reference must be made to drawings.

Battening to external walls, usually from $\frac{3}{4}$ inch to $1\frac{1}{4}$ inch thick; their widths $2\frac{1}{4}$ inches, fixed from 7 to 12 inches apart. If bond timber is not used to nail them to, plugs, or fixings, to be let into the wall.

2285b. Carpenter and Joiner.

Bracketing and cradling is usually, for cornices, coves, &c., $1\frac{1}{4}$ inch thick; for entablatures, circular sofites, and waggon-headed ceilings, $1\frac{1}{2}$ to 2 inches thick.

All *bearers* to be fixed and provided as shall be necessary.

Weather boarding, $\frac{3}{4}$-inch or 6 boards to a 3-inch yellow deal. wrought or wrought and beaded: or 1-inch or 4 boards to a 3-inch deal. Louvre or *Luffer boarding* of 1-inch deal, wrought two sides and splayed.

Warehouse posts must be described with their relation to the weight they are to carry (see Beams and Pillars, 1635, *et seq.*), the caps 3 feet long, with splayed ends, so that the posts may not press into the girders; and iron dowels should pass through the girders to catch the bases of the posts in the floor above. Fir *story posts* are usually about 9 inches square.

Water trunks are made from 4 to 6 inches or more square, of $\frac{3}{4}$-inch to $1\frac{1}{4}$-inch deal; to be pitched and fixed complete, with hopper heads and shoes, wall hooks, hold-fasts, &c.

Park paling is of the following varieties: 4-feet oak cleft pales, 2 arris rails and oak posts; 5-feet oak cleft pales, &c.; and 6-feet oak cleft pales, 3 arris rails and oak posts. Described oak plank at the bottom, and oak capping at top, if required.

Floors.

$\frac{3}{4}$-inch *white* (or yellow) deal, rough, with edges shot.
$\frac{3}{4}$-inch *white* (or yellow) deal, wrought, and laid folding. } These may be of battens for better floors.

1-inch *white* (or yellow) deal, rough, with edges shot.
1-inch *white* (or yellow) deal, wrought, and laid folding.
1-inch *white* deal, wrought, and laid straight joint and splayed headings. } Also of battens.

$1\frac{1}{4}$-inch *white* (or yellow) deal, rough, with edges shot.
$1\frac{1}{4}$ inch *white* (or yellow) deal, wrought. and laid folding.
$1\frac{1}{4}$-inch *white* (or yellow) deal, wrought, straight joint, and splayed headings. } Also of battens.

$1\frac{1}{2}$-inch *white* (or yellow) deal battens, edge nailed, and tongued headings.

$1\frac{1}{4}$-inch *yellow* deal batten (or clean batten), dowelled with oak dowels, with mitred and glued borders.

Warehouse floors.

$1\frac{1}{2}$-inch *yellow* deal, rough, edges shot. $1\frac{1}{2}$-inch *yellow* deal, wrought, and laid folding. $1\frac{1}{2}$-inch *yellow* deal, wrought, and straight joint and splayed headings. 2-inch *yellow* deal, rough, edges shot, and 2-inch *yellow* deal, wrought, and laid folding. 2-inch *yellow* deal, wrought, and laid straight joint, and splayed headings.

All these last may be ploughed, rebated, and feather-tongued.

Put to . . . . floors (or to the whole, if desired) *sound boarding* of $\frac{3}{4}$-inch rough deal fixed upon fillets, to receive the pugging. (See 2287*a*.)

Floors of inlaid or *parquetry* work to be specially described according to drawings.

In *churches*, the floors under the seats are usually of wood, and require rebated and chamfered oak margins, 6 inches by 4 inches, laid flatwise, where they abut upon paved floors. These margins are to be mortised or dowelled to receive bench ends, and the wood floors to be kept 3 inches above the tile floors on which they abut. See *wood block* floors.

Skirtings.—$\frac{1}{2}$-inch (or $\frac{3}{4}$-inch) deal square. $\frac{3}{4}$-inch (or 1-inch) deal torus. 1-inch (or $1\frac{1}{4}$-inch) deal square; or 1-inch deal square skirting, rebated and backed plinth, with fillet nailed to floor. $1\frac{1}{4}$-inch deal torus; or $1\frac{1}{4}$-inch deal torus skirting, rebated and backed plinth, with fillet nailed to floor. If any of these, as to stairs, are raking, and to be scribed to steps, they must be so described, and if ramped or scribed to moulded nosings, or circular on plan.

Dado, nailed to ground: $\frac{3}{4}$, 1-inch, and $1\frac{1}{4}$-inch deal keyed. $1\frac{1}{4}$ inch deal keyed, ploughed and tongued, or feather-tongued, if required. Mention if they are to be scribed to steps, circular on plan, and wreathed, or ramped. Dadoes are now made of framed wainscot, in panels, &c., according to drawings.

Wainscoting, with fascia and skirting.—1-inch deal, square framed; and perhaps dwarf. $1\frac{1}{4}$-inch deal, square framed; and perhaps dwarf. $1\frac{1}{4}$-inch deal, bead butt (or moulded), or bead flush. The number of panels high to be specified. State if any to be made raking, or to have a beaded or moulded capping.

Partitions of deal for the division of rooms.

1-inch deal board, and braced with $\frac{1}{2}$-inch panels.
$1\frac{1}{4}$-inch deal, braced with $\frac{3}{4}$-inch panels.
$1\frac{1}{2}$- inch deal, rough, and ledged edges shot. } These are seldom made.

$1\frac{1}{2}$-inch deal, wrought both sides, and ploughed; or tongued and beaded.

$1\frac{1}{4}$-inch, or $1\frac{1}{2}$-inch, square framed.

$1\frac{1}{2}$-inch, bead butt, moulded and square; or bead flush and square or moulded both sides.

2285c. CARPENTER AND JOINER.

2-inch, square framed; or bead butt or moulded and square; or bead flush and square; or moulded both sides; or moulded and bead flush; or bead flush and bead butt; or bead flush on both sides.

Grounds.—Those of $\frac{3}{4}$-inch deal, of 1-inch deal, of $1\frac{1}{4}$-inch deal, of $1\frac{1}{2}$-inch deal, and whether circular; also 1-inch, $1\frac{1}{4}$-inch, and $1\frac{1}{2}$-inch skeleton grounds (*par.* 2166).

Door cases are usually about 5 by 5 inches for basements; should be of oak in preference to fir. They fit, or are fixed, into the brickwork, and should be tenoned (the tenon being pitched or set in white lead) into a stone step or threshold; any wood sill soon rots.

Door linings.—These are either plain, the commoner sort; or framed, for better work.

1-inch deal, single rebated; or double rebated (that is, so that the door may hang on either side)

$1\frac{1}{4}$-inch deal, single rebated; or double rebated.

$1\frac{1}{2}$-inch deal, single rebated; or double rebated.

Either of the foregoing may be beaded on the edge.

Framed door linings and sofites for doors are—

$1\frac{1}{4}$-inch, square framed in one panel and double rebated: and bead butt or moulded: and bead flush.

$1\frac{1}{2}$-inch, square framed in one panel and double rebated: and bead butt or moulded: and bead flush. If the panels in the linings are to be raised, to correspond with panels of doors, they must be so described.

Framed back linings are—1-inch deal, two panel square; and bead butt. 1-inch deal, three panel square; and bead butt. 1-inch deal, four panel square; and bead butt. If there be more panels, or they are splayed on the plan, or if bead flush, or of a greater thickness, they must be so specified.

Window backs, elbows, and *sofites.*—1-inch deal, keyed; or framed square.

$1\frac{1}{4}$-inch deal, framed square; or moulded or bead butt; or bead flush.

$1\frac{1}{4}$-inch deal, square framed sofite, with one edge circular. } Applicable to bay windows.
$1\frac{1}{4}$-inch deal, square framed sofite, with two edges circular. }

$1\frac{1}{4}$-inch deal, square framed sofite, moulded, or bead butt.

$1\frac{1}{2}$-inch deal, framed square; or moulded; or bead butt: or bead flush. If any of these are splayed, fancy moulded, and with cappings, or are circular on the plan, they must be so specified.

Shutter boxings.—1-inch deal, splayed boxings; 1-inch deal, proper boxings; $1\frac{1}{4}$-inch deal, splayed boxings; $1\frac{1}{4}$-inch deal, proper boxings; $1\frac{1}{4}$-inch deal, boxings with circular head; 1-inch (or $1\frac{1}{4}$-inch) deal, boxings for sliding shutters, with pulley pieces, beads, fillets, and grooves, complete. These, if to be double hung, must be so described.

Shutters to windows.—$\frac{3}{4}$-inch deal, ledged or clamped; and may be in two heights. 1-inch deal, clamped; and in two heights; or clamped in two heights, one panel, bead butt, and square; or one panel, bead flush, and square; or bead butt. These may be described of $1\frac{1}{4}$-inch deal and of $1\frac{1}{2}$-inch deal, but the back flaps need not be more than one inch. The additional panels in height projecting mouldings (if any), and any other variations, must be mentioned.

Shutters, sliding, hung with lines and weights.—1-inch (or $1\frac{1}{4}$-inch) deal, two panels square; $1\frac{1}{4}$-inch deal, bead butt and square (or bead flush and square); $1\frac{1}{4}$-inch deal, bead butt and moulded (or bead flush and bead butt). If of $1\frac{1}{2}$-inch deal, if more panels in height, if circular on the plan, and if *patent* or other *lines* are to be used for the hanging, they must be mentioned.

Outside shutters.—$1\frac{1}{4}$-inch deal, three panels, bead butt and square; or bead flush and square. $1\frac{1}{4}$-inch deal, three panels, bead flush and bead butt; or bead flush on both sides. $1\frac{1}{2}$-inch deal, three panels, bead butt and square; or bead flush and square; or bead flush and bead butt. These may be circular on plan, or contain more than three panels in height.

Staircases.—1-inch yellow deal, steps, risers, and carriages. $1\frac{1}{4}$-inch deal, steps, inch risers, and carriages. $1\frac{1}{4}$-inch deal, steps and risers glued up and blocked to close string moulded nosings, and two fir carriages. $1\frac{1}{4}$-inch deal, steps and risers mitred to cut string, and dovetailed to balusters. $1\frac{1}{4}$-inch deal, steps to winders, mitred to cut string, and dovetailed to balusters, one end circular; or both ends circular. The risers may be tongued to the steps; or feather jointed; or of clean deal. $1\frac{1}{2}$-inch deal, wrought steps, risers, and strong carriages. 2-inch deal, wrought steps, risers, and strong carriages. $1\frac{1}{4}$-inch Oak, treads and risers mitred to string and dovetailed with fir carriage (with solid quarter ends to steps if required), also curtailed step and riser (2187, *et seq.*), returned moulded and mitred nosings, circular (if necessary), with cut plain (and circular) brackets.

Housings to ends of steps and winders, and the same to moulded nosings and circular ends, are to be specified.

2285*d*. Carpenter and Joiner.

String boards to staircases to receive the ceilings of stairs (called strings).—1-inch deal, framed; or framed, rebated, and beaded. $1\frac{1}{4}$-inch deal, framed string board; or sunk and beaded. $1\frac{1}{4}$-inch deal, framed string board, sunk, beaded, and moulded; and mitred to risers. $1\frac{1}{2}$-inch deal, wreathed outside, string glued upright, rebated, and beaded; and sunk; and moulded. The string may be glued up in thicknesses; and also plain or moulded circular cuttings or ramps. 1-inch (or $1\frac{1}{4}$-inch; or $1\frac{1}{2}$-inch; or 2-inch) deal, plain wall string; and these may be moulded.

The principal *staircase* to have $1\frac{1}{4}$-inch pitch pine (or other) treads, with rounded nosing and hollow moulding under same, and inch risers, glued and blocked to fir carriages; the ends of the steps to be housed into $1\frac{1}{4}$-inch wall strings, and 2-inch outer string boards, sunk and staff beaded, and finished at the top with a boldly moulded capping, framed at the bottom and corners into 6 inch square newels, with moulded finials, bases, and pendents, as drawing. Boldly moulded oak *handrail*, 4 inches wide and 6 inches deep, with $1\frac{1}{2}$-inch square oak balusters, stop chamfered.

The *landings* to be formed by joists resting upon boldly moulded stopped beams, as shown on sections.

Handrails to staircases.—$1\frac{1}{4}$-inch (or $1\frac{1}{2}$ inch; or 2 inch) deal, plain wreathed. These may be moulded; as deal moulded $2\frac{1}{2}$-inch handrail; or $2\frac{1}{2}$-inch handrail, ramped (or circular where required); or $2\frac{1}{2}$-inch handrail, wreathed and twisted. Spanish (or Honduras) mahogany (or wainscot) moulded handrail. To be described with all necessary ramps, circular and twist, or with scroll and twist to the curtail step. Mention if grooved for balusters, circular, or sunk for iron cores, mitred and turned caps.

Balusters and newels.—Deal square framed newels; or chamfered. Single and double turnings to *newels* to be mentioned, as also pendent drops, when used. Deal square bar balusters; or dovetailed. Turned balusters, according to drawing, or selected from manufacturers' patterns. Planceer rounded on both edges; or moulded. Fix all necessary iron balusters and stays.

Sash frames are of great variety. Deal cased frame for $1\frac{1}{2}$-inch sashes, oak (or deal) sunk sill with brass (or other) pulleys for single hanging. Ditto, for double hanging. Ditto, ditto, with circular head. Ditto, circular on plan (and with circular head). Deal cased frames for 2-inch sashes, oak (or deal) sunk sills with brass pulleys for single hanging. Ditto, for double hanging (and circular on head and plan, or either). Deal cased frames for 2-inch sashes, oak (or deal) sunk sills with wainscot (or deal) pulley pieces and beads, brass axle pulleys prepared to hang double; and if circular on head and plan (or either). Deal cased frames for 2-inch sashes, oak sunk sills, mahogany pulley pieces and beads with brass axle pulleys, prepared to hang double. Ditto, for $2\frac{1}{2}$-inch sashes; and if circular on head and plan (or either).

Venetian frames.—Deal cased frames for $1\frac{1}{2}$-inch sashes, oak sunk sills, prepared to hang single (or double). And if circular on plan and head (or either). The above serves for 2-inch and $2\frac{1}{2}$-inch sashes; and if wainscot or mahogany.

Casement frames for French casements.—Fir solid wrought frames for $1\frac{1}{2}$-inch (or 2-inch) casements, oak sunk sills (plain or circular on the plan, as the case may be). Ditto, with wainscot or mahogany stiles and beads, to correspond with the sashes. Ditto, for $2\frac{1}{2}$ inch sashes.

Fanlight frames over doors.—$1\frac{1}{2}$-inch deal frames, square framed. Ditto, semicircular head. 2-inch deal, square framed. Ditto, semicircular head. If elliptical, so describe them.

Sashes.—$1\frac{1}{2}$-inch deal ovolo (with circular head or circular on plan). 2-inch deal ovolo (ditto). 2-inch deal astragal and hollow (ditto). $2\frac{1}{2}$-inch deal astragal and hollow (ditto). These may be moulded according to drawing. The above may be of wainscot, Honduras or Spanish mahogany; also to be hung single or double, with patent lines and iron (or lead) weights, and sash-fastenings (patent to be named) complete.

French casements.—2-inch deal ovolo casements. They may have marginal lights, or be circular on plan, or both; or if with astragal and hollow. The same of $2\frac{1}{2}$-inch, with the same modifications. The above may be of wainscot, Honduras or Spanish mahogany. The hanging is commonly with 4-inch iron, or brass, butt hinges; the species of fastening at a price from five to twenty shillings. When Espagnolette fastenings are used, they must be particularly specified.

Shop-fronts vary so much that their thicknesses will only be noticed. They range from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches; the forms of their horizontal sections must be stated, or to be executed according to the drawings. Metal bars are now largely used.

2285*e*. Carpenter and Joiner.

For *revolving* wood or iron *shutters*, the particulars of the manufacturers had best be obtained.

Stall-board, and other shop-fittings, &c., of the like nature, are to be described with reference to the drawings, or to the manufacturer.

The *ceilings* of the principal rooms:—after they are plastered, to be divided into square panels about . . . feet square, by nailing thereon hollowed fillets 2½ inches by 1 inch (or more), neatly scribed at intersections, with staff beads 1 inch (or more) diameter, nailed along the centre of the same, mitred at intersections, and conveyed round walls as a cornice. Care to be taken in laying the joists so that they may form nailing points for these panel ribs.

Friezes and cradling for cornices should be referred to drawings, specifying their height.

Skylights.—The common sort are, 1½-inch deal ovolo skylight (and hipped, and with cross bars). 2-inch deal ditto (ditto). 2½-inch ditto (ditto). If astragal and hollow moulded; or if of oak, to be specified. Small skylights are often made of copper or zinc.

Kerbs for skylights.—1½-inch kerbs to (circular) skylights in two thicknesses, bevelled and chamfered. 2-inch ditto. 2½-inch ditto. These may be elliptical.

Coach-house doors and gates.—2-inch deal, framed and braced, filled in with 2-inch deal, and ploughed, tongued, and beaded. Ditto, filled in with battens. 2½-inch deal, framed and braced, filled in with 1-inch deal, ploughed, tongued, and beaded. Ditto, filled in with battens. These are sometimes filled in with whole deal.

2-inch deal bead butt and square gates, in eight panels; and bead flush and square; and bead flush on both sides. These gates may have more panels; or be framed with a wicket. A sum may be provided for the hanging of gates, and their hinges and fastenings may be inserted at from 10*l*. to 15*l*., or even 20*l*.

Doors.—For out-houses and the like: ¾-inch ledged wrought deal door; ditto, ploughed, tongued, and beaded. 1-inch wrought deal ledged, ditto. 1-inch ploughed, tongued, and beaded. 1¼-inch wrought deal ledged, ditto. 1¼-inch ploughed, tongued, and beaded. 1½-inch and 2-inch deal ledged doors are similarly described. These doors may be hung with ⊢L or cross garnet hinges; and have bolts, locks, latches, and other fastenings, as may be described. External doors with 4-inch cast or wrought butt hinges, and internal doors with cast or wrought iron 3½-inch butts. Water-joint hinges are useful for light outside flap-doors.

For a dwelling house: the *principal entrance door* to be of deal 1½ inches thick, framed flush, with V joints inside; the exterior to be cased with ¾-inch oak boards, with moulded fillets over the joints, the same to return round the head, and to die at bottom on an oak rail, 9 inches deep, sometimes having sunk quatrefoils, &c. The door to be hung on wrought iron ornamental hinges to hooks let into the jambs (or screwed to frames); an 8-inch rim lock and ornamental drop handle, escutcheon, and key-plate, and two 8-inch barrel bolts

The *back, or side entrance, door* to be 1¼-inch, framed, ledged, and braced, covered with ¾-inch wrought oak boarding with chamfered joints, nailed on with rose nails driven through and clenched; hung on hinges and fastened with lock and bolts, similar to those specified for front entrance.

The *internal doors* may be of the following varieties:—1½-inch four-panelled, with hollow on the room side, and ¾-inch diagonal V boarding next the hall or passage; to be hung with fleur-de-lis or ornamental wrought iron hinges, made to clasp the door so as to show on both sides, and fastened with wrought iron latches and ornamental drop rings. 1½-inch four-panelled, square framed, stop chamfered, filled in with upright or diagonal V-jointed boarding, and hung on hinges as previously specified.

1-inch deal 1-panel square door. 1-inch deal 1-panel square door, folding. These are rarely used.

1¼-inch, 2 panels, square; and bead butt and square; and bead flush and square; and moulded and square; and bead butt on both sides; and bead butt and bead flush; and bead butt and moulded; and bead flush on both sides; and bead flush and moulded; and moulded on both sides. When hung folding, to be so specified.

1½-inch deal, 2 panels, square, follows in the same order.

2-inch deal follows in the same order.

2½-inch deal follows in the same order.

1½-inch deal, 4 panels, follows in the same order.

2-inch deal, 4 panels, follows in the same order.

2½ inch deal, 4 panels, follows in the same order.

1½-inch deal, 6 panels, follows in the same order; and so on.

2285*f*. Carpenter and Joiner.

If the panels of 1½-inch doors are raised, or if double marginal doors, so describe them. All the above must be specified as to be hung folding, if the nature of the work so requires.

Wainscot doors.—1½-inch wainscot, 2 panels, square; and bead flush and square; and moulded and square; and bead flush on both sides; and bead flush and moulded. 2-inch wainscot, 2 panels; 2½-inch wainscot, 2 panels; follow in the same order. 1½-inch wainscot, 4 panels, follow in the same order, and may be moulded on both sides; also 2-inch wainscot, 4 panels; and 2½-inch wainscot, 4 panels; also 2-inch wainscot, 6 panels; also 2½-inch wainscot, 6 panels; and so on.

Wainscot sash doors.—2-inch wainscot, with diminished stiles, lower panel moulded, bead flush, with astragal and hollow sash; or ditto, with astragal and hollow sash, moulded on both sides; or 2½-inch wainscot sash doors, diminished stiles, lower panels moulded, and bead flush, with astragal and hollow sash; or ditto, with astragal and hollow sash, moulded on both sides. These may be hung folding, double margined, or moulded on the raising.

Mahogany doors, or best Spanish mahogany if required (of course now veneered)—2-inch Honduras mahogany, 2 panels, moulded and square; or moulded on both sides. 2-inch Honduras mahogany, 4 panels, moulded and square; or moulded on both sides. 2-inch Honduras mahogany, 6 panels, moulded and square; or moulded on both sides. 2½-inch Honduras mahogany, 4 panels, moulded and square; or moulded on both sides. 2½-inch Honduras mahogany, 6 panels, moulded and square; or moulded on both sides. These may be hung folding; with projecting mouldings; or with double margins.

Mahogany sash doors.—2-inch Honduras mahogany, astragal and hollow, bottom panel moulded and square; or bottom panel moulded on both sides; or 2½-inch Honduras mahogany, astragal and hollow, bottom panel moulded and square; or bottom panel moulded on both sides. These may be hung folding; or with double margin; or diminished stiles.

External doors.—2-inch wrought, ledged, framed, and braced, folding (or other) doors, with stop chamfered, arched heads, stiles, rails, and braces, covered on the outside with ¾-inch wrought, tongued, and V jointed oak boarding, hung to solid oak frame (or on hinge-hooks let into stone jambs), with strong, heavy, wrought iron mediæval hinges, and fastened with best rim dead lock cased with oak, and a heavy wrought iron latch, with bold ornamental drop handle and plate, key-plate, &c., all wrought according to detail drawing (or a price to be stated for each article). The frames to be of oak, 6 inches by 4 inches, wrought, double rebated, stop chamfered, grooved, &c., tenoned into stone steps, and to have extra strong hooks on plates screwed to same.

2-inch deal, 4 panels, the lower panels bead butt and square, and the upper panels square both sides; or the upper panels bead butt on the backs; or the upper panels bead flush on the back. The panels may have raised mouldings.

2½-inch deal, 4 panels, the lower panels bead butt and square, upper panels square on both sides; or bead butt on the back; or bead flush on the back; with perhaps raised mouldings.

2-inch deal, 6 panels, lower panels bead butt and square, upper panels square both sides; or bead butt on the back; with perhaps raised mouldings.

2½-inch deal, 6 panels, the lower panels bead butt and square, and the upper panels square both sides; or bead butt on the back; or bead flush on the back; with perhaps raised mouldings, double margined, &c. Describe any of these external doors, if to be hung folding, or with circular or curved heads.

Sash doors.—1½-inch deal, 2 panels, square, diminished stiles, and ovolo sash; and bead butt and square, diminished stiles, and ovolo sash; and bead flush and square, diminished stiles, and ovolo sash; and moulded and square, diminished stiles, and ovolo sash; and moulded and bead butt, diminished stiles, and ovolo sash; and moulded and bead flush, diminished stiles, and ovolo sash; and moulded on both sides, diminished stiles, and ovolo sash.

2-inch deal, 2 panels, square, diminished stiles, and ovolo sash, in the same order. 2½-inch deal, 2 panels, square, diminished stiles, and ovolo sash, in the same order All these may be hung folding, or with marginal lights.

In describing joiner's work, specify the ironmongery to be used; that is, the hinges, locks, fastenings, and furniture. There is now great variety.

Common framed 4-panel doors are usually hung with 3½-inch butts and 7-inch iron rim stock locks. Better doors are hung with 4-inch iron or brass butts, mortise locks and brass knob furniture. Folding doors, if heavy, should have 4½ or 5-inch brass butts, and if necessary to clear mouldings, they should be hung with projecting brass butts, be provided with flush and other bolts, and mortise locks and

2285*g*. Carpenter and Joiner.

furniture. Doors of dining, drawing, and other rooms, where they are required to clear the carpet by rising as they open, should have 4 or 4½-inch rising joint butts. Closet doors have usually 3½-inch butts, with brass tumbler locks and keys. External doors require larger locks, which are usually iron rim locks, or patent locks and keys; also 10 or 12-inch bright rod bolts, chains, staples, &c. Shutters have butts, which for the back flaps are of a less size, and spring bar fastenings. Brass or other china knobs to the front flaps. Doors, mouldings, and joinery are now to be obtained of American and Swedish manufacture, as well as English.

Moulded architraves to doors and windows, are described by their width and mouldings, or referred to drawings.

Columns and pilasters.—1¼-inch (or 1½-inch) deal diminished columns, ... inches diameter. Pilasters similarly specified. Both one and the other to be glued up and blocked. If fluted, to be mentioned; as also any necking grooves to columns. Caps and bases according to the Order, or to drawing, carved, or of papier-mâché, as the expense will allow.

Entablatures got out of deal, as to drawing. To be glued up, blocked, and fixed with all necessary brackets and grounds.

Water-closet, fitted up with 1-inch clean deal (wainscot or mahogany), seat with hole cut therein, riser (panelled and moulded) and clamped flap (not always considered a necessity), square (or beaded) skirtings, with all requisite bearers and pipe-casing. *Privies* are described as to seats and risers the same as water-closets, but sometimes have a lid to cover the hole instead of a flap.

Cisterns, internal and external, must have their cases proportioned in thickness to their sizes. Thus one about 3 or 3 feet 6 inches long, and 2 feet 9 inches deep, will be 1¼-inch deal dovetailed, with requisite bearers, and a cover of ¾-inch deal with a wood handle. For a good-sized external cistern, provide and fix a wrought and dovetailed 2-inch deal cistern case, . . . feet long, . . . feet wide, and . . . feet deep in the clear. Provide and fix all necessary bearers for the same, with all other requisite fittings, and a ¾-inch deal strongly ledged cover, with saddle-back fillets and water channels at each joint. Each water-closet to have a cistern case of 2-inch deal, to contain 36 cubic feet of water, fixed with strong bearers, ledged cover of ¾-inch yellow deal tongued and beaded. All these cisterns are supposed to be lined with lead, or zinc.

Sinks.—For a wooden one lined with lead, 1½-inch dovetailed sink, enclosed with 1¼-inch deal square-framed front (and perhaps sides), and top or door hung with 3-inch butts, with deal or lead skirtings, and other necessary ironmongery. A proper drainer to be fixed at one side.

Plate-rack for scullery to be provided over the sink, and of the same length.

Bath to be fitted up with riser, frame, and clamped flap (of the best Spanish mahogany), provided and fixed with all requisite bearers and other fittings and appurtenances. The flap to be moulded (in front), and hung with 3½-inch brass butt hinges, and the riser panelled and moulded as shown in the drawings, or to follow the windows and doors.

Dresser.—For a good house:—2-inch deal, with cross-tongued top 10 feet long and 2 feet 9 inches wide, supported on strong framed legs and bearers. 1-inch deal pot-board and bearers. Six 1¼-inch sunk shelves, whose widths are to average 7 inches. Back of the shelves to be of 1-inch deal, wrought, beaded, grooved and cross-tongued. 1-inch deal top, 14 inches wide, with moulded cornice. Five drawers with bottoms and dovetailed rims of ¾-inch deal. The fronts to be of 1-inch deal, beaded. A pair of brass (or black) drop handles and a good patent tumbler lock to each drawer; together with all slides, runners, bearers, and other requisite appurtenances. To be fixed complete. Others from 6 to 7 feet long.

Dresser top for scullery, 1½-inch clean deal, 2 feet 6 inches wide, and 6 feet long, cross-tongued, and fixed upon strong wrought and framed legs and bearers.

Cupboard fronts to correspond with the doors of their respective rooms, hung on ornamental S, H L, or other similar hinges, fastened with small tumbler locks, wrought iron key plates, and small twisted or other drop, or fancy, handles. The fittings to closets depend upon the rooms in which they occur; as the attics, bedrooms, nursery, sitting room, kitchen, housekeeper's room, store room, butler's pantry, cook's room, &c.

Dwarf closets.—These vary. 1-inch deal, square framed and moulded in front to follow other doors. The top to have 1½-inch mahogany top, moulded in front, and 3-inch skirtings. One shelf, same depth as closet. The doors to be hung (folding) with 2½-inch butts, a bolt inside, a brass knob outside, and tumbler locks.

2285*h*. Carpenter and Joiner.

Pipe casings, wrought and framed, to be provided where necessary, to hide lead and other pipes of all descriptions the fronts to be made to unscrew for coming at the pipes when necessary.

Larder fittings.—Dresser top of clean deal, $1\frac{1}{2}$ inch thick, 2 feet 6 inches wide, and . . . feet long, to be feather-tongued and fixed on strong framed legs and rails. Two meat rails, 6 feet long, of wrought fir, $3\frac{1}{2}$ by 2 inches, suspended from wrought iron stirrups. A hanging shelf, 6 feet long, 10 inches wide, and $1\frac{1}{4}$ inch thick, suspended from wrought iron stirrups.

Laundry.—To be fitted up with $1\frac{1}{2}$-inch clean white deal washing troughs, wrought two sides, and splayed and put together with white lead (as shown on drawing). $1\frac{1}{4}$-inch deal ironing board, wrought both sides and clamped, hung with hinges to a proper hanging stile. Provide two clothes racks, hung with pulleys and ropes to the ceiling to raise and lower the same.

Dust-bin. See Bricklayer.

Arris gutters to eaves should always be of zinc, or iron for better use, not of wood.

Stable fittings, where the old class of work is required:—

Mangers, &c.—2-inch deal bottoms and $1\frac{1}{2}$-inch deal sides. Wrought oak manger-rails, 4 by 3 inches. Wrought, rebated, and rounded oak manger post, 6 by 4 inches, wrought and framed with bearers thereto. Oak heel-posts, wrought, 6 by 5 inches, and groove for partitions. Oak top rails, 5 by 4 inches, grooved and rounded at the top. Oak bottom rails, wrought, 4 by 4 inches, grooved and arris rounded off. $1\frac{1}{2}$-inch deal partitions, wrought on both sides, ploughed, tongued, and beaded. $1\frac{1}{4}$-inch deal rails on each side, board wide, and the arrises rounded off.

Fronts to hay-racks.—Oak standard, 4 by 4 inches, wrought and framed into oak bearer under the manger. $1\frac{1}{4}$-inch deal fronts, framed for the reception of cast iron hay-racks, well secured. Fix fir bearers and 1-inch deal partitions at each end of hay-racks, with fir arris rails 3 inches apart at the bottom of each rack.

Dressings over stalls connected with heel-posts. 1-inch deal frieze, wrought joints, feather-tongued, and backings thereto, segmental sofites and keystone in centre of arches. Impost mouldings at the springings and moulded cornice to girt about 10 inches.

Line the walls to the height of 5 feet with 1-inch yellow deal, wrought, ploughed, tongued, and beaded, with a $\frac{5}{8}$-inch beaded capping thereon.

Stable fittings have now become an almost distinct trade.

Oak fencing.—The site to be enclosed with an English oak fence, having oak posts 5 inches square, 6 (or more) feet long, the lower end tarred and fixed in the ground 2 feet, and well rammed round with dry ballast or brick rubbish, fixed 9 (or 10) feet apart, and framed with two tiers (or three) of oak arris rails secured with oak pegs. The whole covered with oak cleft pales 4 (5, or 6) feet high, nailed with galvanized iron nails. The bottom to be finished with $1\frac{1}{2}$-inch oak plank 12 inches wide, tenoned to posts. The top of pales to be covered with inch oak capping 2 inches wide, secured with galvanized iron nails. Sometimes the fence fronting the public way is varnished, with two or more coats.

Tar.—Cover the . . . with one (or two) coats of good Stockholm tar.

Churches.—To give general directions for the specification of a church would be impossible. The principles of its timbering may be collected from what has preceded. The old style of *pewing*, planned as drawings, of deal square-framed partitions two panels high; $1\frac{1}{2}$-inch framed doors and enclosures one or two panels high, with stiles, munnions, and top rails 3 inches wide, and bottom rails 6 inches wide. The panels of the doors and enclosures should not be more than a board in width, and the framework round them chamfered. The doors are hung with 3-inch butt hinges, and should have brass knob pulpit latches. Capping to the whole of the pewing, grooved and moulded according to drawing. *Pew fittings* are, $1\frac{1}{2}$-inch wrought and rounded seats, 12 inches wide, with proper bearers and $1\frac{1}{4}$-inch cut brackets not more than 3 feet apart. Seats rounded next the pew doors. *Flap-seats* in the galleries to have strong joints. All the pews to have $\frac{3}{4}$-inch book boards 6 inches wide, with $\frac{1}{2}$-inch rounded capping bearers, and $\frac{1}{2}$-inch cut brackets thereunder, not more than 2 feet 6 inches apart, and the ends rounded next the pew doors. If there be an *organ*, its enclosure would correspond with the pews, or be specially designed for it. *Free seats* of $1\frac{1}{4}$-inch deal, as shown in the drawings; the seats to be 11 inches wide, rounded in front; backs framed with stiles, munnions, and rails, $3\frac{1}{2}$ inches wide, and the standards, ends, and bearers, according to the drawings. *Children's seats* to be of $1\frac{1}{4}$-inch deal, with brackets same thickness, not more than 2 feet 6 inches

2285*i*. CARPENTER AND JOINER.

apart; at least 8 inches wide, and the flap seats, where they occur, to be hung with strong butts. *Pulpits and reading desks* are usually of $1\frac{1}{4}$-inch deal, framed according to drawings, with $1\frac{1}{4}$-inch doors, hung with brass hinges and pulpit latches. Whole deal floors on bearers, 1-inch book boards, cappings and bearers. 1-inch clean deal or wainscot steps and risers, moulded returned nosings, $1\frac{1}{4}$-inch, beaded, sunk and cut string boards, strong bracketed carriages. 1-inch square framed sofite under pulpit floor and stairs, mahogany or wainscot moulded handrail, with caps turned and mitred; square bar balusters with one in ten of iron; turned newels to block steps; seats of $1\frac{1}{4}$-inch deal, 13 inches wide, and proper bearers thereto, together with all appurtenances and requisite fittings for executing the drawings. This exploded manner of fitting up a place for religious worship is well delineated in T. L. Walker, *Architectural Practice*, 8vo., London, 3rd edit., 1841. The details may be occasionally useful.

For more modern work may be specified:—The whole of the *seating* throughout to be formed as detail drawings, of good, well-seasoned English oak (or otherwise), to be wrought, chamfered, and stopped, or moulded and cut, as shown or required; to be carefully framed and put together. The *bench ends* to be (at least) 3 inches thick, tenoned and pinned to the chamfered oak sill. The backs to have solid moulded oak capping. The seats to be $1\frac{1}{4}$ inches thick, and the book boards to be 2 inches thick (fixed flat or sloping), edges chamfered; all to be well housed and cut into bench ends. Fix cut brackets, not more than 4 feet apart, under the seats; and cut brackets, not more than 3 feet apart, under the book boards. All the seats to be kept clear of the piers (if any). See par. 2192*a*.

The carpenter and joiner is to provide and include all such jobbing work, in following or preceding the other artificers engaged on the works and their appurtenances, as may be requisite for the completion thereof in every respect.

FOUNDER, SMITH, AND IRONMONGER

2286. *Cast iron girders and columns.* Reference must be had to Chap. I. Sect. X. (1628*e et seq.*), wherein will be found the method of determining their scantlings; all girders to be previously tested before fixing, by *weighting* at the foundry.

Cast iron cradles, when used for openings, must be described for the particular occasions as they occur.

Chimney bars.—To kitchen chimney two wrought iron cradle bars, each 2 inches wide and $\frac{3}{4}$ inch thick, long enough to extend to the outside of the chimney jambs, and turned up and down (or cocked down and up) at each end. The other openings to have each a wrought iron chimney bar 3 inches wide and $\frac{1}{2}$ inch thick.

Straps, stirrup irons, nuts, bolts, screws, and washers, together with all other wrought iron work for the roofs and partitions, to be provided as may be requisite, and the smith is to deliver to and assist the carpenter in fixing or attaching the same. Where the quantity is uncertain, a given weight beyond the above general direction should be provided in the contract, such part thereof as may not be wanted to be deducted from the accounts after the rate of . . . per cwt. To provide for the carpenter's and joiner's works, and use, and fix thereto, all requisite spikes, nails, screws, and other proper ironmongery, and all requisite brass work, all to be of the very best quality.

Cramps of cast, and wrought, iron, or copper (par. 2284*d*), as may be directed, for the mason; the former to be used where the works are exposed to the air.

Wrought iron door for strong room or opening in a party wall (it may be folding) to be of the best quality (name the manufacturer) with hinges and proper fastenings, of the value of . . . pounds, without fixing.

Cast iron sashes as necessary.

Wedges for underpinning must be described with reference to the thickness of walls they are to catch; each pair must be at least as long as the wall is thick.

Balusters to a back stone staircase and landings.—Wrought iron balusters, $\frac{3}{4}$ inch square, with turned wrought iron newel equal to $1\frac{1}{2}$ inch diameter, with rounded handrail of wrought iron $1\frac{1}{2}$ by $\frac{1}{2}$ inch. The balusters and newel are to be riveted into the handrail at top, and at the bottom let into the stonework, and run with lead.

Balusters to a principal staircase.—Ornamental cast iron balusters, as shown on the drawings, or to pattern by a manufacturer, with top rail of wrought iron $1\frac{1}{4}$ by $\frac{1}{2}$ an inch, let into and firmly screwed to the mahogany (or wainscot) handrail. The balusters and newels are to be riveted into the iron rail, and at the bottom they are to be let into the top or side of the stonework, and run with lead.

Balusters of wrought iron for strengthening the principal staircase when of wood. Every tenth baluster to be of wrought iron, well secured.

Knocker.—Provide and fix . . . iron, or brass, knocker for . . . door (specify a price).

2286*a*. Founder, Smith, and Ironmonger.

Air bricks of cast iron, single or double, and fixed in the brickwork of the outside walls, for the ventilation of the floors; also *air gratings*, . . . in number, 9 inches square.

Area gratings.—Of cast iron, with bars $1\frac{1}{2}$ inch by $\frac{3}{4}$ of an inch, and not more than $1\frac{1}{2}$ inch apart. Frames $1\frac{1}{2}$ inch by 1 inch, and with strong flanges to let into the surrounding stonework, and properly fixed.

Window guards, of wrought iron to the windows of . . . , and . . . bars, to be 1 inch square and 4 inches apart, with framework of iron of the same substance, and let well into and securely fixed to the brickwork in cement.

Coal plates of cast iron, with proper fastenings, to be provided to the coal shoot. Hayward's patent self-locking plate is one of the new patents.

Cast iron ornamental railing, to the windows, or to the balcony in front of the house, as the case may be, according to the drawings, or selected from a manufacturer.

Traps of cast iron, or stoneware, to all communications of surface water with drains, to be of appropriate size, with all gully gratings that may be necessary.

Drains to roads or paths to be of unglazed earthenware pipes, in 2-feet lengths, of a . . . inch bore, laid to a fall of . . . inches in each 100 feet into . . . , with all necessary bends, junctions, &c. Iron gully trap or glazed stoneware trap, or traps, jointed as drains.

The Kitchener apparatus for cooking must be specially named; and in large mansions many modern conveniences are required to be specified. The Carron Company have issued (1887) a book of appliances of various sizes.

Copper.—A copper, . . . inches diameter (or cubical quantity), of copper, or of galvanized iron, with all requisite bars and iron work.

Stable fittings.—No. . . . cast iron hay-racks, 3 feet wide and 2 feet high in the clear. $1\frac{1}{4}$-inch round staves, about 3 inches apart, the frames $1\frac{1}{4}$ by $\frac{3}{4}$ of an inch, with the arris rounded off next the staves. Fix two manger rings in each stall.

Cast iron coping to the walls of the dung-pit $\frac{7}{8}$ of an inch thick, and returned on each side 4 inches down at the least.

Cast iron gratings to stable yards are usually described as of the weight of 1 cwt.

Church and Chapel work. The founder's, smith's, and ironmonger's work is so dependent on the design, that no general instructions can be given.

Cast iron saddle bars to the windows $\frac{5}{8}$ by $1\frac{1}{4}$ inch (or $\frac{1}{2}$-inch square), 12 inches longer than the clear width of each window, with lead lights, laid into and worked up with the brickwork, at the height shown on the drawings, to be fixed on an average 12 inches apart.

Each window to have wrought iron framework for a *hopper casement*, to be fitted up complete, with patent lines, brass pulleys, and all other requisite appurtenances. Or the hoppers may rest on the sill, and be hinged next to it, so that when closed the exterior glazing may be flush, and to be fitted with opening racks and fastenings.

To outside of windows, where necessary, fix 1-inch square *stanchions*, not more than 6 inches apart, with ornamental heads forged to drawing, let into (frames or) stone sill at bottom, and passed through saddle bars with mortises formed thereon.

For church *windows with tracery heads*, provide and build in across the springing of the arch of all windows of 3 lights and upwards, wrought iron bars 2 inches by $\frac{1}{2}$-inch, corked, and well turned up 2 feet from jambs, on each side; these bars to be well galvanized, and fixed with play for expansion or strain, in notches through the mullions.

All *straps*, bolts, nuts, and washers for the various roofs. Where visible, the straps are to be worked to detail drawings; and the washers and nuts to be notched and stamped as directed.

Wrought (or cast) iron *vanes, crosses*, ridge cresting, guards to areas, balconies, &c., according to drawings; all to be securely fixed; the vanes and gable crosses to have stems as long as possible, and to be leaded into the stone or screwed to the roof timbers, as the case may be.

Ornamental wrought iron *hinges, latches*, key-plates, closing rings, &c., on doors, all to be strictly worked according to detail drawings.

Ornamental *grating* of cast iron to pattern, to cover hot water pipe channels in floors.

Cast iron rain-water pipe.—To be $2\frac{1}{2}$, 3, $3\frac{1}{2}$, 4, $4\frac{1}{2}$, 5 or 6 inches diameter, fixed from the roof into the drain, with proper head and shoe, ears or bands, &c., complete.

Eaves gutter.—All overhanging eaves to have a 4-inch cast iron eaves gutter, with all necessary angle pieces, valley pans to internal angles, swan-necks, and socket pipes cast on the gutter to lead into heads of rain-water pipes. The gutters to be fixed on strong wrought iron brackets screwed to the feet of the rafters, and the

2286*b*. Founder, Smith, and Ironmonger.

joints to be screwed together and bedded in red lead putty. Rectangular rain-water *down pipes* are frequently used, with ornamental ears or bands.

Newall's (or other) copper wire *lightning conductor*, with point, properly secured, to . . . (the highest portion of the building), and brought down with all requisite insulators; the end to be carried into the earth for a depth of 3 feet from the surface; and all to be carefully fixed. See par. 2264*k*.

Plasterer.

2287. *Lath*, *plaster*, *float*, and *set* all the ceilings, also the strings of staircases, and the quartered partitions on attic stories.

Render, *float*, and *set* all brickwork in attic stories.

All sides of the kitchen offices and office passages to be plastered with best floated rough stucco, lathed where requisite.

All the remainder of the sides of the interior throughout is to be executed with the very best floated stucco, lathed where requisite. Stucco of offices (or office buildings, if any) to be finished with rough surfaces; all the rest of the stucco to be trowelled quite smooth.

All the arched, groined, panelled, and coffered work, and the bands and architraves, to be executed in gauged stuff, in the best and most accurate manner.

To run *cornices* in plaster round the several rooms, lobbies, passages, and other parts of the building, with enrichments thereto to be accurately modelled in accordance with the drawings (the enrichments may be of papier-mâché). An ornamented rose or flower to the centre of the ceiling of each room on the ground (and one-pair) floor, securely fixed. Those of papier-mâché can be easily screwed to the ceiling joists.

Skirtings to basement or ground story (or both) are to be run in cement round all the rooms, lobbies, passages, &c., 10 inches high, $1\frac{1}{4}$ inch thick, whited when soft, and finally washed of stone colour (or painted).

All necessary *beads*, *quirks*, *and arrises*; all internal and external reveals to be stuccoed; dubbing out where the work may require it, so as to bring out all extra thicknesses and projections; and counter-lathing the work over large timbers and elsewhere, to be done as may be necessary. Enrichments to be carefully trimmed and finished off, and where heavy leaves or embossed work may require it, to be screwed with strong copper screws.

Lathing throughout to be lath-and-half heart of fir laths, free from sap.

If the walls of a *church* are to be plastered, the stone jambs to windows and doors are usually specified to project one inch beyond the face of wall, so as to form a stop for plaster, and afterwards cleaned off and left flush.

Lath for, and plaster to, the spaces between the *rafters* (unless the boarding is intended to be left visible).

To *stucco* in the very best manner with . . . . cement, jointed to imitate masonry, the whole (or part, if such be the case) of the exterior of the building, with columns, pilasters, plinths, entablatures, strings, mouldings, labels, jambs, reveals, chimneys, chimney moulds, decorations, enrichments, and appurtenances of every kind, as shown on the drawings and profiles. Such work to be subject to further instructions from the architect; to be roughly coloured as each portion is executed, and finally coloured with weather-proof colouring, fixed with proper ingredients.

Decorative *chimney pots*, of cement, and of the value of . . . to be provided for each flue.

Pugging.—To fill in upon the sound boarding between the joists, where so provided, with good lime and hair pugging mortar, laid throughout at least 1 inch in thickness. Par. 2247.

Roughcasting.—For the mode of describing this, see Plastering, Sect. IX. (2249.)

Martin's cement, if used for *walls* and partitions, is to be laid in Martin's coarse cement and clean washed dry sand, 1 of cement to $1\frac{1}{2}$ of sand, floated and set with pure Martin's fine cement $\frac{1}{8}$ inch thick. A *skirting* to be 9 inches high, dubbed out with tiles in cement, and run as above described, finished on the top with a . . . moulding, . . . inches in girt, mitred at angles. *Reveals* to be run in pure Martin's fine cement. For *floors*, equal parts of coarse cement and sand, beaten down and keyed $\frac{3}{4}$ thick, and finished with a coat of pure Martin's cement, and brought to a fine surface.

Keene's patent cement.—Brickwork to be rendered with . . . cement and clean sharp sand, in proportion of 9 to 1, and to be laid and set with Keene's patent fine marble cement, highly polished. *Paving* to be formed of 3 inches of concrete, laid with Keene's patent coarse marble cement $1\frac{1}{4}$ ins. thick. *Skirting* will be the same as for Martin's cement.

2287*a*. Plasterer.

Parian cement.—To be laid with coarse quality Parian cement and clean sharp sand in equal proportions, and set with fine white Parian, highly polished.

Portland cement.—Rendering to walls, in proportion of 1 of cement to 3 of clean sharp grey sand Drawn and jointed to form blocks (state size). For rough work the proportion may be 1 of cement to 9 of sand.

Plumber.

2288. The *flats and gutters* to be laid with milled lead of 6 (7 or 8) lbs. to the foot superficial. Where against walls, to be turned up 7 inches; where against slopes, as rafters, to turn up 10 inches. Rolls not to exceed 27 inches apart.

Flashings of milled lead to the walls of 4 (or 5) lbs. to the foot, to be worked in the wall, and to turn down over gutters and flats. Where flashings adjoin the slopes of a roof, they should be described to be formed stepwise into the brick-work, and of an average width of 12 inches.

Hips and ridges to be covered with milled lead 6 lbs. to the foot, and at least 18 inches wide, well secured with lead-headed nails.

Eaves gutters.—To put round the eaves at the curb plate 4-inch iron (or zinc) guttering, fixed complete with bands and brackets, with iron (or zinc) down pipes, . . . inches diameter, with neat heads and appropriate shoes, and let into the gutter, syphon trap, or drain.

To fix . . . *stacks of rain-water pipes* (if to be of lead) from the gutters to the drains, of (5) inches bore, turned up from milled lead of 8 lbs. to the foot superficial, and securely fixed with ornamental cistern heads, as shall be approved by the architect, and 2-inch strong overflow discharging pipes. Similar description for conveying water from the roof or flat of a portico.

Roses pierced with holes of sufficient size to be provided of 10-lb. lead to rain-water cesspools, and pipe heads.

No pipes but of lead or zinc should be used against stone buildings. Cast iron pipes should only be used to offices.

Domes should be covered with lead from 6 to 8 lbs. to the foot superficial, according to their size, and must be well secured with proper seams or rolls thereto.

Tops and sides of dormers to be covered with 5-lb. milled lead, turned down all round full 8 inches. A flashing of 5-lb. milled lead, 30 inches wide, to be fixed over the sill of the dormer door or window, as the case may be.

Aprons of 6-lb. milled lead, and 10 inches wide, should be described to sky-lights.

External mouldings of wood may be covered with 6-lb. milled lead, to turn up 6 inches, and to have flashings of 4-lb. milled lead let into the brickwork, and to be turned down 5 inches.

In London, it is usual to specify that the *water supply* should be laid on for the service of the house in following manner (regulating cisterns are required by some companies):—Lay on water from the main of the . . . . . Company with $\frac{3}{4}$-inch strong cast lead pipe to the cistern of the upper water-closet, with ball-cock complete. Similarly to lower water-closet and to such other cisterns as are provided, with ball-cocks, &c. complete, and to pay all official fees.

Line the *sink* in the scullery, and in the butler's pantry (and other small ones, if any) with 6-lb. milled lead, and fix thereto a 2-inch waste pipe, with brass bell trap complete, to be carried outside on to or under a grating, and so into the drains. (Another to each for hot water.)

Line the *kitchen cistern* with milled lead, bottom 9 lbs. and sides 6 lbs. to the foot, with all soldering thereto. To provide to the same a $1\frac{1}{4}$-inch waste pipe. Line the kitchen *sink* with lead of 8 lbs. to the foot, to turn well over the woodwork and to have a 2-inch strong waste pipe to lead into the drain, with brass bell grate complete. A $\frac{3}{4}$-inch service pipe and brass cock to be provided from the cistern for supplying water to the sink. (Another for hot water).

Water-closets to be constructed and fitted up in every respect complete, with . . . basin, and the very best patent valve apparatus. Soil pipe of $4\frac{1}{2}$-inch bore out of 8-lb. lead, to lead into drain with strong . . . trap; lead service box, 10 inches by 7, and 6 inches deep, of 10-lb. milled lead; 5-lb. lead safe under pan, with 2-inch swan-necked waste pipe. 1-inch supply pipe to the basin, and all other pipes, wires, cranks, handles, and other proper fitments. The *cistern* is to be lined, bottom with 8-lb. cast lead, and sides with 5-lb. milled lead. $1\frac{1}{4}$-inch waste pipe, to be carried outside, with washer and waste complete. (See par. 2220 for modern contrivances).

Inferior water-closets to be provided with stoneware syphon pan, with water laid on, and in all respects to be fitted complete, to modern requirements.

2288a. Plumber.

Provide all stench-traps, syphon-traps, and other similar contrivances as may be named, where the pipes are to communicate with the drains.

Cold bath.—A . . . feet . . . inches bath, if of copper of 16 ounces to the foot superficial, tinned on the inside, and painted in japan to imitate marble, or as may be directed. Lay on the water with strong $1\frac{1}{4}$-inch lead pipe, with brass cock, and fix $2\frac{1}{2}$-inch strong lead waste pipe, with brass washer and plug, thereto.

If the *hot bath* be not of marble (as before stated, see Mason), the following clauses will describe the several positions and varieties of the boilers by which a supply of hot water is obtained in the present day:—

I. Provide a Tylor and Sons' 5 feet 2 inch taper oval-end copper (or galvanized tinned iron) bath, white marbled inside, with copper pipes, mounted in wood cradle, with $1\frac{1}{4}$-inch deal framing, panelled, with French polished Honduras mahogany top. Three of Tylor and Sons' inch roundway bath taps, S.B., with socket keys and handsome levers, hot, cold, waste. A Tylor and Sons' patent bath boiler, with stove front to fit opening of fireplace, with doors and damper (no setting required). Inch lead pipe from cold water cistern to boiler, $\frac{3}{4}$-inch lead pipe to relieve boiler up to and turned over top of cistern (or any convenient outlet). Inch lead pipe for hot, cold, waste, and overflow pipes to bath. Lead safe with waste under cocks, and leave the work perfect; as estimated, at 39*l.* 0*s.* 9*d.*, exclusive of carriage and any bricklayer's, plasterer's, or carpenter's work, cutting away for pipes and making good, fixing bath framing, and graining and varnishing it. A galvanized tinned iron bath is 6*l.* less.

II. Tylor and Sons' 22-gallon copper chimney boiler, with wrought iron band, with bolts and nuts to carry ditto, and stove front to fill up opening in fireplace, with sliding blower, revolving damper, soot door, and bars; as estimated, at 38*l.* 0*s.* 9*d.*

III. Tylor and Sons' copper saddle boiler with unions, a stove front to suit ditto, with sliding blower, revolving damper, soot door, and bars. A galvanized wrought iron cistern, close top, with manhole screwed down, to be fixed with two lines of inch wrought iron pipe from boiler to hot cistern, inch ditto to supply cold water to hot cistern, $\frac{3}{4}$-inch ditto to relieve hot cistern, inch hot, cold, waste, and overflow pipes to bath, &c.; as estimated, at 47*l.* 4*s.* 3*d.*

IV. Provide a 5-feet (larger or smaller, as deemed necessary) strong best make improved kitchen range, with strong wrought iron back boiler with close top, wrought iron oven, and line fireplace with panelled covings. A galvanized wrought iron hot water cistern, &c.; as estimated, at 61*l.* 3*s.* 9*d.*

V. The range fitted with two boilers, one for the bath, the other for domestic use; where a fire is kept sufficiently large to work two boilers, they are recommended. Estimate 4*l.* extra to No. IV.

VI. A range with partially closed fire instead of one with open fire. 4*l.* 15*s.* extra to No. IV.

VII. Tylor and Sons' 22-gallon copper dome-top boiler, with furnace iron work, doors, bars, and damper, and continue as No. I. This boiler may be fixed in the basement, and will supply a hot bath in any apartment below the level of the cold water cistern. As estimated, 43*l.* 15*s.* 3*d.*

Note. In I., the bath and boiler may be fixed in the same or separate apartments; open or close fire at pleasure. All the estimates are framed presuming on a cold water cistern and a rain-water pipe, or a drain, being within 10 feet of the room. In III., the hot water cistern is placed over the fireplace in the room. In IV., the hot cistern is supposed to be 25 feet above the boiler. In VII., the cold cistern is supposed to be 25 feet above boiler. The waste pipe from the bath to the drain should always have as great a fall as possible and never be laid to so small a fall as allowed by placing it within the depth of the floor.

Common *pumps* are generally described as 3-inch pumps, with neat cast iron cases, fixed complete, with proper lead suction pipe to bring sufficient supply of water from well into the cistern, and all other appurtenances. The manufacturer's stock to be seen if others be required. Where water is not laid on, as in London, fix a $3\frac{1}{2}$-inch lifting engine pump, with brass barrel; and provide from the well . . . feet of $1\frac{1}{2}$-inch strong suction pipe; with service pipes to the cisterns, and all cocks and joints that may be necessary.

Provide all *copper and zinc nails* that may be wanted for laying the metal works.

Provide in the contract . . . cwt. extra of milled (or other) lead, including labour and all proper materials as may be wanted and directed by the architect; and if the same or any part thereof should not be used, a deduction to be made for the same on making up the accounts, after the rate of . . . per cwt. for such portion thereof as shall not have been used.

Glazier.

2289. All the windows to be glazed with best crown glass; the offices with second crown glass. To glaze all the front windows with best sheet glass; or with best flattened sheet; or with patent plate; or with British plate; as the case may be, and according to the weight specified. For varieties of glass, and glass for other purposes, see Chap. II. Sect. XII., *par.* 1870 *et seq.* The architect often names the manufactory or firm from which the glass is to be procured, to ensure the proper quality being supplied.

All the glazing is to be properly bedded, stopped in, sprigged, and back-puttied, the convex side outwards (of crown and sheet glass), to be free from specks, blisters, or other blemish; and to be left whole and clean, on the works being rendered up as complete.

Glaze all the windows (of the *church*) and tracery heads (if any) with quarries and borders in strong church lead $\frac{3}{8}$ inch wide. The lead to be secured to the saddle bars and stanchions with strong copper wire, soldered to lead, and securely twisted round the saddle; the glazing to be properly cemented, to be let into the grooves of stonework, and neatly pointed with lime and stone dust.

The *glass* to be Powell's quarries, or Hartley's patent rough cathedral glass, $\frac{1}{8}$ inch thick. The quarries to be of one tint, and the borders of another tint (as for instance, green and yellow).

Skylights and windows, in exposed situations, where much light is not required, may be glazed with Hartley's rough plate glass, $\frac{1}{4}$ inch thick, or less.

Water-closet and similar windows (where privacy is desired), with Hartley's patent rough plate glass, $\frac{1}{8}$ inch thick; with fluted glass; or with diapered; or with embossed glass.

Enumerate any windows to be glazed with ribbed, enamelled, embossed, or stained glass.

Provision to be made in window sills and skylights (where practicable) for conveying condensed water to the exterior of the building.

Painter.

2290. Knot (with silver leaf in best work), pumice down, and smooth, stop, and otherwise properly prepare all the wood and other works intended to be painted.

Paint four times (or till they bear out), with the best oil and colour, all the internal and external wood and iron works, all the stucco, and all other works that are usually painted. The plain painting to be of tints of brown, drab, or stone colour, as may be directed.

The *walls* of the principal staircase, lobbies, and entrance-hall are to be carefully executed imitations of marbles, as directed by the architect, jointed like masonry, in blocks of sizes as directed, and twice varnished with the best copal.

The *doors*, *shutters*, dadoes, skirtings, boxings, architraves, and other dressings on the ground and one-pair floors (and others, if required), are to be grained in addition wainscot (or other wood, as may be specified), in an artist-like manner, and sized and varnished twice with best copal varnish.

Some of the mouldings of doors and shutters may be gilt.

All the wrought woodwork (except the floors, and the work executed in oak) to be stained with . . . stain, once coated with linseed oil, and twice varnished with the best copal varnish. Or, if the deal has been picked, it may be left plain, and only varnished. Or, if selected with much care, the deal and pine may be polished. Inside *oak* work is best left to obtain an effect by use, but where immediately desirable, it may be once or twice oiled.

Pick out the ornamental ironwork on doors, roofs, screens, &c., in black or dark blue. A pattern or diaper is sometimes done in gold leaf upon it.

To *flat* extra, of such tints as may be directed, all the rest of the stucco work and wood work on the principal and one-pair floors.

Distemper the ceilings (or as follows):—

The ceilings and cornices on ground and one-pair floor to be painted four times in oil, and flatted and picked in with such extra colours as may be directed.

The *ceilings* (and perhaps the cornices and centre flowers also) on the two principal floors to be distempered. All the rest of the ceilings, strings, and mouldings are to be whitened.

The sides of the rooms in the attic (as the case may be) story, as well as the lobbies, closets, passages, &c., are to be finished of such tints as the architect may direct.

Stables and coach-house walls, larders, and sculleries, cellars, including vaulting under sides of floors where open, to be lime-whited.

2290*a*: PAINTER.

Sashes to be finished on the outside of . . . colour.

To a *church*: Stop with coloured stopping, twice oil with linseed oil, and twice varnish with best copal varnish, the exterior doors and frames.

Stop with stained stopping, and knot with coloured knotting, the wrought woodwork of roofs; brush the whole twice with boiled oil, and once varnish the same. Pick out the chamfers and mouldings in roofs with vermilion, cobalt blue, chocolate, pale yellow, and white, in two oils, and stencil patterns thereon, according to drawing.

Deal seats, or benches, are to be knotted with stained knotting, stained with . . . stain (approved by the architect), and twice varnished with tackless varnish.

To French polish in the best manner the handrail of the staircase, the mahogany work of the bath and water-closet, and other parts (if any).

All paint and varnish to be of the best quality; sizing and mineral turpentine will not be allowed.

PAPERHANGER.

2291. To prepare and bring to a proper face all the walls and surfaces intended for papering. All the papers are to be approved by the architect, or by his client.

To hang with figured paper, value . . . per yard (or per piece) the rooms (to be described) on the . . . floor, with borders (as may be desired).

The remainder of the rooms to be hung with paper, . . . per yard (with or without borders).

Where satin paper is to be put up, or any of the more expensive descriptions, then to underline (or line the walls) with lining paper, joints rubbed down, and hang with . . . paper of . . . shillings per piece, the rooms on the . . . floor. Borders also, if thought desirable, must be specified.

The entrance passage or hall, staircase, and landings, up to . . . to be papered with Siena marble (or other) paper, value . . . per yard, hung in blocks, or hung horizontally and lined to size blocks with brown lines (or black pencil), twice sized, and varnished (once or twice) with best copal.

A $\frac{3}{4}$-inch gilt . . . moulding to be fixed with needle points round the dressings, and along the top and bottom of the . . . room (or rooms).

BELLHANGER.

2292. Bells to be put from the following places . . . to the several positions marked for them. A 14-oz. bell and . . . oz. copper wire, brass cranks, and . . . spring lever and rose.

The pulls in the principal rooms to be bronze or iron lever pulls of mediæval character, and very strong; the wire of strong copper; the cranks to be best horn cranks. Floor boards over bell wires to be screwed (not nailed) down, for ready removal.

Put $\frac{3}{4}$-inch zinc tubing for the concealment and casing of the wires to the bells, secured by round fine galvanized iron hooks. The bells to be hung and furnished with strong brass T-plate back and spring lever carriages. To be hung on a $\frac{3}{4}$-inch wrought and beaded deal board, secured to wood bricks (or strong wedges) by screws.

The front (and side) entrance door (or yard, or gate) to have bold pendant mediæval wrought iron pull, according to detail drawing, or to be selected.

It is usual to mark the place, both up and down stairs, where the bells are to be hung. Where many bells are fixed together on a bell board they are sometimes described to be so tuned as to form a musical scale. They are also to be numbered; sometimes the names of the several rooms from whence the bells are pulled are painted on the board under the bell.

The *electric*, and the *pneumatic*, bell system will somewhat depend on the patentee selected. The following specification for a twelve-roomed house is taken from Henry F. Joel and Company's Illustrated Catalogue, No. 3:—

To providing and fitting the following system of bells:—

Ground floor. Front entrance. One ornamental bronze pull, marked "Visitors," fixed by the side of the door, to ring and indicate in kitchen.

Tradesmen's entrance. One plain bronzed pull, fixed by side of the door, to ring on a separate bell in kitchen.

Dining-room. Two black and gold porcelain pushes (or walnut wood), fixed one on each side of the fireplace, to ring and indicate in kitchen.

Drawing-room. Two ivory and gold pattern porcelain pushes (or polished brass), ditto, ditto.

Library. Two black and gold line porcelain pushes (or oak wood), ditto, ditto.

Hall. One black and gold line porcelain push (or oak wood) to ring on "Call" bell in (or outside) the servants' bedroom. Also one 3-way pneumatic

2292*a*. Bellhanger.

switch to change the front entrance bell at night, so as to ring on "Call" bell in (or outside) the servants' bedroom.

First floor. Best bedroom. One bed-head pull, fixed by the side of the bed, to ring and indicate in the kitchen. One bed-head pull, fixed on the other side of the bed, to ring a "Chattering call" bell in servants' bedroom (same bell as used for the hall).

Dressing-room. One ivory and gold line porcelain push, fixed by the side of the fireplace (or by the side of the door), to ring and indicate in the kitchen.

Two other bedrooms. In each room, one plain ivory porcelain push, fixed by the side of the fireplace, to ring and indicate in kitchen.

Bath-room. One plain ivory porcelain push, to ring and indicate in kitchen.

Second floor. Two bedrooms. One plain ivory porcelain push in each, to ring and indicate in kitchen.

In all eighteen bells, the switch being taken as one bell.

Gasfitter.

2293. The gas to be laid on from the . . . company's main to the . . . with $\frac{1}{8}$ (or to 3) inch patent strong galvanized wrought iron welded tubing of the . . . diameter, jointed in iron cement, with all necessary bends, elbows, tees, crosses, junctions, stopped ends, diminishing sockets, and nipples, and other necessary joints for the rendering of the whole perfect and complete. The whole to be secured by iron barrel clips or hooks, as the case may require, secured by strong screws. The gas tubing to be stout $\frac{1}{4}$ ($\frac{3}{8}$, $\frac{1}{2}$, or $\frac{3}{4}$) inch composition pipes, soldered at joints and secured by fine hooks, furnished with the requisite galvanized iron (or brass) bends, &c., jointed in iron cement. This tubing is often laid in iron.

Stop cock to be supplied. A meter of . . . value to be provided and fixed on 1-inch wrought clean deal shelf, supported on a pair of plain iron brackets (or one of cut deal).

Gasaliers, pendants, hall lamp, standard, brackets, sun-light, and such like, must depend on the client and the manufacturers.

Each of the principal rooms to have a pendant corona (or other gasalier) of . . . lights, value . . *s.* each, fitted with balance weights and a ball and socket joint (or fitted with the patent balance around the pipe). Bronzed (or brass) bracket burners (swing or armed) in passages (or where else required), value . . *s.* each, complete, to approval.

Church lights are of (wrought iron, bronze, or) brass standards, coronæ, brackets, &c., according to their situations, for gas or for candles (specify value of each).

All lights to be fitted with argand, fish-tail, batswing (or other burners. Ground glass, or figured glass globes, where stated, are sometimes included by the architect. For other details see par. 2264*a et seq.*

Zinc-worker.

2294. *Roofs and flats.*—To be laid with No. . . . or . . . oz. malleable Vieille Montagne (or other) zinc, with 6 in. laps and $1\frac{1}{2}$-inch rolls, turned up 5 inches all round against walls and lights, finished with flashings 6 inches wide, inserted 1 inch into joint of the brickwork, and secured by galvanized iron wall hooks. Cesspools to be formed at the head of rain-water pipes, and the zinc lapped over. The whole to be laid with slotted fastenings lapped and soldered at angles. The trap to be covered, lapped over edge, soldered at joints, and secured by zinc nails. Or—the flats to be covered by "Braby," London, with their No. . . . gauge V.M. roofing zinc, square roll caps, and patent holding-down clips. All ridge plates and stopped ends are to be formed in the solid metal, not grooved in. Stretching of sheets, or soldering, to form stop ends must be particularly avoided.

Gutters to be laid with No. . . . or . . . oz. malleable zinc, with 6-inch laps at drips, turned up under slates for 11 inches on each side and 5 inches against the walls, finished with flashings 6 inches wide, inserted 1 inch into the wall, and secured by galvanized iron holdfasts. Cesspools to be formed, &c., as above described.

Eaves gutter.—To be of 2 (to 5) inch, No. . . . or . . . oz. zinc, fixed upon galvanized iron brackets, furnished with nozzle pieces, cut splash boards, and angles, and to be soldered at the joints. Care to be taken that one end shall be left free to allow the whole to expand and contract.

Rain-water pipe.—To be of 2 (to 5) inch, No. . . . or . . . oz. zinc, with square heads, fixed with socket joints and $4\frac{1}{2}$-inch strong galvanized iron nails, with the plates turned over.

Lining to cistern.—To be of No. . . . or . . . oz. malleable zinc, lapped 2 inches at joints and angles and turned down over edge, secured by strong zinc nails 4 inches apart, and to be soldered at angles.

2294*a*. ZINC-WORKER.

Chimney cowls, ventilating shafts, louver ventilator, perforated zinc, skylight frames, fanlights, &c. For other details see par. 2224*g*.

2294*b*. The following proposed SANITARY SPECIFICATION for a Suburban Villa, by "Hygiene," published in the *Journal* of the Clerks of Works Association, for November 1884, is deemed of sufficient importance to be here reprinted as a guide:—

Dig *trenches* the required depths for all drains as shown on plan; fill in after the drains are laid, and well consolidate the same. Where the drains cross the newly-made ground they must be bedded on a layer of Portland cement concrete 6 inches thick, the bottom of the trench being previously well rammed. Cart away any superfluous earth.

The *pipes* are to be the best salt-glazed socketed drain pipes, free from fire flaws or other defects, straight, and well burnt. No square junctions will be allowed. All drain pipes to be jointed in neat Portland cement, and carefully wiped inside.

Every facility must be afforded to the architect, or his representative, for inspection during the laying of the pipes. The drains are to be tested in lengths as the work proceeds, in any manner the architect may approve. The builder must procure an intelligent bricklayer, or other man to be approved by the architect, to lay the drains and build the inspection chamber.

Lay in the *soil pipes* in positions as shown in red lines on plan, with a continuous and even fall of not less than 2 inches in 10 feet. All soil pipes are to be 6 inches diameter, and waste pipe branches, &c., 4 inches, as shown.

Pay all fees to local board for connections to sewer, and provide and fix a 6-inch galvanized iron flap pipe for inlet to same.

Fix one of Doulton's No. 39 (see list) or other approved *interceptor trap* just within the boundary fence, in position as marked on plan; carry up from same a 6-inch diameter vertical pipe, provide and fix a 4-inch junction in the first length above trap; seal the top of pipe and cover over 6 inches below the ground line with 12 inch by 12 inch by 2½ inch York stone.

Carry 4-inch pipes from junction to a convenient place behind the shrubbery; bring to surface with an easy bend, fix on top a 4-inch square junction pipe, the top to be about 12 inches above the ground. Seal the top with a di c plate, and provide and fix a galvanized iron grating in the junction opening.

Build *inspection chamber*, as shown, near to the corner of house, with Portland cement concrete bottom, well-burnt stock bricks, and Portland cement sides. Provide a channel pipe and a curved junction channel pipe, and fix in chamber as shown; form sloping sides with concrete, and finish with neat Portland cement perfectly smooth, and to the required form. Cover over the top with 2½-inch York stone cover, 4 inches under ground.

Provide and fix in yard 11½-inch square trapped *gully* and dished iron grating, with two 4-inch inlets and 6-inch outlets (prime cost 7*s*., see fig. 19, Doulton's list). Continue drain to inspection chamber, and connect through the side of chamber above the sloping sides.

Continue from the inlets to gully 4-inch branch drains to the two rain-water stack pipes, and finish with an easy bend to receive the rain-water pipe.

Provide and fix an 8-inch by 8-inch trapped gully, with inlet on two sides for bath and lavatory wastes, and connect from gully to soil drain, as shown.

Continue the 6-inch soil drain from inspection chamber to side of house, as shown; insert a junction, and put an easy bend at end of each branch to receive the soil pipes from the water-closets.

Provide and fix Weaver's or other approved *grease trap* (prime cost 25*s*) outside scullery wall, to take waste from sink, and continue to the drain with 4-inch pipes.

Provide and fix in yard at the front of coach-house a 11½-inch square trapped gully, as before described, connect drains from stables, and connect, as shown, to inspection chamber.

Provide and fix 8-inch by 8-inch trapped gully at foot of rain-water pipe in front of house, and continue a 4-inch drain to soil drain.

Note.—If local board will not allow storm-water in the soil drain, a 6-inch storm-water drain must be laid to take all rain-water from roofs and surface of ground.

Connect with a 4-inch branch from rain-water pipe at end of stable, and to join the 6-inch drain from stable just below the gully. This drain must not have any trap in it, as it is required to ventilate this branch.

If any deviation be made from the course marked on the drain plan, the same must be carefully noted and marked on the plan, and then returned to the architect's office.

Internal Fittings.—Provide and fix in best water-closet, first floor, one of Jennings's ornamental Queen's ware combination "Pedestal" closets, automatic flushing tank, ornamental chain and handle, and a mahogany circular hinged flap seat. Prime cost value, 7*l*. 7*s*., exclusive of fixing. (These closets do not require any enclosure.)

Provide and fix in lower water-closet one of Doulton's stoneware (ornamental) combination closets, and all as before specified for fittings to first floor (prime cost, 4*l*. 9*s*. 8*d*, exclusive of fixing).

The soil pipe from water-closet, first floor, is to be 4-inch lead pipe, and to pass through and down the face of external wall, and to connect to branch of soil drain. The soil pipe from the lower water-closet to be as last described, and connect to the branch of soil drain provided for same. Continue the lead soil pipe from first floor water-closet to 8 feet above the eaves to roof, the full size of 4 inches. Put a fixed cone on top.

Provide and fix a 3-inch lead waste-pipe from *bath* through wall and into a 3-inch cast iron pipe down face of wall, and connect to gully provided for same.

Provide and fix a *lavatory* cabinet-stand complete (No. 21, Doulton's list, prime cost, 2*l*. 2*s*.); carry a 2-inch lead waste pipe, and connect to gully provided for same; fix under this lavatory a Beard and Dent's 2-inch trap and inspection cap. Lay on water from the down service pipe with a $\frac{3}{4}$-inch branch pipe and a $\frac{1}{2}$-inch silver-plated urn tap.

Provide and fix in maids' water-closet, and also in man servants' water-closet, one of Doulton's Lambeth flush-out closets, with syphon flushing cistern, handle and chain, all complete.

Connect the flushing cisterns throughout with $\frac{1}{2}$-inch stout lead pipe, and from cistern to water-closets with $1\frac{1}{2}$-inch lead pipe.

Provide and fix in scullery a Doulton's vitrified buff-glazed stoneware sink, best quality, size 3 ft. 6 in. by 2 ft. (prime cost value, 1*l*.); provide and fix a 2-in. earthenware waste pipe, and connect to grease trap outside scullery wall. (Housemaid's slop sinks are not required, the combination closets being available for slops.)

The work must be thoroughly well done; the best materials are to be used; and all to be finished to the entire satisfaction of the architect or his representative.

Sect. XVI.

MEASURING AND ESTIMATING.

2295. The practice of measuring is dependent on rules already given under Mensuration, in Sect. VI. Chap. I. of this book (1212 *et seq.*), in which are described the methods of ascertaining the superficial and solid contents of any figure. The application of them to architecture, in the practice of measuring and estimating the different parts of a building, forms the subject of this section.

2296. For the purposes of measuring, a 10-feet rod, and a pair of 5-feet rods, all divided into feet, inches, and half-inches, and a 2-feet rule divided into inches and eighths and twelfths or tenths of inches, are required. If a tape, say of 50, 66, or 100 feet, be used, it should be carefully checked by a standard, and by the 10-feet rod.

2297. The mode of "squaring dimensions," as usually practised by duodecimals, will be now explained. They are a series of denominations beginning with feet, and then inches and parts of an inch; they form a series of fractions. Feet and inches are marked with their initial letters, but twelfths, or tenths, or seconds by a double accent, thus 2″.

2297*a*. To multiply duodecimals together, write down the two dimensions to be multiplied in such a way that the place of feet may stand under the last place of the multiplicand; begin with the right-hand denomination of the multiplier, and multiply it by every denomination of the multiplicand, throwing the twelve out of every product, and carrying as many units as there are twelves to the next. Placing the remainders, if any, under the multiplier, so that the like parts in the product may be under like parts of the multiplicand; proceed with every successive figure of the multiplier towards the left, in the same manner, always placing the first figure of the product under the multiplier. Then the sum of these partial products will be the whole product. In duodecimals there will be as many denominations below feet as in both the factors taken together.

Example 1.—Multiply 7 ft. 5 in. by 3 ft. 4 in.

```
     7 : 5
     3 : 4
  ----------
     2 : 5 : 8
    22 : 3
  ----------
    24 : 8 : 8
```

Example 2.—Multiply 24 ft. 8 in. 8′ by 3 ft. 7 in.

```
  24 : 8 : 8′
         3 : 7
  -------------
  14 : 5 : 0 : 8
  74 : 2 : 0
  -------------
  88 : 7 : 0 : 8
```

2297*b*. In example I. there is only one place of duodecimals in each factor; there are therefore two places in the product. In the second example there are two places of duodecimals in the multiplicand and one in the multiplier, which make, together, three; there are therefore three denominations in the product. This method of placing the denominations of the factors gives the correct places of the product at once; since like parts of the product stand under like parts of the multiplicand. It also shows the affinity between duodecimals, decimals, and every series or scale of denominations whereof any number divided by the radix of the scale makes one of the next towards the left hand. The consideration is, moreover, useful in discovering readily the kind of product arising from the multiplication of any two single denominations together.

2297*c*. When the number of feet runs very high in the factors, it will be better to write down the product of each multiplication, without casting out the twelve, and add together those of each denomination beginning on the right, and divide by 12, to carry to the next higher place, then add these, and so on, as often as there are places in the whole product.

Example.—Multiply 262 ft. 5 in. by 54 ft 8 in.

262 : 5		
54 : 8		
	2099 : 4	
1048 : 20		
13100 : 250		
197 = $\frac{2369}{12}$		
14345 : 5 : 4		

Thus, under inches, the products being set down and added, they amount to 2369, which, divided by twelve, gives 197 to carry to the place of feet, and 5 remainder. Then adding the feet together with the quantity carried, it gives the whole number of feet; while the operation is extremely simple and free from the troubles of either side operations or useless stress on the memory.

2297*d*. The division of the foot into 12 parts renders the application of the rules of *practice* very valuable in the computation of duodecimals. The practical rule is to set down the two dimensions one under the other, that is, feet under feet and inches under inches, and multiply each term in the multiplicand by the feet in the multiplier, beginning at the lowest; and, if the numbers be large, put down the inches without carrying 1 for every 12 from inches to feet. Then, instead of multiplying by the inches, take such aliquot parts of the multiplicand as the inches are of a foot; after which add the lines together, carrying 1 for every 12 inches.

Example I.—Multiply 7 ft. 5 in. by 3 ft. 4 in.

4 in. = $\frac{1}{3}$	7 : 5
	3 : 4
	22 : 3
	2 : 5 : 8
	24 : 8 : 8

Example 2.—Multiply 262 ft. 5 in. by 54 ft. 8 in.

8 = $\frac{2}{3}$	262 : 5
	54 : 8
	1048 : 270
	1310
	87 : 5 : 8
	87 : 5 : 8
	23 = $\frac{281}{12}$: 4
	14345 : 5 : 4

The same examples have been used to show the relative advantages of the two methods.

2297*e*. Thus far we have treated of the squaring of dimensions to obtain the *superficies* of work. To learn the *solidity* of certain materials, such as timber, stone, and some others, the dimensions have to be cubed. The process is similar to the above, and is continued a further step. One example will suffice to explain the method, and we will take the figures given in the above system.

Example.—What is the cube of a block of stone, 7 ft. 5 in. wide, 3 ft. 4 in. thick, and 12 ft. long?

7 : 5
3 : 4
22 : 3
2 : 5 : 8
24 : 8 : 8 super.
12
296 : 8 : 0 cube.

2297*f*. The abridgment of the labours of practical men is always a matter of importance—being identical with the saving of time which is lost in calculation, and which with the architect is of the utmost importance, when it is recollected what multifarious duties he has to discharge. Hence the following table of squares, cubes, and roots of numbers, up to 1000, will be most acceptable to him. The first column of the Table shows the number, the second the square of such number, the third exhibits its cube. In the fourth column is found the square root of the number, and in the fifth its cube root. Thus, looking to the number 61 in the first column, its square is found to be 3721, its cube 226981, its square root 7·8102497, and its cube root 3·936497. Again, taking the number 784, we find its square to be 614656, its cube 481890304, its square root 28, and its cube root 9·220872.

No.	Square.	Cube.	Square Root.	CubeRoot.	No.	Square.	Cube.	Square Root.	CubeRoot.

2297*h*. A *power* is that number which is obtained by multiplying a number several times by itself. A square is the number muliplied by itself; a cube, twice by itself. The square is called the second power; and the cube the third; when multiplied again by itself it becomes the fourth power (commonly called the *bi-quadrate*); and so on :—

Power.	Of No. 2.	Of No. 3.	Number	4th Power.	5th Power.
I.	2	3	1	1	1
II. or	square 4 or	square 9	2	16	32

2297*i*. We shall now at once proceed to the general principles on which the measurement and estimation of work in the several artificers' departments are conducted; premising that the Manchester Society of Architects have issued a *revised* edition (July 1886) of their recommendations as to the method of taking out quantities and measuring up work, which may possibly be of use and interest to many students. It is reprinted in the *British Architect* for September 3, 1886, p. 233.

2298. Excavator. Digging is performed by the solid yard of 27 cubic feet (that is, 3 feet × 3 feet × 3 feet = 27 feet). Where the ground is soft in consistence, and nothing more is necessary beyond cutting with a spade, a man may throw up a cubic yard per hour, or ten cubic yards in a day; but if of firmer quality, *hacking* becomes necessary, and an additional man will be required to perform the same work; if very strong gravel, more assistance will be required. If, therefore, the wages of a labourer were 2*s*. 6*d*. per day, the price of a yard would be 3*d* for cutting only, without profit to the contractor; 6*d*. for cutting and hacking, and 9*d*. if two hackers be necessary. In sandy ground, where wheeling becomes necessary, three men will remove 30 cubic yards in a day to the distance of 20 yards, two for filling and one for wheeling. But to remove the same quantity in a day to a greater distance, an additional man for every 20 yards will be required.

2299. The quantity of excavation is the length multiplied into the depth and width. In the cases of trenches dug for the reception of walls, and sloped to prevent the earth falling in, a mean width is to be taken. Thus, suppose an excavation 24 feet long, 4 feet wide at top, and 2 feet at the bottom (average width therefore 3 feet), and 5 feet deep, we have for the quantity of earth $\frac{24 \times 3 \times 5}{27} = 13{\cdot}33$ cube yards.

2300. Brickwork. In measuring and estimating the value of brickwork, the following points must be remembered. A rod of brickwork is a mass 16½ feet square; hence the quantity of superficial feet which it contains is 272¼ feet (16·5 × 16·5); but the ¼ of the foot is too trifling to make it worth while to embarrass calculations with it, and consequently 272 feet is universally taken as the superficial standard content of a rod. Its standard thickness is one brick and a half (or 13½ inches). Hence it follows, that a cubic rod of brickwork would be 272 feet × 13½ inches = 306 feet cube. The allowance for the number of bricks is taken as between 4000 and 4500; much depending on the closeness of the joints and the nature of the work. In walling, a reduced foot is generally taken as requiring 17 bricks; a foot superficial in Flemish bond, laid in malm facing, about 8 bricks; and a foot superficial of gauged arches, 10 bricks. In paving, a yard requires 82 paving bricks, or 48 stock bricks, or 144 Dutch clinkers laid on edge, or 36 bricks laid flat.

2301. Tiling is measured by the square of 100 superficial feet; a square will require 800 at a 6 inch guage, 700 at a 7-inch gauge, and 600 at an 8-inch gauge. The gauge necessarily regulates the distance of the laths, and, at the same time must be dependent on the slope of the roof, which, if flat, should not be less than 6 inches, as for instance, above the kerb in a kerb roof; and not more than 8 inches in any case. A square of plain tiling requires about on an average a bundle of laths, two bushels of lime, and five of sand, and at least a peck of oak pins. The laths are sold in bundles of 3, 4, and 5-feet lengths. A bundle of the 3-feet contains eight score, the 4-feet six score, and the 5-feet five score to the bundle. The nails used are fourpenny; they are purchased by the long hundred, that is, of six score, and, in day work, are charged by the bricklayer 5-score to the hundred. The name of nails, as fourpenny, fivepenny, &c., means 4*d*., 5*d*, &c. per 100. The number of nails required for a bundle of 5-feet laths is 500, for 6-feet laths is 600.

2302. A square of pantiling requires 180 tiles laid at a 10-inch gauge and a bundle of 12 laths 10 feet long. (See Table 2321.)

2303. In lime measure, a "hundred" is 100 pecks, or 25 striked bushels (a measure).

2304. In sand measure, 18 heaped bushels, or 21 striked bushels, equal to 1 yard cube, is a single load, and about 24 cubic feet 1 ton.

2305. In mortar 27 cubic feet make 1 load, which on common occasions contains half a hundred of lime with a proportional quantity of sand. Eleven hundred and thirty-four cubic inches make a hod of mortar; that is, a mass 9 inches wide, 9 inches high, and 14 inches long. Two hods of mortar are nearly equal to half a bushel. The following measures and weights it may be also useful to remember: —

$23\frac{1}{2}$ cubic feet of sand = 1 ton; hence 1 cubic foot weighs 95·3 lbs.

$17\frac{1}{2}$ cubic feet of clay = 1 ton; hence 1 cubic foot weighs about 130 lbs.

18 cubic feet of common earth = 1 ton; hence 1 cubic foot weighs nearly 124 lbs.

306 cubic feet of brickwork = 13 tons; hence 1 cubic foot is equal to full 95 lbs.

2306. In the measurement of brickwork, from the surface being 272 feet and the standard thickness $1\frac{1}{2}$ brick, it will be immediately seen that nothing more is requisite than, having ascertained the thickness of each part of the work, to reduce it to the standard thickness above stated, and this will be found sufficiently easy in almost all cases. Where, however, this cannot be done, we can always ascertain with sufficient accuracy the cubic contents in feet of any mass of brickwork; and dividing by 306 we have the number of rods.

2307. We here present an illustration in a wall of the most common occurrence (*fig.* 808*h*), which we will suppose 20 feet long without reference to any wall which might return from it, and thus diminish its length in measuring therewith a *returning wall.* The following is the method of entering and calculating the dimensions.

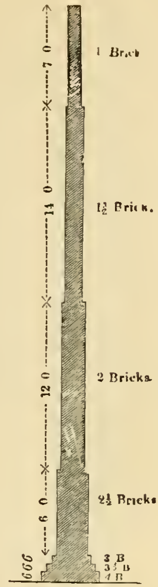

Fig. 808*h*.

	Length multiplied by the Height.	Area.	Number of Bricks in Thickness.	Factors to reduce the Area to Standard of $1\frac{1}{2}$ Brick.	Thickness reduced to $1\frac{1}{2}$ Brick in Feet sup.
Footings 6 courses	20·0 / 6	10·0	4	$2\frac{2}{3}$	26·8
	20·0 / 6	10·0	$3\frac{1}{2}$	$2\frac{1}{3}$	23·4
	20·0 / 6	10·0	3	2	20·0
Basement wall -	20·0 / 6·0	120·0	$2\frac{1}{2}$	$1\frac{2}{3}$	200·0
Ground-floor wall	20·0 / 12·0	240·0	2	$1\frac{1}{3}$	320·0
One-pair wall -	20·0 / 14·0	280·0	$1\frac{1}{2}$	1	280·0
Two-pair wall -	20·0 / 7·0	140·0	1	$\frac{2}{3}$	93·4
					963·4

Therefore the total is 963·4 superficial feet $1\frac{1}{2}$ brick thick, and $\frac{963}{272}$ = 3 rods, 147 feet.

2308. Upon this principle the measuring and estimation of brickwork is conducted, and having the price and quantity of bricks in a rod, and the lime, sand, and labour, which will presently be given, we may come to a pretty accurate knowledge of its value. But there are other articles which will require our attention, to which we shall presently advert. Before proceeding, however, we may as well observe that the above result of 3 rods 147 feet might have been similarly obtained by cubing the mass of brickwork and dividing the whole mass by 306, but with much more labour.

2309. In measuring walls faced with bricks of a superior quality, the area of such facing must be measured, or allowance extra is made in the price per rod of the brickwork.

2310. All apertures and recesses from any of the faces are deducted.

2311. Gauged arches are sometimes deducted and charged separately, sometimes not; but whether deducted or not does not signify, as the extra price must be allowed in the latter case and the whole price in the former. Rubbed and gauged arches, of whatever form, are measured and charged by the superficial foot.

2312. The angles of groins, outside and inside splays, bird's mouths, bull's noses, are measured by the lineal or running foot; but cuttings are measured by the foot superficial. Chimneys are measured solid to allow for the trouble of forming and pargetting the flues. The opening at bottom, however, is to be deducted.

2313. Quarters in bricknogging are measured in, as are all sills, stone strings, and timber inserted in walls. Two inches are also allowed in the height of brickwork for bedding plates if no brickwork be over them.

2314. Ovens, coppers, &c. are measured as solid work, deducting only the ash holes; but all fire stone, Welsh lumps, tiles, &c., though measured alone, are not to be deducted out of the brickwork. Pointing, colouring, &c. to fronts, is measured by the foot superficial. Plantile creesing by the foot lineal.

To estimate the value of a rod of brickwork, the method is as under: —

	£	s.	d.
4500 stocks, at per thousand - - - - -	0	0	0
$1\frac{1}{2}$ hundred of lime = $37\frac{1}{2}$ striked bushels containing 27 feet cube to the hundred - - - - - - -	0	0	0
2 loads of sand - - - - - - -	0	0	0
Labour and scaffolding - - - - - -	0	0	0
	0	0	0
Per cent. profit - - - - - -	0	0	0
Per rod - - - - - -	0	0	0

2315. In measuring and estimating all sorts of artificers' works, the method usually adopted for saving labour in making out the account is to arrange in separate columns each sort of work, and then to add them up and carry the total to the bill. In brickwork, where walls are of different thicknesses, these with their deductions are arranged in separate columns, and then all are reduced to the standard thickness.

2316. The common measure for tiling is a square of 10 feet, containing therefore 100 feet superficial. Claims are made for the eaves to the extent of 6 inches; but in pantiling this ought not to be allowed, as a claim not founded in justice, though custom is pleaded for it.

2317. The following table shows the number of bricks necessary for constructing any number of superficial feet of walling from 1 to 90,000, and from half a brick to $2\frac{1}{2}$ bricks thick; and thence, by addition only, to any thickness or number required, at the rate of 4500 bricks to a reduced rod. Thus, if it be required to find the number of bricks wanted to build a piece of work containing 756 feet super. of walling $1\frac{1}{2}$ brick thick, we find by inspection for 700 feet 11580 bricks; for 50 feet, 827 bricks; and for 6 feet, 99 bricks; in all, 11580 + 827 + 99 = 12506.

Table showing the requisite Quantity of Bricks for a given Superficies of Walling.

10000	75000	70000	65000	16666⅔	15000	13333⅓

The use of the foregoing tables it can scarcely be necessary to explain. They are such as to indicate, on inspection, their value; and we shall therefore leave them without further comment for their application.

2322. When work is performed by the day, or the materials used are to be numbered, as ofttimes necessarily occurs, fire bricks, red rubbers, best marle stocks for cutters, second best ditto, pickings, common bricks, place bricks, paving bricks, kiln-burnt bricks, and Dutch clinkers are charged by the thousand.

2323. Red rubbers, kiln and fire-burnt bricks, are also charged by the hundred. Foot tiles and ten inch tiles are charged either by the thousand or hundred.

2324. Sunk foot tiles and ten-inch tiles with five holes, now never used in the south of England, are charged by the piece.

2325. Pantiles, plaintiles, and nine-inch tiles are charged by the thousand.

2326. Oven and Welsh oven tiles, Welsh fire lumps, fire bricks, and chimney pots are also sold by the piece.

2327. Sand, clay, and loam are charged by the load; lime sometimes by the hundred weight; but the *hundred* of 100 pecks is the more usual measure in and about the metropolis. Dutch terras is charged by the bushel, which is also sometimes the measure of lime. Portland and other cements are similarly charged. Plaster by the bag.

2328. Pantile and plaintile laths are charged by the bundle or load; hair and mortar by the load; hip hooks and T tiles by the piece.

2329 Neither here, nor in the following pages, is it intended to convey to the reader more than the principles on which an estimate is founded. The prices of materials are in a state of constant fluctuation; something approaching a constant value, from the known performance of a good workman, was given in the previous editions from the computations of Peter Nicholson, but they are now omitted. Wood working machinery has also altered the values very materially.

CARPENTRY AND JOINERY.

2330. The works of the Carpenter are the preparation of piles, sleepers, and planking, and other large timbers, formerly much, but now rarely, used in foundations; the centering on which vaults are turned; wall plates, lintels, and bond timbers; naked flooring, quarter partitions, roofing, battening to walls, ribbed ceilings for the formation of vaulting, coves, and the like in lath and plaster, posts, &c.

2331. In large measures, where the quantity of materials and workmanship is uniform, the articles are usually measured by the square of 100 feet. Piles should be measured by the foot cube, and the driving by the foot run according to the quality of the ground into which they are driven. Sleepers and planking are measured and estimated by the foot, yard, or the square.

2332. Plain centering is measured by the square; but the ribs and boarding, being different qualities of work, should be taken separately. The dimensions are obtained by girting round the arch, and multiplying by the length. Where groins occur, besides the measurement as above, the angles must be measured by the foot run, that is, the ribs and boards are to be measured and valued separately, according to the exact superficial contents of each, and the angles by the linear foot, for the labour in fitting the ribs and boards, and waste of wood.

2333. Wall plates, bond timbers, and lintels are measured by the cubic foot, and go under the denomination of *fir in bond.*

2334. In the measurement and valuation of naked flooring, we may take it either by the square or the cube foot. To form an idea of its value, it is to be observed, that in equal cubic quantities of small and large timbers the latter will have more superficies than the former, whence the saving is not in proportion to the solid contents; and the value, therefore, of the workmanship will not be as the cubic quantity. The trouble of moving timbers increases with their weight, hence a greater expenditure of time; which, though not in an exact ratio with the solid quantity, will not be vastly different, their sections not varying considerably in their dimensions. As the value of the saving upon a cube foot is comparatively small to that of the work performed by the carpenter, the whole cost of labour and materials may be ascertained with sufficient accuracy when the work is uniform.

2335. When girders occur in naked flooring, the uniformity of the work is thereby interrupted by the mortices and tenons which become necessary; thus the amount arising from the cubic quantity of the girders would not be sufficient at the same rate per foot as is put on the other parts, not only because of the difference of the size, but because of the mortices which are cut for the reception of the tenons of the binding joists. Hence, for valuing the labour and materials, the whole should be measured and valued by the cubic quantity, and an additional rate must be put upon every solid foot of the girders; or, if the binding joists be not inserted in the girders at the usual distances, a fixed price must be put upon every mortice and tenon in proportion to their size, The binding joists are not unfrequently pulley or chase-mortised for the reception of the ceiling joists; sometimes they are notched to receive the bridging joists on them, and they should therefore be classed by themselves at a larger price per foot cube, or at an additional price for the workmanship, beyond common joisting. All these matters must be in proportion to the description of the work, whether the ceiling joists be put in with pulley mortises and tenons, or the bridgings notched or adzed down.

2336. Partitions may be measured and estimated by the cube foot; but the sills, top pieces, and door heads should be measured by themselves, according to their cubic contents, at a larger price; because not only the uniform solidity, but the uniform quantity, of the workmanship is interrupted by them. The braces in trussed partitions are to be taken by the foot cube at a larger price than the common quartering, on account of the trouble of fitting the ends of the uprights upon their upper and lower sides, and of forming the abutments at the ends.

2337. All the timbers of roofing are to be measured by the cubic foot, and classed according to the difficulty of execution, or the waste that occurs in performing the work. Common rafters, as respects labour, are rated much the same as joists or quarters; purlins, which require trouble in fitting, are worth more, because on them are notched down the common rafters. The different parts of a truss should, to come accurately at the true value, be separately taken, and the joggles also separately considered, including the tenons at the ends of the struts; mortising tie beams and principals, forming the tenons of the truss posts; mortising and tenoning the ends of the tie beams and principals; also the work to the feet of common or bridging rafters. The iron strapping is paid for according to the number of the bolts.

2338. The battening of walls are measured by the square, according to the dimensions and distances of the battening.

2339. Ribbed ceilings are taken by the cubic quantity of timber they contain, making due allowance for the waste of stuff, which is often considerable. The price of their labour is to be ordered by the nature of the work, and the cubic quantity they contain.

2340. Trimmers and trimming joists are so priced as to include the mortises and tenons they contain, and also the tenons at the extremities of the trimmers. But to specify all the methods required of ascertaining the value of each species of carpenter's work would be impossible, with any respect to our limits. They must be learned by observation; all we have to do is with the principles on which measuring and estimating is conducted.

2341. When the *carcass* of the building is completed, before laying the floors or lathing the work for receiving the plastering, the timbers should be measured, so that the scantlings may be examined and proved correct, according to the specification; and in this, as a general rule, it is to be remembered that all pieces having tenons are measured to their extremities, and that such timbers as girders and binding joists lie at least 9 inches at their ends into the walls, or $\frac{1}{3}$ of the wall's thickness, where it exceeds 27 inches. In the measurement of bond timber and wall plates, the laps must be added to the net lengths. If a necessity occur for cutting parallel pieces out of truss posts (such as king or queen-posts), when such pieces exceed 2 feet 6 inches in length, and $2\frac{1}{2}$ inches in thickness, they are considered as pieces fit for use, deducting 6 inches as waste from their lengths.

2342. The boarding of a roof is measured by the square, and estimated according to its thickness, and the quality of boards and the manner in which they are jointed.

2343. Where the measurement is for labour and materials, the best way is, first, to find the cubical contents of a piece of carpentry, and value it by the cubic foot, including the prime cost, carting, sawing, waste, and carpenter's profit, and then to add the price of the labour, properly measured, as if the journeyman were to be paid. It is out of the question to give a notion of any fixed value, because it must necessarily vary, as do materials and labour. The only true method of forming a proper estimate is dependent on the price of timber and deals, for which general tables may be formed.

2344. A load of fir timber contains 50 cube feet: if, then, the price of a load is known in the timber merchant's yard, the approximate value of a cube foot is found as under; say, if taken at 4*l.* 10*s.* per load, then —

	£	*s.*	*d.*
Prime cost of a load of fir - - - - - - - - -	4	10	0
Suppose the cartage (dependent on distance) - - - - -	0	5	0
Sawing into necessary scantlings - - - - - - -	0	10	0
	5	5	0
Waste in converting equal to 5 feet, at $2\frac{1}{10}$*s.* per foot, the load being 105*s.*	0	10	6
	5	15	6
20 per cent. profit on 5*l.* 15*s.* 6*d.* -	1	3	0
	£6	18	6

2345. Now, $\frac{6l.\ 18s.\ 6d.}{50} = 2{\cdot}77$ shillings, or 2 shillings and 9 pence and nearly 1 farthing per foot cube.

2346–50. It is only in this way that the value of work can be arrived at; it is much to be regretted that from no species of labour of the carpenter have been formed tables capable of furnishing such a set of constants as would, by application to the rate of a journeyman's wages, form factors, or, in other words, furnish data for a perpetual price-book. As we have before hinted, the best of the price-books that have ever been published are useless as guides to the value of work. The method of lumping work by the square is as much as possible to be avoided, unless the surfaces be of a perfectly uniform description of workmanship; as, for instance, in hipped roofs, the principal trouble is at the hips, in fitting the jack rafters, which are fixed at equal distances thereon; hence such a price may be fixed for the cubic quantity of hips and valleys as will pay not only for them, but also for the trouble of cutting and fixing the jack rafters. Such parts, indeed, as these should be separately classified; but the analysis of such a subject requires investigation of enormous labour; and as it must depend on the information derived from the practical carpenter, is, we fear, not likely to be soon, if ever, accomplished.

2351. The works of the Joiner consist in the preparation of boarding, which is measured and estimated by the foot superficial. Of this there are many varieties; as, edges shot; edges shot, ploughed, and tongued; wrought on one side and edges shot; the same on both sides and edges shot; wrought on both sides and ploughed and tongued. Boards keyed and clamped; mortise clamped, and mortise and mitre clamped. The value per foot increases according to the thickness of the stuff. When longitudinal joints are glued, an addition per foot is made; and if feather-tongued, still more.

2352. The measurement and estimation of floors is by the square, the price varying as the surface is wrought or plain; the method of connecting the longitudinal and heading joints, and also on the thickness of the stuff; as well as on the circumstance of the boards being laid one after another or folded; or whether laid with boards, battens, wainscot, or other wood. Skirtings are measured by the foot super, according to their position, as whether level, raking, or ramping. Also on the manner of finishing them, as whether plain, torus, rebated, scribed to floors or steps, or whether straight or circular on the plan.

2353. The value of every species of framing must depend on the thickness of the stuff employed, whether it is plain or moulded; and if the latter, whether the mouldings be struck on the solid, or laid in; whether mitred or scribed, and upon the number of panels in a given height and breadth, and also on the form of the plan.

2354. Wainscotings, window-linings, as backs and elbows; door linings, such as jambs and sofites, with their framed grounds; back linings, partitions, doors, shutters, and the like, are all measured and valued by the foot super. The same mode is applied to sashes and their frames, either together or separately.

2355. Skylights, the prices whereof depend on their plans and elevations, are also measured by the foot super.

2356. The value of dado, which varies as the plan is straight or circular or being level or inclined, is measured by the foot super.

2357. In the measurement of staircases, the risers, treads, carriages, and brackets are, after being classed together, measured by the foot super, and the string board is sometimes included. The value varies as the steps may be flyers or winders, or from the risers being mitred into the string board, the treads dovetailed for balusters and the nosings returned, or whether the bottom edges of the risers are tongued into the step. The curtail step is valued by itself, and returned nosings are sometimes valued at the piece; and if they are circular on the plan, they are charged at double the price of straight ones. The handrail, whose value depends upon the materials and diameter of the well hole, or whether ramped, swan-necked, level, circular, or wreathed; whether got out of the solid, or in thicknesses glued up together, is measured by the foot run. The scroll is charged by itself, as is the making and fixing each joint screw, and 3 inches of the straight part at each end of the wreath is measured in. The deal balusters, as also the iron ones and the iron columns to curtail, housings to steps and risers, common cut brackets, square and circular on the plan, together with the preparing and fixing, are valued all by the piece. Extra sinking in the rail for iron balusters is valued by the foot run, the price depending on the rail, as being straight, circular, wreathed, or ramped. The string board is measured by the foot super, and its value is greater or less as it is moulded, straight, or wreathed, or according to the method in which the wreathed string is constructed by being properly backed upon a cylinder.

2358. The shafts of columns are measured by the foot super., their value depending upon the diameter, or whether it be straight or curved on the side, and upon its being properly glued and blocked. If the columns be fluted, the flutes are taken in linear measure, the price depending on the size of the flutes, whose headings at top and bottom are charged by the piece. Pilasters, straight or curved in the height, are similarly measured, and the price taken by the foot super. In the caps and bases of pilasters, besides the mouldings, the mitres are charged so much each, according to the size.

2359. Mouldings, as in double-face architraves, base and surbase, or straight ones struck by the hand, are valued by the foot super. Base, surbase, and straight mouldings wrought by hand, are generally fixed at the same rate per foot, being something more than double-faced architraves. When the head of an architrave stands in a circular wall, its value is four times that of the perpendicular parts, as well on account of the extra time required to fit it to the circular plan as of the greater difficulty in forming the mitres. So all horizontal mouldings on a circular plan are three or four times the value of those on a straight plan, the trouble being increased as the radius of the circle upon which they are formed diminishes. The housings of mouldings are valued by the piece. The value of mouldings much depends on the number of their quirks, for each whereof the price increases. It will also, of course, depend on the materials of which they are formed, on their running figure, and whether raking or curved.

2360. Among the articles which are to be measured by the lineal foot are beads, fillets, bead or ogee capping, square angle staffs, inch ogees, inch quirk ogee, ovolo and bead, astragals and reeds on doors or shutters, small reeds, each in reeded mouldings, struck by hand up to half an inch, single cornice or architrave, grooved space to let in reeds and grooves. And it must be observed, that in grooving, stops are paid extra; if wrought by hand, still more; and yet more if circular. Besides the foregoing, narrow grounds to skirting, the same rebated or framed to chimneys, are measured by the foot run. Rule joints, cantilevers, trusses, and cut brackets for shelves are charged by the piece. Water trunks are valued according to their size by the foot run, their hopper heads and shoes being valued by the piece. Moulded weather caps and joints by the piece. Scaffolding, where extra, must be allowed for.

2361. Flooring boards are prepared according to their length, not so much each; the standard width is 9 inches; if they are wider, the rate is increased, each board listing at so much per list. Battens are prepared in the same way, but at a different rate.

2362. The following memoranda are useful in estimating: —

1 hundred (120) 12-feet-3-inch deals, 9 inches wide (each deal containing, therefore, 2 feet 3 inches cube), equal $5\frac{5}{8}$ loads of timber.

1 hundred (120) 12-feet-$2\frac{1}{2}$-inch deals, 9 inches wide (each deal containing, therefore, 1 foot 10 inches cube), equal $4\frac{1}{2}$ loads of timber.

1 hundred (120) 12-feet-$1\frac{1}{2}$-inch deals equal 1 reduced hundred.

1 load of $1\frac{1}{2}$-inch plank, or deals, is 400 feet superficial.

1 load of 2-inch plank, or deals, is 300 feet superficial.

And so on in proportion.

Twenty-four 10-feet boards, at a 5-inch guage, will finish one square.

Twenty 10-feet boards, at 6-inch guage, will finish one square.

Seventeen 10-feet boards, at a 7-inch guage, will finish one square.

Fifteen 10-feet boards, at an 8-inch guage, will finish one square.

Thirteen 10-feet boards, and 2 ft. 6 in. super, at a 9-inch guage, will finish one square.

Twelve 10-feet boards, and 2 ft. 6 in super., at a 10-inch guage, will finish one square.

Twenty 12-feet boards, at a 5-inch guage, will finish one square.

Sixteen 12-feet boards, at a 6-inch guage, will finish one square.

Fourteen 12-feet boards, at a 7-inch guage, will finish one square.

Twelve 12-feet boards and 4 feet super., at an 8-inch guage, will finish one square.

Eleven 12-feet boards, and 1 foot super., at a 9-inch guage, will finish one square.

Ten 12-feet boards, and 1 foot super., at a 10-inch guage, will finish one square.

Battens are 6 inches wide.

Deals are 9 inches wide.

Planks are 11 inches wide.

Feather-edged deals are equal to $\frac{3}{4}$-inch yellow deals; if white, equal to slit deal.

A reduced deal is $1\frac{1}{2}$-inch think, 11 inches wide, and 12 feet long.

2363. It may here be useful to advert to the mode of reducing deals to the standard of what is called a reduced deal, which evidently contains 1 ft. 4 in. 6 parts cube; for 12 ft. × 11 in. × $1\frac{1}{2}$ in. = 1 : 4·46, or in decimals, 12 ft. × ·91666 ft. × ·125 ft. = 1·375 cube ft. nearly. Hence the divisor 1·375 will serve as a constant for reducing deals of different lengths and thicknesses. Thus let it be required to find how many reduced deals there are in one 14 feet long, 10 inches wide, and $2\frac{1}{2}$ inches thick. Here 14 ft. × ·8333 ft. (or 10 in.) × ·20833 (or $2\frac{1}{2}$ in.) = 2·43042 cube feet, and $\frac{2·43042}{1·375} = 1·767$ reduced deal.

2364. The table which is now subjoined exhibits the prices of deals and parts thereof calculated from 30*l.* to 95*l.* per hundred, a range of value out of which it can rarely happen that examples will occur, though it has fallen within our own experience during the late war to see the price of deals at a very extraordinary height. This, however, is not likely to happen again. The elements on which it is based are —

First.	Price of deals, each being 12 feet long, three inches thick, 10 inches wide. Then from $\frac{30l.}{120}$ we have the prime cost of each deal	5·00
Second.	Profit on prime cost, 15 per cent. - - - - -	0·75
Third.	Planing both sides and waste, the former a constant depending on the price of labour (say 5*s.* per day used in the table), and the latter a variable, increasing with the cost price of the material -	0·8333
	6*s.* 7*d.* as in the table for a 12 feet deal =	6 5833

In the third element a *constant* (the planing) being involved and a *variable* (the waste) increasing with the cost of the material, the latter was eliminated by experiment and found equal to ·4166 shilling for every 10*l.* upwards of the price per hundred of the deals.

The width of the running foot is 9 inches. For instance at 45*l.* per cent. the cost of a foot super. (=144 in.) = 1·25*s.* = 1*s.* 3*d.* and of a foot run ·9375 shilling = 11½*d.* ∴ $\frac{\frac{11 \times \cdot 9375}{1 \cdot 25}}{12}$ = 9 inches. This table is applicable purely to joinery.

Price per hundred.	Thickness.	10 feet long each.	12 feet long each.	14 feet long each.	Per foot run.	Per foot super.	Price per hundred.	Thickness.	10 feet long each.	12 feet long each.	14 feet long each.	Per foot run.	Per foot super.

2365–9. The above table almost explains itself, but one example will be taken for illustrating its use, premising that if deals are at a price between, above, or below that stated in the first column, the rules of arithmetic must be applied for the intermediate prices. Suppose deals, then, to be at 45*l.* per hundred; an inspection of the table shows that the value of 1½-inch deal is 8*d.* per foot super., or 6*d.* run; that a 12-foot deal 2 inches thick is worth 6*s.* 8¼*d.*; and that a foot run of 3-inch deal 11 inches wide, which is the standard width, is worth 11¼*d.* The preceding table, which is applicable purely to joinery, is all that can be here given in general terms as to the prices of work.

2370. Slater. The work of the slater is measured and estimated by the square of 100 feet superficial. The different sorts of slate, and how much a given quantity of each will cover, have been described in Chap. II. Sect. IX. (1798 *et seq.*). To measure slating, in addition to the net measure of the work, 6 inches are allowed for all the eaves, and 4 inches by their length for hips; such allowance being made in the first-named case because the slates are there double, and in the latter case for the waste in cutting away the sides of the slates to fit. When rags or imperial slates are used, an addition allowance of 9 inches is made for the eaves, because those slates run larger than the other sorts.

2371. Mason. Solid works, such as pilasters, cornices, coping, stringings, and others, should be first measured to ascertain the cubic quantity of stone they contain as going from the *banker* to the building; and on this, additional work, as plain work, sunk work, moulded or circular work, must be measured in superficial feet and separately valued. It is usual to allow a plain face to each joint, but no more than one should be taken to a 3-feet length. In staircases the flyers should be taken where splayed on the back, their full length and width by three-fifths of the depth of the riser, to allow for waste in getting two of the steps from the same block of stone. The measurement for the winders seems to be most properly conducted by ascertaining the net cubic contents of them, and then making the allowance for waste. Indeed this is a more proper and satisfactory mode for the flyers. The top of the treads are then taken on the superficies as plain work, and the fronts and ends of the risers as moulded work. In an open staircase, the under side of the flyers is measured as plain work; the under side of the winders as circular plain work; the rebates, cuttings out, pinnings in, &c., as they are found. Cylindrical work, such as of columns, after the cube quantity is ascertained, is measured as equal to plain work twice taken. In Portland dressings to chimneys, wherever edges appear, it is customary to add an inch to the dimensions for extra labour; to marble, ¾ of an inch; or to take the running dimensions of the edges.

2372–3. Paving slabs and stones under 2 ins. thick are taken by superficial measure. Cornices are measured by obtaining their girt, and multiplying by their length for the quantity of moulded work in them.

2374. Founder. The proper mode of estimating cast iron is by the ton or cwt. Moulds for the castings, when out of the common course, are charged extra. Very often, too, cast iron pipes and gutters are, according to their sizes, charged by the yard. Wrought iron beams and girders, of various shapes, are charged for by the ton. (See 1765 *et seq.*) For ornamental castings patterns have to be made; these are usually paid for in addition, and are often expensive.

2375. Smith and Ironmonger. Wrought iron for chimney bars, iron ties, screw bolts, balusters with straps, area gratings, handrails and balusters, hook-and-eye hinges, brackets for shelves, chains for posts, wrought iron columns with caps and bases, fancy iron railing, casements, shutter-bars, and the like, are charged by the pound, at various prices, according to the nature of the work. In the ironmonger's department nails and brads are charged by the hundred, though sold by weight, seldom exceeding 900 to the 1000. Screws, which take their names from their length, are charged by the dozen. Cast, and also wrought butts and screws, cast and wrought back flaps, butts and screws, side or H hinges, with screws, by the pair. All sorts of bolts with screws, of which the round part of the bolt determines the length, by the inch. HL hinges and cross garnet hinges by the pair. Other hinges and screws by the piece. Locks by the piece. Pulleys according to their diameters. On all ironmongery 20 per cent. is charged on the prime cost. Wrought iron ornamental work is charged for according to the time and skill. (See 2253 *et seq.*)

2376. Plasterer. The work of the plasterer is measured, generally, by the yard superficial. The usual way of measuring stucco work to partitions and walls is, to take the height from the upper edge of the ground to half way up the cornice, the extra price of the stucco making good for the deficiency of floated work under it. In ceilings and other work, the surface under the cornice is often taken, because there is no deficiency but in the setting, and that is compensated for by the labour in making good. Cornices are measured by the foot superficial, and estimated according to the quantity of mouldings and enrichments they contain. Where there are more than four angles in a room, each extra one is charged at the price per foot run extra of the cornice. Stucco reveals are charged per foot run, and according to their width of 4 or 9 inches or more. Quirks, arrises, and beads by the foot run, as are margins to raised panels, small plain mouldings, &c. Enriched mouldings are measured by the foot run, and with flowers to ceilings, pateras, &c., must be considered with reference to the size and quantity of ornament; modelling may have to be charged if under 60 feet run. For some of these, papier-mâché and other materials (see 2251), which are much lighter than plaster, are coming now into general use, and from the ease and security with which they are fixed, often supersede the use of plaster ornaments. Scaffolding is charged for when the "hawk" cannot be served from the floor.

2377. Plumber. The work of this artificer is charged by the cwt., to which is added the labour of laying the lead. The superficies of the lead is measured, then multiplied by the weight, as 5 lb. lead, 6 lb. lead, &c., and brought into cwts. Water pipes, rain-water pipes, and funnel pipes are charged by the foot run, according to their diameter; so also are socket pipes for sinks, joints being separately paid for. Common lead pumps, with iron work, including bucket, sucker, &c., at so much each; the same with hydraulic and other pumps, according to their diameters. In the same manner are charged water-closets, basins, air traps, washers and plugs, spindle valves, stop-cocks, ball-cocks, &c. (See 2212 *et seq.*) By the increase of manufacturers of sanitary appliances these are now priced at per article.

2378. Glazier. The work of the glazier is measured and estimated by the superficial foot, according to the speciality as well as the quality of the glass used; it is always measured between the rebates. (See 2225 *et seq.*) Stained and painted glass are usually taken at agreed prices.

2379. Painter. In the measurement and estimation of painting, the superficial quantity is taken, allowing all edges, sinkings, and girths as they appear. When work is cut in on both edges it is taken by the foot run. The quantity of feet is reduced to yards, by which painting is charged for in large quantities. In taking iron railing, the two sides are measured as flat work; but if it be full of ornament, once and a half, or twice, is taken for each side. Sash frames are taken each, and sash squares by the dozen. On gilding we have already spoken in Sect. XII. (2277 *et seq.*) Cornices, reveals to windows and doors, strings, window sills, water trunks and gutters, handrails, newels, &c, are taken by the foot run. Many small articles by the piece. Plain and enriched cornices by the foot run, according to the quantity of work in them. Work done from a ladder is paid for extra. The price of painter's work greatly depends on the purity of the materials employed, as oil, turpentine, &c., as well as on the quality and the number of times over that the work is painted; the labour is usually considered as one-third of the price charged. Scarcely any trade varies so greatly. Imitations of woods and marbles are charged according to the artistic treatment and the labour employed on them, and the quality of the varnish used.

2380. Paperhancer. In common papers the price used to be settled according to the colours or quantity of blocks used in printing the pattern. Now the price appears to depend on the sale, or fashion, of the pattern, or on the manufacturer's pleasure. Until lately the old prices were charged, with a large discount, but now the price marked by some of the leading firms is subject only to the ordinary discount to the trade. Embossed and other papers are of higher prices. These, as well as lining paper, are charged by the piece, containing 63 feet super. The hanging is charged separate, and borders, dadoes, gilt mouldings, &c. by the yard run. (See 2277*c*.)

CHAP. IV.

MEDIUM OF EXPRESSION.

Sect. I.

DRAWING IN GENERAL.

2381. Under this section it is not our intention to enter into the refinements of the art, but merely to make the attempt of directing the student to the first principles of a faithful representation of ordinary and familiar objects, with all their imperfections; or, in other words, of transferring to a plane surface what the artist actually sees or conceives in his mind. This power is of vital importance to the architect, and without it he is unworthy the name.

2382. The usual mode of teaching drawing now in use is, as we conceive, among the most absurd and extravagant methods of imparting instruction that can be well conceived. The learner is usually first put to copying drawings or prints, on which he is occupied for a considerable time. Much more would he learn, and much more quickly, by following the course which the following lines will prescribe. *Outline* is the foundation of all drawing; the alphabet of graphic art. As soon as the student has attained the use of the pencil and the pen in drawing purely geometrical figures, he is prepared to receive the rudiments of perspective. As shown in the following section, the representations of all geometrical solids is dependent upon mechanical means; and these may, if it be desirable, be shadowed truly by the methods given in Sect. III.; but what is now called free-hand drawing is the matter for our present consideration.

2383. Outline, as we have stated above, is the foundation of all drawing, the alphabet of graphic art. Every representation of an object, or series of objects, however complicated, is in reality but a set of outlines composed of straight or curved lines. The knowledge, or rather the power of forming these lines, is essential to the student, and in the same manner that he was obliged to form pothooks and hangers before he proceeded to ellipses when he was taught to write, he should begin his study of free-hand drawing by practising himself in the production of straight lines, proceeding to segments, and then to curves of contrary flexure. It is a good plan to compare the copy with the pattern; and, inasmuch as all formal diagrams that are set as patterns should be perfect, it is desirable that the standards for straight lines, segments, and contrary flexures should be drawn by the teacher himself from rulers; these rulers can be subsequently applied to the copies, and are sometimes the only evidence upon which to make a mutinous pupil conscious of his errors. The student ought not to proceed to the elliptical and oval forms until the hand, first turning one way, can draw a tolerably correct circle; and then, turning in the other direction, can make another equally good. The next step will be to acquire the power of drawing spiral lines in one direction, and of repeating them in another; which will be followed by that of drawing lines either parallel or slowly approximating.

2383*a*. After this, the student is sufficiently advanced to attempt to repeat all these stages with copies of a size larger or less than the patterns; and he will be ready to learn the mechanical use of chalk. This branch of his tuition needs only such examples as the prints, which have been prepared for that purpose, of purely geometrical forms: in this stage the rudiments of shadow are implanted, and the use of the brush may be acquired.

2383*b*. The student will then be ready to learn the mode of obtaining local colour, and of blending his materials so as to obtain tints and shades of the different colours. The next steps would be to draw in chalk, in ink, or in colour, the simplest architectural ornaments, such as a chevron or an ovolo; and to proceed through a course of architectural foliage from prints. The result of such training is usually a confidence in the eye; and, what is sometimes highly important, a judgment so sound as to be able to reproduce any part of a subject that may have been destroyed.

2383*c*. Aptitude of the pupil must be a consideration, but in general a year of steady application may be sufficient so to imbue the mind with the grammar of architectural ornament, as to enable the hand to represent it; after which the student ought to be capable of inventing for himself. Indeed, it is only by such a course that originality in designing ornament can be obtained. The study of natural foliage, first as seen, and then as conventionalized, may be carried out at the same time.

2383*d*. It is very remarkable that all the inferences are false, which usually are derived from the assertion that he who can draw the human figure will be able to draw any other object that is submitted to him for representation. The few men who can *faultlessly* draw the human figure as they see it, may doubtlessly have eyes keen enough and hands true enough to repeat the minutest details so accurately that any comparison of a particular detail with the original shall be creditable to them; but these men have spent years in obtaining, besides delicacy of handling, that knowledge of anatomy which reminds them at every stroke of the pencil that such a muscle is in such a place, that here it overlaps another, that there it dies into a bone, and that consequently they have to mark the curves and angles which occur, for instance, six or seven times between the elbow and the wrist, and to determine how many can be omitted if the scale be less than that of life.

2384. The majority of men who can draw the figure tolerably well can draw nothing else equally correctly: for the reason that their attention has been given to the mechanism of the human form solely; the representation, by our best portrait-painters, of the accessories which they introduce into their pictures, especially of architectural details, is almost without an exception ludicrously inaccurate. Every person who has tried to apply his power of representing geometric forms to the task of copying in chalk from a mask, must be aware of the enormous facility which he acquires by previously studying the usual methods of expressing the totality of the eye, the ear, the nose, and the lips. In a similar manner, the artist who wishes to give the effect of a suite of mouldings, or of a carved ornament, requires to know previously all the parts which compose the work. In other words, some men can pretend to sketch distant rocks and yet miss the very features by which the outlines intimate the geological character.

2385. Such are the reasons which have for many years led to the conviction that the architect's course of drawing should leave the figure alone until he has made one or more studies from carving in each style of art that opportunity presents to him; this is affirmed to be the only method of obtaining a satisfactory appreciation of the minute characteristics which sometimes constitute the differences between styles; and the only method of making a royal road to the object, which some teachers pretend is the easiest, but is truly the most difficult, in art. Having acquired the power of accurate representation of ornament, which involves dexterity in the use of his materials, the student may commence his operations with the figure.

2386. The method proposed in the following pages is old, at least in principle, yet it has been of late years published as new in Paris, by M. Dupuis. ("*De l'Enseignement du Dessin sous le point de vue industriel*," 1836.) The principles of the work, however, are perhaps better expressed and arranged, in some respects, than we might have presented them to the reader: and we shall not, therefore, apologise for the free use we make of it, premising, however, that in respect to the whole figure and the application of the method to landscapes, what follows is not found in the work of M. Dupuis.

2387. Between the ancient mode of teaching the student (we will take the head, for instance, shown in *fig.* 809. as the first roughing of the leading lines of that which in *fig.* 812. has reached its completion) and the method practised by M. Dupuis, the only difference is this, that M. D., instead of letting the student form the rough outline at once from the finished bust, roughing out on paper the principal masses, provides a series of models roughly bossed out in their different stages, which he makes the student draw. The system is ingenious; but as the greatest artists have been made without the modification in question, we do not think it material; at all events, the principles are the same. M. Dupuis, for this purpose, has a series of sixteen models, the first of each four of the series are quite sufficient to show the old as well as his own practice. Thus, in

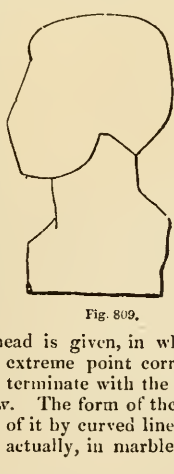

Fig. 809.

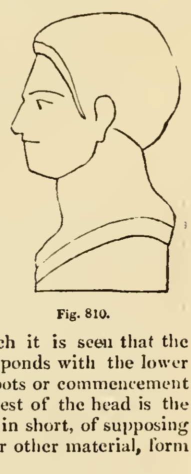

Fig. 810.

fig. 809., the general mass of the oval of the head is given, in which it is seen that the profile is indicated by an obtuse angle, whose extreme point corresponds with the lower part of the nose, and the lines at one extremity terminate with the roots or commencement of the hair, and at the other with the lower jaw. The form of the rest of the head is the result of combining the most projecting points of it by curved lines, in short, of supposing a rough mass, out of which the sculptor might actually, in marble or other material, form the head.

2388. The next step is exhibited in *fig.* 810., with the four principal divisions: the occipital to the beginning of the hair, the forehead to the line of the eyes, the projection of the nose, and the inferior part of the face, with some indication of the mouth.

2389. In *fig.* 811. it will be seen that another step is gained. The eyes (here only one appears, but we speak with reference to the subject, being less in profile), the mouth, the chin, and the ear are more clearly marked out, with some sort of expression of the whole work, but still without details, though sufficiently indicating that little more is necessary to bring the rude sketch of *fig.* 809. to a resemblance.

Fig. 811.

Fig. 812.

2390. In *fig.* 812. this is obtained; but still, according to the degree to which an artist considers finishing necessary, to be further pursued and carried through to make a perfect drawing; all that is here intended being to show the principles upon which the matter is conducted, and upon which we shall presently have further observations to make. It will be observed, that on the shadowing and finishing in this way the drawings the student may make we set no value: when he can draw, if those matters be of importance to him, they will not be difficult of acquisition.

2390*a*. Having accomplished the art of drawing, with tolerable correctness, the figure, the architect will have little difficulty in drawing the most complex productions of nature. The principles are precisely the same; but we wish here to impress upon him the necessity of recurring to nature herself for his ornaments: a practice which will always impart a freshness and novelty to them which even imitation of the antique will not impart.

2391. The port crayon, whether carrying chalk or a black lead pencil of moderate weight and size, say full seven inches long, is the best instrument to put into the hands of the beginner. The first object he must consider in roughing the subject, as in *fig.* 809., is the relation the height of the whole bears to its width; and this determined, he must proceed to get the general contour, without regard to any internal divisions, and thus proceed by subdivisions, bearing the relative proportions to each other of the model, comparing them with one another and with the whole. We will now show how the port crayon assists in this operation. Let the pupil be supposed seated before the model, at such a distance from it that at a single look, without changing the position of his head upwards, downwards, or sideways, his eye takes in the whole of it. The strictest attention to this point is necessary, for difficulties immediately present themselves if he is too near, as well as if he is too far from it. And here let it be observed that the visual rays (see *fig.* 813.) upon every object

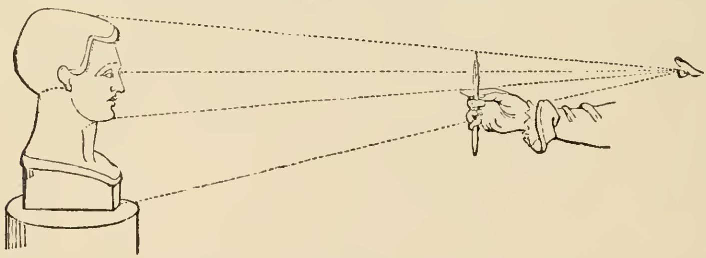

Fig. 813.

may be compared to the legs of a pair of compasses, which open wider as we approach the object and close as we recede from it. This is a law of perspective well known, and which the student may easily prove by experiment, keeping the head of the compasses near his eye, and opening the legs to take in, in looking along them, any dimension of an object. He will soon find that as he approaches such object he must open the legs wider in order to comprise within them the given dimension. Hence every diameter or dimension, separately considered, is comprised in the divergence of the visual rays. It is on this account that, being at a proper distance, any moveable measure which with a free motion of his body he can interpose upon some one of the points of the distance between his eye and the model, may, though much less than the model itself, take in the whole field of view, reach the extremities of the dimension, and consequently become of great assistance in certain mathematical measures. For by applying such a measure to one division only of the model, we shall obtain, as it were, an integer for finding a great many others into which the model may be subdivided.

2392. Thus, taking *fig.* 809., which is profile, and supposing the width at the neck unity, if this is twice and a half contained in the general height of the bust, we have immediately the proportions of one to two and a half, which may be immediately set out on the paper or canvas. This is not all; the integer or unity obtained by the diameter of the neck serves also for measuring the horizontal diameter of the head, and also of the bust; whence new proportions may be obtained. So much for the first casting of the general form. Now, in the entire bust, as respects the head only, suppose we wish to obtain the proportions of the principal divisions, — for example, from the base of the bust to the base of the chin, — we may establish another integer to measure other parts; as, if from the point of view, the distance from the base of the bust to the base of the chin is the same as from the last to the summit of the head, the learner would have nothing more to do in that respect than to divide the whole height into two equal parts. On the same principle, passing from divisions to subdivisions, the distance between the base of the chin and the point whence the nose begins to project, may be found a measure for the height of the nose, and from thence to the top of the cranium. We are here merely showing the method of obtaining different integers for measuring the different parts mentioned; others will in practice occur continually, after a very little practice. We do not suppose our readers will believe that we propose to teach drawing by mathematical rules; we now only speak of obtaining points from which undulating and varying lines are to spring and return, and which none but a fine and sensitive eye will be able to express. But to return to the port crayon, which is the moveable measure or compasses whereto we have alluded, and requires only skilful handling to perform the offices of compasses, square, plumb rule, and level. By interposing it (see *fig.* 813.) on the divergence of the visual rays between the eye and the object, we may estimate the relative proportions; since in the field of view the learner may apply it to the whole or any of the parts, and make any one a measure for another. For this purpose he must hold it, as shown in the figure, steadily and at arm's length. Any portion of it that is cut by the visual rays between any two parts of the object, becomes the integer for the measurement of other parts whereof we have been speaking. This in the drawing will be increased according as the size is greater or less than the portion of the port crayon intercepting the visual rays. This process may be easily accomplished by making, upon one and the same line of the visual ray, the extreme point of the port crayon to touch one of the extremities of the proportion sought upon the model, so that they may exactly correspond. Then at the same time fixing the thumb or fore-finger where the visual ray from the other extremity is intercepted, we shall find any equal length by moving the port crayon with the thumb and fore-finger fixed to any other part we want, as to size, to compare with the first, or by using the same expedient to other parts, other integers may be found. The different integers, indeed, which may be thus obtained is infinite. The port crayon will also serve the purpose of a plumb bob by laying hold of it by the chalk, and holding it just only so tight between the fingers as to prevent its falling, so that its own gravity makes it assume a vertical direction. Doing so, if it then be held up to intercept the visual rays, we may discover the proportion in which a line swells whose directon approaches the vertical, as also the quantity one part projects before another in the model; and comparing this again with the integer, obtain new points for starting from. Again, by holding it before the eye in an horizontal direction, we shall obtain the different parts of the model that lie before the eye in the same horizontal line. By degrees we shall thus soon find the eye become familiarised with the model it contemplates; judgment in arranging the parts supervenes; the hand becomes bold and unhesitating, and the leading forms are quickly transferred to the paper or canvas to be subdivided to such extent as is required by the degree of finish intended to be bestowed upon the drawing.

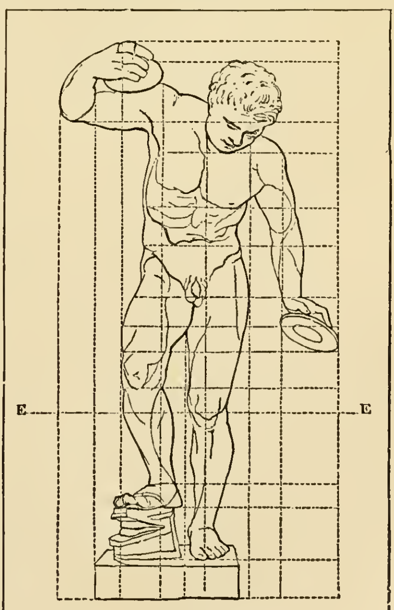

Fig. 814.

2393. The process that we have considered more with relation to the bust is equally applicable to the whole figure. In *fig.* 814. we have more particularly shown by the dotted lines the horizontal and vertical use of the port crayon; but the previous adjustment of some measure of unity for proportioning the great divisions to each other is also applied to it as already stated. In the figure, EE is the line of the horizon, or that level with the eye; it will be seen passing through the knee of that leg upon which the principal weight of the body is thrown.

2394. Though our object in this section is to give only a notion of the way of transferring to paper or canvas such objects as present themselves, we think it proper to hint at a few general matters which the student will do well to consider, and these relate to the balance and motion of the human figure. Geometry and arithmetic were with the painters of antiquity of such importance that Pamphilus the master of Apelles declared, without them art could not be perfected. Vitruvius particularly tells us the same thing, and, as follows, gives the proportions of the human figure: — "From the chin to the top of the forehead, or to the roots of the hair, is a tenth part of the height of the whole body; from the chin to the crown of the head is an eighth part of the whole height; and from the nape of the neck to the crown of the head, the same. From the upper part of the breast to the roots of the hair, a sixth; to the crown of the head, a fourth. A third part of the height of the face is equal to that from the chin to the under side of the nostrils, and thence to the middle of the eyebrows the same: from the last to the roots of the hair, where the forehead ends, the remaining third part. The length of the foot is a sixth part of the height of the body; the fore-arm, a fourth part; the width of the breast a fourth part. Similarly," continues our author, "have the other members their due proportions, by attention to which the ancient painters and sculptors obtained so much reputation. Just so, the parts of temples should correspond with each other and with the whole. The navel is naturally placed in the centre of the human body; and if a man lie with his face upwards, and his hands and feet extended, and from his navel as the centre, a circle be described, it will touch his fingers and toes. It is not alone by a circle that the human body is thus circumscribed, as may be seen (*fig.* 815.) by placing it within a square. For, measuring from the feet to the crown of the head, and then across the arms fully extended, we find the latter measure equal to the former; so that the lines at right angles to each other, enclosing the figure, will form a square."

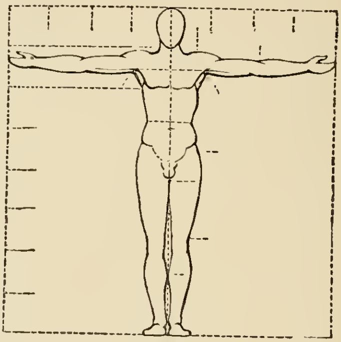

Fig. 815.

2395. "How well," says Flaxman (*Lectures on Sculpture*), "the ancients understood the balance of the figure, is proved by the two books of Archimedes on that subject; besides, it is impossible to see the numerous figures, springing, jumping, dancing, and falling, in the Herculaneum paintings, on the painted vases, and the antique basso-rilievos, without being assured that the painters and sculptors must have employed geometrical figures to determine the degrees of curvature in the body, and angular or rectilinear extent of the limbs, and to fix the centre of gravity." Leonardo da Vinci has illustrated the subject in his *Trattato di Pittura*, a perusal of which cannot fail of being highly beneficial to the student.

2396. As in all other bodies, the centre of gravity of the human figure is that point from which, if suspended, the figure would remain at rest when turned round upon it. Flaxman, by some strange mistake, has described the centre of gravity as "an imaginary straight *line*, which falls from the gullet between the ankles to the ground, when it (the figure) is perfectly upright, equally poised on both feet, with the hands hanging down on each side." (*Fig.* 816.). The fact is, that the centre of gravity is found to be in a line so drawn, or rather removed backwards from it, in a vertical plane returning from that line.

2397. Motion implies change of position; for instance, in *fig.* 817., the weight of the figure is thrown on one leg, hence a line passing through the centre of gravity falls from the gullet on one leg, on which side also the shoulder becomes lowered, and that on the opposite side raised; the hip and knee sinking below those on the side supporting the weight. In *fig.* 818. the dotted lines terminated by the letters ABCD represent lines of motion, as also the extent of such motion. The same are also shown in *fig.* 819., wherein A shows the inclination of the head to the breast; B the extreme bend of the back over the legs, without changing their position; C that of the back bent backwards, the legs

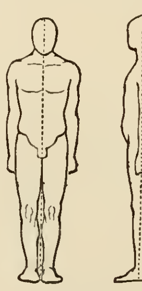

Fig. 816.

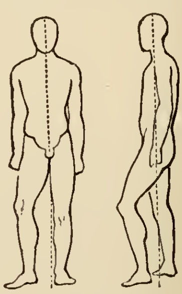

Fig. 817.

remaining in the same position. If the back be bent as far as D, the thighs and legs will project as far as E.

2398. Referring back to *fig.* 817. for comparison, as the commencement of motion, with *fig.* 820., we shall immediately see that the preparation for running consists in throwing the balance beyond the standing foot; and that when the centre of gravity, which is now about to take place, falls out of the common base, the hinder leg must be out, and off the ground, to balance the fore part of the figure, which would otherwise fall.

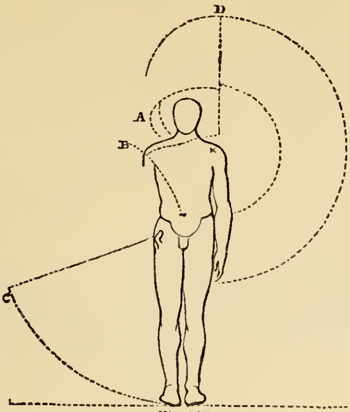

Fig. 818.

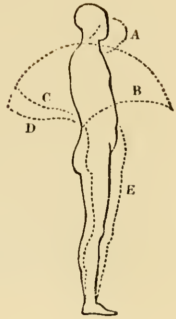

Fig. 819.

2399. In preparing to strike (*fig.* 821.), the figure is thrown back at the beginning of

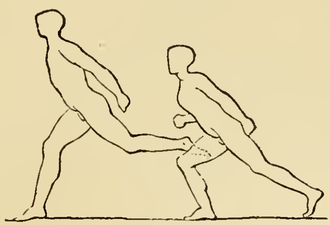

Fig. 820.

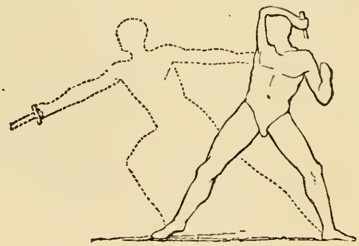

Fig. 821.

the action to give force to the blow: the dotted line shows the extent of the springing forward, in which the action is ended by the fall of the blow upon the object.

2400. In *fig.* 822., bearing a weight, the combined centres of gravity of the figure and

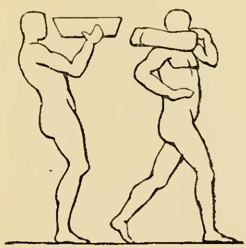

Fig. 822.

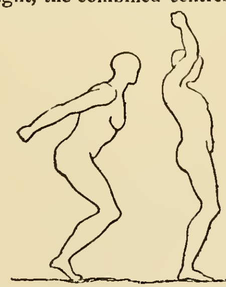

Fig. 823.

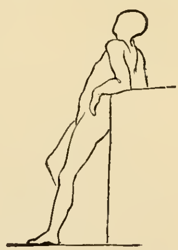

Fig. 824.

the weight to be borne must be found; and through it the line falls between the feet, if the whole weight rests equally on both, or on the supporting foot, if the weight is thrown upon one. Flaxman, who was a finer artist than a geometrician, has, in his lectures, fallen into another mistake on this head, by saying the centre of gravity is the centre of the incumbent weight, which is absurd; because the figure has not only to balance the weight itself, but also its own weight.

2401. In leaping (*fig.* 823.), the body and thighs are drawn together to prepare for the spring; the muscles of the leg draw up the heel, and the figure rests on the ball of the foot; the arms are thrown back to be ready immediately for swinging forward, and thus assisting in the impulse. When the figure alights, the arms, at the instant of alighting, will be found raised above the head; and a line dropped from the centre of gravity will be found to fall near the heels.

2402. In leaning (*fig.* 824.), if on more than one point, the greatest weight is about that point on which the figure chiefly rests.

2403. *Fig.* 825. is a flying, and *fig.* 826. a falling figure, both whereof being in motion through the air rest on no point. In the first it will be observed that the heaviest portion of the figure is bounded by lines inclined upwards ; as in falling the heaviest portion of it has a downward direction We have thought these elements would be useful, as exhibiting those leading principles without the comprehension whereof no motion or action can be well expressed. " Every change," says Flaxman, " of position or action in the human figure will present the diligent student with some new application of principles, and some valuable example for his imitation."

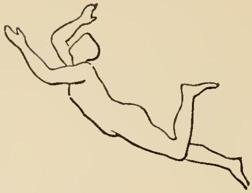

Fig. 825.

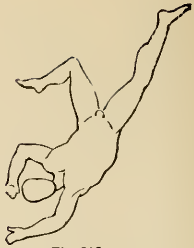

Fig. 826.

2404. We shall close this section with the application of the principles detailed in the management of the port crayon to the drawing of landscapes. The subject of *figs.* 827.

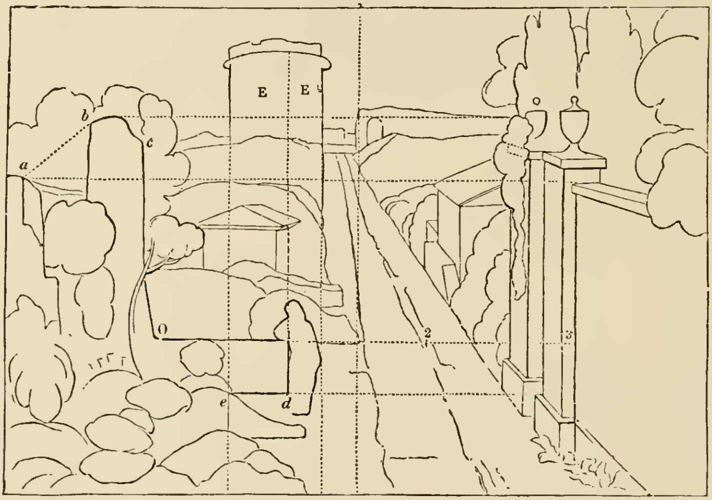

Fig. 827.

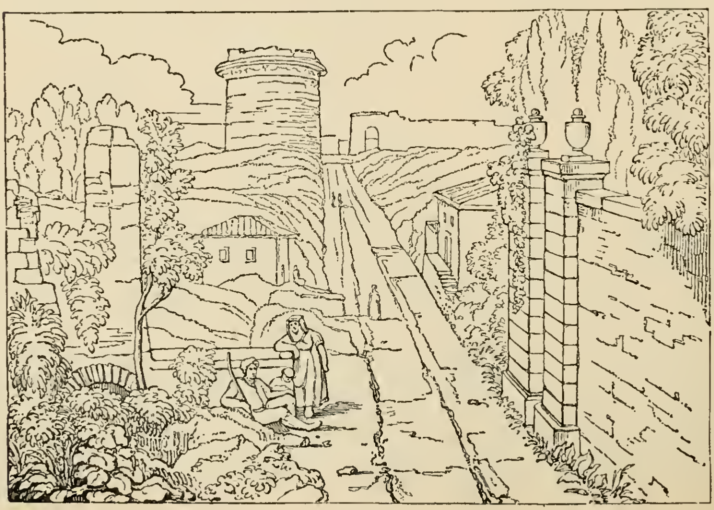

Fig. 828.

and 828. is from a spot a little way out of Rome, the tower of Cæcilia Metella being seen in the distance.

2404*a*. In *fig.* 826. the masses are roughed in from the objects themselves; and the principal mass *abc*01*d* on the left side is first very carefully drawn by itself, being, as respects leading lines and thicknesses, corrected until the eye is satisfied of the truth of its general form. The eye is as high as E and E, which therefore show the height of the horizontal line, and are also, in fact, the vanishing points for the wall on the right-hand side of the picture, and the house on the same side a little beyond it. Holding the port crayon level, and taking on it with the thumb or forefinger the distance 01, we shall find that twice that measure in 2 and 3 will give the junction of the wall with the pier; and that a line continued horizontally from *d* cuts the top of the plinth of the gate pier. The picture happens to be divided into two equal parts by a vertical line drawn through the break in the city wall in the distance. *d*1, continued upwards, determines one side of the house on the right-hand side of the road, and from a point at a break in the foreground intersects the projecting wall at *e*: a vertical line determines the left side of the tower. The remaining horizontal lines, it will be seen, determine other points and lines; and thus it is manifest that the whole arrangement has been accomplished by making the mass *abc*01*d* a measure or unit for ascertaining the size and relative position of the other parts. In *fig.* 828. the detail is filled in, and brought to a higher state of finish.

2404*b*. There is a mechanical method of obtaining the exact relative sizes of objects, and their positions in making drawings from nature or casts, which we will endeavour to explain. If the draftsman take a pair of pretty large sized compasses, and, fastening a piece of string at the joint end of them, hold the points open before his eye, so as to take in the extent of space his drawing is intended to occupy; then tie a knot in the string to keep it between his teeth, so that the compasses points may be kept in any plane always equally distant from the eye; he may, for the various parts of his drawing, by opening or closing the compasses, have their exact relative heights, widths, and positions, to be at once transferred to the drawing.

Sect. II.

PERSPECTIVE.

2405. A perspective delineation is the linear representation of any object or objects, as it or they appear to the eye, and is such a figure of an object as may be supposed to be made by a plane making a section of the body or pyramid of visual rays directed from the eye to the different parts of the object. A delineation so made, being properly coloured and shadowed, will convey a lively idea of the real object, and at the same time indicate its position and distance from the eye of the observer.

2406. Definitions. — 1. *An original object* or *objects* is or are an object or number of objects proposed to be delineated: for instance, a house, a ship, a man, or all or any of them together. In *fig.* 829. the house ABCDFHK is the original object.

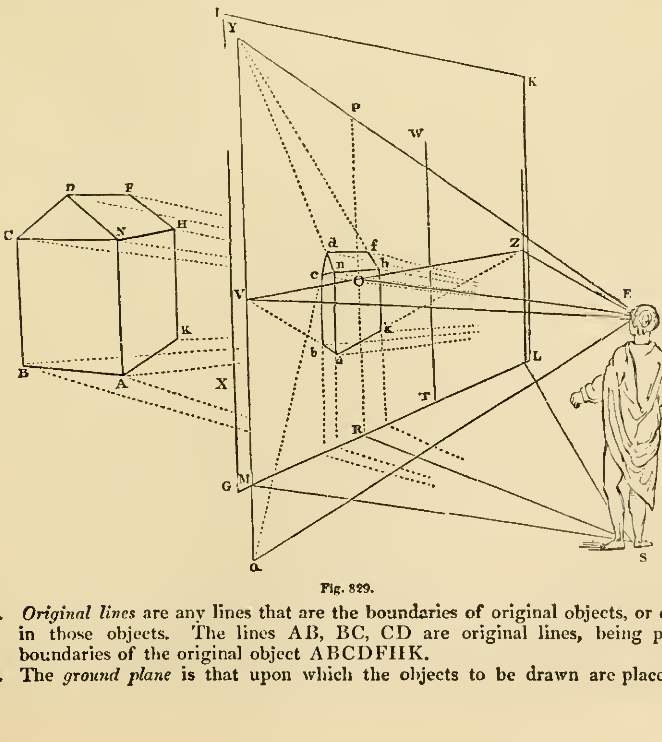

Fig. 829.

2. *Original lines* are any lines that are the boundaries of original objects, or of planes in those objects. The lines AB, BC, CD are original lines, being partly the boundaries of the original object ABCDFHK.

3. The *ground plane* is that upon which the objects to be drawn are placed, and is

always considered a boundless level plane. The plane X in the figure is the ground plane, upon which is placed the object ABCDFHK.

4 *The point of view* or *point of sight* is the fixed place of the eye of the observer, viewing the object or objects to be delineated: E in the figure is such point.

5. *The station point* is a point on the ground plane, perpendicularly under the point of sight or eye of the observer, and expresses on the plan the station whence the view is taken. S is the station point in the figure, being a point on the ground plane vertically under the eye of the observer at E.

6. *The plane of delineation* or *the picture* is the canvas or paper whereon it is intended to draw any object or number of objects. Thus, in the figure, the plane GIKL is the plane of delineation; but, in the extensive sense of the word, the plane of delineation is considered a boundless plane, however circumscribed may be the delineation made thereon.

7. *The horizontal line* or *the horizon* is a line on the plane of delineation in every part level with the eye of the observer or point of view. VZ is the horizontal line on the plane of delineation GIKL. It is supposed to be obtained by the intersection of a plane passing through the eye of the observer, parallel to the ground plane, produced till it touches the plane of delineation.

8. *The centre of the picture* is a point perpendicularly opposite the eye of the observer, or point of view, and is consequently always somewhere in the horizontal line. O in the horizontal line VZ is the centre of the picture, being perpendicularly opposite to the eye at E.

9. *The vertical line* is a line drawn through the centre of the picture perpendicular to the horizon. In the figure PR is the vertical line. It is here worthy of notice that the vertical line determines how much of the view lies to the right and how much to the left of the eye of the artist.

10. *The distance of the picture* is a direct line from the eye to the centre of the picture. EO is the distance of the picture, or plane of delineation, GIKL.

11. *The ground line* is that where the ground plane intersects the plane of delineation, as GL in the figure.

12. *An intersecting point* is one made on the plane of delineation, by producing a line in an original object till it touches the plane of delineation. Thus, T is the intersecting point of the original line BA.

13. *An intersecting line* is one made on the plane of delineation, by producing any plane in an original object till it touches the plane of delineation, or where, if produced, it would touch it. Thus WT is the intersecting line of the original plane ABCDN, being the line, where that plane, if produced, would touch the plane of delineation.

14. *A vanishing point* is that point on the plane of delineation to which two or more lines will converge, when they are the perspective representations of two or more parallel lines in an original object, whose seat is inclined to the plane of delineation. The point V in the figure is the vanishing point of the line AB, being found by the line EV, drawn from the eye of the spectator parallel to it, and produced till it touches the plane of delineation in the point V. For a similar reason, V is the vanishing point of the line CN; it is also the vanishing point for any other line parallel to the line CN, as BA; all parallel lines having the same vanishing point. The point Z is the vanishing point of the line AK, being obtained by a line drawn from the eye parallel to the line AK, and produced till it touches the plane of delineation. The point Z, moreover, is the vanishing point of the original lines DF and NH. And it is to be recollected by the student, that there will be as many different vanishing points of lines in the delineation of an original object as there are different directions of lines in that original object. The point Y is the vanishing point of the parallel original lines DN and FH, being found by the line EY being drawn from the eye parallel to them till it touches the plane of delineation. So also Q is the vanishing point of the line CD. In the process of perspective delineations, as we shall presently see, the plan of the object being drawn, the places of the various vanishing points are found on the ground line, whence they are transferred to the horizontal line by means of perpendiculars raised from them.

15. *A vanishing line* is one supposed to be made on the picture by a plane passing through the eye of the observer parallel to any original plane produced till it touches the picture. The line VZ is the vanishing line of an horizontal plane, and of all horizontal planes, being found by the intersection of a plane passing horizontally through the eye, or parallel to an horizontal plane. The vertical line YVM is the vanishing line of the original vertical plane, ABCDN being the line where a plane passing the eye of the spectator parallel to that plane would touch the plane of delineation. There will be as many different vanishing lines on the plane of delineation as there are different positions of planes in the object or objects; and

all parallel planes will have the same vanishing line. Similarly, all lines lying in the same plane will have their vanishing points in the vanishing line of that plane. All planes or lines in an original object which are situated parallel to the plane of delineation can have no vanishing lines or vanishing points on the plane of delineation.

16. *A visual ray* is an imaginary right line, drawn from the eye to any point of observation. EA and EY, &c. are visual rays, being right lines drawn from the eye to the points A and Y. Hence a number of visual rays directed to every part of an object will form a pyramid of rays, whereof the eye is the apex, and the object the base.

17. *A perspective delineation*, then, is the section of a pyramid of rays producing a perspective projection, and is most commonly considered as being made between the object and the eye. But the section of rays may be taken when they are extended beyond the object; in which case such a section is called a *projected* perspective representation of the object.

2407. It will then be seen that a knowledge of perspective is, as Addison has said, a knowledge of "the science by which things are ranged in picture, according to their appearance in their real situation."

2408. The situation of the objects being given with the plan and position of the plane of delineation and the height and distance of the eye of the observer, the delineation of such objects is truly determinable by rule. The mechanical operations necessary for this purpose form the subject of what follows. It is however necessary, before proceeding to lay them before the reader, to premise that he must thoroughly study and understand the preceding definitions before he can proceed with profit to himself, and we recommend a repeated perusal of them until that be effectually accomplished.

2409. Example I. In *fig.* 830., No. 1., we have the plan of the original object

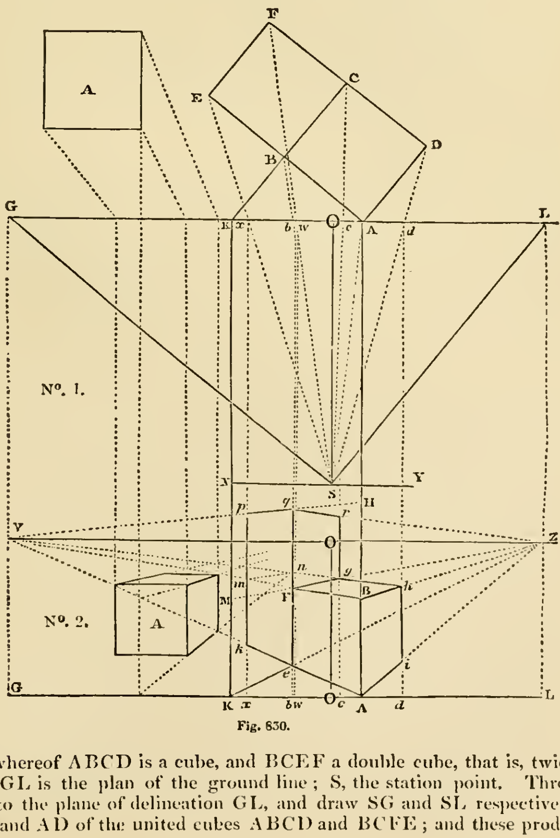

Fig. 830.

EBADCF, whereof ABCD is a cube, and BCEF a double cube, that is, twice the height of CBAD. GL is the plan of the ground line; S, the station point. Through S draw XY parallel to the plane of delineation GL, and draw SG and SL respectively parallel to the sides EA and AD of the united cubes ABCD and BCFE; and these produced to meet the plane of delineation will determine the vanishing points (Def. 14.) of the horizontal lines AE and AD, and of all other horizontal lines parallel to them. Draw the line SO perpendicular to GL, which line being the direction of the eye perpendicular to the plane of the picture determines the point thereon to which the eye should be directly opposite to view it when completed, showing also how much of the object is on one side, and how much on the other of the point of view. We have now to draw the visual rays SA, SB, SE, SF, SC, SD, cutting the plane of the picture or delineation in *b*, *x*, *w*, *c*, and *d*; the point A of the nearest cube touching, itself, the picture at that point. The preparation on the plan is now completed.

2410. The picture (No. 2.) or plane of delineation is to be prepared as follows: — First draw the ground line GL, and to such ground line transfer, by dropping verticals, the points K*xbwc*A and *d*. Above, and parallel to GL, at such convenient height as may be necessary to show more or less of the upper surfaces of the cubes or otherwise, as desired, draw the horizontal line VZ; mark on such horizontal line the point O, to which the eye is supposed to be perpendicularly opposite for viewing the delineation when completed. All the other preparations are obtained from the plan, and may be obtained as follows: — First set off on the horizontal line VZ the points V and Z, which are the vanishing points of the sides AE and AD respectively. As A, the nearest angle of the object, touches the plane of delineation, it is manifest that a line vertically drawn from that point will be of the same height as the object itself, that is, as the figures are cubes, equal to AB or AD in the plan No. 1. Take, therefore, AB No. 2. of the height required, and draw the lines BV and AV, also AZ and BZ, which being crossed by verticals carried up from *xbwcd* will determine the points *ke* and *i* at the bottom, and in *f* and *h* at the top, and *pq* and *r* in the part where the cube is double the height. Drawing *h*V it is intersected by the verticals from the visual rays at *c* and *w*, cutting in *g* and *n*. The line KK forms another line of heights, if desired, for finding the height F*q*; indeed, by continuing any line BC (No. 1.) to K, intersecting the picture, a line of height may be obtained. The representation of the cube marked A will be understood without difficulty, if what has preceded be well comprehended. As by Definition 15. we have seen that all planes or lines in an original object situated parallel to the plane of delineation have no vanishing lines or points in the plane of delineation, so two of the sides of the cube will be bounded by horizontal and vertical lines, inasmuch as those sides lie parallel to the plane of delineation. The vanishing points for the other lines will of course be found in O, which passes through the picture at right angles to it from S, the station point.

2411. Example II. To find the representation of a quadrangular building, situated inclined to the picture, covered with a single spanned roof, having a gable at each end.

2412. Let the rectangle ABCD (No. 4.) (*fig.* 831.) be the plan of the building, the line EF will be the place of the ridge of the roof extending from end to end. Let the line QL be the place of the plane of delineation, and let S be the station point.

2413. Find O the centre of the picture, also the points Q and L, the vanishing points of the lines AB and AD, and their parallels, by lines drawn from S parallel to such lines, and intersecting the picture. Produce the face of the building AD to I for an intersection with the picture, and draw the visual rays intersecting the ground line of the picture in the points *beaf* and *d*. These need not, however, be drawn beyond the plane of delineation.

2414. Prepare the picture (No. 5.) by drawing the horizontal and ground lines VZ and GR at any distance from each other at pleasure; fix upon the centre of the picture O, and draw the vertical line OO; set off the distances of the vanishing points OV and OZ, equal the distances o the vanishing points OQ and OL in No. 4. Draw the intersecting line IL (No. 5.), and all the visual lines, through the points *beaf* and *d*, taken from their respective places and distances *beaf* and *d* (No. 4.), and proceed as follows: —

2415. On the intersecting line IL (No. 5.) set up the height IK equal to the height of the building BC or HG (Nos. 1. and 2.), and draw the lines KZ and IZ, determining the plane *gmop* for the front of the building. Draw the lines *m*V and *g*V, determining the end of the building *ghim*. It now remains to place the roof, which is readily done, but which, however, requires some circumspection in the process.

2416. Place the height of the roof XD (No. 1.) on the intersecting line at IL (No. 5.), and draw LZ, which will give the height of the roof on the angular line of the building *gm* at *r*; from which spot it may readily be transferred to its proper place in the visual line *ek* by the line *r*V, which cuts the line *ek* in the point *k*, the point required. From the point *k* draw the lines *ki* and *km*, completing the gable end of the building. Draw the ridge of the roof *k*Z, cutting the end visual line, in the point *n*; and lastly, draw the line *no*, completing the whole linear delineation of the building *ghiknop*. It is to be observed, that whatever original plane is produced to the picture to obtain an intersection, such intersection serves only to obtain heights in the direction of that plane; whence they may be transferred to other planes in contact with it, as in the present instance. The intersecting line IL (No 5.) is the intersecting line of the plane *gmop*; hence any original height set up

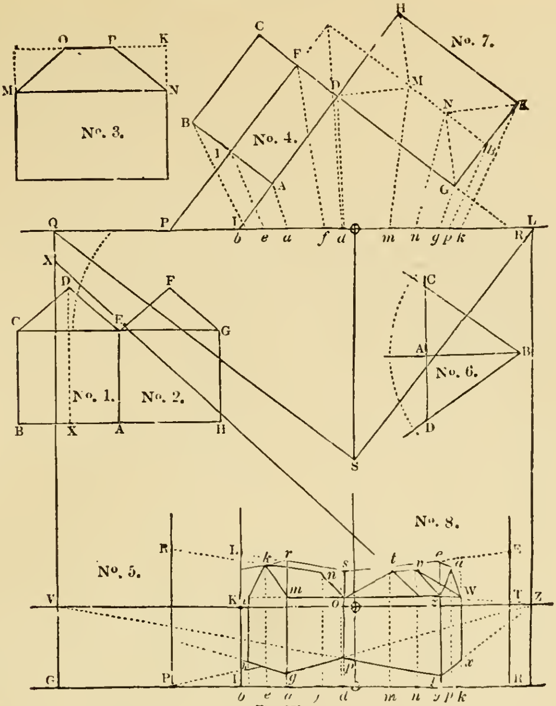

Fig. 871.

thereon can only be transferred throughout the direction of that plane. Thus the height of the roof IL was transferred by the line LZ along that plane to its other extremity *s*; but the line *rs* is not the place of the ridge of the roof, which lies in the middle of the plane *ghikm*, proceeding from the point *k*; but any height on the angular line *gr* is easily transferred along that plane by means of its horizontal vanishing point V, by which means the height of the roof was obtained by the line *r*V at *k*. If, instead of the plane over the line AD (No. 4.) being produced for an intersection, the plane of the middle of the house in the direction of the ridge of the roof had been drawn, and the height of the roof had been set up on that line, it would at one application be transferred to its proper place.

2417. Let the line FE (No. 4.) be produced to P for an intersection, set off the distance OP at OP (No. 5.), and draw the intersecting line PR. On PR set up the height of the ridge of the roof equal XD (No. 1.), and draw the ridge line RZ, and it determines the exact ridge of the roof between the proper visual lines, and will be found to correspond exactly with the ridge obtained by the former process.

2418. The roof may, however, be found by another process, thus:—The slant lines of the roof have their vanishing points on the picture as well as any other direction of lines in the same object. The line *km* (No. 5.) being in the vertical plane *ghikm*, will have its vanishing points somewhere in the vanishing line of that plane. (Def. 15.) A vertical line drawn through the horizontal vanishing point V will be the vanishing line of the plane *ghikm*; therefore the vanishing point of the lines *km*, *ki*, and of all lines parallel to them, will be somewhere in the vertical GVXQ.

2419. Two lines drawn from the eye parallel to any two lines in an object, finding their vanishing points, will make the same angle at the eye as the lines in the object make with each other; for the two lines in the one instance are respectively parallel to the two lines in the other.

2420. The line SQ is drawn from the station S parallel to the line AB (No. 4.), and a line drawn from the station S, making the same angle with SQ as ED does with EC, (No. 1.), will find the vanishing point of the line ED, and this point must be evidently somewhere in a vertical line through the point Q. To obtain this point in practice, take the distance of the vanishing line it is in, that is, the length from S to Q in the compasses, and set off the same in the horizon (No. 5.) from V. to W. At the point W make an angle VWX equal to the inclination of the roof, that is, equal to the angle CED (No. 1.), and produce the line till it intersects the vertical line through the vanishing point V in the horizon in the point X. The point X will be the vanishing point of the line of the roof *km* (No. 5.), and of the line *no*, parallel to it. The slant lines of the roof *km* and *no*, already obtained, will, on application of a ruler, be found to tend to the point X, as above stated.

2421. In the same way the line of the roof *ki* (No. 5.) will also have its vanishing point, and in the same vertical line GVQ. It will be found to be as much below the horizontal vanishing point V as the point X is above it. (Def. 14.)

2422. Let the line AB (No. 6.) be the line of the horizon, and CD the vanishing line of a vertical plane, being the gable end of a house, and let the angle ABC be that of inclination, finding the vanishing point of the slant lines of a roof in one direction. Let the line BD be the line, finding the vanishing point of the slant lines in the other direction, having the same inclination to an horizontal line; then the angle ABD will be equal to the angle ABC, and the distance AD equal to the distance AC.

2423. Example III. To find the representation of a quadrangular building situated inclined to the picture, covered with a single hipped roof.

2424. Let the quadrangle GDHK (No. 7.) be the plan of the building; the line MN will represent the ridge of the roof. The former line QL may be the place of the plane of delineation, and it may be viewed from the same station S. The position and direction of the lines of this object being the same as those of the last example, the preparatory lines will also answer for this. We have then only to draw the visual rays MS, NS, CS, PS, and KS, intersecting the picture in the points *m*, *n*, *g*, *p*, and *k*, and to produce the line DG for an intersecting point at R.

2425. Prepare the picture (No. 8.); let the line VZ be the horizon, GR the ground line, O the centre of the picture, and the points *m*, *n*, *g p*, and *k* coresponding with *m*, *n*, *g*, *p* and *k*. (No. 7.) Draw the visual line lines through those points and the intersecting point R, and proceed as follows: —

2426. On the intersecting line RE set up the height RT, equal the height of the object HG (No. 2.), and draw the lines TV and RV, cutting the visual lines of the front of the building in the points *z* and *o*, *y* and *p*, determining the plane *ypoz* for the representation of the plane of the front. From the angular points *z* and *y* draw the lines *zw* and *yx* to their vanishing point Z determining the plane *yzwx* for the end of the building.

2427. On the intersecting line set up the height of the roof TE equal the height NK (No. 3.), and draw EV cutting the angular visual line of the building in the point *e*, from which point draw the line *ez*, cutting the visual line *pa* in the point *a*, the point of direction of the ridge of the roof. Draw the line *a*V, which, cutting the visual lines through the points *m* and *n* in the points *t* and *v*, determines the exact position of the ridge of the roof *tv*, which is the representation of OP (No. 3.), or of the ridge MN (No. 7.); draw the lines *to*, *vz*, and *vw*, which will complete the whole representation required. In No. 8., if the lines *az* and *aw* be drawn, they will form a gable end *yzawx*, of which the point *a* is the point of the gable, and will answer for the direction of the ridge, whether it be a gable end or a nipped roof, for in both cases it lies in the middle of the breadth of the house; wherefore the line *a*V answers as well the edge of a hipped roof as of a gable end.

2428. In examining the plans (Nos. 4. and 7.) of the two buildings, it will be seen that they are placed at right angles to each other, and in contact at the point D, so that the second example might have been easily accomplished from the first, without the aid of another intersection and other preparatory lines, than the additional visual rays from the angles, which the student will have surely no difficulty in carrying through, without the necessity of encumbering these pages with the detail.

2429. Example IV. In *fig.* 832. No. 1. is the general plan of a church similar to many country churches. ABCD is the main body of it; EFGH its tower; IKLM and MLNO subordinate parts of the building, and *abcd* the porch. No. 2. is its geometrical elevation; the ends and measurements, AB and BC, answering to IM and MO in No. 1., and the points of the roofs D, E, and F. (No. 2.) answering to the lines of the ridges QR, TV, and PL, No. 1. To find the perspective representation of this building on the plane of delineation YZ, the station being at S, the following is, perhaps, the readiest process.

2430. Find the vanishing points Y and Z of the horizontal lines of the building by the lines SY and SZ being drawn from the station parallel to them. O is the centre of the picture. Draw the visual rays from the visible angles of the object in direction to the station S, to intersect the plane of delineation.

2431. When a complicated object, that is, one composed of many parts, is to be drawn, it requires, of course, a great number of visual rays for the precise determination of those parts, and the whole together forms an apparently confused number of lines. The eye, however, which views them properly, does not perceive that confusion; and, if it perplex the student, different coloured inks, or of different shades of depth, may be used to particularise different parts. In the delineation of such an object as the present example, the most important consideration is the choice of a proper intersection; for though any inter-

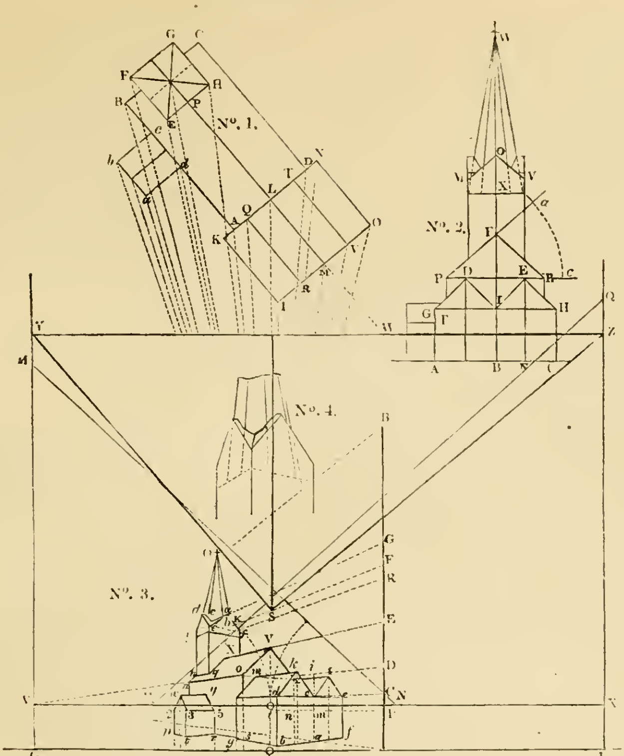

Fig. 852.

section will do, that should be chosen which unites most parts in its direction with the greatest exactness and the least trouble. In the case under consideration, none seems more eligible than the direction of the roof PLM, which produce to W.

2432. In the picture No. 3., GL is the ground line, GV the height of the horizon, the line VX being then the horizontal line. O in the horizon is then the centre of the picture, from which, place the distances of the horizontal vanishing points OV and OX equal OY and OZ, No. 1. AB (No. 3.) is the intersecting line, and all the visual lines on the plane of delineation are drawn conformably to their intersections on the ground line in the plan. On the intersecting line the height AC is made equal to the height AG of the elevation No. 2.; and the lines C*c* and A*a*, being drawn in direction to the vanishing point V, determine the height *ac*; being the height of that part of the building on the visual line answering to the ray from the point M in the plan No. 1. Through the points *a* and *c* draw the lines *de* and *bf* to their vanishing point X, determining the plane *bdef*, the representation of the plane AGHC, No. 2.; the visual lines *bd* and *fe* answering to the rays from the points I and O in the plan. Draw the lines *dh* and *bg* tending to their vanishing point V, to the ray from K in the plan completing the plane *bghd*. On the intersection make the height AD equal to the height of the roof NE of the elevation No. 2., and draw D*i* in direction to V. Through *i* draw the line *kl* to the vanishing point X, touching the visual lines of the roofs in the points *k* and *l*. Draw the lines *km*, *mh*, *kd*, *kc*, *lc* and *le*, which will complete the whole of the structure over the plan IKNO, No. 1.

2433. The height of the roofs of the low buildings is equal to the height of the upright walls of the body of the building, as shown by the line PR in the elevation No. 2.; hence, the line *mo*, and the return line *on*, may be drawn to the visual lines corresponding with the intersections from the angles A and B of the plan From the angle *g* the line *gs* may also be drawn, which will determine the lines *sr*, *rt*, and *tp* of the porch. Make AE on the intersection equal to the height of the roof BF in the elevation, and draw the line EV determining the ridge of the roof between the two visual lines from the points P and L of the plan. Draw the lines of the gable end *vo* and *vz*, the point *z* being obtained by the line *om* drawn to its vanishing point X, cutting the visual line from the angle D of the plan in the point *z*.

2434. Make AG and AF on the intersection equal to the heights of the tower BO and BM of the elevation. and draw the lines GV and FV cutting the visual line from P in the plan, in the points *a* and *b*; through which points draw the lines *ac* and *ef* to their vanishing point X; and the lines *cd* and *eg* to their vanishing point V; the points *g*, *e*, and *f* being in the proper visual lines from the angles of the tower F, E, and H in the plan. The tower will be completed by drawing the lines *dg*, *de*, *ae*, and *af*.

2435. This example elucidates the general practice of vanishing points, which are as well to be obtained of other positions of lines as horizontal ones. It is not always that the vanishing points of inclined lines are required, but they are often useful, and sometimes absolutely necessary. In the geometrical elevation No 2. the lines MO, PF, GD, IE are all parallel lines, as also are the lines OV, FR, EH, and DI, and though situated in different, yet they are in parallel planes, and will therefore have a common vanishing point. A line drawn perpendicularly to the horizon through the vanishing point X (*fig.* 3.), as LQ, will be the vanishing line of the plane of the end of the church over the line IO of the plan, also of the end of the body AD, likewise of the side of the tower EH; and a line drawn through the point V (No. 3.) perpendicularly to the horizon, as GM, will be the vanishing line of the planes over the lines (No. 1.) IK, AB, *ab* of the porch, and FE of the tower, and all lines in those planes, or the boundaries of those planes, will have their vanishing points somewhere in those vanishing lines.

2436. To obtain the vanishing points of the inclined lines of the roofs and tower, take the distance of the vanishing point Z from the station S in the compasses, and apply it on the horizon from X to H. At the point H make an angle with the horizontal line equal the angle of the roofs *a*P*c* (No. 2.); the curve KI and the distance of it from the centre H being equal to the curve *ac*, and distance of it from its centre P: then is the angle KHI equal to the angle of the roof *a*P*c* (No. 2.). Produce the line HK to Q; Q will be the vanishing point of the line *ea* of the tower, also of the parallel lines *ov*, *dk*, and *cl*, which, though obtained by a different process, will all be found, by application of a ruler, to tend truly to that point, as is shown by the dotted lines in the example. Proceeding in the same way with the distance of the vanishing point Y from the station S, we obtain the vanishing point of the same inclination of lines in the other planes of the object. Take the length SY in the compasses, and set it off on the horizon from V to N. At the point N make an angle INT on the horizon equal the angle KHI, that is, equal the angle of inclination of the roof *a*P*c* (No. 2.). The line NT produced to M in the vanishing line GM will be the vanishing point of the line *de* of the top of the tower, also of the lines *w*3 and *y*5 of the porch (the inclination of the roof of the porch being the same as the other roofs of the body of the church), as shown by the dotted lines in the example. The walls of the porch are obtained from the height AP on the intersection, equal the height AT, No. 2., P*m* being drawn to the vanishing point V, and *mn* to X, give the lines *n*5, 53, and 32. We may observe that the inclined lines *af*, *le*, *kc*, and *vz* have a common vanishing point, which, if required, may be obtained; it will be in the same vanishing line with the point Q, and as much below the horizontal vanishing point X as the point Q is above it. to which point, were it obtained, the lines already drawn will be found exactly to tend. It is seldom absolutely necessary to have both those points; in this instance one only of them, the point Q, is obtained, which answers every end required of both; for, supposing it were left to that vanishing point for finding the inclined lines, the visual lines being drawn, and the heights of the upright walls being found, the line *dk* being drawn in direction to the vanishing point Q determines one side of the gable end at the visual line in the middle; the other is accomplished by joining the points *k* and *c* together. So of the other gable, *el* being drawn, *le* is also had by joining together the points *l* and *e*.

2437. To complete the whole, draw the line *xq* on the tower from the point *x* to the angle of the tower, in direction to the vanishing point Q; then draw the lines *qh* and *nh* to their proper visual lines and vanishing points V and Q. The putting on of the spire requires some consideration, and in it we must proceed with some thought and care. The base of it is intended to be a regular octagon. If the two external lines in the geometrical elevation of the spire be continued till they touch the sides of the tower, as is done at K and L (No. 2.), and an octagon be there constructed, extending the square of the tower, it will be the base of the spire. Set up the height of the spire BW (No. 2.) on the intersection (No. 3) at B; also the height of the base line KL at R, and draw the lines BV and RV; the first, cutting the visual line through the centre of the tower in the point O, determines the height of the spire; the other, cutting the tower in the point *u*, determines its base. Through the point *u* draw a line round the tower, and find the points of the octagon in the middle of each face of the tower, to which let lines be drawn from the top O, and the whole will be completed, as shown in the example.

2438. Thus have we gone through the process of finding the representation of rather a complicated object with as little confusion of lines as possible; but one thing succeeding another, and each being required to remain for the student's observance, the whole unavoidably becomes intricate. Indeed, it is not now so perfectly executed but that something remains for the student to complete, which must result from his own study or occupy more space than all we have already written on it. We allude to the intersections that take place at the lodgment of the spire on the top of the tower, to elucidate which it is drawn to a larger scale at No. 4., the mere inspection whereof will convey a full and, we hope, satisfactory idea of what we advert to. The student has been left to complete the base of the octagon, a process so simple that we cannot, if he retain what he has read, believe he will find difficulty in accomplishing, either by visual rays or otherwise. It is next to an impossibility to describe intricate matters like these so as to leave nothing for the exercise of the reader's judgment; for, however copious the instruction, there will always remain sufficient unexplained to keep his mind in action, and afford him the opportunity of exercising his own ingenuity.

2439. Example V. In *fig.* 833. the objects X and Y are plans of columns with bases

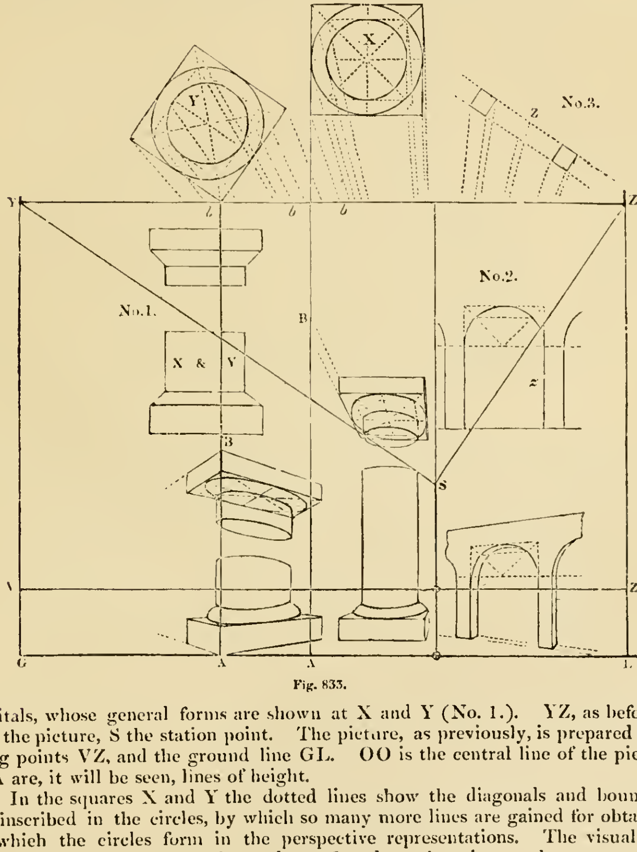

Fig. 833.

and capitals, whose general forms are shown at X and Y (No. 1.). YZ, as before, is the plane of the picture, S the station point. The picture, as previously, is prepared with the vanishing points VZ, and the ground line GL. OO is the central line of the picture, and BA, BA are, it will be seen, lines of height.

2440. In the squares X and Y the dotted lines show the diagonals and boundaries of squares inscribed in the circles, by which so many more lines are gained for obtaining the curves which the circles form in the perspective representations. The visual rays are drawn as in the preceding examples, and transferred to the picture, the process being, in fact, nothing more than making squares following the profiles, which, at the different heights, guide the formation of circles within and around them, of which the upper ones only, for preventing confusion, are shown in the perspective representation. In each series, the extreme width of the appearance of the circle may be obtained by visual rays, as at *b*, *b*, *b*.

2441. At Z and *z* (Nos. 3. and 2.) are the plan and elevation of an arcade, from which it will be seen that the principle of inscribing squares and diagonals is equally applicable to the vertical representation of circles. Presuming that we have sufficiently described the diagram to enable the student to proceed in drawing the examples at large, we shall now submit an example of general application.

2442. Example VI. In *fig.* 834. YZ is the plane of delineation, and the plan of the building, with its projections, roof, and chimneys, is shown in No. 1. In practice, this is generally made on a separate drawing board, to enable the draughtsman to make his perspective

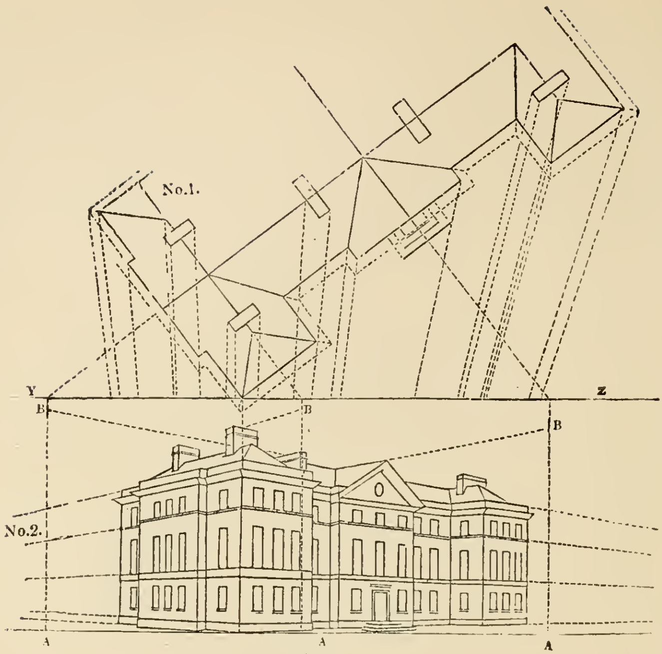

Fig. 834.

outline without injury from constantly working over the paper. Here the vanishing points are too distant to be shown on the diagram; but the reader, from the tendency of the several lines, will easily find where they lie. In the same manner, he will find whereabout the station point is placed. BA, BA, BA, No. 2., are lines for the transference of the heights. The projection of the cornice is dotted round the leading lines of the building on the plan. The rest of the figure cannot fail of being understood and put in practice by the student who has made himself master of the preceding examples.

2443. We shall now turn to a point whereon much difference of opinion has prevailed, namely, the adjustment of what may generally be considered the best angle of vision, within which objects should be seen to obtain the most agreable representation of them. For as this angle is enlarged or decreased by viewing the objects at greater or less distances, their appearance will vary, and their delineation, in consequence, be affected thereby, and distortion of the objects will be the result.

2444. By the angle of vision or angle of view is understood the expansion of the lines proceeding from the eye, by the two extreme visual rays embracing the whole extent of the view, and this whether it consists of one object or of many. Let A (*fig.* 835.) represent the plan of a mansion; let B be the outhouse contiguous to the mansion, and let the places of trees be at CCC and DDD. Let S be the station or point of view from which the whole is seen. Considering the mansion A as a lone object, the extreme visual rays S*a* S*b* form at the eye the angle *a*S*b*; then *a*S*b* is the angle of view under which that object is seen, S*a* and S*b* being the two extreme visual rays embracing the whole extent of the object. Again, if the outhouse B be taken as a single object, then will the extreme visual rays *c*S and *d*S form, at the eye, the angle *c*S*d*, being the magnitude of the angle under which that object is seen. So of any object, the visual rays that embrace its whole extent form the angle of view under which it is said to be seen. It is then manifest that the angle of view will be either large or small, as the eye is near to or remote from the object. Suppose both the objects A and B are to be taken into the view, with the ad-

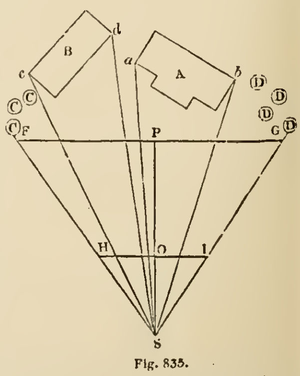

Fig. 835.

dition of the trees to their right and left. Let visual rays be drawn from the trees on both sides to the station S. The angle CSD is the angle of view under which the whole extent is seen, and the rays CS and DS are denominated the extreme visual rays of the view.

2445. Objects may not only be placed too near the eye for comfortably viewing them, but they may be so nearly placed to the eye as to give it pain. The eye only contemplates a small portion at a time; it is only by its celerity and continual motion that it becomes perfectly sensible of a whole and of the many forms whereof it is composed. But when an object, or many objects, widely extended, are placed too near, the traverses of the eye in viewing the whole become painful. Every one must have experienced that this is so, and why so we must leave to others to account for. When the eye is removed to an agreeable distance, the extent of the view to be delineated is at once seen without turning the head to one side or the other, so that all the objects are at once comprehended.

2446. In taking a view, the turning of the head is to be avoided. The view should on no account comprise a greater extent than can be taken by a *coup d'œil*, or than can be viewed by the traverse of the eye alone; and this necessarily confines the extent of that with which we have to deal, and brings the angle of view within certain limits. What the eye can contemplate without trouble it views with pleasure, and beyond a certain extent the eye becomes distracted.

2447. Smallness of object has no relation to the angle of view; a die, or the smallest possible object, may be brought so near the eye as to give pain in looking at it, and a large extent of view may be contemplated with as much ease as a small one, by merely placing the larger one at a greater distance. If the place of the plane of delineation be at FG, then FSG will be the angle of view. If a section of the same visual rays be taken at HI, then HI will be the extent of the picture, and the angle HSI is the angle of view; but the angles FSG and HSI are the same, therefore the eye views both with equal satisfaction: but in this case one must be placed at the distance SO, and the other at the distance SP.

2448. The attempt to select an angle suitable to all the cases that may occur, as the best angle of view, would be as vain as it would be absurd. Different subjects require different treatment. External subjects differ from internal ones; and the last from each other, according to circumstances. Some authors on the subject have laid it down as a rule, that the greatest distance of the eye from the picture should not exceed the width of the picture laterally, which makes the angle of view about 53 degrees; others have insisted that the distance should be less, requiring that the angle of view should not be smaller than 60 degrees; and others allow of a still larger angle. The elder Malton, and his son, to whom we are indebted for all that is valuable in this section, and whose (both of them) experience in the matter was very extended, advise that the angle of view should never exceed from 53 to 60 degrees; the former recommending an angle of 45 degrees as the best, because neither too large nor too small. The elder Malton advises to keep between the one and the other, that is, not to let the angle of view exceed 60 degrees, nor be less than 45, the first being likely to distort the objects, and the last rendering them too tame in the outline. We can add, from our own experience, that the advice is sound; for though, under very particular circumstances, it may be necessary to use a larger angle of view than 60 degrees, such a case does not frequently occur. Much must always be left to the discretion of the artist in respect to points which are to guide the angle of view he adopts. After a little experience, he will find that angle best suited to the circumstances under which his drawing is to exhibit the object or objects.

2449. Example VII. The principles upon which we delineate any of the interior parts of a building are in no wise different from those used for the representation of their external views, for it is of course immaterial whether we represent the external faces of their sides, or those which form their internal faces; the only difficulty which arises in making an internal view being that which arises from the inability, on account of the restricted distance under which they are in reality viewed, of placing the station point at such a distance as to take in a sufficient quantity of the objects to be represented. A person placed in a room can of course only see the whole of one and part of another wall; in short, in every direction he cannot see comfortably more than, as we have above mentioned, forty, or, at the most, fifty, degrees of the objects around him. On this account, and for the purpose of showing more than in reality can be seen, it is customary, and perhaps justifiable, in order to give a more comprehensive view of the interior to be delineated, to place the station point of the spectator out of the room or place, supposing one or more of its sides to be removed. This is, in fact, a delusion, as is every view of an interior possessing any merit that has come under our notice. But for picturesque delineation, it is not only one which is necessary, but one without the practice whereof no satisfactory representation can be given of an interior whose dimensions are not very extended. The section whereon we are now engaged is not supposed to be a treatise on Perspective, but merely a concise developement of its principles so as to give the reader such a general knowledge of the subject as may enable him to pursue it, if he please, from the hints it affords. With this apology for not producing to him a more complicated, though not less useful subject, we proceed.

2450. *Fig.* 836. (No. 1.) represents the plan of a staircase one third the size used for the

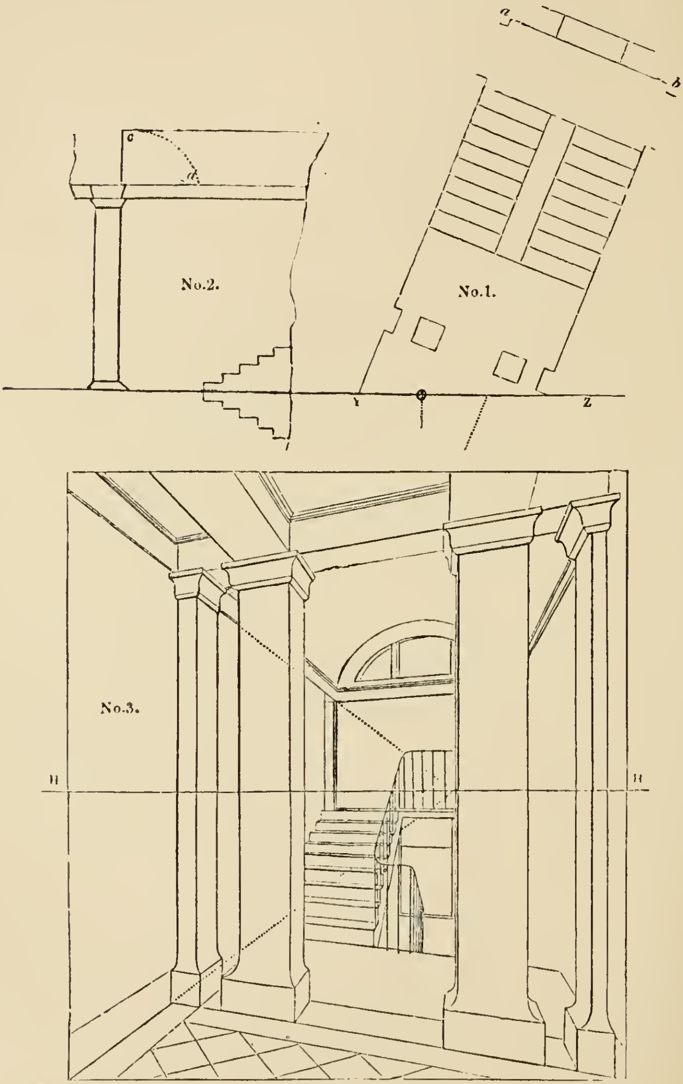

Fig. 836.

purposes of the delineation ; YZ (No. 1.) is the plane of the picture, O is its centre. From the data, therefore, there will be no difficulty of obtaining the vanishing points of the sides Y*a* and *ab*. The diagram is not encumbered with the visual rays necessary for the delineation, which we are to suppose drawn and transferred to their proper places on No. 3., wherein HH is the horizontal line. No. 2. is a longitudinal section of the staircase, wherein are shown the rising and descending steps, and the dotted line *cd* gives the section of the vaulted ceiling over the staircase. It will be immediately seen that the ends of the steps will be determined by visual lines, notwithstanding the ascent and descent of them, because either is determined by referring to any lines of height, which may be obtained from the plan and section, by which the portions seen of the flights will be immediately found and transferred to their respective places on the picture. With these observations we leave the diagram for the exercise, on a larger scale than here given, of the ingenuity of the student.

2451. Example VIII. The last perspective example to be submitted is that of a cornice

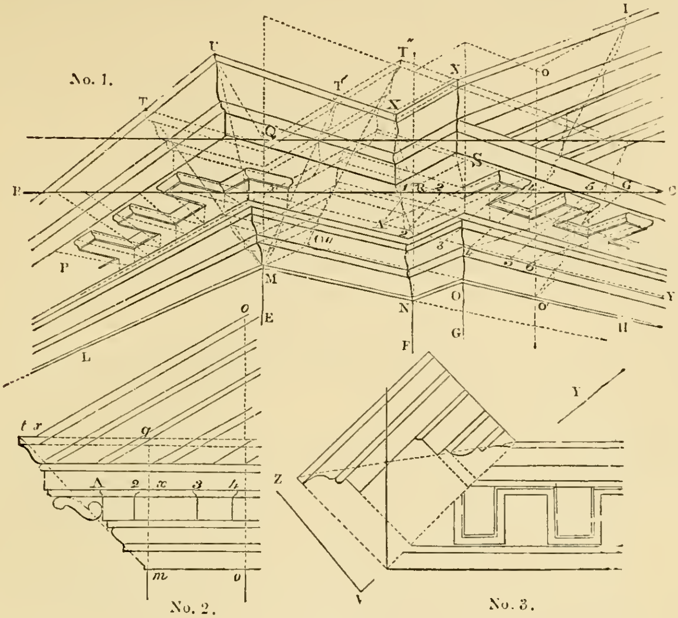

Fig. 837.

(*fig.* 837.), wherein the contrivance of the elder Malton is used for finding the places of the modillions and the other parts.

2452. Let EM, FN, GO (No. 1.) represent the angles of a building in perspective, LMNO being the lower horizontal line of the cornice, whose geometrical elevation and profile are shown in No. 2. Make MQ equal to *mq* the depth of the cornice, supposing the edge EQ to be in the plane of projection; draw PQRS, &c., the lines of the top of the cornice, to their respective vanishing points. Make QT, QT′ in RQ, PQ, produced equal to the perspective projection of the cornice *qt*. Then place the depths of the various mouldings along MQ, and fix the lengths of their projections on the lines drawn to the vanishing points through those in EQ, an operation which may be much facilitated by drawing MT, MT′, by which, in many places, the points of the mouldings are at once determined, as in the case of the top and bottom of the fillets of the ovolo; and very often, if the drawing is not on a very large scale, *mt* and its perspective images MT, MT′, &c. will enable the eye to proportion the mouldings. Thus the perspective projections MQT, MQT′ of the sections of the cornice by the planes of the sides EN, EL, supposed to be prolonged or extended, may be found; and it is manifest that lines through the points of these sections to the proper vanishing points will give the perspective forms of the cornice mouldings as they would appear.

2453. The lines found will by their intersections supply the mitre MQU; but where the scale is large, it is better to obtain mitre sections at each principal angle of the building as shown by the lines MQU, NRX, &c. The planes of the mitres form, of course, angles of forty-five degrees with the sides of the building itself, consequently the vanishing points of QU, RX, &c. may be found by bisecting perspectively the right angles found, or by drawing on the plan lines parallel to the diagonal lines or mitres from the station point to intersect the picture. If these, indeed, are found in the first place, there would be no necessity to draw the square sections MQT, MQT′, inasmuch as lines drawn from the mouldings intersecting the mitre sections to the vanishing points will at once form the perspective representation of the cornice. In practice, this is the usual mode of proceeding, because a skilful draughtsman can pretty well proportion by his eye most mouldings as seen in perspective; but where great accuracy is required, the method of proceeding by square sections is recommended, because, from the great foreshortening of the diagonal line, the smallest inaccuracy of intersection on it will cause very large errors in the mouldings.

When the diagonal sections alone are used, it is clear that the geometrical profile, No. 2., will not be the same as that formed by the oblique section of the cornice: this last must therefore be obtained from a plan and elevation of the mouldings as shown in No. 3.

2454. Instead of finding the square section made by the plane FNGO at the angle OG, it may be drawn on the plane TQM, where it is more readily found by producing the lines whereby the section TQM was obtained; so the lines T′T″, MO″ are set out in perspective equal to the projection of the break of the building ON: moreover by the line T″O″ we may obtain the mouldings of the cornice on the face of the wall GH as produced or prolonged to T″O″, and conversely the cornice in perspective may be drawn from this imaginary section, if it be previously found. Where vanishing points are at an inconvenient distance in drawings, a mode may be adopted to obviate the inconvenience, the principle whereof is this. Let A (*fig.* 837 *a.*) be the vanishing point, CDB a segment of a circle whose centre is A; then if CB be bisected in D, AD will be a vanishing line for such bisection; and if CD be bisected, and a ruler applied to join CD, it will, by the application of a square on CD, give the vanishing line for the new bisection. *Fig.* 837. *b.*

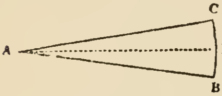

Fig. 837. *a.*

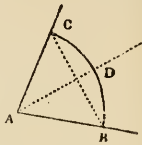

Fig. 837. *b.*

2455. Our next care is to find the vanishing point of the raking mouldings, which may be found from what has already been said, and a perspective section must be made of these mouldings by means of any vertical plane where most convenient; but the best place is through the apex of the pediment, which, as it could not, for want of room, be done in the present example, is taken through the line *oo*, No 2., passing through the extreme left angle of the tympanum of the pediment.

2456. As the mouldings of the pediment (*fig.* 837.) here are of the same depth and projection as in the horizontal parts, they will not, when inclined, coincide with the diagonal section of the horizontal cornice at OS; hence that section, if found in perspective at OS, cannot be used for drawing the perspective representation of the pediment cornice, except for the bead or fillet above the corona, which, from the construction of the pediment, will coincide at this mitre, as we may see in No. 2; whence it may also be seen that the point *x* does not coincide with *t*. X′*x* cannot, therefore, in the perspective represen ation, be drawn through X, the point answering to *t* in the diagonal section NRX. OO′ in the line OH is to be made in perspective equal to *mo*, No. 2., and the whole depth *oo*, and those of the several mouldings on the oblique section, being set upon EQ produced, they are to be transferred to OO′ by means of the vanishing points. The distance O′I is the perspective distance of the projection *qt* of the cornice as before, and is most readily obtained from the section O″T″, which is transferred to the plane O′I, and will be easily comprehended from the figure: the quantity of projection of each raking moulding of the pediment is equal to that of the same moulding where horizontal. Thus the perspective representation of an oblique section made by a plane passing through *oo*, No. 2., is obtained, and the mouldings are then drawn to the vanishing point through the various points, the line IX′ cutting T″X in the point corresponding to *x*, No. 2. As to the modillions, their representations are found with less confusion by planning them apart and using visual rays; but if no plan is used, the following method, invented by the elder Malton, may be adopted:—

2457. Draw BC, the line intersecting the plane of the sofite of the corona, Nos. 2. and 3., through the proper point *x* in MQ at right angles to it, and draw *xy* to the vanishing point. Produce the line corresponding to A in No. 3. to A in *xy*, and transfer A to 1 in BC, so as to be proportional to it in respect of the whole extent. Then set off the proportional widths and intervals of the modillions, as shown on Nos. 2. and 3. on BC, and transfer them by means of the same proportioning point by which *z* was transferred to 1; and from the points 2, 3 4, 5, 6, &c. in *xy* thus obtained, draw on the perspective of the sofite by the use of the vanishing point the lines representing the tops of the modillions corresponding to 2, 3, 4, &c., No. 2. The cymatium round them and the inner angle of the sofite may be drawn by the eye, or where great accuracy is required, the mitre or diagonal sections may be determined as for the principal mouldings already described. At the backs of the modillions the verticals are to be determined either by means of visual rays from a plan, or through the medium of intersections of the perspective lines of the upper parts of them on the sofite, which is as much as can be requisite for guiding us to a correct delineation. The same process is to be used for the modillions on the other sides.

The following is an easy method for dividing vanishing lines in perspective. Let AB, CD be the perspective representation of two parallels, no matter in what plane. It is required to divide the given portion of AB on one of them so that its parts shall be the perspective representation of equal portions of the real line (or in any assigned ratio). Draw BE parallel to CD and equal to AB, and divide it into the required number of equal parts or of parts in the desired proportion beginning at E. Join AE and produce it to meet CD in F. From F draw lines to each of the points of division PQRS of the line AE, and they will cut AB in the required points of subdivision *p q r s*.

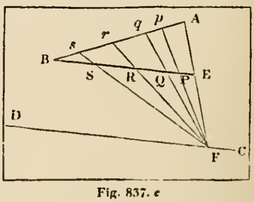

Fig. 837. *c*

Sect. III.

SHADOWS.

2458. Sciography, or the doctrine of shadows, is a branch of the science of projection, and some preparation has been made for its introduction here in Sect. VI. Chap. I. (1110, *et. seq.*) on Descriptive Geometry, which, if well understood, will remove all difficulty in comprehending the subject of this section.

2459. The reader will understand that in this work, which is strictly architectural, the only source of light to be considered is the sun, whose rays, owing to his great distance, are apparently parallel and rectilineal. It is moreover to be premised, that such parts of any body as may be immediately opposed to the rays of light are technically said to be in *light*, and the remaining parts of such body are said to be *in shade.* But when one body stands on or before another, and intercepts the sun's rays from the latter, which is thereby deprived of the action upon it of the rays of light, the part so deprived of the immediate action of the light is said to be *in shadow.* It seems hardly necessary to observe, that the parts of any body nearest the source of light will be the brightest in appearance, whilst those furthest removed from it will, unless under the action of reflected light, be the darkest.

2460. It has been the practice, in architectural drawings, to represent the shadows of their objects at an angle of forty-five degrees with the horizon, as well on the elevations as on the plans. The practice has this great convenience, namely, that the breadth of the shadow cast will then actually measure the depth of each projecting member which casts it, and the shadowed elevation may be thus made to supply a plan of the external parts of the building Now, if in the elevation the shadows be cast at an angle of forty-five degrees, it will on a little consideration be manifest, that, being only projections of a more lengthened shadow (for those on the plan are at an angle of forty-five degrees), the actual shadow seen diagonally must be at such an angle as will make its projection equal to forty-five degrees upon the elevation; because all elevations, sections, and plans, being themselves nothing more than projections of the objects they represent, are determined by perpendicular, horizontal, or inclined parallel lines drawn from the points which bound them to the plane of projection, and similarly, a shadow in vertical projection, which forms an angle of forty-five degrees with the horizon, can only be the representation on such projection of an angle, whose measure it is our business now to determine.

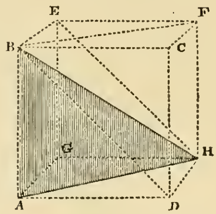

Fig. 838.

2461. In the cube ABCDEFGH (*fig.* 838.) the line BD, forming an angle of forty-five degrees with the horizon, is a projection or representation of the diagonal BH on the vertical plane ABD; and our object being to find the actual angle AHB, whereof the angle ADB is the projection, we have the following method. Let each side of the cube, for example, =10. Then (by 907.) $AD^2 + DH^2 = AH^2$.

That is, $10 \times 10 + 10 \times 10 = 200 = AH^2$, consequently AH = 14·142100.

As BAH is a right angle, we have by Trigonometry, using a table of logarithms, —

As AH (=14·14142100) or Ar. Co. Log. .	9·8494850
To tangent 45°	10·0000000
So AB (=10·00000000) log. . .	1·0000000
To tangent of angle FHB = 35° 16′ .	= 9·8494850

The angle ABH is therefore 54° 44′.

Hence it follows, that when shadows are projected on the plan as well as on the elevation, at an angle of forty-five degrees, the height of the sun which projects them must be 35° 16′.

2462. It is of the utmost importance to the student to recollect this fact, because it will be hereafter seen that it will give him great facility in obviating difficulty where confusion of lines may lead him astray, being, in fact, not only a check, but an assistance in proving the accuracy of his work.

2463. We now proceed to submit to the student a series of examples, containing the most common cases of shadowing, and which, once well understood, will enable him to execute any other case that may be presented to his notice.

2464. In *fig.* 839. we have on the left-hand side of the diagram the common astragal fillet and cavetto occurring in the Tuscan and other pilasters, above in elevation and below in plan. The right-hand part shows the same connected with a wall, whereon a shadow is cast by the several parts. LL is a line showing the direction of the light in projection at an angle of forty-five degrees. It will on experiment be found, by a continuation of the line, or by one parallel to it, to touch the side of the astragal at a, whence an horizontal line drawn along it will determine its line of shade. We here again repeat, to prevent misunderstanding, that in the matter we are now attempting to explain we are not dealing with reflected light, nor with the softening off of shadows apparent in convex objects, but are about to

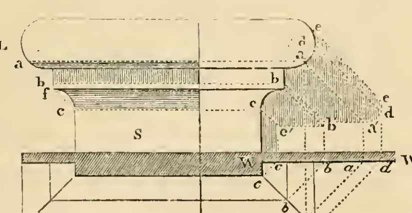

Fig. 839.

determine the mere boundaries of *shade* and *shadow* of those under consideration. The rest must be learned from observation, for the circumstances under which they are seen must constantly vary. This, however, we think, we may safely state, that if the boundaries of shade and shadow only be accurately given in a drawing (however complex), the satisfaction they will afford to the spectator will be sufficient, without further refinement. But it is not to be understood from this that we discountenance the refinement of finish in architectural subjects; all that we mean to say is, that it is not necessary. To return to the diagram: it is manifest that if the boundary of *shade* be at a from that point parallel to the direction of the light a line ab will determine the boundary of *shadow* on the fillet at b, and that from the lower edge of such fillet at f a line again parallel to the direction of the light will give at c the boundary of the shadow it casts upon the shaft S. As, in the foregoing explanation, a was the upper boundary of shade, so by producing the horizontal line which it gave to a on the right-hand side of the diagram we obtain there a corresponding point whence a line aa′ parallel to the direction of the light is to be drawn indefinitely; and on the plan a line *aa*, also parallel to the direction of the light, cutting the wall WW whereon the shadow is cast at *a*. From the point last found a vertical line from *a*, where the shadow cuts the wall on the plan, cutting aa′ in a′, will determine the point a′ in the shadow. The point c, by a line therefrom parallel to the direction of the light, will determine similarly the situation c′ by obtaining its relative seat on the diagonal *cd*, which perhaps will be at once seen by taking the extreme point d of the projection of the astragal, and therefrom drawing dd′ parallel to the direction of the light. From the line *dd*, drawn similarly parallel to the direction of the light, and cutting WW in *d*, we have the boundary of the shadow on the plan, and from that point a vertical *d*d being drawn, the boundary of shadow of the extreme projection of the astragal is thus obtained. The boundary of shadow of the fillet on the right-hand side at *b*, similarly by means of *bb*, and by the vertical *b*b′, gives the boundary point of the shadow from b. The same operation in respect of *cc* gives the boundary of shadow from c to c′ in the latter point. We have not described this process in a strictly mathematical manner, because our desire is rather to lead the student to think for himself a little in conducting it; but we cannot suppose the matter will not be perfectly understood by him even on a simple inspection of the diagram.

2465. In the diagram (*fig.* 840.) is represented a moulding of common occurrence in architectural subjects, and, as before, the right-hand side is the appearance of its shadow on the wall WW on the plan. It will be immediately seen that LL being the projected representation of the rays of light, the line aa determines the boundary of shadow on the ovolo, and that at b, the boundary of its shade, is also given by a line touching that point parallel to the rays, or rather projected rays, of light. On the right-hand side of the figure oo′, drawn indefinitely parallel to the direction of the light, and determined by a vertical from *a*″, the intersection by *a*″*a*″ with the wall, will give o′a″, the line of shadow of oa′. The line aa determines the shadow on the ovolo, and this continued to a′ horizontally gives also a like termination to a″ in the shadow; b, the boundary upwards of the ovolo's shade, is represented to the right by b′, and to the right on the plan by *b*, whence by a vertical cutting the line b′b″ in b″, the boundary of shadow which b′ will cast is obtained. cc on the plan is in projection the distance of the line of shade c′ from the wall whereon the shadow is cast, and its place in the shadow is at c″, cc″b″ being the length of horizontal shadow produced by the circumstances.

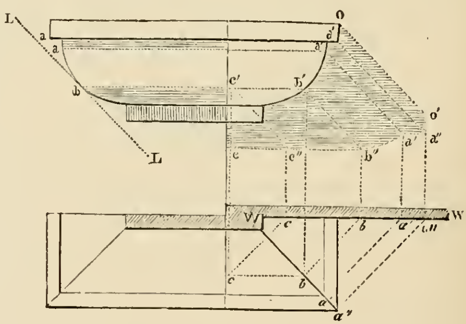

Fig. 840.

In *fig.* 841., which, it will be seen, is a common fillet and cavetto, LL is, as before, the direction of the

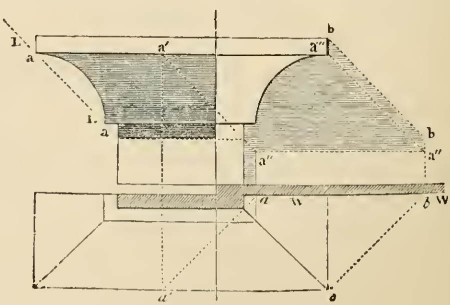

Fig. 841.

light, and aa gives the boundary of shadow, as well of the fillet's lower edge as of the lower edge of the cavetto itself. In respect of the right-hand side of the figure, a'*a'* is a line showing in profile the extent of projection of the fillet before the wall line WW, and from a' a line drawn indefinitely parallel to the direction of the light, and terminated by the intersection of a vertical from *a'* in *a''*, will give the point a' in the shadow. So is bb found through a vertical from *b* on the wall, by a line drawn parallel to the direction of the light from *b* on the plan. The several points being connected by lines, we gain the boundaries of the shadow, wherein a'a''' is represented by a''a''.

2466. *Fig.* 842. exhibits a fillet and cyma reversa or ogee, wherein, as before, LL is the direction of the light at a similar angle to that used on the plan. From the lower edge of the fillet, parallel to the direction of the light, is obtained the point a on the ogee, and from b a similarly parallel line gives the boundary of shadow in c. A line from o in direction of the light, drawn indefinitely, intercepted by a vertical line from *d'*, its projection on the plan in *d* determines o'd, the boundary of the shadow of the fillet on the wall WW. cc''' is the line of profile of the projecting boundary in elevation, of the shade of the ogee before the wall, whereon its shadow is terminated from *c* and *c'''* by a vertical *c''' c'''*. bb', the boundary of shade of the ogee itself, is found in shadow by the line b b''' drawn indefinitely parallel to the direction of the light, and terminated by a vertical from *b'*, the point on the wall correspondent to *b* on the plan, the place of the shade's point in the elevation. By the junction of the lines so found, we shall have the outline of the shades and shadows cast. It is here to be observed, that the portion of light a'b' which the moulding retains is represented in the shadow by a''b''', all the other parts of its curved form being hidden, first by the projection of the fillet, and secondly by the line of shade bb'', which acts in the same way as the fillet itself in producing the line aa', for the moment the light is intercepted, whether by a straight or curved profile, shadow must follow the shade of the moulding, whatever it be; and this is by the student to be especially observed.

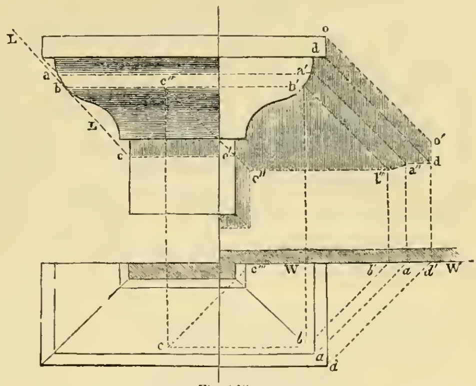

Fig. 842.

2467. *Fig.* 843. exhibits the mode of obtaining the shadows and shade in the cyma recta. LL is the direction of the light, parallel whereto the line ab determines the line of horizontal shadow cast by the lower edge of the fillet upon the cyma, and cd that of the under part of the cyma itself upon the fillet at d. cc' is the upper boundary of the shade of the cyma, and e the point for determining the shadow of the lower fillet, the points abcd corresponding with *abcd* on the plan. WW on the right hand is the face of the wall, whereto the lines *e'e''*, *d'd''*, *c'c''*, *b'b''*, and *a'a''* are drawn parallel to the direction of the light. From *e''d'c''b''a''* vertical being drawn, cutting the indefinite lines oo', a'a'', &c. parallel to the direction of the light in e'', d''', c'', b'', and a'', we have the form of the shadow in elevation. The part from b' to c' of the cyma being in light, its shadow will be the curve c'b'', wherein, if it be required on a large scale, any number of points may be taken to determine its form by means of correspondent points on the plan as for the parts already described.

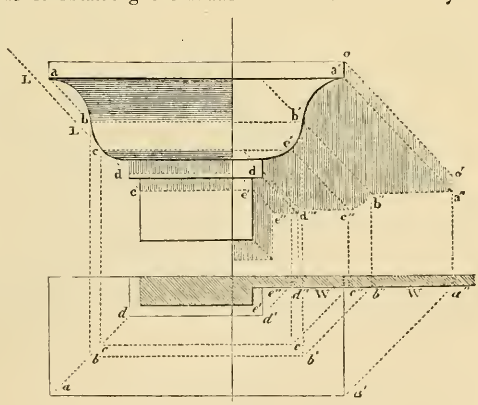

Fig. 843.

2468. *Fig.* 844. is the plan and elevation of some steps, surrounded by a wall, and P in the plan is a square pillar standing in front of them. It will be seen that the line AB corresponds with ab on the plan, as do the points E, F, G, H with efgh, from which verticals determine them in the elevation. The projection of the plinth on the lower step is found by KI and a corresponding line and vertical, which, to prevent confusion, is not shown on the plan. The shadow of the square pillar P is found in a similar manner by the line CD corresponding to cd on the plan, the shadows on the steps being also determined by the points L, M, N, O, through the medium of verticals from l, m, n, o. The left-hand side of the shadow of the pillar is determined in a similar way by the line pq, and QR in the elevation is given by qr in the plan, and is the line representing the back ps of the top of the pillar. It will be observed that we have not described any of the preceding diagrams in a strict way, neither shall we do so in those that follow, presuming that the reader has, from the perusal of the section on Descriptive Geometry acquired sufficient knowledge to follow the several lines.

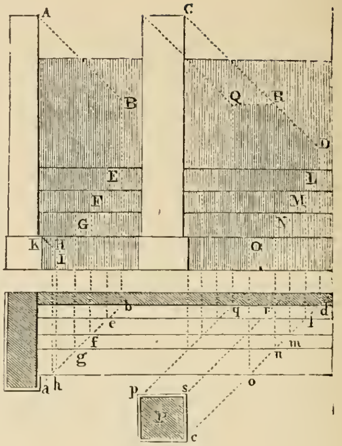

Fig. 844.

2469. The *fig.* 845. is a sort of skeleton plan and elevation of a modillion cornice, but deprived

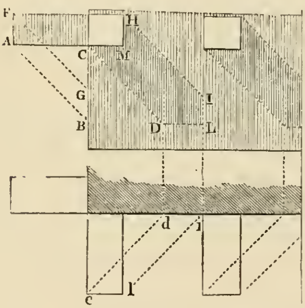

Fig. 845.

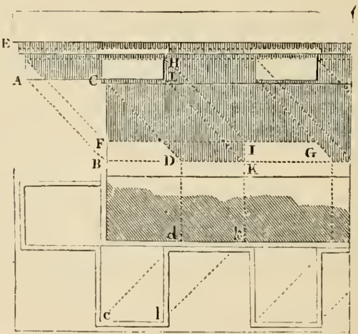

Fig. 846.

of a corona, so as to show the shadows of the modillions, independent of any connection with other parts of the assemblage. FG, HI, and AB parallel to the direction of the light determine, by means of verticals from d and i, the points of shadows from the correspondent points c, l, the points D, L, and I, whereof L is the point of shadow of M.

2470. In *fig.* 846. we approach a little nearer to the form of a modillion cornice. The line EF determines the shadow of the corona, and AB by means of the lines cd, lk, and the verticals dD, kK, the boundary of the side HL of the modillions. A line also drawn horizontally from B will give the under sides of their shadows. FG is a line representing the shadow of the corona.

2471. *Fig.* 847. gives the finished modillion, and the lines Aa, Bb, Cc, Dd will determine, by horizontal lines drawn from them, the shadows which we are seeking. The auxiliary lines, to which no letters are attached, cannot fail of being understood; but if difficulty arise in comprehending them, it will be removed by planning the several points, and, therefrom drawing on the plan, to meet what may be called the frieze, vertical lines to intercept those from the correspondent points in the elevation, and the operation will be facilitated, perhaps, by projecting the form of the curved lines (as seen in the figure) whereof the modillion is formed.

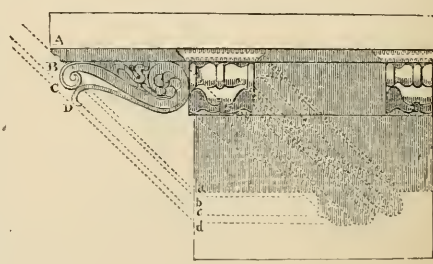

Fig. 847.

2472. *Fig.* 848. will scarcely require a description. It is a geometrical elevation of the

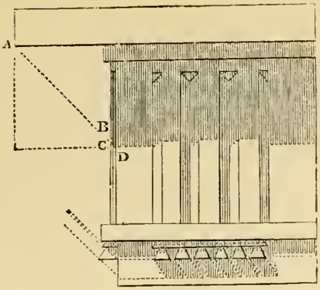

Fig. 848.

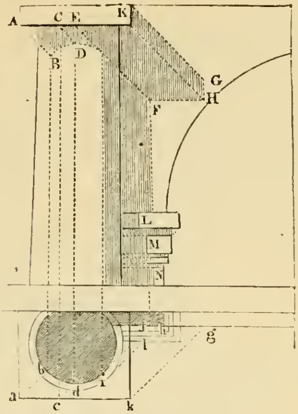

Fig. 849.

Doric triglyph and frieze, with the usual accessories. AB gives the boundary of shadow on the femora of the triglyph, AC the boundary of shadow on the light sides of the glyphs, and AD of the shadow of the corona on the frieze.

2473. *Fig.* 849. is a skeleton representation of a three-quarter column, forming part of an arcade. The abacus is the mere block of material AK. In the plan ab shows the length of the line of shadow AB, and is determined by the vertical bB. In the same way, CD is found by cd and the vertical dD. KG is the representation of kg on the plan, and by a vertical from g the line GH is also determined; H giving also by the horizontal line FH, in which H is already found, the situation of shadow of the point E of the abacus, as also by a vertical from f. LMN are places of the shadow of the column on the impost moulding of the arch, whereof two correspondent points are seen in l and n.

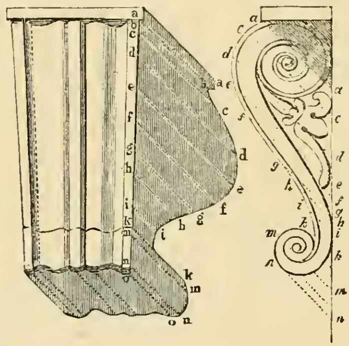

Fig. 850.

2474. The form of shadow of the console in *fig.* 850. will be seen on inspection to have been found from the lines aa, cc, dd, &c. on the elevation, corresponding with *aa*, *cc*, *dd*, &c. on the section, all which are parallel to the direction of the light, and sufficiently explain themselves.

2475. *Fig.* 851. is the elevation and section of a hemispherical niche, wherein are shown the shadows cast thereon by the vertical wall in which it is placed. Through the centre O draw DD at right angles to the direction of the light, and from O draw OA parallel to the direction of the light: A will be found the point in the wall casting the longest shadow. Produce AO indefinitely; and from a, the corresponding point in the section to A on the elevation, draw aa′, parallel to it, which will cut the surface of the niche in a′. Draw the horizontal line a′ a″ cutting AO produced in a‴, and a″ will represent in the shadow the point A in the circumference. Take any other

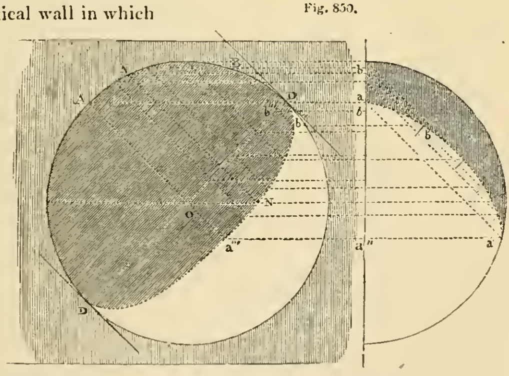

Fig. 851.

point B in the edge of the niche, and by means of a line drawn therefrom horizontally we have the correspondent point b of B in the section. From B draw in the direction of the light the line Bb‴ b″, cutting DD on the diameter in b‴; transfer the point b‴ in the elevation to *b* in the section, and draw bb′ in the direction of the light indefinitely. Then with Bb‴ as a radius from *b* as a centre, describe an arc cutting bb′ in b′; and from b′ draw the horizontal line b′ b″, cutting Bb‴ produced in b″, and b″ will be the point in the shadow corresponding to B in the elevation. To avoid the confusion which would follow the description of the remainder of the operation, we have not encumbered the diagram with more letters of reference; the lines showing, on inspection, similar applications of the process for all parts of the curve. The fact is, that the whole of the shadow may be completed by taking the line DD as the transverse axis of an ellipsis, and finding the semi-conjugate axis Oa by the means above described, for Da″D is a semi-ellipsis in form, inasmuch as it is the projection of a section of a hemisphere. This example is applicable to the shadow of a cylindrical niche with a hemispherical head. The line NN shows the shadow of the portion of the head, and the remainder is obtained by the mere intersection of lines in the direction of the light from different points to the left of N, of which enough has been already given in the previous examples to make the application intelligible.

2476. *Fig.* 852. is the representation of a pediment wherein the section A is that of the

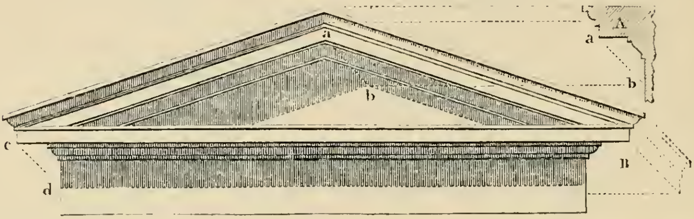

Fig. 852.

mouldings of the pediment at its apex. In the section, ab drawn from the projection a of the corona in the direction of the light, determines the point b therein, wherefrom the horizontal line intercepted by the line ab in the elevation, also drawn parallel to the direction of the light, gives the point b in the elevation. A line from b, parallel to the inclined sides of the pediment on the left, will give the shadow of the corona on the tympanum on that side, and similarly the line of shadow from b on the right side. cd determines the line of shadow on the frieze, and B is the section of the shadow of the assemblage of mouldings on the right.

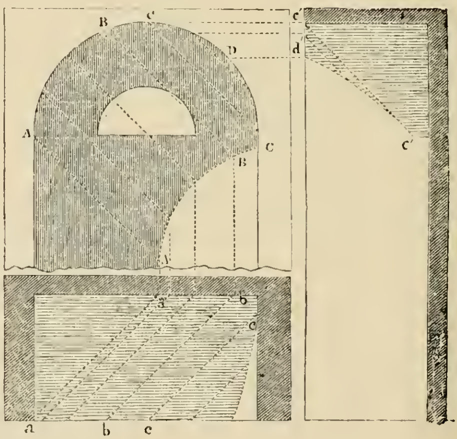

Fig. 853

2477. In *fig.* 853. is given the plan, elevation, and section of a square recess, covered with a cylindrical head. The lines AA, BB, CC of the elevation are determined by aa, bb, and cc of the plan; and in the section c′c′ is the representation of the line cc of the plan. D, the point at which the direction of the light begins to touch the circular head, is d′ in the section.

2478. *Fig.* 854. is the elevation of an arch, below which is its plan and the shadow cast by it on the plane upon which it stands. AA is shown by *aa* on the plan, the corresponding points in the rear of the arch being *a′ a′*, and *a″ a″* the points in the shadow. In a similar way, by BB corresponding with *bb′* on the plan the points *b″ b″* are obtained in the shadow.

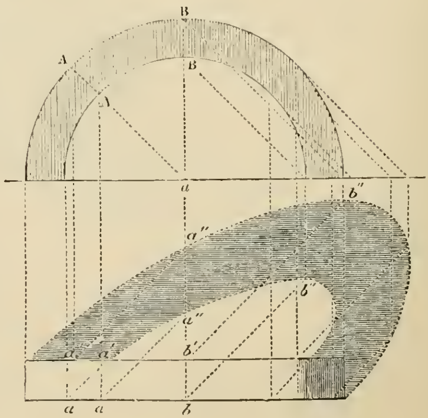

Fig. 854

2479. *Fig.* 855. is the plan and elevation of the upper part of a house, wherein the upper story is occupied by an attic in the centre, against which, on each flank, the sloping roof is terminated. aa on the plan in the direction of the light, produced to intersect the hip at b, gives, by a vertical to B on the elevation, the direction BB of the shadow thereon; and BB cut by AA in the direction of the light, the length BA of the line of shadow, which may, by letting fall the vertical Aa, determine the length aa on the plan. The line of shadow ac is determined by letting fall a vertical from C, where the line of shadow is intercepted by the hip of the roof; and from c the shadow will be found on trial to return as shown in the diagram. E and D on the elevation are found, as seen in previous examples, in ee, and d on the plan, and their shadows at e'e' and d'.

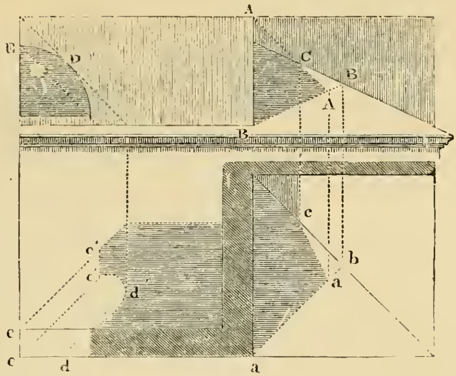

Fig. 855.

2480. What is called an attic base is given in plan and elevation by *fig.* 856. The method of obtaining the shadows thereof in plan and elevation is now to be explained. It is an example which constantly occurs in architectural subjects, and should be well studied and understood. The operations requisite for obtaining a representation of the lines of shadow of the different mouldings in this example depend upon the principles developed in the preceding subsections. The lower portion of the figure exhibits the plan, and the middle portion the elevation of the attic base in question. The uppermost portion of it presents three sections of the mouldings of the base in question cut in three different places parallel to the direction of the light. This last portion of the figure is not absolutely necessary, inasmuch as the profiles in question might have been obtained upon the elevation; but we have preferred keeping it separate to prevent a confusion of subsidiary lines. There is moreover another advantage in thus separating the parts from each other, namely, that of immediately and more distinctly seeing the lines at each selected place, in which the rays of light separate the parts actually in light from those in shadow; and where the student is likely to meet with matters of perplexity, nothing should be left untried to save his time, and, what is often more important, his patience. The mode to be adopted is as follows: —

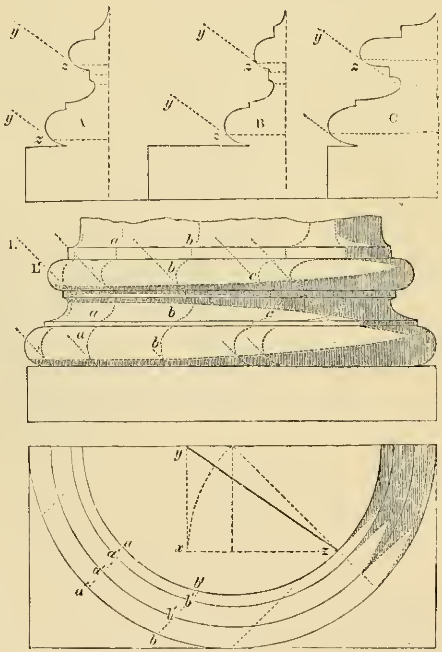

Fig. 856.

Make on the plan any number of sections *a'a'a'a'*, *b'b'b'b'* in the direction of the light, and draw on the elevation the corresponding sections *aaaa*, *bbbb*. LL being the direction of the light, draw parallel thereto tangents to the curves of the convex mouldings, and the boundaries of their shades will be obtained, as will also those of their shadows, by continuing them from such boundaries till they cut the other parts in each section, as will be more especially seen at *cc*. It will be recollected that in our first mention of the projected representation of the line of light and shadow we found that it was an angle of 54° 44′ of the diagonal of a cube. This angle is set out in *xyz* on the plan. We have therefore another mode of finding the boundaries of shade and shadow on the moulding, by developing the sections *a'a'a'a'*, *b'b'b'b'*, &c., as at A, B, and C, and drawing tangents *yz* to the convex mouldings for boundaries of shade thereon, and continuing them, or otherwise, for the other parts, as shown in the diagram.

2481. In *fig.* 857., which represents the capital of a column, a similar method is used to that last mentioned for obtaining the shades and shadows, by means of *a'a'a'a'* and *b'b'b'b'*, which are shown on the elevation by *aaaa* and *bbbb*. We apprehend this will be understood by little more than inspection of it.

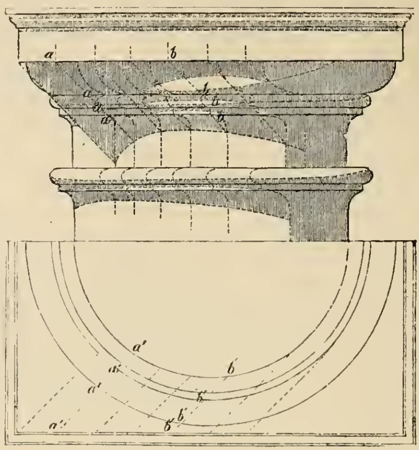

Fig. 857.

It is obvious that the means here adopted for obtaining the lines of shadow are precisely similar to those used in the preceding example. In this, however, the sections of the capital parallel to the direction of the light are made on the elevation, and it will be seen that many of them are not required to obtain an accurate boundary of the lines of shadow sought; for after having obtained those points from which the longest shadow falls, and on the other side those where the line of shadow commences, a curve line of an elliptical nature connects the points found. If the drawing to be made be on a large scale, it may then be worth the architect's while to increase the number of points wherefrom the shadow is to be projected, so as to produce the greatest possible accuracy in the representation.

2482. The shadows of an Ionic capital are given in *fig.* 858. The shadow of the volute on the column is obtained by any number of lines AA, BB, CC, &c. from its different

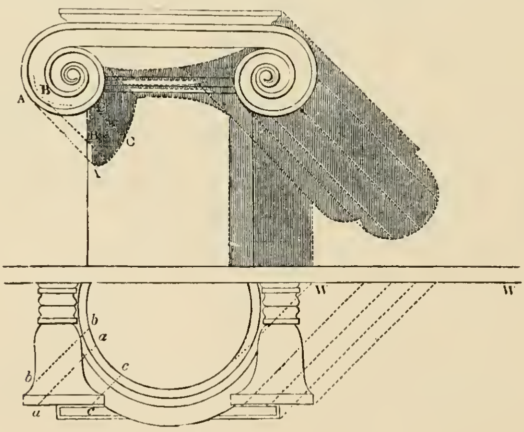

Fig. 858.

parts and verticals from their corresponding ones *aa*, *bb*, *cc*, &c. on the plan, and similarly the shadow of the capital on the wall. In this example, as in those immediately preceding, the employment of sectional lines parallel to the direction of the light is again manifest. The use of them is most especially seen in the example of the Corinthian capital which follows. As a general rule, it may be hinted to the student of sciography, that in the difficulties that may occur, they will be most expeditiously and clearly resolved by the use of the sectional lines, whereon we have thought it proper so much to dilate.

2483. The Corinthian capital in *fig.* 859. will require little more than inspection to understand the construction of its sciography; and all that we think necessary to particularise are the developed projections A, B, C, D, E, F of the abacus and the leaves, whereon the termination of the shadows at angles of 54° 44′, as explained in *fig.* 856., give their respective depths on the elevation.

There is another method of arriving at the result here exhibited, by drawing sectional lines parallel to the direction of the light through the different parts and leaves of the

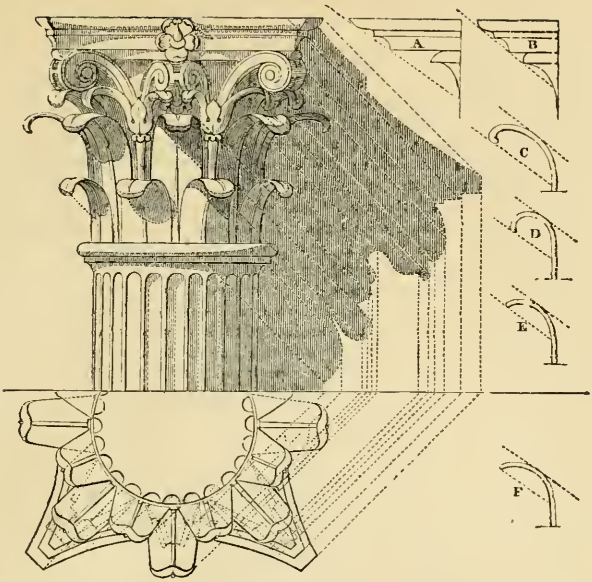

Fig. 859.

capital on its elevation, as in *fig.* 857., and such was the mode we were formerly in the habit of adopting. It however induces such a confusion of lines, that we have long since abandoned it, and have no hesitation in recommending the process here given as the best and most likely to avoid confusion. It is of course unnecessary, in making drawings, to project more than the shadow of one capital, as in a portico, or elsewhere, similar capitals, similarly exposed to the light, will project similar shadows, so that the projection on one serves for the projection on all of them.

2484. For instruction upon the mode in which reflected light acts upon objects in shade and shadow, we must refer the learner to the contemplation of similar objects in relief. The varieties of reflexes are almost infinite; and though general rules might be laid down, they would necessarily be so complicated, that they would rather puzzle than instruct, and under this head we recommend the study of nature, which will be found the best instructress the student can procure.

Sect. IV.

GENERAL PRINCIPLES OF COMPOSITION.

2485. The end of architecture, without whose aid no other art can exist, is not merely to please the eye, but so to provide against the changes of the seasons as to be serviceable to man. Pleasure to the eye may, however, result from the useful, well combined with the beautiful modifications whereof it is susceptible. It is in combining thus that the genius of the architect is exhibited. The art of decorating a well-proportioned edifice is a very secondary and comparatively easy part of his work, though requiring, of course, the early cultivation of his taste and an intimate acquaintance with the parts, whereof this may be taught and that acquired; but the distribution and arrangement of the several portions on the plan, upon which every accessory is dependent, requires great knowledge and considerable experience. And in this is involved not only the general convenience and effect of the building, but what is of much consequence to the proprietor, the cost of the work. None but those practically conversant with the planning of a building would believe the saving that may be produced by proper distribution. In the case of many external breaks, for instance, much addition arises in the length of walls enclosing the edifice, without generally increasing the convenience of the interior, but always when the elevation comes to be adapted to the plan, with the certainty of breaking up the masses, and destroying the simplicity of the effect. This is mentioned merely as an instance of simplicity of plan always producing simplicity of section and elevation.

2486. All ornament in architecture is non-essential, inasmuch as the pleasure received by the eye is not its end. To public and private utility, the welfare and comforts of individuals, which are the ends of the art, every other point must be sacrificed; and it is only when these have been accomplished that we are to think of decoration. An anecdote is related of a certain nobleman, who, having boasted to a friend of the beauty of the façade of his house, which within was exceedingly ill contrived, was told that he thought the peer would do well to take the house opposite, that he might be thus always able to look at it. Those who make the internal parts of an edifice subservient to the project of a façade, and adjust their plan and section to the elevation, must be considered as making the end of less importance than the ornament of the building. Those who work in this mode produce little variety in their designs, which, numerous though they be, consist of but few different combinations, whilst those that result from the natural order of making the façade subservient to the internal parts, which the plan and section impose, are susceptible of infinite variety and decoration.

2487. It is not, however, to be supposed that we are, in what has been said, sanctioning the student's neglect of careful composition and adjustment of the façades. Upon the adaptation of the different fronts of the building to sort with the internal convenience, the greatest care should be bestowed. It is from these his reputation is likely to flow, because they are the parts most susceptible of comprehension by the public. The architect will, upon every succeeding day's experience, find that the two objects are not incompatible; but if such a case, which is possible, arise, he had far better sacrifice the façade, considering first the comforts of those who are to inhabit the house, and then the gratification of those who are only to look at it.

2488. Durand has well observed that compositions conducted on the above principles must please. "Has not nature," says that author, "attached pleasure to the satisfaction of our wants, and are our most lively pleasures other than the satisfaction of our most pressing wants? These wants are better satisfied in the interior distribution of a building than in the exterior." Who leaves the Pantheon without more satisfaction than he expected from the view of the portico, fine though it be? Again, faulty as are both St. Peter's and St. Paul's, will any one who understands the subject aver that he has received more pleasure from their respective façades than from their noble interiors? The pleasurable sensations produced by both are entirely dependent on their interior distribution. But when we find that in the former of these buildings there is no mockery of a dome, the interior and exterior being as far dependent on each other as the circumstances of construction would permit, whilst the dome of the latter is worse than a mockery, the interior and exterior domes having nothing in common with each other, the last being no more than a timber leaded appurtenance to the fabric, Wren, with all his greatness, for great he was, shrinks into nothingness by the side of Michael Angelo, although the external form of the dome of London be more elegant than that of the Vatican. This is a strong but not a forced illustration of our opinions, the good sense whereof must be left for appreciation to our readers, who, we doubt not, on a little reflection, will concur with us.

2489. In ninety-nine cases out of a hundred the student will find that a good distribution of his plan leads him, with anything like ordinary tact, to the composition of good sections and good elevations, far better, indeed, than he could arrive at by pursuing an opposite course. In domestic Gothic architecture, this is notorious, for in that a regular distribution of the openings would often produce the tamest and least picturesque effect. The Gothic architects placed windows internally where only they would be serviceable, letting them take their chance in the exterior. It is not to be understood, because such would be rather *outré*, that this method will exactly suit the principles of composition in Italian architecture; but it is well known to practical men that a required opening in a particular place, instead of being a blemish, may be converted on many occasions into a beauty. Indeed, it is incontrovertibly true that distribution and disposition are the first objects that should engage the architect's attention, even of him whose great aim is to strike the attention by ornament, which can never please unless its source can be traced to the most convenient and economical distribution of the leading parts. Theorists may be laughed at, but it does not move us, nor diminish our regret to see many architects without any other theory than that whereon, in an inverted position, their own wild fancies are grafted. If what we have stated be true, and from the nature of things we cannot imagine a controversy can arise upon our observations, the talent of the architect is to be estimated, as Durand properly observes, according to his solution of the two following problems: —

First. For a given sum, as in private buildings, to erect the most convenient and suitable house for his employer.

Second. The requisites in a building being given, as in public buildings, to erect it at the smallest possible expense.

2490. An investigation of all the modes of accomplishing these desiderata can only be fully effected in a work of much larger extent than this; but we have, in the practical parts of our volume, so prepared the reader, that he will not generally be at a loss in respect of the construction of a building, whatever its nature or destination

Sect. V.

DRAWINGS NECESSARY IN COMPOSITION.

2490*a*. For the thorough comprehension of a projected edifice, at least three drawings are necessary, the *plan*, the *section*, and the *elevation*. The first is a horizontal section of it, the second the vertical section, which shows the building as if it were cut in half, that half nearest the spectator being removed from its plan, so as to permit the inner parts to become visible, and the third is the geometrical appearance of the front represented as if viewed from an infinite distance, in which no convergence of the lines would be seen.

2490*b*. In making a design, it is always better to put the general idea together on a single sheet of paper, and consequently, in most cases, on a small scale. This, in afterwards making the drawings, is, as may be necessary, increased in size. The three parts being drawn under one another, as shown in *fig.* 895*a*., wherein the middle diagram is the plan, the lower one the section, and the upper one the elevation. By thus beginning on a single sheet, in which the whole is before the eye, the corresponding lines are more readily transferred from one part to another. Having drawn through the middle of the paper the vertical AA, cut at right angles by the horizontal line BB, draw the required centres or axes of the walls CC and DD, and supposing the building is to be square, with the same opening of the compasses set out the axes of the return walls EE and FF. Having determined the thickness of the walls, one half may be set out on each side the axes, as in *ee*, *ff*, *cc*, and *dd*, and then the lines showing the thicknesses of the walls may be drawn. The width of openings in the walls may be next set out, half on each side the axes BB and AA, first drawn towards *bb* and *aa*, and the lines drawn to their places. Having thus proceeded, we shall discover that not only has the plan been drawn, but at the same time a considerable portion of the section and elevation. To distinguish the voids from the solids, the latter should be coloured or hatched, and then the next step will be as follows: — Parallel to the principal axis BB, draw the ground lines GG and GG. From these lines the heights of the building, its cornice and openings, may be set up in the section and elevation; and afterwards, the height of the roof and projection of the cornice having been determined, they may be set out and drawn. In the section, as in the plan, it is usual either to colour or hatch the solid parts, as we have done in the figure.

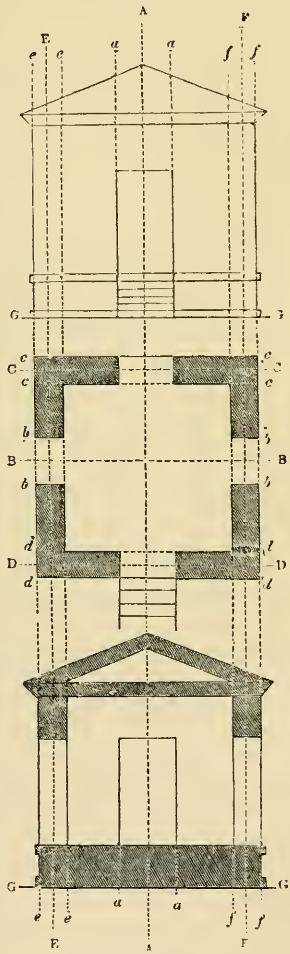

Fig. 859*a*.

2490*c*. Simple as the above process may be, it contains the whole elementary part of the mechanical process necessary for making a design. It might have been conducted on a more complicated mass, but had we done so, it would not have been so well understood, and we therefore deprecate any observations on the simpleness of our process by those who have been brought to know these things by practice and experience. We do not, however, feel we should discharge our duty before closing this section, without a censure on the attempt to convert drawings of *geometrical* elevations and sections into picturesque representations, because such practice is not only injurious to the art, but is dishonest, and has a tendency to mislead the architect's employer; and we are sorry to say that it is not unfrequently done with such a view. We denounce it, and without hesitation aver that the casting of shadows on a design is only admissible for the purpose of showing the relative depths of projecting parts; and when so admitted, the medium should be confined to Indian ink or sepia, and thrown in merely in masses, the apertures being just slightly filled in with the same colour.

Sect. VI.

WORKING DRAWINGS.

2491. Working drawings are those made of the parts at large for executing the works, which could not be well done from drawings on a small scale, wherein the small parts would not be either sufficiently defined, or could not be figured so as to enable the workman to set out his work with accuracy. They are generally in outline, except the sectional parts, which are frequently tinted to bring the profiles more readily before the eye.

2491*a*. It is obvious that though drawings made to a twelfth or a twenty-fourth part of their real size may well enough supply the wants of the workman where there is no complication in the distribution and arrangement, and where there is a simple treatment of regular forms, of right angles and the like; yet in all cases wherein we have to deal with the minor details of architecture, and in construction, where the variety of forms used is infinite from the variety of the circumstances, nothing short of drawings of the full, or at the least of half, the size will safely guide the workman.

2491*b*. The art of making working drawings, which must have been well understood at all periods of the practice of architecture, involves a thorough knowledge of projection, or descriptive geometry, and consists in expressing by lines all that occurs for the development of every part of the details of a building, in plan, elevation, and profile, each part being placed for the use of the workman with clearness and precision. All the rules by which working drawings are wrought are dependent on the matter in this work already communicated to the reader, excepting only those details of the orders, and some other matters, which will be found in Book III. But we shall here, nevertheless, briefly replace before him the leading principles whereon working drawings are to be prepared. And first, he is to recollect that solids are only represented by the faces opposite to the eye; secondly, that the surfaces by which solids are enclosed are of two sorts, that is, rectilinear or curvilinear. Those bodies in which these properties are combined may be divided into three sorts: 1. Those which are bounded by plane surfaces, such as prisms, pyramids, and generally all straight work. 2. Those in which there is a mixture of straight and curved lines, as cylinders, cones, or portions of them, voussoirs of vaulting, and the like; and 3. Those solids wherein a double flexure occurs, as in the sphere, spheroid, and in many cases of voussoirs.

2491*c*. We should, however, unnecessarily use our limited space by further entering on these matters, on which enough has been said in previous sections. The plain truth is, that working drawings are to be so made for the use of the artificer as to embody on a scale, to prevent any mistake, all the information which this work has already given on construction, and that which follows in the more refined view of architecture as a fine art.

2491*d*. In works whose magnitude is not of the first class, the drawing of every part, both in construction and in those which involve the work as one of art, should be given of the full size whereof it is proposed to be executed. Where the building is large, as also the parts, this may be dispensed with; but then it becomes (the detail being drawn on a smaller but fully intelligible scale) the duty of the architect to see that the drawings he furnishes are faithfully drawn out to the full size by the artificer on proper moulds. Often it is useful—never, indeed, otherwise—to *offer up*, as it is called, small portions of mouldings on the different parts of a building, to ascertain what the effect may be likely to be at the heights fixed for their real places. In these matters he should leave no means untried to satisfy himself of the effect which his first drawings *in small* is likely to produce when executed.

2491*e*. We have presumed that the architect is so far educated as to have acquired a full knowledge of all that rules can teach, and that, strictly speaking, he has proportioned his work in conformity with them. Still, in real practice, there are constantly so many circumstances which concur in making it almost necessary to depart from established rules, such as surrounding buildings, where it is of importance to give predominance to a part for the purpose of making it a feature, that the expedient of trying a portion of the proposed detail in the place it is actually to occupy, is a matter that we would advise every architect to adopt after he has made and studied the working drawings whereof we treat.

2491*f*. We have not alluded to the matters of carpentry and joinery, in which it is often necessary to give the artificer information by means of working drawings; but the methods of trussing in carpentry, and of framing in joinery, often require working drawings. What has already been exhibited under those heads (2031, *et seq.*) will prevent his being left uninstructed, and will, moreover, have afforded such information as to prepare him, by the exercise of his own ingenuity, for such cases as may not have been specially given in the examples herein contained. We therefore here close our observations under this section by an intimation to the student, that the proper preparation of working drawings for the use of the artificer tests his acquaintance with the theory and practice of the art, and is of the utmost importance to the pocket of the employer, which it is his duty as a gentleman incessantly to protect.

BOOK III.

PRACTICE OF ARCHITECTURE.

CHAP. I.

GRECIAN AND ITALIAN ARCHITECTURE.

Sect. I.

BEAUTY IN ARCHITECTURE.

2492. The existence of architecture as a fine art is dependent on *expression*, or the faculty of representing, by means of lines, words, or other media, the inventions which the architect conceives suitable to the end proposed. That *end* is twofold; to be useful, and to connect the use with a pleasurable sensation in the spectator of the invention. In eloquence and poetry the end is to instruct, and such is the object of the higher and historical classes of painting; but architecture, though the elder of the arts, cannot claim the rank due to painting and poetry, albeit its end is so much more useful and necessary to mankind. In the sciences the end is utility and instruction, but in them the latter is not of that high moral importance, however useful, which allows them for a moment to come into competition with the great arts of painting, poetry, and eloquence. It will be seen that we here make no allusion to the lower branches of portrait and landscape painting, but to that great moral and religious end which fired the mind of Michael Angelo in the Sistine Chapel, and of Raffaelle Sanzio in the Stanze of the Vatican and in the Cartoons. Above the lower branches of painting just mentioned, the art whereof we treat occupies an exalted station. In it though the chief end is to produce an useful result, yet the expression on which it depends, in common with the other great arts, brings each within the scope of those laws which govern generally the fine arts whose object is beauty. Beauty, whatever difference of opinion may exist on the means necessary to produce it, is by all admitted to be the result of every perfection whereof an object is susceptible, such perfections being altogether dependent on the agreeable proportions subsistent between the several parts, and those between the several parts and the whole. The power or faculty of inventing is called *genius*. By it the mind is capable of conceiving and of expressing its conceptions. *Taste*, which is capable of being acquired, is the natural sensation of a mind refined by art. It guides genius in discerning, embracing, and producing beauty. Here we may for a moment pause to inquire what may be considered a standard of taste, and that cannot be better done than in the words used on the subject by Hume (Essay xxiii.): "The great variety of tastes," says that author, "as well as of opinion, which prevails in the world, is too obvious not to have fallen under every one's observation. Men of the most confined knowledge are able to remark a difference of taste in the narrow circle of their acquaintance, even where the persons have been educated under the same government and have early imbibed the same prejudices. But those who can enlarge their view to contemplate distant nations and remote ages are still more surprised at the great inconsistence and contrariety. We are apt to call *barbarous* whatever departs widely from our own taste and apprehension, but soon find the epithet of reproach retorted on us, and the highest arrogance and self-conceit is at last startled on observing an equal assurance on all sides, and scruples, amidst such a contest of sentiment, to pronounce positively in its own favour." True as are the observations of this philosopher in respect of a standard of taste, we shall nevertheless attempt to guide the reader to some notion of a standard of taste in architecture.

2493. There has lately grown into use in the arts a silly pedantic term under the name of Æsthetics, founded on the Greek word Ἀισθητικὸς, one which means having the power of perception by means of the senses; said to be the science whereby the first principles in all the arts are derived, from the effect which certain combinations have on the mind as connected with nature and reason: it is, however, one of the metaphysical and useless additions to nomenclature in the arts, in which the German writers abound, and in its application to architecture of least value; because in that art form is from construction so limited by necessity, that sentiment can scarcely be said to be further connected with the art than is necessary for keeping the subordinate parts of the same character as the greater ones under which they are combined; and, further, for thereby avoiding incongruities.

2494. It is well known that all art in relation to nature is subject to those laws by which nature herself is governed, and if we were certain that those rules of art which resulted from reason were necessarily and actually connected with sensation, there would be no difficulty in framing a code of laws whereon the principles of any art might be firmly founded. "Principles in art," as well defined by Payne Knight, "are no other than the trains of ideas which arise in the mind of the artist out of a just and adequate consideration of all those local, temporary, or accidental circumstances upon which their propriety or impropriety, their congruity or incongruity, wholly depend." By way of illustrating the observation just made, we will merely allude to that maxim in architecture which inculcates the propriety of placing openings over openings and piers over piers, disallowing, in other words, the placing a pier over an opening without the exhibition of such preparation below as shall satisfy the mind that security has been consulted. There can be no doubt that a departure from the maxim creates an unpleasant sensation in the mind, which would seem to be immediately and intimately connected with the laws of reason; but there is great difficulty in satisfying one's self of the precise manner in which this operates on the mind, without a recurrence to the primitive types in architecture, and thence pursuing the inquiry. But in the other arts the types are found in nature herself, and hence in them no difficulty occurs in the establishment of laws, because we have that same nature whereto reference may be made. We shall have to return to this subject in the section on the Orders of Architecture, to which we must refer the reader, instead of pursuing the subject here.

2495. Throughout nature beauty seems to follow the adoption of forms suitable to the expression of the end. In the human form there is no part, considered in respect to the end for which it was formed by the great Creator, that in the eye of the artist, or rather, in this case the better judge, the anatomist, is not admirably calculated for the function it has to discharge; and without the accurate representation of those parts in discharge of their several functions, no artist by means of mere expression, in the ordinary meaning of that word, can hope for celebrity. This arises from an inadequate representation having the appearance of incompetency to discharge the given functions; or, in other words, they appear unfit to answer the end.

2496. We are thus led to the consideration of *fitness*, which, after all, will be found to be the basis of all *proportion*, if not proportion itself. Alison, in his *Essay on Taste*, says, "I apprehend that the beauty of proportion in forms is to be ascribed to this cause," (fitness) "and that certain proportions affect us with the emotion of beauty, not from any original capacity in such qualities to excite this emotion, but from their being expressive to us of the fitness of the parts to the end designed." Hogarth, who well understood the subject, concurs with Alison in considering that the emotion of pleasure which proportion affords does not resemble the pleasure of sensation, but rather that feeling of satisfaction arising from means properly adapted to their end. In his *Analysis of Beauty* that great painter places the question in its best and truest light, when, speaking of chairs and tables, or other common objects of furniture, he considers them merely as fitted from their proportions to the end they have to serve. In the same manner, says Alison, "the effect of disproportion seems to me to bear no resemblance to that immediate painful sensation which we feel from any disagreeable sound or smell, but to resemble that kind of dissatisfaction which we feel when means are unfitted to their end. Thus the disproportion of a chair or table does not affect us with a simple sensation of pain, but with a very observable emotion of dissatisfaction or discontent, from the unsuitableness of their construction for the purposes the objects are intended to serve. Of the truth of this every man must judge from his own experience." We cannot refrain from continuing our extracts from this most intelligent author. "The habit," he says, "which we have in a great many familiar cases of immediately conceiving this fitness from the mere appearance of the form, leads us to imagine, as it is expressed in common language, that we determine proportion by the eye, and this quality of fitness is so immediately expressed by the material form, that we are sensible of little difference between such judgments and a mere determination of sense; yet every man must have observed that in those cases where either the object is not familiar to us or the construction intricate our judgment is by no means speedy, and that we never discover the proportion until we previously discover the principle of the machine or the means by which the end is produced."

2497. The nature of the terms in which we converse shows the dependence of proportion on fitness, for it is the sign of the quality. The natural answer of a person asked why the proportion of any building or machine pleased him, would be, because the object by such proportion was fit or proper for its end. Indeed, proportion is but a synonyme of fitness;

for if the form be well contrived, and the several parts be properly adjusted to their end, we immediately express our opinion that it is well proportioned.

2498. There is, however, between proportion and fitness, a distinction drawn by our author, which must be noticed. "Fitness expresses the relation of the whole of the means to the end; proportion, the proper relation of a part or parts to their end." But the distinction is too refined to be of importance in our consideration; for the due proportion of parts is simply that particular form and dimension which from experience has been found best suited to the object in view. "Proportion," therefore continues Alison, "is to be considered as applicable only to forms composed of parts, and to express the relation of propriety between any part or parts and the end they are destined to serve."

2499. Forms are susceptible of many divisions, and consequently proportions; but these are only subordinate to the great end of the whole. Thus, for instance, in the constantly varying forms of fashion, say in a chair or table, the merely ornamental parts may bear no relation to the general fitness of the form, but they must be so contrived as to avoid unpleasant sensation, and not to interfere with the general fitness. If we do not understand the nature of its fitness, we cannot judge of the proportion properly. "No man," says Alison, "ever presumes to speak of the proportions of a machine of the use of which he is ignorant." When, however, we become acquainted with the use or purpose of a particular class of forms, we at the same time acquire a knowledge which brings under our view and acquaintance a larger circle of agreeable proportions than the rest of the world understand; and those parts which by others are regarded with indifference, we contemplate with pleasure, from our superior knowledge of their fitness for the end designed. The proportions of an object must not in strength be carried beyond what is required for fitness, for in that case they will degenerate into clumsiness, whilst elegance, on the contrary, is the result of the nicest adjustment of proportion.

2500. Fitness cannot exist in any architectural object without *equilibrium* in all the parts as well as the whole. The most complete and perfect notion that can be conceived of *stability*, which is the result of equilibrium, may be derived from the contemplation of an horizontal straight line; whilst, on the contrary, of instability nothing seems more expressive than a vertical straight line. These being, then, assumed as the extremes of stability and instability, by carrying out the gradations between the two extremes, we may, extending in two parts the vertical line, obtain various forms, more or less expressive of stability as they approach or recede from the horizontal line. In *fig.* 860. we have, standing on the same base, the general form of the lofty Gothic spire; the pleasing, solid. and enduring form of the Egyptian pyramid; and that of the flat Grecian pediment: which last, though in its inclination adjusted on different grounds, which have been examined in Book II Chap. III. subsect. 2027, *et seq.*, is an eminent instance of stability. The spire, from its height and small base, seems to possess but a tottering equilibrium compared with the others.

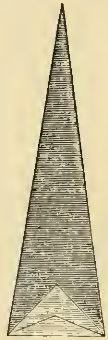

Fig. 860.

2501. Stability is obviously dependent on the laws of gravitation, on which, under the division of statics, not only the architect, but the painter and sculptor, should bestow considerable attention. We cannot for a moment suppose it will be disputed that at least one of the causes of the beauty of the pyramid is a satisfactory impression on the mind of the state of rest or stability it possesses. Rest, repose, stability, balance. all meaning nearly the same thing, are then the very essential ingredients in fitness; and therefore, in architectural subjects, instability, or the appearance of it, is fatal to beauty. Illustrations of this exist in the famous Asinelli and Garisendi towers at Bologna, and at Pisa in the celebrated leaning Campanile.

2502. It may be objected to what we have written, that fitness alone will not account for the pleasure which arises in the contemplation of what are called the orders of architecture, and Alison seems very much to doubt whether there be not some other cause of beauty. It will, however, be our business to show how the ancients, their inventors, considered principally their fitness; and upon these grounds to show, moreover, how the proportions in ancient examples varied, and may be still further varied, without infringing upon the principles which guided them in the original invention. Payne Knight has well observed, "that the fundamental error of imitators in all the arts is, that they servilely copy the effects which they see produced, instead of supplying and adopting the principles which guided the original artists in producing them; wherefore they disregard all those local, temporary, or accidental circumstances upon which their propriety or impropriety, their congruity or incongruity, wholly depend." "Grecian temples, Gothic abbeys, and feudal castles were all well adapted to their respective uses, circumstances, and situations; the distribution of the parts subservient to the purposes of the whole; and the ornaments and decorations suited to the character of the parts, and to the manners, habits, and employments of the persons who were to occupy them: but the house of an English nobleman of the 18th or 19th century is neither a Grecian temple, a Gothic abbey, nor a feudal castle; and if the style of distribution or decoration of either be employed in it, such changes and modifications should be admitted as may adapt it to existing circumstances, otherwise the scale of its exactitude becomes that of its incongruity, and the deviation from principle proportioned to the fidelity of imitation." This is but another application of the principle of fitness which we have above considered, the chief foundation of beauty in the art. We have shown how it is dependent on stability as a main source of fitness, and here subjoin some maxims which will lead the student to fitness in his designs, and prevent him from running astray, if he but bring himself to the belief that they are reasonable, and founded upon incontestable grounds, which we can assure him they are.

First. Let that which is the stronger part always bear the weaker.

Second. Let solidity be always real, and not brought to appear so by artifice.

Third. Let nothing be introduced into a composition whose presence is not justified by necessity.

Fourth. Let unity and variety be so used as not to destroy each other.

Fifth. Let nothing be introduced that is not subordinate to the whole.

Sixth. Let symmetry and regularity so reign as to combine with order and solidity.

Seventh. Let the proportions be of the simplest sort.

Eighth. Let him recollect that nothing is beautiful which has not some good and useful end.

If, after having made his design, he will scrupulously test it by these maxims *seriatim*, and will strike out what is discordant with the tenor of them, he will have overcome a few of the difficulties which attend the commencement of his career.

2503. We are not of the same opinion with those who, on a geometrical elevation of a building, draw lines from its apex, which, bounding the principal parts of the outline, find a pyramidal form, and thence infer beauty of general outline. If those who favour such a notion will but reflect for a moment, they must see that this cannot be a test of its effect, inasmuch as the construction of a geometrical elevation of any edifice supposes it to be viewed at an infinite distance, whereas, in fact, it is most generally viewed under angles which would puzzle the most learned architect, without full investigation, to discover the primary lines which they assume to be the causes of its beauty. The obscurations and foreshortenings that take place are at points of view near the building itself; and, however judicious it may be to form the general masses in obedience to such a system, so as to produce an effect in the distance that may be in accordance with the principle, it would be extremely dangerous to lay the principle down as a law. The finest view of St. Paul's is perhaps a little east of Fetter Lane, on the northern side of Fleet Street; but it would puzzle any one to discover its pyramidal form from that point of view.

2504. The beauty of the proportions of architecture in the interiors of buildings is dependent on those which govern the exteriors. Much has been said on proportions of rooms, which, hereafter, we shall have to notice: we mean the proportions of their length to their breadth and height. That these are important, we cannot deny; but whether the beauty of a room is altogether dependent on the due adjustment of these, we have some doubts; that is, under certain limits. We here address ourselves more particularly to that fitness which, in ornamenting a ceiling, for example, requires that the beams which appear below the general surface should invariably fall over piers, and that in this respect corresponding sides should be uniform. In the study of this point, Inigo Jones is the great English master who has left the student the most valuable examples of this branch of the art.

2505. It may, perhaps, be useful to observe generally that the bare proportions of the interiors of apartments depend on the purposes for which they are intended, and according to these we seek immediately for the expression of their fitness. This point, therefore, involves on the part of the architect so general an acquaintance with the most refined habits of his employers, that we should be almost inclined to agree with Vitruvius on the multifarious qualifications necessary to constitute a good one. Certain it is that no instructions he can receive for building a mansion will qualify him without an intimate acquaintance with the habits of the upper classes of society.

2506. We have already stated that it is hopeless to arrive at a fixed standard of taste. That considered worthy of the appellation will not be so considered in another. "The sable Africans," says Knight, quoting from Mungo Park, "view with pity and contempt the marked deformity of the Europeans, whose mouths are compressed, their noses pinched, their cheeks shrunk, their hair rendered lank and flimsy, their bodies lengthened and emaciated, and their skins unnaturally bleached by shade and seclusion, and the baneful influence of a humid climate." In the countries of Europe, where some similarity of taste may be expected, the tyranny of fashion, no less than that of habit and circumstance, has, and always will have, its influence on the arts. Within the short space of even a few months we have seen what is called the *renaissance* style of architecture imported from France, drawing into its vortex all classes of persons, many of them among the higher ranks, possessed of education to have patronised better taste; and in architecture, and some other arts, no one solves the question of what is really right by saying that there have been errors in the tastes of different ages.

2507. The specimens of Greek sculpture, whose beauty is founded in nature herself, will throughout all time excite the admiration of the world; because in this case, the standard or type being nature, mankind generally may be supposed to be competent judges of the productions of the art. But it is very different in architecture, whose types in every style are, as respects their origin, uncertain; and when we are asked whether there be a real and permanent principle of beauty in the art, though we must immediately reply in the affirmative, we are at the same time constrained to refer it to the quality of fitness. If this were not the case, how could we extend our admiration to the various styles of Egyptian, Grecian, Roman, Gothic, and Italian architecture? These at first appear, compared with each other, so dissimilar, that it seems impossible to assign beauty to one without denying it to the rest. But on examination each will be found so fitted to its end, that such cause alone will be found to be the principal source of the pleasure that an educated mind receives from each style; and that thence it arises, rather than from any certain or definable combinations of forms, lines, or colours that are in themselves gratifying to the mind or agreeable to the organs of sensation. If this be true, what becomes of the doctrine of the German æsthetical school, so vaunted of by self-constituted critics and reviewers, who pass their judgment *ex cathedrâ* on works they have never seen, and, strange to say, are tolerated for a moment by the public? The truth is, the public rarely give themselves the trouble to judge; and unless led, which is easily done by the few, do not undertake the trouble of judging for themselves. That the Egyptian pyramid, the Grecian and the Roman temple, the early Christian basilica, the Gothic cathedral, the Florentine palace, the Saracenic mosque, the pagoda of the East, are all beautiful objects, we apprehend none will dispute; but there is in none of them a common form or standard by which we can judge of their beauty: the only standard on which we can fall back is the great fitness of them, under their several circumstances, for the end proposed in their erection.

2508. We are thus unavoidably driven to the conclusion that beauty in its application to architecture changes the meaning of the word with every change of its application; for those forms which in one style are strictly beautiful on account of their fitness, applied to another become disgusting and absurd. By way of illustrating this, let us only picture to ourselves a frieze of Grecian triglyphs separating the nave and clerestory of a Gothic cathedral. From what we have been taught to consider the type of the Doric frieze connected with its triglyphs an idea of fitness immediately arises in the mind; but we cannot trace its fitness in a dissimilar situation, neither can we comment on such an incongruity better than in the oft-quoted lines of Horace: —

> "Humano capiti cervicem pictor equinam
> Jungere si velit, et varias inducere plumas
> Undique collatis membris, ut turpiter atrum
> Desinet in piscem mulier formosa supernè;
> Spectatum admissi risum teneatis amici?"

The influence of circumstances in every age has imparted to each style of architecture its peculiar beauty and interest; and until some extraordinary convulsion in society give the impetus to a new one, we are constrained to follow systems which deprive us of other novelty than those of changes which are within the spirit of the universally established laws of the art. Turn to the Gothic churches of the present day, — the little pets of the church commissioners and clergy. What objects of ineffable contempt the best of them are! The fact is, the religious circumstances of the country have so changed that they are wholly unsuitable in style to the Protestant worship. Had, with the scanty means afforded to the architects, such a model as St. Paul's, Covent Garden, been adopted, we might have seen a number of edifices in the country, though

> "Facies non omnibus una
> Nec diversa tamen,"

that might have been an honour to the age in which we live, and suitable to the circumstances of the times.

2509. Unity and harmony in a work necessarily enter into that which is beautiful; and it will not therefore require any argument to show that from a mixture of styles in any building incongruity and unfitness, and consequently a want of unity and harmony, must be the result. Hence we cannot agree with those wise reviewers who advocate the possibility of amalgamating the arch with the severe Grecian style. We leave them to their dreams, and trust that before we give them credence we may have some proof of their practical power in this respect.

2510. Symmetry is that quality which, as its name imports, from one part of an assemblage of parts enables us to arrive at a knowledge of the whole. It is a subordinate, but nevertheless a necessary, ingredient in beauty. It is necessary that parts performing the same office in a building should be strictly similar, or they would not *ex vi termini* be symmetrical; so, when relations are strictly established between certain parts, making one the measure of another, a disregard of the symmetry thus induced cannot fail of destroying beauty. But here again we have to say, that for want of attention to the similarity of the parts, or neglect of the established relations on which the whole is founded, they have lost their symmetry, and have thus become *unfit* for their purpose; so that thus again we return to fitness as the main foundation of beauty.

2511. Colour abstractedly considered has little to do with architectural beauty, which is founded, as is sculpture, on fine form. We are here speaking generally, and are not inclined to assert that the colour of a building in a landscape is unimportant to the general effect of that landscape, or that the colours used on the walls of the interior of a building are unessential considerations; but we do not hesitate to say that they are of minor consequence in relation to our art. We believe it would be difficult to paint (we mean not in the sense of the artist) the interior of the banqueting room at Whitehall, were it restored to its original destination, and divested of the ruinous accessories which from its original purpose have turned it from a banqueting room into a chapel,—we believe, we say, that it would be difficult to paint it so as to destroy its internal beauty. But as we intend to be short under this head, we shall quote a brochure touching on this subject published by us in 1837.

2512. One of the beauties tending to give effect to the edifices of Greece has been on the testimony of almost all travellers, the colour of the materials whereof they are composed. Dr. Clarke observes that a warm ochreous tint is diffused over all the buildings of the Acropolis, which *he* says is peculiar to the ruins of Athens. "Perhaps," says the author, "to this warm colour, so remarkably characterising the remains of ancient buildings at Athens, Plutarch alluded" (*In Vita Pericles*) "in that beautiful passage cited by Chandler, where he affirmed *that the structures of Pericles possessed a peculiar and unparalleled excellence of character; a certain freshness bloomed upon them and preserved their faces uninjured, as if they possessed a never-fading spirit, and had a soul insensible to age.*" It is singular that recent discoveries have incontestably proved that this species of beauty at all events did not originally exist in them, inasmuch as it is now clearly ascertained that it was the practice of the Greeks to paint the whole of the inside and outside of their temples in party colours. It had been some time known that they were in the habit of painting and picking out the ornaments on particular parts of their buildings; but M. Schaubert, the architect of the King of Greece, found on examination that this fell far short of the extent to which this species of painting was carried, and M. Semper, another German architect, has fully corroborated the fact in his examination of the Temple of Theseus. The practice was doubtless imported into Greece from Egypt, and was not to be easily abandoned, seeing the difficulty of falling away from the habits of a people whence it seems certain the arts of Greece more immediately came. It is by no means uncommon for a person to be fully alive to all the beauties of form, without at the same time having a due feeling or perception of the beauty resulting from harmony in colouring. It is therefore not to be assumed that the Greeks, though given to a practice which we would now discourage, possessed not that taste in other respects which has worthily received the admiration of posterity. The practice of painting the inside and outside of buildings has received the name of *polychromatic* architecture, and we shall here leave it to the consideration of the student as a curious and interesting circumstance, but certainly without a belief that it could add a charm to the stupendous simplicity and beauty of such a building as the Parthenon.

2513. After all that we have said of fitness, it will be expected that in *decoration* it shall form a principal ingredient. By the term decoration we understand the combination of objects and ornaments that the necessity of variety introduces under various forms, to embellish, to enrich, and to explain the subjects whereon they are employed. The art of decoration, so as to add to the beauty of an object, is, in other words, that of carrying out the emotions already produced by the general form and parts of the object itself. By its means the several relations of the whole and the parts to each other are increased by new combinations; new images are presented to the mind whose effect is variety, one great source of pleasure. From these observations two general rules may be deduced in respect of decoration. *First*, that it must actually be or seem to be necessary. *Second*, that such objects must be employed in it as have relation to the end of the general object of the design. We are not to suppose that all parts of a work are susceptible of ornament. Taste must be our guide in ascertaining where decoration is wanted, as well as the quantity requisite. The absence of it altogether is in many cases a mode of decoration. As in language its richness and the luxuriance of images do not suit all subjects, and simplicity in such cases is the best dress, so in the arts of design many subjects would be rather impoverished than enriched by decoration. We must therefore take into consideration the character of the building to be decorated, and then only apply such ornament as is necessary and suitable to that character. We may judge of its necessity if the absence of it causes a dissatisfaction from the void space left; of its suitableness, by its developing the character. History has recorded the contempt with which that decorator was treated who ornamented the senate house with statues of wrestlers, and the gymnasium with statues of senators.

2514. By some the art of architecture itself has been considered nothing more than that of decorating the buildings which protection from the elements induces us to raise.

2515. The objects which architecture admits for decoration result from the desire of producing *variety*, *analogy*, and *allegory*. We here follow Quatremère de Quincy. (*Encyc. Method.*) The first seems more general than the others, as being common among all nations that practise building. It is from this source we have such a multitude of cut-work, embroidery, details, compartments, and colours, more or less minute, which are found in every species of architecture. It would be useless for the most philosophical mind to seek for the origin of these objects in any want arising out of the mere construction, or in any political or superstitious custom. Systems of conjecture might be exhausted without arriving one point nearer the truth. Even in the most systematic of the different kinds of architecture, namely, that of the Greeks, we cannot avoid perceiving a great number of forms and details whose origin is derived from the love of variety, and that alone. In a certain point of view, thus considered, an edifice is nothing more than a piece of furniture, a vase, an utensil, the ornaments on which are placed more for the purpose of pleasing the eye than any other. Such, for instance, are the roses of caissons in ceilings and sofites, the leaves round the bell of the Corinthian capital, the Ionic volutes, and many others, besides universally the carving of mouldings themselves. These ornaments, drawn from the storehouse of nature, are on that account in themselves beautiful; but it is their transference to architecture, which in the nature of things can have but a problematical and conjectural origin, that seems to indicate a desire to vary the surface. Unless it was the desire of variety that induced them, we know not what could have done so.

2516 It has been well observed by the author we have just quoted, that though the art has been obliged to acknowledge that many of its decorations depend in their application on such forms as necessity imposes, and in the formation of them on chance, caprice, or whatever the love of variety may dictate, yet in the disposition of them there must reign an order and arrangement subordinate to that caprice, and that at this point commences the difference between architecture as an art subservient to laws which are merely dependent on the pleasure imparted to the eye, and those which depend on the mere mechanical disposition of the building considered as a piece of furniture. Architecture, of all the arts, is that which produces the fewest emotions of the minds of the many, because it is the least comprehensible in regard to the causes of its beauty. Its images act indirectly on our senses, and the impressions it seems to make appear reducible chiefly to magnitude, harmony, and variety, which after all are not qualities out of the reach of an architect of the most ordinary mind, and therefore not — at least the first and last — unattainable where economy does not interfere to prevent the result to be attained.

2517. Analogy, the second of the objects by which decoration is admitted into architecture, seems to be resultant from the limited nature of all human inventions in the arts, and the power of being unable to invent except by imitation and alteration of the forms of objects pre-existent. It is most difficult to discard altogether what have been considered types in architecture, and that difficulty has so prevailed as to limit those types to their most probable origin in the case of the orders.

2518. The reader will begin to perceive that our analogy in decoration tends upon trees for columns, the ends of beams for triglyphs, and the like. Whatever truth there may be in this analogy, it is now so established as to guide the rules of decoration that are involved in it; and it must be conceded, that if we are desirous of imitating the peculiar art of any country, we have no hope of success but by following the forms which the construction in such country engenders; and we must admit that, as far as external circumstances can direct us, the architecture of Greece, which, modified, has become that of the whole of Europe, and will become that of America, seems so founded on the nature of things, that, however we may doubt, it would not be prudent to lead the reader away from the consideration, and perhaps from a belief, that such is the truth. Without holding ourselves bound by the analogy of the types of the tree and the cross beam, which appear to have guided the architects of Greece, we can without hesitation assert, that whenever those have been abandoned the art has fallen on the most flagrant vices; witness the horrors of the school of Borromini, where the beams are broken, pediments, which are the gables of roofs, are broken into fantastic forms, and none of the parts seem naturally connected with each other. The works of the school in question seem indeed so broken up, that the study of them would almost convince an impartial and competent judge that the converse of its practice is sufficiently beautiful to establish the truth of the types whereon we have here and before expressed our scepticism. "Sitôt," says De Quincy, "que le génie decorateur s'est cru libre des entraves de l'analogie, toutes les formes caractéristiques se sont contournées, perverteés, et dénaturées, au point qu'il y a entr'elles et celle de la bonne architecture, plus de distance qu'entre celles-ci et les types de la primitive construction."

2519. In the decoration of architecture, neither of the other two means employed are more important than that ocular language which architecture occasionally employs in its ornaments. By its use architecture is almost converted into painting, and an edifice becomes a picture, or a collection of pictures, through the aid of the sculptor. We shall refer to no other building than the Parthenon to prove the assertion. Here the history of the goddess is embodied in the forms of the building, and to the decoration thus introduced the subordinate parts of the sculpture, if it be not heresy so to call them, is kept so under that we are almost inclined to cry out against their not having been principals instead of accessories. This is the true principle upon which buildings should be decorated to impress the mind of the spectator with the notion of beauty, and the principle which, carried out, no matter what the style be, will insure the architect his most ample reward, reputation. The matter that is supplied by allegory for decoration in architecture may be considered under three heads — *attributes*, *figures*, and *paintings*.

2520. The first takes in all those foliages, plants, flowers, and fruits, which from their constant use in sacrifices were at last transferred from the altar to the walls of the temple. The garlands, festoons, chaplets, and crowns which we find sculptured on temples seem to have had their origin from the religious ceremonies performed in them; as do the instruments of sacrifice, vases, the heads of the victims, pateræ, and all the other objects employed in the worship of the ancients. Thus, in architecture, these have become conventional signs, indicating the destination of the buildings to which they are applied. From the particular application of some ornaments on temples we derive in the end a language in the arts of imitation. It was thus that the eagle grasping in his talons the attribute of Jupiter, came to represent eternity and omnipotence; the myrtle and dove of Venus, the passion of love; the lyre and laurel of Apollo, to point to harmony and glory; the spear and helmet of Mars, to represent war. Palms and crowns became the emblems of victory, as did the olive the emblem of peace. In the same way the ears of corn of Ceres, the serpent of Esculapius, the bird of Minerva, and the cock of Mercury were equivalent to the expression of abundance, science, and vigilance. Instruments of the arts, sciences, in short, all objects useful to the end for which an edifice is erected, naturally become signs of that edifice; but applied otherwise become absurd. What, for instance, could be more ridiculous than placing ox sculls and festoons on the frieze of a Protestant church? — and yet this has been done in our own days.

2521. Figures of men and animals come under the second head. The application of these may be seen to their highest perfection in the Parthenon, to which we have already alluded. They may be introduced in low, high, or full relief. In the last case their situation is usually that of a niche. We shall say no more on the subject of figures than that of course they must have relation to the end for which the edifice is erected, and if not in that respect perfectly intelligible are worse than useless.

2522. The walls of Pompeii furnish ancient examples of the decoration obtained by the aid of painting, as do the loggie of the Vatican and the ceilings of the Farnesina modern examples of it. Herein the moderns have far surpassed anything we know of the ancient application of painting. Sculpture, however, seems more naturally allied to architecture than painting, and, except in purely decorative painting on walls and ceilings, the introduction of it seems bounded within narrow limits. The rules as to fitness of the subjects introduced, applicable to the first two heads, are equally so under that of painting.

Sect. II.

THE ORDERS.

2523. An order in architecture is a certain assemblage of parts subject to uniform established proportions, regulated by the office that each part has to perform. It may be compared to what organisation is in animal nature. As from the paw of a lion his dimensions may be deduced, so from a triglyph may be found the other parts of an example of the Doric order, and from given parts in other orders the whole configuration may be found. As the genus may be defined as consisting of *essential* and *subservient* parts, the first-named are the column and its entablature, which, as its name imports, is as it were the tabled work standing on the column. The subservient parts are the mouldings and detail into which the essential parts are subdivided, and which we shall hereafter separately consider. The species of orders are five in number, Tuscan, Doric, Ionic, Corinthian, and Composite, each of whose mass and ornaments are suited to its character and the expression it is intended to possess. These are the five orders of architecture, in the proper understanding and application whereof is laid the foundation of architecture as an art. The characters of strength, grace, and elegance, of lightness and of richness, are distinguishing features of the several orders, in which those characters ought to be found not only in the column employed, but should pervade the whole composition, whereof the column is, as it were, the regulator. The mode of setting up, or, as it is technically termed, profiling an order, will be given in a subsequent part of this section. Here we shall merely observe that the entablature is subdivided into an architrave, which lies immediately upon the column, a frieze lying on the architrave, and a cornice, which is its uppermost subdivision. The height of these subdivisions together, that is, the whole height of the entablature, is one fourth that of the column according to the practice of the ancients, who in all sorts of entablatures seldom varied from that measure either in excess or defect. "Palladio, Scamozzi, Alberti, Barbaro, Cataneo, Delorme, and others," says Sir William Chambers, "of the modern architects, have made their entablatures much lower in the Ionic, Composite, and Corinthian orders than in the Tuscan or Doric. This, on some occasions, may not only be excusable but highly proper; particularly where the intercolumniations are wide, as in a second or third order, in private houses, or inside decorations, where lightness should be preferred to dignity, and where expense, with every impediment to the conveniency of the fabric, are carefully to be avoided; but to set entirely aside a proportion which seems to have had the general approbation of the ancient artists is surely presuming too far."

2524. As rules in the fine arts which have obtained almost universal adoption are founded on nature or on reason, we may be pretty certain that they are not altogether empirical, albeit their origin may not be immediately apparent. The grounds on which such rules are founded will, however, in most cases become known by tracing them to first principles, which we shall here endeavour to do in respect of this very important relation of height between the column and its entablature. We were first led into this investigation by the perusal of a work by M. Lebrun, entitled *Théorie de l'Architecture Grecque et Romaine deduite de l'analyse des Monumens antiques*, fol. Paris, 1807; but our results differ very widely from those of Lebrun, as will be seen on reference to that work.

2525. One of the most obvious principles of proportion in respect of loads and supports, and one seemingly founded on nature herself, is, that a support should not be loaded with a greater mass or load than itself; or, in other words, that there should be an equality between weights and supports, or, in the case in point, between the columns and entablature. In respect of the proportion of the voids below the entablature between the columns or supports, a great diversity of practice seems to have prevailed, inasmuch as we find them varying from 1·03 to 2·18, unity being the measure of the supports. Lebrun makes the areas of the supports, weights, and voids equal to one another, and in what may be termed the monumental examples of the Doric order, such as the Parthenon, &c., he seems borne out in the law he endeavours to establish; but in lighter examples, such as the temple (Ionic) of Bacchus at Teos, where the supports are to the voids as 1 : 2·05, and in the temple of Minerva Polias, where the ratio is as 1 : 2·18, he is beyond all question incorrect: indeed there hardly seems a necessity for the limitation of the voids he prescribes, seeing that, without relation separately to the weight and support, stability would be obtained so long as the centre of gravity of the load fell within the external face of the support. If it be admitted that, as in the two examples above mentioned, the voids should be equal to the supports jointly, we have a key to the rule, and instead of being surprised at the apparently strange law of making the entablature one fourth of the height of the column, we shall find that no other than the result assumed can flow from the investigation.

2526. In fig. 861. let AB be the height of the column, and let the distance between the columns be one third of the height of the column = CD. Now if AB be subdivided into four equal parts at *a*, *b*, and *c*, and the horizontal lines *ad*, *be*, and *cf* be drawn; also, if CD be divided horizontally into four equal parts, and lines be drawn perpendicularly upwards intersecting the former ones, the void will be divided into sixteen equal parallelograms, one half whereof are to be the measure of the two whole supports BC and DE; and DE being then made equal to one half of CD, it will be manifest, from inspection, that the two semi-supports will jointly be equal to eight of the parallelograms above mentioned, or one half of the void. We have now to place the entablature or weight AGHI upon the supports or columns, and equal to them in mass. Set up from A to F another row of parallelograms, each equal to those above mentioned, shown on the figure by AFKI. These will not be equal to the supports by two whole parallelograms, being in number only six instead of eight; dividing, therefore, 8, the number in the supports, by 6, the number already obtained, we have 1·333, &c., which is the height to be assigned to AG, so that the weight may exactly equal the supports, thus exceeding one quarter of the height of the support (or column) by $\frac{333}{1000}$ of such quarter, a coincidence sufficient to corroborate the reason on which the law is founded.

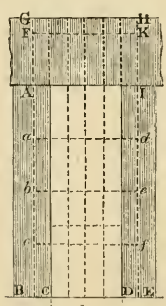

Fig. 861.

2527. From an inspection of the *figs.* 861, 862, 863, it appears that when the void is one third the height of the supports in width, the supports will be 6 diameters in height; when one fourth of their height, they will be 8 diameters high; also that the intercolumniation, called systylos or of two diameters, is constant by the arrangement. When the surface of the columns, as they appear to the eye, is equal to that of the entablature, and the voids are equal to the sum of those surfaces, the height of the entablature will always be one third of that of the columns. Thus, let the diameter of the columns be $=1$, their height $=h$, their number $=n$. Then the surface of the columns is nh; that of the entablature the same. As the surface of the voids is double that of the columns, the width of the intercolumniations is double the width of the columns, that is, $2n$ diameters, which, added to the n diameters of the columns, gives $3n$ diameters for length of the entablature; therefore, the surface of this entablature is nh, and its length being $3n$, its height must be $\frac{nh}{3n}=\frac{h}{3}$ exactly.

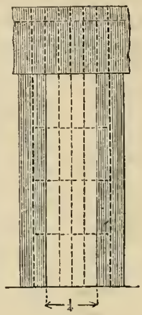

Fig. 862.

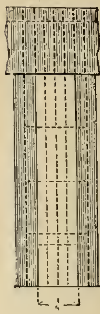

Fig. 863.

2528. Trying the principle in another manner, let *fig.* 864. be the general form of a tetrastyle temple wherein the columns are assumed at pleasure 8 diameters in height.

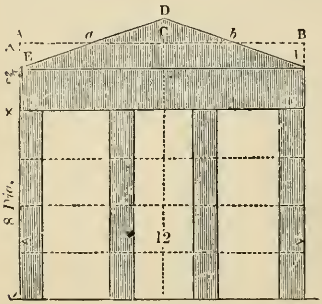

Fig. 861.

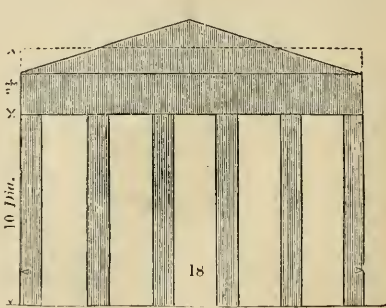

Fig. 865.

Then $4\times 8=32$ the areas of the supports; and as to fulfil the conditions the three voids are equal to twice that area, or 64, they must consequently be in the aggregate equal to 8 diameters, for $\frac{64}{8}=8$, and the whole extent will therefore be equal to 12 diameters of a support or column. To obtain the height of the entablature so that its mass may equal that of the supports, as the measures are in diameters, we have only to divide 32, the columns, by 12, the whole extent of the facade, and we obtain two diameters and two thirds of a diameter for the height of the entablature, making it a little more than one quarter of the height of the column, and again nearly agreeing in terms of the diameter with many of the finest examples of antiquity. If a pediment be added, it is evident, the dotted lines AC, CB being bisected in a and b respectively, that the triangles AEa, bFB are respectively equal to CDa and DbC, and the loading or weight will not be changed.

2529. Similar results will be observed in fig. 865., where the height is ten diameters, the number of columns 6, the whole therefore 180, the supports being 60. Here $\frac{60}{18}=3\frac{1}{3}$ diameters will be the height of the entablature. This view of the law is further borne out by an analysis of the rules laid down by Vitruvius, book iii. chap. 2,; — rules which did not emanate from that author, but were the result of the practice of the time wherein he lived, and, within small fractions, strongly corroborative of the soundness of the hypothesis of the voids being equal to twice the supports. Speaking of the five species of temples, after specifying the different intercolumniations, and recommending the eustylos as the most beautiful, he thus directs the formation of temples with that interval between the columns. "The rule for designing them is as follows: — The extent of the front being given, it is, if tetrastylos, to be divided into $11\frac{1}{2}$ parts, not including the projections of the base and plinth at each end; if hexastylos, into 18 parts; if octastylos, into $24\frac{1}{2}$ parts. One of either of these parts, according to the case, whether tetrastylos, hexastylos, or octastylos, will be a measure equal to the diameter of one of the columns." . . . . "The heights of the columns will be $8\frac{1}{2}$ parts. Thus the intercolumniations and the heights of the columns will have proper proportion." In the same chapter he gives directions for setting out aræostyle, diastyle, and systyle temples. The tetrastylos, he states, is $11\frac{1}{2}$ parts wide and $8\frac{1}{2}$ high; the area therefore of the whole front becomes $11\frac{1}{2}\times 8\frac{1}{2}=97\frac{3}{4}$.

The four columns are $4 \times 8\frac{1}{2} = 34$, or very little more than one third of the whole area; the remaining two thirds, speaking in round numbers, being given to the intercolumns or voids. The hexastylos (see *fig.* 865.) is 18 parts wide and $8\frac{1}{2}$ high; the whole area therefore is $18 \times 8\frac{1}{2} = 153$. The six columns are $6 \times 8\frac{1}{2} = 51$, or exactly one third of the whole area; the voids or intercolumns occupying the remaining two thirds. The octastylos is $24\frac{1}{2}$ parts wide and $8\frac{1}{2}$ high. Then $24\frac{1}{2} \times 8\frac{1}{2} = 208\frac{1}{4}$. The eight columns are $8 \times 8\frac{1}{2} = 68$, being a trifle less than one third of the area, and the voids or intercolumns about double, or the remaining two thirds. The average of the intercolumns in the first case will be $\frac{11\frac{1}{2}-4}{3} = 2\frac{1}{2}$ diameters. In the second case $\frac{18-6}{5} = 2\frac{2}{5}$ diameters. In the third case $\frac{24\frac{1}{2}-8}{7} = 2\frac{357}{1000}$ diameters.

2530. A discrepancy between practice and theory, unless extremely wide, must not be allowed to interfere with principles, and therefore no hesitation is felt in submitting a synoptical view of some of the most celebrated examples of antiquity in which a comparison is exhibited between the voids and supports; certain it is that in every case the former exceed the latter, and that in the earlier examples of the Doric order, the ratio between them nearly approached equality. In comparing, however, the supports with the weights, there is every appearance of that part of the theory being strictly true; for in taking a mean of the six examples of the Doric order, the supports are to the weights as 1 : 1·16; in the five of the Ionic order as 1 : 1·05; and in the four of the Corinthian order as 1 : 1·04, a coincidence so remarkable that it must be attributed to something more than accident, and deserves much more extended consideration than it has hitherto received.

If instead of taking the apparent bulk of a column, that is, as a square pier, we take its real bulk, which is about three quarters ($\frac{3}{4}$) that of a square pier of the same diameter and height; the height of the entablature will be one fourth of the height of the column; for $\frac{3}{4}$ of $\frac{h}{3} = \frac{h}{4}$.

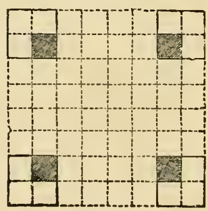

Fig. 866.

There is a curious fact connected with the hypothesis which has been suggested that requires notice; it is relative to the area of the points of support for the edifice which the arrangement affords. In *fig.* 866 the hatched squares represent the plans of quarter piers of columns in a series of intercolumniations every way, such intercolumniations being of two diameters, or four semidiameters. These, added to the quarter piers, make six semidiameters, whose square 36 is therefore the area to be covered with the weight. The four quarter piers or columns = 4, hence the points of support are $\frac{4}{36}$ of the area = 0·111. Now in the list (1583.) of the principal buildings in Europe the mean ratio is 0·168, differing only 0·057 from the result here given; but if we select the following buildings the mean will be found to differ much less.

Temple of Peace	-	0 127
S. Paolo fuori le Murà -		0 118
S. Sabino	- -	0 100
S. Filippo Neri -	-	0·129 Sum = 0·474. Mean $\frac{0·474}{4}$ = 0·118.

MOULDINGS.

2531. The subservient parts of an order, called mouldings, and common to all the Roman orders, are eight in number. They are—1. The *ovolo, echinus,* or *quarter round.* (*Fig.* 867.) It is commonly found under the abacus of capitals; and is also almost always placed between the corona and dentils in the Corinthian cornice: its form gives it the appearance of seeming fitted to support another member. It should be used only in situations above the level of the eye. 2. The *talon, ogee, or reversed cyma* (*fig.* 868.) is also, like the ovolo, a moulding fit for the support of another. 3. The *cyma, cyma recta,* or *cymatium* (*fig.* 869.) seems well contrived for a covering and to shelter other members; it is only used properly for crowning members, though in Palladio's Doric, and in other examples, it is found occasionally in the bed mouldings under the corona. 4. The *torus* (*fig.* 870.), like the astragal presently to be mentioned, is shaped like a rope, and seems intended to bind and strengthen the parts to which it is applied; while, 5. The *scotia* or *trochilos* (*fig.* 871.), placed between the fillets which always accompany the tori, is usually below the eye; its use being to separate the tori, and to contrast and strengthen the effect of other mouldings as well as to impart variety to the profile of the base. 6. The *caretto, mouth,* or *hollow*

Fig. 870.

Fig. 871.

Fig. 872.

Fig. 873.

Fig. 874.

(*fig.* 872.) is chiefly used as a crowning moulding, like the cyma recta. In bases and capitals it is never used. By workmen it is frequently called a *casement*. 7. The *astragal* (*fig.* 873.) is nothing more than a small torus, and, like it, seems applied for the purpose of binding and strengthening. The astragal is also known by the names of *bead* and *baguette.* 8. The *fillet*, *listel*, or *annulet* (*fig.* 874.) is used at all heights and in all situations. Its chief office is the separation of curved mouldings from one another.

2532. In Grecian examples, the sections of mouldings are obtained by portions of an ellipse, parabola or hyperbola, all parts of a conic section, so that they give a greater delicacy of outline than do the Roman examples. " These latter," writes J. B. Papworth, in his edition (1826) of the work by Sir W. Chambers on *Civil Architecture*, "produced *similar* quantities of middle tint, light, and shadow; the Greeks carefully avoided this sameness, and judiciously and tastefully made the shadows to prevail distinctly. Hence in all their works we find the result of a superior understanding of the principles and effects of light and shade, which are opposed to each other, and relieved with great skill; whereas, in the Roman style, being divided and broken, they are certainly less beautiful and less capable of affording the charms of reflected light than the vestiges of Grecian art,

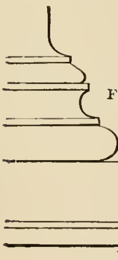

Fig. 874*c*.

which by their well-studied proportions merit respect and imitation." Sir William observes on these different mouldings that their inventors meant to express something by their different figures, and that the destinations above mentioned may be deduced not only from their figures, but from the practice of the ancients in their most esteemed works; the cyma and cavetto are constantly used as finishings, and never applied where strength is required; the ovolo and talon are always employed as supporters to the essential members of the composition, such as the modillions, dentils, and corona; the chief use of the torus and astragal is to fortify the tops and bottoms of columns, and sometimes of pedestals; and the scotia is employed only to separate the members of bases, for which purpose the fillet is likewise used not only in bases but in all kinds of profiles.

2533. The names of the Greek mouldings are the same as those already mentioned; and there is another (*fig.* 874*b*) called from its appearance a *bird's-beak moulding*, comprising the outline of the echinus hollowed out below and then brought down with a curve into the fascia. It is chiefly used in the capital of an *anta* or pilaster, as in *fig.* 883. *Fig.* 867*b*. is a quirked *ogee*, having a separation from the fascia above to obtain a depth of shadow. *Fig.* 868*b*. is a quirked *ovolo*. *Fig.* 867*a*. is used in the cap of the Doric order. *Fig.* 869*a*., *the cyma recta*, used as the crowning member of a cornice, was often elegantly decorated. *Fig.* 868*c*. is an ogee projecting further than the ordinary form. *Fig.* 874*c*. is an outline of the base of the Choragic Monument of Lysicrates at Athens, showing a combination of mouldings; three of the mouldings being inverted. Examples of Greek capitals are given on pages 906 and 907, in addition to those in *Figs.* 883 and 887.

2534. The simplest method of describing the contours of mouldings in Roman or Italian architecture is to form them of quadrants of circles, as shown in Figs. 867 to 874. Where circumstances justify a variation, the ovolo, talon, cyma, scotia, and cavetto, may be either described from the summits of equilateral triangles, or be composed of portions of the ellipsis, but the section of the torus and astragal is always semicircular.

ORNAMENTS OF MOULDINGS.

2535. In ornamenting the profile of an order, repose requires that some mouldings should be left plain. If all were enriched, confusion instead of variety would result. Except for particular purposes, the square members are rarely carved. There are but few examples in the best age of the art in which the corona is cut; indeed at this moment the only one that occurs to us wherein work is in fine style is that of the three columns in the Campo Vaccino. So where the ovolo above and talon below it are carved, the dentil band between them should be uncut. Scamozzi, in the third chapter of his sixth book, inculcates that ornaments should be neither profuse nor abundant, neither are they to be too sparingly introduced. Thus they will be approved if applied with judgment and discretion. Above all things, they are to be of the most beautiful forms and of the exactest proportions; ornaments in buildings, being like the jewels used for the decoration of princes and princesses and persons of high rank, must be placed only in proper situations. Neither must variety in ornaments be carried to excess. We have to recollect that, being only accessories, they must not obtrude upon but be kept subordinate to the main object. Thus ornaments applied to mouldings should be simple, uniform, and combining not more than two distinct forms in the same enrichment; and when two forms are used on the same moulding they should be cut equally deep, so that an uninterrupted appearance may be preserved. Mouldings of the same form and size on one and the same profile should be similar; and it is moreover a requisite of the greatest importance, so to distribute the centres of the ornaments employed that the centre of one may fall exactly over the centres of those below, of which the columns of the Campo Vaccino form an example for imitation in this respect. Nothing is more offensive than, for example, to see the middle of an egg placed over the edge of a dentil, and in another part of the same moulding to see them come right, centre over centre, and the like negligent and careless distribution. This may always be avoided by making the larger parts regulate the smaller. Thus where there are modillions they must be made to govern the smaller ornaments above and below them, and these smaller ones should always be subdivided with a view to centring with the larger parts. The larger parts are dependent on the axes of the columns and their intercolumniations; but all these must be considered in profiling the order. It will of course be necessary to give the ornaments such forms as may be consistent with the character of the order they enrich. The enrichment of a frieze depends upon the destination of the building, and the ornaments may have relation to the rank, quality, and achievements of the proprietor. We do not agree with Chambers in condemning the introduction of arms, crests, and cyphers, as an unbecoming vanity in the master of the fabric. These may often be so introduced as to indicate the alliances of the family, and thus give a succinct history of its connections. In Gothic architecture we know the practice induced great beauty and variety. We have before observed, in Sect. I. of this Book (2520.), that the instruments and symbols of pagan worship are highly indecorous, not to say ludicrous, on edifices devoted to the Christian religion.

2536. In carving ornaments they must be cut into the solid, and not carved as if they were applied on the solid, because the latter practice alters their figure and proportion. In fact, every moulding should be first cut with its contour plain, and then carved, the most prominent part of the ornament being the actual surface of the moulding before carving, observing that all external and re-entering angles are kept plain, or have only simple leaves with the central filament expressed on or in the angle. In the circular temple of Tivoli the principle of cutting the ornament out of the solid is carried out so far, that the leaves, as usual in most examples of the Corinthian order, instead of being mere appliquées to the bell of the capital, are actually cut out of it.

2537. The degree of relief which ornaments ought to have is dependent on their distance from the eye and the character of the composition: these matters will also regulate the degree of finish they ought to possess. There are some mouldings whose profile is indicative of bearing weight, as the ovolo and talon, which by being deeply cut, though themselves heavy in character, are thereby susceptible of having great lightness imparted to them, whilst such as the cyma and cavetto should not be ornamented deep in the solid. The imitation from nature of the objects represented should be carefully observed, the result whereof will impart beauty and interest to the work on which such attention is bestowed.

CHARACTERS OF THE ORDERS.

2538. In the First Book of this work, Sect. XI. (133, *et seq.*) we have considered the history of the five orders of architecture; we shall here offer some general observations upon them before proceeding to the detail of each separately. The orders and their several characters and qualities do not merely appear in the five species of columns into which they have been subdivided, but are distributed throughout the edifices to which they are applied, the column itself being the regulator of the whole composition. It is on this account the name of orders has been applied to the differently formed and ornamented supports, as columns, which have received the names of the Doric, Ionic, Corinthian, Tuscan, and Composite orders, whereof the three first are of Grecian origin, and the two last, it is supposed, of Italian or Roman origin. Each of these, by the nature of its proportions, and the character resulting from them, produces a leading quality, to which its dimensions, form, and ornaments correspond. But neither of the orders is so limited as to be confined within the expression of any single quality. Thus the strength indicated in the Doric order is capable of being modified into many shades and degrees of that quality. We may satisfy ourselves of this in an instant by reference to the early compared with the later Doric column of the Greeks. Thus the columns of the temple at Corinth are only four diameters high, while those of the portico of Philip are six and a half.

2539. As the Doric seems the expression of strength, simplicity, and their various modes, so the Ionic, by the rise in height of its shaft and by the slenderness of its mass, as well as by the elegance of its capital, indicates a quality intermediate between the grave solidity of the Doric and the elegant delicacy of the Corinthian. Bounded on one side by strength, and by elegance on the other, in the two orders just named, the excess of elegance in the Corinthian order ends in luxury and richness, whereof the character is imprinted on it.

2540. We cannot here refrain from giving, in the words of the excellent Sir Henry Wotton, a quaint and homely, but most admirable description of these five orders, from his *Elements of Architecture.* " First, the *Tuscan* is a plain massive rural pillar, resembling some sturdy, well-limbed labourer, homely clad, in which kind of comparisons, Vitruvius himself seemeth to take pleasure." (Lib. iv. cap. 1.) . . . " The *Dorique order* is the gravest that hath been received into civil use, preserving, in comparison of those that follow, a more *masculine aspect* and little trimmer than the *Tuscan* that went before, save a sober garnishment now and then of *lions' heads* in the *cornice*, and of *triglyphs* and *metopes* always in the *frize.*" . . . " To discern him will be a piece rather of good *heraldry* then of *architecture*, for he is knowne by his place when he is in company, and by the peculiar ornament of his *frize*, before mentioned, when he is alone." . . . " The *Ionique order* doth represent a kind of feminine slendernesse; yet, saith Vitruvius, not like a light housewife, but, in a decent dressing, hath much of the *matrone.*" . . . " Best known by his trimmings, for the bodie of this *columne* is perpetually *chaneled*, like a thick-pleighted gowne. The *capitall* dressed on each side, not much unlike women's wires, in a spiral wreathing, which they call the *Ionian voluta.*" . . . " The *Corinthian* is a columne lasciviously decked like a courtezan, and therefore in much participating (as all inventions do) of the place where they were first born, *Corinth* having beene, without controversie, one of the wantonest towns in the world." . . . " In short, as plainness did characterise the *Tuscan*, so, much delicacie and varietie the *Corinthian* pillar, besides the height of his rank." . . . " The last is the *compounded order*, his *name* being a briefe of his *nature* : for this pillar is nothing in effect but a *medlie*, or an *amasse* of all the precedent *ornaments*, making a new kinde by stealth, and though the most richly tricked, yet the poorest in this, that he is a borrower of his beautie." Each of the orders, says De Quincy, is, then, in the building to which it is applied, the governing principle of the forms, taste, and character of that system of moral order met with in Grecian architecture which alone seems to have suited the physical order of proportions with each part, so that what is agreeable, ornate, and rich is equally found in the whole as in the parts.

2541. On the two Latin orders we do not think it necessary to say more than that they will be fully described in following pages. The invention of new orders must arise out of other expressions of those qualities which are already sufficiently well and beautifully expressed; hence we consider, with De Quincy, to attempt such a thing would be vain. Chambers thus expresses himself on this subject, without the philosophy of De Quincy, yet with the feelings of a learned and experienced architect: " The ingenuity of man has, hitherto, not been able to produce a sixth order, though large premiums have been offered. and numerous attempts been made. by men of first-rate talents to accomplish it. Such is the fettered human imagination, such the scanty store of its ideas, that Doric, Ionic, and Corinthian have ever floated uppermost, and all that has ever been produced amounts to nothing more than different arrangements and combinations of their parts, with some trifling deviations, scarcely deserving notice; the whole tending generally more to diminish than to increase the beauty of the ancient orders." Again: " The suppression of parts of the ancient orders, with a view to produce novelty, has of late years been practised among us with full as little success; and though it is not wished to restrain sallies of imagination, nor to discourage genius from attempting to invent, yet it is apprehended that attempts to alter the primary forms invented by the ancients, and established by the concurring approbation of many ages, must ever be attended with dangerous consequences, must always be difficult, and seldom, if ever, successful. It is like coining words, which, whatever may be their value, are at first but ill received, and must have the sanction of time to secure them a current reception."

2542. In the progress of the five orders, from the Tuscan up to the Composite, taking seven diameters for the height of the Tuscan column, and eleven for that of the Composite, if the entablature be taken of the same absolute height in all, and at the same time in height one quarter of that of the column, we shall have the height of the entablature in terms of the diameter of the column, as follows: —

In the Tuscan order	. $\frac{1}{4}$ of $\frac{7}{1}$	$= 1\frac{3}{4}$ entablature diameters high.
In the Doric order	. $\frac{1}{4}$ of $\frac{8}{1}$	$= 2$ entablature diameters high.
In the Ionic order	. $\frac{1}{4}$ of $\frac{9}{1}$	$= 2\frac{1}{4}$ entablature diameters high.
In the Corinthian order	$\frac{1}{4}$ of $\frac{10}{1}$	$= 2\frac{1}{2}$ entablature diameters high.
In the Composite order	$\frac{1}{4}$ of $\frac{11}{1}$	$= 2\frac{3}{4}$ entablature diameters high.

HEIGHT AND DIMINUTION OF COLUMNS.

2543. Vitruvius tells us that the ancients were accustomed to assign to the Tuscan column seven of its diameters for the height; to the Doric, eight; to the Ionic, nine; and to the Corinthian and Composite, ten. Scamozzi, the leader of the moderns, adopts similar proportions. But these are not to be considered as more than an approximation to the limits, nor as relating to the proportions between the heights and diameters of the ancient Doric examples, whereof in our First Book we have examined certain specimens. This work cannot be extended to a representation of the variety under which the orders have appeared in their various examples of each order. The works in which they are contained must be consulted for particulars of detail in this respect. Our intention is to give general information on the subject, and to follow, with few exceptions, in that respect, the precepts of Vignola, as tending to the most generally pleasing results, and as being also those which have been adopted on the Continent for general instruction in the art.

2544. We have already spoken (2524, *et seq.*) of the general proportion of the height of the entablature to that of the column as one fourth, and, without returning to the discussion of the propriety of that proportion, will only here incidentally mention that Scamozzi, Barbaro, Alberti, and Palladio have not assigned so great a height to their entablatures, chiefly it appears, because they seemed to consider the slenderness of the columns in the more delicate orders unsuited to the reception of heavy burdens. If, however, the reader will bear in recollection what has been said at the beginning of this section relative to the supports and weights, it will directly occur to him that the practice these great masters sanctioned is not founded upon just deductions. Chambers seems to have had a glimpse of this theory, but without any notion of its developement, when he says, "It must be remembered that, though the height of an entablature in a delicate order is made the same as in a massive one, yet it will not, either in reality or in appearance, be equally heavy, for the quantity of matter in the Corinthian cornice A (*fig.* 875.) is considerably less than in the Tuscan cornice B, and the increased number of parts composing the former of these will of course make it appear far lighter than the latter." He was, however, nearer the exact truth where he speaks in a previous passage of the possibility of increasing the intervals between the columns.

2545. The diminution or tapering form given to a column, whereof all the authors find the type, whether truly or not, in that of the trunk of a tree, in the ancient examples, sometimes commences from the foot of the shaft, sometimes from a quarter or one third of its height, in which case the lower part is a perfect cylinder. Though the latter method has been mostly adopted by modern artists, the former seems more to have prevailed among the ancients. Of the method of entasis, that is, of swelling columns as they rise, we have already spoken in the First Book (144.). A curve of diminution, if we may so term it, in which the lower part does not much vary from the cylinder, but never much exceeding its boundary for the height of one third upwards, is the best, and to something like that we now come. Blondel (*Resolution des quatre principaux Problemes d'Architecture*) says, that the best and simplest instrument for the diminution of columns is that invented by Nicomedes for describing the first conchoid, which, applied at the bottom of the shaft, gives, by continued motion, both the swelling and the diminution. Vignola had not strictly anticipated Blondel in this method, which, it is said, was that used for the columns in the Pantheon; but the old master had come so near to it that we shall first describe Vignola's method, and then that proposed by Blondel. Vignola having already spoken of the common practice, says,

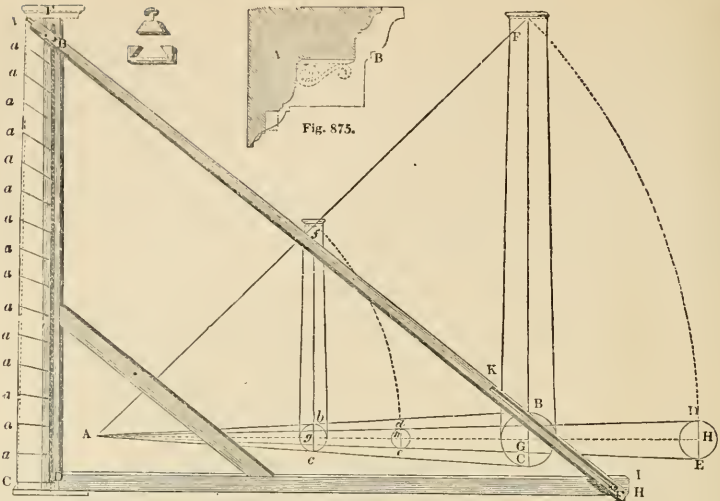

Fig. 875.

Fig. 876.

(Stampani's edit. *Dei cinque Ordini d'Architettura*, Roma, 1770, cap. 7. p. 51.), "In respect of this second mode, it is my own discovery, and will be soon understood by the figure, though not so well known as the first named. The measures of the column having been fixed, namely, the height of the shaft and its upper and lower diameters, from C (*fig.* 876.), draw an indefinite line through D perpendicular to the axis of the column. From A, the extreme point of the upper semi-diameter, to B, a point in the axis, set off CD the lower semidiameter. Through B from A draw the line ABE, cutting the indefinite line CD in E, and from the point of intersection E and through the axis of the column draw any number of rays, as EB*a*, whereon, from the axis towards the circumference, setting off the interval CD, any number of points *aaa* may be found, and through them a curve being drawn gives the swell and diminution of the shaft.

2546. This method is so far defective as to require the curve to be drawn by hand on the application of a flexible ruler through the points found. To remedy the defect, Blondel, who on investigation of the curve found it to be a conchoid, applied the instrument of Nicomedes for the purpose, the description of which instrument here follows. The height of the shaft and the upper and lower diameters of the column having been determined, as also the length (*fig.* 876.) of the line CDE, take three rulers, FG, ID, and AH, of which let FG and ID be fastened together at right angles in G. From top to bottom let a dovetail groove be cut down the middle of FG, and at E on the ruler ID, whose length from the centre of the groove in FG is the same as that of the point of intersection from the axis of the column, fix a pin. On the ruler AH set off the distance AB equal to the lower semidiameter of the column CD, and at the other end of the ruler cut a slit through it from H to K, the length whereof must at least be equal to the difference in length between EB and ED, and its breadth sufficient to admit the pin fixed at E to pass through the slit, and allow the ruler to slide thereon. Now, the middle of the groove in the ruler FG being placed exactly over the axis of the column, the ruler AH in moving along the groove will with its extremity A describe the curve A*aa*C, which curve is the same as that produced by Vignola's method, except that the operation is performed by the continued motion of the ruler AH. If the rulers be of an indefinite size, and the pins at E and B be made to move along their respective rulers, so as to be able to increase or diminish at pleasure the lengths AB and DE, the instrument will answer for drawing columns of any size.

2547. The diminution of the column as respects quantity is rarely in ancient examples less than one eighth of the lower diameter of the column, nor often more than one sixth, as will be seen in the subjoined examples. One sixth is the diminution recommended by Vitruvius, and followed by Vignola, in all his orders, except the Tuscan. In the following table the first column contains the order; the second, the example; the third, the height of the column in English feet and decimal parts of a foot; the fourth column shows its diameter in similar terms; and the fifth the ratio of diminution. The dimensions are from Perrault, reduced here from French to English feet.

2548. The recommendation of Vitruvius (lib. iii. c. 2.) to give different degrees of diminution to columns of different heights has been combated by Perrault in his notes on the passage; and we are, with Chambers, of opinion that Perrault is right in his judgment, inasmuch as the proper point of view for a column fifty feet high (*fig.* 876. unshaded part) ought not to be at the same distance as for one of fifteen, the point being removed more distant as the column increases in height, and therefore the apparent relation between the upper and lower diameters would appear the same. For supposing A to be a point of view whose respective distance from each of the columns *fg* FG, is equal to the respective heights of each, the triangles *f*A*g* FAG will be similar; and A*f*, or A*h*, which is the same, will be to A*g*, as AF, or its equal AH, is to AG: therefore, if *de* be in reality to *bc* as DE is to BC, it will likewise be apparently so: for the angle *d*A*e* will then be to the angle *b*A*c*, as the angle DAE is to the angle BAC; and if the real relations differ, the apparent ones will likewise differ. "When, therefore," observes Chambers, "a certain degree of diminution, which by experience is found pleasing, has been fixed upon, there will be no necessity for changing it, whatever be the height of the column, provided the point of view is not limited; but in close places, where the spectator is not at liberty to choose a proper distance for his point of sight, the architect, if he inclines to be scrupulously accurate, may vary; though it is, in reality, a matter of no importance, as the nearness of the object will render the image thereof indistinct, and, consequently, any small alteration imperceptible." Our author afterwards adds: "It must not, however, be imagined that the same general proportions will in all cases succeed. They are chiefly collected from the temples and other public structures of antiquity, and may by us be employed in churches, palaces, and other buildings of magnificence, where majesty and grandeur of manner should be extended to their utmost limits, and where, the composition being generally large, the parts require an extraordinary degree of boldness to make them distinctly perceptible from the proper general points of view."

SUBDIVISION OF ENTABLATURES.

2549. We have spoken of the entablature as the fourth part of the height of the column. In general terms, its subdivisions of architrave, frieze, and cornice are obtained by dividing its height into ten equal parts, whereof three are given to the architrave, three to the frieze, and four to the cornice; except in the Roman Doric order, in which the whole height of the entablature is divided into eight parts, of which two are given to the architrave, three to the frieze, and three to the cornice. From these general proportions variations have been made by different masters, but not so great as to call for particular observation. They deviate but little from the examples of antiquity; and the ease with which they may be recollected render them singularly useful.

MODE OF MEASURING THE ORDERS.

2550. Several methods have been used for forming the scale of equal parts, by which the orders are measured; but they are all founded on the diameter of the column at the bottom of the shaft; for those that use the module or semi-diameter as the measuring unit (which all have done in the Doric order) must still recur to the diameter itself. The authors have also usually divided it into thirty parts, but all concur in measuring by an unit founded on the diameter. We shall follow the practice of Vignola in describing the orders, that master dividing the diameter into two equal parts, of which each is the unit of the scale for profiling the order. The *module* for the two first orders, the Tuscan and Doric, is divided into twelve parts or *minutes;* and for the Ionic, Corinthian, and Composite orders into eighteen parts, by which minute fractions are avoided.

2551. For drawing or *profiling*, as it is called, an order, the proper way is to set out the height of the leading parts and their projections, and then proceed to the subdivisions of each. As a general rule, we may mention that it is usual to make projections of cornices nearly or quite equal to their heights.

APPLICATION OF THE ORDERS.

2552. The application of the orders among the ancients was exceedingly extensive. Porticoes abounded about their cities; their temples were almost groves of columns, with which also were profusely decorated their theatres, baths, basilicæ, and other public buildings, as were no less the courts, vestibules, and halls of their private dwellings. The moderns have in a great measure imitated their example, and their use has very much exceeded the limits of propriety. The maxim of Horace, "Nec Deus intersit," has in no case been more violated by architects than in the unnecessary introduction of the orders on the façades of their buildings. The test of fitness being applied to their employment is the best that the young architect can adopt.

Sect. III

THE TUSCAN ORDER.

2553. The reader, in *fig.* 877., has before him the geometrical representation of the Tuscan order and its details. A shows the plan of the sofite of the cornice, and B is a plan of the capital. The example is from Vignola's profile, whereon we consider it proper to remark, in conformity with an opinion before expressed (2532, 2533.), that the ovolo which crowns the cornice is an improper moulding for the situation it occupies. The substitution for it of a fillet and cyma recta would have been much more suitable, and would have also been more pleasant in effect.

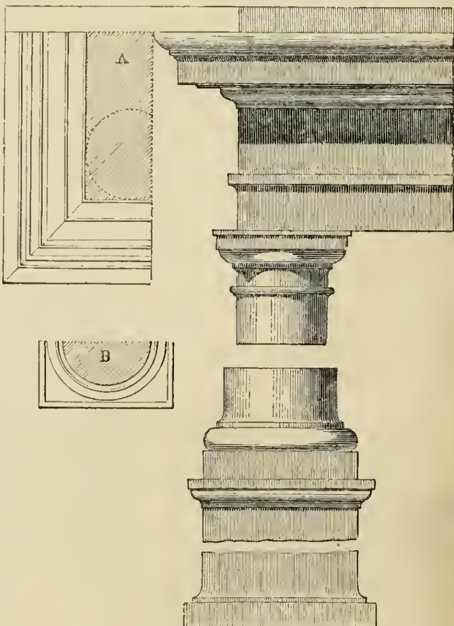

Fig. 877.

2554. "The Tuscan order," says Chambers, "admits of no ornaments of any kind; on the contrary, it is sometimes customary to represent on the shaft of its column rustic cinctures, as at the Palace Pitti in Florence, that of the Luxembourg in Paris, York Stairs in London, and many other buildings of note. This practice, though frequent, and to be found in the works of many celebrated architects, is not always excusable, and should be indulged with caution, as it hides the natural figure of the column, alters its proportions, and affects the simplicity of the whole composition. There are few examples of these bandages in the remains of antiquity, and in general it will be advisable to avoid them in all large designs, reserving the rustic work for the intercolumniations, where it may be employed with great propriety, to produce an opposition which will help to render the aspect of the whole composition distinct and striking." Our author proceeds to observe, that "in smaller works, of which the parts being few are easily comprehended, they may be sometimes tolerated, sometimes even recommended, as they serve to diversify the forms, are productive of strong contrasts, and contribute very considerably to the masculine bold aspect of the composition." Le Clere allows their propriety in the gates of citadels and prisons, and also considers them not out of place for gates to gardens or parks, for grottoes, fountains, and baths. Delorme made abundant use of them in several parts of the Thuilleries, covering them with arms, cyphers, and other enrichments. They are to be found in the detail of the Louvre, with vermiculated rustics. De Chambrai, who banishes the Tuscan order to the country, nevertheless admits that the Tuscan column may be consecrated to the commemoration of great men and their glorious actions, instancing Trajan's column, one of the proudest monuments of Roman splendour, as also the Antonine column.

2555. Having adjusted the size of the module with its subdivisions of twelve parts, so that the paper or other material on which the order is profiled may contain the whole of the order, it always being understood that the representation for practical purposes need not include the whole height of the shaft of the column, whose minutiæ of diminution may form the subject of a separate drawing, the first step is to draw a perpendicular line for the axis of the column. Parallel to the base lines are then to be drawn, according to the dimensions (parts of the module) given in the table subjoined; and the beginner, as well as the more practised man, is recommended not to set up these as they are given separately, but in every case to add the succeeding dimensions to those preceding rather than to set them off one by one, which, on a small scale, causes minute errors in reading off from the scale to become in the end large in amount. By the adoption also of such a practice the work corrects itself as it proceeds. As the heights are set up, the projection of each member from the axis of the column is to be set off, and this should be always done on both sides at the same time, by which *gulling* of the paper from the point of the compasses, and errors in other respects, are avoided. The *fig.* 878. is

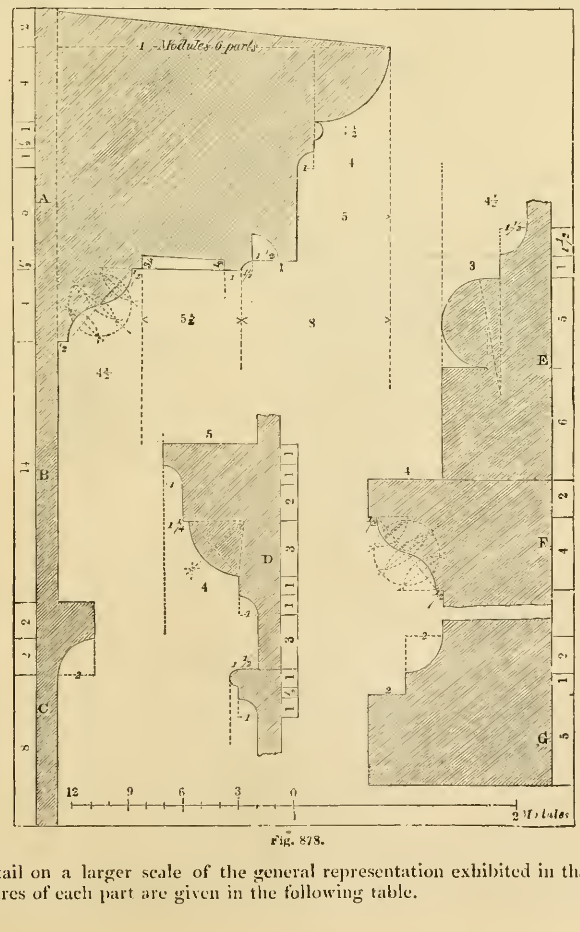

Fig. 878.

but the detail on a larger scale of the general representation exhibited in that preceding The measures of each part are given in the following table.

Table of the Parts of the Tuscan Order.

Mouldings whereof the Parts are composed.			Heights of Mouldings in Parts of a Module.	Projection from the Axis of Column in Parts of a Module.

		Plinth - - - -	5	20½

2556. Vitruvius in this order forms the columns six diameters high, and makes their diminution one quarter of the diameter. He gives to the base and capital each one module in height. No pedestal is given by him. Over the capital he places the architrave of timber in two thicknesses connected together by dovetailed dowels. He however leaves the height unsettled, merely saying that their height should be such as may be suitable to the grandeur of the work where they are used. He directs no frieze, but places over the architrave cantilevers or mutuli, projecting one fourth part of the height of the column, including the base and capital. He fixes no measure for the cornice, neither does he give any directions respecting the intercolumniations of this order. The instructions are not so specific as those which he lays down for the other orders, and there have been various interpretations of the text, which unfortunately cannot in any of the suppositions be tested on ancient remains. The whole height, according to the measuring unit which we have adopted from Vignola, is 16 modules and 3 parts.

2557. Palladio makes the height of his Tuscan column 6 diameters, and diminishes the shaft one fourth of a diameter. The height of the base and capital are each half a diameter. He provides no pedestal, but, instead thereof, places the base of the column on a zoccolo, or lofty plinth, whose height is equal to the diameter of the column. He leaves the intercolumniation unsettled, merely hinting that as the architraves are of timber, they, the intercolumniations may be wide. The whole height by him assigned to the order is 9 diameters and three quarters of the column. The whole height according to our scale is 19 modules and 6 parts.

2558. Serlio makes the column of the order 5 diameters exclusive of base and capital, each of which are half a diameter in height, and his diminution is one quarter of the diameter. He gives half a diameter to the height of the architrave, and an equal height to the frieze and to the cornice. His pedestal is with a plinth and base, a die, and cymatium, the whole being a third of the height of the column. He gives no rules for the intercolumniations, though in book 4. he inserts a diagram wherein intercolumns appear, merely saying that they are equal to 3 diameters. The total height according to our measure is 19 modules and 3 parts.

2559. Scamozzi makes the shaft of his column 6 diameters, and diminishes it one fourth part of its diameter. The heights of the base and capital are each half a diameter. To the entablature he assigns for height one fourth of the height of the column, including its base and capital, less half its diameter. He places a sort of triglyph in the frieze, which arises from a misconception of the text of Vitruvius. The height of his pedestal is a fourth part of that of the column, with base and capital, less half a diameter. The whole height in our measure is 21 modules and 9 parts.

Sect. IV.

THE DORIC ORDER.

2560. The Doric order of the moderns is of two sorts: mutular and denticular, the former is represented in *fig.* 879. A is a plan of the sofite of the corona; B, a plan of the

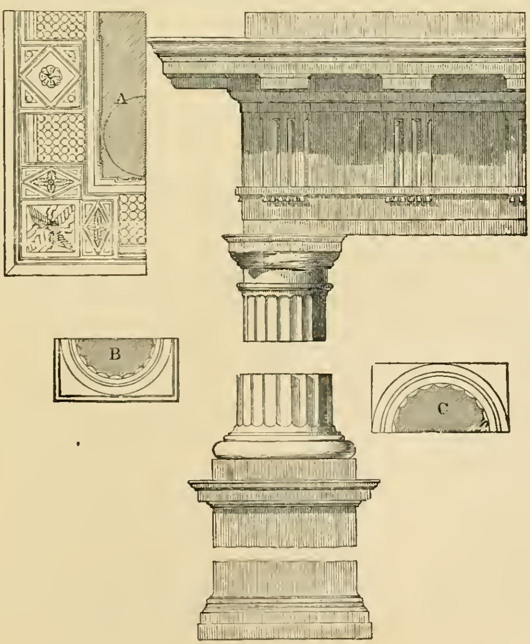

Fig. 879.

capital; and C, a plan of the base. In the frieze the channelled projections are called *triglyphs*, and the spaces between them *metopæ*, which should in breadth be equal to their height, which is that of the frieze. The shaft is usually channelled with twenty *flutes*. Over the triglyphs are distributed *mutules* or modillions, and another peculiarity is the introduction of *guttæ* or *drops*, which decorate the soffite of the cornice and the feet of the triglyphs.

2561. Daviler, speaking of the two Doric entablatures given by Vignola, admires the elegance of their composition, and scarcely knows which of them to select as the most beautiful. "The first" (or denticular), hereafter immediately subjoined, says Chambers, following that author, "which is entirely antique, is the lightest, and consequently properest for interior decoration or objects intended for near inspection; the other, composed by Vignola himself from various fragments of antiquity, being bolder, and consisting of larger parts, seems better calculated for outside works and places where the point of view is either distant or unlimited. On polygonal plans, however, the mutule cornice must be avoided, because the soffites of the angular mutules would form irregular and very disagreeable figures: neither should it be employed in concaves of small dimensions, for the same reason: nor in places where frequent breaks are requisite, it being extremely difficult, often impossible, to prevent the mutules from penetrating and mutilating each other in various unsightly manners; and wherever this cornice is used on a convex surface, the sides of the mutules must be made parallel, for it would be both disagreeable and unnatural to see them broader, and consequently heavier in front than where they spring out of the mutule band." We have elsewhere observed that there is very great difficulty in distributing the parts of the Doric entablature, on account of the intervals between the centres of the triglyphs, which necessarily confine the composer to intercolumniations divisible by three modules, thus producing spaces which are often too wide or too narrow for his purposes.

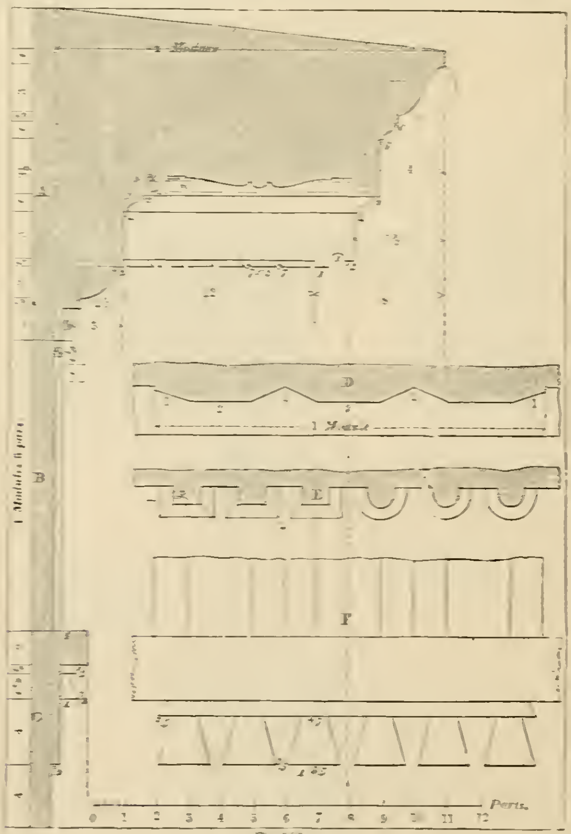

Fig. 880.

2562. In *fig.* 880. the entablature of the mutular Doric order is given to a larger scale than that of the preceding figure; and we subjoin, as in the Tuscan order, —

Table of Parts of the Entablature of the Mutular Doric.

Mouldings whereof the Parts are composed.		Heights of Mouldings in Parts of a Module.	Projections from Axis of Column in Parts of a Module.
Cornice A, 18 parts.	Fillet of the corona	1	34
	Cyma	3	31
	Fillet	¼	31
	Cyma reversa	1	[illegible]
	Corona	3½	[illegible]
	Cyma reversa	1	[illegible]
	Mutule	3	[illegible]
	Drip	½	[illegible]
	Gutta of the mutule	½	[illegible]
	Echinus or quarter round	2	12½
	Fillet	½	[illegible]
	Capital of the triglyph	2	11
Frieze B. 18 parts.	Triglyph	18	[illegible]
	Metope	18	10
Architrave C. 12 parts.	Listel	2	12
	Capital of the guttæ	½	11½
	Guttæ	1½	11½
	First fascia	6	10½
	Second fascia	4	10

D is the plan of a triglyph to double the scale.
E is the plan of the round or square guttæ.
F is the elevation of the triglyph and its guttæ.

2563. To obviate the difficulties mentioned in 2561. relative to the triglyphs, they have often been omitted and the entablature left plain, as in the Coliseum at Rome, the colonnades of St. Peter's of the Vatican, and in many other buildings. This, says Chambers, is an easy expedient; but as it robs the order of its principal characteristic distinction, the remedy is a desperate one, and should only be employed as a last resource.

2564. The Doric order was used by the ancients in temples dedicated to Minerva, to Mars, and to Hercules. In modern buildings, Serlio (lib. iv. c. 6.) recommends it in churches dedicated to saints remarkable by their suffering for the Christian faith. Le Clerc suggests its use for military buildings. "It may," says Chambers, "be employed in the houses of generals, or other martial men, in mausoleums erected to their memory, or in triumphal bridges and arches built to celebrate their victories."

2565. As the difference between the mutular and denticular Doric lies entirely in the entablature, we give in the following table the whole of the details of the order,

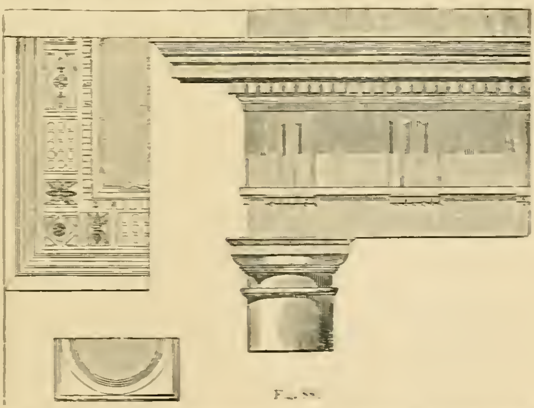

Fig. [illegible]

observing, that from the capitals downwards, the measures assigned to them are the same for each. *Fig.* 881. represents the entablature of the denticular Doric and its parts.

which, with those of the capital, base, and pedestal, are in *fig.* 882. given to a larger

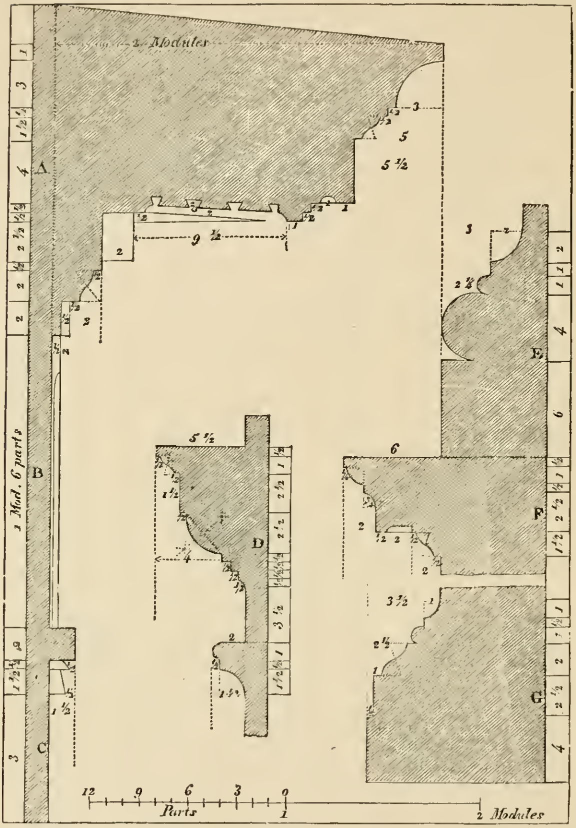

Fig. 882.

scale, as we have before represented the parts of the Tuscan order. The general table is subjoined : —

	Members composing the Order.	Heights in Parts of a Module.	Projections in Parts of a Module from Axis of Column.
	ENTABLATURE.		
A, Cornice, 18 parts.	Fillet of corona - - -	1	34
	Cavetto - - - - -	3	31
	Fillet - - - - -	$\frac{1}{2}$	26
	Cyma reversa - - - -	$1\frac{1}{2}$	30
	Corona - - - - -	4	$28\frac{1}{2}$
	Drip - - - - -	$\frac{1}{2}$	$27\frac{1}{2}$
	Fillet - - - - -	$\frac{1}{2}$	25
	Gutta under the corona - -	$\frac{1}{2}$	$24\frac{1}{2}$
	Dentil - - - - -	3	15
	Fillet - - - - -	$\frac{1}{2}$	13
	Cyma reversa - - - -	2	$12\frac{1}{2}$
	Capital of triglyph - - -	2	11
B, Frieze, 18 parts.	Triglyph - - - -	18	$10\frac{1}{2}$
	Metope - - - - -	18	10

Members composing the Order.		Heights in Parts of a Module.	Projections in Parts of a Module from Axis of Column.
C, Architrave, 10 parts.	Listel	2	11½

	Inverted cyma	2	19
	Second plinth	2½	21
	First plinth	4	21½

2566. Vitruvius, with more clearness than in the others, describes the Doric order (book iv. chap. iii.). In order to set out its proportions, he tells us, though not giving a direct rule, that its pedestal is composed of three parts, the cymatium or cornice, the die, and the base; and that the base and cimatium are composed of many mouldings, whose individual proportions, however, he does not give. He assigns no particular base to the Doric order; but, nevertheless, places under half a diameter in height the attic base, whose members are the plinth, small fillet, scotia, and the upper torus with its superior and inferior fillets, together with the apophyge of the column. He gives to the projection of the base a fifth part of the diameter of the column. The height of the shaft he makes of 6 diameters, and its diminution a sixth part of the diameter. The capital's height he makes equal to half a diameter, and divides it into three parts, one for the abacus and its cymatium, another for the echinus and its fillets, the third for the hypotrachelium. To the architrave he assigns the height of one half diameter of the column, and to the frieze 50 parts of the module (semidiameter divided into 30 parts), including the fascia, forming the capital of the triglyphs. His cornice consists of 30 parts of the module, and its projection 40. The whole height which he gives to the order is, in the measure here adopted, 17 modules and 20 parts.

2567. Palladio makes the Doric pedestal rather less than 2¼ diameters of the column, dividing it into three parts, the base, die, and cymatium. To the die he assigns nearly a diameter and one third of the column. To the cymatium a little more than one third of the diameter. He uses the attic base to the order, but, for the sake of carrying off the water, turns the plinth into an inverted cavetto (*guscio*), ending in the projection of the cymatium of the pedestal. To the shaft of the column he assigns various proportions, directing that if accompanied with pilasters, it should be of the height of $8\frac{5}{12}$ diameters, and if entirely isolated, 7 or at most 8 diameters high. He cuts the shaft into 24 flutes, and diminishes it the tenth part of its diameter. The height of his capital is half a diameter, and, like the annotators on Vitruvius, he decorates the neck or frieze, as they both call it, with roses, adding, however, other flowers, and making its projection a little more than a fifth part of the diameter. To the architrave, frieze, and cornice he gives a little more than one fourth part of the height of the column, so that the whole height of his order is in our measure 24 modules and a fraction above $2\frac{1}{2}$ parts.

2568. Serlio makes the height of the pedestal of his column a little less than 3 diameters, with its base, die, and cymatium. The height of the die is set up equal to the diagonal of a square, formed on the plinth of the column. The height of the cymatium, according to the strict text of Serlio, should not be less than that of the base; but he altogether omits any mention of its projection. His base is the attic base, to which he assigns a projection of a quarter of a diameter. The column is 6 diameters high, and has 20 flutes. His capital differs only from that of Vitruvius in its projection, which is rather more. The architrave and frieze do not much differ from those already described. The projection given to the cornice is equal to its height. The whole height in our measures amounts to 23 modules and 5 parts.

2569. The Doric order as described by Scamozzi is not very dissimilar to those already described. The pedestal is by him made 2 diameters and a little more than a quarter, with a base, die, and cymatium, and the projection barely a quarter of the diameter of the column, to which he gives the attic base. His column is $7\frac{1}{2}$ diameters high, and the diminution a fifth part of the diameter. There are 26 flutes on the shaft, separated from each other by fillets, whose width is one third of the flute. This author gives three different sorts of capitals for the order: the first has three annulets; the second has only the lower annulet, the two upper ones being changed to an astragal; the third, instead of the two lower annulets, has a cyma reversa. Lastly, above the corona he places a cyma reversa, and in the other parts does not vary much from the preceding authors, especially in the frieze and architrave, except that in the last he uses two fasciæ. To the cornice he assigns the projection of five sixths of a diameter of the column. His whole entablature is a little less than one fourth the height of the column, including base and capital. The whole height of the order in our measures is 23 modules and 8 parts.

2570. In *fig.* 883. the profile of the Grecian Doric from the Parthenon at Athens is given. Though very different to those we have already described of this order, the resemblance is still considerable. Its character is altogether sacred and monumental, and its application, if capable of application to modern purposes, can scarcely be made to any edifice whose general character and forms are not of the severest and purest nature. The various absurd situations in which the Grecian Doric has been introduced in this country, has brought it into disrepute; added to which, in this dark climate the closeness of the intercolumniations excludes light, which is so essential to the display of architecture under the cloudy skies with which we are constantly accompanied in high latitudes. The diameter of the columns in the original is 6 feet 2·7 inches.

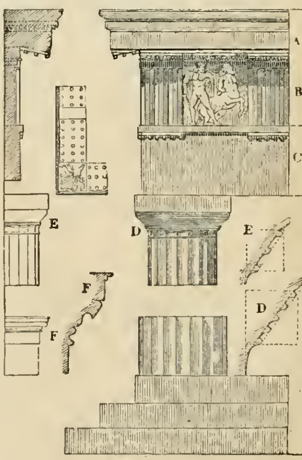

Fig. 883.

2571. Lest we may be reproached with neglecting to submit to the student in this place (and the remark equally applies to the following section on the Ionic order) more examples of the Grecian Doric, we would here observe that this work is not to stand in place of a parallel of the orders. Nothing would have been easier than to have placed before him an abundance of examples; but they must be sought elsewhere, inasmuch as the nature of our labours requires general, not special, information in this respect. We have not, however, refrained in the first book (142, *et seq.*) from entering into details respecting the Grecian Doric, which we consider much more valuable to the reader than would be the exhibition of a series of profiles of its principal examples. We have, moreover, at that place, suggested some criteria of their comparative antiquity. We do not think the nice copying of a profile into a modern work any other than a disgraceful exhibition of the want of ability in the man, we cannot call him artist, who adopts it, and shall be much better pleased to leave the student in doubt, so that he may apply himself *pro re natâ* to the matter which calls his genius into play. From what we have said on *the orders* in Sect. II. of this Book, (2523, *et seq.*), relative to the order, and on *mouldings*

(2532, *et seq.*), it must be quite clear that the variety of every order, keeping to first principles, has not been yet exhausted, neither is it likely to be so.

TABLE OF THE PARTS OF THE GRECIAN DORIC (PARTHENON).

Members composing the Order.		Heights in Parts of a Module and Decimals.	Projections in Parts of a Module from Axis of Column
ENTABLATURE.

	Second step or plinth	6·70	21·80
	Third step or plinth	6·90	30·84

2572. The minutiæ of the Grecian Doric, as we have just observed, cannot be given in a general work of this nature. In its smaller refinements it requires plates on a much larger scale than this volume allows. The reader, therefore, must be referred to *Stuart's Antiquities of Athens* (original edition), and the publications of the Dilettanti Society, for further information on the subject of the Grecian Doric. All that was here possible was to give a general idea of the order. In the figure, E is the section of the capitals of the inner columns of the temple on a larger scale. DD relate to the principal columns. F is a section of one of the antæ or pilasters to double the scale of the capital. The centre intercolumniation 4 modules $\frac{55}{100}$, from axis to axis of columns. The principal Grecian Doric examples are — the Parthenon, the temple of Theseus, the propylæum and the portico of the Agora at Athens; the temple of Minerva at Sunium; the temple at Corinth; of Jupiter Nemæus, between Argos and Corinth; temple of Apollo and portico of Philip in the island of Delos; the temple of Jupiter Panhellenius at Egina, and of Apollo Epicurius at Phigalia; the two temples at Selinus; that of Juno Lucina and Concord at Agrigentum; the temple at Egesta, and the three temples at Pæstum. (See 142, *et seq.*)

SECT. V.

THE IONIC ORDER.

2573. Of the Ionic order there are many extant examples, both Grecian and Roman; and, except the debased later examples of the latter, there is not that wide difference between them that exists between the Grecian and Roman Doric. The Ionic has been considered as deficient in appearance as compared with the other orders, on account of the irregularity of its capital, which, on the return, presents difficulties in use. These difficulties are not obviated by the practice of the Greeks, who made an angular volute on each extremity of the principal façade, and then returned the face of the capital. With all our respect for Greek art, we think the expedient, though ingenious, a deformity; albeit, in the case of the type being a timber architrave, we must admit that the face of the capital should lie in the direction of the superincumbent beam.

2574. In the example given (*fig.* 884.) we have, as in the examples of the preceding

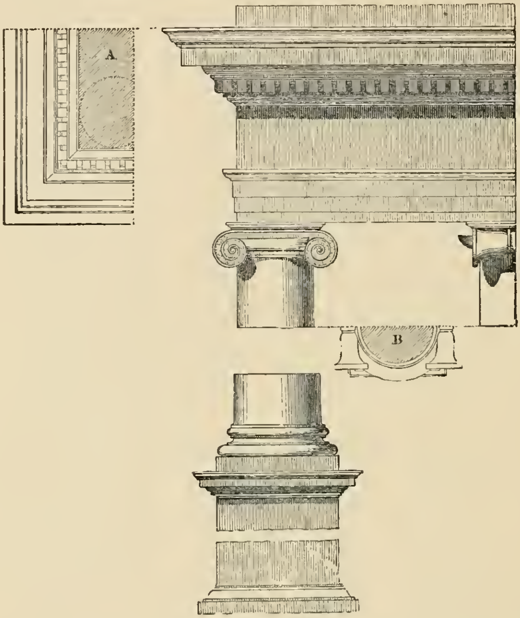

Fig. 884.

orders, selected the profile of Vignola as the most elegant of the moderns; and the reader will here recollect that in the Ionic, Corinthian, and Composite orders, the module or semi-diameter of the column is divided into 18 parts. In the figure, A is a plan of the sofite of the cornice, and B a plan of the capital. The method of tracing the volute will be given in a subsequent figure: previous to which, as in the orders already given, we subjoin a table, showing the heights and projections of the parts of the order.

	Members composing the Order.	Heights in Parts of a Module.	Projections from Axis of Column in Parts of a Module.
	Entablature.		
A, cornice, 34 parts.	Fillet of cyma - - -	$1\frac{1}{2}$	46

H, Base, 10 parts.	Congé		2	25
	Fillet		1	27
	Bead		1⅓	28
	Cyma reversa		3	27⅓
	Fillet		⅔	31⅔
	Plinth		4	33

The flutes in this order are separated by a listel.

2575. The letters to the leading divisions of the above table refer to the *fig.* 885., wherein the parts are drawn to a larger scale, and wherein 1 is the eye of the volute, presently to be described.

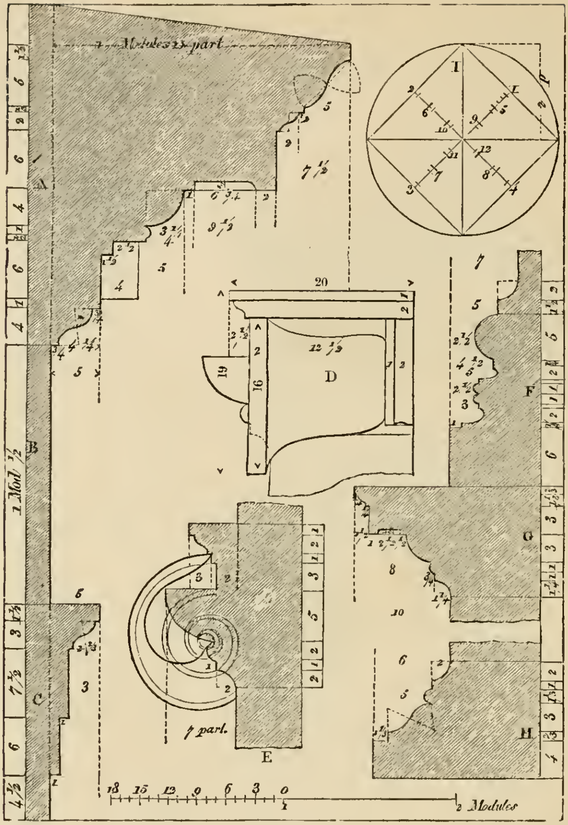

Fig. 885.

2576. *Fig.* 886. shows the method of drawing the volute, the centre of whose eye, as it is called, is found by the intersection of an horizontal line from E, the bottom of the

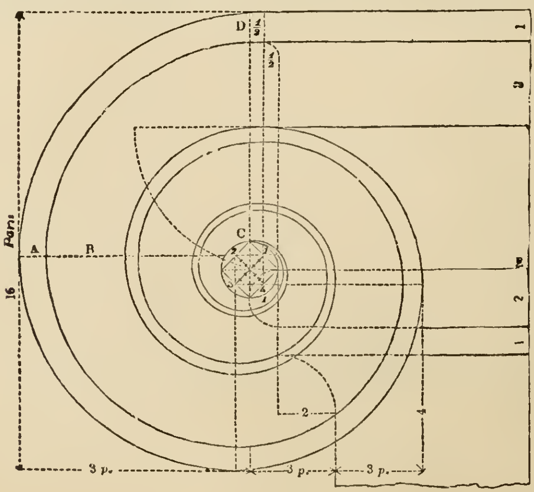

Fig. 886.

See fig. 615c.

echinus, with a vertical from D, the extremity of the cyma reversa. On the point of intersection, with a radius equal to one part, describe a circle. Its vertical diameter is called the *cathetus*, and forms the diagonal of a square, whose sides are to be bisected, and through the points of bisection (see I, *fig.* 885.) the axes 1, 3 and 2, 4 are to be drawn, each being divided into 6 equal parts. The points thus found will serve for drawing the exterior part of the volute. Thus, placing the point of the compasses in the point 1, with the radius 1 D, the quadrant DA is described. With the radius 2A another quadrant may be described, and so on. Similarly, the subdivisions below the points used for the outer lines of the volute serve for the inner lines. The total height of the volute is 16 parts of a module, whereof 9 are above the horizontal from E, and 7 below it.

2577. Vitruvius, according to some authors, has not given any fixed measures to the pedestal of this order. Daniel Barbaro, however, his commentator, seems to think otherwise; and, on this head, we shall therefore follow him. The height of the pedestal is made nearly a third part (including its base and cymatium) of the height of the column. To the base of the column he assigns half a diameter, and to the shaft itself nearly 8 diameters, its surface being cut into 24 flutes, separated by fillets from each other. His method of describing the volute is not now thoroughly understood; and it is, perhaps, of little importance to trouble ourselves to decypher his directions, seeing that the mode of forming it is derived from mathematical principles, as well understood now as in the days of the author. The architrave he leaves without any fixed dimensions, merely saying that it must be larger or smaller according to the height of the columns. He prescribes, however, that the architrave, frieze, and cornice should together be somewhat less than a sixth part of the height of the column, with its base and capital. The total height he makes the order, according to our measures, is 25 modules and nearly 9 parts.

2578. Palladio gives to the pedestal 2 diameters and nearly two thirds of the height ot the column. He adopts the attic, though without rejecting the Ionic base, and makes it half a diameter high, adding to it a small bead, which he comprises in the height of the shaft, which he makes 8 diameters in height. To the architrave, frieze, and cornice, taken together, he assigns a little less than one fifth of the height of the column, including its base and capital, and makes the projection of the cornice equal to its height. The total height of the order, in our measures, is, according to him, 27 modules and nearly 8 parts.

2579. Serlio, in this order more than any of the others, varies from Vitruvius. To the pedestal he gives, including base, die, and cymatium, a little more than a third part of the height of the column, with its base and capital. To the shaft of the column he gives 7 diameters, and diminishes it a sixth part of its diameter. His capital is that of Vitruvius, as far as we can understand that master. His mode of constructing the volute differs from other authors. His directions are, that having found the cathetus, which passes through the centre of the eye, it must be divided into eight parts, from the abacus downwards, one whereof is to be the size of the eye of the volute, four remain above the eye, and three below that part comprised below the eye. The cathetus is then divided into six parts, properly numbered by figures from 1 to 6. With one point of the compasses in 1, and the other extended to the fillet of the volute, he describes a semicircle, and so on with semicircles consecutively from 2 to 6, which will ultimately fall into the eye of the volute. We cannot speak in high terms of Serlio's method, and therefore have thought it unnecessary to accompany the description with a figure. It is rather a clumsy method, and we fear, if exhibited in a figure, would not satisfy our readers of its elegance. The height of his architrave, frieze, and cornice together is a little less than a fourth part of the height of the column, including the base and capital. The whole height of his order, in our measures, is 25 modules and 6 parts.

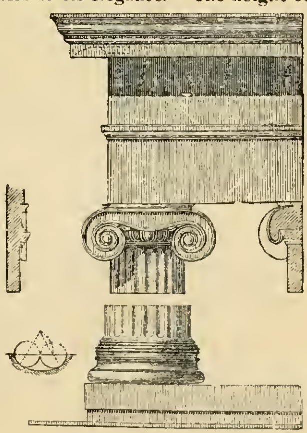

Fig. 887.

2580. Scamozzi directs that the pedestal shall be with its base and cornice two diameters and a half of the column. He uses the attic base, and, like Palladio, gives an astragal above the upper torus. To the shaft of the column he assigns a height of little less than 8 diameters, and makes its diminution a sixth part of the diameter. He adopts the angular capital, something like the example of that in the temple of Fortuna Virilis. The height of his architrave, frieze, and cornice is a little less than a fifth part of the height of the column, with its base and capital. The total height of his order, in our measures, is 26 modules.

2581. The principal examples of the Grecian Ionic are in the temples of Minerva Polias, of Erectheus, and the aqueduct of Hadrian, at Athens; in the temple of Minerva Polias at Priene; of Bacchus at

Teos; of Apollo Didymæus at Miletus; and of the small temple on the Ilyssus, near Athens, whereof in *fig.* 887. the profile is given, and below, a table of the heights and projections of the parts. It is to be observed, that in the Grecian Ionic volute the fillet of the spiral is continued along the face of the abacus, whilst in the Roman examples it rises from behind the ovolo. Some of the Athenian examples exhibit a neck below the echinus, decorated with flowers and plants. The entablatures of the early Ionic are usually very simple. The architrave has often only one fascia, the frieze is generally plain, and the cornice is composed of few parts. In Book I. Chap. II. (153, *et seq.*) we have already examined the parts of the Grecian Ionic, and thereto refer the reader.

Table of the Parts of the Grecian Ionic in the Temple on the Ilyssus.

Members composing the Order.		Heights in Parts of a Module and Decimals.	Projections in Parts of a Module from Axis of Column.

	Congé	1·080	
	Shaft	17 mod. 7·110	above 15·360 below 18·000
Base, 33·27 parts.	Apophyge	1·080	
	Fillet	0·450	18·960
	Bead	1·080	19·320
	Horizontally fluted torus	6·120	22·500
	Fillet	0·450	22·500
	Scotia	6·000	21·840
	Fillet	0·450	23·640
	Torus	5·760	24·960
	Plinth	11·880	26·520

The height from the top of the echinus to the centre of the eye of the volute is 15·72 parts. Total projection of the volute from axis of column, 27·90. The flutes are elliptical on plan (*fig.* 887.), and the distance between axes of columns, 6 mod., 3·24 pts.

2581*a*. An Ionic capital from the celebrated Temple of Diana, at Ephesus, can now be seen at the British Museum, having been recovered during the explorations made in 1872, by Mr. J. T. Wood. The shaft was 6 feet 1 in. diam., and a part of its base was found *in situ*.

Sect. VI.

THE CORINTHIAN ORDER.
