WITH the present number of the *Builder* we present our readers with the ground-plan and a perspective view of the design of Herr Paul Wallöt, a Frankfort architect, who gained one of the two first prizes in the competition for the new Imperial House of Parliament in Berlin. The Parliamentary Commission charged to provide a house for the Imperial Legislature has already made a definitive choice of Herr Wallöt's design, and has appointed the successful author as architect of the new edifice. Herr Wallöt's plan, however, before being carried out, is to undergo some changes and modifications derived partly from some of the other successful designs to which the Committee have awarded prizes, and partly from others which they have subsequently purchased. In its main outlines, nevertheless, the future House of the German Imperial Parliament will be a reproduction of Herr Wallöt's plan, the modifications desired not being of any considerable extent. Before proceeding to any special remarks upon the successful design, we may permit ourselves some general observations, on the result of the competition. We may promise that we published in the columns of the *Builder* at the time the competition was announced a complete translation of the programme, including the conditions of the contest, the dimensions of the site, and a full catalogue, with dimensions of the rooms required in the new building. One of the principal difficulties of the problem, it will be remembered, was the constructed site which had been fixed upon. One side of the edifice was to face the Königsplatz, which has become one of the most interesting spots in Berlin since the erection of the Column of Victory in its centre in celebration of the triumphs of the German arms in 1870 and 1871. In the new Parliament House it was one of the conditions that the chief entrance should not be on the Königsplatz side, but on one of the other three sides nearer the city. The site of the new House is about 200 yards to the north-west of the Brandenburg Gate, which terminates the celebrated avenue, Unter den Linden. One side of the Königsplatz is formed by the open border of the well-known park, called the Thiergarten. On another side is Kroll's Theatre, and opposite this is the site chosen for the new edifice. There is no doubt it is one of the finest and most suitable spots for the purpose which could have been chosen within the enlarged precincts of the German capital. The Königsplatz, we may parenthetically remark, is destined, at some future period, to have erected upon one side of it,—we believe that now occupied by Kroll's Theatre,—a new palace, as the principal town residence of the new line of German emperors, an addition which will make it vie with the Lustgarten as the finest square in Berlin.

For the competition for designs for the new German Parliament House only the short space of three months was allowed. But the premiums were, for Germany, numerous and liberal,—two first premiums of 750*l.* each, three second premiums of 500*l.* each, and five third of 250*l.* each (see *Builder* of June 24th inst).—the result being that an unprecedented number of competitors took part in the contest. The total number was 180, and the number of sheets of drawings sent in was upwards of 2,000. They were on view from the last week in June to late in July, and were exhibited at the Provisional Gallery of Fine Arts in the Cautianplatz, Berlin, where they were daily visited by architects and artists from all parts of Germany as well as by crowds of the general public of the capital. One result of the competition has been to call out a host of young architectural talent previously without distinction, the two first-prize takers being comparatively young men, and most of the others being by no means amongst the hitherto best known names amongst the architects of Germany. Speaking generally, the native critics are well satisfied with national progress evinced by this competition. Compared with the 1872 competition, the recent contest shows that German architects have, in the interim, without losing anything in the way of taste and learning, become more practical. In the former competition the prevailing failing as to the designs was that they sacrificed internal propriety and prac-

tical adaptation to the end in view to external effect. The idea then aimed at was, less to provide the Legislature with the most convenient house of business than to present to spectators a splendid monumental edifice. In the present year, while exterior effect has not been lost sight of, the internal arrangements, as evidenced in the ground-plans of Herren Wallot and Thiersch and many other competitors, are a vast improvement on the great majority of the designs delivered in the competition of ten years back.

Among the designs sent in this year there was but a very small percentage in the Gothic style, and not one of them gained a prize or other distinction. The majority of the designs were in the strict Renaissance style, many of them enriched by motives derived from the German variety of that style. Few were in the more pronounced German-Renaissance style, nor were there many following strictly Hellenic forms. In nearly all the designs stone was the material chosen, the number preferring brick facings being very few.

In a Parliament House all other parts of the plan are, as a matter of real value, subordinate in importance to the hall in which the legislators sit to debate and make the laws. To give some external expression to this fact appears an aesthetic necessity, and this necessity should guide the architect in giving a monumental character to the edifice. The hall of session should, in fact, make itself in some form apparent in the external configuration of the building, and this has, in fact, been done in most cases by the competitors in the recent contest. The general solution has been found in surmounting the hall by a more or less lofty cupola. In some instances temple pediments, or pyramidal and terrace-like structures, have crowned the principal hall of session; in others we find towers and spires and other more fantastic shapes. By far the most common crown to the edifice, however, has been the cupola; both the cupola properly so called, and those forms consisting of a low pavilion or tower with tent-shaped or imperial roof, and with or without colonnade, &c. So afraid, however, were many of the competitors of going to excess in the monumental direction that their cupolas or other forms of crowning structure over the Hall of Session err in the opposite direction. They are too modest and too low, and do not stand out with sufficient prominence in comparison with the rest of the building. There are not wanting examples, however, of excess in the contrary direction.

The winner of the first premium, Herr Wallot, in his cupola over the Session Hall, and his success with the jury was, in fact, largely due to the ingenuity he displayed in the solution of this portion of the problem. Herr Wallot proposes to build over the Hall of Session a lofty and open structure, so that the light can fall without hindrance through the sides upon the overhead lights of the Session Hall. By this means the House, which in Germany always sits in day time, obtains an excellent overhead light without the objectionable zenith light. Upon the open walls Herr Wallot constructs his dome-like curved roof,—a novelty which has been called a monumental baldachin or canopy. The way in which Herr Wallot has performed this part of his task is very original, and has won for him much praise with German critics.

The design of Herr Wallot was placed first amongst the competing plans by the almost unanimous vote of the jury. The critics who have seen the exhibition of the whole of the designs at Berlin have in general endorsed this verdict. This unanimity is due, amongst other excellences of Herr Wallot's work, to his exceedingly successful ground-plan. The problem that had to be solved was one of no ordinary difficulty, considering the shortness of the time allowed, the very limited dimensions of the site, the number, variety, and peculiar requirements of the interior apartments, and the numerous other stringent conditions imposed.

In spite of the conditions laid down in the programme, Herr Wallot has in some points ventured on solutions not contemplated by the Commission, but whatever he did in this way has been approved by the judges. Instead of one chief entrance for members, as demanded in the programme, Herr Wallot has provided three, each with appropriate vestibule. Those on the north and south sides are for the regular

business, while the third and principal one, facing the König's-platz, and which was called for chiefly by aesthetic considerations, the author has provided for grand ceremonial occasions. In the centre, between these three openings, lies a grand staircase, covered in with glass overhead, and leading into the great Ceremonial or Festival Hall. On both sides of the staircase-hall, on the ground-floor, are the postal and telegraph offices. In the south-west and northern wings, on the ground-floor, are committee-rooms and audience apartments. The central grand staircase affords a convenient and appropriate means of communication between the chief rooms and halls used by the deputies on the principal floor and the apartments on the ground-floor.

All the subordinate entrances to the house are from the east or Sommer-strasse side. Here are two large portals, which, while serving as carriage entrances, leading into the eastern courts, also lead to the staircase conducting to the Bureau, or business offices of the Reichstag, and intended for the use of the general public having business to transact there. On the other side they lead to the staircase to be used by the Federal Council, and conducting to galleries or *loges* used by the Court and the diplomatic corps. There are two other entrances in the staircases conducting to the galleries set apart for the use of visitors, the reporters and representatives of the press, and the members of the local Parliaments of the various German states. The writing-rooms of the official shorthand-writers, which are accessible direct from the Hall of Session, lie on the ground-floor, between the two last-mentioned entrances. The other rooms on this floor are for the records of the House, or for use as offices of the Bureau, or as apartments for the servants resident on the premises.

As regards the upper floor of the house, where it is not absorbed by the lofty halls of the principal floor, extending up through both floors, the most interesting portions are those connected with the galleries and *loges* overlooking the Hall of Session. Those on the southern and half the eastern side are for members of the press, those on the other half of the eastern side, as well as on the northern side, are for the members of the Federal Council and Reichstag, and for the Imperial Court and the Corps Diplomatique, while those on the western side are for the general public or "strangers." The writing-rooms for the members of the press and the accessory apartments connected with the Court *loge* are on the eastern front of the building upon this upper floor.

The merits of Herr Wallot's ground-plan, as we have already intimated, are not surpassed by any other design produced at the competition. The whole *ensemble* is symmetrically grouped about two axes, a longer and a shorter one, and the entrances and staircases are arranged so that every part of the house is easy to find and readily accessible. While the distribution of the interior and the application of the space at command are very advantageous, the architect has contrived at the same time to obtain from the conformation of the interior powerful motives determining the configuration of the exterior. With all this he has never lost sight of the main purpose of the building, but has subordinated external effect as well as internal arrangement to the one principal object, that of providing a convenient house for the work of legislation. In the matter of lighting Herr Wallot has provided four open courts in the interior of the edifice, each of about 14 metres wide by 21 metres long; and by this means, as well as by the fact that the house stands detached on all sides, every part of it is well supplied with daylight, which is the more important, as the German Parliament never sits by night. It is only in the central division of the building, which is 48 metres wide, that skylights are applied, and the only case of indirect lighting is that of the corridors in the eastern wing.

There have been several objections urged against Herr Wallot's ground-plan. One of the principal defects in the eyes of German critics is the position assigned to the Ceremonial Hall. According to the programme, this was required to be next to the Hall of Session, the largest of all the apartments in the building. It was to be capable of accommodating several hundreds of persons, and was intended for the use of large conferences and for certain occasional fes-

tivals and solemn state ceremonies. By the position assigned to it in Herr Wallot's plan it will necessarily be in constant use while the House is sitting as a thoroughfare to most of the other parts of the buildings. It, therefore, lacks the seclusion which was contemplated in the original scheme. Some of the competitors have, in fact, made this ceremonial hall the centre and pivot of their entire ground-plan. However, in Herr Wallot's plan the large Refreshment Hall could easily serve all the purposes required in the Ceremonial Hall. Another objection is to the position of the Reading-room for daily and periodical literature. It will be this room and the refreshment department that members will most frequent when they are not in their seats in the House; and, according to most critics, the large Reading and refreshment rooms should be close together instead of being, as in Herr Wallot's plan, at a considerable distance from each other on different sides of the building. It has been suggested that the reading room (No. 36) shall change places with the Committee-room (No. 32), whereby this objection would be obviated. Further objections have also been raised against the position of the reporters' gallery, which is at the back of the seats of the members of the Federal Council, and to the unsuitable arrangement of the corridors connected with the cloak-rooms. In a climate like that of Germany, where heavy fur overcoats are necessary in the open air in winter, the cloak-room, we may remark by the way, is a far more important consideration in all public buildings than in the comparatively mild climate of England. Other objections are to the out-of-the-way spot in which Herr Wallot has placed the principal sitting-hall of the Federal Council, and to the entrance staircase for the Federal Council and Court, which are thought not to be in a sufficiently prominent position. However, the limited dimensions of the site are the principal cause of all these minor defects; nor is it possible to see how, under the circumstances, they are to be avoided. Moreover, none of the points to which exception has been taken in Herr Wallot's ground-plan are very serious drawbacks, and weigh as nothing against the prevailing excellences of the design.

The Hall of Session is, for acoustic reasons, to be fitted with a straight wooden ceiling. Below this, and above the arches of the *loges* overlooking the house, there is a rather high frieze. This the architect appears to intend to have adorned with paintings, but in case the light entering from under the cupola is insufficient, windows may, if desired, take the place of such ornamentation here.

As regards the exterior of the building, the illustration enables the reader to form a better idea of it than any amount of mere verbal description. Suffice it to say that the architect has succeeded in giving it a monumental character, but one which is more likely to charm and please than to startle or overawe the spectator. The best German critics agree that, in point of originality of character, the design of Herr Wallot surpasses all its competitors. The effect of the exterior is heightened by the cupola or dome with which the architect has crowned the Hall of Session. There appears no doubt that the form, at once imposing and charming, of this crowning point of the new German Imperial Parliament House is destined to be intimately associated with all representations of the capital of the German Empire in future.

Next to the cupola, the most prominent features in the façade of the new House will be the corner towers. They are to be 18 metres square, and will rise to a height of 33.5 metres, or about 110 ft., above the street level, the height above the main cornice of the building being 12.5 metres, or about 40 ft. These four towers are of a purely ornamental character, and do not rise from any internal necessity in the structure of the building itself. They form, nevertheless, an indispensable feature in the façade of Herr Wallot's Parliament House, of which they are a very effective adornment.

The gainers of the two first premiums, Herr Paul Wallot and Professor Thiersch, are both comparatively young men, the former being under thirty years and the latter hardly thirty years of age. Singularly enough, whatever success they have hitherto had as architects has been in the city of Frankfurt-on-the-Main. Herr Wallot was born at Oppenheim, on the Rhine. He received his professional education at the

Berlin Bau-Akademie, and afterwards travelled for the sake of architectural study in Italy and England. Subsequently he settled as a private architect in Frankfurt, and has there carried out a number of remarkable private edifices in the Zeil and other principal streets. In several recent competitions in Germany and Austria he has been a competitor, and his designs have invariably attracted notice. The other first prizeman, Professor Thiersch, is the nephew of the well-known Professor Thiersch, of Munich, who distinguished himself under King Louis I. of Bavaria. Herr Friedrich Thiersch, the successful competitor in the German Parliament House competition, studied at the Polytechnicum at Zurich, in Switzerland. He has erroneously been described as a pupil of the celebrated German architect, Herr Gottfried Semper. For several years after finishing his academical course, he worked practically in the office of Messrs. Myhas & Blantschli, architects, of Frankfurt. This firm has of late years competed in a series of prize competitions, and has been very frequently successful. In the preparation of these winning designs the young Herr Thiersch has always had a considerable share. In decorative work Herr Thiersch has more particularly distinguished himself, and the decorations of the new Frankfurt Opera-house are chiefly due to him. For three years past Herr Thiersch has been a professor at the Munich Academy and School of Art, an appointment to which he was called on the recommendation of Professor Piloty.

On July the 16th Messrs. Wallot and Thiersch were entertained at a banquet by their colleagues and fellow-members of the Architects' Club and the Artists' Society, at Frankfort-on-the-Main. The festival was held in the grand saloon attached to the Zoological Gardens of the city, and was a great success. The two architects were congratulated on their success by Herr Lewald, the President of the Club, in the name of all the members. Each of them was at the same time presented with a gold laurel wreath and likewise with a diploma of honour. One of the speakers, Herr Viereck, expressed the universal sentiment of the Frankforters when, in winding up his speech, he remarked that, "It could not but be a proud feeling for this ancient Imperial city that it had been the lot of two architects trained within her walls to have supplied the best designs for the edifice which is destined to be the symbol of the re-established German Empire."

**Building By-Laws at Brighton.**—A builder named Monckton was charged at Brighton with two distinct breaches of the Building By-laws, for permitting a new house in Havelock-road to be inhabited without giving notice to the Town Council that it was ready for occupation; and for neglecting to provide proper ventilation to the drainage. He pleaded guilty; but, as no penalty could be imposed under the By-laws in the first case, the Deputy Stipendiary convicted in the second, and fined the defendant 2l. and costs.

#### MODERN ENGLISH POTTERY.

SOME short time ago the Council of the Society of Arts arranged an exhibition of Modern English Pottery at their house in John-street, Adelphi. They had not sufficient room to accept all the works offered, but a very fine selection was made, and it is to be regretted that it was not more widely known and visited than was the case. We give in alphabetical order the names of the firms, seven in number, whose works formed the exhibition, and we are enabled to supplement this list with representations of a few of the works sent:—

Messrs. T. C. Brown-Westhead, Moore, & Co., Staffordshire.

Messrs. Henry Doulton & Co., Lamheth Potteries, and Potteries, Burslem, Staffordshire. Mr. John Harrison, Lintthorpe Pottery, Middlesbrough-on-Tees.

Messrs. Maw & Co., Benthall Works, Broseley, Shropshire.

Messrs. Mintons, Stoke-on-Trent.

Messrs. Josiah Wedgwood & Sons, Etruria, Stoke-upon-Trent; and The Worcester Royal Porcelain Company, Worcester.

Messrs. Brown-Westhead, Moore, & Co. exhibited two large vases of a fine ivory colour; upon which were grouped raised birds and flowers in gold and silver, of a remarkably realistic character. One of these vases we show.

Messrs. Doulton had three distinct exhibits. On the centre table were various kinds of Doulton ware, and on one side of the entrance was a collection of Lamheth Faience and Impasto ware. On the other side, a collection of earthenware, made at Burslem, Staffordshire. We have before now described some of their processes, and were amongst the first to give encouragement to their early efforts.

In the hall were two large vases of Doulton ware on pedestals, standing altogether about 6 ft. in height. These were ornamented with incised animal groups, designed by Miss H. B. Barlow. There was also a large bowl and an elevated stand, of which we give a view.

The collection of Doulton ware may be divided under the following three heads:—1. Salt-glazed decorated stoneware; 2. Salt-glazed *pâte sur pâte*; 3. Silicon ware. The whole of these wares are subject to one firing only, and are fired in the open kiln.

There is very great variety in the first class. The decoration consists entirely of original designs, and, except in the case of pairs, no two objects are exactly alike. It is of incised, modelled, and applied work, and the treatment is both natural and conventional. The forms are also very varied, and vases, jugs, cups, and candleabra in many shapes were represented. Besides these, there were some small square panels in colours, with figure subjects illustrating fabrics, modelled by Mr. George Tinworth. In the second class, there were some specimens of *pâte sur pâte*, in which the decoration is produced by coloured clays or slips laid on, and modelled with the brush. It is, in fact, painting on the solid body with an earthy pigment. The third class, or silicon ware, is a new manufacture of considerable hardness. In the earlier specimens, the silicon ground is elaborately covered with a bluish applied work of simple design, as in the sample we illustrate, but a much more delicate result has now been obtained by the application of a *pâte sur pâte* decoration.

There was a large display of specimens of Lintthorpe ware in vases, tazas, flower-pots, card-trays, fruit-dishes, &c. These are varied in shape and tone of colour, but all have a rich glaze. The ornamentation is but slightly marked on the surface, and is chiefly obtained by shades of colour. There were, however, some plaques with a rough ground, on which were raised flowers. Lintthorpe is a suburb of Middlesbrough-on-Tees, and the pottery was started on his estate at that place by Mr. Harrison a few years ago, chiefly on the suggestion of Dr. Dresser. The material is a common red-brick clay, and the artistic effects are chiefly obtained from the originality of forms and from the parti-coloured glazes. Some of the shapes have been derived from Egyptian, Moorish, Indian, Chinese, Japanese, and other examples. Considerable picturesqueness may be perceived in the form of the handles of some of the objects. Low-toned reds, mottled olives, browns, and yellows, are found in great variety. Where so much depends upon colour, it is not easy to

reproduce the effect in black and white; we give a view of one of the vases exhibited by Mr. Harrison.

Messrs. Maw & Co., of the Benthall Works, Broseley, Shropshire, exhibited a large collection of painted tiles and tile-panels, some of them decorated with landscapes, mosaics, and mouldings in coloured clays; also vases, jugs, and tazas in various coloured glazes.

Messrs. Minton, of Stoke-upon-Trent, made a considerable show of a variety of different wares. There were several tea-sets, vases, plates, trays, plaques, &c. One of the porcelain tea-sets was of open work filled in with a pink glaze. Some of the vases were imitation Svèrus porcelain, and the plaques were richly ornamented with gold.

Messrs. Josiah Wedgwood & Sons, of Etruria, Stoke-upon-Trent, sent many objects representative of the historical wares of their firm, and also of those which have been introduced of late years. There were several reproductions of old vases which have made the name of Wedgwood famous. One of the works illustrated is Flaxman's vase. It represents Apollo and the Muses in black and white relief, but the vase is sometimes made in pale blue. With the pedestal, this, which stands 19½ in., is the largest piece made by Messrs. Wedgwood. The illustration at the bottom of the page shows a vase of diced design in chocolate jasper, ornamented with small bas-reliefs. It is one of several used in the decoration of Lord Dysart's mansion at Buckminster. Some fine chimney-pieces were shown. In the decoration of Lord Dysart's mansion at Buckminster Park, Grant-ham, which is now being reconstructed by Mr. H. R. Ricardo, plaques and medallions are being largely used. Some of the solid jasper fronts for clocks and the medallions and plaques were exhibited.

The Worcester Royal Porcelain Company, the last we have to mention, exhibited an important collection of vases and other decorative objects, besides services, showing the various classes of decoration now in use in the works at Worcester. On the site of these works the original establishment was founded in 1751, and some of the old buildings still remain. The first important alterations were carried out in 1840, and many additions have subsequently been made. The fame of the works is originally due to Dr. Wall, who produced a beautiful artificial porcelain as the result of his scientific researches. Dr. Wall died in 1776, and the remaining partners carried on the works until 1783, when the whole establishment was sold to Mr. Flight. Many changes have been made since then, and the present Joint Stock Company commenced in 1862, with Mr. R. W. Binns, a previous partner, as managing director. The earliest designs of the original Worcester Company were nearly all painted in blue. At present the manufacture of the works embrace the following varieties:—Fine porcelain, ivory porcelain, vitreous stone-ware or semi-porcelain, crown-ware, parisian majolica, terra-cotta, &c. The raw materials used consist of china clay and china stone from Cornwall, felspar from Sweden, fireclay from Stourbridge and Broseley, marl from Broseley, flint from Dieppe and Gravesend, calcined bones, both home and American. The vases, jugs, &c., were mostly of ivory porcelain, a special body introduced by Mr. Binns twenty-six years ago, when he was in partnership with Mr. Kerr. The vase we illustrate is one of the finest works at present produced by the company. The ivory ground is covered with diaper work, and upon this the artist has made an arrangement of natural ferns, modelled and gilded with great delicacy.

Quite early in the resuscitation of the Worcester Porcelain Works it was our privilege to assist the movement very considerably, and, strange to say, this was very fully and agreeably acknowledged at the time by the persons concerned.

When the Council of the Society of Arts again organise an exhibition of Modern English Pottery, they must do it on a larger scale, and take steps to render it more widely known.

**Social.**—The *employés* of Messrs. Bingley, Son, & Follie, slate merchants, Millbank, Westminster, held their annual banquet at the King's Arms, Weybridge, on Saturday last. Mr. Follie presided, and expressed the pleasure it gave him and his partners to be present on such occasions, and trusted that they might long continue to enjoy their annual holiday.

MODERN ENGLISH POTTERY.

AN INQUIRY AS TO THE PRINCIPLES OF ART DECORATION.

Is the art of surface decoration referable to ascertainable laws of colour harmony, and, if so, from what source should the artist seek his inspiration? The universal agreement that certain combinations are beautiful, or the reverse, suggests the affirmative of the one part of the question, and the answer to the second part is obviously that the truth is to be found alone in the study of the book of nature.

The student, then, should first of all remark the effects of light as revealed in the rising or the setting sun, from whose glorious harmonies he will be able to derive the teachings which will guide him to the exposition of artistic truth in the practice of his work. This is to say, he will see all the force and beauty of gradation, from light to yellow, thence to orange, red, crimson, purple, violet, &c., and will be careful in avoiding every discordant note of colour in the treatment of those portions of his work which have reference to one another, as an architrave or a column to a flat surface, as a capital or base to a shaft, and as the parts of any of them to each other. Thus, green is a good colour for a wall, and blue for a ceiling. In Nature this arrangement is continually before us; and brown and green and greenish brown trunks are interspersed amidst the natural wall. So, given a green flat surface, the column or pilaster attached to, or in connexion with it, may well and harmoniously be painted another green, or a brown, not only because Nature so paints the trunks, amidst the green leaves, but because green and brown are colours in harmonious relation. Paint the pilaster in connexion with your green wall a bright vermilion, and a discordant result will be at once apparent.

This does not mean, however, that vermilion may not be employed in any case where green is the colour principally concerned, but that, if employed, it must be led up to through a series of harmonious gradations. Thus (confining ourselves to green) we will suppose for the purposes of illustration that our wall has received an agreeable tint of sage or neutral green,—a reposeful colour, and one always welcome to the jaded vision. But this is not enough; our art instincts demand that, at least, we have a hand following the lines of the ceiling, and another at about the level of the eye, when sitting down. Now, what is the first colour to be superimposed on our neutral green ground? Clearly, another green a few shades darker as the groundwork of the hands. The hands, however, being drawn, we find that the wall surface below that, at the level of the eye, now bears a different relation to the whole; we, therefore, demand another tint; let it be painted a brownish green. This, in its turn, develops the necessity of another hand of a deeper tone or colour following the line of the floor, which will paint a dark bronze-green. Thus, in architectural order, we have base, dado, subbase, surface, and cornice.

From plain surface to straight defined line, the instinct leads us thence to curves, and we essay what is termed ornament in our treatment of the bands and surfaces. First, where shall we begin? The artist intuitively selects the main surface of the wall between the surface and the ceiling, which he will decorate with a leaf and flower design lighter than the ground, and reaching in gradation almost to white in the corolla of the flowers. He will paint the shadows of the leaves and flowers a darker green than the body of the wall, and the corolla he might even sparingly pick out in gold. For this treatment a natural wall of leaves and blossoms played on by the sunlight may be supposed to have furnished the hint. This surface decoration being accomplished, we have, so to speak, killed the plain green of the band below, which may be brought to life by first striking an almost white-green narrow line, followed by others in three or four gradations of tint, until a darker green than the band is reached. These will form the upper border. The lower border should begin with a line of darker green than the surface of the band, followed by others, until a dark bronze-green is reached. The surface of the band within the borders now demands decorative treatment, in which brown, purple, and blue may be so harmonised in leaf and flower, interspersed, as to suggest Nature's horizontal tints. The dado, on its brownish-green ground, may be dispersed in brown, green, and gold, and the dark bronze-green base relieved by lines of gold. All this lower portion leading up to the horizontal band above the dado

may not inaptly typify the ground or natural floor studded with varied vegetation. There remain but the upper band at the ceiling, which should be done in alternate lines of gold and grey; and the ceiling, which may be painted a light blue, to complete the typical picture of a landscape on the walls of our apartment.

This, however, assumes nothing beyond the embodiment of the principle which is at the root of true decoration. There is no reason why, instead of a prevailing green colour, one of an opposite nature,—red, for instance,—should not be adopted so long as the same principles are observed in its treatment. To paint green leaves on a red ground, or to have painted red leaves on our green ground, would be a clear departure from them, and the result repulsive to the least cultivated observer, ignorant of any reason wherefore. A highly-cultivated taste is necessarily conversant with the principles of beauty which minister to it.

Although, admittedly, the adoption of any one prevailing colour is not absolutely wrong, provided it be subjected to harmonious treatment, it may be observed that some colours are not only repellant and unwelcome at first sight, but become positively harmful to the vision by their continuous presence. No quality or arrangement of colour can be truly beautiful on which the eye does not delight to feast or dreamily repose. That which hurts the eye cannot be admitted largely into the domain of art. Thus, as we cannot look at the mid-day sun, or even on a field of poppies, without pain, or on mounds of scorée and plains of upturned peat without weariness; and, on the other hand, as the eye revels or reposes amidst the greens, and browns, and violets, and purples, which Nature lavishly sets forth to our view, so should we select those colours as key-tones in art, which her exemplar teaches us are beautiful.

This does not, of course, preclude the use of any one or another colour, except in the sense of degree as to depth. Thus, following the principles observed in the treatment of our typified landscape, we will now suppose red to be the prevailing tint or key colour to be worked upon. Our main surface would be scarcely deeper than salmon, from which would spring crimson tians, dark browns and chocolates for the bands, dados, and bases, and vermilion and black and gold ornamentation in the bands, and so on, following the method laid down for the other portions.

The objections to the use of deep or intense colours for broad surfaces, unless they are destined as backgrounds for sculpture or paintings, are,—firstly, their tiring or painful effect upon the eye; and, secondly, their great absorbent power as regards light. To mitigate the first, designs in lighter colours might be painted upon them, with the result, however, of practically destroying their effect as dark surfaces; or, secondly, designs in dark colours might be employed, but these alone would only intensify their light-absorbing power. We will then suppose that a dark red be given as the key-stone for decorative treatment in accordance with the principles already laid down. For the bands a still darker red, or a chocolate, would be used; for the dado, a rich brown, and bistre for the plinth. Next, what is to be done with the main surface between the dado and the ceiling, so as to qualify the light-absorbing power, without painting upon it a design which would practically bring it to a much lighter surface? Inferentially, it has been suggested that this would be effected by placing sculpture or hanging paintings; but as we are not concerned with a picture or sculpture gallery, we must look to our art to supply the need in question.

In conformity with the principle that the eye of taste demands the effect of lines to break up or relieve surface monotony, we are irresistibly driven to adopt them in the present case; the true artistic impulse being to suggest the semblance of windows or mirrors, which it will seek to do by symmetrically-arranged relieving lines of gold; these, by their strong reflecting power, compensating for the undue absorption of light by the dark surface. Gold would necessarily be used here considerably in the entire treatment of the work, not in masses, but in narrow lines, straight or curved, relieved by deep browns, chocolates, or blacks. The colour for our ceiling in this case would be a red tempered grey, the true tint being obtained by a graduated treatment of the upper band, which represents the cornice.

It goes without saying that these principles apply to the decoration of walls and ceilings under the most elaborate architectural forms and breakings-up of surfaces. Where plane surfaces of any great extent do not exist, the necessity for qualifying their absorbent tints is less exigent. As a rule, when broken-up surfaces are treated in polychrome, the salient ones should have more reflective tints than the receding, not necessarily lighter, but warmer. This is strictly in accordance with Nature's teaching, and must be followed in decorative art if it is to be worthy of the name.

All colour culminates in gold or its analogue, which is to say in the most highly reflecting expression of tint. The glittering whiteness which it displays when under a strong light is due to its power of giving back with interest the chromatic quality of every sort of light which is thrown upon it; or of the colour of whatever surface it is laid upon. Thus its employment in decorative art is of the highest importance, and its right or wrong use will go far to make or mar a work well considered in other respects.

The effect of gold lines upon a broad ground of chocolate, green, purple, blue, or maroon is as forcible and telling as upon one of dark red. The non-reflecting qualities of all these colours demands the juxtaposition of gold,—the cumulative colour *par excellence*,—to strike out, or develop, sympathetically, their latent power, enhancing the while its own inherent beauty. The effect of gold lines upon a broad surface of orange or vermilion, however, would not be such as to commend itself to the eye of taste.

That gold, the culmination of colour, centre of light, or source of colour, may be used with artistic effect upon surfaces whose tints are so far removed as almost to touch the borders of negation, may appear inimical to the doctrine that bright colours must be led up to by gradation, and that the juxtaposition of colours is only permissible when they are related by strain. But this is not so. It is in conformity with the principles laid down and so far illustrated that gold, or even silver, may, in the circle of colour harmony, unite with the nearest or remotest blue, as the stars reveal the beauty of night, and the sunlight that of the midday sky; but a golden sun set in a blood-red sky would be contrary to the conditions of subjective existence.

Nature, then, whether revealed in the sublime glory of the rainbow, or the painting of a flower, is the only true source from which the decorative artist can draw instruction and inspiration. But how little she has been studied hitherto is made abundantly evident by the many examples of what may be termed polychrome mistakes that have been perpetrated. Assuming it to be true that decorative art in colour may legitimately be applied to moulded architectural or sculptural forms, it is clearly the business of the artist to develop, not bide, their qualities; yet how frequently are vaulted roofs disfigured by meaningless reds and blues picked out in moulding and dog-tooth in the ribs of the groin and arches? This is hideous and untrue, and as destructive of the architectural beauty which these features would derive from their own native colour and chiaroscuro as the war-paint upon the body of a Red Indian is to the natural beauty of his skin.

It follows, where form rules, colour must obey. We paint our canvas or our wall, but our sculptural or architectural feature is its own subject, and the material in which it is wrought or expressed can embody all its beauty and meaning. The vandalism that would paint sculptured leaves of any colour, most of all green, is at one with that which would paint white marble mouldings red. The house-painter is here the superior of both sculptor and architect.

Perhaps, with the exception of the purest white, and rarest and most costly variegated marbles, there is no building stone that is not susceptible to enhanced beauty by the help of external colour applied to its plain surface. But where the material is not ugly,—as is a dead brick wall, which we plaster, or colourless and bare, as is the plaster surface which we decorate,—but has positive chromatic beauties, as nearly all building stones have, these should be accepted as the key-tones to the harmony of all superimposed decoration.

True knowledge is indispensable to the artist who would essay to emphasise the sombre grandeur of the red sandstone, or the ærial majesty of the oolites and white limestones of which our cathedrals are severally the structural expressions. At the outset several questions came up for consideration. To what extent the

## "TO BE OR NOT TO BE."

PADDINGTON PARK.

At a moment when, though somewhat tardily (and if the effort is not made very vigorously the opportunity will be lost for ever), the question of creating Paddington Park is being again energetically mooted by some of the leading men and leading journals of the day, it more especially behoves this paper to advocate this important scheme. The *Builder*, as the late Mr. Street, R.A., remarked on the occasion of the presentation to its editor of the royal gold medal, has ever been one of the chief organs in advocating not merely art, pure and simple, as embellishing this vast city and charming the eye, but in striking deeper still, and exposing the crying evils of bad drainage, bad ventilation, bad buildings, especially as they affect the condition and happiness of the lower classes (and without these remedies mere beauty is but as a "whited sepulchre"), and should feel bound now to continue its efforts.

There will always be, alas! in a vast and ever-increasing city like this, overcrowded neighbourhoods, hotbeds of disease, where, if people keep alive, they still do so with a diminished vitality; and the only remedy possible,—the only possible antidote to the poison,—is pulling down the houses here and there, and forming open spaces, playgrounds, if I may call them so, in which adults and children can for the nonce get their lungs inflated with a purer air. From amongst the numerous letters on the subject which have appeared, I should like to quote one from the *Daily Telegraph*, bearing on the subject, and signed "Fieldfare"—

"As it seems to me impossible that a word can be said in favour of building upon the pleasant patch of isolated verdure on the northern hem of Paddington, I will leave the question you have so opportunely brought before the public to be solved, as I cannot but hope it will be, by wise counsellors. My purpose now is to edge in a plea for open spaces in general. Will you permit me, in a very few words, to submit a practical proposition? It is, that in all future extensions of the town a compulsory law shall provide for the inviolate reservation of a title of open ground for every hundred acres built upon. We have reached a certain danger, which can only be averted by some such plan as I suggest. Richmond, Twickenham, and other towns outside London, though threatened by its advancing strides, now begin to estimate the value of the old rustic green, happily preserved in their midst. So should it be, I contend, with every new suburb. Let the rapacity of builders be held in check by the Legislature. Compel every 'improving neighbourhood' to retain a village green proportioned to the acreage of streets and houses. There is no way but this out of the perils now besetting Londoners and their children."

But if such a harsh word as "rapacity" can be applied to builders, even their rapacity would in this case be short-sighted policy. The nearer to fresh air the more easily lethargic, the more likely they are to secure lucrative tenants. The architect, the builder, in these modern days, plays an ever-increasingly important rôle in the onward progress of civilisation and humanity. If a sound mind in a sound body be the highest earthly desideratum, so a fowl tenement lowers and debases a man's moral nature, whereas a clean and sweet abode has indubitably an influence in tending to make a man "live up to it." Overcrowding must always militate against a happy state of things; and that our forefathers were of this opinion is evident from the edicts issued in those cheery days of pretty rural England (1580), when one "paysed as for a lamb, 3d. for a pint of claret wine, and 4d. for a pecke of oysters;" those days of May-scented turf-lands, of quaint old rustic inns, when Bond-street and Conduit-street were so much country that my Lord Mayor Harper and aldermen hunted the hare, killed him, then to dinner at my Lord Mayor's banqueting-house (Stratford-place), then after dinner to hunt the fox, which, after much hallooing, they killed in St. Giles." Well, in those days the great queen, and her successor, James I. (1602), issued restrictive edicts for restraining the increase of buildings, and in 1657, during the Commonwealth, so necessary were open spaces thought to be that an Act was passed inflicting a penalty of 100l. upon every person who should erect any dwelling-house, out-house, or cottage without assigning four acres of ground to each respectively. Shade of Elizabeth! what would she say now?

In Paddington, there is crowded together a population (according to the census of 1881)

of 107,000, and according to a later computation, of 130,000 souls,—more than the whole population of Brighton,—and of the 244 municipal cities of the boroughs of England and Wales, there are only sixteen having a larger population than Paddington. If their park be taken from them they have no open space nearer than a mile and a quarter or mile and a half. The well-known sanitary reformer, Dr. Hardwicke, pointed out the absolute necessity of securing the 80 acres that yet remain from the encroachment of bricks and mortar. At one time they could have been secured for less money than is now demanded by the Ecclesiastical Commissioners, into whose hands the Paddington Park estate, once belonging to the see of London, has now passed, and is administered by them under two trustees, who have it on a ninety-nine years' lease, with power to let, but not to sell. To obviate this difficulty, a Bill was brought before Parliament, but not passed; a similar Bill, with certain clauses eradicated, is to be again brought before Parliament. Towards the 200,000l. necessary for the purchase of the park, the Metropolitan Board will give 80,000l.; 30,000l. is already raised in subscriptions (and this, it is calculated, will soon reach the sum of 50,000l.). But if the deficit of 70,000l. be not made up, the scheme must fall to the ground. More shame to London if it do; for it is not Paddington alone this question concerns, but London at large,—the wealthy even, whose lot has been cast in pleasant places, who have the large areas of Hyde Park, St. James's Park, and squares innumerable. Little by little their palatial residences have swallowed up the few spots left to the moderate incomes of the poorer gentry. But they would do well not to stand by and see the poorer still deprived of even that he hath. They little dream how neglect of the considerations urged may forge an arm that will strike with unerring aim through the triple panoply of indifference, of luxury, and wealth. For the pestilence that flies by night, that stalks abroad in the noonday, is held in such slight check on the borders of poverty, and in these days of rapid communication it can penetrate by such undreamt-of and indefeasible channels into the very strongholds of the high and mighty of the land, that if self-preservation be really held by some to be the first law of nature, that very consideration alone should bring moneyed and energetic recruits to that band of excellent gentlemen who act on the higher and diviner law, and who, like Alon Ben Adhem, in Leigh Hunt's beautiful poem, "Love their fellow men."

CARLEON.

## THE CRYSTAL PALACE ENGINEERING SCHOOL.

THE certificates gained by the students at this school during the summer term were distributed on Saturday by Sir James N. Douglass, Engineer-in-Chief to the Trinity House. In opening his address, Sir James expressed his satisfaction at finding the practical nature of the training at this school, for he held that real hard work was the foundation of success in the profession. He believed it to be the backbone of his own career. As an illustration of what he meant as real work, he alluded to a practice of this school which he thought admirable, viz., the making of a fictitious order for some part of an engine or other work, the design and construction of which were carried out from beginning to end by the students. The Civil Engineering students were engaged in such works as the preparation of plans for Parliament, the making of plans, calculations, and estimates for an imaginary railway and dock, and the actual survey of existing engineering works. He was particularly interested in the thorough nature of this training, and congratulated the principal of the school upon it. In the colonial section, where young men are prepared for life abroad, he was glad to find upon inquiry that the students were taught the use of the soldering-iron, for such tools must always be ready to the hand of the colonist. He had often been struck at the facile way in which the gipsies, with no tools other than a pair of pliers and a soldering-iron, made works both of use and beauty, and he failed to see why other people should not acquire the ability to do the same. At any rate, he would be well assured that this should be the case with his own sons.

The report, which was read by Mr. F. K. J. Shenton, showed very satisfactory work. The Lecture examination of the term has been on "Railway and Dock Work," and of twenty-one students eligible, sixteen have passed with success. The first places were obtained by A. J. Allen, G. C. Borton, and D. Allport, with 212, 196, and 184 marks respectively out of 277. The first places in the drawing-office were gained by F. E. Ross, D. Allport, and A. J. Allen; in the pattern-shop, by G. C. Borton, F. J. Piggott, and C. T. Spencer; and in the fitting-shop, by J. R. Pratt, J. A. W. Branton, and F. N. Dymond. In the second year's course, the civil engineering section, the chief honours were taken by R. P. Barnes, J. R. Crook, H. Skinner, E. S. Tiddeman, and A. H. Winfield. The good positions attained by the school was indicated by Mr. J. W. Wilson, the principal, who gave a recent case that had come under his notice.

In proposing a vote of thanks to the examiners of the term, Mr. James Clemenston, M.I.C.E., and Mr. W. Lawford, M.I.C.E., Mr. Shenton said that he attributed much of the success of the school to the great aid that had been given by eminent men in the profession.

The proceedings terminated with a vote of thanks to Sir J. N. Douglass, who said in reply that he could, on behalf of the council of the Institution of Civil Engineers, assure the directorate of the school and its pupils of the good feeling of that body to them, and of the readiness to aid they would always find in its members.

## COST OF ROAD WATERING IN SOUTH LONDON.

At a meeting of the Lambeth Vestry, held on the 10th inst., Mr. Dunkin, chairman of the special committee appointed on the question of road-watering, reported that they had fully considered the question which was referred to them by the vestry, as to the expediency of having the water for road-watering charged by meter for the future, and not by mileage, as at present. The present arrangement, the report stated, involved an annual payment of 1,550l., and an additional sum of about 135l. for the maintenance of stand-posts, to the Lambeth Waterworks Company; and to the Southwark and Vauxhall Company a yearly sum of about 880l. The committee caused negotiations to be opened with both companies as to the terms and conditions on which they would supply the vestry with water by meter. Both the companies expressed a dislike to the proposed arrangement, pointing out in their replies that in their judgment it would be better that the old arrangement of mileage rates should be continued. Eventually, however, the Lambeth Company offered to supply the water by meterage, for the lower districts, at rates varying from 8d. to 1s. 3d. per thousand gallons, and for the upper districts at rates varying from 1s. to 1s. 6d. In the case of each district, each stand-post was to be charged as a separate supply, 30s. each to be paid for fixing each meter. In the lower district, a minimum rate of 2l. 10s. per quarter, should the charge for water actually consumed not reach that sum; and in the upper district, a minimum rate of 3l. 15s. per quarter. As the vestry have in the lower district forty-eight stand-posts, and in the upper district forty-two stand-posts, this minimum rate alone would come to 1,110l. per year. The committee, in their negotiations with the Lambeth Waterworks Company, tried to get the company to treat the entire water consumed by the vestry as one supply, but this the company refused to do, and insisted upon the quarterly minimum for each stand-post. The negotiations with the Southwark and Vauxhall Waterworks Company resulted in their offering the vestry an arrangement precisely similar to the arrangement offered by the Lambeth Waterworks Company for the lower district; that was, at rates varying from 1s. 3d. to 8d. per thousand gallons, according to supply taken, each stand-post being treated as a separate supply, with a minimum of 2l. 10s. per quarter, which would give a minimum of 430l. per year for the Southwark and Vauxhall Waterworks Company, as there are forty-three stand-posts. The committee sought information from adjoining parishes, as to the terms on which they obtained water for road-watering. The general replies from the parishes stated that the alteration to meterage caused a saving to the parish, but it was believed

in all cases the former rates of mileage were greater than those paid in Lambeth. On referring to the special Acts of Parliament of the Lambeth Waterworks Company, there was no scale given for supply of water by meter, section 38 of the company's Act of 1848 only providing that water for other than domestic purposes may be supplied by agreement. On referring, however, to the Southwark and Vauxhall Waterworks Company's Act of 1852, it was found that by section 57 the company are bound, at the request of any owner or occupier of any premises situate in or adjoining any street in which any main or service pipe was laid, and who required a supply of water by measure for purposes other than the purpose in respect of which rates were by the Act provided or limited, to afford a supply of water, by meter or other fit and sufficient instrument, to be made for measuring and ascertaining the quantity of water so supplied, and the company might charge for such supply not exceeding the following rates, viz.:-Not exceeding 50,000 gallons, 9d. per 1,000 gallons; exceeding 50,000 and not exceeding 100,000, 8d. per 1,000 gallons; exceeding 100,000 and not exceeding 200,000 gallons, 7d. per 1,000 gallons; exceeding 200,000, 6d. per 1,000 gallons, with a minimum of 25,000 gallons per quarter, which would give a minimum of 18s. 9d. per quarter. The scale given by this section was much more favourable to the consumer than the scale offered by the Southwark and Vauxhall Water Company to the vestry, the scale of the section varying from 9d. to 6d. per 1,000 gallons, with a minimum of 18s. 9d. per quarter, whereas the scale offered by the company was from 1s. 3d. to 8d. per 1,000 gallons, with a minimum of 2l. 10s. per quarter. The scale as contained in the above section was pointed out to the company, and they had been asked to supply water for road purposes on the scale given in the section; but this the company had declined to accede to, and they insisted upon the higher scale before set out. Under these circumstances, the committee thought it right to be advised by counsel on the powers of the vestry to enforce an equitable arrangement by meter against the two companies, and a case was accordingly laid before Mr. Poland, and he had advised that, under the combined operation of the company's special Acts, the Waterworks Clauses Act, 1847, and the Railway Clauses Consolidation Act, 1845, the vestry could have the rates settled by a police magistrate, and they recommended that the clerk be authorised to instruct Mr. Poland to appear on the summons. Should the decision of the magistrate be in favour of the vestry, the committee then recommended that similar proceedings should be adopted against the Lambeth Waterworks Company.

Mr. Dunkin, in moving the adoption of the report, stated that the committee had experienced great difficulty in dealing with the water companies, who had shown considerable reticence in regard to the questions put to them. Of course the companies had a great objection to the proposed alteration, particularly in regard to the adoption of the meter system, which would tend to reduce the receipts of the companies from 3,000l. to about 1,000l. per annum, as far as the parish was concerned. The parish was at the present time assumed to be using 40 millions of gallons of water annually; but really there was no reliable record of the quantity consumed. The parish of Newington had lately adopted the meter system, with the result that the amount paid for watering the streets was reduced to something like 3800l. per annum. As a matter of fact, the cost of the water consumed by Newington was 13l. per mile, while Lambeth Vestry paid at the rate of 25l. per mile. If the vestry adopted this recommendation of the committee, they would, while reducing the cost of road-watering, really know what they paid for.

The report was adopted.

**Bristol Tramways.**—The directors have accepted the tender of Mr. A. Krauss, contractor, &c., Bristol, for laying the new double line between the city and suburb of Redland, about three miles and a quarter, of single tramway. Mr. Kincaid, of London, is the engineer for the same. The works will have to be commenced in six weeks, and finished within nine weeks from the commencement. The contractor (Mr. Krauss) is already well known in connexion with the lines constructed at Bristol, Bath, York, &c.

**STRAIGHTENING THE SPIRES OF THE ST. MARIENKIRCHE AT LUBECK.**

THE St. Marienkirche or Church of St. Mary is beyond question the finest of all the sacred edifices in the ancient Hanseatic port and free city of Lubeck. It was erected in 1304, and is built of brick in that particular Gothic style which is frequently met with on the shores of the Baltic. The church has three naves, the central one being of the unusual height of 127 ft. The two towers, which form so conspicuous a feature of the city, are no less than 407 ft. high. For some time past these have required new roofing, but before the work was commenced it was determined, after much discussion, to perform on them a preliminary operation of a somewhat hazardous and uncommon description. Every visitor to Lubeck will have noticed that the two spires are tilted very considerably out of the perpendicular. The height of the tower from the ground to the commencement of the spire is 130 ft., while to the top of the spire the distance is 217 ft. further, making the total elevation as above stated, 407 ft. The top of the southern spire has for years inclined to the south and west. The deviation from the perpendicular was 12 ft. towards the south and 9 ft. to the west. The rafter work dates from the year 1350. The operation which it was decided to attempt was to bring this spire into its original vertical position. Not a few professional men predicted that the result would be a disaster. However, it was remembered that in the year 1855 a Lubeck builder, Herr Albrecht Grube, had actually performed a straightening operation upon the leaning southern tower of the Lubeck Cathedral with perfect success, and accordingly the authorities were not to be deterred from attempting the same thing with the spires of the Marienkirche. The operations on the southern spire were commenced some time ago, and last week were completed with perfect success. They were carried out by a Lubeck carpenter, Herr Krause, under the direction of a Building Inspector of the city, Herr Schwiening, who promises to publish a detailed description of the method he adopted in executing the work. All that is at present known on this point is that the straightening of the spire was effected by help of a number of small iron screws. In consequence of this success it has been determined to proceed in like manner with the similarly leaning northern spire of St. Mary's.

**EXCAVATIONS AT LEWES.**

THE *Sussex Advertiser* announces that excavations of a highly-interesting character are now on the point of being undertaken in the grounds of the ancient Priory of St. Pancras, at Lewes, under the direction of Mr. Somers Clarke, jun., F.S.A., and under the local supervision of Mr. W. H. St. John Hope, of Cambridge, whose name is well known to antiquaries. The researches promise to be of national interest. The Priory of St. Pancras, founded by William de Warenne and Gundrada, is one of the most ancient specimens of Norman architecture in this kingdom. Considerable historical interest attaches to the building, partly on the ground that it is one of the very few houses of the Cluniac order once established in this county. The Cluniacs were noted for the splendour of their appointments, the magnificence of their churches, and the openness of their hospitality. The great Monastery of Clugny, in Burgundy, possessed a church which was exceeded in size by few, if any, in Europe. Its plan presented the unusual feature (in France) of eastern and central transepts; a plan we find in England, at Canterbury, Lincoln, Beverley, and several other places. It is evident that the great church at Lewes was planned in the same way. The foundations of the eastern portion of the great church, and also part of the chapter-house, were laid bare in the year 1847, at the time of the construction of the Brighton and Hastings Railway. The bones of the noble founders were also discovered. Since then nothing has been done. It is, however, sufficiently evident, from an examination of the remains, and a comparison with others of a somewhat similar nature, that beneath the surface must lie a large portion of the nave and choir of the church, together with the bases of the western towers; also the substructures of the dormitory, refectory, infirmary, and other important adjuncts con-

nected with a monastery of the first importance. A rough description, by Portenari, who superintended the demolition of the church in 1537, gives a list of the number of pillars and the dimensions of certain parts of the building. It is now intended to open up the rest of the ruins. The work will be watched with keen interest by archaeologists. Mr. Somers Clarke appeals for funds to enable him to carry out the undertaking. Considering the national importance of the excavations, such funds ought to be forthcoming from a wider area than the county which they immediately concern. The Society of Antiquaries and the Sussex Archaeological Society would probably help.

**THE GREAT INTERNATIONAL FISHERIES EXHIBITION, 1883.**

This exhibition, the preparations for which are now being vigorously pushed forward by influential and energetic general and executive committees, promises to be fully worthy of its title, as above set out. It has for its patron her Majesty the Queen, and for its president H.R.H. the Prince of Wales. The long list of distinguished and representative vice-presidents is headed by H.R.H. the Duke of Edinburgh, who, it need hardly be said, takes a special and active interest in the undertaking. The scope of the exhibition is wide, embracing as it does everything relating to the culture, preservation, capture, curing, transport, sale, and consumption of fish. In connexion with recent discussions as to fish-market accommodation in London and elsewhere, we have lately been assured that "the harvest of the sea" is practically unlimited; nevertheless, we know that fish is not always obtainable in the market at so cheap a rate as could be desired for so important a food-staple. The coming exhibition is eminently calculated to promote a better state of things in this respect, and therefore we need scarcely bespeak for it the best consideration of our readers.

The Exhibition will include, in Section I. of Class I., ships and boats of all kinds coming under the denomination of fishing craft (shown by models or otherwise); fishing gear, tackle, and appliances; models of harbours, piers, or slips for fishing purposes; appliances and methods for breaking the force of the sea at the entrances of harbours and elsewhere; methods of protecting submarine cables from injury by fishing operations; and a number of other matters connected with sea-fishing too numerous to mention here. Section II. of the same class is assigned to fresh-water fishing. Class II. will seek to illustrate the economic condition of fishermen, and will include models and plans of dwellings for those "toilers of the sea." Class III. will exemplify the commercial and economic aspects of fisheries and industries connected therewith, and will include models of fish-curing establishments, methods of preserving, packing, and cooking fish, and numerous illustrations of the industrial uses to which what may be called "residual products" can be put. An important division of this class will be that concerned with the sale and transport of fish, embracing as it will all kinds of appliances during transport or otherwise, together with models and plans of fish-markets and their accessories. Class IV. will be set apart for fish-culture, and will illustrate, partly by models and drawings, the varieties of fish hatching, breeding, and rearing establishments, with all apparatus and implements connected with the same. Class V. will be allotted to natural history; Class VI. to the history and literature of fishing, fishery laws, and fish commerce; while Class VII. will comprise loan collections coming within the scope of any of the foregoing classes.

It is proposed that the exhibition shall be opened on May 1st, 1883, in part of the Horticultural Gardens, South Kensington, and the surrounding International Exhibition Galleries. The exhibition is to remain open for not less than six months. There seems to be ample justification for the adoption of the word "International" as part of the title of the exhibition, for we learn that the Government of the United States, recognising the importance of the objects in view, has voted a fund of \$50,000 for the expenses of the American section of the exhibition, and has applied for a space of 10,000 square feet. The Government of the Netherlands and that of Norway and Sweden have also promised their earnest co-operation. From the

colonies, too, satisfactory replies have been received, especially from Canada and New Zealand, these colonial Governments having each already voted a grant in aid of the objects of the exhibition.

Conferences are proposed to be held for the purpose of reading and discussing papers or essays on subjects connected with the Exhibition, and a considerable number of money prizes are offered for prize essays on certain specified subjects. In addition to the gold, silver, and bronze medals and diplomas of honour which will be awarded to exhibitors, a large number of special money prizes will be given for specific objects. A list of these, as well as of the subjects for prize essays, together with the regulations to be observed by exhibitors, may be had by those interested on application to Mr. J. W. Mollett, Secretary to the Executive Committee of the Exhibition, 24, Haymarket. Mr. Mollett, it should be stated, has been appointed secretary in consequence of the resignation by Sir B. T. Branderth Gibbs of his executive functions as director and secretary, but the Executive Committee express their pleasure that they will have the benefit of his assistance and advice as one of the vice-presidents of the Exhibition.

#### FULHAM INFIRMARY.

At the last meeting of the Fulham Board of Guardians, a letter from the architects, Messrs. Giles & Gough, was read, stating that their plans would be ready next week, and asking whether they should be sent on to the Local Government Board before coming before the Guardians. It was decided that the plans should go at once to the Local Government Board.

Twenty-five applications were received for the post of quantity surveyor for the new building, including several from provincial surveyors. Messrs. Maughan & Cuxson offered to do the work for  $\frac{1}{2}$  per cent.; Messrs. Strudwick & Mennie for  $\frac{1}{4}$  per cent. (or a lump sum of 250*l.*); Mr. Wall, Mr. Withers, and others for  $\frac{1}{2}$  per cent.; Mr. Jackson, Mr. Davis, and others for 1 per cent.; and Mr. Hisben for  $\frac{1}{4}$  per cent. Most of the remainder did not name any rate. The Board, having resolved that the remuneration should be at the rate of not more than 1 per cent. of the value of the work selected for voting upon.—Mr. Jackson, Messrs. Lansdowne & Harris, Maughan & Cuxson, F. Miller, Quilter & Hardcastle, and Strudwick & Mennie. The choice ultimately fell upon Messrs. Quilter & Hardcastle, who were appointed subject to their agreeing to carry out the work at a charge not exceeding 1 per cent. upon the outlay.

#### ABERDEEN.

*Art Gallery.*—At a special general court of the president and governors of Robert Gordon's College, held on the 4th inst., the president—Lord Provost Eslemont,—made an official statement of procedure relating to the steps which are being taken for the establishment in Aberdeen of an art gallery and museum, observing that the Finance Committee of the Art Institution had got together a sum of 10,000*l.*, and that they considered themselves in a position to proceed with the erection of the building. The question was considered by the gentlemen present in an informal way, the result being that the governors resolved to communicate with the Museum Committee on the subject in order to ascertain whether they desired to find ground, and if so to what extent, upon the property belonging to the college.

*Proposed City Improvements.*—At the meeting of the Town Council on the 7th inst., Lord Provost Eslemont, who presided, moved that it be remitted to the Improvement and Finance Committees to consider and report as to the propriety of making application to Parliament in the ensuing session for a City Improvement Bill, also as to the improvements to be included in the scheme and the means of defraying the cost. In the Improvements Bill referred to it is embodied a scheme for a considerable extension of the city boundary, and for the construction of several new thoroughfares in different parts of Aberdeen. Provision is made for the construction of a wide street towards the Aberdeen Links, in direct line with Castle-street, at the junction of which with the Links it will verge into a roadway encompassing the present race-course, and leading by a drive to the north pier

on to Donmouth and Bridge of Don. This drive was suggested some five years ago by Sheriff Dove Wilson as part of a scheme of improvements laid before the St. Nicholas Association, as to whose objects we have informed our readers. The proposed carriage-way along the bank of the Dee, from the Suspension Bridge to the Allanvale Cemetery, is another feature of the scheme. It is also proposed to ask powers from Parliament for the widening of Schoolhill, and for the construction of a broad street carried on a viaduct to the northern end of Union-terrace. In submitting his motion, Lord Provost Eslemont said he thought no city that had gone on making good lines of thoroughfare had ever regretted doing so. At one time a considerable expense had been brought on the city by the carrying out of the magnificent scheme for the making of Union-street, which was constructed at a very great cost, but he was sure there was now no citizen who did not consider that it was the very best thing that could have been done. Other large towns had been moving in this direction of city improvements, and Aberdeen should not lag in the rear. Bailie Donald seconded the adoption of the motion, which was unanimously approved.

#### BUILDING PATENT RECORD.\*

##### APPLICATIONS FOR LETTERS PATENT.

- 3,713. W. H. Avis, Folgate. Folding seats. August 4, 1882.  
 3,737. B. J. B. Mills, London. Ceramic composition. (Com. by F. Gillet, Paris.) August 5, 1882.  
 3,741. A. Bonquic, Paris. Manufacture of bricks, tiles, pavings, &c. August 5, 1882.  
 3,749. A. M. Clark, London. Fabric for wall-hangings, &c. (Com. by A. Hutchinson, Paris.) August 5, 1882.  
 3,758. A. R. Harding & J. W. Harding, Leeds. Apparatus for the ventilation of railway carriages and buildings, &c. August 7, 1882.  
 3,775. J. C. Blomfield & J. McGurn, Fernmanagh. Manufacture of bricks, tiles, or slabs. August 8, 1882.  
 3,783. D. D. Healey, Brighouse. Asphaltic apparatus. August 9, 1882.  
 3,793. J. S. Willway, Bristol. Door mat and scraper combined. August 9, 1882.  
 3,811. C. H. Southall, Leeds. Apparatus for cleaning windows. August 10, 1882.  
 3,816. H. J. Haddan, London. Stoves. (Com. by D. M. Graham, Massachusetts, U.S.A.) August 10, 1882.  
 3,817. H. J. Haddan, London. Apparatus for securing doors and windows against burglars. (Com. by W. Kilian, Berlin.) August 10, 1882.

##### NOTICES TO PROCEED

have been given by the following applicants on the dates named:—

- August 8, 1882.  
 1,652. J. J. Wheeler, London. Curbs of roads and footpaths. April 5, 1882.  
 1,655. H. Conolly, London. Waterclosets. April 5, 1882.  
 August 11, 1882.  
 1,695. C. H. T. Beamish, Queensdown. Construction of breakwaters, retaining-walls, &c. April 8, 1882.  
 3,353. G. Dalton, Leeds. Brick-making machinery. July 14, 1882.

##### ABRIDGMENTS OF SPECIFICATIONS.

Published during the Week ending August 12, 1882.

- 5,725. M. B. Nairn, Kirkcaldy. Manufacture of linoleum.  
 This machine automatically mixes the cement and ground cork in specified proportions. Dec. 30, 1881. Price 6*d.*  
 5,747. A. M. Clack, London. Roofs and coverings for protection of buildings in course of construction, &c. (Com. by A. C. de Barbaran, Paris.)  
 Light vertical iron stanchions are erected outside the walls, so made that as the wall is raised the stanchions can be lengthened. These support a roof which travels in guides on the stanchions, and is raised by chains as required. The stanchions can be clamped to the walls to support them. Dec. 31, 1881. Price 8*d.*  
 30. W. W. Hughes, London. Fire-grates.  
 The basket has bars all round, and an air-flue is formed round the back and sides to support combustion. (Pro. Pra.) Jan. 3, 1882. Price 2*d.*  
 33. S. L. Hunt, London. Street-cleaning and sweeping apparatus.  
 This consists of a horizontal cylinder from which a sep-

ment is cut on one of the surfaces of which is a metal plate and on the other an india-rubber plate. These are brought to bear on the ground as required. Jan. 3, 1882. Price 4*d.*

42. E. G. Lakeman, Modbury. Stoves and furnaces.

The products of combustion are conveyed from the fire through a flue which passes down outside the stove, and up again through the fire. The flue is here perforated and the smoke, &c., is consumed. Jan. 4, 1882. Price 6*d.*

54. J. Wetton, Abergavenny. Chimney-pot.

This consists of two cylinders, the internal one forming the smoke-flue. The outer cylinder is longer than the other, and is raised a little at its base so that a current of air is induced upwards into the space between the two cylinders. (Pro. Pra.) Jan. 5, 1882. Price 2*d.*

76. J. H. Johnson, London. Domestic fire-places. (Com. by M. Perrot, Paris.)

These consume anthracite coal. The back and sides are solid, and a loose slab is arranged in close proximity to the upper surface of the fuel, leaving only a narrow slit in the fore part of the fire-place for the escape of gas to the chimney. This slab can be raised or lowered as required. The upper part of the front of the grate is closed by a mantle. Jan. 6, 1882. Price 6*d.*

81. J. L. Forham, London. Preparation of materials for facilitating the preparation of whitewash and distemper.

The materials are size, glue, gelatine, and whiting, which are mixed in a powdered state, and can be made ready for use by adding water. Jan. 6, 1882. Price 4*d.*

96. S. Collett, Willenhall. Lock and latch spindles.

To enable the spindle to be used for doors of different thicknesses, both ends have threaded angles, and when the handles are screwed on, a screw passes through the handle, and the spindle into the opposite side of the handle. (Pro. Pra.) Jan. 7, 1882. Price 2*d.*

112. H. J. Haddan, London. Apparatus for making bricks. (Com. by L. Jäger, Ehrenfeld, Cöln, Germany.)

This machine is actuated by hand power. Three boxes are arranged radially round a vertical post, and a long lever presses the brick in one box while it lifts a brick out of the second. At the same time the third box is being filled. The lever is then lifted, and the form turned round by hand, bringing another brick to be pressed. (Pro. Pra.) Jan. 9, 1882. Price 2*d.*

121. A. C. Engert, Bromley-by-Bow. Stoves or fire-grates.

The fuel-holder is in form of half a barrel divided longitudinally, and is mounted on pivots so that it can turn on a horizontal axis. Bars are placed in front of the grate. The holder is completely filled with fuel which is ignited at the front, and as the fuel burns away, the fuel-holder can be turned. Jan. 9, 1882. Price 4*d.*

209. T. R. Shelley, Smethwick. Glazing greenhouses, conservatories, &c.

The glazing bar has a middle vertical web rising above the glass. In the lower supporting webs are grooves for receiving vulcanite or other packing, on which the sheets of glass rest. Loose stops are passed through the web and can be turned down to hold the glass. Jan. 11, 1882. Price 1*0s.*

#### THE GERMAN BRICK-MAKING INDUSTRY.

OVER-PRODUCTION of bricks has been a source of complaint amongst the brickmakers in the neighbourhood of Berlin, and a meeting was held some weeks ago to devise a remedy for this acknowledged evil. General approval was expressed of the suggestion made that the cessation of work for the season should take place on September 15th, being one month earlier than usual. By this means the equilibrium of demand and supply might be restored, it was considered. A committee was appointed to deal with the question in detail, and to report to another general meeting of the trade to be held at an early date.

#### PRIZES FOR ARCHITECTS.

Sir,—I think the following is worthy of a space in your miscellanea as a companion advertisement to that of the Guardians of the Kidderminster Union. In my opinion (if anything) it surpasses in audacity and cool impudence anything yet published. And (as you put it) this conduct can only be justified by the fact that the invitation has been responded to.

The building for which plans are invited will cost at least 2,000*l.*

THOMAS KISSACK.

#### "TO ARCHITECTS."

THE Guardians of the Omskirk Union are desirous of receiving COMPETITION PLANS for buildings to be used as Vagrant Wards, Relief Offices, and Dwellings for Officers.

First prize, 5*l.* 5*s.*; second prize, 2*l.* 12*s.* 6*d.*

All the plans sent in to become the property of the Guardians. The ground plan may be seen and further information on application to No. 3, Sefton-street, Bolton.

Plans to be delivered on or before the 1st AUGUST next, at 53, Sefton-street, Airedale.

WILLIAM PARR,  
 Clerk to the Guardians.

\* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street.

THE HYDE PARK CORNER IMPROVEMENT SCHEME.

In the House of Commons on Saturday last, on the resolution authorising the vote for the Royal Parks and Pleasure-grounds,

Lord Elcho said that this vote of 3,000*l.*, though it came under the general head of Royal Parks, was practically for the removal of the reservoir at the west end of Constitution-hill as part of the plan for the improvement of Hyde Park Corner. The question was where the reservoir was now to be placed, and until the House knew that it would be sanctioning a vote of which it did not know the meaning, he believed it was intended to place it in Hyde Park, where for a long time to come, until it was covered by trees, it would necessarily be a most unsightly object.

Mr. Shaw-Lefevre said that it was intended to remove the reservoir to Hyde Park, but the actual spot was not yet settled.

Lord Elcho said that was exactly the fault that he found with the proceedings of the Government. The whole plan should have been settled and explained to the House before the vote was asked for; but, as things were, the House was called upon to sanction a plan without an opportunity of considering it. As far as he could judge, the proposal of the right hon. gentleman would fail to diminish the plethora of traffic at Hyde Park Corner, would disfigure rather than embellish that part of the metropolis, and, if it did not succeed, would do irreparable damage. The stoppages in the traffic were at Hamilton-terrace and at Hyde Park Corner. The plan of the First Commissioner left the width of Piccadilly from Park-lane to the Corner the same as now, therefore the congestion would not be relieved at all. But after he had gone to the expense of a model and of plans, and had got the promise of 20,000*l.* from the Metropolitan Board of Works, and of 3,000*l.* from the Duke of Westminster, he amended his plan. When he had done all, he did not meet the block that had to be dealt with. He had to go to the Board of Works to ask them to widen his plan, thus confessing an oversight on the most important point. The Council of the Royal Institute of British Architects had considered the First Commissioner's model and plan, and they pointed out that there was no indication of an increase of width at Hamilton-place. Although he had since proposed to widen Piccadilly, the extra width would only be that of a footpath, and this was quite inadequate. But even his amended plan would not meet the difficulty. He ventured to call the attention of members to what he denominated a rival revival of earlier plans, and, as the right hon. gentleman would not allow it to be exhibited along with his own, he had obtained permission to place it in the cloak-room, where lithographed copies might be obtained. This combination of plans was to be found in the office of the First Commissioner. If it were tried and failed, there was nothing in it to prevent the ultimate adoption of the right hon. gentleman's plan. It divided itself into two parts. On the north of Piccadilly there would be a new road in the park from Stanhope-gate to the Corner, and the present road, with a new opening into Park-lane, would be made a street outside the park. South of Piccadilly from Hamilton-place a new road would be made to Grosvenor-place, and at the intersection of Constitution-hill there would be a bridge. A temporary bridge might be constructed for a trial, and the permanent structure might be made as ornamental as possible. This plan would leave the reservoir and the Arch untouched, and it would relieve both Hamilton-place and Hyde Park Corner, giving a continuous route to traffic from the north to Victoria Station and the East. The plan he recommended could be an ornamental one, and would greatly facilitate traffic. By it the Duke of Wellington's arch would remain untouched, and the hospital would not be interfered with.

Mr. Shaw-Lefevre said that the removal of the reservoir had long been considered desirable, it supplied the public offices with water, and it was expedient to increase the pressure of water by removing it to a higher point in Hyde Park. It would not be a disfiguring object, as it would be almost wholly concealed from sight. With respect to the main part of the scheme, he must remind the House that this subject had exercised the minds of successive Commissioners and of the House for many years past. When it

became his duty to deal with it, he had come to the conclusion that that which he proposed was at once the boldest and the most certain to afford a remedy, and the most likely to obtain the various consents. The essential feature of that plan was the cutting off the corner of the Green Park in a line from Hamilton-place to Halkin-street, and the promotion of an open place in which as many roads could be made as would properly distribute the traffic and remove the block. It was one condition of the plan that the Wellington Arch should be removed from its present position to the point at which Constitution-hill in future would meet the open place, about 100 yards to the south of its present situation, where it would form the royal entrance to the Green Park. It was said by some that the general features of the scheme could be carried out without the removal of the arch. That was not so, first, because if the arch were left where it was, it would not be possible to widen the upper part of Grosvenor-place, and without this widening the block could not be removed; and secondly, because, if left in its present position, the gradients or other conditions would require that the road between the two parks should not pass under the arch, but round one side of it, and through one of the side gates into Hyde Park, and thus all the dignity of the approach and the meaning of the arch would be lost. The noble lord had objected that the arch in its new position would not be square with the gateway to Hyde Park and to other buildings. This was true; it would be at right angles to Constitution-hill, but would not be parallel or at right angles to other buildings. This might be a serious defect if it were at all near to other buildings, but it would be at a considerable distance, and would no longer be a part of the group of arches at the entrance of Hyde Park. He had very high artistic authority for saying that the effect would not be bad, but, on the contrary, decidedly good. The word asked was a formidable one, but there was no canon of art against buildings being asked to one another; on the contrary, the greatest artists in architecture the world had known, — namely, the Greeks, — were of an opposite opinion; they rather avoided placing buildings at right angles or parallel to one another, and in the Acropolis he need hardly remind hon. members that the group of buildings the most celebrated in the world were purposely not placed at right angles or parallel to one another. The noble lord had called to aid the Institute of Architects, and had claimed that they had condemned the official plan. It was true that some days ago the council of that Institute came as a deputation to him and presented to him an alternative plan prepared by their secretary. They told him, however, that they were not united on the subject, and he had no difficulty in proving to them that there were more serious objections to the plan of their secretary, and they left him under the impression that the majority of them were convinced. They subsequently sent a deputation to the Metropolitan Board with another plan, but this again was open to other objections, and the Board unanimously declined to adopt it. The noble lord seemed to think it a serious matter that the Institute of Architects should express an opinion. He could not, however, accept their council as an arbiter in such matters. Till the present time, the Institute had never undertaken to advise the Government or the public in such questions. But, though he had not consulted the Institute of Architects in its collective capacity, he did not adopt this scheme without taking advice from a great number of persons well qualified to give opinion. He did not hesitate to say that it had been approved of by the great bulk of persons who were qualified, — by such men as the late Mr. Street, Mr. Waterhouse, Mr. Ferguson, the well-known writer on architecture, Mr. Holford, and numerous others. It had also been approved by her Majesty the Queen, who had been graciously pleased to give up a small part of the garden of Buckingham Palace. It had also been approved by the Metropolitan Board, who find the main portion of the money, and by the public Press generally. He, therefore, ventured to hope the House would not support the noble lord in his desire to postpone the scheme. It was his conviction that if this plan were postponed no other alternative would be more fortunate or more acceptable, and the only result would be that the difficulty would remain for an indefinite period unsolved and without a remedy.

Mr. Craig approved the plan of the First Commissioner of Works.

Mr. Poddie thought that, as far as the question of relieving traffic was concerned, the plan of the noble lord was the better of the two. His chief objection to the Chief Commissioner's plan was that the place which it would create would be cut up into too many small plots and gardens. The plan, however, might by some modifications be made much more acceptable.

Mr. Warton urged that further time should be allowed to consider this matter. There was no reason why the Chief Commissioner should press the matter on now.

The resolution was agreed to.

In the House of Lords on Tuesday, The Marquis of Ailsbury asked her Majesty's Government whether it was seriously intended to carry into effect the alterations proposed by her Majesty's First Commissioner of Works at Hyde Park Corner; and, if so, when those alterations might be expected to be commenced.

The Earl of Milltown said that he desired to supplement the question of the noble marquis by asking whether, in the event of these proposed improvements being effected, the Government would avail themselves of the opportunity thus afforded to throw open the roadway down Constitution-hill to the public.

Lord Sudeley said that he had to state that immediately the vote was passed by the other House steps were at once taken to commence carrying out the great improvement at Hyde Park Corner. The first thing that had to be done was to remove the reservoir from its present position to a suitable place in Hyde Park; and tenders had already been invited for carrying this out. The First Commissioner had not yet decided whether the arch could be moved in one block on rollers, or whether it would be necessary to pull it down and rebuild it, but it was hoped that this matter would be settled in a few days. The Government hoped that the cutting off the corner of the Green Park would entirely remove the congestion of traffic which had for so long been a standing nuisance to that part of the metropolis, and they believed that, of the numerous schemes which had been suggested, this formation of a large place would be the boldest and happiest solution of a somewhat difficult problem. It was not proposed at present to open Constitution-hill to the public. The question had not been under consideration.

The Duke of Cambridge said that he was very glad that what was now proposed was to be carried out; but he was convinced that the block in the traffic at Hyde Park Corner would never be got rid of until a subway had been made from Hamilton-place, under Piccadilly, to Grosvenor-place.

The Earl of Redesdale asked whether it would not be possible to place the statue of the Duke of Wellington on a pedestal opposite to Apsley House.

Lord Sudeley said that the First Commissioner had received a great many representations respecting what should be done with the statue of the Duke of Wellington. Among many conflicting opinions, he has not yet decided what would be best to be done; but, if the arch were obliged to be pulled down, then he would take care that experiments were made to see how the Duke would look on a pedestal in the middle of the proposed "place" or similar position. If the arch were not pulled down, but were rolled into its new position without having to take down the statue, then it was probable it would be better to leave it alone. The matter was, however, still under consideration.

THOMAS EDWARDS, ARCHITECT.

SIR, — In reply to a recent communication of mine, which you were good enough to insert in the *Builder*, I have now the pleasure of stating that I am indebted to the courtesy of Mr. Thos. Ferris, of Rosewyn, Truro, for the information that Thomas Edwards was an architect from London, who built one or two mansions in Cornwall, including Tehidy, the seat of the Bassetts, in the early part of the last century, and the fine house once belonging to Mr. Wm. Lemon, in Prince's-street, Truro. He was also the architect of the very indifferent spire and west front of St. Mary's Church, Truro, now removed to make room for the new cathedral there. It may interest some of your readers to know the foregoing.

WALTER H. TREGELLAS.

## THE ANCIENT MONUMENTS BILL.

In the House of Commons, on Tuesday, on the motion for going into Committee on this Bill,

Mr. Beresford Hope said he trusted this was the last time when the memorable words "Ancient Monuments Bill" would be in the paper. He congratulated his hon. friend the member for the University of London on his great success. For years he had fought by the side of his hon. friend. There was a great deal of misunderstanding about the Bill. He thought the most ridiculous of all arguments raised against it was that it was a destructive measure ever brought before Parliament. It would preserve monuments of immense value from the effects of willful ignorance and selfishness. The Bill had made its way slowly, but surely, and he was sure that when it was put in the Statute-book it would be hailed with satisfaction.

The motion was then agreed to, and the House went into Committee on the Bill.

Clause 1 was passed. On Clause 2, Mr. Shaw-Lefevre moved to add an amendment to the end, providing that the cost of the maintenance of ancient monuments should, subject to the approval of Her Majesty's Treasury, be defrayed out of moneys provided by Parliament. The amendment was agreed to, and the clause was added to the Bill.

On Clause 3, Mr. Shaw-Lefevre moved an amendment empowering the First Commissioner of Works, with the consent of the Treasury, to purchase out of moneys to be provided by Parliament any of the ancient monuments to which the Bill applied. The amendment was made, and Clause 3, as amended, was agreed to.

Clause 4 was added to the Bill, and Clause 5 was struck out. Clauses 6 and 7 were agreed to without amendment. Clauses 8 and 9 were amended and added to the Bill.

Mr. Shaw-Lefevre then brought in a new clause in place of Clause 5, and providing for the appointment of an Inspector of Ancient Monuments. The new clause was added to the Bill.

Sir J. Lubbock moved a new clause, authorising the Crown, by Order in Council, to apply the Act to any other monument of the same character as those in the schedule. The schedule, he said, was adopted from his Bill, and had been carefully drawn up by very high authorities. But it was only typical; it never pretended to be a complete list. A power of addition had always been contemplated, and his right hon. friend had kindly intimated to him that he would accept the clause.

Mr. Shaw-Lefevre said that he quite approved the new clause. It only applied to monuments of a "like character" to those in the schedule to the Bill.

The new clause was added to the Bill. On the schedule, Sir J. Lubbock moved an amendment, standing in the name of the hon. member for Donegal, to include in the schedule the earthen and stone enclosure known as "Grianan of Ailbhe," in the parish of Burt and barony of West Innishowen, county Donegal. The amendment was agreed to, and the schedule was passed.

The Bill, as amended, was reported to the House, and was then read a third time and passed.

## TREATMENT OF ARCHITECTS.

Sir,—I wish to bring before you notice the following facts (for what they are worth), if you care to make use of them, acting only with a view to the benefit of my profession.

It is the old story. A few weeks ago a competition was announced in your paper for a new club at Bury St. Edmund's, with the usual invitation to compete, and stating that plan of site and instructions could be obtained by applying to the secretary.

This advertisement was not contained in the following week's *Builder*, and, after application having been made more than once for the said instructions, would-be competitors were informed that, owing to the number of applications made, the competition had fallen through, or words to this effect. It since turns out that an Ipswich architect has been introduced by a "young" member of the committee, and who has straight off appointed him as architect.

I have merely to observe,—and perhaps you will agree with me,—that I think this mode of

proceeding not creditable. These gentlemen have not only made use of your paper for no purpose, but have deceived architects generally. M.

## LABOUR IN AUSTRALIA.

The following is an extract of a letter from Nolyambo, New South Wales, dated June 11th, 1882. May I advise "Ours not Blessed with Incumbrances" to go to Australia? E. SCOTT.

"We want people at home to be better informed as to the resources of these colonies, and to be impressed with the fact that there is a good field for any amount of capital. And another thing we want is the stoppage of your present plan of shipping your 'de'er-do-waels' out here; they are of no use to the colonies, and only go to the dogs at an increased pace. And another point people at home must learn is that this is by no means an El Dorado, where any fellow with a good education and *nothing else* can at once make his way. Send us good steady skilled operatives in thousands, but keep your surplus 'gentlemen' at home, or rather, make them mechanics and then send them out here prepared to work with their physical powers. But men with education only and no capital are at a large discount, and every steamer makes the discount larger. We want good labourers and mechanics."

## RAILWAY FARES.

Sir,—Apropos to and in illustration of your remarks on railway fares and cost of passenger transit being dependent upon long running with few stoppages, and *vice versa*, I may mention that Messrs. Cook advertised an excursion by the Midland, from Birmingham to Scarborough and back for 5s. on Bank Holiday, a distance of 173 miles each way, or 346 miles in all, or at the rate of six miles a penny nearly. The journey out was performed in six hours, or one hour under express time, and the return journey in seven hours,—including a stoppage of nearly an hour close home on account of insufficient accommodation at the station, and consequent crowding of trains,—and without a hitch; 2,500 persons availed themselves of the opportunity of spending ten or eleven hours on the sea-coast on that occasion, and I doubt not at a considerable profit to their health and to the pockets of the promoters. I can answer for one.

E. GRIMES.

## BUILDING CONSTRUCTION.

Sir,—Walking out the other day, "our custom of an afternoon," we found ourselves on the outskirts of the Regent's Park, and at a garden gate we observed a curious pair of plasterers or piers, "for each seemed either." They were of that chocolate colour now so common, which gives the spectator a pleasing doubt whether the material intended is wood, stone, marble, or what else in nature or art; and upon a second glance we noted a peculiar unevenness of surface. Going near to examine, and sounding them, we found that these piers were encased with zinc, somewhat warping in the sun, and having their exteriors painted in the aforesaid chocolate with good oil and lead colour. This new form of building construction may be a hint to many, and, if duly developed, may cause this century in future times to be known as the "age of zinc," although it has been suggested in view of the present great trade in imported provisions that tin may dispute the honour. H. & R. FOWELL.

NEW WORKHOUSE BUILDINGS,  
ST. PANCRAS.

The Board of Guardians having intimated that they would themselves appoint the quantity surveyor, the Workhouse Accommodation Committee met on the 8th inst., and, after considering the qualifications and standing of the applicants (about twelve in number), selected the three following firms as fully entitled to the confidence of the Board, viz., Messrs. Mangban & Coxson, Messrs. Sandall, Corderoy, & Farthing, and Messrs. Stoner & Sons, the votes obtained by each firm being nine, eight, and seven respectively.

The Committee's report was presented to the Board on the 10th inst., when Messrs. Sandall, Corderoy, & Farthing were appointed. The total outlay contemplated is about 100,000*l.*, and the surveyor's charge allowed by the Board is  $1\frac{1}{2}$  per cent.

## CHURCH-BUILDING NEWS.

Kennington.—Mr. W. Grantham, M.P., recently laid the foundation-stone of a new mission church in Pilgrim-street, Upper Kennington-lane. The building, which will accommodate between 400 and 500 people, is intended to supplement the ministerial work carried on in the parish of St. Mark's, Kennington, by the Rev. Mr. Montgomery, the vicar, and the Rev. Tilden Smith, his curate. A freehold site has been secured adjoining the gas-works, and the cost of the building, inclusive of the price of the land, will be about 1,800*l.* The building will be composed of red bricks and picked stocks. It will comprise a vestry and two class-rooms,—the latter being capable, when occasion demands, of being thrown open so as to augment the accommodation of the chief room, which will be 55 ft. 6 in. in length by 23 ft. broad. The architect is Mr. W. H. Harrison, the builders are Messrs. Andrew & Nanson, of Brixton, and Mr. Handley is clerk of the works.

Worthing.—The foundation-stone of a new church at Worthing, to be called Holy Trinity Church, was laid on the 10th inst. in the presence of a large number of spectators, by Mrs. Loder, wife of Mr. R. Loder, M.P. The church will be erected of red brickwork, both inside and out, with Bath stone dressings, and red tile roof; it is to be in the Early English style, and will have a tower and spire as soon as funds will allow of its entire completion. The dimensions of the church are as follow:—the length of the nave is 69 ft. 2 in., inside measurement; chancel, 28 ft. 5 in. long; width of church, inside, from aisle to aisle, 60 ft.; and the height from the apex of the main roof to the floor line is 48 ft. The architects are Messrs. Coe & Robinson, 4, Furnival's Inn, London; the builder is Mr. Peters, of Horsham; Mr. S. R. Smith, A.R.I.B.A., is acting as clerk of the works.

Sedgley.—On the 8th inst. the foundation-stone of the new chancel for the Church of St. Mary the Virgin was laid by Mr. Alfred Hickman. The church has been built about twelve years, a temporary erection having been used for a chancel. On the north side of the chancel space is left for an organ-chamber, and on the south side for two vestries. At present only the chancel is being proceeded with, and this will afford space for eighty sittings. The erection will be in keeping with the church, of red bricks, faced with Gornal stone. At the east end there will be a tracery window erected at a height which will allow of a handsome reredos being placed below it. The work is being done by Messrs. J. Jones & Son, Sedgley, from plans by Mr. T. H. Fleming, Wolverhampton. The total cost of the chancel will be 800*l.*

## VARIORUM.

"A HANDBOOK OF THE INDUSTRIES OF THE BRITISH ISLES AND THE UNITED STATES," by G. Phillips Bevan, F.G.S. (Bogue), though a small book, treats clearly a large subject. The object of the work is to explain in simple language the resources and industries of each country together with the physical and geographical causes that have led to their existence. Mr. Bevan is a practiced writer, and has his subject well in hand.—"Sanitary Houses and How to select One," by F. A. Bond, M.B. Edin. Univ. (Kegan Paul & Co.), is clearly written, but very slight. After all that has been said and written on the subject, so superficial and slight an essay should not be necessary; however, as there are possibly still persons to whom it may serve as a first awakener we willingly recommend it as well adapted for that purpose. We have been saying the same things as will be found in the pamphlet for these thirty years and more, and cannot have too many assistants in the good work.—*Nature* is a weekly illustrated journal of science (Macmillan & Co.), and those who read it regularly will find themselves acquainted with all that is new in science. It well deserves the position it has attained.—*Knowledge*, conducted by R. A. Proctor (Wymans), goes on agreeably and well. Those who supposed at its starting that "stars" would too greatly prevail have ceased to think so. Everything is touched in turn, and touched with knowledge. When we find the editor quietly replying to a correspondent, "I fear it would be difficult to prove that diamonds are condensed comets," we have a good indication of his patience.—Harper's new *Month*

includes under the title "Lying in State in Cairo," a full and illustrated account of the recent wonderful discovery of royal mummies and their deposition in the Museum at Boulak. Let us hope that the scoundrel Arabi, with his army, may not get into Cairo, or we may have reason to regret that the discovery was made so soon.

Miscellaneous.

**Electric Light Speculation: a Dividend of 100 per cent.**—An extraordinary general meeting of the shareholders of the Anglo-American Brush Electric Light Company was held on the 10th inst. at the City Terminus Hotel, Sir H. Tyler presiding, for the purpose of confirming a resolution passed on the 18th of July, altering the articles of association, and providing that "The directors may from time to time, of their own authority, pay to the members, in proportion to the amount paid up, or credited as paid up, on the shares held by them respectively, such bonus and such interim dividends as in the judgment of the directors the position of the corporation justifies." The Chairman formally moved that the resolution be confirmed, and said its object was simply to enable the directors to distribute the sum of 245,000*l.*, which they held at the disposal of the shareholders, and for which warrants had been prepared. That sum would furnish them with the very satisfactory interim dividend of 100 per cent. upon all they had subscribed in the undertaking. Mr. Seldon seconded the resolution. Mr. Hammond hoped the chairman would give the shareholders an assurance that there was no foundation for the statement that the company had made no profit on its manufacturing business, and that its only source of obtaining money was by the sale of sub-concessions. The chairman said that a rough balance-sheet had been prepared, and it was found by that means that there was a profit on their manufacturing business during the first six months of the year of 30,000*l.* He regretted the amount of speculation which had taken place with regard to the sub-concessions. There had been too much speculation going on, and too little real manufacturing work performed. The shares of the company, he also thought, had risen to a higher price than was justifiable. The directors could not control the speculation which was going on, but he would not encourage it by making any prophecy as to the future of the company. The resolution was agreed to.

**Art-Union of London.**—The pictures selected by prize-holders of the Art-Union of London this year have been placed on exhibition in the galleries of the association, at 112, Strand. There are seventy-one oil-paintings and seven-teen water-colours purchased with prizes ranging from 10*l.* to 100*l.* from nine exhibitions,—namely, those of the Royal Academy, the Royal Hibernian Academy, the Royal Scottish Academy, the Society of British Arts, the Grosvenor Gallery, the Royal Society of Painters in Water-Colours, the Institute of Painters in Water-Colours, the Royal Albert Hall, and the Society of Lady Artists. The choice of the prize-winners who have selected these works for themselves has fallen for the most part on sunny landscapes and domestic scenes, the collection including one or two excellent delineations of life on the Thames. The exhibition, which is free on presentation of address-card, will remain open until September 2nd. The print for the current year,—"*Stolen by Gipsies: the Rescue*,"—is an excellent specimen (engraved by Messrs. J. H. Jeens & Lumb Stocks, R.A.) of the work of Mr. J. B. Burgess, A.R.A. It will, no doubt, prove very popular. The cost of producing it, moreover, will be so much less than was that of the series of prints given last year, that a much larger amount will, of course, be available for the purchase of pictures.

**The new Thoroughfare between Charing-cross and Oxford-street.**—Steps have already been taken for making, at all events, a beginning of this long-needed public improvement. The materials of about forty houses about Newport-market having lately been sold by Messrs. Eversfield & Home, the structures themselves are in process of demolition, and in the course of another month a large portion of the following streets will have disappeared—Newport-court, Little Newport-street, Market-street, Market-street, Prince's-row, Lichfield-street, Hayes-court, and Grafton-street.

**North of England Institute of Mining and Mechanical Engineers.**—The annual meeting of members was held in the Wood Memorial Hall, Newcastle, on the 5th inst., the president, Mr. G. B. Forster, in the chair. The secretary, Mr. Binning, read the annual report of the finance committee, which stated that the finances of the Institute are in a very satisfactory condition. He next read the annual report of the council, which stated that the thirtieth year of the Institute has been one of uniform prosperity, the progress made has been of a permanent and solid nature, showing that the Institute is becoming more and more secured against the fluctuations of the funds derived from subscriptions. There have been many valuable additions to the library, and exchanges have been made with a great number of foreign societies. This has been done to such an extent that few, if any, libraries out of London are in possession of such valuable information respecting the progress of mining science in all countries, and this has enabled the council to publish extracts and translations from such foreign papers as seemed to deserve particular attention, which will materially add to the interest of the transactions. In this the council have been assisted by Professor Lebour, who has devoted much time and attention to this department.

**Steam Wheels.**—A new kind of steam-engine has been recently patented in Austria by Professor Wellner, of Brünn. The so-called steam-wheel (according to the account in the *Polytechnischer Journal*) consists of a simple water-wheel, mostly immersed in hot water in a closed vessel. Steam is admitted at the lower part, and forces the coils of the wheel upward, producing rotation. The steam fills more and more of the cells on the rising side, and at length begins to escape into the steam space above the water. Steam may either be produced directly at the lower part or conducted to the vessel from elsewhere. The upper tube for outlet of steam may lead either into the open air or into a condenser. The mechanical work consists in the ascent of the specifically lighter steam in the heavier liquid. These steam-wheels may either be used as independent motors or in connexion with ordinary steam-engines; in the latter case the escape steam of one kind of machine is utilised for the other.

**The World's Production of Lead in 1881.**—Herr Landsberg, the general manager of the Stolberg Company, has, in an annual report to his company, given an estimate of the production of lead in Europe for 1881. The following is Herr Landsberg's estimate for Europe:—Spain, 120,000 metric tons; Germany, 90,000; England, 67,000; France, 15,000; Italy, 10,000; Greece, 9,000; Belgium, 8,000; Austria, 6,000; Russia, 1,500; total, 325,500. Herr Landsberg estimates the production of the United States at 110,000 tons. As the output of Mexico, South America, Canada, and Australia is small, it is probably safe to assume that the world's production is about 440,000 tons of lead. This does not include China, which is a heavy consumer of lead, and is not unlikely a producer of some importance; nor does it include Japan, of whose output we have no figures. It will be seen, therefore, that the United States takes second rank among the lead-producing countries of the world.

**Iron Age.**  
**Light.**—An installation of fifty "Swan" incandescent lamps has just been completed at No. 279, Edgware-road, for Mr. Bowron, provision merchant, who expects to save a great deal from the use of those lights, owing to the absence of heat, which, before these lights were used, caused a great amount of damage. The work has been carried out by Messrs. Edmundson & Co., 19, Great George-street, Westminster, who are also engaged in several much larger installations for several country mansions, where the absence of heat and smoke is also expected to effect a considerable saving.

**Cramlington.**—Extensive additions and alterations are being made to the Blue Bell Hotel, Cramlington, for Sir Mathew White Ridley, bart., M.P., from the designs and under the superintendance of Mr. J. J. Lish, architect, Newcastle-upon-Tyne.

**Timber Burnt at Archangel.**—Lloyd's agent at Archangel, writing under date of the 31st of July, states that a large fire occurred on the 18th of July on the timber premises of Messrs. E. H. Brandt & Co., and destroyed all their deal-yards, worth about 30,000*l.*

**Exhibition and Competitions at Ghent.**—The *Chambre Syndicale Provinciale des Arts Industriels* was founded at Ghent in 1866, with the object of "stimulating the genius of artistic creation in relation to industrial applications, contributing to popularise the study and sentiment of the beautiful in the production of industrial objects, which derive a portion of their value from their form, so facilitating and encouraging the efforts of industrial artists and artisans in the conception and execution of original works of good taste." For the present year the *Chambre Syndicale* announces an Exhibition of Industrial Art, to open in the halls of the Ghent Casino, on August 28, and to continue until October 18, following. Like the former, it will comprise two sections:—1. Modern, including: (a) a general exhibition of objects of industrial art manufactured in the country; (b) competitions in designs for such objects; and (c) competitions in manufactured objects. 2. A section of objects anterior to the nineteenth century, relating to industrial art, Belgian or foreign. Besides the prizes in the competition, medals of silver-gilt, silver, and gold, as well as honourable mentions, will be accorded to such exhibits as evince the greatest merit in design, taste, and execution, or which illustrate a new industry; while medals will also be granted to the designers of successful exhibits. Division A (*Baukunst*) comprises (1) ornament in stone, carton, pierre, plâster of Paris, artificial stone, &c.; (2) natural and artificial marbles, pavement, &c.; (3) joinery, including doors and floors. The *Président d'Honneur* is M. Léon Verhaeghe de Naeyer, Governor of East Flanders; the president M. Constant Verhaeghe de Naeyer; and the secretary, M. Emile Varenbergh, Ghent.

**Technological Examinations.**—The directors' report of the results of the fourth examination in technology conducted by the City and Guilds of London Institute, has recently been issued. The examination was held on the evening of May 24, when 1,972 candidates presented themselves. From the returns received in November last it appears that 3,467 students were at that time attending technical classes in different subjects under the direction of the institute. As compared with last year, a great increase is observable in the results of the recent examination. In 1881 1,563 candidates were examined at 115 centres in 281 different subjects, of whom 895 passed; in 1882, 1,972 candidates were examined at 147 centres in 37 subjects, of whom 1,222 passed. The difficulty which still exists of finding competent teachers prevents the formation of technical classes in many places where such classes are greatly needed. This difficulty, it is expected, will begin to lessen with the opening of the central institution in Exhibition-road. With the view of lightening somewhat the conditions of registration of teachers, the committee have resolved to receive applications from teachers under the Science and Art Department who can adduce evidence of having acquired in the factory or workshop a practical acquaintance with the subject which they desire to teach. The report calls attention to two great deficiencies in the training of the candidates who come up for examination in technology—to their want of elementary science knowledge and to their want of skill in drawing. Of the 1,222 successful candidates, not more than 400 are entitled to the full certificate as having passed the Department's examination in the science subjects.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS. Six lines (about fifty words) or under..... 4s. 6d. Each additional line (about ten words)..... 6s. 6d. Terms for Series of Trade Advertisements, also for Special Advertisements on front pages, Competitions, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED. FOUR lines (about THIRTY words) or under..... 2s. 6d. Each additional line (about ten words)..... 6s. 6d.

REFUSES TO ADVERTISEMENTS. Addressed Box —, Office of "The Builder." Cannot be forwarded, but may in some cases be called for, and the Office receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:— For "Situations Wanted" Advertisements..... 3d. per Week. For all other Advertisements..... 6d. per Week.

PAYMENT IS ABSOLUTELY NECESSARY. \*\* Stamps need not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher.

Addressed to No. 48, Catherine street, W.C. Advertisements for the current week's issue must reach the Office before THREE o'clock on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 12s. per annum. Foreign. Remittances payable to DOUGLAS FOURDRINER, Publisher, 48, Catherine-street, W.C.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down. RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [ADVT.]

Box Ground Stone. Is the best for use in all exposed positions, being a well-known and tried weather stone. 50,000 feet cube in stock. PICTOR & SONS, Box, Wilts. [ADVT.]

Douling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Douling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [ADVT.]

Douling Freestone, of best quality, supplied from their own Quarries and Kilns by STRAËLE & HANS, Stoke, Ilminster. Agent, Mr. E. CRICKMAY, 4, Broad-street-buildings, Liverpool-street, London, E.C. [ADVT.]

Asphalte. Scyssel, Patent Metallic Lava, and White Asphaltes. M. S T O D A R T & C O. Office: No. 90, Cannon-street, E.C. [ADVT.]

Asphalte.—The Scyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouses, floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tan-rooms, and terraces. [ADVT.]

Immense quantities of DRY WAINSCOT, DRY MAHOGANY, DRY WALNUT, in all thicknesses. B. J. HUDSON & SONS, White Asphaltes, 38, Great Peter-st., S.W. London. [ADVT.]

J. L. BACON & CO., MANUFACTURERS OF IMPROVED HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c. OFFICES AND SHOW-ROOMS:— No. 34, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. Illustrated Pamphlet on "Heating" post free.

CHAPPUIS' PATENTS FOR REFLECTING LIGHT. DAYLIGHT REFLECTORS OF EVERY DESCRIPTION, ARTIFICIAL LIGHT REFLECTORS.

WHY BURN GAS?—CHAPPUIS' REFLECTORS DIFFUSE DAYLIGHT.—They are exclusively adopted by and fitted at Buckingham Palace, all H.M. Government Offices, Houses of Parliament, H.M. First Commissioner of Works, the Metropolitan Board of Works, British Museum, South Kensington Museum, Royal Institution, Guildhall Museum, on board H.M. Ships, also Railway Companies' Offices, Hospitals, Institutions, Banks, Insurance Offices, Manufactories, Private Houses and generally from Noblemen's Mansions to Artisans' Workshops. 30,000 in use in London alone. Patronised by leading Architects, Engineers, Contractors, &c., &c.

N.B.—For Prospectuses and Diagrams, address Stamped Envelope to P. E. CHAPPUIS, Patentee and Manufacturer, 69, FLEET-STREET, LONDON.

NOTICE.—The POLYGONAL REFLECTOR (Latest Patent) FOR ARTISTIC and PICTURE GALLERIES. Its construction allows of the angle of light being readily altered so as to reflect in any desirable direction.

### Measurement and Design.\*

IF we pass from buildings at large to details, to inquire how far mensuration comes into design in these matters, we have to divide design for this purpose into two groups,—that which consists in the moulding or modelling of surfaces, apart from carving, and that which consists in the production of surface ornament either by carving, drawing, or painting. The essential distinction between these two classes of ornamental detail is that the first is sectional design, the second design on a plane superficies. It is true that the mouldings, the flutings, and the other means of diversification of surfaces which come

under the same head, and the object of which is to produce play of light and shade, and to emphasise lines of horizontal or vertical structure, are, when complete, appreciated by the eye as parts of a superficies; but they are designed in section, and thus a peculiar element comes into the designer's work,—the consideration of the actual effect when executed of profiles which are only seen as profiles when in the course of designing them, and when executed are never seen from that point of view, but only as surfaces presenting certain modifications of light and shade, from which the profiles can, by a practised eye, be approximately inferred, but which are sometimes very deceptive in this way, and convey impressions to the eye considerably at variance with their actual forms.

There is thus a curious discrepancy, in this class of work, between the manner in which it is looked at when in process of being designed, and that in which it is regarded when complete; and it is only probable in such a case that profiles would be often drawn to please the eye or the judgment when regarded as profiles, which would be no more effective in execution than a profile which might look much less symmetrical and satisfactory to the eye in a sectional drawing. The exception to this is when the moulding is in such a position and of such design that its entire profile can be seen as a profile when *in situ*, as in the case of the ovolo moulding of a Classic capital. Every moulding cannot be discerned in profile even in

such a position as this; the typical style of moulding of an Early English capital, for instance, does not show its whole profile; the deep undercuttings which form the shadows are lost to the eye, and only appear as intervals of shadow; the profile at this part might be almost any shape, provided it recedes sufficiently from the face to produce the desired depth of shadow; and, as a matter of fact, these hollow portions of Gothic mouldings, which were often assumed by draughtsmen to be portions of circles until the cymagraph was applied to them, are very irregularly drawn, and mostly present no systematic or normal curve. It is needless to add that during the fervour of revived Mediaevalism, this fact was no sooner discovered than it was set down as one of the peculiar beauties of Gothic moulding, and all circles and regular curves were voted vulgar in comparison. No doubt, had it been discovered that all the curves in Mediaeval mouldings were truly struck from centres, it would equally have been asserted that this was the one true method, and the precision and exactitude of the masons of the Middle Ages would have been lauded as furnishing a model for us to follow. Fortunately, we are not all of us tied to precedent so much, and can judge the question on broader grounds.

When mouldings are so placed that their profile is distinctly seen, there can be little question that their most refined effect will be produced by delicate curves which follow a true mathematical gradation, as is the case, for instance, with the best examples of the ovolo of the Doric capital. In the case of mouldings on a small scale, it would be superfluous refinement to attempt this, as the eye can get as near to a true gradation as it is possible to estimate by the eye itself, which is all that is necessary. In profiles on a larger scale, such as that of the Doric capital just alluded to, the mathematical description of the curve is theoretically as necessary as in the case of a quadrant of a circle on the same scale: we want to have the curve perfect, and on a large scale the unaided hand is not sufficient, though it may approach nearer to perfection in drawing a long parabolic curve than in drawing a circle. There are two or three reasons for this; less change in the position of the hand is necessary for such long curves than for a quadrant or more of a circle; and in segments of the parabola, hyperbola, or ellipse, as used for the outer profile of a moulding, there is no centre point, as there is in the quadrant of a circle, on either side of which the curve must be exactly equal. Perhaps it may be added that the ellipse and the other related conic curves approach more nearly in their outline to the prevalent outlines in natural bodies, and especially of the human figure; and there may probably be some connexion between the love of and study of the nude figure by the Greeks in sculpture, and their preference for elliptical rather than circular curves in the

mouldings of their architecture. Nevertheless, when the profile is on a tolerably large scale, the mathematical delineation of it by means of instruments is a further assistance towards securing that very delicate refinement and gradation of curve which is the peculiar beauty of the conic section curves, and in this respect we may say that measurement (taking that word in its broadest sense as the adoption of any means of geometrically exact delineation) may be an assistance to and even an important part of design. And as far as this applies to profile curves, it may also apply to those curves which, though not seen in profile in execution, are seen in nearly full light, and do not recede so much as to lose the requisite light to define their modelling. Take the flutings of a column, for instance; it may be worth while to profile these, when making the template, as true elliptical sections, for a more delicate gradation of light and shadow may be ensured by this means than can be attained either by segments of circles or by hand-drawn curves, and it is for the sake of shadow-gradation chiefly that mouldings are introduced at all into architecture, or at least it is by shadow-gradation that they produce their characteristic expression.

When once these more delicate curves are introduced into the details of a building, they seem to have a claim to be carried out throughout it. The mere circle, at least in convex mouldings, can hardly be intermingled with elliptical mouldings; it is too strong for its company; and the hand-drawn profiles which may accompany elliptic mouldings should follow their character, and partake of their refinement and delicacy of curve. This is the case with the best Greek mouldings; the refinements of compound curvature are carried out throughout them, and they left it to the Romans to be content with large and mechanically-designed circular contours. For this reason it has been very truly said (by Owen Jones) that though on a first glance at the buildings *en masse* there might not seem so much difference between a Greek temple and its Roman copy, especially as there is often a great scale about the latter which adds to its effect, a few mouldings taken from each would suffice to show that the Greeks were a people of far higher refinement in perception and execution alike. In the Mediaeval mouldings we have something which is of a higher type than Roman detail; but they are so by virtue of their boldness, effectiveness, and the perception which they show as to the best way of handling the material used. They are, however, the least scientifically drawn of all that we have been mentioning. It is true that the refinement of the Greek profiles would have been thrown away in coarse stone, or at least could not have lasted long; but the Gothic mouldings might have been more truly and scientifically profiled than they usually are, without being any less effective in result, and so far their record is against them, and leads

\* See p. 230, ante.

to the conclusion that their merits have been a little exaggerated. They show greater variety, however, than those of any school of Classic architecture.

An intermediate class of ornament between mouldings and free ornamental design is that which consists in repetition of some very small and simple unit or of a simple geometrical form, such as a square panel. In this case measurement is the very essence of the design, and must be carried out with minute precision. The taste for Japanese whims and irregularities, probably, has led some persons to imagine that there is a kind of charm in having ornament of this description looking as if it had been intended to be regular, but had been carelessly carried out. We have often seen it asserted that in Greek repetition ornaments, such as the bead and reel, the carver made no attempt at precise verisimilitude in each repetition, but was content to leave slight differences, and that the design gained in effect by these irregularities. This we take to be pure nonsense. The effect of the ornament consists in precise and regular repetition, and there is every appearance, in executed antique examples of this kind of ornament, of the intention to make each member as uniform and mechanically correct as possible; and rightly so. When an ornament is used obviously as a repeating ornament, its repetition should appear perfect and complete. Whether it is a very worthy employment for a man to be engaged in cutting so many hundred repetitions of the same form is another thing; but repetition is repetition, is effect *per se*, and should be carried out fully or avoided altogether.

When we come to the domain of decorative design properly so called, we find, among work which can be included in that category, almost every imaginable degree from purely geometrical to purely naturalistic work. On the geometric side we have Saracenic ornament, which, although it shows considerable beauty of free-hand work in small details, is in its main lines and motives almost entirely the outcome of "measurement." It is ornamental effect resulting from geometrical puzzles, and though it must be admitted that its general effect is admirable, there is really much more of ingenuity and contrivance about it than of pure taste or invention. It looks exceedingly rich and intricate, but its intellectual value has certainly been over-rated. It is a proof of the usefulness that geometry may have in producing ornament; an ornament which, when the *eu* is once given, can be enriched to almost any degree by merely a little modification and multiplication of the subordinate details. The case is more complex when we come to consider ornament which is not so confessedly based on geometry. Owen Jones, indeed, contended that all ornament is based on geometrical spacing and figures; but when he wrote Japan had not been discovered. The question whether all ornament is or should be so geometrically based or not is the very one we are examining here. How far is "measurement" the necessary or proper basis of decorative design?

On the whole, the principal of equal spacing and repetition must be held to underlie most surface ornament that has existed. The very simplest and what may be called the embryo idea of ornament is that formed by the repetition of some form, however simple, on the opposite side of a centre line. Forms which, when first sketched, of themselves hardly present much appearance of what we usually call ornament, seem to assume this sometimes in a degree surprisingly disproportionate to their first promise, when doubled so as to form two halves of a symmetrical whole. The kaleidoscope is a sufficient illustration of this; and the reason for it is that the symmetrical repetition suggests the idea of "design," in the significance of thought and deliberate intent, applied by the designer in arranging his materials. This idea of deliberate and considered arrangement is carried further when we find a design arranged so as to repeat itself over a large surface in regular spacing, and it is this element which Owen Jones thought must be always present in ornament. There is no doubt that it does characterise most of the surface ornament existing in the world, and that by this means of repetition a very good decorative effect may be produced with very simple materials; and it is equally certain that purely naturalistic forms imitated, without symmetrical arrangement or repetition of any kind, are not ornament, and for this reason, that ornament

must include the application of human thought and contrivance,—that we signify more briefly by the appropriate word "design." Mere imitation of nature, however good, is not this, has not this quality of human invention. It is only more or less good imitation. The vases illustrated in last week's *Builder* (page 249, *ante*, "Modern English Pottery") may serve to illustrate this. The first Doulton ware specimen is ornamented with sprigs which are partially naturalistic, at all events not symmetrical, but they are symmetrically arranged in relation to the general division into parts of the whole vase. The next one, "Doulton's silicon ware," has for the elements of its ornament a few very simple forms, but they are arranged symmetrically on a definite plan; "measurement" pervades in every detail, and here, again, as in the Saracenic patterns, measurement produces ornament and the appearance of design. The elements of the ornament are but four or five very small isolated forms, which, if merely figured on the surface without arrangement, or drawn on paper, no one would care about in the least; but these, symmetrically spaced and repeated, form ornament, and withal very pleasing ornament. On the other hand, the jar figured at the bottom of the page, by Brown-Westhead, Moore, & Co., is wreathed with a perfectly naturalistic raised modelling of wreaths of flowers and birds; very pretty work, but not ornament; it is sculpture, it has no relation to its position or to the object on which it is placed, and no arrangement showing design. It is pictorial art, a higher thing in itself, possibly, than ornament, but also a different thing, and not to be confounded with ornament or applied in the same manner. It is imitative work, not the application of the mind of the designer towards producing an effect of his own. That is what ornament is: it is not the painting of an imitative repetition from nature, but the invention of the ornamentist acting on hints from nature. And hence the mere adoption of a flower or spray in naturalistic form, and its regular repetition over a space, as we see so often in wall-papers, hardly deserves the name of ornament. There is no thought in it: it is merely the mechanical repetition of a natural form. To raise it to the quality of design, properly so called, it should be treated by the designer in such a manner as to make it his own, and to make it appear as if it were intended and calculated for symmetrical repetition.

We wish, however, to suggest the question whether symmetrical spacing and repetition is always, according to the usual dictum, necessarily an element of ornamental design. It enables us to make ornament, so far as it goes, and satisfactory ornament, out of very simple elements. And when used, it should be frankly used, and allowed to show itself as repetition, and not elude observation. There is rather a fashion at present for semi-naturalistic wall-papers and wall-drapers, which are in reality pieces of repetition in regular spacing, but which are adroitly contrived so as to "hide their joinings," as far as possible, and appear at first glance like one continued floral pattern inconsidering all over the wall. This is all very well at first glance, but when the eye notices the same spray, the same half-open bud or crumpled leaf, apparently with so much of the freedom of nature, repeating itself conscientiously every 2 ft. or 3 ft. apart, there is a feeling of incongruity in finding a pattern, apparently so natural, to be in reality so artificial. If there is repetition, let the repetition be marked, not evaded. But we have one final and possibly heretical suggestion to make, in the form of a question, whether this same resource of repetition so constant in surface ornament, may not be after all a concession to circumstances rather than a necessary element. That is to say, it is well to have a small bit of really good design and repeat it over a whole surface. Would it not, after all, be still better to have a good design which, without repetition, will spread itself over and fill the whole surface? There seems to be a tacit feeling in favour of this idea implied in that very attempt to give that effect to recent wall-paper designs to which we have just referred. Practical considerations would make it impossible, certainly, to carry out design on this large scale often. It would require much more thought on the part of the designer, in the first place. It is one thing to fill four square feet of surface with ornament; another thing to fill 400: and it would, of course, be enormously

more expensive in execution: but it would be a much higher act of decorative creation to make, as it were, one growth of the whole ornamental design. In such a case the element of measurement would come in in the details, which should be clean and symmetrical, no attempts at imitating the actual growth of natural foliage, but a creation of the designer's, founded on natural types or principles, and treated with the precision of the draughtsman, just as in the case of Greek honeysuckle detail. But, instead of merely repeating such detail as this in regular succession, the designer would give it a growth of its own, and make it spread, freely and without repetition, over the whole space to be covered, and thus at last escape from the trammels of mensuration. It is but seldom that such an attempt could be made, but it would be worth trying when circumstances admitted of it.

#### ST. ANNE'S SCHOOLS COMPETITION.

THE St. Anne's Society having procured a site at Redhill for the erection of new schools, and offered premiums of 250*l.*, 150*l.*, and 100*l.*, for the three best designs for such schools, the plans sent in competition have been on view during part of this week at the present schools at Streatham-hill.

It may not be out of place to say a word about the society, and the object for which the proposed buildings are to be erected, about which, probably, many of our readers know nothing. It was founded in the first year of the reign of the queen after whom it is named, when some gentlemen formed themselves into a society for clothing and educating twelve boys, the sons of parents reduced to a necessitous condition; and a school-house was provided in the parish of St. Anne and St. Agnes, Aldersgate. In 1790 a girls' school was added to this establishment, the number being limited at first to thirteen girls. The number increased as the funds of the society increased, and in 1820 thirty boys and thirty-two girls were under instruction. These numbers have not been increased since, as the town school afforded no further accommodation; but in 1795 a country school or asylum was established in connexion with the original charity, and located first at Lavenham, a place well known to architects for its magnificent church. Among those concerned in founding the country school were Wilherforce and Whitbread. This new establishment at first accommodated twenty boys, who were selected from the town school, to which it was, therefore, a kind of "chapel-of-ease," so to speak; but before long the principle of admission was changed, and the country asylum was received independent of the town school, and received inmates who were eligible according to the conditions from any part of the country. After a few years, the asylum was removed to Peckham, in Surrey, where it remained till 1825, when the present building at Streatham-hill was in part constructed for the accommodation of a matron, a master, a mistress, 100 boys, and 50 girls. Since then the numbers of those desiring and having claim to admission increased very largely, and in 1855 the building was considerably added to and brought to its present state by the addition of new dormitories, lavatories, &c., at a cost of 4,000*l.*, and the school now contains 200 boys and 147 girls, and the necessity for enlargement has again made itself felt. The committee are now proposing to rebuild entirely, on a site further from London, and hence the present competition.

The instructions to competing architects required a building with accommodation for the number of boys and girls named above, at a cost of not more than 35,000*l.*, including everything except furniture.

From a considerable number of plans submitted in competition, the committee have selected, for the first premium, that with the motto "By Study," by Messrs. Crickmay & Son; the second premium is awarded to that marked "Per Se," by Mr. Matthew Wyatt and Mr. T. S. Archer; and the third to that marked "Economy," which is by Mr. Rovedino.

The problem is not a very difficult one in planning: it is the provision of a double school, for boys and girls, connected with certain portions, *viz.*, the dining-hall and the administration department, which are equally related to both schools. The placing of these in the centre and the schools at opposite wings seems, therefore, the almost inevitable arrangement. As the schools for boys and for girls are not

required to accommodate the same numbers, and the rooms required are not precisely the same either, even apart from numbers, the place does not naturally suggest a symmetrical arrangement on either side of the centre, and this fact, as well as considerations relating to architectural expression, seem to point naturally to a distinct treatment of the boys' and the girls' side. The authors of the first premiated designs, however, do not seem to have regarded it in this way, as they have treated the building as a block with almost entirely symmetrical wings on either side of a centre. The style selected is "Queen Anne," which, considering the history of the institution, is perhaps the most suitable aesthetically, and not unsuitable practically. The building is very plain; there is a short tower over the central entrance, which appears (according to one of the sections) to be utilised for an extract ventilation flue from the dormitories generally; on either side of this extends the main longitudinal block, containing administrative and residential rooms and a long corridor, and the working-rooms for boys and girls respectively form a cross block at either end of the long one. Behind the centre of the longitudinal block are kitchen-offices, pantries, &c., and behind these, again, the large dining-hall, with an open-timber roof, and reached by short passages out of the principal corridor, which passages run outside of the pantries, &c., on either side, so that these rooms are only, apparently, lighted by borrowed light from the passages, which does not look very well. The boys' block contains school-rooms for senior and junior boys, capable of being divided into class-rooms; the girls' block, school-room, work-room, and music-room, the latter being divided into small rooms, with, we hope, some special means in the division walls for deadening sound,—and with a common passage running before them. It is with regret that we see a music-room provided for the girls only, and none for the boys, so that the committee are still under the common delusion that music is essentially a female "accomplishment," and that no special opportunities for learning it need be afforded to boys,—in which idea they are decidedly behind the age. The assistant master's and mistress's sitting-rooms are agreeably arranged in bay-windowed rooms, projecting from the principal corridor in the longitudinal block; but the latrines, which also open out of this corridor, are not so well placed, and require more decisive isolation and ventilation. There appears to have been consideration for the systematic ventilation of the dormitories, which occupy most of the first and second floors. The infirmary, a separate building, is not very well planned; it is in a cross form, one wing for kitchen, &c., one for ordinary illnesses, another for infectious diseases, the fourth contains the day-room: in this block the treatment of the latrines is more satisfactory, but the meeting of the four departments at the centre of a cross plan is by no means in keeping with the best sanitary principles of planning such a building. The chapel is placed apart from the main building, and in no sort of relation to it, and is in Gothic style. This is architecturally a mistake. There is no reason whatever for having the chapel in different style to that of the rest of the building. It requires a special design and treatment, but not a special style. The authors, by the way, exhibit two sets of plans, and it is the alternative set that has been accepted; the two differ, however, in no material points, but only in the smaller area of some of the rooms in the alternative one, the main object of which is a certain degree of economy. We question whether the committee have done wisely in preferring the smaller plan; the saving will not be much, and space is a great matter.

The authors of "Per Se" have adopted the idea, which we prefer, of treating the boys' and girls' sides differently; the dining-hall and the administrative department come in the centre, but symmetry is nearly discarded otherwise, and the different portions of the plan are arranged rather with regard to their relation to one another and to the convenient fitting-together of the various buildings. Covered playgrounds are added outside the school-room departments, and a swimming-bath behind the dining-hall: all which are desirable adjuncts. The plan, though not to appearance quite so simple as the first-named one, is as good a one in the main, and in some details, such as the placing and arrangement of the latrines, it is better; the

plan of the separate infirmary is much better than in the first premiated one. The style is more ornate, embodying what is now sometimes called "Free Classic," consisting in a reminiscence of Jacobean, with other touches of more modern type. We do not admire it very much however, and the double towers and cupolas, one on either side of the centre entrance, look rather pretentious and useless. The chapel is in the same style as the rest of the building, and is made to group with it. On the whole, this seems to us the best plan of the set, but its architectural treatment is more costly and not very refined, and, on the whole, less suited to the class of building than that of "By Study."

In the case of the third premiated design, "Economy," we confess we can hardly see the claim it has to be put in the running with the two others at all, as it is much inferior to them, though it may be admitted that if the third premium was bound to be given there is, perhaps, no other set worth consideration to which there is not some more decided objection than could be urged against this one. The "economy" seems to consist in reducing the rooms mostly to very narrow proportions, in fact, cutting down the area of floor as far as possible, in a manner which necessitates very long blocks and a considerable spreading out of the building over the ground, which would be by no means convenient in the general working of the school; and even if the schoolrooms and playgrounds have sufficient area, it is in a bad form, long and narrow; and the spreading out of the administrative department along a set of small rooms the whole length of the very long main corridor is not convenient or desirable. The chapel, which ought to be equally connected with both sides of the school, is placed rather as if it belonged to the girls' department. The plan altogether wants concentration.

The choice unquestionably lies between "By Study" and "Per Se," and so far there is nothing to complain of in the decision. Had the authors of the last-named shown more refinement and simplicity in their architectural treatment, we should have had little hesitation in pronouncing theirs to be the most to be recommended. As it is, the merits of the two are rather evenly balanced. Among the others, "Comme il faut" deserves credit for hard work bestowed on a very elaborate set of drawings, unfortunately of doubtful merit in regard either to plan or design; "Reth-baus" is a pretty and architecturally clever design, with its plan very compact, but the arrangement of the buildings around quadrangles, and very small ones too, is a fatal objection. "Standard" sends some good drawing, including a pretty perspective view, but the plan is rambling and not practical. There are several other agreeable drawings, but nothing in planning that is not open to a good deal of criticism, and the committee seem to have been well advised in the award of the premiums, and to have made the choice on practical grounds. Mr. Whichcord was appointed the professional assessor, and among the conditions of the competition it was laid down that until the decision was made public no competitor should send any drawings, photographs, or printed statements to any member of the Committee, under pain of disqualification,—a very wholesome regulation. The Committee did not bind themselves to employ the author of the first premium design necessarily, but to employ one of the three, on his giving satisfactory evidence of his experience, and producing a builder's estimate not exceeding his own by more than 10 per cent. There seems to have been every effort to single out the best work and to deal perfectly fairly with the competitors, which is more than can be said of all architectural competitions.

**The "Novelty" Theatre.**—The new theatre which has been for some time in course of erection in Great Queen-street, Lincoln's Inn Fields (nearly opposite the Freemasons' Tavern), is approaching completion, and will it is expected, be opened about the middle of October. It is the property of a limited company, of which Mr. James Albery, the dramatist, is one of the directors. The theatre, which is about the size of the "Vaudeville," in the Strand, will be lighted by electricity. It has been erected from the designs of Mr. Thomas Verity, architect, the contractors being Messrs. Kirk & Randall, of Woolwich.

#### DR. SCHLIEMANN'S NEW EXCAVATIONS IN THE TROAS.

At the thirteenth annual congress of the German Anthropologists, which has just been held at Frankfort-on-the-Main, Dr. Schliemann read an important paper upon his latest excavations on the site of ancient Troy. In the course of his remarks the learned gentleman said:—Three years ago I was under the belief that I had for ever finished the excavations at Troy, and I thought I had proved that the small settlement, the substructure of whose houses I had found at an average depth of 8 metres underneath the remains of four later cities, lying one above another, must necessarily be the Troy which had been rendered immortal by Homer. Subsequently, however, doubts arose in my mind, and it soon became impossible for me to believe that the poet could have represented a diminutive settlement, which was capable at the utmost of accommodating three thousand inhabitants, as a great and powerful city, with an acropolis capable, for ten long years, of defying the united army of all Greece, and only conquered at last by cunning. Accordingly I determined to make an additional five months' search, in order finally to settle this very important question. For this purpose I secured the services of two eminent architects. One of these was Herr Wilhelm Dorpfeld, of Berlin, who, for a period of four years, had conducted the technical portion of the German excavations at Olympia. The other was Herr Joseph Hofer, of Vienna. They had both received premiums from the Government in order to pay visits for the purpose of study in Italy.

Through the kind intercession of the German Chancellor, I received a new and more liberal firm from the Sultan, permitting me to make archaeological researches anywhere in the Troas. Armed with this authority, I commenced the excavations afresh in Hisarlik, on the 1st of March this year. I employed 150 men on the work, and that remained the number of my labourers throughout up to the finish. I further received the assistance of a considerable number of vehicles, drawn by horses and oxen, to carry away the rubbish. As the country where the work was carried on was most insecure, I received, during the whole period of the excavations, the protection of eleven gendarmes, whose pay amounted to 30*l.* a month. Fortunately, I had had my old wooden cottage looked after since the spring of 1879, and I now found it, as well as my tools and implements, still in good condition. With the exception of the three first days, we had, without cessation throughout all March and April, a cold north wind, which every day became a regular storm, and drove the dust into everybody's eyes, and was almost the death of us through the cold.

One of our first labours was to lay bare all the foundations of Greek and Roman buildings in the part of Hisarlik till then unexplored. We also had to collect the sculptured blocks belonging to these edifices as well as other sculptured remains belonging to buildings unknown or imperfectly identified. Among the latter a small Doric temple deserves particular notice, as it appears to be identical with that small and inconsiderable shrine of Pallas Athene which, according to Strabo (viii., 593), was seen here by Alexander the Great. The architects are, however, of opinion that the remains of the sculptured blocks belonging to this building are not archaic enough to have belonged to the temple of the goddess just mentioned, which, according to Herodotus (vii., 43), was visited by Xerxes. Of the later buildings, the oldest is a large Doric temple of marble. It is to this temple that the splendid metope belongs which I discovered here ten years ago, and which represents Phœbus Apollo with the quadriga of the sun, and which is now deposited with the Trojan Collection in Berlin. This temple is without doubt identical with that which Strabo (viii., 593) tells us was built here by Lysimachos. As it is by far the largest of all the temples, I entirely agree with the architects that it must necessarily be the shrine of Pallas Athene, the protective goddess of Ilium. I may here mention that, according to the evidence given by the architects, I was quite mistaken in supposing that I had destroyed the temple of Pallas Athene nine years ago. It was only the substructure of a Roman Stoa, which I was compelled to destroy in order to reach the older remains beneath it. Among the buildings which can be identified, I will

further mention a marble Doric portico of the Roman period, of which some steps still remained *in situ*. Two smaller buildings in the Doric style are also worth noting, as well as a very large beautiful marble gate of the Acropolis, in which both the Ionic and Corinthian orders were represented. Sculptured blocks belonging to all these structures are to be seen in abundance in the neighbouring churchyards of Halli Kisi and Kum Kisi, where they have been used as gravestones.

Far larger than any of these edifices is the large theatre I have excavated. It is hewn out of the solid rock immediately to the east of the Acropolis. It overlooks the Hellespont, and was capable of accommodating upwards of 6,000 spectators. On the stage side, I found structures of which is well preserved, the sub-structures of which are the pillars of the Corinthian, Doric, and Ionic orders, as well as immense masses of chips and fragments of marble statues, and a lime-kiln, in which all the statues appear to have been burnt to make lime of. A head and numerous hands and feet of statues; a relief-medallion on which is represented the she-wolf suckling Remus and Romulus; and among the remaining evidences of the former splendour of this theatre. It belongs to the Roman period, and was probably constructed by Sylla or Julius Caesar.

In the countless shafts and pits I sank in the Lower City to the east, south, and west of the Acropolis, I found the substructures of numerous large buildings belonging to the Macedonian or Roman period. One, which was covered with beautiful marble tablets and adorned with a long row of granite pillars, was probably the Forum. In many of the houses of Novum Ilium we uncovered mosaic floors or pavements, all of which are unfortunately more or less destroyed. In all the pits and shafts to the south and west outside Hisarlik, I found beneath the Hellenic and Roman buildings, large quantities of broken earthenware dating from the oldest pre-historical settlements. In one of the shafts immediately to the south of the Acropolis there was found a well-preserved piece of relief-sculpture belonging to the Roman period, and containing a representation of Hercules as well as a beardless figure.

The most remarkable discoveries I made, were in the three lowest pre-historic settlements, on the hill of the Acropolis. My two architects proved beyond any doubt that the first settlers here only erected one or two large buildings, which were enclosed by a high wall, 2 metres in thickness, and consisting of small stones united with mud or clay. A considerable portion of the ruins of this are to be seen in my large northern pit. The length of this first settlement did not exceed 46 metres, and its breadth cannot have been more considerable. The architecture of the buildings of this first settlement is still a complete mystery to my architects, for at distances of 3½ metres, 5½ metres, and 6 metres, we have five parallel inner walls, about four-fifths of a metre in thickness, which have no cross walls, and therefore form long halls. However, we were only able to lay them open to the width of my long northern pit, or to about the length of 30 metres. The walls consist of small stones, mixed with earth, and in several parts their ornamentation is still preserved.

We may assume, with the greatest probability, that this first settlement is one of the lower cities, and that it extended in a southerly and westerly direction. In fact, the earthenware articles, found there in the lowest layer in my pits and shafts are identical with those of the first settlement of the Acropolis, and leave hardly a doubt about the position of the place. This first settlement appears to have stood here for many centuries, as the rubbish there had gradually collected to a height of 2½ metres. From this first city I have brought away an axe made of nephrite, and two earthenware articles, one of which, at any rate, is ornamented with an owl's head.

My architects have also demonstrated that Herr Brnrouf and I had not correctly distinguished and kept separate the ruins of the two following settlements; that is, the second and third cities. We had quite correctly regarded the walls, which are three metres in depth, and consisted of large blocks as part of the foundations of the second city, but we had not classified with the latter the layer of burnt ruins lying immediately above, and which really belongs to it, but had reckoned these ruins as

part of the third city, with which they had nothing to do. What had led us astray was the immense mass of rubbish, consisting of burnt bricks, that lay upon the ruins of the second city, which had been destroyed by some tremendous catastrophe. This rubbish quite had the appearance of having originated from houses that had been destroyed by some terrible conflagration. In truth, however, it is nothing more than the ruins of bricks walls which had been first built up of lumps of unburnt clay, and had afterwards, for the sake of greater solidity, been burnt by great fires simultaneously lighted on both sides. The city that had been burnt down, therefore, was not the third, but the second. The layer of rubbish belonging to this, however, as the third city was erected immediately upon it, is but trifling, often being only from one-sixth to one-fifth of a metre in depth. That the walls above mentioned were first erected of clay, and that this was afterwards burnt, is confirmed partly by the circumstance that the clay mortar between the bricks is burnt precisely in the same manner as the bricks themselves, and partly by the fact that the upper parts of the walls are the least burnt,—often, indeed, hardly at all so.

Besides the three temples, although I have unearthed almost the entire Acropolis within its walls, I have discovered only three, or at most four, buildings of large dimensions. Owing to the large number of those rooms and their ground-plan, we conclude that these were dwelling-houses. How many houses there were it was, however, impossible precisely to determine without first making out a plan of the entire Acropolis. This, however, unfortunately, the War Minister at Constantinople most strictly forbade us to prepare. The walls of Hisarlik, only to get plans of the Fortress of Kum Kaleh, distant about four or five miles from Hisarlik, and quite invisible from the latter place, and that we were only using the excavations at Troy as a pretext for effecting criminal purposes. He accordingly caused the military guard constantly to keep watch over us, and their orders were to prevent us from taking measurements of the house walls at Troy by means of tape or cord, and even from making drawings within the excavations themselves. The Turkish Commissioner, in fact, had been charged to take my architects prisoners to Constantinople if they attempted clandestinely to take the most trivial drawing or measurement. I hope that the German Chancellor will be able to find means of removing those petty hindrances to the advance of antiquarian science, for the *chargé d'affaires* at Constantinople wrote to inform me that he was unable to obtain any concessions in this direction.

All the above-mentioned buildings on the hill of Hisarlik were surrounded by a fortified wall, composed of large and small stones mixed with earth. On the south and south-west side this wall is preserved. It served as the foundation of an extensive brick wall, which was probably provided with a number of towers. This foundation is laid under an angle of 60°. Its perpendicular height is 7½ metres, while the oblique surface measures 9 metres. On the northern side the foundation consists of very large blocks. As this side overlooks the plain, the great wall, the upper part of which was built of brick, doubtless presented an imposing aspect, and probably led the Trojans to attribute it to Possidon and Apollo.

The second settlement upon the hill formed only the Acropolis, while to the south-east, south, and south-west, lay the adjoining lower city. The existence of this lower city is first proved by the wall which runs in a south-easterly direction, and which, unlike the oblique fortified wall of the Acropolis, stood quite perpendicular. It consisted of large unburnt bricks, with small stones in the interstices. The existence of the lower city is also confirmed by the circumstance that, in the lowest layers on the plateau below the castle hill, a great mass of pre-historic terra-cottas have been found. In form and material the latter are identical with those of the second settlement upon Hisarlik. Another fact telling in the same direction is found in the arrangements of the south-western gate. In the second settlement there is but one simple appliance for closing it, while the settlers belonging to the third city had added two more, because it then no longer opened into the lower city, but directly into the open country, as there was no lower city during the third settlement. A further proof of the existence of a lower city is the presence of three

gates. We had already found on the south-east side a gate of the third city, in the middle of which was the sacrificial altar depicted in my "Ilios," plate No. 6. One metre and a half below this we found the third great gate of the second settlement, which, however, appears only to have been erected after the second gate had been burnt down and covered with rubbish. A much more weighty argument, however, in favour of the existence of a lower city is to be found in the number and arrangement of the buildings situate within the Acropolis.

Since, however, none of the later cities, down to the time of the erection of Novum Ilium, had a lower town, the ruins of that belonging to the second settlement stood deserted for many centuries. The brick walls were broken up, and the bricks were applied for new buildings upon Hisarlik. I now believe the tradition mentioned by Strabo (xiii. 599), according to which Archacanax, of Mitylene, built the walls of Sigeion with the stones of Troy, for by these only the stones of the lower town of the second settlement and probably the stones of the walls, can be meant. In spite, therefore, of my extensive excavations in the lower town of Novum Ilium, it is only natural that I found no stones or bricks belonging to the lower town of the second settlement, although in several spots I found the natural rock levelled and prepared upon which I found large masses of slate tablets which at one time served to cover the floors which as I found many of them still *in situ*. But that all the clayey floors were covered with such tablets is not probable, for many of them in the great catastrophe were melted and received on the surface a glass-like appearance owing to the silica contained in the clay. In my opinion, this could not have happened if the floors had been covered with slate tablets.

Of gold, we found this time only a small diadem and an ear-ring of the usual Trojan shape, and in addition an ornamental sceptre-top. Of silver articles, we found four or five pins and numerous ear-rings, which through chlorine had been welded together. I also discovered at the spot marked "r" in plan I. of my "Ilios" a small deposit of bronze articles, consisting of two square nails, respectively 0.9 metre and .18 metre in length; six well-preserved armlets, two of which are of threefold form; three small battle-axes, of from .105 to .120 metre in length, two of which have a hole pierced through them at one end; also another battle-axe, .230 metre in length. All these axes are of the usual Trojan form. I further found three small, well-preserved knives, a dagger, .22 metre long, of which the handle is square, and which was, doubtless, fixed either in wood or bone. This dagger in the great fire had been bent round. Our find also includes a lance-head and an exceedingly singular cast ring, of about the size of our table-napkin rings. It is .045 metre broad, its diameter being .068 metre. It is marked into five divisions, each with a cross. By far the most important object found, however, was a bronze idol, of the most primitive form, ornamented with an owl's head. One hand rests upon the breast,—it appears to be a female idol,—the other arm is broken off. Behind, it has a support seeming, probably, simply to maintain the idol in an upright position. Its dimensions are .155 metre in height, the weight being 440 grammes. I consider it probable that this bronze figure is a copy or imitation of the celebrated Palladium, which was of wood. It is fortunately broken into three pieces, and it is to this circumstance that on dividing our find with the Turkish Government I obtained this portion of it, as the three pieces were covered with dust, and by an inexperienced eye could not be made out. Terra-cotta quarters we found in considerable numbers, twenty-six of them in one heap, in front of Temple A. We also found many beautifully polished axes of diorite, besides five of beautiful nephrite; further, numerous hand-millstones of trachyte, mortars and pestles, countless crushers of granite, porphyry, and so on. There were also numerous hattering-balls of hematite, one of them weighed 1,130 grammes, another found in the third, 520 grammes. In ivory, I found a remarkable article with five projecting half-spheres, like No. 983 in my "Ilios." We also found two knife-handles in the form of pigs or dogs, like No. 517 in the "Ilios." In earthenware I found various specimens of oivurns and tripod vases, as in former excavations. Particular interest attaches to the excavations I carried on this year in four so-called tombs of

Trojan heroes. For permission to explore the two at the foot of the promontory of Sigeum, respecting which tradition ascribes the larger to Achilles, and the smaller to Patroclus, 2000l. sterling was demanded of me three years ago. I now received the same permission for 3l. sterling. I reached the rock at the depth of 64 metres. I there discovered a bronze arrow-head without harbs, in which there is still seen the tops of the little flanges used to fasten it to the shaft. I likewise found there an iron nail and a mass of fragments of earthenware made by hand, (which was only slightly burnt, being thick and heavy, and of grey or black colour; they are similar to what are found in Hissarlik underneath the Macedonian walls, but their age is difficult to determine. Similar fragments of pottery are also found in the grave of Patroclus, which, therefore, appears to belong to the same epoch as that of Achilles. As in all tumuli previously explored by me, I failed to find any trace of bones, ashes, or carbonised remains in these two heroic tombs. The third excavation I carried out was in the tumulus on the opposite shore of the Hellespont, near the ruins of Eleus. The tradition of all antiquity ascribed this to the hero Proteus. It is now popularly called Kara Agrateh Tepch; that is, Black Fire Hill. Its diameter is 126 metres, and it is now 10 metres high, but as it is cultivated, it was probably once much higher. I was greatly astonished to find the surface of this mound covered with fragments of those glittering black terra-cotta dishes with long horizontal tubes, or those vases with double perpendicular pipes for hanging up. Such fragments are found in Hissarlik only in the ruins of the first settlement. What I was most astonished at was the fact that the fragments in question appeared quite new, although they probably had been for 4,000 years more or less exposed to the air; in fact, even the lime with which the indentations of the carving were filled was still preserved quite fresh. I at the same time collected several fragments of pottery like what is found in the second settlement at Hissarlik; I also obtained several stone hammers. In the middle of this remarkable tumulus I employed four labourers in sinking a shaft 3 metres long and broad, when suddenly the military governor of the Dardanelles ordered the work to be discontinued. In two days I had sunk 2½ metres, and obtained a rich collection of interesting stone tools and pottery. At ½ metre deep I found in this tumulus a layer of bricks mixed with straw, and slightly burnt, similar to those found in the second and third cities at Hissarlik. After this I proceeded to explore the three tumuli above Tepeh, but unfortunately here, too, the work was stopped by the same authority before I could obtain any result.

DESIGNS FOR CROSSENS NEW CHURCH.

In answer to an invitation to compete for two premiums, some thirty-seven plans were sent. The problem to be solved was difficult. It was to provide 400 sittings for 2,400l. As might be expected, some excellent designs were sent, but which also plainly could not be erected for the meagre sum named. These were thrown out of the contest, but the struggle was still a close one. Eventually, the committee gave the first premium to Mr. J. W. Common, of Leeds, for an Early English design; while the second premium was awarded to Mr. Ernest Johnson, of Southport, whose design showed a large west tower, having a gallery, and also seats in the haisement. All the plans were then publicly exhibited in the Atkinson Art Gallery, where for four weeks they have been largely viewed by residents and visitors, the daily return averaging about 400.

**Drinking Fountain in Lincoln's Inn-fields.**—On Monday morning a new fountain was unveiled in Lincoln's Inn-fields, under the auspices of the Metropolitan District Fountain and Cattle Trough Association, in memory of the late Mr. Philip Twells, formerly M.P. for the City of London. Several members of the family were present, and the ceremony was performed by Mrs. Twells, who, in a few appropriate words, declared the fountain open to the public. It is built of granite, and its cost is estimated at about 1,000l. The architect was Mr. R. Keirle.

THE LATE PROFESSOR JEVONS, AND THE COAL PANIC OF 1872-73.

THOSE of our readers who remember the coal panic of 1873, and the careful investigation, in the columns of the *Builder*, both of the subject of our coal supply, and of the report of the Commission appointed in 1866 "to inquire into the several matters relating to coal in the United Kingdom," will have heard with pain of the premature death, by drowning, in the forty-sixth year of his age, of Professor W. Stanley Jevons, whose application of the formula of arithmetic progression to the returns of the yield of our coal-fields raised the first alarm as to the limits of their possible capacity. To the statements of Mr. Jevons, we suppose there is little doubt, the appointment of the Royal Commission may be directly traced. That the subject was so treated by the report of the Commission as to impart to the public the panic which had evidently seized the Commissioners, was not the fault of Mr. Jevons. It is plain that the Commissioners were terrified by the steady march of the columns of figures cited by the Professor,—and that they so far lost their heads as to fall altogether to inquire whether any natural causes would be likely to come into operation to change the law of increment at any given time. As the matter stood, it was, in fact, one of those scientific conundrums that present such ridiculous, but perfectly logical, conclusions. Our readers may have seen a very accurate calculation of what advantages might have been secured to the posterity of Adam had that patriarch had the providence to lay up a single halfpenny, at compound interest, for their benefit. We forget the answer, and it is not worth while to lose time in hunting for it; but the extinction of the national debt would have been a mere fleabite in the prodigious result of interest upon interest for six or seven thousand years. Such things are very well as exercises, but have to be carefully dissociated from daily life. The existence of banks, and of the modern commercial system of investment, is, of course, the suppressed assumption which allows such an hypothesis to be put on its legs.

The alarm note struck by Mr. Jevons was, indeed, something very different from a scientific puzzle. In the year 1864 the yield of our collieries was 92.8 millions of tons of coal. In 1854, the first year in the returns published by the Board of Trade, it had been 64.6 tons. We may note in passing that the yield of 1855 was 61.4 millions of tons, or positively 3.2 millions less than that of the previous year. This fact alone might have convinced a careful observer that ten or eleven years,—in the course of which such a retrogression had occurred, was not enough to establish the inexorable rigidity of a law, such as that which was supposed to be threatening the extinction of our furnaces. In the eleven years from 1854 to 1864, then, the increase in the annual yield of coal had been 28.2 millions of tons, or 43 per cent. on the yield of the earlier year. We are not sure that these were the exact figures taken by Mr. Jevons, but they are those of the official returns for the years we have named. An increase of 43 per cent. in eleven years, is equal to an annual increment at the rate of a little more than 3½ per cent. (which gives 41 instead of 43), or to a duplication of the original figure in twenty years. In sixty years, therefore, the duplication occurs, as matter of tabulation, three times, so that by A.D. 1914 the 64.4 million tons of 1854 would amount to 515.2 millions of tons, by 1934 to 1030.4 millions of tons, and so on.

Now it might have been thought that a Royal Commission, consisting, or purporting to consist, of picked men, would have begun by saying to one another, "We are not met to verify a statement of progression, which is a mere matter of abstract arithmetic, but to inquire, on the broadest grounds, whether there is any cause for just alarm as to the exhaustion of our collieries. If men continue to abstract coal, sooner or later all the coal will be extracted. That is an axiom as certain as that all men must die, and in itself it is not much more practically alarming. Are there any steps that we can suggest to prevent the waste of coal?" Instead of this, however, the Commissioners took the ugly figures to be,—not only indisputable as figures, but,—a practical guide to an anticipation of the future. And then,—no doubt with the best intentions,—finding that the end of coal drew near, upon paper, they tried to soothe the public mind by doubling the esti-

mates of the capital on which the future had to draw,—on the money in the bank,—that is to say, on the quantity of the coal beneath the surface. At 4,000 ft. in depth the temperature of 122° Fahrenheit is the least that can be anticipated; and in coal-mines, where the increase of heat with depth is greater than in other strata, it probably is much more. Not only is this a more than tropical heat for the air,—in the shade, be it remembered,—but the heat of the soil is too great to be touched by the naked foot without pain, and rapid disablement; nor do we apprehend that boot soles would make any very great or permanent difference. However, the Commissioners trusted that, by and by, some means would be found for cooling the earth at this depth; and reported that "it might fairly be assumed that a depth of at least 4,000 ft. might be reached." And down to this prodigious depth, counting as "available coal" everything that looked black, they reported that there existed 90,000 (or to be exact, which in such a case is no doubt a virtue, 90,207) millions of tons of coal. Our own estimate at the time, if we remember aright, was that down to the limit of blood heat, which we take to be the hottest temperature at which human labour is available, we might estimate the coal beneath our fields at 61,000 millions of tons, of which, however, more than a third could only be extracted at prices rising to the limit of commercial impossibility.

It is not surprising that coal-owners, on the one hand, and coal-consumers on the other, should have thought that there was something irrefutable in the menace, to avoid the terror of which grave men, sitting in a snug chamber at Westminster, proposed to send miners into driftways of the temperature of from 92 degrees to 123 degrees Fahrenheit. The price of coal sprang up from the date of the report, and in 1873 the price in the Thames, which had fallen 1d. per ton in the year after Mr. Jevons first made the calculation thereon, sprang to 31s. 3d.; having been 19s. in 1866, 18s. 2d. in 1871, and 23s. 10d. in 1872. In other local markets, as at Cardiff, proportionate rises occurred. It is true that the year 1873 was one of generally inflated prices. But it is not so sure to what extent the general rise followed rather than preceded that of coal. Every one will remember that at the time the rise in the price of coal was put forward as an excuse for every possible augmentation of cost, and we are disposed to think that it was probably the main cause, and that a rise involving much distress, check to business, and national collapse, was traceable in the main to the work of the Duke of Argyll's Commission.

It should have been obvious to those gentlemen that, besides the question of heat, which they so gallantly disregarded, there were other elements which could not fail to come in to arrest the march of the tabular increment. Price, as we pointed out at the time, was one of them. And price did rise, as we said it would; and what was more, as prices rose efficiency of labour declined. In the year 1869 each miner, on an average, sent to bank 312 tons of coal; in the year 1874 each miner only sent 249 tons to the surface. With rise of price,—especially when connected with decrease of industry in the heter-paid workmen,—it is obvious that foreign coal will come into the market. A cargo of coal, in spite of the proverb, was said to have been actually sent to Newcastle. Long before any practical difference between the value of our estimate and that of the Commissioners could come upon the carpet, it is clear that the importation of foreign coal would have become an element in the price of coal in England, and in the activity of our own mines.

Another consideration should have been no less conclusive as against the enormous annual yields on which, at rather distant dates, the exhaustion of our coal supply hinged. The 500,000,000 tons that were to be extracted, according to the tabulation, in A.D. 1914, would require the labour of 2,000,000 miners. By 1934 double that number would be requisite. But this demand would have left so few able-bodied men for the discharge of all other industrial occupations in the country, that the coal raised could not by any possibility have been consumed,—a balance that, in point of fact, would have been reached at a much earlier period,—but which the Commission never thought of striking.

Peace to the ashes of the Professor. We do not think that the coal panic was attributable to his calculations, except in so far as indirectly

they frightened the Commission, and so frightened the country. But there is a great comfort to those of us whose mathematical acquirements are of an humble order, to those of us who hate long sums, and to those of us who, as practical men, are always disposed to think that something has been overlooked, when frightful calculations of statist and political economists are brought forward to confound us.

#### THE FORTHCOMING INTERNATIONAL SANITARY CONGRESS.

The fourth International Congress of European sanitary reformers is about to meet at Geneva. The discussion will be held at the University from the 4th to the 9th of September, and an exhibition of sanitary appliances at the Plain Palais from the 1st to the 15th of September. Considerable care has been displayed in the organisation of the congress, and there is every prospect of a brilliant success. Dr. Paul Bert and Dr. A. Pronst, both members of M. Gambetta's cabinet, will be present and read papers, while M. Pasteur has prepared a special treatise on the "attenuation of virus." A programme of the proceedings, published in pamphlet form, and in German and French, gives not merely a list of the subjects to be discussed, but a synopsis of the arguments of the opener of each discussion, and this, with respect to the meetings of the sections as well as the general meetings. Thus we find that the third section embraces all the questions relating to architecture, engineering, and industrial hygiene, and we are promised a paper on the all-important problem of the disposal of sewage, by M. A. Durand Clay, chief engineer of the Paris Ponts et Chaussées, professor at the École des Ponts et Chaussées and the École des Beaux-Arts. Dr. T. Moore, of Columbia, United States, will give some account of American ideas on this matter. Then M. Lasins, of Zurich, professor of architecture of the Federal Polytechnical School, will describe a simple, economical method of warming and ventilating workmen's dwellings. M. Bourrit, professor of architecture at the Lausanne Academy, is to speak on the hygiene of private dwellings. Dr. Brouardel, professor of forensic medicine, and Dr. Armand Gantier, demonstrator of chemistry at the Paris Faculty, will read papers on incidental poisoning by small doses, such as that produced by lead paints, wall-papers loaded with arsenic, &c. Finally, M. Émile Trélat, whose name will be familiar to our readers, will discuss the advantages and disadvantages of permeable coatings to inhabited dwellings.

In the other sections, and at the general sittings of the congress, which will be held in the afternoons, there are many questions that must at least indirectly interest architects. For instance, the contagious nature of phthisis, now generally admitted, increases enormously the importance of domestic sanitation. We look to cleanliness, good drainage, ventilation, and disinfection as the means of reducing the death-rate from the zymotic diseases, which are the cause of fifteen out of every hundred deaths; but now it will be demonstrated, at the third general sitting of the congress, that these same means will tend to destroy the virus of those chest diseases which kill in England twenty-six out of every hundred persons. Good sanitation will, more than any other cause, contribute to reduce the prevalence of consumption. The discussion on short-sightedness will also involve many questions of practical interest to the architect; notably, the best means of providing light in class-rooms. A very elaborate paper on typhoid fever opens out the entire question of house drainage and public sewers, while another debate on hospital barracks also promises to be of special interest. Such are the subjects particularly fitted for discussion by architects and sanitary engineers; but, of course, every subject inscribed in the programme is of general interest to the sanitary reformer and student.

England, as usual in these International gatherings, is poorly represented, though we are glad to notice the promised presence of the Nestor of sanitary reform, Mr. Edwin Chadwick, C.B., who will read a paper on the principles of sanitary administration in England. Perhaps at the last moment, however, a larger number of Englishmen will be present to take part in the proceedings, though, as yet, there are hardly any English names inscribed in the list of speakers. Of course, the official

language of the congress will be French, but speeches in other languages will be allowed, and a summary membership made on the spot. The terms of membership are simple, and its privileges extensive. A letter stating qualification—and the only qualification is that of studies which have a tendency towards the preservation of public health—should be sent, together with a subscription of twenty francs, to the Secretary General of the Congress, Dr. P. L. Dunant, 4, Rue Puits St. Pierre, Geneva. In exchange, a full report of the proceedings will be received, the programmes, &c., and a document which will serve as a gratuitous ticket from Geneva to Calais. Thus the expense incurred by members will be for the single and not the double journey. We trust, therefore, that England, the leading nation in sanitary science, will not be among the last to send representatives. In all probability from sixteen to eighteen nationalities will have some representative men present, and in many instances these are selected by their respective Governments. In England all depends on the initiative of private individuals; but we trust that the spirit of enterprise among our sanitary reformers, in the Social Science Association, for example, will not be as wanting on this as on former occasions. An excellent opportunity is now offered of carrying far afield those principles of hygiene which we hold dear at home. Continental sanitary reformers all feel that, on these subjects, England can speak with the voice of experience; and yet, when after an interval of two years, this great international gathering takes place, it is found that but few Englishmen are present, and that the majority of these are utterly unable to deliver a speech in French. From Russia, Germany, Italy, Spain there are brilliant speakers, familiar with all the graces of French oratory; and as Englishmen are, as a rule, better linguists than the Latin races, we can see no good reason for being so poorly represented.

#### TISSANDIER'S ELECTRIC BALLOON.

The balloon is at present the only apparatus by means of which man is able to rise in the air. In future, when suitable motors and contrivances for directing them have been invented, we may find it possible to pass through the air like birds. The solution of such problems ought never to be deemed as impossible, although with our present mechanical and physical aids it need not be expected. If we now desire to ascend to the clouds, we have to fall back upon the balloon with all its imperfections. Ever since the balloon was first invented, it has been the constant endeavour to find means and provide methods for navigating it. Many proposals have been made, of which not one has been successful, and a good many have been absolutely ridiculous. We witness how ignorant inventors equip circular balloons with sails, without considering that the balloon floats quietly in the moving masses of air, and, if once separated from the earth, receives no longer wind pressure from the side. Others suggest the employment of wheels and other means, which may serve on land or in the water, but not in the air for a practical horizontal motion.

The first experiments of any importance for directing the movements of balloons were made in 1852 by Henri Giffard, the later inventor of the injector. Giffard was the first to point out that, in order to obtain a slight horizontal movement, an elliptical form must be given to the balloon, so as to reduce the resistance in the air, which for the greater part depends upon the section of the balloon, to a minimum for the movement in the direction of the longitudinal axis. In that year, Giffard constructed an elliptical balloon of a cubic contents of 84,650 ft., 145 ft. long and 39 ft. in diameter in the centre. The balloon was held by a network upon a central wooden beam, at the end of which was fixed a sail serving as a rudder. A small high-pressure engine was fixed in the car, revolving an air screw 110 times per minute. The balloon was filled with ordinary gas. Giffard made his first ascent with this balloon on September 26, 1852, and attained a horizontal speed of 7 ft. to 10 ft. per second, which, however, was considerably exceeded by that of the prevailing wind.

In 1872 Dupuy de Lôme made a similar experiment with a balloon of a volume of 105,945 cubic feet, which supported thirteen persons,

who turned the screw themselves; but he obtained no better result than his predecessor. If Dupuy de Lôme had employed an engine of corresponding weight, he would have had a motive-power ten times as great as his disposal; but he considered a steam-motor to too dangerous. To use fire under a balloon filled with hydrogen gas, the most combustible of all gases, would be to suspend a Damocles' sword over the heads of such experimenters. An insignificant leakage in the balloon and a passing spark would be all that is required to cause the immediate destruction of the balloon with its passengers. A steam-motor, moreover, loses constantly in weight, as it emits 22 lb. of water in the form of steam per hour and horse-power, and during the same time consumes 9 lb. of coal. If, consequently, the balloon is balanced at starting for a certain elevation, it becomes constantly lighter, and will continue to rise. Of course, the steam raised could be again condensed, and the gas of the balloon used for firing; but, by this arrangement, the whole apparatus would become more complicated, and the general risk increased. Very light and powerful engines have been constructed which may, at some future time, become very useful for aerial navigation, but which, nevertheless, have little prospect of success with a gas-balloon on account of their dangerous nature.

We thus arrive at the application of stored electricity as motive power for the air screw, as shown in the model by Gaston Tissandier at the Paris Electrical Exhibition. M. Tissandier stated, in his lecture before the French Academy of Sciences, that the recent improvements made in dynamo machines and the Planté secondary battery for storing electricity induced him to make experiments with a view of using them for aerial navigation by means of balloons. Secondary batteries are light, contain a large amount of motive power, and thus offer special advantages for this case, as they constitute no danger to a balloon filled with gas, do not lose in weight, and may be put in and out of action in the simplest manner. M. Tissandier's experimental balloon was of an elliptical, pointed form, 11 ft. 6 in. long, and had a diameter of 5 ft. in the centre, and a volume of 48½ gallons. The balloon was filled with pure hydrogen gas, and had a lifting power of about 4½ lb. A Siemens motor, constructed by G. Trouvé, and weighing nearly half a pound, was fixed to the lower end of the balloon, and revolved a double-headed screw of 18 in. diameter, at the rate of 6½ revolutions per second, by the aid of a Planté secondary battery, propelling the whole aerial vessel at a speed of 3 ft. per second for fully forty minutes. With two secondary elements weighing 1½ lb. each, and a screw of 21 in. diameter, the balloon attained a speed of 7 ft. per second for ten minutes.

M. Tissandier had a second model constructed of 13 ft. in length, which was to be seen at the late Electrical Exhibition in the Palais de l'Industrie. The balloon was conducted through the building on a wire stretched across it, as it is still to be seen in the Conservatoire des Arts et Métiers. The weight of the motor and the element was less than 4 lb., so that it did not exceed the lifting power of the balloon, and the whole apparatus was not suspended on the wire, but was merely guided by it. The screw, of a diameter of 11 in., was revolved by a Trouvé machine of a weight of ½ lb.; the speed depending upon the tension and the quantity of the current. The apparatus was supplied with an adjustable rudder. The large electric balloon projected by M. Tissandier is to have the following dimensions. The electric machine is to weigh 5 cwt., and the secondary batteries 17 cwt., representing about 5 horse-power. These will be carried by an elliptical balloon of a volume of 106,000 cubic feet. The balloon is to be 131 ft. long, and its diameter in the centre to be 607 ft. The balloon would have a lifting power of 3½ tons, and consequently would be able to support 1 ton weight of passengers, ballast, &c., besides the batteries and the machinery. With the air calm, its speed would be from twelve miles to fifteen miles per hour, which, of course, could be maintained for only a few hours. M. Tissandier intends constructing such a balloon shortly, and undertaking voyages with it over and round Paris. The problem of aerial navigation can by no means be considered as solved with this balloon. Even if the first experiments should not give satisfactory results, some advantage will be gained by the general evidence they will supply of the practicability of the idea.

## AN AMERICAN WRITER ON ENGLISH ARCHITECTURE.

THE well-expressed opinions of the cultivated traveller on any country that he may visit invariably afford instruction; a special interest, however, is attached to the views of the American visitor to our shores. There is that sufficient community of language, literature, history, and traditions between us and our consins, the absence of which leads on the part of all other "foreigners" to such amusing expressions of opinion regarding our country as, from time to time, are to be met with, even from highly-educated sources. It is additionally interesting when we have brought before us the views of a cultivated literary student, such as Mr. Richard Grant White, who, in his lately published work, "England Without and Within," has given us the result of his experience during several months' residence among us. A glance suffices to show that his work is not the crude ill-digested expression of the hasty traveller or sight-seer, but of an observer who, long before reaching our shores, has prepared himself by a lengthy course of reading and thought.

To the cultivated American, England is always "the old country"; what, we have Mr. Morley's recent assurance, Longfellow once said of his countrymen, that they were only Englishmen under a different sky, is largely to be true throughout all the eastern portion of the States, by all true Americans, of whom Mr. White is so characteristic a specimen. As a self-styled "unmigrated Yankee, not one of whose forefathers had been in England for 240 and odd years," Mr. White, like his countryman, Hawthorne, shows more than once his contempt of the far too lightly styled "Americans," who may, it is true, hail from the States.

Mr. R. G. White's work has so far received from the reading public in this country a most flattering reception; and very interesting, not only to its American but to its English readers will much of the work be found. In most cases the views of the author are clearly the result of well-weighed consideration; but there are points over which our critic might have passed with less confidence of tone. It is not our intention, nor indeed would it enter our province, to speak generally of Mr. White's work. It is to the casual reference made by the author to the artistic beauties he had the opportunity of seeing during his visit that we wish to draw attention.

Mr. White seems to us to show want of the critical faculty, to say nothing of historical reverence, when he speaks as he does of St. Paul's as "outside and inside the noblest building he ever saw." "Its forms are without beauty, its lines without meaning, its round windows are ridiculous. Its outside is not only ugly in form, a huge piece of frivolity, but its discolouration gives it a most unpleasant look." The reverence which the author so constantly expresses failed him singularly here at a point where it was most wanted. Our author's criticisms are scarcely less severe when he declares the City public buildings to possess the beauty of fitness, "for they look just what they are,—the creations, the abode, and the stronghold of British Philistinism,—rich, substantial, tasteless, and oppressively respectable"; again, he will find few to agree with him when he complains that even distance cannot render the House of Parliament "imposing," a fault which, whatever may be the faults of Barry's grandiose design, could not possibly be found by any one who has ever enjoyed the privilege of observing constantly from Westminster Bridge the long pile under the varying aspects of sunrise and sunset; while we can imagine Sir Edmund Beckett's feelings when Mr. White expresses his delight at "the grand, sweet voice" of Big Ben. But the *finale* of this paragraph is perhaps the most curious. "The parish churches are mostly by Wren or in his style, and are ugly with all the ugliness possible to a perversion of the forms of Classic architecture."

Though such opinions are somewhat calculated to weaken one's confidence in our author's judgment, yet it must be agreed that he is right in not finding that the newer parts of London near South Kensington are externally very interesting; he finds, however, that the houses are very handsome. "The pretentious talk I have heard about Fifth Avenue houses leads me to say that there are hundreds of houses in the

best parts of London, around Hyde Park, on Carlton-terrace, and in other like places, which are far finer, much more noble, as Peppys would have said, than any that are to be found in New York, in Boston, or in Philadelphia." And our author here compares the modern houses of London and New York; the difference, he asserts, being "that the former, while less showy than the latter, are more spacious, and have more of the dignity which accompanies large and well-proportioned size. . . . The notion that rows of houses all alike are not found in England is altogether wrong; in the new parts of London such rows, and of very handsome houses, are common, while in the new parts of smaller towns the houses built for people of moderate means stand in rows of from a dozen to two dozen, as like each other as one brick is like another." In our shops, Mr. White complains of a remarkable "absence of show and pretension, and he utters a very justified complaint respecting the irregular manner in which the streets are named and numbered. Of Fleet-street our author has naturally much to say, of the Old Cock Hostelery and the quiet Temple Gardens; he expresses his surprise at the rubbishy way in which we demolished Temple Bar, though the surprise is qualified by the remark that "the removal of the obstruction, architecturally not very admirable, shows how, at the last moment, the English mind can rise to the emergency of a great reform."

We can thoroughly understand Mr. White's "new and delightful sensation" of surprise at finding a town like Windsor so little increased in size after its centuries of existence, a town "neither great nor growing," and plainly without enterprise. "It gave rest to a certain stunned and weary feeling which comes upon one in the streets of New York, and in the streets of other places which are daily, with more or less success, doing all they can to be like New York, that dashing, dirty demure of cities." Old and enthusiastic student of Shakspeare as Mr. White was, he was wise enough not to allow himself to be carried away at Windsor, where so few traces of the haunts spoken of by the poet now remain; indeed, as our author admits, he "found little of interest; the town is not new, but it is modern, and its Elizabethan features have all been improved away." The incident of the ruins of a burnt house meeting our critic's eye affords him the occasion to give us his opinion of the mode in which many of our English houses are built. "The house had not been wholly destroyed, and the skeleton still held together. It seemed to have been built some forty or fifty years ago. I was surprised at the flimsiness of the construction. The bricks were poor, and the mortar was bad. A house so built may be found anywhere, and I should not mention this, but as the occasion of remarking that I found the same inferior builder's work wherever I went in England. According to my observation, modern English houses, unless they are built with special care and unusual expense, are very slightly put together with bad materials and poor workmanship. It is the custom to put up the shells of houses, usually three or four together, and to leave them to be finished according to the wishes of an intending tenant or purchaser. I examined many of these without finding one even tolerably well built. . . . The mortar, although it had been set for years, would crumble under the touch of my stick, or even my thumb-nail. And walls of the modern-built villa houses that I visited were rarely more substantial, while the joiners' work was both slight and coarse. I also remarked that where recent additions had been made to the height of garden-walls, the mortar in the new parts, although in general it was plainly ten or twenty, or even thirty years old, was more like mud than mortar. Indeed, I did not see in England in a new private building of moderate pretensions, any mortar worthy of the name. This attracted my attention, I need hardly say, because of the notion generally prevailing and sedulously encouraged by British writers, that all English work is distinguished from other work of its kind by excellence of material and thoroughness of workmanship; that although it might not have elegance, it was sure to be substantial. I did not find it so. In this respect, in many ways I was disappointed. That such was once the character of the work of English artisans and manufacturers is not to be disputed, but during the last fifty years this glory of England seems to have departed." Severe as is this view, must

it not be admitted that in too many cases it is only too true?

Windsor Castle, Mr. White, of course, saw pretty thoroughly, but probably the most interesting portion of the chapter, "A Day at Windsor," is devoted to the description of the antique and far too little known Church of St. Andrew at Clewer, one of the oldest in the kingdom, and concerning which we can thoroughly believe our author finding many grown-up Eton boys had never seen.

In his chapter on "Rural England," in comparing our cottages, picturesque though the writer admits them to be, he is of opinion that the corresponding unsightly wooden houses of the United States, "in real comfort and in healthiness, are superior; for they are dry and warm. Their shingle roofs keep out the rain, which comes through thatch, or soaks and rots it, and their clap-board sides do not become reservoirs of cold dampness. Rheumatism is not so common among those who live in them as it is among the English rustic folk," while a very proper mention is made of the carelessness in our villages respecting the objects that are "in unnecessary nearness to the house." "There are no indications that the inhabitants are anything more than tillers of the ground, and that when work is done they put it and its belongings out of sight and out of mind, and change their occupation with their clothes." Indeed, we can understand any one accustomed to the comfort and independence to be met with among the farmers of New England and the Middle States being somewhat surprised at the condition of the corresponding class in the old country; but, as our friend admits, whether they would be such good farmers "I very much doubt; whether they would have been more respectable men, or even happier, I shall not pretend to decide." The chapter on "Rural England" is of great interest, and the result of much observation. To many an English reader it will afford valuable matter for reflection. The same may undoubtedly be said of the succeeding chapters on English Men and English Women, on English Manners and Habits, on "Nobility and Gentry," and several others.

Hampton Court gives Mr. White another opportunity for an attack on poor Wren. "The first sight of the palace itself," the writer remarks, "is very disappointing, for the principal front which it presents shows, at a glance, the hand of the architect of St. Paul's." The seventeenth century, in spite of its peculiar interest, literary and historic, and its essential connexion with the New England of which Mr. White is so characteristic a citizen, comes off hardly at his hands. Speaking of the famous Lely beauties, our friend remarks that they are "poor, flimsy, meretricious things." Had his remark been applied to the originals, we could understand it from so stanch a descendant of the Puritans of the *Mayflower* days, but he goes further when of these portraits he says that, "Even the flesh tints, which are the best part of them, are weak and washy, and the drawing is very bad. The eyes are, I think, the worst that I ever saw in paintings of any pretension." We are sorry to see our critic going beyond his province, his views, social, political, and historical, it is instructive to hear, but his artistic criticism not possessing the same solid foundation of experience we must object to. The remark made during a walk from Twickenham to Hampton Court, on the high-sounding names given to some of the scrubby little roadside cottages with a neglected patch of earth or grass before them, which the writer met with on the way, is more to the point.

The chapter entitled "A Canterbury Pilgrimage" contains some interesting and carefully gathered information. "There is no place in England," truly remarks Mr. White, "excepting London and Westminster, which is so enriched by memories and by memorials of the past; and yet I found intelligent, well-educated men in London and elsewhere, not three hours away, who had never seen Canterbury and its great cathedral." Mr. White, of course, put up at the "Rose" inn, on the difference of which from the hotels of his own country he has much to say. Our author is charmed with our inns, where "you do not feel as if the house were a mere continuation of the street, except the paving-stones and the carts and horses." With Canterbury our author is enchanted, as a town which like so many others in England has "manifestly grown and not been made to order, not put in sections by con-

tract . . . one house built in a certain place, and in a certain way, because its builder chose to build it there and in that way"; and this charm of our old towns which appeals to the American visitor, let our builders see that they respect and endeavour to continue. Mr. White, though he admits he did not go to Canterbury to "muse among antiquities nor to study architecture," after seeing the cathedral, with which, of course, he was much impressed, did not neglect to visit St. Martin's Church, with its thirteen centuries of hoary antiquity, that lie buried beneath the ivy that clammers round the old tower and over the Roman bricks of the walls.

Speaking of Cambridge, our author remarks that the architectural interest of Oxford "is so great that Cambridge is too much neglected in this respect. Its college buildings are so beautiful that only to see them would be worth a journey from any part of England,"—a statement that all who know the old town will fully bear out. Oxford and Cambridge, with many of their interesting traditional customs, are well described by Mr. White, who had the advantage of excellent introductions to the authorities. Of Oxford he does not hesitate to say that "it is the most beautiful place" he saw in England; indeed, he is inclined to think "the most beautiful town in the world," and Mr. White warmly urges on his countrymen who may visit England "with a desire to see its characteristic beauties to give at least two or three days to Oxford."

It is a serious and lengthy chapter,—one dealing with a subject which, as Mr. White himself says, is of equal importance to his countrymen as to us,—the chapter on the "National Vice" of drunkenness,—a vice of which, however, "it is to be said," he remarks, "that there are reasons for it, which do not exist in other countries. England lacks good" [this he explains afterwards as meaning "soft"] "water, and produces no wine." The statement that "many people cannot drink the water of England unqualified, without being made ill," can be thoroughly borne out by fact. Mr. White is not severe on the national vice: he only bewails its prevalence, and particularly its saddest form, among the women; he is only one more of those who openly aver that "such steady besotted drunkenness seems to be at the bottom of much of the distress and most of the crime in England." It would seem, however, our author concludes, that we are gradually freeing ourselves of the vice. Abstemiousness in England is not so easy or desirable as it is in America, "and hardest, although most desirable of all things everywhere, is not abstemiousness, but temperance."

Mr. White, of course, does not neglect a description of the obligatory pilgrimage of every good American to Warwick and Stratford-on-Avon; for even those Americans who are only hurrying through our country to Paris never fail to visit Shakespeare's birthplace, "the proportion of these being very much larger," remarks Mr. White, "than that of the cultivated Britons who render their personal homage to him whose works are our richest common inheritance." But with Stratford Mr. White is sadly disappointed. "The truth is," he admits, "the Stratford that I knew (and about which I had read so much, and the topography of which I had studied until I could have gone straight to every place I wished to see without a guide) was Shakespeare's Stratford, and that has passed away. The truth is, that in the stead of old Stratford, there is now a successful place of business"; and he concludes, after describing his other disappointments, by advising no one to go to Stratford "who would preserve any elevated idea connected with Shakespeare's personality"; but we consider Mr. White is going too far when he roundly declares of the poet's monument in the church that "it is ugly; the staring painted figure-head-like bust hideous."

On his return to London our author admits to a positive feeling of "getting home again," as, in spite of the little beauty of our metropolis, its dullness and dinginess and commonplace character, yet the whole of it outside of the City proper has a home-like look." Some of our streets remind Mr. White of the thoroughfares in his own country, a fact which any one who knows America can fully bear out. "There is," in fact, as he very sensibly points out, "no indication of a difference of character between the people who built London and those who built New York and Philadelphia. The unlik-

ness is produced simply by the fact that the newer and larger parts of the latter places were laid out, projected, and that the whole of the former slowly grew"; however, as an impression, Mr. White admits to finding "striking" the general unlikeness of London to towns in the United States, an unlikeness "very much greater at the present day than it reasonably should be." Certainly, the older parts of New York singularly resemble the older parts of London. On our London states Mr. White does not exercise his usual artistic severity of criticism; he even finds their number "great." "It could hardly be otherwise in the capital of a country with such a history as England's." Compared with New York and the cities in "the States," this is, of course, true; but it hardly suffices when we think of the Continent.

Without any affectation of thoroughness, Mr. White has placed before his countrymen, and, indeed, before English readers, who, perhaps, will most profit by a perusal of his book, a curious and instructive picture, which fully answers to its title, of "England Without and Within."

#### THE WOODWORK OF MODERN HOUSES.

It is at all times a matter of satisfaction to those engaged in the building trade to observe, during the demolition of buildings that have been erected for fifty years or more, the perfectly sound state in which the timber taken out of them is usually found to be.

It is, of course, to be expected that oak, and such other English hard woods as were introduced into buildings before foreign building woods were so largely imported as is now the case, will remain sound even after the lapse of a considerable length of time. Our references do not, however, relate to English woods, but to the building woods now in common use.

Similar woods are continually being taken out of buildings that have been erected for fifty or sixty years, and we find them generally to be in a perfectly sound state.

Those whose recollections of the building trade date back for such a length of time are able to remember that many of the convenient sizes now imported in the shape of deals, battens, and boards were formerly unknown, and that the bulk of the foreign timber that was then imported reached this country in the shape of hewn logs, which, on their arrival here, were sawn into the required shapes, mostly by the laboriously slow process of "hand-sawing."

The complete development of the foreign sawn-wood trade does not, indeed, date back any great number of years. The practice of sawing the hewn logs on this side was at once a slow and costly process, and concurrently with the improvements which were introduced in respect to wood-working machinery, the foreign sawn-wood trade developed with rapid strides. Although, however, the wood began to be shipped, for the greater part, in a sawn state, the sizes in which it was shipped were very few. For a long time even the merchants on this side did not welcome any innovations in respect to sizes, and, as we have remarked, it is only of recent years that the trade can be said to have completely developed. At that period Norway began to export sawn wood.

It does not appear to be generally known amongst those who make use of wood as a constructive material, that the wood shipped to us from Norway is, taking it all round, of a much inferior quality to that shipped from Sweden or Russia. Otherwise it would be difficult to account for Norwegian wood being so often specified for purposes for which it is altogether unsuitable.

It is well that it should be widely known that the trees of the Norwegian forests rarely attain to a size sufficient for anything larger to be cut from them than small-sized battens, and that what few larger sizes are capable of being produced are generally extremely sappy, or otherwise are affected with taint.

It is, perhaps, not too much to say, that the elements of decay are always more or less present in Norwegian wood, and that, under favourable conditions, the symptoms of decay rapidly develop.

Whilst directing these remarks particularly to Norwegian wood, we should not overlook the fact that there is annually being shipped to this country a large amount of Swedish wood which is altogether unfitted for building purposes. The trade designation of the quality of such wood is usually "Fiftbs," and occasionally

"Sixtbs" quality, and it may be remarked, as a matter for dissatisfaction, that the importation of these lower qualities has of late years been largely on the increase. There are several reasons which could be furnished for this being the case.

One reason is, that the immense importations of foreign building woods that have occurred have, in some parts, practically depleted the accessible forest lands of their best growths, and trees are to-day being converted into deals and battens which, in the early days of the importations, would certainly have been discarded.

Another reason is that the fierceness of modern competition is such as to induce some builders to take work in hand to do for less money than it is capable of being done for; and in the endeavour to turn it out at the lowest possible cost there have been builders who have been induced to introduce a class of undesirable wood, although they have possessed a full knowledge of the inferiority of the article. In cases where there has been no efficient clerk of the works employed, architects have been hoodwinked, and, in their absence, the inferior wood has been placed in position.

The gravest cases have, however, occurred when there has been neither architect nor clerk of the works employed to superintend matters, and when the property has been erected merely for speculative purposes. In many such cases, —we say it advisedly,—absolutely-rotten timber has often been introduced into new buildings.

In what may be termed common speculative house property, endeavours are being constantly made to "scamp" the sizes of the hearing-timbers, which are being pinched in every direction.

Deals, 3 in. by 8 in., are made to do service for 3 in. by 9 in. deals; battens, 2 in. by 6 in., are substituted for 2 in. by 7 in. Such sizes as 2 in. by 6 in., 2 in. by 5 in., 2 in. by 4 in., 2 in. by 3 in., 2 in. by 5 in., and 2 in. by 4 in. are "squeezed" into service; and in the generality of cases legitimate strength is being robbed.

Even taking the case of flooring-boards, which it might well enough be thought would not be hid down of a less thickness than 1 in., they are now frequently cut three out of a 2 in. batten, instead of being prepared out of foreign sawn boards, which always run full of wood, and consequently can be produced planed without their thickness being reduced below 1 1/2 in.

It is not the case that all architects are aware that such sized battens as 2 in. by 6 in. are largely imported, and so it sometimes occurs that when 2 in. by 7 in. are specified, and 2 in. by 6 in. are used in their stead, exception is not taken to what are regarded only as badly-manufactured battens, some of which appear to be strangely short of wood, but others of which may measure a trifle over the specified size. The fault,—if looked upon as a fault,—is regarded as being unintentional, and is therefore generally excused.

The important part of the case to property-holders, and especially to those who have made money advances upon property, is that these "off sizes" of small stuff, such as we have mentioned, are, for the greater part, shipped from Norway,—and Norway wood, as we have pointed out, is undesirable for building purposes, on account mainly of its proneness to decay.

High-class, and, indeed, respectable, builders generally do not buy Norway wood, excepting, perhaps, their imported Norwegian flooring-boards, and the best wood in Norway is selected for flooring purposes. The remarks, therefore, which we have made, will be objectionable only to a class that have done much injury to those legitimate contractors whose desire it is to turn out good work.

To such builders as desire to do their work well, equally as to architects and clerks of works, it is important to explain that an immense amount of very common building timber is annually being imported, and that this timber generally goes into consumption immediately upon its arrival.

It does not pay importers to keep such stock on hand, because it is a quality which rapidly deteriorates, and therefore it is pushed off at the best obtainable figures.

Purchasers of house property which has been put up on speculation should insist upon some of the flooring-boards being taken up here and there, so that the condition of the joints can be sufficiently examined, and any deficiency in the quality of the wood used detected.

Architects being made aware of the fact of the increased importation of "fifths" and "sixths" quantities of Swedish red wood, will do well to take precautions against the larger sizes of redwood deals being introduced of too inferior quality.

It is a logical surmise that so long as the importation is on the increase the consumption is equally on the increase, and it is quite possible that all the inferior wood is not used up in speculatively-built house property.

We are inclined to the belief that common wood is not largely used for joinery work. There is little economy in using inferior wood when much labour has to be bestowed upon it; and even common-class builders have been wise enough, it seems, to recognise this fact.

Yet, even in respect to wood used for joinery purposes, it should be borne in mind that steam power machinery is more largely every day brought into service, and that a commoner class of wood can be worked up by the aid of machinery than can profitably be used when the articles are produced by hand-labour.

The firmness of a building is not, however, affected by the quality of the joinery work. It is almost alone with the bearing woods that we have to deal, and the most important feature is, that the bearing timbers are hidden from view, and consequently their unsoundness is not likely to be detected until some catastrophe occurs.

It may be reflected that few accidents arising out of the inferiority of wood have to the present occurred. What is desired to be pointed out in this paper is, that the heavy importation of the inferior sorts of wood have occurred during recent years, and that the effects of these importations have yet to be experienced.

Our forefathers paid an infinite amount of respect to the durable qualities of English oak; and although still relying upon the useful, cheap, and abundant building woods which are now shipped to us from Northern Europe, and from the New World, some of our modern house-builders would do wisely to follow their ancestors' example, and, seeking to do fair work, discard the use of woods the quality of which it is not fitting should be employed, and make use only of building timber of a legitimate quality.

In respect to contract work, the case rests very much with architects, for if clients are advised to accept, under any circumstances, the lowest tenders, without respect to the reputation of those estimating, there will always exist the risk that a certain class of builders, who are in the habit of sending in low estimates, will seek to recompense themselves by making use of inferior and insufficient material.

#### SWALEDALE AND ARKENDALE.

SOME of the Yorkshire dales have been long known for their beauty and for their historic associations. Turner did much to popularise Wensleydale, and the poems of Wordsworth largely contributed to the opening out of other dales; but some of the Yorkshire valleys are still unknown regions, even to the great bulk of the tourists. One of these districts that is comparatively little visited is that of Swaledale and Arkendale, or Arkengarthdale. Partly because it is on none of the great roads, partly because of the absence of railways, and to some extent because it contains no town of great population or importance, the district is one that is not much visited. But though it has not the pastoral beauty of Wensleydale, there are attractions and associations in the more northern dale that should not be overlooked, and that make it and its adjoining valley worth a visit.

Richmond is the terminus of the railway. It is an ancient town, whose impregnable rocky castle looks down upon the little river Swale, and shelters the rugged stony little town that struggles along the brow of a hill, and down its sloping sides towards the woods of Easby. That old castle is so seated on the precipitous bank of the Swale that it literally fulfils the words of the laureate, and "claps the crag with crooked hands." Seven hundred years have passed since the erection of the noble keep, but its dimensions are still vast, and its masonry fresh, and on its rock, with the river rippling below, and the ivy about its ruins, it is the first object and the chief that strikes the eye. From its ancient hall there is a view so grand that when George, Prince of Wales and "first gentleman in Europe," visited it, he declared it com-

manded the noblest prospect he had ever beheld. To the south there rise the hills that shut in the valley, to the north the town is at the foot, whilst east and west the course of the river is through changing woods, and past temples, abbeys, and ruins, that make it a prospect without a dull inch. Richmond is a town of ruins. The gazer from the castle walls sees the little cell of St. Martin's near the parish church, the ruins of Easby Abbey, standing "most stately and delicate aslant the sparkling" Swale; and the solitary tower of the Grey Friars rising from four of the "most graceful arches in the north." It is a town that has had its history, and that connects a sedate present with a troublesome past. It was the chosen seat of lordly families,—the Scropes, the Marmions, and the king-making Nevilles. Its earls and their vassals fought at Flodden Field and Bannockburn; near it some of the great religious houses fixed seats; the Roman roads passed close to it; and Cataractonium brings up the memory of the conquering people. Three centuries ago Leland described Richmond Castle as "in mere ruine," but it still keeps stately guard over the pleasant little town, and preserves the continuity of the memories of the past.

Upwards, the course of the Swale is through a land where industry, except that of agriculture, is on a miniature scale. Some bold bluffs shut on the scene from the sight in Richmond, but the course by the river-side road is one that is pretty and pastoral. The road winds with the river at a low level, and the sound of the stream is in the ears most of the way. The roads are not tree-shaded, but high hedges grow, dotted here and there with trees. The land is chiefly pasture, and only occasionally is there the farmstead or the cluster of cottages that form here the village. Upwards, on either side, the land rises, field after field in glowing green, until the open moor crowns it, or to the north-west Arkengarth, as in the days of Scott, "lies Sark afar." Reeth, a small town some twelve miles west of Richmond, may be said to be the centre of the dale. It is isolated, remote from railways, and without distinctive industry, except the lead-mining that in the adjacent hills has been pursued for many generations. So secluded and so pursuing the even tenour of its way, Reeth is a spot where life idles. Spring visits it tardily, but flushes all the valley with tender green, and throws a glamour over the hills that shut it in. The little Arkle here joins with the Swale, and the high hills and limestone scars, the green valley, with its fringe of trees near the river, and the grey farmhouses, form a picture of peaceful rural life that the absence of the smoke of a locomotive adds to. Here the dale branches. To the north Arkengarth-dale rises right up into the moorland, whilst westward the path by the Swale leads ruggedly up by the great limestone hill at Keesdon, and the pretty waterfall there, to the junction on the bleak uplands, and the watershed of the Swale and the Ure, the Lund and the Eden. Beyond Reeth, either way, the scenery loses its sylvan character, and borrows a little of the gloom from the hills it winds near. From the little hamlet of Arkle to Tanhill, the road runs close to the Arkle beck, and the ripple of the water is the only relief to the dreariness and the isolation of the road, which passes under the shadow of Taylor Rigg, Stainmore's "shapeless wall" being to the north. Moorland leads away towards the fair valley of the Eden. The other path, along Swaledale, passes Healaugh, associated with John o' Gaunt, the pretty mining village of Gomersdale, where a glen seeds down its lead-tinted stream, and Muker, where roads to other dales strike off, and which is the capital of Upper Swaledale. Beyond there is Keld, and the road rises till it lands itself on the debatable land where the borders of two northern counties meet.

It is a wild region, but it has its charms. Its industry is that of lead mining, pursued in a primitive style. In and near some of the village streets you may see the old-fashioned "bndle," and in one at least the washing of the lead is done by females. The arrangements of the industry and the modes of payment are of an antique type; the weights are ancient ones, and the types of character of the workers and of the whole of the Dale population are in an olden groove,—"frosty, but kindly," thrifty,—as they needs must be,—hospitable, taciturn, and somewhat grave. The few miles that take us from the crowded populations of the coal-mining districts of Durham seem to have also

taken us back a century or two; and the passing of time here is not that of the fever-throb of towns, but that of the regular quiet of Shakespeare's shepherd. It is a life that has its round broken only by the variations in the seasons, and the fluctuations in the slight return to the lead-mining industries; but it is, on the whole, a contented life in a quiet, peaceful, and pastoral district.

#### RUSSIAN NEWS.

THE desire of various members of the Architectural Associations of both St. Petersburg and Moscow to profit by the Russian National Exhibition now open at the latter city, has led to some practical steps being taken with a view of holding an architectural conference at Moscow. Moscow, indeed, has never been known so full in summer-time as it has been this year. The exhibition has attracted a large concourse of people, a large proportion of whom come with the desire rather to learn than to seek amusement. For an architectural congress the moment is also favourable. Several members of the societies have for some time been in consultation to decide upon a programme of the proceedings. It is almost needless to say that not only the numerous architectural models and other objects which form a department of the exhibition, but also the many and varied architectural monuments of the elder metropolis, offer great advantages for such a gathering.

Fires are probably more frequent in Russia than in any other European country, on account of the houses being almost everywhere, except in a few large towns, constructed of wood. The cry of *paschar* (fire) is one but too familiar to Russian ears. It is worthy of note that nearly all the Russian insurance companies have decided to make an auxiliary gift from their funds to the various fire-brigades which have shown special activity and effectiveness.

The destruction of the Blaguin Bridge has drawn attention to the desirability of some means of securing these structures, which in Russia are very frequently of wood, from the danger of fire. The Town Council has proposed to insure all the wooden bridges within its jurisdiction for the sum of 1,200,000 roubles. In the same connexion Mr. Spjeshnev has again brought a proposition, invented by him for covering wooden structures, and thereby rendering them unflammable, to the notice of the St. Petersburg Town Council. Some time ago this proposition was examined and approved by the Technical Department of the Municipal Administration, and subsequently the head of the police, Mr. A. A. Kozlov, applied to the Town Council, with the suggestion that it should be made obligatory upon the proprietors or lessees of places of amusement to have the stage parts of such establishments thoroughly secured against the risks of fire. This proposition was made to the Council immediately after the fire at the Ring Theatre in Vienna, but was pigeon-holed for four months, during which period the Arcadia Theatre, the Krestof Villas, and the bridge were all burnt.

We may add that by order of the Governor of Nijni-Novgorod some experiments have been conducted on the large market plain, with a view to test the efficacy of Mr. Spjeshnev's protective preparation. Experiments with a like purpose are also shortly to be conducted by sanction of the St. Petersburg Chief of the Police, in the Semeonofsky Place, where a series of wooden houses, which are to be the subject of the trials, is in course of erection.

It may be interesting to know that land shuttling on the new St. Petersburg port has increased about fourfold the value it fetched last year, when sites in the village of Bolyinka were purchasable for from 8 to 10 roubles the square sazhen, and have now risen to from 40 to 45 roubles. A good deal of business is being done in the purchase of land at present.

The freshwater canal of St. Petersburg, which intersects the Kanonorsky Island, will be filled by five syphons, which, with the aid of hydraulic machines, will fill the canal with water to the depth of 24 ft. in the course of two months.

A Russian orthodox church is to be built in Japan, under the dedication of the Resurrection of Christ. The funds for its construction are being supplied by private offerings, which will be forwarded to the Russian Church Mission in Tokio. The sums already collected amount to more than 130,000 roubles.

Among the rather numerous competitive designs for the church to be built over the spot where the late Emperor was assassinated, we, some time back, mentioned the plans of the Superior of the Sergiev Monastery, the archimandrite Ignatius, who studied architecture practically before he entered the ecclesiastical state. It is reported that these plans have now been approved in general, and that they will be adopted, subject to some slight change in matters of detail. For use in the edifice when completed, the brothers Buch have made an offering of two magnificent altar candlesticks, enriched with plating and gilding, and which are at present being exhibited in the Moscow Exhibition. Their value is 2,500 roubles.

Several of the imperial residences are, it is said, to be given up to public or national uses. Thus, the Catherine Palace, situate at some distance from the capital on the right bank of the Neva, and the Potemkin Palace, not far off, are to be devoted to public purposes, while the palace built for Alexander I. at Taganrog is to be given to the municipal authorities of that city with a view to its conversion into a museum of local antiquities, in which the surrounding district abounds, in consequence of the number of Greek colonies formerly existing there.

The Crimean nobility have decided upon the erection, in Stuferepol, of a monument to the Empress Catherine II., in celebration of the hundredth anniversary of the annexation of the Crimean Khanate to the Russian Empire, which was completed on April 3, 1783.

It would be difficult to overrate the importance of the proposed railway in the South of Russia, and the immense benefit to trade and agriculture which it would confer. It is to extend from the Tichoretsky Station on the Rostoff-Vladikavkaz Railway, over nearly 50,000 versts to the New Russian or Odessa Bay, where, at its western terminus, a landing-place for ships is to be constructed. The chief engineering difficulties lie in the section between its western terminus and the junction for the Crimea, as here much tunnelling will be needed.

#### "OVERBECK."\*

MR. BEAINGTON ATKINSON has through these many years been at considerable pains to make himself thoroughly acquainted with the characteristics and tendencies of German art, and also with the lives of the great modern German painters. He has already rendered the English public good service by his work entitled "Schools of Modern Art in Germany," and he is now, we are pleased to learn, crowning the good work by writing the lives of the German artists, leading off with that of the saintly designer and interesting enthusiast "Overbeck."

The vocation of the fine arts is illustration in the widest sense, and the adaptation of illustration to its various purposes. The illustrators themselves may be broadly divided into two factions, into the spiritualistic and the materialistic schools; the intellectual faction disdaining the more sensuous elements, and the materialistic the more intellectual. These two tendencies are generally pushed to extremes by diametrically opposite natures, such as those of the austere Overbeck and the rollicking Rubens. Between the two polar extremities, the mental and the physical, the two characteristics are found variously differentiated *inter se*, now inclining to this side and now to that, but very rarely coalescing in that just and balanced proportion that constitutes the perfect union of the soul and body of art.

Overbeck was an extreme instance of the German school of some forty years since, and was regarded as such even by his professional associates, though the school itself leaned to the intellectually-extreme view of the purpose of art. The opinions of those who were partisans of this German faction are thus ably summed up by Mr. Atkinson:—

"The opinion upheld was that the idea or mental conception constituted the chief value of any art work; that outline or form was the direct language or vehicle of such idea; and that colour, light, shade, surface-texture, or realism, were subordinate if not derogatory elements."

The following is the artist's own expression of these views:—

"The picture embodies not so much historic fact as an idea, the intent being not to lead the spec-

\* "Overbeck." By J. Beaington Atkinson. London: Sampson Low, Marston, & Co.

tator to the real, but to something beyond. The purist painter, then, proceeds to express his invincible reluctance to study the subject from the side of life; models he had carefully avoided, because he feared that a single glance at Nature would destroy the whole conception."

But we should not forget that, when Overbeck and that devoted little band of German painters were promulgating those extreme views in Rome, European art was, with rare exceptions, utterly destitute of thought, and sorely needed authoritative weight to be cast into the intellectual side of the scale. The immediate effect of the propaganda and their works on the outer world is thus recorded:—

"The cause of the Germans was greatly strengthened, and the opposite party felt the defeat. The Italians, too, were taken by surprise to find themselves beaten by foreigners on their own ground. A natural consequence of the success was further commissions, and the fortune no less than the fame of the revivalists was made. Singularly enough, the modern Romans came forward as the next patrons. Niebuhr, writing from Rome in 1817, says:—'It is a significant fact that some foreigners, even Italians, are beginning to pay attention to the works of our friends.'"

The history of the German brotherhood in Rome will always remain a romantic episode in the story of art in the nineteenth century. And the He-Jed, and the modes of study pursued by these German pre-Raphaelites, whilst they dwelt in the old Franciscan convent of Sant' Isodoro on the Pincian Hill, and up to the time when they were commissioned to paint those famous frescoes in the Casa Bartholdi, is graphically told by Mr. Atkinson. The painting of those frescoes will become a more and more important historical incident, as it is an event from which the revival of mural painting in Germany, nay, in Europe, will date.

Human experience is, as a rule, far too limited to permit any safe inferences to be drawn regarding artistic proclivities from the personal appearance of the artist, but in Overbeck's case the personal appearance was the outward and visible expression of the spirit within. Mr. Atkinson has photographed the great man from the life:—

"The bodily and mental aspect of Overbeck is well known. I myself had the privilege of first seeing the painter when in the Cenot Palace, as far back as the year 1848. My journal describes a man impressive in presence, tall and attenuated in body, worn by ill-health and suffering, the face emaciated, and tied round by a piece of black silk. The mind had eaten into the flesh, the features were sorrow-laden. The voice sank into whispers, the words were plaintive and sparse; noiselessly the artist glided among easels bearing pictorial forms austere as his own person; meekly he offered explanations of works which embodied his very soul, timidly sought retreat, and passed as a shadow by,—the emblem of an art given in answer to prayer, and pertaining to two worlds."

It is consolatory, however, to learn that, in spite of self-denying ordinances and martyrdom by the world, he was able to bear up and preserve his facility with the pencil till his eightieth year.

Mr. Atkinson writes well and sympathetically. The advent of his book is opportune, for it is an able record of a life firm of purpose, never for a moment swerving from the mission it had accepted, with which it believed itself entrusted; a firmness of purpose that trampled many weaknesses under foot. We may criticise Overbeck's extreme bias; but, after all, the intellectual side is that "better part" which has received divine sanction in art. Overbeck not only revived art on the lines of its ancient earnestness; but he endowed it with that intellectual "strain" which has borne such good fruit in Germany, and which is destined to characterise the new art-era,—an era in which it will be sought to realise, to give form, to a wider range of mental conceptions than of old time. The "Life of Overbeck" is a standing rebuke to that host, infirm of talent and of will, who enter upon art with no other purpose than to send their "bits" to the exhibitions, and whose little best will but place them on a level with penny celebrities.

**Exeter Constitutional Club.**—At a meeting of this Club on Monday last, it was announced that Mr. E. Webb's design for the club premises had been adopted, and that he was preparing specifications and working drawings to carry out the work, for which tenders had been invited.

#### PORTAL OF THE ANCIENT MONASTERY OF ST. DOMINGO, IN SALAMANCA.

THE erection of this edifice was commenced on the 30th of June, 1524, and finished on the 18th of February, 1610, from the designs of the architect, Juan de Alava. Its foundation is due to Brother Juan Alvarez, of Toledo, of the family of the Dukes of Alva, and Brother Domingo, of Soto, an eminent *scavot*.

The style of its architecture is that found in parts of the cathedrals of Seville and Segovia, that is, the last and decaying period of pointed architecture, with the decorations in the style called by the Spaniards the Plateresco, or that of the silversmith.

The bas-relief above the doorway, representing the Martyrdom of St. Stephen, is the work of the Milanese architect, Croni; the other sculptures of the façade were executed by a Spanish artist, Alonso Sardino. The monastery occupies an area of 2,142 square metres. It was the monks who formerly occupied this building who took under their care the projects of Christopher Columbus. Its history, indeed, is intimately mixed up with that of the discovery of America, Columbus having been lodged and maintained there during the whole time of his stay in Salamanca.

#### PROFESSIONAL MEN IN THE WITNESS-BOX.

A CASE has lately been heard, in which an order for the demolition of unhealthy houses was successfully maintained by the Cubiswick Improvement Commissioners, and in which several points of general interest arise. Dr. Dudfield, of Kensington, amongst others, had deposed that demolition was the only remedy for their evil state. Dr. Collyer, the medical officer for Hammersmith, on the contrary, in giving evidence against the order for demolition, stated that in his district there were many similar buildings, and that he considered them fit for habitation. Surveyors on both sides were also heard. As the Court affirmed the order, and expressed the opinion that the Commissioners were "amply justified" in the steps they had taken, the question, What about the "many similar buildings" in Hammersmith? naturally arises. We hope that the Board of Works of that district will require their medical officer to report on these buildings, and to give his reasons for not having them demolished also.

After hearing the professional evidence on each side, the Court arranged for one of their number to view the premises, presumably for the purpose of having an independent opinion on the question. This action shows the value that judges set upon professional evidence. It is a matter of common observation that as many professional witnesses can be obtained on one side of a case as on the other. We would not say that the fact of being engaged on a particular side of a case influences professional men in their opinion about it. But it is very remarkable, to say the least, that solicitors should be able to know the exact men who can unhesitatingly take their side in a case. The position of the legal profession differs from that of the other professions in this matter. A solicitor or counsel may believe that his client is a scamp, or that the case is a bad one, but that does not weaken his influence, as he does not give any testimony whatever in it. He simply undertakes to do the best he can for him. Other professional men, however, give their opinions as to the facts of the matter, and swear that a given thing is, or is not, good or bad, as the case may be. Until professional men take up a more independent position in the witness-box they may expect to have these practical comments on the value of their evidence made by judges.

**Fever at Bangor.**—The outbreak of typhoid fever which has for the last four months raged in Bangor and the district presents no sign of abatement, fresh cases being reported almost daily. The officer of health has for the second time condemned the filter beds at the reservoir, which, he says, are infected with germs of typhoid, and recommends that the water should be allowed to pass direct from the river, pending a proposal to take it from Ogwen, or one of the large river lakes.

THE BILDER, AUGUST 26, 1882.

PORTAL OF THE OLD CONVENT OF ST. DOMINGO, IN SALAMANCA, SPAIN.—JEAN DE ALAVA, ARCHITECT.

ST. PAUL'S SCHOOL, KENSINGTON

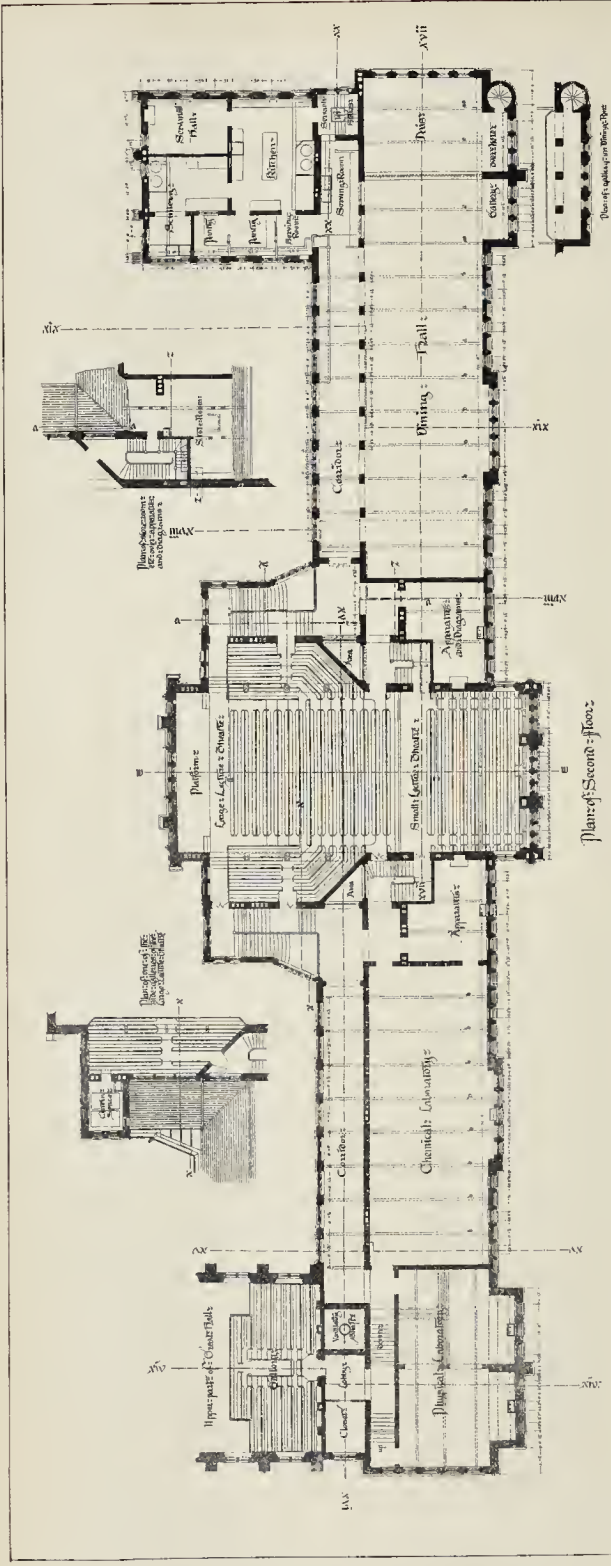

Wyman & Sons, Printers, C<sup>t</sup> Queen St.

WATERHOUSE, A.R.A., ARCHITECT.

**ST. PAUL'S SCHOOL, KENSINGTON.**

This important building, of which we publish illustrations, occupies a site on the south side of the Hammersmith-road, bounded on the east by Edith-road, and on the west by Red Cow-lane; and is in the midst of a neighbourhood now being rapidly improved, and of which, in time to come, it will, no doubt, be the chief ornament.

Mr. Alfred Waterhouse, A.R.A., is the architect.

As will be seen from the plan, the classrooms stretch right and left from the central block, which consists of the main entrance and board-room on the ground-floor; on the first floor, the art school, &c.; and on the second floor, the large and small theatres. These have been so arranged that the partition between them may upon short notice be readily removed and display one grand theatre, 88 ft. long and 40 ft. wide, with lateral extensions at its south end, which make it then 64 ft. wide.

The great hall, where all the scholars can be assembled at any time, and which is provided with a gallery for friends, stands at the south-east angle of the building,—a noble apartment, 80 ft. long, and 50 ft. to the panelled ceiling, having in addition at its south end a semicircular apse, in which is placed the platform.

Of the other important rooms, the library is placed at the north end of the west wing, and is 50 ft. by 36 ft.

The dining-hall, 125 ft. long, and which, with its corridor, divided from it only by an open arcade, is 41 ft. wide, occupies nearly the whole of the west flank of the building. The west end of this room is provided with a raised dais and a gallery at one side, to which access is obtained by means of a small turret staircase. Upon this floor also the whole of the eastern flank is occupied by the physical and chemical laboratories.

Connected with the school building by a long cloister stands the master's house, with its offices and porter's lodge.

The sanitary offices of the school are kept separate from the main building; they lie to the east of it, and are connected with it by a bridge which spans the roadway from the Hammersmith-road to the cricket-ground. A little to the south of these offices five-courts have been erected. Both the Eton and Harrow patterns have been adopted. On the south side of the school is the cricket-ground, which will be one of the finest in the metropolis. The structure is built of red brick and red terracotta, and the roofs are covered with brinded tiles. Walker's granolithic steps and landings are extensively used throughout the work. The contractors for the whole work are Messrs. J. Parnell & Son, of Rugby, Messrs. Doulton & Co. supplying the terra-cotta.

**DURBAN TOWN HALL, NATAL.**

At a meeting of the Corporation of Durban, Natal, held on July 6th, the first premium (100*l.*) was awarded to the set of drawings marked "P P P" by Mr. N. M. Dudgeon, of Durban, and the second of 50*l.* to the drawings marked "Nemo," which are by Mr. Samuel Minsgrave, A.R.I.B.A., of Trinity House Lane, Hill. "P P P" is in the Classic style, and found favour with the local press before the selection was made. The arrangement of the plan was thought second to none, and far superior to most of the other designs.

The design marked "Nemo" was also pointed to as one likely to be selected. The only objection raised was that it was "a little too churchy."

**Science and Art Department.**—The following candidates have been successful in obtaining Royal Exhibitions of 50*l.* per annum each for three years, and free admission to the course of instruction at the following Institutions:—1. The Normal School of Science and Royal School of Mines, South Kensington and Jermyn-street, London; Christopher J. Whitaker (22), engineer, Accrington; George Gibbens (19), painter, Lewtonstone; Isaac T. Walls (22), student, Accrington; John H. Tomlinson (20), apprentice, Newcastle-on-Tyne. 2. The Royal College of Science, Dublin: Arthur Adams (23), engineer, Birmingham; Abraham Firth (21), assistant teacher, Stockport; Sidney A. Sworn (16), student, Southampton.

**THE BRITISH ARCHÆOLOGICAL ASSOCIATION AT PLYMOUTH.**

THE thirty-ninth annual meeting of the British Archæological Association commenced at Plymouth on Monday. The Association has never before met in Plymouth, but in 1876 it had a very pleasant meeting in Cornwall, under the presidency of the Earl of Mount-Edgcombe. The present congress commenced with the reception of the members of the Association by the Mayor (Mr. C. F. Burnard) and Corporation in the Council-chamber. Complimentary speeches were then made. The Mayor, in a hearty speech, welcomed the Association to Plymouth, and Mr. Thomas Morgan, F.S.A., hon. treasurer, and Mr. George R. Wright, the congress secretary, returned thanks on behalf of the members. After these proceedings, the members inspected the Corporation insignia and plate, upon which Mr. Lambert and Mr. R. N. Worth offered some observations. Mr. Worth then read an interesting paper on the Borough Records,—a very valuable series,—which mainly owe their preservation to the painstaking labours of the late Mr. Henry Woolcombe, F.S.A., formerly Recorder of Plymouth.

After partaking of luncheon, the visitors proceeded to view some of the churches, old buildings, and other antiquities in the town, beginning with St. Andrew's Church. Mr. Worth briefly recounted the chief points in the history of the church, a building which Mr. Loftus Brock spoke of as one of the finest illustrations extant of Devonshire Perpendicular. The "Abbey," so called, was then inspected from the churchyard, and Mr. Worth stated that he had been fortunate enough recently to obtain very good evidence that it was not an abbey at all, but the old "prysten" or clergy-house of the town. Charles Church was the next place of rendezvous, and here Mr. Brock spoke very highly of the design of the unknown architect. Post-Reformation Gothic churches were very rare, and this was one of the finest in the kingdom. It was very evident that in some respects the designer had followed St. Andrew's; but for the very beautiful great east and west windows he had clearly gone to the cathedral at Exeter. If the very wonderful galleries and high pews were swept away the real beauty and adaptability of the building would be recognised. The next point of interest was the old Dominican monastery in Southside-street, now and long occupied by Messrs. Coates & Co. as a distillery. On the way thither Mr. Worth called a halt at the head of Buckwell-street, and stated that he had an interesting statement to make. Hitherto all efforts to discover the exact locality of Sir Francis Drake's residence in Plymouth had failed, but within the past few weeks it had been his good fortune to obtain evidence from deeds of Drake's occupancy, prior to Buckland Abbey, of a bonse and garden at the corner of Looe and Buckwell streets.

The Duke of Somerset, who was announced as the president of the congress, was, unfortunately, not able to take any practical part in the gathering. It was hoped that his Grace would write an address for some one else to read, but even this his health would not permit him to do. His place was taken by Sir James Picton, who, in the course of an inaugural address delivered in the evening, said,—We are justly proud of our English institutions, with their roots firmly fixed in the past, and their vigorous branches stretching forward into the unknown future. But history does not consist entirely of written documents, however valuable their contents may be. The surface of our country is studded with historical records, written in the stone and brick and earth works which bridge over the period between the ages before the dawn of written history, and connect them without a break with the living present. Written history without these, however eloquent, would be comparatively tame, spiritless, and uninteresting. There are thousands of objects all over our country which have special associations with the past, or, at all events, form links in the chain which binds the remotest ages with the present. Going further back, the Roman remains give evidence supplementary to written history. The mining operations of the Romans, of which such extensive *debris* remain; the splendid roads which traversed the country in all directions, many of which are still in use; the great wall and stations of Hadrian, all manifest the application of engineering skill and

capital which could only have existed under a settled and wisely-administered Government. Further back still we come to the twilight of English history, which is ultimately lost in darkness. Here written evidence fails us; but we are not without a clue to guide us through the labyrinth to certain definite conclusions. The cromlechs, the stone circles, the dolmens, the barrows, the grave-mounds, the pit dwellings, the primitive fortifications, supply in themselves no certain indications of the date of their construction, but they afford very strong evidence of the state of society, and the manners of those who erected them. Further back still we are introduced into the habitations of the cave-dwellers, where man struggled for supremacy with the cave lion and the bear, and used the primitive weapons of bone and flint for the capture of the fish and deer on which he subsisted. Again we go back until we reach the drift period, where we have the earliest intimation of human life in its incipient stage of feeble progression. Now, reasoning from analogy and comparison, we are able to draw certain conclusions from what we here find, and to present, with tolerable accuracy, a picture of the forefathers of our race in their earliest development. These earlier stages belong more properly to what is called palæontology, but it is difficult to draw the line where archæology ends and palæontology begins. As investigation goes forward the two will of necessity blend together and form a single department of inquiry. A very cursory glance will show that there is ample scope and verge enough for a union of effort devoted to one common end,—the examination and elucidation of our relics of antiquity of all ages and of every description. This is the origin and the *raison d'être* of the British Archæological Association. I have given the reasons for its existence, and indicated the scope of its inquiries. I wish now to say a few words on the objects it has in view and the means of carrying them out. Its main purpose is to call attention to the precious relics of antiquity which remain amongst us, to facilitate their inspection and examination, to inquire into and illustrate their history where practicable, or otherwise to deduce from their own internal evidence the conclusions to which they lead, to encourage an intelligent study of our antiquities and of the art and science displayed in their construction, to place on record the results of the annual meetings and visits in the various localities, and last, but not least, to engage public sympathy in the guardianship and preservation from injury of these precious remains. Now, many valuable objects, especially of the pre-historic character, have been and still are consigned to destruction through simple ignorance of their value. Much may be done by keeping the public alive to the importance of preserving our national monuments. This leads to another vexed question, which has raised considerable discussion. I mean the so-called restoration of our ancient buildings, especially churches. The revival of Mediæval architecture within the last fifty years, concurrently with what is called the Oxford ecclesiastical movement, drew attention, especially amongst the clergy, to the neglected and dilapidated state of our churches in some instances, and in others to their degradation and disfigurement by the interpolation of galleries, box-pews, and re-buildings in an altogether unworthy style. Considerable zeal was manifested in improving this state of things by removing the excrescences, and endeavouring to restore the buildings to their original condition. Zeal, however, is not always accompanied by sufficient knowledge and wisdom, and hence it has too frequently happened that the restoration has resulted in an error of the opposite kind, and in the attempt to reproduce a specimen of pure Mediæval architecture all the flavour of antiquity has been done away, and the residuum has become a raw, cold, staring building, reminding us rather of the modern contractor than of the hoary freemason of old. . . . Much mischief has been done, but there are still many fine buildings which have hitherto escaped the ravages of the restorer. It is to be hoped that all who have a true reverence for antiquity will lend their aid to prevent all needless desecration. The true principle of restoration is this,—Where an unsightly excrescence has been introduced, remove it; where a stone is decayed, replace it; where the walls are covered with whitewash, clean them down. If tracery is broken, match it with new of similar character, but spare the antique surface. Do not touch

the evidence which time has recorded of the days gone by. I say nothing of buildings in ruins or in danger, which of course must be rebuilt in the style best suited to the purpose.

On Tuesday morning the members proceeded by special train to Horsham, whence they proceeded in carriages to Buckland Abbey, upon which Mr. Brock read a paper. He observed that it was seldom that the members of the British Archaeological Association had had the advantage of inspecting the remains of so varied a number of the houses of the religious orders, once so numerous in our land, as during the present congress. At Tavistock they would see the remains of the older order of Benedictines; Plympton was for Austin Canons, and at Tor Abbey they would see the site of a Premonstratensian House, one of the so-called Reformed Orders, placed away from the haunts of men. The site of Buckland, a low valley beside the stream, was clearly that of an abbey of Cistercians. Buckland Abbey, Mr. Brock went on to say, was founded by Amicia, the wife of William, Earl of Albemarle, and she signed the foundation-deed in 1280. Of the history of the monastery there was little to add beyond that it was founded and dissolved. It was a curious fact in relation to the churches of the Cistercian order that hardly one was now used for divine service. This was no doubt owing to the fact that the sites were away from the population, and, in most instances, the churches were demolished for the sake of the materials. Here, at Buckland, we had a curious and unusual example of its retention. Here the church was kept standing, and was converted into a dwelling. It consisted of a spacious nave, which had no aisle, and never had any; a low central tower, which was still intact, and a single transept. The original arrangement of the church were, in fact, as anomalous as its present appropriation, and showed that the establishments of the Cistercians were not always set on the same unvarying plan, as some believed. The church appeared to have been adapted to its present use as a dwelling-house in the time of Queen Elizabeth, and there were many objects of interest of that date remaining in it. Apart from the well-known portrait of Sir Francis Drake, who lived there for many years, and whose descendants still owned it, there was a curious chimney-piece with his arms on it in the tower.

The visitors next drove to the interesting and picturesque village of Buckland Monachorum, almost every house of which, as Sir James Picton pointed out, contains some traces of the hand of the Medieval builder. The church was the central point of interest; and in it Mr. Brock made some interesting remarks. He said it was a very charming fifteenth-century church, somewhat different from the usual type of Devonshire church, and he was extremely glad to find it was kept in such beautiful order, and had been restored on such good principles, with respect to the preservation of the old work. The building differed from the ordinary type of Devonshire church in that it had both north and south transepts, and a chancel arch without the roof of the nave and chancel being continuous. The work, too, was of somewhat earlier date than most of the other local churches. The mouldings and traceries were deeper and cleaner than in the ordinary Devonshire church, and it was very interesting to notice how skilful were our ancestors in the use of granite. That hard, and, as we considered, unpractical material was here used, almost as we should use a Bath stone, while the ancient builders had here taken advantage of the great blocks in which it was found to work the pillars for the arcade in one stone, 10 ft. or 12 ft. in height. The roof of the Chantry Chapel, to which the Drake family had succeeded when they had obtained property in the parish, showed the marvellous way in which the granite had been worked. The eighteenth-century monument in this chapel, Mr. Brock said, was worth much more attention than such monuments usually deserved. It was a monument to Baron Heathfield, of Gibraltar renown, and was by the elder Bacon. On rejoining the carriages, the visitors proceeded to Princetown. The weather over the moors was very gloomy, and, just before Princetown was reached, a thick misty rain came down, and not only obscured the view, but made travelling otherwise disagreeable. Luncheon under the welcome cover of the time perfectly oblivious to the weather; but subsequently, when thoughts were turned towards resuming

the programme, matters took a less agreeable turn, and, after some delay and consultation, it was resolved to drive at once back to Tavistock, and catch an earlier train than that arranged for the return journey to Plymouth. A small party did, indeed, in the intervals, reach the Cyclopean Bridge at Blackbrook, under the guidance of Mr. C. W. Dymond, F.S.A., who had also undertaken to explain the prehistoric remains at Merivale Bridge, consisting of hut-circles, avenues, menhir, sacred circle, &c., but the weather did not permit.

In the evening there was a meeting in the Plymouth Athenæum, when the President of the Plymouth Institution (Mr. R. N. Worth) delivered a brief address on local antiquities and history. The chair was then taken by Mr. Morgan, and the following papers were read, viz.:—"Glimpses of Municipal Life in the Olden Times," by Sir James Picton; "Drake and his Voyage of Circumnavigation," by the Rev. W. S. Lach-Sayras; and "The Name and Arms of Drake," by Dr. Drake.

The members spent the whole of Wednesday in making excursions. In the morning they went to Totnes, whence they at once proceeded down the River Dart upon a river steamer. At Dartmouth they visited the Church of St. Saviour, subsequently returning to Totnes, where they found a great deal to interest them.

#### FIREPROOF PAINTS.

The catastrophe at Vienna gave a great impetus to the inquiry for fireproof paints. It contributed somewhat to our knowledge of the materials that may be used for coating objects so as to render them almost incombustible. To make that acquaintance more general, it will not be out of place to enumerate the various means that have from time to time been recommended for rendering objects fireproof. Such means have been known for a long time; unfortunately their use has hitherto been more or less neglected, and it is only now that their usefulness is receiving due recognition. Thus, soluble glass has been known for a long time as a safe covering, but the instances in which it has been applied are very rare indeed, although its action is remarkable. In one case an experimenter demonstrated the protective properties of soluble glass by leaving a wooden stirrer saturated with it in the intense heat of a coke-oven, without its taking fire. It was charred only after it had remained there for some time. Of course, wood covered with such paint, and its pores well penetrated by it, will ultimately burn; but it is ignited only with the greatest difficulty, and the fire spreads so slowly as to render a large fire to mix soluble glass with whitening, which mixture turns after a time into an insoluble combination. In order to cause the paint to penetrate the wood, it is best to warm it well before application. Soluble glass is not to be recommended for dress materials or woven stuffs generally; it makes them too stiff, and also spoils the colour. Its use would be best limited to wood, stiff linen, scenery in theatres, &c.

The following application is also recommended for wood. One part of perfectly sound English Roman cement, two parts of washed scouring sand, one part of fresh cheese (curds), and three-quarter part of butter-milk are well mixed, and the wood coated twice with the mixture. While applying it, the mixture must be well stirred, to prevent the sand setting at the bottom of the vessel. The first coat must be allowed to dry,—which would not take long in summer,—before the second is put on. Surfaces to be thus coated had better be left rough and unplanned, which gives them the appearance of stone. In order to insure durability, woodwork in a horizontal position receives three coatings of varnish mixed with green earth; for slanting surfaces, two coats are sufficient; for vertical surfaces one coat suffices. For smooth surfaces, two parts of the above cement, one part of fresh cheese, and a quarter part of butter-milk are taken. But only so much must be prepared of these mixtures as is used up at once.

If 100 parts by weight of alum are dissolved in 800 parts of boiling water, and twenty-five parts of English sulphuric acid are added to the solution when cold, an excellent fireproof grouting is obtained, which, if the respective parts are so many kilograms, costs about 2s., and must be applied to the wood twice.

To prevent the alum being destroyed by the moisture of the atmosphere, the following coating is recommended. Ten litres of lime powder and ten litres of fresh but poor cheese are worked well with about three litres of water with a wooden shovel, ten litres of sand and as much water being added during mixing as is required to convert the whole into a stiffish mass. It is advisable to strain this mass through a medium sieve before use. Mineral or metallic colour may be added.

Potash solved to saturation in water is also a protective covering for wood. After this coating has been applied, the wood receives three or four applications of a mass prepared of one part by weight of potash, twenty parts of yellow clay, and 1½ parts of flour, and mixed with water to the consistency of ordinary size-colour. A fireproof coating may also be obtained by mixing twenty-four parts of slaked lime, one part of fat blubber, one part of powdered gypsum, two parts of fine sand, four parts of brick-dust, three parts of hammer-slag, and four parts of chopped calf's hair, with enough bullock's blood to produce a good combination of the several materials. A mixture of lime and alum is likewise said to give a good fireproof covering to wood, which must be well saturated with it; also a mass consisting of twenty-five parts of borax, twenty-five parts of Epsom salts, and 100 parts of water; further, a mixture of three parts of slaked lime, two parts of screened wood-ashes, and one part of fine sand, rubbed with linseed oil to a point readily applied. Another fireproof covering consists of 66½ parts of gypsum, 33½ parts of sulphate of ammonia, and 100 parts of water.

For effectually rendering woven fabrics fireproof, tungstate of soda, which comes into the market in the form of white needles, takes the first place. When it is desired to use it for impregnating dresses, covers, curtains, &c., it is dissolved in five times its quantity of water, and a small quantity of phosphate of soda is added. The material, after being completely saturated with it, is wrung out, and dried in a moderately warmed room. If this substance is used, the materials impregnated with it are not only protected against fire,—they carbonise but slowly,—but they preserve their natural suppleness and elasticity. Unfortunately, this substance is too dear to find general application. The mixture, above mentioned, of borax and Epsom salts might, however, take its place, and is considerably cheaper. Both possess the valuable property that they do not destroy even the finest threads; but those colours which water damages are injured likewise by them. For tissues, in using the two last-mentioned substances, the following is a good proportion for mixing. Shortly before use, two and a quarter parts by weight of Epsom salts and three parts of borax are dissolved in twenty parts of water. The latter must be warm, and the whole is stirred with a wooden stick until the salts are completely dissolved. Impregnation is effected in the same way as in the case of tungstate of soda; only it is advisable, instead of wringing out the immersed materials, to mangle them between two cloths in an ordinary mangle. If the stuffs are to be ironed out at once, and it is desired to give them the requisite stiffness, the necessary quantity of starch is a once added to the warm solution.

Paper and woven stuffs may also be treated with a solution of three parts of phosphate of ammonia, two parts of sal ammoniac, one part of sulphate of ammonia, and a little chloride of calcium in forty to fifty parts of water. If starch is mixed with it at the same time, no more water is required, not even for damping down. The salts become somewhat harder, but the change is unimportant. A combination of gypsum and phosphate of ammonia, mixed in varying proportions of quantity, according as the material to be impregnated is coarse or fine, is said to be also a capital protection against fire, which has, besides, the advantage of cheapness. Vanadates, on the contrary, are dear, but they may be recommended because they do not injure either the colours of the tissues to which they are applied or deposit white crusts on the surface.

There is no need to further extend this list, which includes some very valuable means for arresting the spread of fire. They have all been tested more or less by experts, and found efficient. In the immediate vicinity of a flame materials impregnated with them may take fire, but they merely get charred, and burn but slowly. Some of the above means have

been tried in this country, but not any of them have, to our knowledge, been extensively applied. It appears to us, therefore, desirable that the lessons conveyed by the recent trials with asbestos paint should be noted. The preparation of that paint has been described before; but it may be as well to state, briefly, once more that the substance known as Italian asbestos is mixed in a finely-divided state with the other ingredients which make up the paint to be used. It has been repeatedly stated, and practically demonstrated, that paint thus prepared renders the objects to which it is applied as a protective covering perfectly fireproof. All who witnessed the latest experiment on the Thames Embankment, a few weeks ago, must have come away with the impression that a substance has been found which will resist fire long enough for all necessary measures for the saving of human lives to be taken before the flames become uncontrollable.

**THE STRENGTH OF QUARRY STONES.**

In our issue of July 22nd\* we called attention to a theory which had been propounded by Herr Müller, of Magdeburg, according to which the strength of quarry stones is in direct proportion to their specific gravity.

A detailed criticism of Herr Müller's statements has since appeared, in which Dr. Böhme, of Berlin, takes up the position that the principles on which this theory rests are erroneous. He denies that any fixed rule can be applied to the settlement of the question at issue, in view of the differences which are known to exist in the various particles of which quarry stones are composed, and also in view of the varied character of the influences to which these stones have been subject in the process of their formation. With a compression spreading over a long period, and gradually increasing in power, greater strength must, he considers, be attained than by the action of a sudden and violent force, the molecules having an opportunity in the former case of becoming thoroughly knit together.

The results of the experiments made by Dr. Böhme may be summarised as follows (the strength being shown in pounds per square inch):—

<b>(a) Limestone with a specific gravity of 2.68:—</b>			
	5 wet samples.	5 dry samples.	
Lowest strength .....	7151.18	7297.95	
Highest strength.....	9984.84	10581.91	
<b>(b) Limestone with a specific gravity of 2.70:—</b>			
	11 wet samples.	11 dry samples.	
Lowest strength .....	8050.22	8659.22	
Highest strength.....	10738.36	12515.80	
<b>(c) Limestone with a specific gravity of 2.71:—</b>			
	6 wet samples.	6 dry samples.	
Lowest strength .....	7196.83	7879.54	
Highest strength.....	12316.72	13068.60	
<b>(d) Limestone with a specific gravity of 2.72:—</b>			
	5 wet samples.	5 dry samples.	
Lowest strength .....	9073.27	9690.50	
Highest strength.....	15033.71	14934.15	
<b>(e) Sandstone with a specific gravity of 2.54:—</b>			
	Wet samples.	Dry samples.	
No. 1 .....	12487.40	13688.60	
No. 2 .....	15488.80	14907.02	
<b>(f) Sandstone with a specific gravity of 2.56:—</b>			
	Wet samples.	Dry samples.	
No. 1 .....	10169.44	9700.10	
No. 2 .....	18518.24	18062.37	
<b>(g) Sandstone with a specific gravity of 2.59:—</b>			
	Wet samples.	Dry samples.	
No. 1 .....	8932.04	8700.10	
No. 2 .....	11051.27	11349.56	
No. 3 .....	17224.45	16754.40	

From these results Dr. Böhme argues that it is impossible to assume that exact connexion between specific gravity and strength which Herr Müller claims to have established. Quarry stones are, he remarks, masses of a very heterogeneous character. Their specific gravity is produced by the substances of which they are composed, which are of different specific gravities, while the proportion in which each component substance exists in the bulk, is also liable to fluctuations of a more or less important

character. He maintains that the strength of the stones principally depends upon the manner in which these various component parts are united. In the detailed consideration of this branch of the subject, the various influences to which the stones have been exposed, are elements of primary importance.

It is remarked that in porous and relatively light descriptions of limestone, the close union of the component particles is sometimes productive of a greater resisting power than is found in other descriptions where great strength might be looked for, but which have been formed with relative quickness, and, therefore, under circumstances unfavourable to their qualities of resistance.

Comparison between stones of Plutonic, and those of Neptunian origin, is not possible, according to Dr. Böhme, who points out the fact that porous hard lava, which is considerably lighter than sedimentary limestone and sandstone, is usually possessed of greater resisting power than either of these varieties.

Being, for the most part, a criticism on Herr Müller's theory, there are several points in Dr. Böhme's remarks which invite further debate, and doubtless the attention which has been thus drawn to the subject in German technical circles will lead to its eventual discussion in a complete form. The important divergence in the results of the two series of experiments on limestone would almost seem to point to some differences in the substances experimented upon or in the application of the tests. In the limestone experiments, the principle of a simultaneous increase of specific gravity and strength would not seem to be exactly controverted, but Dr. Böhme's arguments are, to some extent, borne out by the figures quoted in connexion with his tests of sandstone. Doubtless his main intention has been to show the futility of any attempts to arrive at reliable data on the subject, and in this object he seems to have been more or less successful.

**THE HARRIS FREE PUBLIC LIBRARY AND MUSEUM.**

THE plans for the Harris Free Library and Museum at Preston, the foundation-stone of which is to be laid by the Duke of Albany during his visit to Preston in the Guild Week, commencing on the 4th of September,—have been on view in the council chamber at the town-hall during the last few days. The designs have been prepared by Mr. James Hibbert, who was commissioned by the Harris Trustees to visit several buildings of a similar character in this country and on the Continent, the result of Mr. Hibbert's visit and report being that he was appointed the architect to prepare the designs.

The building will be of the Greek Ionic order, and will have four distinct frontages, being completely isolated from the buildings around it. The principal elevation is on the west side, overlooking the market-place, and almost at right-angles with the north frontage of the town-hall. The height of the frontage to the parapet and the apex of the portico is 80 ft., and the extreme height to the top of a central lantern, 112 ft. The portico consists of six massive fluted columns, with bold capitals. It is surmounted by a bold overhanging cornice, and the tympanum is filled in with a group of figures representing *Muerva* surrounded by literature, science, and the arts. The frontage is 130 ft. The bases of the columns of the portico, and its floor level, are about 10 ft. above the street level, and the entrance to the building is under the portico by flights of steps on the north and south sides. Immediately under the tympanum of the portico is the carved inscription in large characters, "To Literature, Science, and Art." The eastern elevation of the building faces Lancaster-road, a fine thoroughfare, about 60 ft. in width, leading out of Church-street, the principal street in the town. It is uniform in length with the Market-place frontage. The north and south frontages are each 170 ft. in length and will face two new streets, each 50 ft. in width, which are about to be constructed in connexion with certain town improvements intended to be carried out simultaneously with the erection of the Free Library buildings. The design of the principal elevation is maintained in the three last-named frontages, ornamental columns being carried along the

face of the several elevations. The building will cover a ground-area of about 25,000 ft.

The building will contain three floors above the street level, in addition to the basement. The ground-floor portion will contain the lending libraries, patents library, reading-room, news-room, workroom for the collection of models connected with the industrial arts, the museum, curator's workroom, and the entrance staircase and central hall. The collection of models connected with the industrial arts will be placed on the ground-floor portion of the central hall, with the object of bringing them under the daily observation of visitors passing to and from the lending department and the adjacent reading-room and news-room. The newsroom on the south side, and the reading-room on the north side, are each 29 ft. by 55 ft.; one of the lending libraries is 50 ft. square, and the other 55 ft. by 29 ft. The central hall is 54 ft. square, and is continued, by the staircase, on all the floors, being lighted by the lantern immediately over a central well. The principal floor contains the reference libraries, on each side of the central hall. They are each 30 ft. in width, and 120 ft. in length. The central hall portion of the principal floor will be set apart as a museum of casts and reproductions from the antique. On the principal floor there is also a conversation-room, and a room for chess and draughts. The whole of the upper floor will be devoted to museum and fine-art purposes. The museum galleries are arranged round three sides of the central hall and staircase; one side being devoted to the fine arts, the corresponding side to natural history and physics, and the remaining side between those to the department of general archaeology, ceramic, and the finer kinds of industrial art, and illustrations of ethnology. The east end of the central hall portion of this floor, 55 ft. by 29 ft., will be devoted to general antiquities, coins, and gems. Specimens of sculpture after the antique and later schools are intended to form a feature in the institution, and these will be for the most part placed in the staircase and central hall. The basement floor will contain the heating apparatus, storage-room, libraries work-room, and museums storage-room.

The arrangement of bookcases shown on the plans provides for shelving 89,825 volumes, of which 30,350 volumes are proposed for the lending library, 5,000 volumes for the library of patents, and the remaining portions for the reference libraries.

The estimated cost of the building itself is 70,000l., and the cost of the site 25,000l., which is provided by the Corporation. The total cost of the building and site will thus be about 95,000l. The Harris trustees contribute in the aggregate 90,000l., viz., 70,000l. for the cost of the building, 5,000l. for the purchase of books for the Harris Reference Library, 5,000l. to be expended in purchasing examples of the fine and industrial arts; and they further place a sum of 10,000l. with the Corporation, on interest at 4 per cent., to be expended annually in additions to the reference library, museum, and art galleries.

**PROPOSED NEW GRAND LODGE FOR ENGLISH FREEMASONS.**

OWING to the vast increase of brethren in Freemasonry during the time that H.R.H. the Prince of Wales has occupied the chair of Most Worshipful Grand Master, a suggestion has been made to acquire the site of the National Opera-house on the Thames-embankment, for the purposes of erecting a temple suitable for the accommodation, and worthy of such an important body, as that of Freemasonry in England.

The site, so magnificently placed, and owing to its proximity to so many railway stations, the Clubs, and the Houses of Parliament, would prove most convenient for the brethren.

The suggestion was made by Mr. Matt. Wyatt and Mr. T. S. Archer, by whom designs have been prepared, and which are now being submitted to some of the influential brethren in the Craft.

**Fulham Infirmary.**—In our report last week in reference to the appointment of a quantity surveyor, it was stated that Messrs. Maughan & Cuxson had offered to do the work for half per cent. We are requested to state that they were one of the firms who did not name any rate in their application.

\* See p. 107, ante.

## THE HISTORY OF ENGINEERING IN LEEDS.

This was the title of a paper read by Mr. A. H. Meysse-Thompson, before the annual meeting of the Institution of Mechanical Engineers, held in Leeds last week. In the course of the paper the writer said:—Mechanical engineering appears to have made but little progress prior to the commencement of the present century. The necessary machinery for the various mills in the district, whether driven by wind or water power, was of a very simple character; and the appliances for colliery working, or for the smelting and working of iron, were of a very primitive description. It was about a hundred years ago that improvements in the steam-engine gave an impetus to mechanical engineering throughout the country; and the genius of Matthew Murray soon enabled the Leeds district to take a prominent place in this industry. Murray commenced his career in Leeds at a flax-mill of John Marshall, about the year 1780, at a time when the manufacture of flax by machinery was just commencing; and by the improvements which he introduced into the machinery he gave to the flax trade of the district a start which it has never lost. Perhaps his most important inventions in this class of machinery were the harking-machine (which procured him the prize of the gold medal of the Society of Arts), and his machine for wet flax spinning by means of sponge weights, which proved of the greatest practical value. Murray continued in Messrs. Marshall's service up to the year 1795, when, realising the great want that existed for trained mechanics and organised works for the better manufacture of improved flax machinery, he secured the co-operation of Fenton & Wood, and started,—in the works known as the Round Foundry, and now in the occupation of Messrs. Smith, Beacock, & Tannett,—the well-known firm of Fenton, Murray, & Wood, afterwards Fenton, Murray, & Jackson. Not only did Murray manufacture flax-machines, but he also turned his attention to engines for driving them; and so successful were the latter, that engine-building soon became a large branch of his manufacture. Two engines of his make, one of fifty horse-power, the other of sixteen horse-power, are still driving machinery at Messrs. Titloy, Tatnam, & Walker's, Water Hall Mills, Holbeck. For one of his engines, sent to Russia, he received a gold medal from the Emperor. Whether this medal was the only payment received for the engine, history does not state. At the commencement of the present century all the engines for flax-spinning were of the beam type. The long D slide-valve, usually employed in those engines, was, according to Smiles, either invented or greatly improved by Murray; and it was probably owing to the difficulty experienced in getting the two surfaces of the valve perfectly true to one another that he was led, if not to the invention, at all events to the development, of the planing-machine. So rapidly did his business progress in the north of England that James Watt found him a formidable rival,—so formidable, indeed, that the firm of Boulton & Watt bought up the land round his works to prevent their extension. In 1812, in conjunction with Blenkinsop, Murray brought out what was undoubtedly the first locomotive engine ever successfully employed for commercial purposes. It was constructed for the conveyance of coal from the Middleton Colliery to Leeds, a distance of about three miles and a half, and was capable of dragging thirty loaded coal-wagons at a speed of between three and four miles an hour. It continued to run for many years. Murray's works were the school in which numbers of engineers of note in the early part of the present century were educated, many of whom started works in Leeds and elsewhere. In the year 1826 mechanical engineering in Leeds comprised:—(1), textile machinery; (2), locomotives; (3), fixed engines, all of which were then made solely by the firm of Fenton, Murray, & Wood. As time went on, the large textile manufacturers began to require tools for the repairing of their machinery, and about the year 1837 the manufacture of such tools became a distinct branch of trade, two firms starting at that time solely for this purpose. The tools required for machine repairing were tools suitable for general engineering manufacture, such as lathes and planing-machines; and it is interesting to observe how little these two machines,

which are still the leading tools of engineering shops, have been altered from their original forms. Between the years 1830 and 1840 the railway system had become established, and so rapid was its development that a large and increasing demand for locomotives quickly came into existence. In the year 1837 a steamer actually crossed the Atlantic, and shortly after a new manufacture, viz., that of the marine engine, was initiated. This revolution in the mode of transit by land and water created a new branch of the tool trade, owing to the fact that the manufacture of locomotive and marine engines required special machinery, of larger dimensions than had previously been used or found necessary for other purposes. The tool-makers in Leeds were not slow in meeting this fresh demand on their resources, and the tool trade rapidly grew, until about the year 1852, when it received a farther impulse from the change at that time made in ship-building by the substitution of iron for wood. This new industry created a demand for still heavier tools, not only for the building of ships, but also indirectly for the preparation and manufacture of the iron in the ironworks. So rapid was the growth of this branch of manufacture that it is not surprising to find that by the year 1866 the tool trade of Leeds had grown to very large proportions, employing about 8,000 men. At the present time the trade is one of the most important industries of the town. . . . . The manufacture of cut nails has made most rapid strides of late years. Formerly nails were made in presses by manual power. In 1819 steam was first applied in Leeds to this manufacture by Messrs. Roberts, who cut a ton a week, which was then regarded as a large quantity. Since that time the machines have been wonderfully improved. A nail is now cut, headed, and pointed at one stroke; and by a recent improvement a self-acting feed is provided, thus further diminishing manual labour very considerably. In the year 1858 Mr. Kitson, in a paper read before the British Association, estimated the number of hands employed to be 188, of whom 100 were women; and the annual weight of nails made to be 3,452 tons. At the present time the annual make of nails is about 15,000 tons, employing nearly 600 hands, of whom about two-thirds are women. There are six works established for the manufacture of what is generally known as best Yorkshire iron, which is obtained from an ironstone in the lower coal measures, and commonly known as argillaceous carbonates. The total amount of this ore raised in 1881 was 320,981 tons, all of which was consumed by these six works. The excellence of the pig iron produced is also due partly to the fuel. What is known as "better-bed" coal is exclusively used for the coke employed in smelting, its remarkable freedom from sulphur making it especially suitable for smelting purposes. The superior quality of the manufactured iron is due not only to the purity of the pig, but also to the extreme care exercised in all stages of the manufacture; the fact of its commanding the highest price in the market being sufficient proof of its excellence.

## LONDON AND MIDDLESEX ARCHAEOLOGICAL SOCIETY.

## VISIT TO SILCHESTER.

On the 17th the members of the London and Middlesex Archaeological Society, joined by representatives of the Berkshire Archaeological Society and the Newbury District Field Club, made an excursion to Silchester. The major portion of the party travelled from Waterloo by South-Western Railway to Basingstoke, where a carriage was in waiting, and an agreeable drive brought them to The Vyne, the historical seat of the Chute family. After a short stay they resumed their journey to Silchester, where Mr. James Parker, of Oxford, gave a descriptive account of the ruins, expressing his firm conviction that Silchester was the Calleva Atrahatum of the Romans, situated at the junction of several of the great Roman roads, one leading to Venta Belgarum (Winchester) and the south, another to London *via* Fontibus (Staines), and another to Spang (absorbed by the town of Newbury), and thence to Aqua Solis (Bath), Cirencester, Gloucester, and Caerleon, South Wales. The place was the chief rendezvous of the Atrigatii, and a tribute city. Coins bearing date A. D. 50 and 60 had been found, but from the bulk of the coins unearthed there was

reason to suppose that the city was founded in the reign of Constantine. The walls, considerable remains of which still exist, are one mile and a half in circumference, and inclose 130 acres of ground. The site forms part of the estate of the Duke of Wellington, who is the possessor of many most interesting relics of the Roman occupation discovered at Silchester, including a bronze eagle belonging to a Roman legion (the only specimen ever found), tessellated pavements, &c. Lord Jeffrey describes the view from the north wall leading from the amphitheatre as the most imposing he had ever seen. Mr. Parker said the city was probably built in the third century, the site being chosen from its central position. As it was a tribute city, large sums of money were accumulated there, and it became necessary to fortify it. The walls, gates, forum, temple, Roman villas, baths, amphitheatre, and the contents of the museum were successfully described, and in the evening the party returned to town. The arrangements were carried out by the hon. secretary, Mr. S. W. Kershaw, F.S.A., assisted by Mr. Walter Money, of Newbury.

## SOMERSET ARCHAEOLOGICAL SOCIETY.

The thirty-fourth annual meeting of the Somersetshire Archaeological and Natural History Society commenced at Chard on the 15th inst. A local museum was arranged in the Town-hall, under the direction of Mr. W. Bigwood, of Taunton, the assistant secretary and curator. There was a good attendance at the general meeting under the presidency of Mr. Charles I. Elton.

The annual report, read by Mr. E. Green, one of the hon. secs., was of a satisfactory nature, and its adoption was moved by the Very Rev. the Dean of Wells, the seconder being Mr. J. Murch, of Bath, who invited the members to visit the important excavations which were now being made in the neighbourhood of Bath. In that neighbourhood by far the most important and interesting discovery of modern years had been made during the last twelve months. For many years it was known that in the neighbourhood of Bath there was probably a large structure many feet under ground, and a few years ago the City Surveyor of Works, in making alterations in the city, discovered, 15 ft. below the surface, the remains of a very large Roman bath, corresponding in importance with those of Rome itself. He hoped those who might find themselves in the neighbourhood of Bath would do them the honour of going to see the excavation.

The President then delivered an interesting address, dealing with the antiquity of man as exemplified by the barrows and other remains of the district. He said the history of man in the Somersetshire hills went back to a very remote antiquity, recent discoveries having shown that men of the Palaeolithic age lived in the valley of the Avo. Stone axes were almost the only relics of these oldest inhabitants, and they hardly knew more than that these men chased wild beasts. Geologists had made it certain that Somerset and the hills which bounded it were once quite 100 fathoms higher than now, and that the whole shelf, from the Bay of Biscay to the North of Scotland, was dry ground, while enormous herds roamed on the grassy plains which existed where the Bristol Channel now flows.

The members then visited the Cornhill banqueting-hall, church, and grammar school. After luncheon there was a carriage excursion to Membury camp, church, and old moating-house, and an evening meeting was held at the Town-hall for papers and discussion.

The second day's excursion embraced the Roman villa at Wadford, Combe St. Nicholas Church, Northlay barrow, Whitcraunton Church, camp, barrow, and manor-house, the President inviting the society to luncheon, the President House, the seat of the Bonnor family, was then visited, also Wambrook Church; and another evening meeting was arranged for papers and discussion.

The third day's programme comprised Leigh House, Ford Abbey, Winsham Church, Weyford Church and manor-house, returning by Rounham and Cheriton Down to Cricket St. Thomas Church and lodge.

The Telephone to Brighton.—The United Telephone Company are making arrangements for connecting Brighton with the metropolis.

PROPOSED NEW BRIDGE AT BEDFORD.

The designs sent in for this work have been on view in the Corn Exchange, Bedford, and are described in the *Bedfordshire Times* of the 19th inst. The number of designs sent in exceeded anticipation. Mr. A. Billingham, London, sends in an estimate for the bridge and approaches of 17,721. 6s. 11d. His design is that of a lattice-girder bridge of three irregular spans, with stone piers and abutments. The next highest tender is that of Mr. F. Walsh, Burnley, which amounts to 17,412l., and includes the whole of the work proposed to be carried out. He suggests the erection of a bowstring-girder bridge of one span, which alone would cost 10,610l. He also sends in an alternative estimate of 15,837l. if ordinary stone be used instead of granite in the abutments and retaining walls. Mr. W. Hillman, Newcastle-on-Tyne, comes next with a tender of 14,557l. His design shows an iron arch bridge of three spans, with stone abutments, wing walls, and cast-iron columns. Messrs. Dyne, Steele, & Co., Newport, Mon., estimate for a wrought-iron arch bridge of two equal spans, with brick and stone pier and abutments. The estimate for it reaches 14,300l. Mr. C. W. Whitaker, Westminster, sends in the plan of an iron arch bridge of three equal spans, the estimate for which, together with the approaches, amounts to 9,740l. Mr. R. H. Twigg, Westminster, shows a perspective view of a continuous girder bridge with three openings, the piers being of brick with stone dressings. The estimate given with it is 13,800l. Mr. Whitehead's (Lincoln) estimate of 8,490l. is for a continuous girder bridge of three spans, with brick and stone abutments and piers. The design from Mr. Jepson, of Stockport, is also that of a continuous girder bridge, with a centre pier of stone and brick, his estimate of 12,500l. including the approaches. The carrying out of a design sent by Mr. A. Henningsway, Westminster, is estimated to cost 12,110l., the bridge alone, which is designed as a lattice-girder bridge, of two small and one large span, with open parapets, being estimated to cost 10,070l., and the approaches 2,040l. Mr. J. B. Everard, Leicester, sends a perspective view, with plans and details, of a bridge with one large centre span and two smaller side arches, all of wrought iron, with brickwork piers and abutments, and stone dressings. The tender for this bridge is 11,260l. 12s. Messrs. H. Young & Co., Westminster-chambers, send in the plan of a bridge, designed by Messrs. Maynard & Cook, engineers, Westminster, the bridge itself being estimated to cost 6,500l., while the approaches, ornamental work, &c., bring up the total to 11,700l. The bridge, of which a perspective is shown, is a light-looking structure of three spans, one large and two small, with open iron girder arches. A tender coming close to it,—viz., that of Mr. Parkinson, is 11,650l.—is also for a three-arched bridge of wrought iron, the spandrels being filled in with lattice work. Messrs. Heenan & Wodehouse, Newton Heath Ironworks, near Manchester, contribute the design of a lattice-girder bridge of three irregular spans,—a large central and two small side spans,—the piers being of ornamental brickwork, and the wing walls of the same material. The bridge was designed by Mr. N. H. Heenan, C.E., and the estimated total cost, including the approaches, is 11,412l. Without the approaches, which the firm suggest should be carried out by a local contractor, the tender would be 11,780l. less. Mr. J. B. Read's (Westminster) design is that of a wrought-iron bridge of three nearly equal spans, having piers of brick with stone facings. The tender for it is 8,700l. Mr. W. Warle, Newcastle-on-Tyne, sends the design of a bowstring girder bridge of one span, abutments of brick and stone, with concrete filling. 10,494l. is the estimated cost, including the buttresses and approaches. The Cleveland Bridge and Engineering Company, Darlington, send a perspective of an iron archway-bridge, of three spans, but no details, estimating the cost of its erection, together with everything included in the advertisement and tender, to be 9,945l. Mr. J. J. Henderson's (Dundee) estimate of a lattice-girder bridge of three nearly equal spans is 9,500l. Messrs. Clarke & Moore, Hull, send in three designs; 1 and 2 are bowstring girder bridges of one span, while design 3 is that of a bridge of three spans, with a large central bow-string, and two smaller side girders. The columns supporting the bridge are of cast iron, filled with concrete, while the abutments

are of masonry. Design 1 is estimated to cost 11,965l.; design 2, 7,460l. 6s. 9d.; design 3, 6,485l. 10s. 8d. Two designs are sent by Mr. Oscar Reichenbach, Westminster. One is that of a three-arched girder bridge, of equal spans, with a highly-ornamented balustrade. This and the approaches are estimated to cost 6,484 12s. 6d. The other design is of a brick bridge of three spans. A perspective is shown giving it the appearance of a substantial structure. The tenders for this amount to 6,088l. 1s. Messrs. Dawson & Fison, Queen Anne's Gate, Westminster, tender for the whole of the work, their estimate reaching 9,530l. Their design shows a continuous lattice-girder bridge of one large central and two small side arches, resting entirely on iron columns, it being proposed to build the abutments of brick. Mr. T. D. Evans, South Shields, estimates the construction of an iron bridge, &c., of two unequal spans,—one a bowstring and the other a flat lattice girder span,—to cost 8,191l. 2s. Mr. W. Gallon, Tottenham, sends the design of a wrought-iron bridge of three arches,—one of 80 ft. and two of 60 ft.,—resting on brick piers and abutments, the piers bearing castellated caps, the total cost being 9,757l. Mr. R. S. Miller, Wolverhampton, estimates the whole of the work at 9,000l. The design he sends possesses a feature not seen in either of the other plans; it shows the roadway suspended from two iron girder arches, which rest on brick piers with stone dressings. Messrs. McKeone & Robinson, London, tender for a design by Mr. T. Claxton Pidler. The estimate for bridge, approaches, and all materials comes to 7,800l. The bridge is a continuous lattice girder one with a large central span of 85 ft. 4 in., and two of 62 ft., resting on cast-iron cylinders 6 ft. in diameter, with wing walls of rubble stone and ashlar dressings. Messrs. J. Tiltston & Company, Leeds, compete with the design of a lattice girder bridge of three equal spans of 66 ft. 8 in., with brick abutments and cast-iron central columns. The bridge itself is estimated to cost 5,700l., but the approaches bring the tender up to 9,800l. Mr. J. Webster (Liverpool) sends in three designs; one is a continuous girder bridge of three equal spans. This design comes to 7,003l. 5s. 6d. The second, estimated to cost 7,053l. 10s. 5d. in construction, is a bowstring with flat lattice-girder sides; while the third is a wrought-iron arch bridge of three spans resting on brick piers with stone facings. The abutments also show stone dressings. The tender for this amount to 7,427l. 13s. 4d. If a parapet wall be erected on each side instead of a wooden fencing, there will be an additional 429l. 10s. in each case. Messrs. Pogo & Nunn, Theobald's-road, London, send in a design of a wrought-iron three-arched bridge, of apparently equal spans. The piers, which are composed of brick and stone work, are built on iron cylinders 2 ft. below water-mark, and the estimated price is 10,500l.

PROGRESS OF THE LIVERPOOL DOCK WORKS.

SLUICING THE PLUCKINGTON BANK.

THE report of the Engineer to the Mersey Docks and Harbour Board, Mr. George Fosbery Lyster, on the general state and progress of The Dock works of Liverpool and Birkenhead, and of the expenditure in his department, has just been issued. The report is dated from July 2, 1881, to July 2, 1882, and gives the clearest internal evidence, not only of the prosperity of the Dock Trust, but of the remarkable result of one year's activity in the most practical department of the estate. The points of the voluminous document is summed up in two lines at the end of the report, to the effect that the whole of the docks and appliances belonging to the Mersey Docks and Harbour Board had been maintained in efficient working order, while the total amount of expenditure involved in effecting this object figures at 561,258l. 18s. 6d. One of the most interesting features is a statement with regard to the landing-stages and approaches, which reads as follows:—

The Pluckington Bank.—The whole of the sluicing outlets at the George's Pier were completed, and their systematic working was commenced, in the middle of September last. By this time the "tail" of the Pluckington had so far extended as to cause the stage to ground for a length of 1,130 ft. on the east and 510 ft. on its west side. The quantity of sand and silt

to be removed before it would become waterborne at a 10-ft. ebb being about 20,000 tons, representing a depth of from 6 ft. to 7 ft. from its southern extremity to No. 2 bridge, and about 5 ft. thence to a point slightly short of No. 4 bridge. After the sluicing had been continued for some time, and the sand sufficiently removed abreast of the outlets, that operation was necessarily suspended for some months, while the northern portion of the bank was being reduced by scraping, scoring, and ultimately by excavating between the east side of the stage and the river wall northward, and beyond the range of the sluices. This latter operation was effected by means of Priestman's patent grab-bucket, which was found most effective for this special class of work. In March the partial working of the sluices was resumed, and towards the end of April they were run "full bore," and since then they have been in regular operation during the low water of spring tides. The effect has been that the southern portion of the bank (abreast of the sluices) upon which the stage rested has been so far removed as to admit of the structure being fully waterborne for this length, thus fully indicating the ability of the sluices to carry out the work for which they were designed. In consequence of the great rushing force of the water through the sluice months, the tendency, by reason of the "backlash," was to undermine the concrete "apron" which had been extended along the front of the outlets and beyond the foundations upon which the pipes rested. To obviate this I adopted a system of saddle-piling, which has secured their safety. In the beginning of May the scoring operations under the stage and to the northward of the sluices were stopped, but it has been found necessary to continue the "grab," as a deposit still occurs along the foreshore north of No. 2 bridge; here, also, the stage is fairly waterborne at low spring tides, but the depth is not so great as that along its more southern section. It having been found tedious and inconvenient to work the sluicing paddles by hand-power, an Otto gas-engine has been applied for the purpose, and thus the operation is largely facilitated.

With regard to the works of dock extension now in progress, we append some particulars.

New North Works.—The excavation for this dock is nearly completed, and that for the wall-foundation is in a forward state. The south wall, for a length of 1,000 ft., is built to a height of 2 ft. above old dock sill datum, and the remaining 372 ft. of its length is raised to the old dock sill level. The west wall, 566 ft. in length, averages in height 18 in. above datum. The north wall, for a length of 108 ft., averages 2 ft. in height above the datum, and a further length of 1,052 ft. is at an average height of 3 ft. below it, the foundation of the remaining 448 ft. of its length being not yet laid. Of the east wall, 202 ft. lineal is built to an average height of 3 ft. below datum, and the remaining 223 ft. of its length is not yet commenced. The masonry pits are ready to receive the machinery for actuating the gates. The whole of the sheds upon the quays are now completed, with the exception of the floor of the western half of that on the north quay of No. 3 branch. The roadways of the various "tongues" intervening between the branch docks are completed, and the approach roadway to the north shed of No. 3 branch, as well as the road flanking it on its north side, have been paved for a width of 40 ft., and fenced off from the works still in progress. The quays at the east ends of the branches are necessarily for the present in use as unloading berths and as depôts for materials for the works in progress. The roadway flanking the shed on the west quay of the Alexandra Dock, which includes a double line of railway, is completed for a width of 56 ft., and the remaining 34 ft. along this position is levelled off with the rock *d'bris*. A building erected for the purposes of sheltering the passages between the Langton and the Alexandra Docks, also providing workmen's cocoa-rooms and electric-light engine-house, and a police hut, has been constructed near the river-wall abreast of the passages referred to. The works in a forward state, and is nearly ready for use. Wind-screens in eounection therewith have also been partially constructed. The Langton Dock entrances, having been opened on the 8th September last, were for some time worked to a limited depth of 9 ft. below the datum in consequence of the unfinished condition of the basin. This depth was in March last increased to 11 ft. below that level, or 1 ft. short of

the maximum depth intended, viz., 12 ft. The completion of the basin to its 14-ft. level has since so well advanced as, doubtless, to admit shortly of the entrances being brought into use at their full working depth, viz., 12 ft. below old dock sill. . . . The following figures represent the general quantities of work done in connexion with the foregoing during the past year, viz. :—Excavations, 411,500 cubic yards; masonry, concrete, and brickwork, 47,398 cubic yards; paving to quays and roadways, 18,322 square yards; piling, 647 cubic feet; permanent railway along the quay, 337 lineal yards; asphaltic floors in sheds, 113,000 square yards; zinc covering to roofs, 140,000 square yards.

**New Works at the South End.**—The excavations for the new docks south of Brunswick Graving Docks is now in progress; about 62,000 cubic yards have been removed during the past year, making a total of about 124,000 cubic yards from the commencement, which have chiefly been deposited to form the quays. Additional appliances have been provided to push on the work in this position with greater speed, and with this object an increased number of men have been drafted from the completed works on other parts of the estate. A length of 300 ft. of the river-wall across the gap south of the Toxteth Dock has been built up to a height of 20 ft. above datum. The foundations of this part of the work were taken down to a level of 17 ft. below the old dock sill, on to the rock, which was found to underlie a bed of gravel 2 ft. in thickness. The quantity of masonry built amounts to 5,400 cubic yards. The raising and strengthening of the river-wall southward of this point and abreast of the dock are progressing favourably, 227 lineal feet having been built to the required height of 31 ft. above the old dock sill. The masonry necessary to close the old entrance to the Harrington Dock is completed. North of Herculaneum Half-tide Dock, the excavation of Dock K to the depth originally intended, viz., 12 ft. below the old dock sill datum, having been nearly completed, the consideration of lowering both sills and dock from 10 ft. and 12 ft. to 12 ft. and 14 ft. respectively, was entered upon by the Board, and these changes having been favourably considered, an order was given accordingly. The work involved by the increase depths is now in course of progress. The total quantity of excavation, mostly rock, removed from the dock, is about 587,000 cubic yards. The masonry of the walls is completed, and that of the south passage, with its side walls and bridge pits, is also finished. The bridge which is to span the 60-ft. passage is ready for fixing in place, having been built in the dock-yard. At the Herculaneum Half-tide Dock a dam is in course of erection in front of the south entrance, to exclude the tidal water, so as to admit of the work in connexion with the lowering of the sills from their present level of 8 ft. to 12 ft. being carried out.

#### BUILDING PATENT RECORD.\*

##### APPLICATIONS FOR LETTERS PATENT.

- 3,829. T. S. Wilson and H. T. Johnson, Manchester. Apparatus for ventilating sewers, soil-pipes, &c. Aug. 11, 1882.  
3,844. E. A. Brydges, Berlin. Manufacture of reed fabrics for ceilings. (Com. by P. Strauss and H. Ruff, Cottbus, Prussia.) Aug. 12, 1882.  
3,900. W. J. Henry, London. Smoke-consuming gratings. Aug. 15, 1882.  
3,909. W. P. Thompson, London. Construction of roads and ways, &c. (Com. by A. C. d'Almeida, Paris.) Aug. 16, 1882.  
3,921. S. Fisher, London. Fabrics for covering walls. Aug. 16, 1882.  
3,929. H. Darby, London. Apparatus for heating baths. Aug. 16, 1882.  
3,930. G. Henderson and D. McNeil, London. Water-waste preventer. Aug. 16, 1882.  
3,944. G. J. Dickenson, Albany, U.S.A. Sash-fasteners. Aug. 17, 1882.

##### NOTICES TO PROCEED

have been given by the following applicants on the dates named :—

August 15, 1882.

- 1,836. W. Walker, New York, U.S.A. Manufacture of artificial stone. April 18, 1882.

\* Compiled by Hart & Co., Patent Agents, 25, New Bridge-street.

1,857. W. Blyth, Barton-upon-Humber. Manufacture of bricks and tiles, &c. April 18, 1882.

August 18, 1882.

1,751. W. P. Thompson, London. Window-cleaning chairs, &c. (Com. by A. Dormitzer, New York, U.S.A.) April 13, 1882.

1,792. A. W. L. Reddie, London. Ventilators for buildings, &c. (Com. by A. Huber, Cologne.) April 14, 1882.

3,301. P. S. Webb, London. Preserving from corrosion the surfaces of piers, bridges, &c. July 12, 1882.

##### ABRIDGMENTS OF SPECIFICATIONS.

Published during the Week ending August 19, 1882.

46. W. Manington, London. Open fireplaces or grates, &c. Jan. 4, 1882. Price 6d.

The fireplace is quite separate from the chimney recess, and has round its back and sides double walls, the space between which is used for heating air, which passes into the room through a chamber above the fireplace. The fire-basket has a solid bottom, and horizontal bars at the back. Above there is an adjustable hanging door, or register, governed by a rod and cam, whose handle is in front of the stove. By shutting this the smoke is made to pass to the back of the fireplace behind the horizontal bar, where it is consumed.

77. H. Reid, London. Machinery for moulding and forming cement and other concretes, for paving, &c. Jan. 6, 1882. Price 2d.

The moulds are given a vibratory motion, so that all the corners are filled up. No drawings have been filed, and the machine, therefore, cannot be described.

119. E. R. Wethered, Woolwich. Window sash-fastenings. Jan. 9, 1882. Price 6d.

The locking-bolt has a stud on it, which travels in a slot in the casing of the sash, and its end is a T-shaped head. The slot is of an L shape, and when the bolt is pushed out the stud traverses the shank of the L, and the head passes through the catch on the upper sash. The bolt is then turned so that the stud traverses the base of the L-shaped slot, and the T-shaped head locks the sashes.

135. F. Holmes, New-cross. Manufacture of fire-lighters. Jan. 10, 1882. Price 6d.

A conical or tapered hole is formed through the fire-lighter, which is made in a die, and a plunger presses the material in the die.

162. A. T. Angell, London. Syphon-traps for drains. Jan. 12, 1882. Price 2d.

At the bottom of the inlet end of the syphon is a siphon, through which all the water passes in a small stream into the centre of the water contained in the syphon. (Pro. Pro.)

172. J. Jackson, London. Apparatus for mixing the materials used in the making of concrete. Jan. 12, 1882. Price 6d.

From the hopper the materials fall down a main shoot, in which are a series of inclined shelves so arranged that the material in falling is thrown from one to another. Water may be mixed with the materials during their descent.

188. J. Parrott, Wallington. Warming and ventilating apparatus. Jan. 13, 1882. Price 2d.

A chamber is made below the grate, in which air is warmed and then discharged into the room. (Pro. Pro.)

199. J. F. Hayne, London, and G. B. Lovelace, Birmingham. Stoves, lamps, &c. Jan. 14, 1882. Price 2d.

A double casing is formed round the stove or lamp, through which air is admitted into the interior, and in which it is warmed. (Pro. Pro.)

411. C. Pieper, Berlin. Sewerage gullies. Jan. 27, 1882. Price 6d.

A deep vessel is formed, the walls of the upper half of which are perforated. The mud falls to the bottom of the vessel, and as it fills with water the straw or other floating material is prevented from flowing out by the outlet from the upper part of the vessel by the grating. If this outlet gets choked the water can pass away by a syphon-pipe, which rises out from the lower part of the vessel leading to the sewer.

#### EXETER ART EXHIBITION.

The second Art Exhibition held in the Albert Memorial Museum was opened on the 15th inst. It consists of works of art from residents in Devonshire. There are some good original designs in the department for decoration and furniture. Mrs. Hobbath, Exeter, sends a design for linoleum, and another for wall decoration; Mrs. Bishop, Starcross, oil-paintings of summer and winter for hall decoration, design for interior decoration and dining-room, art-furniture in perspective; I. Lemon, Exeter, design for dining-room door in oil-colours; G. Mitchell & Son, Exeter, tapestry panel screen of good design by Miss Elsie Fortescue, Torquay. In the Art-Furniture department, Messrs. Wilson & Son, Exeter, exhibit a wood chimney-piece and mantel in the Queen Anne style in American walnut; Mr. Mark Rowe shows chimney-piece and over-mantel, in mahogany, in the Queen Anne style. In art-needlework some good specimens are exhibited. A gipsy table-cloth, embroidered with silk, original design by Miss Sarah Hayward, Exeter; small table-cloth, in

imitation of Eastern embroidery, by Miss Johnson, Torrington; a coat of arms and the arms of Exeter, worked on silk, by Miss Sarah Cockerham, Alington; the "Death of Douglas," "The Laccemaker," and "The Pedlar," by Mrs. Pepin, Exeter. Some good designs for lace: Design for lace shawl,—ground-ivy and cinquefoil; Honiton lace bouncer,—potato and cuckoo-flower; Honiton lace collar,—violets, by Miss E. B. Becker, Exeter; design for lace for bamerettes, and design for priest's stole, by Miss Mary E. D. Lott, Honiton; design for lace shawl, by Miss H. J. K. Cornish, Ottery St. Mary. All the works now seen are greatly in advance of those exhibited at the first Exhibition, last year.

EXETER.

#### METROPOLITAN BOARD OF WORKS.

The Board's offices at Spring-gardens will be painted and cleaned internally during the recess, the contractors being Messrs. Greenwood, of Arthur-street West. The Board-room will, at the same time, be warmed and ventilated upon an entirely new system. This portion of the work will be carried out by Mr. D. O. Boyd, of Maddox-street, in accordance with drawings and a specification prepared by Mr. George Valliamy, the architect to the Board. The Board's offices, as we have had occasion to note from time to time, have been added to considerably since their first erection, and the difficulty of maintaining efficient ventilation in the interior has been consequently increased. Our public buildings appear to be considered unworthy even of the sanitary precautions which are applied to private houses.

#### PERCENTAGE ON PRIVATE STREET IMPROVEMENTS.

A LOCAL Government Board inquiry was held in the Vestry-hall, Chiswick, on Monday last, by Inspector Thornhill Harrison, in respect to an application by the Chiswick Improvement Commissioners, for the sanction of an order of 1986/7, for the making up and taking over of about thirty-five private streets, under the 182nd section of the Public Health Act, 1875. The usual notices had been issued to the adjoining owners, and they had failed within the month to make them up according to the Act. A long discussion arose as to the 5 per cent. on the cost of the works, which was included in the contractor's tender, but which was, as in former cases, to be paid to the Clerk and to the Surveyor to the Commissioners for the preparation of the plans and specifications, and for making out the appraisements of the costs and collecting them. The Local Government Board had decided that 2 per cent. only was a fair sum to be added to the actual cost of the works, and that nothing should be allowed for the preparation of the plans. It was contended that the Improvement Commissioners would have to prepare the plans and specifications, and do all preparatory work up to the time of serving the notices, whether the adjoining owners or the Commissioners were to do the work. The 2 per cent. paid to the surveyor for the preparation of the plans should not have been put on the tender at all, as the Commissioners called upon the adjoining owners to make up their streets according to their plans. If the owners had done the work, neither the Commissioners nor the surveyor could charge anything for the preparation of the plans and specifications. If the owners did not do the work, and the Commissioners did it, and their surveyor superintended the execution of the work, which in most cases it was desirable that he should do, it was a fair thing to charge 2 per cent. for that superintendence.

Mr. Cannon, solicitor, informed the Inspector that he had been sent by the Chiswick Ratepayers' Defence Association to object to the charge of 5 per cent. made upon the owners. The subject of that charge had created a great deal of talk in the neighbourhood.

The Inspector further stated that he had nothing to do with the salaries of the Clerk or the Surveyor. The Commissioners might, if they chose, make arrangements so that those salaries should cover the per-centage for the execution of the work; but the only addition that could be made to the actual cost of the work was 2 per cent.

The Clerk said that it was in consequence of the adjoining owners failing to make up the roads themselves that they were charged the 5 per cent. The Inspector, in reply to the Clerk, gave it as his opinion that the Commissioners were not entitled to charge even the expenses of collecting the appraisements of the costs. Even interest on the borrowed money could not be charged. He contended it was the duty of the surveyor, as soon as the work was done, to ascertain the cost of the work, and, having done that, to apportion the cost among the adjoining owners; and there was no reason why the money should not be got when the work was finished. There was nothing in the Act about interest or legal expenses. The Commissioners did not borrow the money to do the work, but they borrowed it, as it was wanted. If there was any interest, the money should come out of the general funds of the rates, as the making up of the streets was desirable on public as well as private grounds. The Clerk pointed out that the Master of the Rolls had recently laid down the law that the Commissioners could not make a demand for the money until three months after the appointment of the costs, that was to say, if the adjoining owners had not done the work within that time the appraisements. That was only fair, as there might be overcharges against which it would be necessary to apply.

The Inspector said that notwithstanding that decision only 2 per cent. beyond the actual cost could be charged. The Inspector took evidence as to the manner in which the streets had been constructed, and said that the reply of the Local Board would be given soon.

**THE NEW MUNICIPAL BUILDINGS FOR GLASGOW.**

Mr. G. LINWOOD writes to the *Glasgow Herald* with reference to the choice of material for these buildings. He says:—

"Every one in Glasgow is familiar with the appearance of the Municipal Buildings in Ingram-street. The stone of the more recent portion of the buildings is undergoing a cautious process of decay. From time to time it has been patched up, and a sorry sight it presents to-day. Are we to have a repetition of the Ingram-street fiasco by perpetuating the admirable designs of Mr. Young in a material which cannot stand the smoke-laden atmosphere of our city? Why not use granite freely throughout the new buildings? That material would certainly be a vast improvement upon the soft and questionable freestone, and Glasgow would at last have a municipal building worthy of her traditions. That fact would amply compensate for a little extra expense in the building materials. I venture to throw out the suggestion in the hope it may receive some support at the hands of those chiefly concerned,—the citizens of Glasgow."

The Council of the Glasgow Institute of Architects have now nearly completed their arrangements for the exhibition of sketch designs of the plans sent in for competition in connexion with the New Municipal Buildings. There were in all 100 competitors. The exhibition will open on the 2nd of September.

**NOTES FROM BRIGHTON.**

*The Health of the Town.*—The Committee appointed to vindicate the reputation of the town as a health-resort against the statements made in the *Lancet* and elsewhere have issued a pamphlet, entitled "Brighton as it is." As may be supposed, it makes the most of the great natural advantages possessed by the town, and appeals to the Registrar-General's returns of the annual rates of mortality in support of its main position, viz.,—that those natural advantages combine to make the town one of the healthiest in the kingdom. According to the writer, in 1876 Brighton was first (showing the lowest death-rate) on the Registrar-General's returns of the annual rates of mortality in "the twenty large towns of England." She was second on the list in 1877, third in 1878, second in 1879, first in 1880, and first again in 1881. We are told that the statements complained of are resented "not so much because they made unpleasant and damaging charges, but because they were not borne out by facts." Without at the present time making any damaging statements, it may not be out of place for us to warn the municipal authorities against the assumption that efforts are not necessary on their part to put the town in a right condition. Some years ago, on the occasion of the visit of the Social Science Association to Brighton, so charming in many parts, the Conductor of this journal, after a survey of the less frequented parts, as a member of the Health Section, found himself compelled to make some statements which raised the ire of some of the inhabitants, but which were, nevertheless, perfectly correct, and called loudly for attention. We mention this as showing that a town which to the ordinary observer, and even to the reader of average results, presents a satisfactory aspect from a sanitary point of view, may yet have its black spots obvious to those who know where to look.

*Proposed Western Lawn.*—At the meeting of the Brighton Town Council last week, the Works Committee reported that they had instructed the surveyor to bring up a plan showing what space on the beach between the West Pier and the Western toll-house was available for the purpose of a lawn or public promenade; and Mr. Sendall said he hoped the plans would be ready for the next council meeting.

*Road Gullies and Catch-pits at Hove.*—The attention of the Hove Commissioners having been drawn to that portion of Sir Joseph Bazalgette's report upon the drainage of Brighton and Hove, which suggested the making of catch-pits in connexion with the street gullies, in order to intercept the road *debris*, their surveyor (Mr. E. B. Ellice-Clark) was requested to prepare plans for carrying out the necessary work, and at the monthly meeting of the Board on the 17th inst., the plans were adopted, and, upon the recommendation of the Works and Improvements Committee, it was resolved to borrow 2,500*l.* to defray the cost.

*Encroachment of the Sea at Hove.*—Considerable inroads having been made of late by

the sea upon the foreshore at Hove, the Commissioners of that district have directed Mr. E. B. Ellice-Clark, their surveyor, to report as to what remedial measures he would recommend. At the last meeting of the Board, Dr. Millard said the sea had encroached still more during the previous forty-eight hours, and was then within eight yards of the lawns. He suggested, for the consideration of the surveyor, a similar system to that adopted at Littlehampton, where he explained how groynes were erected with their land ends at angles of about 60 degrees, and meeting at the seaward ends, forming a triangle. The sea, he said, washed up over these, and the shingle was retained in the "quarters."

**PROVINCIAL NEWS.**

*Birkenhead.*—In his annual report to the Mersey Docks and Harbour Board, Mr. G. F. Lyster, the engineer to the Board, alludes to the increased provision which has been made in the Birkenhead Docks for the importation of cattle and dead meat. The lairage on the north side of the Alfred Dock has been furnished with pens and water-troughs similar to those in the sheds, the floor concreted, and a water service laid. By this arrangement accommodation is provided for 374 cattle. At Woodside four chill-rooms, each capable of holding 250 carcasses of beef, have been erected. The refrigerating machinery, which is being provided by Messrs. Haslam & Co., of Derby, will shortly be ready for use.

*Hull.*—On the 18th inst. a large number of the members of the Institution of Mechanical Engineers visited Hull for the purpose of inspecting the new Alexandra Dock works of the Hull and Barnsley Railway and Dock Company and the large engineering and ship-building establishment of Earle's Company, situated to the eastward of the River Humber. The party included the president of the society, Mr. Westmacott, C.E., Mr. Abernethy, C.E., Mr. Kilson, C.E., Mr. E. Samuelson, and many other gentlemen. At the Alexandra Dock works there are some 2,000 men employed, principally in excavating and walling. Of the former, two and a half million cubic yards have yet to be got out. The men, with the assistance of the steam navvies, cranes, &c., are getting out fully 120,000 cubic yards per month. When the works are completed there will be 1½ mile of dock walling, and a similar extent of sea-wall. The visitors were greatly interested in the working of the hydraulic and steam excavators, and also inspected the hydraulic engine-house and observed the powerful engine constructed for hydraulic and other purposes in motion. Messrs. Lucas & Aird are the contractors, Messrs. A. C. Kourtyz & G. N. Abernethy being the resident engineers. The visitors subsequently proceeded to Earle's ship-building yard and engineering works, which cover an area of 20 acres, and do the whole of the work in connexion with the construction of ships and their engines.

*Salisbury.*—The Wilts and Dorset Banking Company have been making extensive additions to their premises in Salisbury's picturesque market-place. The original building was built from the designs of Mr. Henry Hall, some twenty years ago. It is of classic character, as regards its style of architecture,—boldly and freely treated. The present work, now drawing near completion, is a continuation of the main structure,—an undertaking fully prepared for in designing the original facade, and in the general planning. The front is entirely of Ham Hill stone, and exhibits much fine masonry and carving. Mr. Hall has acted as architect for the additions. Upon the parapet of the building is a large sculptured representation of the double-headed and collared eagle, the arms of Salisbury. This is in Portland stone, and the work of Mr. Harry Hems, of Exeter, by whom the whole stone-carving upon the new portion of the building has been executed. The builder who commenced the work did not complete it. It has been finished by Mr. Barber, builder, of Brown-street, Salisbury.

**Dwellings in Flats for the Middle Classes.**

—The London Scottish Dwellings Society has been established, for the erection of dwelling-houses for the middle classes in London and its suburbs, divided into flats or floors as in Scotland, and in order to meet the wants of families, at rents ranging from 20*l.* upwards.

**ZANZIBAR CATHEDRAL.**

Our readers are aware that even in this remote district the services of the church will not be wanting in reverence for the lack of suitable fittings. A large shipment of church furniture has lately been sent out there, which comprises amongst other things, brass lectern, altar cross, vases, candlesticks, "Hesperus" lamps, choir-desks, hangings, carpets, &c. The order was entrusted to the firm of Jones & Willis, of Great Russell-street, London. As the goods had to be carried on men's backs for a long distance up the country, they were packed in cases not exceeding 40 lb. in weight. The same firm have now on view a novel kind of font in polished brass, designed by the architect, Mr. C. F. Hayward, F.S.A., of 20, Montague-street, Russell-square, for the same cathedral.

**THE REGULATION OF RAILWAY CLOCKS.**

Sir,—Now that electricity is being used in so many ways to make so many improvements, it is quite in season, I think, that something should be done to regulate the time of railway clocks. I do not know whether it has been generally noticed (perhaps not), but it is a fact, that very few clocks at our principal railway termini and stations tally with one another. I have taken notice for the past few weeks of this, and have invariably found a difference of two, three, and even more minutes; but the climax was reached only two or three days ago, when the times of the dials at King's-cross and Notting-hill showed a difference of eight minutes. Seeing what many men of business may lose by these differences, and how many private people may be put to inconvenience of waiting, by missing trains through this neglect on the part of some one, and being in view the facilities which the railway companies possess for altering this nuisance, surely something might be done, without very great expense, to grant the public a boon, the absence of which at present is the cause of many losses both of time and money. Should you think fit to devote a small space to the above facts, the influence of your journal might be the means of bringing about some kind of reformation.

JAS. R. MORGAN.

**CASE UNDER THE METROPOLITAN BUILDING ACT.**

BY-LAWS: BAD MORTAR.

On Wednesday, August 16, Mr. S. Muncey, builder, was summoned to Worship-street Police Court by Mr. A. Payne, District Surveyor for East Hackney (South) and North Bow, for constructing two houses in Hepscott-road, Hackney Wick, with mortar mixed with earthy matter. Samples of the mortar used in lieu of sand were shown in court. Defendant's counsel at first denied that the material had been used, and called a surveyor who affirmed that the mortar was good; but subsequently one of the defendant's own witnesses admitted having mixed the mortar with materials similar to the specimen shown.

The defendant was fined 60*s.*

**CHURCH-BUILDING NEWS.**

*East Teignmouth.*—East Teignmouth Church has been re-opened, after works of internal restoration costing 1,100*l.* Not long since, owing to the exertions and influence of the Vicar (the Rev. H. C. Dethon), a new chancel, costing, with all its decorations, 2,500*l.*, was erected, and this had the direct effect of rendering apparent the necessity for renovating the interior of the nave. Plans were prepared by Mr. R. Medley Fulford, of Exeter, under the instructions of a restoration committee, which had Mr. E. Atkins as secretary, and the work was undertaken, and has been successfully carried out, by Mr. Robert Davis, of Newton. The old wooden galleries on the north and south side of the nave have been removed, as also has the partition which separated the transepts from the body of the church. The stunted transepts now have the effect of making the church cruciform, and have been appropriated to the use of the public, being filled with free seats. In the place of the old and unsightly stone and plaster windows, there have been put Bath stone windows of neat design filled with tinted cathedral glass, the tracery being enriched by a little colour. The whole of the windows have, with two exceptions, been treated in this way, the exceptions being the

north transept window, which will be filled in with stained glass by Miss Consins, and the western window in the north aisle, which is the gift of Miss Frupp, of The Grove, Teignmouth. To provide accommodation in the place of that which has been taken away by the removal of the side galleries, a gallery has been constructed across the whole of the west end of the church. The entire building has been fitted with comfortable seats of pitch pine. Sitting accommodation is now provided for 847 persons. The aisles have been cemented preparatory to tiles from the Aller Pottery being laid, and the pews are floored with red deal. The warming apparatus has been supplied by Messrs. Haden & Son, of Trowbridge.

**Cullercoats.**—On the 4th inst. the Duke of Northumberland laid the foundation-stone of the new Church of St. George, Cullercoats, which is to serve the wants of a new ecclesiastical district which has been formed, comprising Cullercoats and the northern portion of Tynemouth. The Duke has given the site, and undertakes the entire cost of the erection, which, it is estimated, will amount to about 18,000l.; he has also given a site for a vicarage-house; and, jointly with the Ecclesiastical Commissioners, has provided an endowment to the amount of 300l. a year. The church will be of the Thirteenth-century character, and of lofty and commanding proportions. It will consist of a nave, enclosing an area of 84 ft. by 56 ft., with western narthex treated as a baptistery, and entered by porches on the north and south sides. The chancel, with apsidal eastern termination, will be 50 ft. long and 21 ft. wide. A tower, in which it is proposed to place the organ, will be south of the western bay of the chancel; and the corresponding position on the north side of the chancel will be occupied by a transept about 20 ft. square, with a large vestry west of it. The total length of the church from east to west will be 153 ft., and the greatest breadth from north to south about 90 ft. The church is to be faced both inside and outside with local stone. The nave and aisles will be divided into five equal bays, and separated by simple arcades with circular columns and plain moulded arches. There will also be a narrow triforium, not pierced, and a lofty clearstory, with windows of two lights. The external surface of the clearstory walls will be unbroken, and the bays will be marked by buttresses on the aisle-walls, with a single lancet window in the centre of each bay. The nave and aisles (as well as the rest of the church) will be groined with plain quadripartite groining, with a timber roof over of steep pitch. The height inside will be 44 ft., and to the point of ridge 20 ft. higher. The chancel, including the apse, will be divided internally and externally into nine bays by upright shafts; externally the walls will be plain up to the level of the sills of the windows, 25 ft. above the floor. These windows will be of two lights, with blank arches on either side, thus giving the effect of a continuous arcade. A tall wall-arcade will surround the chancel at the floor-level. The blank triforium of the nave will be continued round, and the clearstory windows will be widely splayed, so as to completely fill each bay. The tower will rise to a height of 90 ft., and will be covered by a broach-spire of about the same elevation. The church is being built from plans prepared by and under the superintendence of Mr. J. L. Pearson, R.A., of London. The whole of the works are being executed by Mr. Walter Scott, Newcastle, under the superintendence of Mr. S. Chivers, Mr. Pearson's clerk of works; and Mr. Wm. Moore is foreman in charge.

#### DISSENTING CHURCH-BUILDING NEWS.

**Ashton.**—A new Wesleyan chapel is being erected at Ashton, near Preston. The chapel will afford accommodation for 250 worshippers, with minister's vestry, large class-room, heating-chamber, and other offices, at the west end. Local contractors are carrying out the various works from the plans and under the superintendence of Mr. David Grant, architect, of Preston.

**Widnes.**—On the 20th inst. the memorial-stones of what is in future to be known as the Hartland Wesleyan Chapel, Widnes, were formally laid. The new building will cost about 2,500l. Mr. Isitt, of Bradford, is the architect. The dimensions of the building will be 50 ft. by 53 ft., and it will be Italian in character. There will be two entrances from Irwell-street. The pews will be of deal, stained and varnished. The exterior will be of patent bricks.

#### Miscellaneous.

**Bakehouses in "Merrie Islington."**—Dr. C. Meymott Tidy, the medical officer of health for Islington, in his annual report, just issued, of the sanitary condition of the parish, refers to the extract from the report of her Majesty's Chief Inspector of Factories and Workshops upon London bakehouses which some few months ago was quoted and commented upon in the public journals, and in which the condition of the bakehouses was alleged to be most unsatisfactory. He states that, although the report in question referred only to the east end of London, he had felt it his duty to direct an inspection to be made of the bakehouses in Islington, with a view to ascertain their present condition under the new régime as contrasted with their condition in the beginning of the year 1879, when they were first taken under the supervision of her Majesty's inspectors, and also for the purpose of having any defects now existing remedied as speedily as possible. In March, 1879, when the bakehouses were last previously inspected by the vestry sanitary officers, in one instance only was any accumulation of refuse found under the troughs, and there were no other sanitary defects observed at that time. As a result of the inspection just made, in forty-five instances accumulations of refuse were found under the troughs, and twenty-five inlets to drains were untrapped. In eight bakehouses the paving was defective. In two there were stack pipes open at the top and connected with the drains at the bottom. In a single instance a drain-pipe was found open for the reception of the water overflowing from the water receptacle. Three of the more recently constructed bakehouses had water-closets in them, while five old ones were similarly circumstanced. Dr. Tidy points out that more frequent inspection is required in order to prevent such scandalous violations of sanitary laws.

**Free Opening of St. Paul's Cathedral.**—The Dean of St. Paul's, writing to the Lord Mayor, who is one of the trustees of the fabric of the cathedral, on the agitation to secure the free opening of St. Paul's one day in each week, says:—"The cases are not the same at Westminster and St. Paul's. At Westminster the chapels for which a free day is given are all on the floor of the church, with open spaces about them, and people go in one way and come out at the other end. At St. Paul's the places for which a free day is asked are the crypt, with its dark corners and recesses, and the upstairs portions of the building, to which access is by long, narrow, winding staircases and passages, without any possibility of a separate entrance or exit, and where a block and crush, not unlikely in the case of the exceptional crowds of a free day, would be very dangerous. This is a matter of cubic feet which we cannot alter." With every desire to aid those who seek to open our public buildings, we are inclined to agree with the Dean and Chapter in what they say as to the difficulties of freeing entirely the upper parts of the building. A very low fee one day in the week would probably best answer the purpose.

**Plumbers as Fire-raisers again.**—On Wednesday afternoon what proved to be a damaging fire broke out at 394, Clapham-road, at the private house of Mr. E. Roddin. Some plumbers had been at work upon the roof, and while they were gone to dinner it was found that the top part of the house was on fire. An alarm was immediately raised, and the firemen were very soon on the spot, but the second floor had become thoroughly alight, and the flames threatened to attack the whole of the house. The roof of the next house, which was unoccupied, caught fire, and the flames spread here to the second floor. The official report ascribes the cause to "plumbers at work."

**The War in Egypt.**—The cabins of the Peninsular and Oriental steamers now on duty as hospital ships in Egyptian waters, have been painted throughout with Griffiths's enamel paint, manufactured by Messrs. Griffiths, Berdoe, & Co., of Liverpool and London.

**Ventilation of the Reform Club.**—Messrs. Robert Boyle & Son's system of ventilation has been adopted for the Reform Club by the committee and architects, and Messrs. Boyle have received instructions to proceed with the work at once.

**The new Roman Catholic Cathedral at Portsmouth** was opened on the 10th inst. The foundation-stone of the building was laid in December, 1879, by the late Dr. Danell, R.C. Bishop of Southwark. It was the wish of the late bishop to undertake the work of the nave first, of which five bays, forming part of the permanent church, have been built, in the hope that funds would come in to enable the transept, chancel, and side chapels to be proceeded with. But the lordship's death intervening, steps had to be taken to close in the eastern end, and provide such sanctuary and sacristry accommodation as was absolutely necessary. It consequently happens that the church has two unsightly temporary ends. The style of architecture is Early or Geometrical Decorated, (temp. about 1450; and the material of the exterior is Farnham dark red brick, with Portland stone dressings, the roof being covered with tiles. The internal masonry is of Beer stone and the walls are plastered. The contractors are Messrs. Patman & Fotheringham, of London; Messrs. Hammer & Co., of Bournemouth, supplied the benches; and the gas fittings, altar-rail, and several fittings were furnished by Messrs. Burns & Oates. The original design (which we illustrated and described in our volume for 1879, pp. 1052-53) was from the pencil of the late Mr. John Crawley, of Bloomsbury-square, London, and since his death, the works have been completed under the superintendence of Mr. Joseph Stanislaus Hansom, F.R.I.B.A., of South Kensington. Mr. Bromfield, whose death occurred just at the completion of the building, was clerk of the works, Mr. Adams being the builders' foreman.

**A Party of Belgian Architects, sculptors, painters, archaeologists, and ecclesiastics, members of the Guild of St. Thomas and St. Luke** whose object is to promote the study of Christian art, have come over to England, on a fortnight's tour, with the intention of visiting the principal ecclesiastical sites. On Monday they arrived in Canterbury, and spent several hours in the cathedral, the Dean and the Bishop of Dover acting as ciceroni. The party numbers nearly eighty, and includes Professors Reusens, of Louvain; Canon Delbigne, of Brussels; M. Van Henkelom, president of St. Bertholomew Guild, Utrecht; M. Jules Helvig, of Liège; and M. Blancart, of Ghent. The other places to be visited by the travellers are Rochester, London, Winchester, and Oxford.—*Standard.*

**Hydraulic Power.**—The Hydraulic Power Company is about to set up a powerful ram in the neighbourhood of Blackfriars Bridge, on the Surrey side, together with engine power to work the force-pumps; and from this central hydraulic ram mains under great pressure will extend along such thoroughfares as are likely to afford remunerative patronage for the system. From the mains, of course, smaller pipes will be carried into the premises of those who may require hydraulic force, the charge being based on the actual amount of water discharged from the machine into a meter, at a rate of 4s. per 1,000 gallons. The use to which the power will be mainly applied is the working of lifts and cranes.

**Festive.**—Messrs. Bangs & Co., hilders, of Bow, invited their foremen, some thirty-five in number, to dine with them on Saturday last at Epping, and treated them liberally. Mr. Bang presided, and Messrs. Anstis, Lambert, and Poston spoke, as very old servants in the firm.—On the same day the clerks and foremen in the employ of Mr. W. Brass, hilders, of Old-street, held their first annual cricket match and dinner at the Red Lion Hotel, High Barnet.

In the cricket match the clerks were victorious. We chronicle these outings, though similar events are just now so numerous that we can scarcely undertake to mention all of them.

**Islington, near Lynn.**—A painted window has just been erected in the church of Jesus; and below it, a memorial brass, with the arms of Bagge impaling Keppel. They have been executed by Mr. Taylor, of Berners-street, by Mr. Thomas Bagge, in memory of his wife, who was a descendant of the Earls of Albemarle.

**Etchworth.**—A memorial retables has just been erected in this church by Mr. J. R. Corbett to a near relative. It consists of a carving Carrara marble, representing the Last Supper with a framework of red Mansfield stone. The work has been executed by Messrs. Mayer & Co. of Munich and London.

**Building Exhibition for 1883.**—A meeting of the exhibitors at the three last exhibitions of building materials held at the Agricultural Hall took place last week at the Cannon-street Hotel, for the purpose of considering a proposal that the next meeting should be held at the Hyde Park Hall, Albert-gate, instead of Islington. Mr. Trickett presided, and explained the objects of the meeting, after which there was a discussion as to the best site for the next exhibition. It was stated that difficulties had arisen which would prevent the Agricultural Hall being used for the purpose, and that Mr. John Black, the promoter of the former exhibitions, had taken the Hyde Park Hall for the next one, at the same time that the Agricultural Hall authorities had decided to hold an exhibition of their own. Ultimately, a committee, consisting of Mr. Black, Mr. Rafferty, and Mr. Shrapnell, were appointed to confer with the Agricultural Hall authorities on the subject, and report to another meeting. Touching this matter, Mr. Philip Shrapnell writes to say that the meeting refused to entertain Mr. Black's proposal for the removal of the exhibition; and the only resolution passed was one appointing a committee of Mr. Black's friends to wait upon the Agricultural Hall Company, for the purpose of endeavouring to induce them to reconsider their decision. In this connexion, we note that a company has recently been registered, whose object is the construction of an Agricultural Hall at Kensington. The building is to have a superficial area of 188,000 ft. sq., or about 60,000 more than the large hall at Islington, so famous for excess and coarse exhibitions.

**The Law Memorial, Northampton.**—A committee has been formed for the purpose of building an organ-chamber at All Saints' Church, in memory of the late Mr. E. F. Law, architect, Northampton. At its last meeting, the Vicar, who was in the chair, announced that Mr. Hill (the head of the firm of Messrs. Hill & Son, organ builders, London, who rebuilt the organ at All Saints' Church about forty years ago) had been down to see the church and organ, and to give an opinion upon the proposed alteration, and that he had spoken very favourably of it, saying that the tone of the organ would be practically quite as good in the proposed chamber as in the gallery, while it would be much better placed in the chamber for accompanying the musical part of the services. He then reported that he had since received an offer from Mr. Hill to remove the instrument and reconstruct it, doing all necessary alterations and repairs for the sum of 100l. Mr. E. Law then produced plans for the construction of an organ-chamber just large enough to hold the organ, the plan involving no further alteration of the present walls of the church than the removal of the glass and stone tracery from the north-west window of the chancel, and the north-east window of the church. This plan was approved of by the committee.

**Presidents of Departments, Social Science Congress.**—The appointments of presidents of departments for the forthcoming Social Science Congress at Nottingham have now all been made. The following is the list:—President of the association, Mr. George Wood at Hastings, M.P.; Department of Jurisprudence, Mr. Henry Fox Bristow, Q.C., Vice-Chancellor of the Duchy of Lancaster; Department of Crime Section, Sir John Pope Hennessy; Department of Education, Mr. William Woodall, M.P.; Department of Health, Sir Rutherford Wood, K.C.B.; Department of Economics, Professor Bonamy Price, M.A.; Department of Art, Mr. George Aitken, A.R.A.

**Finances of the Commissioners of Sewers.**—The *City Press* estimates the total liabilities of the Commissioners of Sewers at early a million sterling, and remarks that if this be so, it will require about 40,000l. a year to pay the interest, and about 20,000l. a year to gradually pay off the principal. 60,000l. a year means a rate of 4d. in the pound, and how will such an addition to the present amount of the Consolidated Rate be received by the ratepayers?

**Metallurgical Science.**—A medal and prize of the annual value of twenty guineas at King's College has just been founded by Dr. Siemens, R.S., "with the object of stimulating the students of King's College, London, to a high standard of proficiency in metallurgical science." The first award will be made at the end of the 1883.

**Monument to the Prince Imperial at Woolwich.**—The erection of the monument to the memory of the late Prince Imperial is rapidly approaching completion on the green in front of the Royal Military Academy at Woolwich Common. The larger of the two blocks of polished granite, which will form the pedestal, and on which the statue of the unfortunate Prince will stand, will bear the following inscription:—"Napoleon, Prince Imperial. Born in Paris, March 16, 1856. Killed, fighting in South Africa, June 1, 1879. Gentleman cadet, Royal Military Academy, from November 18, 1872, to February 16, 1875. Erected by upwards of 25,000 officers and men from all branches of Her Majesty's forces." The statue will be of bronze, and rather larger than life-size. The granite blocks will also bear four bronze eagles, four wreaths enclosing the letter "N.," and surmounted by a crown and the motto of the Royal Artillery. It is expected that the statue will be unveiled soon after the gentlemen cadets return to the Academy from their summer vacation at the end of September.

**The Use of Lime in Coal Mining.**—On Monday, a series of interesting experiments took place in the workings of the Wharfedale Silkstone Collieries, near Sheffield, the object being to test the new method of winning coal by the use of compressed lime instead of blasting powder. The experiments, which were witnessed by the officials of this and other collieries, took place in the Parkgate Seam. A hole about 3 in. in diameter, and 4 ft. deep, was drilled through the solid coal and cleaned out, a perforated iron tube was then inserted, and the lime cartridge 3 in. long, put in. When the lime had been rammed home, and the hole made up, a forcing-pump was used to inject water into the bottom of the tube. Simultaneously with the injection of water the reading process began, and in thirty minutes about ten tons of coal came down almost in an unbroken mass. Of the whole of the fall, not more than 6 per cent. of the coal was small, a much smaller percentage than under the old system. It is anticipated that compressed lime will eventually supersede the use of blasting powder and thus revolutionise the system of winning coal, greatly, as appears to be likely, conducing to the safety of the miner.

**Fires.**—Referring to the report in the *Times* of the inquest on the two unfortunate workmen who were killed at the fire at Messrs. Bayley's Cotton Mills, Bolton, on Wednesday last, I venture to suggest a simple method by which a large number of persons may readily leave buildings under similar circumstances. Fires at cotton-mills are rapid, a great source of evil being the staircase, by which the conflagration is conveyed to the various floors, and the operatives at work above where it originated are soon in a panic of great confusion, and on making for the stairs find that means of exit cut off. Many jump from a great height, some slide down the hoist-chain or water-spout. The suggestion I refer to is that iron staples be driven into the bottom of the building, so as to form a permanent ladder, and those in danger could easily get out of the different windows on to it, and so make their escape. —CHARLES R. WHITE.

**The Will of Mr. George Somers Leigh Clarke,** late of 29, Cockspar-street, Pall-mall, architect, and of Walpole, Chislehurst, who died on the 4th ult., was proved on the 29th ult. by Mrs. Louisa Harker Clarke, the widow and acting executrix, the value of the personal estate being over 10,000l.

TENDERS

For desks fittings, and chairs, for the Board-room of the Hove Commissioners, at the New Town-hall, from designs by Mr. Waterhouse, A.R.A.:—  
 E. Boucher ..... £540 0 0  
 J. F. Clappell ..... 384 2 0  
 Maple & Co. .... 364 1 3  
 Morris & Norton (accepted) ..... 332 16 0

For the erection of a pair of semi-detached villas, West Hill, Dartford. Mr. R. Cruwys, architect:—  
 Simons Bros. (accepted).

For the erection of a semi-detached cottage, and alteration to house adjoining, West Hill, Dartford. Mr. R. Cruwys, architect:—  
 Watson (accepted).

For rebuilding the Olive Branch, Crawford-street, for Mr. Shaw. Mr. W. E. Williams, architect:—  
 Marr (accepted) ..... £2,427 0 0

For reinstating, after fire, the Prince Albert, Old Ford-road, for Messrs. Truman, Hanbury, & Buxton:—  
 Marr (accepted).

For alterations to factory, Fashion-street, for Messrs. Scammell & Nephew:—  
 Marr (accepted).

For building Nos. 30, 32, and 34, Greenwich-road, Greenwich, by Mr. F. H. Straw, Mr. John Hinson, 80, Leman-street, E. architect.— S. J. Jerrard, Lewisham (accepted) £2,820 0 0

Accepted for completing the Royal Aquarium Hall, Marine Parade, Great Yarmouth. Messrs. Bottle & Olley, Regent-street, architects.— Beech & Cork, Yarmouth (for brick-layer's, plasterer's, slater's and mason's work) £3,680 0 0

B. Springall, Yarmouth (for carpenter's, joiner's, plumber, glazier, and painter's, and smith and iron-founder's work) 3,190 0 0 Messures Bros. & Co., London (for iron roof principals, purlins, &c.) 1,060 0 0 Gibbs & Canning, Tamworth (for terra-cotta work) 820 0 0 G. Ginton, Costessy (for moulded brickwork) 300 0 0

For the erection of a house, for Mr. J. Howell, in Brouncey-road, South Acton, Mr. N. Knappthorne, Acton, architect.— J. C. Potter, Acton-green £380 0 0 W. Gilding, Chiswick 357 0 0 G. Hooper, Acton 315 0 0 C. Simpson, Acton (accepted) 296 17 6

For new Board Schools at Blenheim, Mon., for the Trevelin School Board. Mr. E. A. Lansdowne, Newport, Mon., architect.— Davis, Cardiff £1,220 0 0 Parfitt, Pontnewydd 1,200 0 0 Burgoyne, Pontypool 1,188 10 0 Chapman, Pontypool (accepted) 1,153 7 6

For additions and alterations to the City of London Lying-in Hospital, City-road, for the Governors thereof. Mr. H. H. Collins, 61, Old Broad-street, architect.— A. E. Robinson 41,395 0 0 Bevan & Dallman 1,380 0 0 R. Abraham 1,253 0 0 Green 1,108 13 6 Saley & Son (accepted) 1,100 0 0

For warming and ventilating, by their new hydro-caloric apparatus, the first section of one wing of Greenwich Hospital Schools.— J. Weeks & Co., Chelsea £360 10 0

For schools and teachers' residence at Faversham, Kent, for Mr. Richard Gibbs. Mr. John Jenkins, architect.— Shrubsole £2,963 0 0 Whiting (accepted) 2,943 0 0

For house and offices, Mount Harry, Seven Oaks, for Mr. A. Thorne. Mr. John Jenkins, architect.— Comtable £2,420 0 0 Wilsbire 2,500 0 0 Durtall (accepted) 2,335 0 0

For additional wing and alterations to No. 3, Upper Phillimore-gardens, Kensington, for Major H. R. Worthington. Mr. Robert Willey, 68, Ludgate-hill, architect.— Onthwaite & Son, Smithfield £2,809 0 0 Woodward, Finsbury 850 0 0 Nash, Kensington 789 0 0 Nye, Ealing 775 0 0 Peany & Co., Ealing (accepted) 759 0 0

For alterations and repairs at 23, Clevel-street, Holborn, for Mr. George Barber. Messrs. Lavender & Dixon, Bedford-row, architects.— W. & H. Salmon (accepted) £695 0 0

For labour only in building bed and shed for new engine, at the Albion Flour Mills, York-road, King's-cross, for Messrs. Powers & Sons. Mr. J. G. Kaynes, 14, Great James-street, Bedford-row, architect.— W. & H. Salmon (accepted) £125 0 0

Accepted for the erection of a Wesleyan Chapel, at Ashton, near Preston. Mr. David Grant, architect, Guildhall-street, Preston.— Thos. Croft Preston (brickwork, &c.) Harrison & Aston, Preston (stonework). Jas. R. Bradshaw, Preston (slating and tiling). R. Crossdale, Preston (plumbing, glazing, &c.). Wm. Whitehead, Preston (carpenter and joiner's work). Wm. Gellard, Preston (plastering). Metcalf & Dilworthy, Preston (heating).

For rebuilding the Burlington Tavern, Burlington-street, for Mr. Docker. Mr. Geo. Treacher, architect.— Canning & Mullins £1,993 0 0 G. Kirk 1,837 0 0 Ansell 1,814 0 0 J. Beale (accepted) 1,759 0 0

Accepted for a detached residence, Margaret-street, St. John's, Wakefield. Mr. William Watson, architect, Wakefield.— Flower Bros. (excavating, brick, and stonework) £765 11 8 Layd (carpenter and joiner) 339 0 0 Thompson (plumbing, glazing, iron, bells, and gas) 225 0 0 Driver (plastering) 70 0 0 Ryecroft (slating) 46 0 0 Naylor (painting) 22 5 0

Accepted for detached residence, Newstead-road, St. John's, Wakefield. Mr. William Watson, architect.— G. Fawcett (excavating, brick, and stone) £500 0 0 Loyd (carpenter and joiner) 313 0 0 Thompson (plumbing, glazing, iron, bells, and gas) 110 0 0 Driver (plastering) 68 0 0 Ryecroft (slating) 35 0 0 Naylor (painting) 20 10 0

Accepted for a detached residence, Esplanade-road, Scarborough. Mr. William Watson, architect.— Petch & Fox £1,200 0 0

Accepted for rebuilding premises in Northgate, Wakefield, for Mrs. Scowby. Mr. William Watson, architect.— Flower Bros. £299 0 0

For the erection and construction of sewage purification and disposal works, for the Leyton Local Board. Contract No. 1. Mr. J. C. Mellis, engineer. Quantities by Messrs. Hovenden, Heath, & Berridge.— Holterell £2,810 0 0 Bell 9,743 0 0 Saunders 9,459 0 0 Gentry 6,250 0 0 Ford & Everett (accepted) 7,912 0 0

Accepted for painting and decorative work required by the Town Council of Brighton. Mr. Philip G. Lockwood, Borough Surveyor.— Ewbank, Hudson, Kearsley, & Co. (104 per cent. below schedule prices).

\* Two other tenders were received, each offering to do the work at 51 per cent. under schedule prices.

TO CORRESPONDENTS.

J. C. M.—W. W.—W. T. D.—J. S.—J. D.—C. E.—S. H.—S. R. J.—P. M.—M. & C.—G. C.—J. G. R.—E. J. M.—A. F. M.—W.—H. L.—R. C.—W. E.—B.—E.—R.—J. P.—R.—M. D. G.—R. W.—J. P.—J.—J. W.—H.—J.—B.—E.—W. S. H.—W. H. F.—E. A. L.—A. W.—H. J. H.—B. S.—J. H.—C.—F. (under consideration).—C. E. C. (next week).—Justice (the story has been often told). All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.—Six lines (about fifty words) or under 4s. 6d. Each additional line (about ten words) 9s. 6d. Terms for Series of Trade Advertisements, also for Special Advertisements, on application. Competition Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.—FOUR Lines (about thirty words) or under 2s. 6d. Each additional line (about ten words) 9s. 6d. REPLIES TO ADVERTISEMENTS.—Addressed Box, Office of 'The Builder.' Cannot be forwarded, but must in all cases be called for, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER.—For 'Situations Wanted' Advertisements 3d. per Week. For all other Advertisements 6d. per Week. PREPAYMENT IS ABSOLUTELY NECESSARY. \* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher, Addressed to No. 41, Catherine-street, W.C.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.—'THE BUILDER' is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 10s. per annum, Per post. Remittances payable to DOUGLAS FOURDRINER, Publisher, 41, Catherine-street, W.C.

Best Bath Stone. WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down. RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [ADVT.]

Box Ground Stone. Is the best for use in all exposed positions, being a well-known and tried weather stone. 50,000 feet cube in stock. PICTOR & SONS, Box, Wilts. [ADVT.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [ADVT.]

Doubling Freestone, Of best quality, supplied from their own Quarries and Kilns by STABLE & HANN, Stoke, Ilminster. Agent, Mr. E. CRACKLEY, 3, Broad-street-buildings, Liverpool-street, London, E.C. [ADVT.]

Asphalte. Seyssel, Patent Metallic Lava, and White Asphaltes. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [ADVT.]

Asphalte.—The Seyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.]

Immense quantities of DRY WAINSCOT, DRY MAHOGANY, DRY WALNUT, in all thicknesses. B. J. HUDSON & SONS, Whitfield-st., W., and Great Peter-st., S.W. London. [ADVT.]

'Lightning.'—Accidents to buildings would be unknown if J. W. GRAY & SONS' Patent System of Conductors, as fitted to the House of Parliament, the Royal Palaces, Principal Churches, Cathedrals, and Public Buildings were universally adopted.—Estimates free on application at 58, Fenchurch-street, London, E.C.—[ADVT.]

MICHELMORE & REAP Manufacturers of CHARLES COLLINGS'S PATENT COLLINGS'S PATENT HINGES LEVER, SCREW, & BARREL BOLTS Self Acting 'FALL DOWN' GATE STOPS, and IMPROVED GATE FITTINGS of every Description 36A, BOROUGH ROAD LONDON, S.E. Discount to Builders. Illustrated List two stamps.

### What is "Proportion"?

N connexion with the question whether the existence of measurable ratios between the different parts of a design is an integral element in design,\* there is the question what is really meant by the term "proportion," which so often comes into controversies on this subject. Architects and architectural critics have talked about "proportion" from time immemorial. Whenever there is an argument as to whether or not the antique or the Medieval builders used special ratios of height, breadth, and length in their buildings, and in the scale of their details, the word "proportion" is always forthcoming, usually on the side of the measurement theory. The proportions of buildings cannot be good, the advocates of geometry will say, unless the respective sizes have a certain ratio to one another. The reply will be that proportion is to be judged by the eye, not calculated by figures. We feel certain buildings to be well proportioned, others to be ill proportioned. They are the one or the other, for we see and feel that they are, but we cannot put the reason in the form of a mathematical proposition. The public get hold of the word and make fine havoc with it, as when they repeat the heresy that St. Peter's is so well proportioned that you do not perceive its size. This little formula of amateur criticism is by no means dead yet; we heard it delivered, with all the confidence of innocence, over a dinner-table the other day, and no doubt a suggestion that it was a popular fallacy would have been received as a very unkind, not to say ungentlemanly, rejoinder. It is too much, perhaps, to expect that those who use such an absurd phrase at all should be able to explain what they mean by the words, or why it should be an advantage or a beauty in a building that it should look smaller than it really is. The phrase would be all right and true enough if people would leave out the "well," and say merely "St. Peter's is so proportioned that it looks smaller than it really is," which would be a simple statement of a fact in brief terms. But if we pause to inquire what is the intellectual idea summed up in the words "so proportioned" in that case; what is meant by proportion, and how it affects the apparent scale

of the building, possibly even some of those whose conception of the matter is correct would find it difficult to express that conception in definite language.

The idea of proportion involves the idea of relation to some standard, and may be used in reference either to the relation of parts to each other, the relation of parts to the whole, or the relation of the whole to some separate external standard. But of what nature is this relation, and what renders it pleasing or unpleasing, as the case may be?

In considering that point, we have one great difficulty to deal with at the outset. It is exceedingly difficult,—perhaps we might say in many cases almost impossible,—to decide how much of the impression of good or bad proportion is due to mere habit of the eye. There is no doubt that habit has a good deal to do with it. We are habituated to certain proportions in the parts of a Classic cornice, and a certain degree of projection relatively to the height of the cornice, and so on; and a cornice with only half the usual projection would strike our eyes with a certain degree of annoyance of the same nature as that which we feel when we hear bad grammar or mispronunciation from an uneducated man. Yet it would be hard to prove that there is any special fitness in the precise degree of projection usually allotted to the Classic cornice. A very much less projection in a Gothic cornice of the same depth does not displease us, because in connexion with Gothic detail we are accustomed to a less projection of that particular member of the architecture. It is possible that if we had always been accustomed to see Doric columns of the thick proportions of the ancient Corinthian or Silesian Doric, we should feel the column of the Parthenon to be over-attenuated, which now we feel to be about the golden mean of proportion for that style. It is possible that were we accustomed to see men with necks 18 in. long we should regard the ordinary length of neck as it does exist with dissatisfaction, as somewhat of a *visus natura*. It is possible, but we do not think it is probable. For in both these cases, as in many others that might be named, our judgment is influenced, even without our knowing it, by the practical suitability of the parts for the office they are to perform. Where this practical suitability is not much influenced by change in the proportion, there our sense of proportion may be, and probably is, largely due to habit. But these cases, whether in natural or artificial constructions, are by no means so numerous as they may at first be supposed to be. In natural constructions,—*i.e.*, in men and animals,—there are very few such cases; Darwin has taught us that. Almost every portion of human and animal construction has taken its characteristic shape because that shape was best suited to the circumstances of life among which the organism was placed, and under which, in fact, it assumed

its form; and a very slight observation of the circumstances of its life enables us to recognise this suitability of the form, and to respect it as well proportioned. No doubt, any one who had not previously seen a giraffe, and saw one for the first time in a loose-box at Regent's Park, would think it an absurd and ill-proportioned animal. But let him see it feeding off the top sprouts of a palm-tree, and it would assume a very different aspect. It would appear just proportioned to the situation, and even the upward slope of the back to the shoulders would appear as a part of the general up-reaching tendency of the whole make of the creature, and completely in harmony with its elongated neck. And in like manner there is a relation between the symmetry which we feel to exist in what we call a well-shaped human figure, and the circumstances to which that shape is adapted. The bodily figure is, in fact, to use a phrase often applied to mental characteristics, the "creature of circumstances," and it is impossible that we, with our present experiences of life, should regard any figure materially differing from the normal human figure as well proportioned, because our experience tacitly teaches us that no proportions materially different from these would be suitable to the circumstances of actual life and movement, and to the tasks which the body has to perform. The attempts of painters like Fuseli and Rossetti to produce ideal forms of men and women, which shall be superior to the actual forms of life, have therefore always failed and always must fail to satisfy the eye, because we can only judge of proportion in the human figure in relation to our own human experience of life, and an ideal figure could only satisfy us if we could realise to ourselves an ideal life to which that figure would be related, and in regard to which it would appear properly proportioned. As to what is called a canon of proportion of the human figure, that merely means a practical recognition of the fact that the best figure will be that which is, in all its points, best proportioned to its work; and the system of settling that proportion by taking the mean measurements of a great number of the most typical figures is the perfectly logical and correct one, because the measurement which is found to predominate will necessarily be the one which is best proportioned in relation to existing circumstances.

The application of this reasoning to architectural design appears to furnish the key to one meaning, and perhaps the most important meaning, of the word "proportion" in regard to work done by human hands. We say one meaning because, as we shall have to notice just now, there is another sense in which the idea of proportion may be regarded, involving a different class of relationship. But in considering the proportions of a building with reference to the forces operating upon the building, we get an explanation of the difference between good

\* See articles on "Measurement and Design," in the two preceding numbers.

and bad proportion analogous to that which is illustrated by the relation of the human figure to the forces with which it has to deal. Take a column as an example: the object of a column is to hold a portion of a building aloft; height is a requisite, therefore, to it; a very low and stumpy column would appear as a feature ridiculously falling short of its obvious intention. But stability is also a requisite of the column, as of every part of architecture, and therefore the height must be limited to that which will appear, when regarded in relation to the thickness of the column and to the mass it has to carry, as not too great for perfect stability. Regarding it in this light, we can see that the Parthenon column has a claim to be regarded as better proportioned than that of Corinth or Pæstum; in the latter the appearance of stability is in excess. But any considerably greater height given to the Parthenon column would spoil its proportion by too much reducing stability, in consideration of the massive design of the superstructure. The columns of the Ionic and Corinthian order allow greater height in relation to the width, but the entablature also is lighter. In Gothic architecture an immensely increased tenacity is given to the column (if we regard the vaulting shaft as taking the place of the column), and yet it looks agreeable to the eye, but that is because we know that the whole thing is play; the shaft does not support the weight of the vault, it merely supports, or appears to support, the lines of the ribs. The appearance of a shaft of even half that degree of tenacity relatively to its height, if it were really doing, or appearing to be doing, work, would be unbearable. We can compound with the effect of thin iron columns under a much more massive superstructure of stone; it is not agreeable chiefly because our eyes are accustomed to see stono proportions carried throughout a building, and the thin columns disagreeably clash with the habit of proportion to which the eye has been accustomed; still, we know as a fact that they are stable and equal to their work, and the sense of disproportion can be to some extent got over. Make their surface a complete imitation of stone, and the sense of disproportion would be unbearable.

This sense of statial proportion, more or less, governs visual proportion throughout the building. A shallow architrave, with a deep and heavy frieze, offends our sense of proportion, independently of all habits of taste and all ideas as to mathematical proportion, because we feel that the architrave is not sufficient for its work. The converse, a heavy architrave and a light entablature, is equally offensive to the sense of proportion, the architrave being "disproportionately" heavy for what it has to do. Lighten the architrave proportionately to the frieze, and then we at once find that the column is too massive for the superstructure, and our sense of visual proportion is again offended, for the same reason, because the statial proportions are wrong. And when builders show, as the builders of Beauvais did, a marked want of perception as to proportion, although the visual disproportion might withstand the attacks of criticism, the statial disproportion comes to its aid and compels a readjustment, whether the builders will or no.

This connexion between visual proportion and statial proportion may be exemplified in the utter want of proportion which is to be observed in much semi-barbarous architecture, where, as in many examples in Hindu and Cambodian architecture, the superstructure is out of all proportion to the substructure, and ponderous cupolas are piled up on an insignificant base; and the principle may be traced also in regard to ornamental design. In designs based upon foliage, for example, there must be preserved an apparent proportion of strength between the stems and the ornaments which they carry. A foliage-design in which the stems should be thick and heavy, and the conventional foliage springing from them small and light, would inevitably affect the eye with a disagreeable sense of wrong proportion, and vice versa. It only needs a recognition of the principle to trace its influence continually in discriminating the good or bad qualities of decorative design.

There is, however, another practical consideration having its influence on proportion; one which comes under the head of proportion referable to some outside standard not contained in the structure itself. In regard to architec-

ture this outside standard is the human figure itself. All buildings are erected by human hands for human use in one way or another, and hence the scale of the human figure becomes, in regard to architectural proportion, a kind of "constant," the effect of which must always be taken into account. And here, we may venture to suggest, is perhaps the true explanation of the better effect of some proportions of height, length, and breadth as compared with others. We will not deny that there may be something in the idea that certain geometrical ratios in such dimensions, in interiors, tend to give a better effect than others. But we may suggest that it is quite possible, even probable, that the good effect of such proportions really lies in their relation to the height and proportion of the human figure, and (a point which is seldom taken into account in such speculations) to the visual angle which human vision is capable of including. The capability of grouping of congregations of men so as to be within sight and hearing of each conveniently is another point to be taken into account in the proportioning of interiors. To take a very simple and obvious instance, the proportion and scale of doorways is always tacitly made with some reference to the proportion as well as to the scale of the figure. A wide square doorway would be a very suitable form of entrance to a stable, and in fact, is the form that ought to be adopted, much more often than it is; but every one would feel that an entrance so shaped, whatever its positive scale or size, was relatively of the wrong proportion for an entrance doorway for human beings. However colossal an entrance may be made in point of actual measurements, the instincts of civilised builders have always taught them to preserve in such entrances the usual relation of height to width which has been found the most convenient and suitable for a doorway; and the same instinct influences the general shape of all the openings in buildings, even up to the chancel arch of a large church or cathedral. Buildings are made by and for a race of beings standing upright, not going on the ground or on all fours; and this fact influences almost without our knowing it, all the proportions of openings in buildings. In the range of angle of our vision, again, we may probably find the secret of the feeling as to proportion of length to breadth, rather than in the mere numerical ratio of measurements considered *per se*. A square room is a bad form, because in a square room the eye can only take in barely one side at a glance, and that only when standing with the back against the opposite wall. A room in the proportion of 3 to 4, or even 4 to 5, allows of one side and part of the return sides being easily seen at a glance, and therefore adapts itself better to the range of vision than a square room. For the same reason, a height which is suitable in a large room is too great for a small room, because the eye cannot then take in the ceiling-line along with the floor-line: the two are beyond the angle of vision. A very low room brings too great a proportion of the floor and ceiling space into the field of view in comparison with the wall space, and thus produces a sense of disproportion, besides being at variance with the demand which upright stature, and the height of the eyes from the ground, creates in favour of a certain elevation in the roof above the eyes. A very long narrow room puts the people and objects at the further end disproportionately far from the eye, and suggests the necessity of movement from one part to the other in order to take it all in; conveying the idea of a passage to move through, rather than a room in which we may conveniently occupy one station.

Thus we may trace in all the proportions of size in an interior, a relation to the scale and movement and power of vision of man, which renders them, to our feeling, well or ill proportioned, according as their proportions are true or not in their relations to ourselves. It may be better to have the length and breadth of a room in an exact ratio to one another; the employment of exact ratios is, in any rate, very much led up to by the mere habit of employing fixed standards of measurement, and renders the subdivision of parts by measurement, in the setting out of details, much simpler by the avoidance of fractions; all which are good substantial reasons in its favour. But that the proportioning of the sides of an apartment according to exact ratios is in itself a chief cause of the appearance of good proportion certainly seems questionable, on the ground that it is a refine-

ment which the eye does not really appreciate, and of the existence of which we cannot be certain by mere observation, until actual measurement has proved it to us: whereas the proportion in relation to our movements and to the visual angle of vision we can readily appreciate. And, therefore, if we were required to pin our faith to any geometrical method of making well-proportioned rooms, we should prefer to dwell not on the relative lengths of the walls in measured feet, or modules, or whatever else we like to term them, but on the relation of the proportions to the range of vision, as calculated from the chief probable points of occupation in the room. If we took the proportions in thus calculating the visual angle from one extreme end of the room, no doubt it would practically come to nearly the same thing as setting out the lengths of the walls in certain proportions. But as a room scarcely ever is looked at from the extreme end, the pretence that its good proportion consists in a relation of the lengths of the sides, which are never actually seen by the eye simultaneously, rests on a very doubtful basis; and it seems much more reasonable and logical to suppose that the true key to the problem is the way in which the room would be seen from an ordinary and habitual point of view, and the angle which would be subtended by that portion of the whole design which it is desirable to be able to see in one view.

But there is also the relation between the building and the actual stature and scale of the being who erects it,—the proportion of positive sizes,—to be considered. This is the most obvious and superficial of all the relations between man and architecture, yet it is one the effect of which has often been strangely overlooked, even to a certain extent by such thoughtful artists as the Greeks. The human figure is the scale by which every building is measured, and to which every building is finally referable. Consequently, the average scale of sizes of parts and details which has been determined by reference to those features (such as doors) which are directly influenced by the scale of the figure, cannot be materially altered without creating a confusion or falsification of scale. This is apparent pre-eminently in the case of doorways themselves: a gigantic doorway only deceives the spectator as to the scale, and dwarfs the building, unless it is accompanied by such details as may aid in restoring the scale. The Mediæval architects seem to have been much more conscious of this fact than the Greek architects, inasmuch as, while giving grandeur and dignity to their doorways by immense recessed portals, they nevertheless left the actual and "practicable" doorway in most cases about the average size, so that the scale referable to the figure was preserved. In the Greek temples there is very little idea of scale in this sense. Two temples, of which one is twice the size of the other, present no apparent difference in scale when seen separately in drawings; it is only when a scale or a figure is added that we can say whether the columns are 15 ft. or 30 ft. in height. This is a distinct defect in Greek architecture, and in this respect there is more true feeling for scale shown in the system suggested by the Romans and pruned by placing in order of average scale over another in a lofty building, instead of increasing the positive size of the order, and with that lessening the relative scale of the building. We ought to be able to tell from the appearance of a building in the drawing about what size it is; the increase of scale being given, not by increasing the scale of parts, but by multiplying parts on the ordinary scale. The opposite process pursued in St. Peter's is what gives rise, of course, to the often-quoted fallacy about its proportions, referred to just now. It is not a design for a colossal building, but a design for a building of average size magnified; and to make its scale appear true we should require men 12 ft. or 14 ft. in height to inhabit it.

To sum up: we conclude that good proportion in a building and its details depends upon a correspondence between visual proportion and statial proportion in the first instance, and a true reference of the whole building to the stature, vision, and movements of man. There are other points which might be regarded as coming under the head of proportion, but which cannot be referred to so decisive a standard. We may mention two of these: one is that portions which have different functions should not repeat precisely the same length or width,

should not be identical in dimension. As a single instance, take the case of a column or shaft. Where, as in a Gothic shaft, a band is placed in the centre of the height of the shaft, and the treatment of the surface of the shaft is the same, above and below, we feel that the proper place for the band is precisely in the centre of the height. But where we have the upper portion of a column fluted and the lower part plain, for instance, we then feel that the dimensions of the two parts should not be the same,—that the division should not be central; though it is difficult to say why this should be so, and it comes more, perhaps, under the head of the more vague perception of taste than as a question of proportion. Another point is that the predominant character of proportions should be carried out consistently throughout the details of a building; i.e., that if the principal masses of the structure, and their supporting piers, are more than ordinarily massive, this character of massiveness should be consistently carried out through all the details. But this again, though it has a certain bearing on the question of proportion, is hardly to be identified with it, and belongs rather to what may be called in the abstract "character," a quality in design which arises from the consistent treatment of every detail so as to intensify the leading idea of the design, whether that idea be grace or massiveness, energy or repose, brightness or gloom. Such qualities as these, however, can only be felt, not defined; they belong to the region of taste and sentiment. But proportion, although we may question whether it can be reduced, as some think, to a mathematical formula, is nevertheless a quality in design closely connected with practical questions, and with which logic and reason have at least as much to do as taste and artistic perception.

#### SCIENCE AND PRACTICE AT SOUTHAMPTON.

THE address of Dr. Siemens, as president of the British Association, on August 23rd, deals with topics that have a special interest to many of our readers, as having been not infrequently handled in our own columns. On most of them we are happy to note the full and unhesitating agreement between the views then expressed by this distinguished physicist and our own. More especially do we refer to his expression in the address of the importance of that solidarity which exists between science and industry, on which we very recently remarked, and to the statement that it is to the union of theory and practice that we owe the rapid progress of the present day; the two orders of men "both merging more and more into one class, that of pioneers in the domain of nature."

We shall not attempt an abstract of an address which is *in extenso* so easily attainable by the reader; but we must, in the first place, express the feeling of disappointment with which we read the reference of Dr. Siemens to one point on which he must be regarded as an authority of the first weight, that of the application of electricity to locomotion. The electric railway, said the President, "possesses great advantages over horse or steam power, for our towns, in tunnels, and in all cases where natural sources of energy, such as waterfalls, are available, but it would not be reasonable to suppose that it will in its present condition compete with steam propulsion upon ordinary railways." We have no choice but to accept this statement, far as it falls short of the brilliant promises to which we have, not so very long ago, listened on this subject. But we do not accept it as the last word of science. Rather, as it appears to us, does it indicate that the method of transmission of the electric force by a continuous rail or overhead wire, as to which we have always had serious doubts, is not a step made in the true direction in that to seek for the solution of the problem of locomotion. What may be done by accumulated force, and the use of secondary batteries, is as yet almost unexplored. Nor do we hold it to be unlikely that the establishment of electric accumulators at proper distances, fed by a continuous current, but able to supply large power on instant demand, may prove to be the key to the problem. The total loss by transmission and reconversion of electric energy (while it may be less) Dr. Siemens thinks it safest to estimate, with Dr. Hopkinson, at 50 per cent. When, however, water-power, tidal force, or any other inexpensive motor is obtainable, the loss of 50

per cent. in transmission becomes comparatively unimportant. We have seen at low great a disadvantage the locomotive works, not only as to the delivery of its power, but also owing to the great weight of the engine itself, the proportionate addition to the weight of the rest of the rolling stock, and the consequent increase in the cost of the whole superstructure of the railway. As to this, Mr. Fowler, in his address to the mechanical section of the association, struck a new but perfectly distinct note, when he said that an ideal railway should have gradients of about one in twenty falling each way from the stations, with a piece of horizontal line connecting them. As to this, however, it must be remarked that such a section would involve a duplication of the entire railway system; the undulating arrangement being applicable to short stages, but altogether inappropriate to such long runs as that of the 180½ miles from Leeds to London, accomplished a few months ago within three hours, or at a rate of more than sixty-two miles per hour. We may note here, in passing, as confirmatory of some recent remarks of our own, that Mr. Fowler has found that 60 per cent. of the whole power exerted by the engines on the Metropolitan Railway is absorbed by the brakes. This makes the cost of locomotive power for one mile on that line equal to the cost for two miles and a half in such a case as that above cited; and fits, as accurately as may be, with our own estimate of the cost of locomotion on the Metropolitan Railway, per ton mile of loaded train.

Passing from the consideration of the application of electricity to locomotion to that of the use of the same subtle and mighty agent as a stimulant to vegetation (though we thus reverse the order of the address), we find that there is little to be added to the statements of Dr. Siemens's paper on the subject read before Section A last year, to which we called attention at the time, with the exception of the prosecution of further experiments on the cereals.

"Towards the end of February, with the first appearance of mild weather, the plants under the influence of an electric light of 4,000-candle power, placed about 5 metres above the surface, developed with extreme rapidity, so that by the end of May they stood above 4 ft. high, with the ears in full bloom, while those not subjected to the rays of the electric light were under 2 ft. in height, and showed no signs of ear." It is extraordinary that the statement, by a man who has given such hostages to science, of the action of this magical farmers' friend, has not attracted the efforts of the promoters of companies. It remains, of course, to be seen whether this wonderful quickening of the growth of the individual may be in any way produced at the cost of the race; and whether the seedlings, or the seedlings' seedlings, of electrically-grown wheat and barley would retain all the reproductive energy of wilder grasses. But when we reflect on the immense energy of tropical vegetation, we are inclined to think that the above fear, though by no means to be neglected without trial, may prove to be baseless. And, if so, what a future is before the agriculturist.

In another part of that wide and ample range which is so practically familiar to the President of the Association for the year, another of our frequent topics of discussion was dealt with in language almost identical with our own. Dr. Siemens looks to gas as the fuel of the future. A pound of gas, he told his audience, yields in combustion 22,000 heat units, or exactly double the heat produced in the combustion of a pound of ordinary coal. A pound of coal, however, if it must be remembered, will only produce 0.16 lb. of gas, although the value of the by-products of distillation,—tar, coke, ammoniacal liquor, and, if only it were extracted, sulphur,—exceeds the cost of the coal used for gas-making by nearly 60 per cent. The cloudy canopy of London, Dr. Siemens states, on the estimate of Professor Roberts, contains in a winter's day 50 tons of soot; that is to say, of comminuted carbon, and five times that weight of carbonic oxide. The use of gas for all heating purposes, we hold with Dr. Siemens, is one of the promises of the future, the delay in the accomplishment of which is somewhat unaccountable; and we further agree that the distillation will probably hereafter be effected in the mine, the gas being sent by pipes from the bottom of the shaft, so that it would be only the tar, coke, and other by-products that would have to be raised mechanically through the shaft.

The triumphs which Dr. Siemens has already won over matter, in so many provinces of its wide-spread and diversified realm, have perhaps exposed him to the noble and unusual fault of being too ready to give credence to anticipations, more brilliant than solid, in departments less familiar to his footsteps. Thus, he says that the estimated cost of the Panama Canal is 20,000,000*l.*, and that more than this sum having been subscribed, it appears unlikely that political or climatic difficulties will stop M. de Lesseps in its speedy accomplishment. A communication lately made to the Société des Ingénieurs Civils, at Paris, by M. Hersent, one of the warmest supporters of M. de Lesseps, gives a very different outlook. Down to May last the clearance of timber and brushwood from about half the track of the projected canal is all that M. Hersent can point to in the way of preparation for actual working, with the exception of borings, soundings, the erection of sheds and hospitals, the purchase of materials, and other such-like preliminary work, involving the movement of a total quantity of earthwork equal to about the contents of a yard run of the deepest cutting shown on the section. Out of 257 Europeans despatched to Panama since January, 1881, "for the service of the survey and of the works," 39 per cent. were either dead or had fled the spot in thirteen months,—a numeric statement which fairly tallies with the last accounts of the desertion of the locality in troops by the intended laborers. And the estimated cost is not 20,000,000*l.*, but more than 40,000,000*l.* The capital of the company, as constituted, is 12,000,000*l.*, and half of it has been already called up. Nor, as far as we have seen, have any nautical men failed to ridicule the idea of the rival project of a ship railway, "to take the largest vessel, fully laden and equipped, from sea to sea, over a gigantic railway across the Isthmus of Tehuantepec, a distance of 95 miles." As to these matters, the civil engineer, the naval engineer, and the prudent man of business, alike shake their heads. Have we so far exhausted the practical that we should rush after the purely visionary?

The student of science suffers, on occasions like the present, under something of the *embarras des richesses*, when so many eminent men, within such narrow limits of time and of space, do their best to give a brilliant *résumé* of the condition of those branches of science with which they are severally most familiar. And it is a striking proof of the advance of science, and of the constant specialisation and subdivision to which that advance subjects the general conception, to find two such addresses as those of Dr. Siemens and Mr. Fowler, each dealing with pressing questions of the engineering of the day; each in itself full and lucid, and yet in no way overlapping one another.

The references made by Mr. Fowler to the Channel passage,—a matter to which he has long devoted special attention,—have much value at this time. It is due, not to any defect on the part of the naval engineer, but to the neglect of the harbour capabilities of the French coast, that the state of the steam ferry across the Channel is such as to allow the idea of the construction of a more costly, more dangerous, and far more personally disagreeable mode of communication to be even mentioned without a smile. To this great defect the French Government is now engaged in providing a remedy. Nor do we doubt that a few years will witness the provision of so swift, steady, and healthful a mode of steam ferry that very few persons would hesitate to use it in preference to a choky tunnel of twenty-eight miles long, were such a useless tube actually constructed. As to goods, the cost by sea is less than one-third of that possible by railway, even apart from the enormous dues that would be requisite to pay for the construction and maintenance of a tunnel.

In compensation for that increase of special knowledge to which we referred, as limiting the amount of information within the grasp of the individual student, we have, however, to note that rapid increase in the electric communication, so to speak, of thought between departments the most widely distinct, to which the general advance is, perhaps, mainly due. Thus the improvements in the manufacture of steel directly affect the prospects of navigation, and will not be unfeeling in any branch of industry. And the humble investigations which have been undertaken in order to discover what are the best and the cheapest methods for illuminating

and for warming our houses, shops, factories, and streets, have sprung at one vast leap to the orb of the sun, and are now engaged on the problem whether the absorption of the actinic rays due to the energy of that mighty planetary centre occurs in the solar or in the terrestrial vicinity, or, as Captain Ahney considers, " somewhere between the solar and the terrestrial atmospheres."

#### STRICTURES ON STORIES.

A STUDENT may sometimes not unremuneratively employ his time in devoting careful attention to a set of the most unsatisfactory compositions of a particular class that he can bring into comparison. An example which is purely repulsive in every respect will conduct to as little edification as delight when taken by itself, but when collated with another which has some redeeming characteristic, it brings this into relief and directs attention to the points at which nature, that most truly abhors vacuity of expression, is ready to develop beauty if art and reflection will only do justice to their share of responsibility. Such an opportunity is not wanting for those whose habitual route carries them through such streets as Gloucester-place or the Harley-street, of which the name recalls the heiress of Queen Anne's minister. What flowers are to be found, what honey to be gathered, in this architectural wilderness, which seems almost too barren to root a weed? If we look out and ponder as we pass along, the walk may not be unenjoyable. The original blankness has provoked some later protests, some struggles, however often futile and ill-directed, to obtain relief. After a few such courses of observation we may appreciate the seriousness, as regards architectural fitness and effect, of an omission which is all but universal in street after street, mile after mile, of domestic habitations in London, but chargeable also on many compositions which put themselves forward as studied and finished, as exemplars of elegant and even noble style.

When a dwelling has to be foregone altogether, or else run up in the most economical fashion which is consistent with stability and endurance as weathertight, there is no more to be said, but in cases where it appears that expense is lavished on internal spaciousness and decoration, while neither care nor expense has been bestowed to alleviate what must be an obtrusive hideousness for generations who have to pass the exterior, perforce, and cannot help seeing it, not only our artistic but our moral sympathies rebel. The suggestion of the unsympathetic and unsocial is oppressive, and as justly to be resented, if it were worth while to give way to resentment, as the more actively offensive parade of vulgarity in overdone ornament. Many great mansions are there in the London bequeathed to us by our ancestors, which have all the characteristics within of noble mansions, but that are as bald and unrelieved without as any stretch of more moderate dwellings in Welbeck-street or Wimpole-street. Let us give attention to one point of failure which is common and more excusable here, but by its very undisguised grossness directs us to consider how far the same flaw is a drawback to the consistency and dignity of far more pretentious structures. What is in question is the incongruousness of false exterior indication of stories or omission of any such indication at all. It requires all our appreciation of the heauty of the composition to excuse the solecism, which has been justly pointed out in the Banqueting Hall of Inigo Jones, that what is one room internally is made to look on the exterior as if it were in two stories. Conversely, in the buildings which we are now concerned with, they might for anything that is shown exteriorly, consist of one single apartment from line of door-step to parapet. It is only in certain cases that balconies to the drawing-room windows give intermittent assurance of a floor-line; it is, again, only in certain cases that a flat hand gives one indication of a line of floor somewhere above; in any case whether this is introduced below the windows of the second story, or the still higher story is left so insignificant to be allowed such an acknowledgment, for anything that is shown by external sign two ranges of windows light a single story. It is true that we know very well that they do not; we are too familiar with the regulation interiors to require information on the point, to be misled by its failure. But the artistic purpose which underlies such indi-

cations is not in any case direct information, but indirect significance; an artist insists on an expressive feature not to solve a difficulty but to satisfy a sentiment. When the windows of the chief story have elaborate dressings and are crowned by pediments, as at Somerset House, they occasionally approach the small windows above them so nearly that these, comparatively insignificant as they are, do not suggest the thought of another story, but may possibly pass for mere upper lights of a colossal apartment. If this deception can really be made effectual, there is no doubt that a considerable degree of dignity is gained; but the gain, like other illicit gains, is at the cost of severe sacrifices in other directions, and, moreover, is precarious; it were better sought for by a more legitimate stratagem, which is not far to seek. It seems to be with some intention of adding dignity to a principal story by robbing that above it, that a line of moldings, sometimes even approaching the importance of a cornice, is observed to be occasionally formed by a continuation of those of the sills of the upper windows. But "the stern avenger" of outraged equity "is behind"; and not far or long behind. The upper story accepts its acknowledgment as a story, as an individuality; but the exaggeration of its line of window-sill does not compensate for the entire suppression of its true line of floor. If the most strongly-pronounced line has a pretension to mean anything, it will act as meaning that floor and sill are coincident, be the consequences to convenience what they may.

In the Strozzi Palace at Florence, where the sills of each of the upper stories are united by held string-courses, these do really represent the lines of the floors, but from the height and dimensions of the windows it seems quite consistent that this should be so. Many of the palaces at Genoa give excellent examples of frank recognition of the division of stories by simple hands of progressively-graduated breadth according to height, with very slight projection. Suppression of this distinct intimation of condition of occupancy, involves forfeiture of a grace which is worth conserving,—the expressive gradation of dignities between various horizontal divisions of the structure. Of course, the gradation will not easily be graceful if graceful propriety does not exist in the characteristic purpose which ultimately dictates the application and distribution of space. If a mezzanine over a ground-floor is pinched to the dimensions of a loft, the best course to be taken is certainly to conceal the fact that it is a distinct story, if that be possible; the same course will recommend itself if attics are to be no better than cock-lofts. But architecture asks for better employment than taxing invention for schemes to mask the mean and the unbecoming, and to hide away vulgarity under an ill-fitted veneer of dignity and decorousness. The local habitations which it is its pleasure and privilege to provide are understood as required to harmonise with the circumstances and requirements of inmates of well-balanced dispositions and appreciative of consistency. In many of the Venetian palaces, while the ground-floor is manifestly given up to the utilitarian purposes, of the merchant princes, the *piano nobile* above it is scarcely distinguished in dignity, as in the Pesaro, from that above it; much of the charm of gradation is in consequence wanting; but no inconsistency is involved, inasmuch as the magnitude and splendour of the structure suggests that there must naturally and easily be quite ample secondary and subservient accommodation out of sight. But in too many Italian façades, not those of Palladio exclusively, there is a very harsh transition, indeed, from openings which are suggestive of firmness and magnificence to others close above or close below them of such depressed and confined proportions as to suggest not only contrasted condition of the respective inmates, but their inconsistent and unpleasant proximity.

The acceptance of the principle that stories are to be allowed expression exteriorly, by no means necessitates a frittering of effect. We have only more favourably at command the resource of harmonious gradation of forms and dimensions, and dignities. But gradations must be sufficiently distinct to pronounce themselves if monotony is to be avoided; and held as they may on occasion here, they must not be overbold, must not be violent, if diversity is not to lapse into discord. The Italian palaces alluded to constantly offend by harsh conjunction of unduly contrasted features, even in

compositions which contain so much that is admirable that a critic often finds himself hastening to overlook or forget such imperfections, and disposed to sacrifice conscience rather than spoil pleasure. But justice must take its course, and a just sense of harmony rebels against the intimate companionship of windows stately and elegant, with such openings of windows the best Italian architects constantly ranged with them, and often below the same cornice. It may be that herein the architecture gave a true reflection of the habits of a society which strained resources to the utmost to vie in splendour of public receptions and festive assemblies, and submitted willingly to cramped accommodation in private apartments, and had no consideration at all for the miserably confined lodgings of dependents; but this agreement does not make the architecture any more worthy of imitation than is the society in respect of such deep-seated disorders. The architectural discord is peculiarly offensive when associated windows are not only contrasted by means in dimensions and absence of ornament, but have the difference in form which is equivalent to a rude contradiction. We turn from one design of Palladio to another to be offended as by a wrench in progress from one window of the appropriate erect oblong form, to another above it, which shows as an oblong laid on its side, and sometimes of dimensions that would appear to reduce it to a peep-hole. Such a form would be disagreeable even for a window so large as manifestly to preclude apprehension of an inconvenient lowness of the apartment it pertained to. The unpleasantness is seriously aggravated when no indication of a line of floor sets us at rest as to the relative height of those who should look out of the window; but this is not the limit of aggravation, of compound aggravation; these objectionable forms of windows are sometimes inserted in an attic above an order, where they bring us near other suggestions of discomfort in the slope of a roof; or they are inserted inconspicuously in a frieze under a cornice. In the Library of St. Mark at Venice we have such flat openings, only with rounded corners, inserted in the frieze over an otherwise noble composition, and their form, dimensions, and position alike make us shrink from even a conjecture as to what may be their relation to apartments in the interior.

Harmonious gradation, therefore, in avoidance of violent, of screaming, contrasts in magnitudes or forms, must be studied if well-defined stories are to be effectively combined; and the skilful grouping of stories,—the indication of two or more as having some special relations,—is still another resource for conferring unity and concentration upon a design which, otherwise from limitation of its features, gives little scope for variety. The leading principle of such grouping must needs be the expressive indication of the immediate or remoter relations of different stories, whether in immediate sequence or not, in respect of dignity. The topmost story and hasement may thus be shown as correlative and the others as connected. In a mansion, a residence of importance, where the urban restrictions of the ground-plan do not come into consideration, the problem is simplified, as offices and all appurtenant apartments can be kept out of sight or treated separately, and there is no need to consider how a park or garden front is to be kept in countenance under the incongruous intrusion of windows in a basement.

But when the conditions of a metropolis,—at least, such a metropolis as London,—are to be dealt with, the case is altered, whether the design of a moderate dwelling-house is in question or that of a noble mansion, a public office or a clubhouse. The ordinary dwelling-house presents the problem in its most frequent as in its typical aspect. The question of the architecture of flats is becoming urgent; but, for the present, an Englishman's house is his castle, or, as some have said, is his island, by mere continuation of the insular instincts of his geographical situation. And the domestic systems which animate these settlements are very uniform in general type, and their characteristics have tended to mould a material envelope on the same prevailing pattern. In place of moat or channel there is the defensive area, and this, when liberally spaced in large structures and screened by balustrade or solid parapet, gives an admirable base line; it also houses the offices in happy contrast to the ground-floors or hasements of Italian palaces,

with their windows protected by repulsive grilles or openings recipient of all dust and ordure from the immediate common level of the roadway. The ground-floor is then raised so high as to frustrate prying inlook, provides hall and dining-room, study or library or business room, and handsome access to the floor above; here, in the light and elevation, come reception rooms and elegant retreatments; above, again, are the superior bedrooms, baths, &c.; over these the domain of the young,—nurseries, schoolrooms, rooms for piano practice; and, lastly, over all, the rooms of the female servants, and space to spare.

How, then, shall systems of stories such as these prove susceptible of grouping exteriorly with propriety and effect? A gradation in heights is naturally suggested by successive purposes; the true difficulty seems always to be encountered in the management of the topmost, but in truth the least esteemed, story. Yet, least esteemed as it may be, it is in possession of a place which of necessity brings it conspicuously into evidence. Constantly we find it so treated as if only tolerated at all under compulsion, and making itself all the more obtrusively offensive, as if resentful of such treatment. Who can look up at Hope House, in Piccadilly, and not commiserate the architect who found himself obliged to stack a garret upon an attic, which gave him a conclusion on which he would so willingly have paused once for all. There seems no more helpful solution for the difficulty than to smother heart of grace, and resolve to treat the topmost story handsomely; to smother the transition from the story below it by not admitting too great a difference between them, and so attain to that compromise so dear to diplomacy,—a pretentious *modus vivendi*. This will certainly be in favour of a certain humaneness of style; expense may be increased, but we are only dealing now with cases in which it will be compensation for some extra expense that a treatment is avoided which shall suggest that as the work came to an end, resolution which had so far sustained expenditure lost heart, and hurried to conclusion as the best it might, even though bad might be its host. Architectural style merits most cordial approbation when it succeeds in a combination like that which the Roman critic held to be characteristic of the happiest literary style:—

"The happy point by him was hit,  
Who mix'd utility with wit."

But too true it is that internal convenience and external grace are seen all around us scowling at each other as natural enemies, and we have to stand by, distressed friends of both parties, as they fight the quarrel out; in many of such streets as we have alluded to, graceful seems fairly beaten out of the field; at most it makes some show of asserting itself about the doorway as if to leave a protest behind while effecting escape after endurance of disrespect no longer tolerable. Elsewhere with somewhat of the overbearing violence natural after such provocation, it shows itself as inconsiderate of the claims of a competitor who should be its sympathetic ally. In the symmetrically designed ranges of houses in the Regent's Park rejoicing in all the freshness of triangular paint, ornamental architecture has its own way without restriction, and arches and arcades, porticos, plasters, and cornices make the most of their opportunity, let those who seek comfort and convenience behind them murmur as they may. Again, the chief suffering falls to the lot of the unfortunate upper stories. The order attached to the facade finds it necessary to its dignity to push up its cornice beyond the level of their floors, and up to the line of their window-sills,—a cornice with such a projection as to cut off all view of the Park from the windows, if, indeed, the windows also were not in many instances forced up to such a height from the floor that outlook in any case would be inconvenient. But it is in these and the like cases that the conflict of the powers is, in fact, intermedic,—is mutually destructive; for fatal to the true dignity of the exterior aspect is the betrayal by the only half-hidden deformities of windows peering over the edges of parapets or peeping between balustrades, of the tyrannous clumsiness by which the victory, such as it is, has been achieved.

If this objectionable result is recognised, but the contest is still to be sustained under the conditions of maintaining a certain theory of dignity at any cost, there remains an even more desperate expedient. This troublesome story,

inevitably topmost in position, while in purpose and suggestive associations inferior and subordinate, has to be hustled out of sight. The wall of the front shall not be pierced to give it light by windows so small and of such depressed proportions as to be significant of meanness, or by any windows at all; but it shall be raised so as to mask, and, indeed, to imply disallowance of the existence of, any such story, which still can receive light behind it by unseen skylights. This is a stratagem which has found favour with the designers of some club-houses of very imposing character. The difficulty which it should then be incumbent upon a designer to surmount, but which it must be said he too often takes the liberty magnificently to ignore, is in what manner to suggest to the spectator any reasonable explanation of the excessive height of blind wall above the highest visible windows of what exhibits itself as the uppermost story. In stately Italian palaces it is consistent that the proportion of blank wall above a window should be large, and the top of the window proportionately nearer the floor; so is the requirement of welcome shade reconciled with sufficiency of light; but in our northern latitude that light is most valuable which enters near the level of the ceiling, and a blank space which inevitably is taken to imply a large interval from ceiling to window, carries the suggestion of the cavernous, of oppressive and uneasy gloom within. Little relief is given by an attempt to produce animating play and variety by a deep cornice with overcharged mouldings, or a frieze below it enriched with festoons and emblems. This is one of the cases in which cumbrousness of apology only attracts attention to the seriousness for the need of excuse.

The existence of the suppressed story is at last only imperfectly, indeed often only carelessly, masked, and one hint of dishonesty shakes faith more extensively. A suspicion will intrude that the magnificently distributed facade is, in fact, but a jacket, so to speak, and an ill-fitting jacket. May we not be looking at what is, in fact, but an ornamental box, within which conveniences may be stowed away, ingeniously enough for economy of space and in positions where the owners by familiarity can lay their hands upon them, but positions scantily expressed by the external ornament, contents having as little organic connexion with their envelop as the anatomy of a hermit crab with the shell which it casually appropriates?

The battle of life, it is true, is not to be carried on and carried through without certain compromises, and the conflicts involved in the practice of architectural design are episodes in the general battle, and participate in its conditions. Mere blunt conscientious intentions will not be a sufficient guide in either case. Neither life nor architecture is so simple that we can find our way through their difficulties by only meaning well. The artistic sense, like the moral sense, has to be sharpened by reflection, and cultivated by exercise, and refined by observation of examples, by reverential attention to spontaneous promptings, that do not at once explain themselves. It is in such promptings that imagination often volunteers good aid to studious invention, and so is cleared many a problem quite as intricate as the detection in a complex of requirements for convenience, of a scheme which, while subordinating the lower, makes it conduce by harmonious contrast to the special dignity of the lofty, and achieves appropriate characteristic expression by the peculiar terms of their association.

#### THE ART OF THE CALIPHS.

It is what has come to be understood as the existing "art movement," not one of the least important factors may undoubtedly be said to have been the influence of the art of the East, as it has been revealed to us since the Great Exhibition of 1851; and not alone the art of Japan, of China, of Turkey, and of India, but the art of Persia, of Egypt, of Algiers, and Moorish Spain, has found its admirers among the most refined of our leaders in matters of taste. Japan, we may say, has already begun somewhat to pall upon the public, in spite of its wonderful and brilliant products; but the art of Persia, the art of the Moors,—in a word, the art of the Caliphs,—ever since the day that Algeria was conquered by the French half a century ago, and the contemporary romantic poets and painters sang and pictured the beauties of the

Alhambra and the Dreams of the land of the Arabian Nights, has had among the refined its passionate admirers in England and in France. Its delicate products, its choice and exquisite illuminated manuscripts; its filmy, fairy-like, and gorgeous fabrics and tissues; its embroideries and rugs, which the painters ever since the Renaissance have admired; its finely-tempered arms; its patiently-elaborated damascened caskets; its brilliant pottery, have peculiarly appealed at all times to the artistic temperament. Among the great periods of art, that of the Mussulman caliphs of the East and West now takes its place as not the least brilliant in artistic history; the art which the descendants of the simple shepherd Arabs who rallied round Mahomet developed from their contact with the peoples whom they conquered, and whom they found living amidst the relics of a brilliant past civilisation.

When Mahomet died, A.D. 622, the direction of his growing empire, left without a head, fell to the care of Abou-Beker, the father of the prophet's favourite wife Ayesha. On assuming the supreme authority Abou-Beker refused to take the title of king or prince, contenting himself with the modest title of caliph or "successor," a title borne to the present day by the Sultans of Turkey. As the Mussulman empire extended further and further before the conquering armies of the Moslems, the power was sub-divided into several caliphates, of which the three principal were those of the East, settled at Bagdad, to which it had been moved from Mecca; that of Spain, settled at Cordova; and that of Egypt, at Cairo. Under these rulers the Mussulman empire was in a short century extended from India to Spain. Contemporaneously with their power was developed an art with the beauties of which all persons of refinement are familiar, but of the elements, the details, the variations and successive creations of which we are still but imperfectly informed. The most brilliant productions of this art of the caliphs we have been taught to seek in Spain, where Cordova will always remain, with its picturesque Moorish battlements, "the city of the Caliphs," and where the Alhambra will for many a generation to come fulfil the traveller's utmost dream of all that he may have read and pictured of Oriental splendour.

But if we turn to the Arab art to be found in countries like Syria and Egypt, where the influences brought to bear on its development varied so completely from those of Spain, a great difference will be seen existing between the art of the Arabs proper and the Moors of the West,—between the art of the caliphs of the East and that of the caliphs of the West.

With the Moorish architecture and art generally the artistic world has long since been made familiar, and though it may be said that there it was that the art of the caliphs flourished in its greatest brilliancy, yet it must be remembered that in Egypt and Syria also the caliphs exercised their power. Damascus, Aleppo, Bagdad, and Cairo were cities in which the artistic tastes of the caliphs of the great days of Moslem power were exercised, and which, to this day, bear the evidence of their magnificence. For us, however, at the present moment, the Caliphate of Egypt possesses the most interest; it is it with which we are now daily brought into contact, and the threatened fate of the brilliant capital, Cairo, the second city in importance in the Mussulman empire, has not unjustly roused the warmest fears of the artistic world.

We possess but few authorities respecting the subject of the art of the caliphs, the works in existence are chiefly of an illustrative character. In a previous paper on the art of the Arabs mention was made of M. Bourgoïn's "Arts Arabes"; it consists, however, of but a few pages of text, the rest being composed of a valuable and elaborate series of drawings and studies of the geometric principles of Arabic art; the same may be said of M. Coste's work, previously referred to, and of Hay's "Views in Cairo." Girault de Prangey's works, published now hard on forty years since, still remain invaluable for purposes of study, the use of "the admirable instrument invented by M. Daguerre," to which the author makes reference, rendering the illustrations unimpeachable for their accuracy. But the letterpress is scanty; it is only on the Arab art of Spain that De Prangey is discursive. Information, in fact, is still sadly wanting on the subject, and a field lies open for much interesting and attractive study. As one of the results attendant on our present action in

Egypt, we may not unreasonably look forward to fresh acquisitions made in our limited acquaintance with the art of the Egyptian caliphs.

With the brilliancy of its creations, travel and our museums have of late years rendered the inquiring public comparatively familiar; but we as yet form only a very scant idea of the splendour and refinement of the life of the caliphs who opposed our hardy Crusaders. It would, indeed, be difficult to imagine a greater contrast than that afforded by the existence led by the Orientals and that of the sturdy English, French, and German warriors who, in the deepest twilight of the Dark Ages, sallied forth from their gloomy fortress homes and rough castle life to break in upon the no less brave and warlike but refined Infidels. In the history of Western art and civilisation, the influence exercised by the Crusaders is well known, the result of the contact of our boisterous warriors with the cultivated and artistic Easterns.

The refinement in which they lived was indeed ideal, and the art of the caliphs all that the "Arabian Nights" have ever pictured to the mind of the most romantic. When we see the grandiose mosques which still stand in all their ruined beauty, to attest the magnificence of their builders, we can understand that there is no exaggeration in the stories of the historians of the artistic splendour of the caliphs who opposed our steel-clad "Red Cross Knight." Accustomed as we have become to the luxuries of our modern civilisation, our eyes feasted in museum after museum, in exhibition after exhibition, with the creations of the art of every land from the most ancient times, we can still scarcely picture to ourselves such rareties of decorative splendour as those which filled the palace of the caliph of Cairo, Mostanser, the father of Mostali, from whom, never let it be forgotten, Jerusalem was taken by Godfrey de Bouillon in the last year of the stirring eleventh century. We have, in the pages of the Arab historian, Makrisi, the very curious and detailed relation of the pillage by his discontented Turkish officers of the caliph's palace at Cairo. The account, perhaps for the first time brought before English readers, gives us some idea of the art of the caliphs of this brilliant period of Arab history.\*

Never, it would seem, was life more tormented than that of the Egyptian caliph Mostanser. Attacked in his palace by his own guards, like Job, he found himself reduced to the extremest misery. The priceless treasures of the palace, collected year by year for generations previously, he saw scattered among his mutinous officers and servants. The jewellers called in to value the contents of the treasury could only assure the pillagers that such objects as they were called upon to appraise were beyond all monetary value. We are told of bushels of pearls, 1,200 rings of gold and silver, ornamented with precious stones of every species and colour, all heirlooms; caskets of gems which, the jewellers assured the officers, it was impossible to value, they were such as could alone be owned by princes. One casket Makrisi mentions as full of vases of the purest rock crystal, and other caskets filled with vases of precious metals. Numerous other choice objects of crystal are cited by the historian, who refers to a large number of enamelled plates of gold; 9,000 caskets of different forms, lined with silk and enriched with gold, each the case of crystal and other goblets; more than 100 cups of bezoar, on which were engraved the name of the Caliph Haroun al Raschid—this shows their age, the caliph being the contemporary of Charlemagne, ninth century; coffers filled with poignards of gold and silver gilt, with handles of precious stones; innumerable inkstands, round, square, large, and small, of gold and silver, sandal and alow wood, of ebony and ivory, enriched with precious stones, and remarkable for their perfection and elegance; coffers filled with cups of gold and silver, of every size and of the most perfect work; a multitude of porcelain jars of every colour, full of camphor; cups made of amber from Schabar; bladders of musk from Thibet, and alow-wood closets full of furniture; huge basins for washing purposes, each supported by feet representing animals, and all of immense value; a multitude of cages filled with porcelain; a golden mat on which had been married the caliph Mamoun; twenty-eight plates of enamel enriched with gold, a present from the Greek emperor. An immense number of coffers

\* We owe this information to research in a somewhat out-of-the-way source, the "Mémoires sur l'Égypte," by M. Edméne Quatremère, Paris, 1811.

filled with mirrors of steel, porcelain, and glass, all enriched with filigree of gold and silver, and bordered with precious stones, the handles of cornelian and other gems, and contained in cases of velvet and silk of gorgeous patterns, all fitted with locks of gold and silver; a large number of parasols, the canes of which were of gold and silver; nearly a thousand utensils of silver enriched with gold, to which the fineness of the work and beauty of the chasing gave an additional value. Numbers of chess-boards of silk, embroidered in gold; the "pieces" of ebony, gold, silver, and precious stones; 400 large cages of gold filled with jewels of every sort. Furniture of silver of great weight; 4,000 golden vessels for narcissus flowers to be placed in, and 2,000 others for violets; 36,000 pieces of crystal; 22,000 figures of amber of great weight, innumerable figures of camphor; 800 pieces representing melons; a turban enriched with stones,—one of the most curious and precious objects in the palace. From the perfume store was taken a quantity of Indian alow-wood, pieces of camphor and amber of great weight; a buffet, of porcelain, of immense size; a rare crystal box; a golden peacock enriched with the most precious stones, its eyes of rubies, its feathers of gold enamelled with all the colours of the original; a cock of the same metal, with a crest of rubies of great size; a gazelle, the body covered with precious stones, its belly white, a tissue of pearls of great value; a piece of amber in the shape of a lamb; a melon of camphor of immense weight contained in a golden net enriched with stones; another, in a golden box of immense weight; an egg of rubies of immense weight; a crystal basin; a table of sardonyx, large enough for several people to sit at; a golden date-palm tree of inestimable value, in a golden case, the fruit of precious stones representing the date in all the degrees of its maturity; a gonola, with its flags and carpets complete, made for the Vizier Ahmed, and for which an immense sum had been paid for work alone, apart from the material; thirty-six other gonolas are mentioned, which served for the court, all richly carpeted; a garden, the soil of which was of classed silver gilt, the earth of amber, the trees of silver, the fruits of amber and other precious materials, the whole of immense weight. More than 50,000 pieces of Danasak are spoken of, all enriched with gold; carpets, which had never been used, are mentioned as having been in thousands, some of red damask enriched with gold and of the most exquisite work, representing parks and elephants. From the warehouses were dragged 3,000 pieces of red damask; a number of tents completely furnished with sofas, tiles, cushions, carpets, and curtains; tapestries of the greatest value; silk tissues; mats of gold and silver, adorned with elephants, birds, and other animals, some with portraits of former caliphs, one with a map of the empire, very old and of immense value; a tent of red satin woven with gold made for the caliph Mostanwakel. The palace of the caliph Mostanser contained, in addition, a prodigious number of arms, swords, lances, and cuirasses of every kind, many of them historical weapons; harness enriched with gold and silver and stones; bundles of pikes, 200,000 pieces of armour, all of the richest kind; hundreds of bucklers and standards of gold and silver, and trappings of incredible value gathered together since the foundation of the palace in the previous century. The whole of the armoury was, it would appear, reduced to ashes through the carelessness of a servant. Among the treasures lost were a number of tents of immense value, some described minutely as gorgeously decorated with woven and embroidered animals, peacocks, &c., in China silk of every colour, and all accompanied with their fittings. Some of these tents were so vast as to require twenty camels to transport them from place to place. The pole of one tent, "the great rotunda," was of silver and gold, and was no less than 65 cubits in height; the tent, 6 cubits in diameter, and 20 cubits round. It was formed of sixty-four pieces of stuff; 100 camels were required to move it. All the interior was adorned with embroidered figures of great beauty. It is worthy of remark that the tent was fitted with a very large ventilator. In the making of the tent no less than 150 workmen had been employed during nine consecutive years. Many other tents are mentioned, one as requiring 200 men to set up. We must postpone, however, what we have to say further.

#### COLCHESTER CASTLE.\*

CONSIDERING that a century and a half has passed by since Morant wrote his "History of Essex," and of Colchester Castle, and that no more modern historian duly qualified for the task, if we except Mr. Buckler, has entered the field since his day, it is certainly time that publicity should be given to the results of the long and frequent scrutiny to which archaeologists and antiquaries of late have subjected that most interesting fabric. It is not too much to say that, thanks to the summer congresses of our chief archaeological societies, and to the interest in such studies which has been fostered by local associations during the last thirty or forty years, new light has been thrown upon many such relics of antiquity, and a new life has been in many cases given to their existence.

This is especially true of Colchester Castle, which, though long since deprived of its upper story, and called even by Camden in his day a "ruin," still crowns over the north-eastern portion of that town, which once was a rival to London, and the capital of a kingdom, or, at all events, of a province, and sixteen or seventeen centuries ago the head-quarters of the Roman eagles in Britain.

The writer of the work before us, who, unfortunately, is anonymous, has spared no pains to get at the bottom of the real history both of Colchester and of its castle; and in so doing he has been allowed by Mr. Jas. Round, the owner of the castle and its demesnes, to examine all such documents as contain authentic information about its early history. Some of those were unknown to Morant; and on others much additional light has been thrown by the deeper study of the early history of this country, which has marked the second half of the nineteenth century.

There can be now no doubt, since Roman coins and sculpture have been found *in loco* in sufficient quantities to prove it, that the whole of the plateau occupied by Colchester and its western suburb of Lexden formed the site of the Camulodunum of Imperial Rome. On the north and east this site was strengthened by the Colne, then probably a larger river than now; whilst on the south ran a smaller stream,—still called the Roman river,—which was fringed on the other side by a forest. These streams formed the peninsula on which Camulodunum stood; and it is possible, as hinted by our author, that Lexden was the actual residence of Cunobelin.

That such a position should have been chosen as the station of several Roman cohorts, and the residence of their commander, was almost a necessity where the choice was so limited; and accordingly we find that Claudius, when he entered Britain in triumph, founded here that huge encampment, the outlines of which are probably still roughly preserved in the plan of the existing streets of Colchester. From after the date of this invasion, the Roman Colonia, named Camulodunum, sprang into being among the conquered Trinobantes. Thereafterwards rose a heathen temple in honour of the deified Claudius; and here, after the temporary outbreak of British spirit in the person of Boadicea, the city was re-founded, and its walls were built more strongly than before, in such a way as to have lasted down to the present day. In fact, it is doubtful whether, except at Lincoln and at Chester, more perfect specimens of Roman buildings remain than the present walls of Colchester.

But what about the castle itself? There have not been wanting those who have rashly concluded that it is also a Roman structure, and that in looking on its walls, as they now stand, they are looking on an edifice which was reared in the days of Imperial Rome. The writer of the work before us has brought forward only to demolish the theory of the late Rev. Henry Jenkins, who thought that the castle is a temple erected in the earliest ages of history to the memory, or in honour, of the Emperor Claudius; and there are others who have fallen in with the view. All this, and much more of the same kind of theories, might very easily have been broached and have found supporters in the days when every round arch which the Normans built in England passed for "Saxon," and when the first principles of architecture, whether ecclesiastical or secular, had to be worked out anew, as the Anglo-Saxon grammar has been worked out during the last quarter of a century.

\* "The History and Antiquities of Colchester Castle," Colchester: Benham & Co. 1882.

The writer sees little or no reason for believing the legend which identifies Colchester with the birthplace of Constantine the Great; but he seems more disposed to accept the tradition that the Arthur of Camelot may have had more to do with Camulodunum than is generally supposed. If so, the prosaic Essex must put in a rival claim to the poetic region of Cornwall. "Does not Arthur himself tell us, with characteristic contempt for history?" our author asks, "I have understood that *Belinus* and *Brennius*, knights of Britain, held the Roman Empire in their hands for many days, and also *Constantine*, the son of *Helen*, which is open evidence, not only that we owe Rome no tribute, but that I, being descended from them, may, of right, myself claim the Empire?" Is it, then," he continues, "too much to ask, that when, in the Laureate's Vision, we see

'The river, winding clearly,  
Down to tower'd Camelot,'

we may be suffered to roam in fancy to the mystical birthplace of Constantine, to that 'Royal seat' of the great Camobelin, which arose by the waters of the Colne?"

Those, however, who have seen, and have carefully examined the castle of Colchester, with every wish to accept the legendary story, can find nothing in the fabric to justify a supposition that in its present shape it had any existence before the Norman Conquest. Camden, writing in the reign of Elizabeth, observes that "historians report it to have been built by Edward, son to Alfred, when he repaired Colchester." Norden, the Essex topographer, writes, about the same time, as follows:—"Colchester, in the times of Saxons, was much battered and ruined by the wars of the Danes. Edward the Elder repaired it, and built a strong castle in it, of which there are still some remains, but ruined almost with age." Speed also attributes it to Edward. Later historians, however, such as Dugdale and Morant,—the latter basing his authority mainly on documentary evidence,—assert that the castle is of Norman origin, and that it was "built by Eudo Dapifer, upon the remains of King Cœl's Palace."

The more that we examine in detail the configuration of Colchester Castle, the more closely shall we see it to resemble that of the keep, or White Tower, of the Tower of London, with this exception, that in its area it is nearly double the size of the latter. The keep of Colchester Castle,—for this is in reality all that is now visible above ground,—is a huge, oblong structure, about 152 ft. by 111 ft. square, whereas that of the Tower of London is only 116 ft. by 96 ft. The general arrangement was similar in both, namely, a basement, which was used for collargo or storage; a first floor, which served as quarters for the garrison; a second floor, which was the principal one, for the state apartments; and a fourth, or attic story, which was used as a kind of fighting deck. This arrangement remains perfect in the Tower of London, but at Colchester, the two topmost floors have all but disappeared. Both buildings are similar with regard to the arching of the loops, their tortuous and intricate communications, and in the absence of fore-buildings. Each is entered in precisely the same peculiar manner; in each there is one, and only one, large newel staircase, leading from the floor to the summit, and in each there are similar large apartments; the windows, formed in the same manner, are similarly situated, and each possesses a general similarity of plan. "In short," as our author remarks, "to recur to Dr. Stukeley's opinion, 'they are works of the same time and manner, and probably of the same hand.'"

It may be said, however, that all along the best antiquaries, Morant included, have looked upon Colchester Castle as a Norman structure. But these persons have too readily taken upon trust the statement that its erection was the work of Eudo Dapifer, under William Rufus. Mr. Freeman, in a later edition of his "Norman Conquest" (1877), has gone so far as to accept the above statement, for, side by side with Eudo's authentic foundation, the tradition of his building the castle has been allowed to creep in. He writes: "The house of Rye rose high in William's favour. One son, Robert, became Bishop of Leez, and another, Eudo, the king's dapifer and Sheriff of Essex, founder of the house of St. John, at Colchester, and, in all likelihood, builder of the neighbouring castle, *castell of Norman donjons*." The writer of the present work, however, shows good reasons for holding, in spite of such tradition, that the

Castle of Colchester was the work, not of a subject, but of a king, and that the king who erected it was the Conqueror himself. "Not only does the architecture, when rightly understood," he writes, "itself bear witness in our favour; not only have we definite proof that in 1091, at any rate, the castle was already standing, but we should also infer the fact from the very history of William's reign. 'Most of the castles whose foundation is distinctly recorded, naturally belong to places which came into William's hands in the course of later warfare. But there were castles in southern and eastern England also; and it is most likely that their foundation at least, if not their completion, was among the very first works of William's reign. In one case, indeed, we have distinct evidence of the fact. The borough of Norwich . . . stood at no great distance from the sea which separated, or rather united, England and Denmark . . . Norwich was, therefore, a point which called for special attention . . . A fortress was therefore built within the walls of the city.' (Freeman's "Norman Conquest.") Now it is obvious that this argument would apply with even greater force to Colchester. A town of importance, both from its size and its fortified position, it stood at the head of a great estuary, and was thus peculiarly exposed to the danger of Scandinavian invasion. Its capture by the Danes would have been a serious blow to William, and it is absolutely certain that he must have hastened to strengthen it with a fortress. If a warning was needed to convince him of the danger, it was afforded in 1069 by the Danish raid up the valley of the Stour. But though a temporary building must have been then early erected, the existing fortress was a work of his later years. I venture to think that we may safely assign its erection to the period between the accession and the invasion of St. Cnut, that is, between the years 1080 and 1085. At no time during the reigns of the Conqueror and his sons was the danger so great to the east coast, and the need of its defence so urgent."

The history of the castle from and after the days of our Norman sovereigns may be very briefly stated. During the revolt of the barons against King John it was alternately in the hands of the rival armies. It was captured by Prince Louis, the Dauphin of France, in 1217, but was retaken in the following year. In the reigns of Mary and Elizabeth alike its gloomy chambers and dungeons had to serve as a prison for many who were condemned to suffer for "conscience sake," both Protestants and Catholics.

Under the brief rule of Cromwell the fair town of Colchester, with its large intermixture of foreign Protestant settlers and its traditional hatred of ecclesiastical persecution, formed one of the strongholds of the Parliamentary party. Its castle, however, from its situation and its ruinous condition alike was rendered of no account in the military history of the siege. History tells us how the gallant and loyal officers, Sir Charles Lucas and Sir George Lisle, were shot by Fairfax, under orders of a council of war, beneath the walls of the castle. For a century and a half, at least, after that date Colchester Castle seems to have done duty chiefly as a prison, and to have accommodated within its gloomy walls almost as many quakers as Wisbech Castle received of Roman Catholic priests.

In the last century a large part of the northern wall was demolished by a Mr. Wheely, who also destroyed the well and caused much other havoc, which, had it proceeded, might have left but little of the building standing; but, happily, about the middle of the last century, the fabric and the adjoining lands were purchased by an enthusiastic antiquary, Mr. Charles Gray, M.P., who, in his turn, bequeathed them to the Rounds, a family in whom taste and reverence would seem to be hereditary, and who have taken good care that, so far as it is in the power of man to do so, the progress of decay shall be arrested.

**Westerdale, Yorkshire.**—On Sunday last an oak roredo, erected in the parish church of Westerdale to the memory of the late Hon. Col. O. Duncombe (the gift of the family), was unveiled in the presence of a large congregation. The work was executed from the design of Messrs. Perkin & Bulmer, architects, of Leeds, by Mr. J. W. Appleyard, also of Leeds.

#### THE ARCHITECTURAL ASSOCIATION EXCURSION.

THE thirteenth annual excursion did not carry the members far from London,—Kettering being the head-quarters, and Oakham, which was reached thence by railway, being the furthest point. The London members of the Association are apt to look upon London as the point to measure from,—but do not quite take in the situation when they do so,—for an excursion, just at home like this last, made some of the excursionists travel about 600 miles, in straight travelling, out and home again. More than half of those taking part this year came from country towns and from Ireland. Mr. E. G. Hayes, the president of the Association, took the chair at all meetings, generally guided the party, and represented the Association officially. When the time came for thanking the officers, Mr. C. R. Pink, who has been the active excursion secretary so many years, received due honour; as also Mr. J. A. Gotch, of Kettering and London, who had furnished local knowledge and taken a good deal of pains. Some of the buildings were described by Mr. James Fowler, of Louth. We subjoin some notes partly taken from an intelligent account of the excursion written by one of the party, and printed in the *Northampton Herald*. This will give our readers a general idea of the district and the visits. Some notes on a few of the more interesting topics will appear in a future number of the *Builder*.

The objects of the excursion being more architectural than archaeological, and the search being rather for beauty than mere antiquity, the most ancient remains in the county were passed over in favour of work of the Middle Ages and the Renaissance. On the first day the excursion started for Oakham. Here the fine church was visited, very thoroughly restored by Sir G. G. Scott; and thereafter the Castle Hall,—the most perfect Norman banquet-hall existing. The building consists of what may be termed a nave and two aisles, and the uninitiated might well be forgiven if they thought themselves inside an ancient church. But it never was a church. In those days there was no sharply-defined style applied exclusively to churches, while a totally different one was employed for houses. All were built with similar details, varying according to the use to which they were put. The principal reason why we are accustomed to regard Gothic architecture as essentially ecclesiastical is that most of the houses in which it was employed have perished, whereas the churches have escaped. The carving here is especially fine, and includes what is said to be a portrait of Henry II., in whose reign the hall was built; but as another contemporary carving is said to be James I., these assertions must be taken for what they are worth. At Burley-on-the-Hill a short stay was made to enjoy the magnificent prospect, and take notice of the plan of the house and its colonnades. Exton Hall, the seat of Lord Gainsborough, was next on the programme, and the picturesque ruin of what was once a very fine Elizabethan hall received the attention it deserved, as well as the finely-treated tower of the church, with its characteristic spire-capped lantern. The church was restored by Mr. Pearson some thirty years since. A long drive over the Rutland hills brought the party to Lyddington, where a mid evening visit was made (metaphorically speaking) on the Bede House. This is one of the most interesting buildings in the neighbourhood, abounds in picturesque groupings, and has carved cornices, some very fine stained glass, and other magnificence. It must not be supposed that all these glories were originally lavished on the poor. The place was once a bishop's palace, but becoming the property of a private individual in the sixteenth or early seventeenth century, it was converted into a bed-house; and very few bedesmen are so handsomely lodged as those at Lyddington.

The next day (Tuesday) saw the party off in carriages, starting from the Royal Hotel at Kettering, the very comfortable head-quarters of the excursion, to Loddington, where the church and the Manor House claimed attention. The church is a remarkably fine one for so small a village, and adds a very elegant example to the spires for which the county is famous. The hall is, however, even more interesting than the church, inasmuch as it has come down to us unmodernised in plan, and one can see at

this day just the arrangements which satisfied a squire from the reign of Henry VII. to the middle of last century. The western wing is the earliest in date, and contains a fine open fireplace and cellars. The rest of the house dates from Elizabeth's reign, when nearly every house in the kingdom was improved, and many were newly built. The entrance-hall is surrounded with ancient panelling, where the difference between the way of working in Elizabeth's time and Charles II.'s may be seen at a glance. From Loddington the party went to Rothwell (called generally Rowell), where the rambling old church, which contains examples of work of almost all dates, and Tresham's delightful Market-house, occupied much attention. The church here is the largest in the neighbourhood, being as wide as Kettering Church, and considerably longer. The Market-house is a silent witness to the misfortunes of its author, the most ingenious man the county has produced. The Manor-house was admired for its door and staircase, but at the date when this house was built architecture had already commenced the rapid decline which brought it to the bottomless pit of early nineteenth-century work. Of its style, however, the doorway at the Manor-house is a very good specimen, and does considerable credit to its builder, the celebrated Serjeant Hill. From Rothwell a drive by Stoke Albany, where the remains of the Manor-house were inspected, and the very perfect details carefully sketched and measured, and by Wilbarston, whose dilapidated church struck melancholy into the hearts of the visitors, brought the party back to Kettering.

On Wednesday Warkton Church and the remarkable monuments of the Montagues by Roubiliac (about 1750) and Peter Matthias Vangelier (1781) were visited, and then Weekley, with its charming village-green lying between the hospital, the church, and the great trees of Boughton Park. No village can vie with Weekley in the delightful calm of its green, where the ancient bedesmen "grow old with the silent years," as the motto over their door has it, and endeavour, as far as changed circumstances will permit, to follow out the quaint rules laid down for their guidance by the Sir Edward Montague who founded their house 270 years ago. From Weekley, a walk through the park and past Boughton House led to Geddington, where the church, the cross, and the ancient bridge justified well a stay of some two hours. After Nave-house,—the only little church, and the Dove-house,—the only relic of the once extensive mansion of the younger branch of the Treshams,—came the great visit of the day,—to Rushton Hall. It would occupy columns to describe the Hall, which is one of the most impressive pieces of Elizabethan architecture in the country. It has not the picturesque variety of Drayton and Rockingham, nor the elaborate detail of Kirby; its attraction consists in its simplicity and quiet dignity, chiefly arising from the fact that the original design was adhered to by the successive builders. The main bulk of the mansion would seem to have been begun by the grandfather or great-grandfather of that Sir Thomas Tresham who will always occupy a prominent place in the memory, if only for his taste for quaint and symbolical building. The author of the Triangular Lodge and Rothwell Market-house left his mark on his ancestral home as well, and when he died, and the estate passed from his son, in consequence of his complicity in the Gunpowder Plot, the Cockayne, who purchased Rushton, completed what the Treshams left unfinished. Scarcely less interesting than the house are the beautiful grounds, in whose alleys Dryden walked and wrote "The Hind and the Panther." In a distant corner of the grounds stands the Triangular Lodge, the only building of Sir Thomas Tresham's which is known to have been completed, and which, thanks to the care of its owner, Mr. Clark Thornhill, is in admirable condition. The Lodge is a mass of symbolism, apparently preaching in stone the mystic doctrine of the Trinity. Some of the numbers still defy all attempts at elucidation. It is illustrated pretty fully in a very early volume of the *Builder*.

The next day Drayton was the first place visited. In associations Drayton is in no way inferior to Rushton and its gardens, with their green lawns, clipped yew-walks, "berceaux and cabinets de verdure," and bright parterres, are alone worth a long journey to see. The house itself dates from the times when an English-

man's house was in very truth his castle, and from that time to this its checkered history is told by the jumble of styles in which the work is executed. Drayton has never been sold nor alienated, but by marriage it has passed through many hands, and every hand has left its mark. The mass of the walls is probably of the time of the Edwards; the windows, doors, chimney-pieces, and other features by which the date of a structure is most easily determined, are nearly all due to extensive alterations during the reign of William III. One wing is entirely Elizabethan, from its splendid vaulted cellars, where mighty barrels of beer stand in cobwebs and fungus, up to the chimneys, which recall Kirby. But here, too, alterations have been made, and the long gallery at top with one side furnished with ancient volumes, looks as if Lady Betty Germaine might have left it only a few months instead of a century. Lady Betty was Horace Walpole's friend, and she received Drayton from her husband, whom his turn had received it from his first wife, the last of the Morgantons, who were descended lineally from the original owners. Walpole's famous letter on Drayton was written July 23, 1763. Lady Betty left the estate to Lord George Sackville, from whom the present owner is descended. Her graceful reception and agreeable hospitality were in harmony with the traditions of Drayton. Lovick Church was next visited, notable externally for its bold tower, octagonal lantern, and flying buttresses; and notable internally for its fine brass of Sir Henry Greene (died 1467), and its alabaster tombs of Ralph Greene (1420) and Edward Stafford, Earl of Wiltshire (died 1499),—both exquisite works,—unique in parts. The "old oak" at Lovick, over ninety yards round the ends of the branches, will, it is feared, go quickly to its end. Last year the inside of the tree was burnt out. The fire was got under without the aid of the fire-engines, but the noble relic of the great forest was fearfully injured. At Lyveden stands another of Sir Thomas Tresham's buildings, quite as ingenious, and very much less bizarre than the Triangular Lodge. Lyveden New Building is not only remarkable for its quaint symbolism (the Passion being here commemorated), but for the purity of much of its architectural detail, very unusual for the time in which it was built. The Old Building is, in fact, rather younger than the New Building, but stands on the site of one of the ancient family seats of the Treshams, and between the two buildings are remains of fish-ponds and terraces, which bear witness to the lordly scale of the gardening of Elizabeth's time. Brigstock was the last halting-place. Here the remains of a considerable Saxon church, incorporated with the Medieval building, indicate the existence of an early civilisation in that part of the county, a fact further confirmed by the records of Rockingham. The Manor-house is largely of a date previous to Elizabeth's time,—the great era of house-building,—and is supposed to have been the birthplace of that Sir Edward Montague, the Lord Chief Justice, who founded Boughton and the family of Montague of Boughton, and now lies buried in Weekley Church. In this house is an ancient wardrobe, which "goes with the house," because too large to be taken away; also a sixteenth-century bedstead, in which King John, of evil memory, "slept the night before he crossed the water." (!)

On the last day, Friday, the Association first drove to Rockingham, and thence by Grettton to Kirby. Rockingham has had, perhaps, a more eventful history than any house in Northamptonshire. From the earliest times it seems to have been a stronghold. William the Conqueror found it fortified, and left it more so. All the early kings, especially John, used to hunt here, and much of the place, as built by them and their successors, remains to this day, surrounded by later additions. The family of the present owner, Mr. Watson, obtained possession of the place in Henry VIII.'s reign, and the larger part of the existing buildings were built by them at various times, chiefly during the seventeenth century. The effect of the mixture of styles, and the commanding position of the place, give it a charm of its own. Nothing more interesting, each in its own way, could be found in any part of England than Rushton, Drayton, Rockingham, and Kirby. Kirby was the last important place visited, and it is the richest in detail. Here may be seen, side by side, the work of two of England's greatest architects, John Thorpe and Inigo Jones. Thorpe seems to have designed a considerable amount of

work, completing a house carried well forward previously by "Humfre Stafford,"—as he called himself on the parapet outside the great hall; while at a later date (1638, &c.) Inigo Jones was employed to remodel some of the façades. Kirby is, indeed, a melancholy place. Ruin works swiftly and silently before our very eyes. Every visit reveals some fresh disaster. Even now the south-eastern staircase, with its elaborate ceiling, trembles to its fall, and it is only held in place by pieces of the wooden wall-lining. The roof of the great hall has leaked till the wall is green and crumbling, and very soon this magnificent apartment will be open to the sky. Trees are growing on the walls and rending them to pieces, and if the cruel neglect is continued, a few years will see the last stones hurled to the ground to be broken up, as stones are at the present moment being broken up, to mend roads. Stanion Church, which has a good Perpendicular arcade and an elegant tower and spire, was seen and sketched on the way to Kettering. The proceedings thereafter were the final dinner, a little speech-making, and a due remembrance of "Auld lang syne." Saturday morning was spent at Kettering Church. Its tower and spire of the same class as Oakham and All Saints, Stamford, but with many points of difference in general arrangement and in detail, had been well in view all the week,—from near and far as the party left and came back towards their headquarters; and its pleasing outline in the centre of many a picture will dwell in memories which will recall with pleasure many other good points seen and noted in the interesting district.

#### THE APPROPRIATION OF WAGES AND INCOME.

IN the Economic Science and Statistics Section of the British Association meeting at Southampton, Professor Leono Levi read the report of a committee appointed for the purpose of continuing the inquiries into the appropriation of wages and other sources of income, and considering how far it was consonant with the economic progress of the United Kingdom. The report set forth that out of a gross personal expenditure amounting to about 878,000,000, or about 83 per cent. was probably spent on necessities, and 150,000,000, or 17 per cent. on luxuries and waste. Out of a net or national expenditure of about 684,700,000, or about 614,000,000, was probably spent on necessities, and about 70,000,000 on luxuries, the percentage being respectively 89 and 11. The action in reality spent only the half of what the individuals spent on luxuries, because large portions of these consisted of taxes and profits of distribution which remained in the country. Of late years the expenditure on the necessities of life had greatly increased, and a comparison of the quantities per head consumed of the principal imported articles showed not only that people had much greater command over the articles of food than they previously enjoyed, but that their expenditure on these occasions had increased in a larger proportion than the expenditure on alcoholic drinks and other luxuries. Likewise the expenditure on house rent had largely increased, partly from the increased cost of houses, and partly from the greater capacity of the people to enjoy the comfort of a commodious home. Comparing 1851 with 1831, there was a large increase in the number of persons living in houses at high rents. Another evidence of the increasing prosperity of the country and of the productive manner in which the money was spent was that there was reason to believe that the labouring classes represented 70 per cent. of the population, and the middle and higher classes 30 per cent. In other words, 26 million persons might be taken to belong to the labouring classes, and 11 million persons to the middle and higher classes. The approximate division of expenditure between the classes was as follows:—Gross personal expenditure.—Working classes, 429,000,000; middle and higher classes, 454,400,000. Net or national expenditure.—Working classes, 333,300,000; middle and higher classes, 351,400,000. With regard to the relative expenditure of the classes on necessities and luxuries, the figures were as under:—Working classes.—Personal expenditure, 80 per cent. on necessities and 20 per cent. on luxuries; national expenditure, 90 per cent. on necessities, and 10 per cent. on luxuries. Middle and upper classes.—Personal expenditure, 86 per cent. on

necessaries, and 14 per cent. on luxuries; national expenditure, 89 per cent. on necessities and 11 per cent. on luxuries. The working classes appeared thus to devote a larger proportion of their incomes to luxuries than the middle and higher classes, a fact all the more to be regretted since they were thereby left with so much less available for necessities. The total income of the people of the United Kingdom might be taken at about 1,000,000,000. Estimating the total earnings of labouring classes at 436,000,000, and those of the middle and higher classes at 564,000,000, it would be seen that after expenditure there would be left to the working classes a surplus of 13,000,000; and to the middle and higher classes one of 110,000,000. The general results of the inquiry were not discouraging. It was gratifying to know that the great bulk of the income of the people was productively expended, and that though much devoted to luxury, and a goodly portion was wasted, still a handsome annual surplus remained for reproduction, which went to swell the capital of the nation.

In the discussion which followed, Professor H. S. Foxwell said that the whole report was based on a distinction between what was called necessary and luxurious expenditure. Such a distinction was quite one of gradation. It was impossible to draw an absolute line, and there would be very great dispute about the point at which the Professor drew it. For instance, the Professor excluded from the list of necessities amusements and other things which many persons would include. The dull and most intolerable form of life would be that in which people were only consuming and producing necessities, a life which must cease for want of energy. He thought that consumption was considered somewhat too narrowly. He regarded it as an incentive to industry.

Mr. Hurst urged that it was by some people enjoying luxuries that numbers of other persons were enabled to get bare necessities of life.

Mr. McKnight referred to the culpable mispending of money involved in the giving of the dinners of large London companies, and pointed out that while the working classes spent 9,200,000 on tobacco, they only expended some 1,100,000 on education.

Mr. Stephen Bourne submitted that, taking them broadly, the conclusions of the report must be considered to be correct, and contended that all labour should be applied to that which was useful, though it might not all be reproductive.

Sir Rawson Rawson remarked that it appeared that the expenditure of the upper class family was only two and a half times that of a labouring class family. Another still more extraordinary fact was that the taxation paid by the working classes was 16s. 1d. per family, and for the middle and higher classes 16l. 6s. 10d. Again, the surplus after expenditure in the case of the working classes was 3 per cent. on the income, and in the case of the upper classes 20 per cent. It was also remarkable that the expenditure of the lower classes on beer and spirits was just double that of the upper classes, while, of course, on wines the excess was in the upper classes. He noticed that whereas the increase in the consumption of spirits, wine, and tobacco, between 1840 and 1880, was 75 per cent., the increase in regard to cocoa, raw sugar, and tea was 272 per cent.

After replying upon the discussion, Professor Levi referred to the fact that during the year two members of the committee, Professor Jevons and Sir Antonio Brady, had died, and moved a resolution, which was seconded by Sir Rawson Rawson, and carried, setting forth that the section deeply deplored the loss of the late Professor Jevons, a former president of the section and a member of several committees at different places.

#### HOUSES WITHOUT DAMP-PROOF COURSES.

At a meeting of the directors of the Nineteenth Century Building Society on the 30th ult., at the offices, Adelaide-place, Mr. H. Waldemar Lawrence in the chair, the following resolution was passed, on the motion of Mr. Mark H. Judge—

"That, as certain houses now being built in West Ham, and proposed to be purchased through the Nineteenth Century Building Society, have been found by the society's surveyors to have no damp-proof course, the directors refuse to advance any money on property so built, and hereby instruct the Secretary to ask the local authorities whether such houses are being built with their approval."

#### MODERN FACILITIES FOR LOCOMOTION AND TRANSPORT.

MR. JOHN FOWLER, C.E., as president of the Mechanical Science Section of the Southampton meeting of the British Association, in his inaugural address, said:—

Of all the important sections of the British Association, the one over which I have now the honour of presiding is, you will all, I think, admit, at once the most practical and the most characteristic of the age. In future times the present age will be remembered chiefly for the vast strides which have been made in the advancement of mechanical science. Other days have produced as great mathematicians, chemists, physicists, warriors, and poets, but no other age has made such demands upon the professors of mechanical science, or has given birth to so many men of eminence in that department of knowledge. Though a member of the profession myself, I may venture before my present audience to claim that the civil engineer is essentially a product and a type of the latest development of the present century. Telford has admirably defined the profession of a civil engineer as "being the art of directing the great sources of power in Nature for the use and convenience of man, as the means of external and internal trade, as applied in the construction of roads, bridges, aqueducts, canals, river navigation and docks, for internal intercourse and exchange, and in the construction of ports, harbours, moles, breakwaters, and lighthouses, and in the art of navigation by artificial power for the purposes of commerce and in the construction and adaptation of machinery, and in the drainage of cities and towns." This definition, written more than half a century ago, is wide enough to include all branches of engineering of the present day, although amongst those specifically mentioned the departments presided over by the railway engineer, the locomotive superintendent, and the electrician will be looked for in vain. As Telford was beyond all question the most widely experienced and far-seeing engineer of his time, this little omission well illustrates and justifies my statement that the typical civil engineer of the day is a late product of the present century; for even Telford never foresaw the vast changes which railways, steam, and electricity would evolve in the course of a few years.

There have undoubtedly been published during the last fifty years many works of mark and merit, but the work which above all others would, I think, have astonished and perplexed our ancestors, is the little one known to all the civilised world as "Bradshaw." This indispensable handbook of the nineteenth century testifies that the face of the country is dotted over literally with thousands of railway-stations; that between many of these stations trains run at two-minute intervals, whilst the distance between others is traversed at a mean speed of nearly sixty miles an hour. The public are often justly indignant at the want of punctuality on some railways, but they should blame the management and not the engineers, for the daily conduct of the heavy traffic between England and Scotland shows, that notwithstanding the constantly varying condition of wind and weather in this climate, a run of 400 miles can, on a properly laid out railway, and with suitably designed rolling-stock, be accomplished with certainty to the minute, if the management is not at fault. On the Great Northern Railway, for instance, of which I am consulting engineer, the 400 miles between London and Edinburgh is traversed in nine hours, or deducting the half-hour allowed at York for dining, at the mean rate of no less than forty-seven miles per hour including stoppages. A few months ago the Duke of Edinburgh was taken on the same line of railway from Leeds to London, a distance of 186½ miles, in exactly three hours, or at a mean rate, including a stop at Grantham, of over sixty-two miles an hour. I know of no railway in the world where this performance has been eclipsed.

An essential condition of the attainment of high speed on the railway is that the stopping places be few and far between. The Great Northern express previously referred to makes its first halt at Grantham, a distance of 105 miles from London, and consequently but little power and time are lost in accelerating and retarding the speed of the train. In the instance of the Metropolitan Railway, on the other hand, the stations average but half a mile apart, and

although the engines are as powerful as those on the Great Northern Railway, whilst the trains are far lighter, the average speed attainable is only some twelve miles an hour. No sooner has a train acquired a reasonable speed than the brakes have to be sharply applied to pull it up again. As a result of experiment and calculation, I have found that 60 per cent. of the whole power exerted by the engine is absorbed by the brakes. In other words, with a consumption of 30 lb. of coal per train mile, no less than 18 lb. are expended in grinding away the brake blocks, and only the remaining 12 lb. in doing the useful work of overcoming frictional and atmospheric resistance.

Nearly thirty years ago, when projecting the present system of underground railways in the metropolis, I foresaw the inconveniences which would necessarily result from the use of an ordinary locomotive, emitting gases in an imperfectly ventilated tunnel, and proposed to guard against them by using a special form of locomotive. When before the Parliamentary Committee in 1854, I stated that I should dispense with firing altogether, and obtain the supply of steam necessary for the performance of a single trip between Paddington and the City from a plain cylindrical egg-ended boiler, which was to be charged at each end of the line with water and steam at high-pressure. In an experimental boiler constructed for me, the loss of pressure from radiation proved to be only 30 lb. per square inch in five hours, so that practically all the power stored up would be available for useful work. I also found by experiment that an ordinary locomotive with the fire "dropped" would run the whole length of any railway with a train of the required weight. Owing to a variety of circumstances, however, this hot-water locomotive was not introduced on the Metropolitan Railway, though it has since been successfully used on tramways at New Orleans, Paris, and elsewhere.

A reference to the Underground Railway naturally suggests the wider question of tunnels in general. To foreign engineers belongs the honour of having boldly conceived and ably accomplished tunnel-works of a magnitude which would have appalled a canal engineer. I need only refer to the Mont Cenis Tunnel, over 7½ miles in length, commenced in 1857 and finished in 1870; the St. Gothard Tunnel, 21 miles in length, commenced in 1872 and finished in 1882; and the Hoosac Tunnel, 4½ miles in length, commenced in 1854 and finished in 1875. In all cases rock of the hardest character had to be pierced, and it is needless to remark that without the aid of the machinist in devising and manufacturing compressed air machinery and rock-boring plant the railway engineer could not have accomplished the task. Tunnels under broad navigable rivers and estuaries have been a subject of discussion by engineers for at least a century, but the only one at present completed is the unfortunate and costly Thames Tunnel. Two important works of the class are, however, now well in hand, namely, the Severn Tunnel at Portskewet, and the Mersey Tunnel at Liverpool.

In many cases of tunnels under estuaries, special appliances could be used which would obviate all risk and make the successful completion of the work a mathematical certainty. A tunnel under the Humber, about a mile and half in length, projected by myself in 1873, the Bill for which was subsequently passed by the Commons and thrown out by the Lords, is of very fine silt, and I proposed to build the tunnel in lengths of 160 ft., under the protection of rectangular iron caissons, 160 ft. long by 42 ft. wide, sunk by the pneumatic process. As the pressure of air in the caissons would always be slightly in excess of that due to the head of water in the river, no interruption from influx of water could ever occur, and the operation of building the tunnel in lengths inside this huge diving-tail would be as certain and free from risk as the everyday work of sinking a bridge-pier by the pneumatic process.

At the beginning of the present century a committee was appointed to consider the "practicability of making a land communication by a tunnel under the river Forth, at or near Queensferry." In a report dated November 14, 1805, it was recommended that a double tunnel should be constructed, at an estimated cost of 164,000l., or at the rate of 30l. per yard, exclusive of shafts and pumping. The surveyors reporting grounded their belief in its

practicability upon the fact that at Borrow-stowness coal workings had been carried under the same Firch for a mile, and that at Whitehaven coal was worked for the same distance under the Irish Sea, in both places less water being met with under the sea than under the land. The report concludes in the following words:—"That a more easy and uninterrupted communication betwixt every part of a country increases the intercourse of commerce, arts, and agriculture, all must know. Ferries are still and often a formidable bar in the road. Of these in this country, the one under review at Queensferry is, perhaps, the most conspicuous. It is, in fact, the connecting point betwixt the north and south of Scotland, and indeed of the realm, and in this point of view the improvement of it must be considered a national object." These words are as true and applicable to the case in 1882 as they were in 1805. A ferry still is the only means of communication across the Forth at Queensferry, though the traffic has increased a hundredfold. Parliament, by the passing of the Forth Bridge Act during the present session, has given a practical recognition of the truth of the statement in the above-quoted report, that the improvement of the Forth passage is a "national object."

#### MURAL DECORATION IN GERMANY.

THE political union of Germany has done much of late years to render men's minds capable of appreciating the work of such men as Janssen and others, who have, to a certain extent, founded a new school of German art. Though they no longer reside there, Düsseldorf claims the merit of having sent out these apostles of a new artistic creed, and as the *Kölnische Zeitung* lately remarked, Rhineland has every reason to be proud of this new school of monumental painting which has been so successfully inaugurated within the bounds of the province.

The principal work on which Herr Janssen has lately been engaged is the mural decoration of the Erfurt Town-hall. The sides of the staircase leading to the principal chamber will in a short time illustrate Thuringian legends and episodes from the life of Luther, in which the traditions of the old city afford the artist a great variety of subjects for treatment. The walls of the principal chamber have been covered with representations of local historical events. Three of the walls (each about 45 ft. in length) have been thus ornamented, the windows taking up the greater part of the fourth or western side. There are nine subjects treated, six of them being strictly historical, and three allegorical. The latter are above the entrance doors and are on a gold ground, which harmonises with their general character.

On the north side of the room the series of pictures commences with the introduction of Christianity in 719 by St. Boniface, who is represented in his monk's garb preaching to a crowd. The assembly includes many of the barbarian invaders who had settled in the district of Erfurt, whose gigantic stature and warlike mien contrast effectively with the figures of women and children which complete the *tableau*.

The diet held in St. Peter's Church, Erfurt, in 1181, by Frederick Barbarossa is strikingly represented. The principal circumstance delineated is the request for the emperor's pardon, which Henry the Lion made on that occasion, after his unsuccessful resistance during the previous year to the imperial authority.

The storming of the fortress of Ilmenau by the Erfurt ironworkers, and the attack on the town-hall in the year 1509, are delineated with much dramatic effect. The latter event is depicted at the moment when the populace has succeeded in breaking into the magistrates' chamber, and when its leaders are stating their demands.

The entry into the city of the Elector, John Philip, of Mayence, forms the subject of another of the pictures, and the richness of colouring which the costumes enable the artist to introduce with strict appropriateness adds much to its effect.

The last of the principal works represents the destruction of an obelisk made of wood and of canvas painted to represent marble. This monument had been erected by the French during their occupation of the city in the year 1810, and bore the inscription, "To Napoleon the Great." When the Prussians came time

afterwards occupied Erfurt, the citizens destroyed this memorial of foreign invasion, and the moment selected for the vivid sketch of the event Herr Janssen has reproduced is that at which the destruction of the obelisk was taking place.

The allegorical paintings correspond in a general way with the historical works we have described, and serve to fill up many points of interest in the history of the old Thuringian city.

The town-hall at Hanover has also been treated in a more or less similar style by Herr Scafer, who has during the last five years been associated with the architect, Herr Hase, in the restoration of the building. The principal chamber is more than 70 ft. in length, and about 36 ft. wide. In the absence of such events in the local history as would admit of effective pictorial representation, the artist has produced on an extensive scale a series of allegorical pictures of the rivers of North Germany. Heraldic figures are also introduced in an appropriate manner, and various symbolical delineations complete the mural decoration of the chamber.

#### ENGLISH IRON IN GERMANY.

ACCORDING to a statement in the German press, on account of the low rates of freight from the United Kingdom to Hamburg by steamer, and the facility which the railways in Germany afford for the transport of imported iron, the Berlin purchasers for manufacturing purposes can get the English article at a price which competes successfully with the products of native industry. The first cost of iron at the works in Germany seems to be about 25 per cent. above the value of Scotch iron *f.o.b.* at Glasgow. The railway carriage to Berlin costs nearly as much as the freight, duty, and railway carriage on the imported article. Hence the supposed advantages of the protective policy are lost. The matter is being brought before the Imperial Government of Germany with a view of obtaining such concessions in the railway rates of carriage of iron as would do something towards assisting the position of the German iron industry, and thus swelling the traffic receipts of the various lines interested.

As an instance of the extent to which our iron is used in Germany, it is stated that the lamp-posts in Berlin are made of English metal.

So much the better for the Berliners, looked at properly.

#### THE ENGLISH CHURCH AT PONTRESINA.

THE English church at Pontresina, in the Engadine, was opened on August 19, and consecrated by the Bishop of Bedford. A novel feature in the church is the substitution of wood for stone in the nave arches and clearstory. The plan is that of a parallelogram, 78 ft. by 56 ft. There is no external indication of the chancel, as the site was so limited in length that it was necessary to carry the aisles to the full extent of the ground in order to gain the required accommodation. A porch occupies the second bay on the south side. The side walls are 2 ft. 3 in. thick, of rubble with granite dressings; they vary in height as the ground falls rapidly from east to west, so much so, that there is a height of 20 ft. below the floor at the west end. This is utilised as a store-room, and could be adapted for warming apparatus. It has wide pointed arches towards the west, and at the sides. The style is Pointed, of the simplest character. The church is lighted by lofty triplets at the east and west, and by low coupled lancets at the end; the windows of the clearstory are trefoils pierced through the woodwork, those of the chancel bay are quatrefoils.

Internally there are five bays, formed by clustered wooden columns composed of four semicircular shafts with Early English capitals; from these spring smaller shafts supporting the principals of the nave, the wooden arcade, and the principals of the aisle roof. The spandrels are filled with plain boarding; those in the chancel are panelled; the arches are strengthened by struts, the intervening spaces being filled with open tracery. The easternmost bay forms a spacious chancel. A high screen divides the organ-chamber on the north side, and a similarly enclosed screen the vestry on

the south side from the chancel. The altar, which is very massive, has six circular columns, with foliated capitals.

The plans were furnished by Mr. R. P. Pullan, who had designed a smaller church for the same site in 1874, and were excellently carried out by Mr. Ragatz, of Zurich. H. R. H. the Princess Christian, who has taken the greatest interest in the progress of the church, presented a handsome frontal, executed by the ladies of the South Kensington School of Needlework under Mr. Pullan's superintendence. The Princess also carried out the greater part of the floral decorations for the day's consecration. Mr. and Mrs. Bancroft were liberal contributors to the edifice,—they gave the central light of the eastern triplet, by Mayer, and also the bell. The Rev. J. W. Ayre, of St. Mark's, Grosvenor-square (the summer chaplain), who originated the present plan and collected the funds for its execution, presented the jewelled cross. The Rev. J. Nixon gave an ornamental fald-stool; and many of the visitors to the happy valley of Pontresina contributed largely to the funds. The church seats 350 persons.

#### ROOD SCREEN AND IRMENSÄULE, HILDESHEIM.

We have previously given views and descriptions of the beautiful old Medieval town of Hildesheim and its interesting cathedral, and it is now our intention to speak more in detail concerning the remarkable rood-screen and the very ancient and singular column called "Irmensäule," which stands upon the flight of steps leading to the choir of the church.

The rood-screen in Hildesheim Cathedral is one of the most remarkable examples of the Early Renaissance to be found in Germany. It appears to have been erected about the year 1550, and its erection may be accounted for by the fact that in 1542 the cathedral was taken possession of by the Lutherans, who excluded the bishop and canons from the building, and subsequently closed it altogether. After the battle of Muhlberg, however, in which John Frederick, Elector of Saxony, was taken prisoner by Charles V., the church was given back to its original owners, and the bishop and canons were re-established, and this rood-screen is probably a portion of the restoration which the cathedral underwent at that time. This must not be confused with the entire restoration of the building after the thirty years' war, when the church was covered internally with plaster ornaments in the Rococo style. The names of the architect and sculptors employed upon the rood-screen at Hildesheim appear to have been lost, and it is rather strange that this beautiful and interesting work is unnoticed by those indefatigable antiquaries, Kugler and Rosegarten. All that appears to be known is that it was erected at the expense of a canon of the cathedral, named Freitag. It is constructed of a very fine sandstone, and (called in Germany "kreidesandstein") brought from the neighbourhood of Munster, in Westphalia. It is in a most remarkable state of preservation. The position of the pulpit in the centre of the screen is, as far as we know, unique. The desk for the Gospel consists of an eagle composed of brass, gilt. Whether there was originally an altar in front of this pulpit is doubtful, but the arrangement of the steps and platform would seem to suggest that one was intended, although the present altar is certainly modern.

The Irmensäule which stands upon the steps in front of the screen is of very great antiquity and was either an object of worship in Pagan times, or was used as a column supporting a statue of the god Arma. The metal-work hearing candles, which this column supports, dates from the twelfth century. The many other works of art contained in this cathedral have been previously described in this journal, and the great "corona," bronze font, and stall have been illustrated.

#### WINDOW SCREEN FROM CAIRO.

THIS is one of several fine specimens of lattice woodwork now in the South Kensington Museum. The workmanship is somewhat rude, but admirably adapted to its purpose. In its original position, high up in some Eastern street and with a beautiful play of light and shadow upon it, the screen, no doubt, looked most picturesque.

ASSEMBLY ROOM, LION INN,  
COLCHESTER.

The Assembly Room to be built at the Old Red Lion Inn, High-street, Colchester, of which my drawing is an internal view, is part of a large addition now being carried out under my direction for the owner, Mr. W. Wilberforce Daniel. It has been designed in character with the house, one of the few remaining examples of Domestic Tudor buildings in the country.

It was probably built about 1470 as an inn, but I can find no mention of it prior to 1529, at which date it had its present name, but, I should imagine, had been renamed somewhat prior to that date, as the spandrels over the entrance-gateway are filled in with very hold carvings of St. George and the Dragon, from which I infer that was the original sign of the house.

In carrying out extensive restorations during the past two years I have found (covered up some seventy years since) many beautifully-moulded beams, floor-joists, carved corbels, &c., and the greater portion of the first-floor panels in a very good state of preservation, but now covered with lath and plaster, but which I hope eventually to uncover and restore.

The whole of the internal and external walls above the basement are constructed of oak and chestnut timbers filled in with wattle and clay.

At some future time I will ask you to kindly publish a drawing of the street front as restored, it being, I think, a very interesting example of fifteenth-century timber construction.

F. EVELYN MORRIS.

THE UNITED WESTMINSTER  
ALMSHOUSES.

We give a view of the new Westminster Alms-houses. They are intended for eight married couples and eighteen other persons of good character, not less than sixty years of age, who have been resident in the United parishes of St. Margaret and St. John the Evangelist, and have been erected in pursuance of a scheme of the Charity Commissioners, dated 11th July, 1879, which consolidated the Ancient Alms-house Charities, founded and endowed by the Rev. James Palmer in the year 1656, by Mr. Emery Hill in the year 1708, and by Mr. Nicholas Butler in the year 1675, the Charity of Mr. Emery Hill having been generously endowed, in the year 1859, by the late Mr. James Chadwick, an old inhabitant of Westminster, with the sum of 1,500*l.* new 3 per cents, and by his widow with the like sum of 1,500*l.* in the year 1860, in order to increase the monthly allowances to the inmates. When originally founded, Palmer and Hill's Charities had attached to them schools for the instruction of a certain number of boys, but by the Endowed Schools Act, 1869, the scholastic branches and nearly one moiety of the endowments of these two charities were transferred to the United Westminster Schools, and thereupon Mr. Frederick Seager Hunt, the treasurer of Palmer's Charity, the late Mr. Wm. Freeman, the treasurer of Emery Hill's Charity, and Mr. Edgar Horne, the chairman of the Trustees of Butler's Charity, came to the conclusion that it would be to the interest of the charities that the three Alms-house Branches, some of which were occupying very valuable sites, should be amalgamated, and they accordingly brought the matter before their respective Boards, who at once concurred in an application being made to the Charity Commissioners for a scheme for that purpose, which met with the entire concurrence of the Commissioners.

The trustees sold the freehold sites of Palmer and Butler's Alms-houses in Victoria-street, in May, 1880, which enabled them to purchase the freehold of the site of Emery Hill's Alms-houses, on which the new Alms-houses have been built. The site had been previously held on renewable leases from the Dean and Chapter of Westminster, but whose power of renewal had lapsed by the transfer of their property to the Ecclesiastical Commissioners.

The new buildings were commenced in May, 1881, and provide for the same number of almshouses as the old foundations, with the great advantage that the almshouse have two rooms each instead of one, and after providing for their comfort in every way, and a separate laundry and drying-room, so as to supersede the necessity of washing in their living-rooms, and a sum of 100*l.* a year for exhibitions in com-

plance with Mr. Nicholas Butler's will, the trustees have already been enabled to grant pensions of 20*l.* a year to eighteen persons living with their relatives and friends.

The building consists of a centre and two wings. The south wing contains twelve almshouses, to accommodate the number maintained in the old Palmer's Alms-houses. The north wing contains twelve almshouses, to accommodate the number maintained in the old Emery Hill's Alms-houses; and the centre block contains two almshouses, to accommodate the two married couples formerly maintained in the old Butler's Alms-houses, besides the board-room and offices, the rooms of the superintendent, who is to be responsible for the internal management of the almshouses and the comfort of the almshouses; also a separate infirmary, and apartments for the nurse.

The buildings have been erected by Messrs. Adamson & Sons, from designs by the late Mr. Robert Richard Armit, upon whom they reflect great credit for the thoughtfulness and care exhibited. Since the lamented death of Mr. Armit, Mr. Cole A. Adams, who had been associated with him in preparing the plans and drawings, has superintended the completion of the buildings, with the assistance of Mr. Thomas Higgs, the clerk of the works, to the entire satisfaction of the trustees.\*

THE ARCHITECTURAL AND  
ENGINEERING CONGRESS AT HANOVER.

The fifth congress of the Union of Architects' and Engineers' Societies (which has just been held at Hanover) was arranged two years ago, and during the interval the worthy burghers of that city have been keeping before them the important nature of the event. On a previous occasion in 1862, there had been a meeting of a similar character at Hanover, though it was apparently before the incorporation of the body which summoned this congress. The importance of Hanover as a centre of artistic influence has increased of late years, Herr Schaper having contributed, by his mural decoration of the restored town-hall, towards the result thus arrived at.

The preliminary assembly of delegates (forty in number, from nineteen societies) met on the 15th ult. After some business of a formal character had been transacted, a resolution was adopted asking the Hamburg Society to prepare specimen forms of contracts made with architects. It was also resolved to ask the Government to publish in their present form the details of public buildings in Germany which have lately been collected. The latter and more economical employment of water, from agricultural, industrial, and commercial points of view was likewise discussed. A commission was appointed to report on the best means of preventing the profligate expenditure of architectural work which sometimes takes place in public competitions. The question of normal regulations for the delivery of iron constructions was referred for special discussion to the Saxon Association of Engineers and Architects, which had already been dealing with the subject. The question of technical education in connexion with architecture was the subject of lengthy deliberation. Reports were presented on the subject from Munich, Hanburg, Hanover, Stuttgart, Cologne, and Schleswig-Holstein. The present system was generally considered as being unsuitable to existing requirements.

At the second assembly of delegates, which took place on the 19th, Herr Kohler alluded to the proposed restoration of the castle at Heidelberg, and mentioned that the renovation of this monumental work would be an appropriate gift from the German nation to the University of Heidelberg, on the 500th anniversary of its foundation which it will be celebrating in 1886. The question of utilisation of water which had been brought forward on the preceding day came up for further discussion, and was referred to a select commission. The unfavourable position in which young architects are at present situated in Germany was the subject of a special

\* The following are the names of the trustees of the Alms-houses.—Mr. Frederick Seager Hunt, chairman; the Venerable Archdeacon Jennings; Sir Henry Arthur Hunt, C.B.; Mr. John Letson Elliot; Mr. James Alfred Hallett; Mr. George Taverner Miller; Mr. Herbert Teas, Steward; Mr. Geo. Andrew Spottiswoode; Mr. Jos. Carter Wood; Mr. Edgar T. Horn; Mr. Wm. Goldsmith; Mr. Geo. Burt; Mr. Geo. Francis Trollope; Mr. Thos. John White; Mr. R. Saby Freeman; and Mr. William Mann Trollope, clerk and solicitor to the trustees.

report from the Berlin Society. According to the particulars brought forward, the overcrowded state of the profession becomes painfully apparent when an official position is being competed for, and the opinion is ventured that this state of things is likely to grow worse rather than to improve, unless the extensive publication of the facts of the case serves to deter candidates for admission to the profession from continuing their efforts in that direction. The suggestion was also made that the suspension of works of a public character should be so arranged that a larger staff of technical men should be employed. The use of glazed tiles for roofing and facing purposes, and the system of normal models for rolled iron, were also discussed. The further elucidation of the subject of "Typical Dwelling-house Plans" was entrusted to the Mid-Rhenish Society. A question of special interest was also brought forward with reference to the effect of the season at which wood is cut, on its quality and durability. The proposal to erect a monument to Semper was approved, and the proceedings of the delegates then terminated.

The festivities which took place on Sunday, the 20th, in connexion with the reception of the guests, were characterised by the heartiness of friendly feeling which the occasion inspired. The railway station is well known to travellers in North Germany as being one of the best specimens of its kind on the Continent, and being provided with the electric light, was striking in its general appearance. Addresses of welcome, delivered at the Rath-haus by Herr Culemann and Professor Lange, were appropriate in their character.

On Monday, the 21st, the business of the Congress commenced in earnest, under the presidency of Herr Köhler, the secretaries being Herr Sprengel and Herr Demangel. The first paper was read by Herr Kymann, upon "The Value of Exhibitions for Technical Purposes." He referred to the technical skill developed in the construction of suitable buildings, and contrasted the principles which have guided French and English architects in the general internal arrangements of such structures. The Paris Exhibition of 1878 he considered as having been specially valuable to the cause of architecture, inasmuch as it enabled the careful observer to note the prevailing features of the art in its modern French form, and, at the same time, gave due prominence to details affecting the restoration of Mediaeval structures. Another useful feature of the display was the facility of contrasting the iron constructions of various nations. As a general argument, he maintained that the careful and intelligent arrangement of objects not absolutely novel was often of more practical use than the exhibition of articles, which, though new, were not placed with due discrimination and knowledge of their relations to surrounding objects. In conclusion, he remarked that the too great abundance of exhibitions which had existed was being remedied, and while advocating special exhibitions in preference to those of a comprehensive nature, he expressed himself as opposed to such special displays as sought to cover too wide an expanse of science, art, or industry, considering that the more limited the scope, the better was the prospect of the advancement of technical progress in the direction selected for illustration.

The work of the sections commenced at noon. That of architecture occupied itself in the first instance with Herr Hase's paper on German town-halls in general, with special reference to that of Hanover. There are, it would seem, not many old town-halls in Germany, and none of them have retained their original form without alteration. The oldest is that of Dortmund, which dates from the twelfth century, and in which provision is made for festivities and public assemblies, as well as for the administration of justice. That of Gelnhausen has some points of resemblance with the Dortmund structure, and dates from the same period. That of Lübeck (which as early as 1276 suffered from a fire) shows the influence of Italian art in its general character, this fact being explained by the important commercial relations existing between that city and the ports of Southern Europe. The remains of this notable building enabled Viollet-le-Duc to complete his studies as to the architectural features of town-halls of the period named. The edifices at Stralsund and Rostock partake to a certain extent of the general features of that of Lübeck. In Dantzic, however the town-hall is of a different style of

architecture, dating from the early part of the sixteenth century. It has a tower, such as is found in similar buildings constructed about the same time. This structure seems to have been designed for judicial and municipal purposes alone, there being no provision for banqueting-rooms, &c., in its architectural arrangements. The custom seems to have sprung up about this time of building a hall for festivities close to the town-hall. The Luneberg building is, however, an exception in this respect. The town-halls of Göttingen, Einbeck, and Duderstadt were alluded to as being picturesque in their general plans. The town-hall of Hanover was referred to in special detail. One of the wings dates from the year 1435, and the façade towards the market-place from about 1470. The thirty years' war was injurious to the general prosperity of the district, and the town-hall was allowed to get into a condition which necessitated the restoration commenced in 1654. It had been proposed some twenty years ago to build a new town-hall, but at the urgent instance of the Union of Architects and Engineers the restoration of the old building was determined upon, the artistic success of the work being too well known to need detailed comment.

The Engineering Section was occupied with the discussion of the best means of regulating the stream in the case of navigable rivers, the treatment of the subject having special reference to the Weser. Professor Fränkel described his invention for indicating the tension of different parts of a building under various degrees of burden.

In the progress of the discussion as to the prevention of danger from fire in theatres, Herr Unger urged the necessity of a legislative basis for the regulation of architectural matters affecting theatres. Herr Giese pointed out that no progress of an important nature had been made of late years in the machinery of theatres. Further deliberations on the subject were entrusted to a select commission of delegates. Before the close of the Congress this body reported on the advisability of a proper code of rules being adopted by the German Parliament, which should be drawn up by technical authorities versed in the different branches most interested, such as architecture, stage machinery, theatrical arrangements in general, fire extinguishing, &c.

The engineering section was particularly active during the entire congress. The subject of the flexion of iron bridges was discussed with special reference to the periodical inspection of such structures for the purpose of avoiding catastrophes. The Central Union recently submitted a scheme for this purpose to eight different governments and fifty-five railway administrations. The answers received (from about one-third of the companies thus addressed) show certain differences of opinion on the subject. One company has for years taken steps of a similar character to those recommended. Another thinks them too detailed, and only needful in the case of new bridges. Others have been themselves framing regulations on this subject, which will, in one instance, be replaced by the new scheme. Several companies express their appreciation of the plan, which they intend to adopt. The most suitable interval between these periodical examinations is thought by various administrations to be from three to five years, the latter term being specially applicable to small bridges. The methods of testing the flexion seem to be varied in their character, as also in the manner of applying the weight. Some companies employ an ordinary goods train, but in most cases two locomotives are placed with their fore parts together, and with goods trucks attached. A third engine is sometimes added, but in such cases it is empty. Many of the companies which have furnished such particulars precede the trials with moving weight by a test lasting five minutes with weight not in motion. A proposal made by Dr. Fritzsche, of Dresden, that the importance of uniformity in the tests applied should be represented to the various railway companies, was adopted.

An important paper was read by Professor Inze, of Aix-la-Chapelle, on the use of steel for building purposes, in which he attributed its limited employment to the reluctance of the profession to use a material the merits of which had not been fully ascertained. He alluded to the progress German steel manufacturers have been making of late years, and stated that exports have been made to England for Ad-

miralty purposes. As to the application of steel to building purposes, he remarked that recent trials in England had resulted favourably, while the extra expense of steel against iron was, in some instances, of a relatively unimportant character.

The Congress was noteworthy for the important part which out-of-door work occupied in the proceedings. The various interesting architectural features of Hanover were the subject of special attention.

The visits paid to Brunswick and Bremen by the Congress were also of a highly interesting character, and amply repaid those whose zeal in the cause of professional science induced them to take these two railway journeys in addition to that which had to be undertaken in the first instance to reach the scene of the Congress itself. The usual festal adjuncts were not wanting at any of the points named.

In connexion with the Congress an exhibition took place of the plans sent in for the competition which recently took place for the building of the German Reichstag's new abode. This exhibition was numerously attended, not only by those who had come to the Congress, but also by the public at large.

#### THE BRITISH ARCHÆOLOGICAL ASSOCIATION AT PLYMOUTH.

RESUMING our notes \* of last week's archæological congress at Plymouth, we proceed to go a little into detail as to Wednesday's proceedings, already briefly mentioned. The excursion for the day was to Dartmouth and Totnes. At Dartmouth, St. Saviour's Church was commented upon by Mr. Loftus Brock, who pointed out that the west end corresponded to the date of dedication, and that the east end corresponded to the time of Hawley. The main walls, however, appeared to be of an earlier date. The figures on the pulpit had been taken out, and the emblems and arms of Charles I. inserted. There appeared to be many dates scattered over the church, and the date of the ironwork on the south porch was much discussed, and generally agreed to have been inserted at the time of some repair. The handsome rood-screen was generally admired for the variety of its tints and intricacy of its workmanship. Mr. Brock directed the attention of the visitors to the altar-piece, by Brockdon, the Totnes artist.

On the floor of the chancel the fine brasses were subjected to no small amount of scrutiny and impromptu observations offered by Colonel Bramble. On leaving the church the visitors proceeded to inspect the picturesque old houses in the Butterwalk. Sir James Picton was of opinion that they could certainly not be older than the reign of Elizabeth. Many of the visitors went to the castle, and a small section mounted the hill to see the old church.

The afternoon was devoted to Totnes, where the large granite pebble known as "Brutus's Stone" was inspected. Tradition alleges that on it Brutus of Troy landed, but Mr. Edward Windeatt, a local antiquary, did not appear to cherish a vast amount of respect for the tradition (the haselness of which, if we mistake not, was demonstrated by Dr. Freeman some years ago), in spite of the fact that it has, for a long period, been customary to proclaim from this stone the accession to the crown of a new Sovereign. Thence the visitors wended their way to East-gate,—one of the four original gates, of which two only now remain. The East-gate, which has been much modernised, formerly consisted of two arched portals,—one for carriages, which was enclosed with gates, and a smaller one, "a needle's eye," for foot passengers. It was the roon over the gateway, however, which most enchanted the spectators, there being there a beautiful specimen of the Early Renaissance in the form of a fine coloured carved frieze above the linen panelling, and surrounding the room. The frieze Mr. Brock took to be of sixteenth-century date, and of French or Flemish workmanship. Mr. Windeatt observed that this theory would correspond with the fact that about the time mentioned the merchants of Totnes had considerable dealings with the French and Flemish, and Mr. Brock added, that there was even now carried on a very considerable trade in old carvings from France and Flanders. At Totnes Church the first point that engaged attention was the fact that the fabric was built of red sandstone. It

is curious that there is no other red sandstone building within five miles. The red sandstone in this case appears to have been brought up the river in boats,—a theory supported by the fact that in dredging large blocks of red sandstone have been found in the river. According to Mr. Windeatt, who acted as guide, the earliest notice of the existence of a church in Totnes is in a charter of Jndhel de Totnais, the Norman Baron to whom the Conqueror granted the borough, by which he grants the church referred to in the charter as "eclesiam Sancto Marie de Totoneo" to the great Benedictine Abbey of St. Sergius and St. Bacchus at Angers. The church appears to have been rebuilt, and the new one consecrated by Bishop Bronescombe in 1259. The church was again rebuilt about 200 years afterwards, Bishop Lacy, in 1432 granting an indulgence of forty days to all who contributed to the work. Over the outer doorway of the south porch are the remains of an ancient sun-dial, and what appears to have been three coats of arms. The higher one has the appearance of being the town arms. The inner doorway has over the remains of a saint's niche, and a shield with the arms of Bishop Lacy. About half-way up the fine old tower are three niches containing figures. The centre one is supposed to represent Bishop Lacy, and under the figure, in raised letters,—"I made the Tour." One of the principal objects of interest in the interior is the very handsome carved stone rood-screen under the chancel arch, with two parolose screens. It appears from some ancient documents, that in 35 Henry VI. an order was made by the Corporation (who up to 1836 had control of the church), that the chancel should be divided from the church with freestone, as the cathedral church at Exon was. This screen has recently been restored. The Corporation stalls, which are handsomely carved, were erected in 1636, and stood in front of the screen; they now face the entrance transept. In the south wall of the chancel is a hagioscope, and on the north side a fine rood turret, with stone staircase leading to the rood-loft; the base of the turret has the remains of two piscinas. In the south aisle were noticed the remains of a Perpendicular tomb, to the memory of Walter Smith, who died in 1555. Under the tower arch is a marble monument to the memory of Christopher Blackhall and his four wives. It formerly stood on the south side of the chancel, but has been moved during the restoration to its present position, and Mr. Brock condemned the change in no measured terms. A kneeling figure, with hands clasped, represents the husband, who died in 1635, and beneath are the kneeling figures of his four wives. The restoration of the church had been conducted by Sir Gilbert Scott on such commendable lines that it was with some difficulty that Mr. Brock could bring himself to utter his censure. An adjournment having been made to the ancient Guildhall of the borough, where the visitors were cordially well welcomed by the mayor (Mr. Edward Harris), an inspection was made of the old charters, seals, maces, cups, &c. From the Guildhall the visitors went to the castle of Totnes, which has a circular keep situated on a lofty mound.

On Thursday there was an excursion to the Tavistock and Lydford district. Arrived at Lydford Church, Mr. Brock remarked that the tower was altogether different from anything the Association had yet seen in Devon, and the plan was that of a very ancient building. Having examined the exterior, he found structural indications that the western part never formed a portion of the original building, and it was very possible that the original church consisted only of a simple nave and probably a small chancel. The western part was of the date of the south aisle itself. They had within the walls of this very simple little building evidence of how the growth of the church must have commenced thus from smaller things than we saw now. The tower was built some 2 ft. away from where the old western wall formerly existed. On the north side there were evidences of the outside jamb, the quoins being visible. The builders of the tower, like wise men, erected it so that it would not interfere with the services of the church. With respect to the age of the church, he would not venture to assign a date to the rough walling on the north side where the original wall commenced, because it might be of very great antiquity indeed. Taking the font, however, as evidence of its workmanship, it appeared to be of very early Norman date, but the researchers

which had been made into our old fonts of recent years has shown us several fonts of Saxon date not at all unlike the one here. The windows on the north side of the church were insertions of about the middle of the fourteenth century. To the whole of the remainder of the church,—the beautiful western wall, and the south aisle,—they might assign the middle of the fifteenth century. The tower was particularly interesting, and he commended it to the special notice of the visitors. It was built entirely of granite, and the work was massive and good. The dilapidated condition of the roof Mr. Brock did not suffer to escape his attention, and suggested that it would give the custodians of the fabric some trouble before long. On leaving the church the visitors proceeded to Lydford Castle, where Mr. Worth, F.G.S., undertook to guide the party. There was, he said, no more suggestive site in Devonshire, because they had direct evidence in the earthworks that they were standing within the precincts of one of the great forts of the Damnonii. The church was dedicated to St. Petrock, one of the Saxon saints, which indicated that the origin of Lydford was very early. The castle was surrounded on all sides by valleys, and the point was one of the strongest that could be selected, the earthworks being the most formidable in the county. The place was of such importance in the Saxon times that a mint existed there, and there were in existence several specimens of pennies dating from Saxon times. Before Plymouth existed the Saxons came up and destroyed the mint at Lydford. Whether Lydford itself was destroyed they had no evidence, but its inhabitants must have rapidly recovered themselves if it was, because, in the reign of Edward the Confessor, there was only one town which surpassed Lydford in importance, and that was Exeter. In answer to inquiries, Mr. Brock said that probably much of the existing stonework only dated back as far as the time of King John.

At Tavistock the excursionists found a substantial luncheon awaiting them, provided by His Grace the Duke of Bedford. This having been partaken of, and the Duke's health toasted, the party adjourned to Tavistock Church, upon which some observations were offered by Mr. Brock, who said that the first date found in connexion with the church was 1184, when an important record was discovered which made it clear that the fabric existed in 1134, dedicated to St. Enstachius. The next date found was 1318, when the Bishop of Exeter dedicated the church, which had apparently been rebuilt at that time. He regretted with Mr. Rundle that many rare old documents had been destroyed, in one of which mention was made of a payment to the sacristan of the monastery. Here, as at St. Andrew's, Plymouth, remarked Mr. Brock, the architecture fitted in very badly with the dates. The south aisle he took to be the aisle of St. Thomas à Beckett. It was curious to find in the building occasional traces of the work of the fourteenth century. There was evidence that the church must have been all but remodelled a little later. The building itself exemplified all the points to which he had drawn attention as characteristic of Devonshire churches. There was no clear story, there was the pointed barrel roof, the windows were broad and lofty. There was a chancel arch, which was a usual thing, and there was a western tower, which was a very unusual thing. At the east end they would see fragments of older work. Their experience led them to believe that in these western counties, when Saxon England was under a cloud of heathenism, there existed Christian churches. It was surprising to find that in Devon and Cornwall there were more churches dedicated to the older saints than were to be found in any other part of the country. Escorted by Mr. Brock, the visitors next proceeded to view the site and remains of a church which was probably as large as Exeter Cathedral—Tavistock Abbey. The extent of the space occupied by the buildings, cloisters, and courts had been ascertained from old rentals, in which a certain area is designated as the "Abbey Scite." The remains of the abbey, from the precincts into the gardens, orchards, &c., which probably were extensive, as considerable traces of ponds (perhaps the fish-ponds) were found when the foundations were being excavated for the houses now standing there. The old boundary-walls enclosing the abbey-site,—those facing the river,—having a walk formed on it just below the battlements. A tower-like building of two

stories at the south-west corner of the abbey, which has always been known as the Still House, was much admired, the upper story having been entered from the walk on the south boundary-wall. It has been much altered on the inside. The building now used as the Unitarian Chapel Mr. Brock thought to be undoubtedly the refectory. The stone niche or pulpit in the north wall, where the reader at the meal times of the monks was placed, was original roof still remains, hidden by the plastered ceiling, but the mouldings of the purlins and the ornamental portions of the principal timbers, which projected before the line of the circular ribs, have been cut away. Considerable attention was paid to the entrance to the refectory, with a groined ceiling of stone, and a chamber over, which was formerly approached by a circular stone staircase. This chamber had a handsome oak roof, with trefoiled principles, now much decayed. It is proposed to make a *fac-simile* restoration of roof. Passing on, Mr. Brock indicated the position of an oblong building, the last portions of which were removed about seventy years since, which had been considered to be the kitchen. From what Mr. Rundle had heard from old inhabitants it probably had at one time an upper story. The archway of the site of the watergate had been taken down within Mr. Rundle's remembrance. It was a low four-centred arch of granite, of about 8-ft. opening, and was shown in some old engravings of the remains of the abbey buildings. Formerly there was a ford across the river at this spot, the bridge and weir being of modern construction. Tavistock had, up to the middle of the last century, only two bridges across the Tavy. The east bridge (now destroyed), which was situated some distance above the abbey, and is shown in old engravings of the town as having several pointed arches; and the west bridge now existing, but much modernised, near Fitzford. Nothing of the interior of the upper story of the town gate is left, and the roof is modern. It must have been an apartment of considerable importance; the stone staircase, now taken away, was in the tower at the south-east corner. From what Mr. Rundle had seen at various times when excavations have been made in the road in front of the Bedford Hotel, he felt that he would not be far wrong in saying that there stood the abbey church. The arch, of Early English date, now standing in the churchyard might have been a part of the north side. Eucastic tiles have been found, forming portions of the floor, at about 7 ft. or 8 ft. below the present surface, and near the eastern end a large slab of stone was come upon which seemed to have formed the top of a tomb, and had an abbot's staff carved upon it. Pieces of white Beer stone, richly carved, which looked like portions of tabernacle work, have also been dug up. When old houses in the town, built about the middle of the seventeenth century, have been taken down, numbers of blocks of stone, parts of cusped tracery, foliated capitals of columns, and arched panellings have been discovered built into the walls. These are almost all their Early English or Middle Perpendicular in style. There is a tradition that the chapter-house was where the present Bedford office is now placed. The outer walls were pulled down in the beginning of last century for the sake of the stones, which, it is said, were used for some erections, now part of the Bedford Hotel. In the construction of the abbey, granite was extensively employed for the pinnacles, windows, staircases, &c., but the bulk of the walls, all the square ashlar, much of the tracery of windows, carved caps of columns, and ribs and filling of the groins were made of a compact trappean ash stone, found about two miles from Tavistock. It was a very durable stone. In the more delicate work of the interior of the church a white stone, coming from Beer, was very extensively used, as evidenced by the quantities of pieces of finely-carved work which have at different times been dug up or found embedded in walls built since the dissolution of the monastery. Some of these were richly gilt and coloured.

At an evening meeting held on the return of the excursionists to Plymouth, Mr. J. Phillips read a paper on Abbotkerswell Church, in which it was stated that in the course of recent examinations of the church for the purpose of restoration, (which is about to be undertaken under the direction of Mr. Butterfield), there was discovered, beneath plaster

and whitewash, a much mutilated figure of an effigy, offering various points of interest and speculation as to its purport and date. For this latter, and comparing it with others, it may pass as contemporary with the later portion of the church, and a most singularly graceful and accomplished piece of sculpture it has evidently been. In height it stands about 7 ft. It is completely hollowed out at the back, so that there is now probably nowhere more than a thickness of 4 in. The stone may be Purbeck freestone, but Mr. Phillips thinks it is not unlike that which is raised near Amiens. The head has been encircled by a sculptured crown, with a fillet, in which are ornaments representing precious stones. From beneath the crown fall massive tresses of hair, brought out with unusual elaboration in the sculpture; also from beneath the crown depends a veil at the back. The robe falls in folds to the ground, and has been elaborately decorated, both in a light and also in a black pigment. The sculptured crown of the head has been for the most part cut away. Mr. Franks, of the British Museum, to whom a sketch was sent, could only compare it to the crown of Richard Cœur de Lion in the Cathedral of Rouen. The present position of the figure is very puzzling. It was suggested that at the rebuilding of the church by the abbot and monks of Sherborne, to whom the history of the Lady Goddelm must have been familiar,—as the first mention of the parish is in a cartulary of their abbey, and concerning whom they probably had more information than has reached us,—they desired to commemorate the munificence of the royal lady who founded the church, which had become one of their benefactions.

The other papers read were on "The Antiquity and Antiquities of Plymouth," by Mr. Worth,—and as to which the Rev. W. Lach-Szyrna lamented the destruction of Old Plymouth,—and on a Plymouth hero, "Robert Blake, Colonel and General at Sea, 1657," by Mr. E. G. Bennett.

On Friday there was an excursion to Dartington, Berry, Pomeroy, and Compton Castle. Dartington Hall, the seat of Mr. Arthur Chamberowne, was first visited. Mr. Brock pointed out that the plan of the building was like most of the Domestic houses of the period. It consisted of two quadrangles. The larger of the two, the remains of which still exist, had the domestic offices on both sides of it. The second quadrangle was smaller, and consisted of the best apartments. The work that remained was undoubtedly of the time of the rebuilding of the hall by John Holland, Duke of Exeter, the style being the Transition from the Decorated to the Perpendicular. The mullioned and transomed windows in the tower were no doubt Elizabethan insertions; and the battlements and some of the corbels beside the tower were, he understood, rebuilt by Ugin some years ago.

Berry Pomeroy Castle was treated of in a paper read by Mr. Lyman, who stated that the structure was of the Edwardian period. Mr. Myers spoke of the care which was evidently taken of the ruin by its owner, the Duke of Somerset.

At Compton Castle attention was called to a paper by Mr. Gordon Hills in a past volume of the *Journal* of the Association.

At the evening meeting in Plymouth an interesting paper on "The Old Cornish Tongue and its Remains" was read by the Rev. W. S. Lach-Szyrna.

On Saturday there was a carriage excursion to Slade Hall, Cornwood Church, Fardel, near Ivybridge, and Plympton. At Slade Hall extracts from Risdon's "Survey of Devon" were read appertaining to the building and to Fardel.

Cornwood Church was described by Mr. Brock as one of the most instructive churches to study which the visitors had seen during their tour. I think (he went on to say) we may trace here the gradual development of the church plan from a building comparatively small to one of the present size. The nave I take to be the original form of the church, with, as in this case, the addition of a western tower. The western tower survives; but nothing of the title nave remains. The tower, therefore, of this church is the oldest part; and it is of early date, say—for the purpose of fixing a date,—A.D. 1160 or 1170. The work is, therefore, semi-Norman in its character, the belfry windows being semicircular-headed, and the little tower arch pointed. The remainder of the building, like so many of the Devonshire

churches, is in the Perpendicular style. I can scarcely trust myself when I find flowing Decorated windows in the walls. They are modern, like so many other portions of the building. The pillars between the aisles and nave are very curious, built of granite, and one stone forming each shaft. Following the usual arrangements of these Devonshire churches the older parts are built of rag stone, and the later parts of granite. There are some pretty monuments here. I am glad also to find that the old Jacobean or Elizabethan pulpit has been retained, and a very pretty example it is.

At Fardel, Mr. George Wright read a paper discussing the question whether Sir Walter Raleigh was born at Fardel. He said:—We are now looking upon a spot where much of his early life was passed, and the associations connected with his name become all the more vivid, and the picture, as it were, of the great past in which he was so intimately concerned rises before us. Lysons, in his "Magna Britannica," says:—"Fardel was, in the reign of Henry II., the property of Warren Fitz-Joell, whose heiress brought it to Newton, and the heiress of Newton to Raleigh, of Smallridge. The manor belonged in the reign of William the Conqueror, to Ralph de Pomroy, and afterwards to the Mohuns. In the reign of Henry III. it became the property of Wymand Raleigh, a younger son of the Nettlecomb family, an ancestor of Sir Walter Raleigh, whose grandfather, Wyman Raleigh, conveyed the manor to Sir Nicholas Hyde, Chief Justice of the King's Bench. Fardel was one of the principal seats of the Raleighs, and it was supposed, though erroneously, that the celebrated man of whom I have been speaking was born there. Fardel was, without doubt, his occasional residence. His father was the first of the name that lived there. A letter from Sir Walter Raleigh to one of the Duke family was, a short time since, to be seen at Ullertown House, pasted on a little board for its preservation, with a glass over it. East Budleigh, Poer Hayes, since called Duke's Hayes, was the property and residence of the ancient family of Poer, whose heiress brought it to the Dukes. The old mansion at this place is celebrated, says Lysons, as the birthplace of Sir Walter Raleigh, whose father had a long lease of it under the Dukes, and here, in 1552, the celebrated Sir Walter Raleigh was born. In the letter referred to, dated from the Court, July 26th, 1554, addressed to one of the Dukes' family, he expresses his wish to purchase this place, observing that, if, having been born in the house, he would rather seat himself there than anywhere else.

From Fardel the company drove to Ivy-bridge, and dined together at Mallet's Hotel. On the return journey to Plymouth a halt was made at Plympton, and a couple of hours agreeably occupied in inspecting the old castle and the two churches of St. Mary and St. Maurice, Mr. Brooking Rowe giving an interesting address in reference to the origin and probable date of the castle ruin, and the chief architectural features of the two churches. A brief visit was paid to the Plympton Grammar School, the birthplace of Sir Joshua Reynolds, and also the place where the two other eminent artists, Sir Charles Eastlake and Benjamin Robert Hayden, received their early education.

On Monday last, Port Eliot, St. Germans, and Trematon Castle were visited.

#### UNWRITTEN HISTORY: HOW TO READ IT.

THIS was the subject of an interesting discourse given in the Skating Rink, Southampton, last week, by Dr. John Evans, F.R.S. It was a lecture addressed to the townspeople, and attracted a crowded audience.

Dr. Evans commenced by expressing his approval of the custom, observed now for some years, for one of the members of the association to be deputed to deliver a lecture to the operative classes. Such an occasion afforded a good opportunity of treating some subject which lay within the range of all observers of what was going on in the world and which might be of local interest. It was not easy to find such a subject; yet if he spoke of those who in remote times had lived and laboured in this part of the globe, he should have a theme of general human interest. If, in addition to giving particulars of their mode of life, he pointed out the methods by which our knowledge of the

manners and customs of remote antiquity was obtained, he should assist his hearers to appreciate the value of the application of scientific methods to the study of the past, and to feel that our knowledge of antiquity rested upon something more secure than vague conjecture. The neighbourhood was the home of some of the witnesses he would call. Our best evidence of what must have been the condition of occupants of the earth without the most simple appliances of modern civilisation was to be found in the relics of the past found buried in the earth. The town was formerly known as Hamtune, and North and South were prefixed for distinction. Ham was home, and Tune was probably derived from the name of the river in each case. Going back beyond the Roman occupation of the island we entered the border of the domain of unwritten history. The ancient Britons had coins; particular forms had been found in particular districts; the inscriptions on some determined the names of British princes and the districts in which they reigned. In Hants and Sussex were found coins struck by two princes as to whom written history was silent. In the southern counties, and especially in Kent, coins had been found which were, no doubt, imitations of those made by Philip, the father of Alexander the Great. There was evidence of an uninterrupted succession of coins copied the one from another. The coins justified us in saying that the Southern Britons were sufficiently civilised to make use of a coinage 150 B.C., or a hundred years before Caesar came. Besides coins of gold, silver, and brass or copper, with devices derived from Gaulish copies of a Macedonian original, there were others cast in tin with devices in imitation of some coins of the Marseilles. Many of these had in relief the grain of the wood in which they were cast. They had been found with iron tools and weapons near Lewes. In graves which must have belonged to the first few centuries before Christ there had been found swords of iron, with ornamental bronze sheaths. It was the custom to bury with the dead a number of ornamental or useful objects, and in graves in the Austrian Tyrol had been found swords with hilts of ivory inlaid with amber, daggers with golden sheaths, helmets, girdles, bracelets, brooches, and vessels of bronze. In other graves have been found swords, spear-heads, and hatchets of bronze, of which the iron weapons appear to be imitations. It was inferred that the bronze weapons must have been in use when iron was introduced as a substitute. The terms, "iron age," "bronze age," "stone age," meant certain stages of civilisation, the chronological periods of which would vary in different parts of the world. It was not known when it was discovered that an admixture of tin made copper harder and more fusible, but the discovery was made independently in the New World, for some of the weapons and tools of Peru, made before there was any contact with Europeans, were of bronze of the ordinary composition. The bronze period of Britain was well illustrated by relics (representations of which were shown on the wall). There were swords, spear-heads, daggers, shields, chisels, gonges, and hatchets or axes. In the best-named weapons the gradual development of the socket from the flat hlaudo was traced in curious detail, and the conclusion was drawn that the art of casting hatchets with a socket was introduced into this country from abroad. The bronze-using people were skilful both in founding and in the manufacture of ornaments, and a dagger had been found in Wiltshire as delicately inlaid with gold as any ornament of our own time. But man's history in this stage might be better read on the Continent than at home. In Switzerland, Italy, and the South of France the foundations had survived of the artificial islands carried on piles above the water which the men of those days built to protect themselves against their enemies or wild animals. Those men were bunters and fishermen; to some extent too they were husbandmen, and reaped their corn with sickles of bronze. They made vessels of clay, they could spin and weave both linen and woollen cloth, they possessed domesticated animals,—the dog, ox, sheep, goat, and even the horse. Besides bronze, they used flint for their weapons and other appliances. The number and varieties of instruments of that metal found in Britain seemed to carry us back to 1200 or 1400 B.C. as the beginning of the

bronze period. But the flint arrow-heads and scrapers and the use of stone for battle-axes carried us back to a still earlier chapter of unwritten history. It was astonishing that men in so low a stage of civilisation should have been able to furnish themselves with so many and such perfect appliances made of stone,—hatchets and adzes of flint, with carefully ground edges, hollowed chisels, drills, hammers, knives, and saws. The presence of spindle-whorls, the small fly-wheels by which hand-spinning was carried on,—proved that the art of spinning was known, and charred fragments of woven garments had been found in the lake dwellings of that primitive time. Wheat, barley, and millet, too, were cultivated, and the apple and pear were not only eaten, but stored up for winter consumption. It was impossible to trace the beginnings of that Neolithic period, as it had been called, although we might fix within some centuries the time at which bronze began to supersede stone as material for the most necessary utensils of life. But the circumstances under which the implements of those days were found proved that the general physical features of the country, the alternation of hill and dale and the beds of streams, were much the same as they are in the present. In the facts which he had mentioned there was little to prove the inaccuracy of the popular chronology which fixed the creation of the world about 6,000 years ago. But within the last twenty years a marvellous vista of antiquity had been opened out to us by the researches of geologists. The drifted deposits of the Test and the Itchen, and more strikingly those of the Aron, which joined the sea at Christchurch, proved that the earth was many times older than she had formerly been supposed to be. Some of those drift beds were as much as 90 ft. or 100 ft. above the existing river, and it must have required an enormous amount of time to scoop out channels of such a depth. The discovery also of the bones of the elephant, rhinoceros, hyæna, lion and reindeer, of the pouched marmot, and the Greenland Lemming, pointed to climatic conditions as diverse as could well be imagined from those under which we now lived. At Southampton itself there were beds of old gravel capping the hill at the common, 150 ft. above the sea level, and yet the top of that hill must at one time have been a valley surrounded with hills. Thus the aptness of the comparison, "as old as the hills," was lost, for—

"The hills are shadows and they flow  
From form to form, and nothing stands,  
They melt like mist, the solid lands,  
Like clouds they shape themselves and go."

The Stone Age was divided into two periods. That which he had been describing was called the Surface Stone or Neolithic Period, while the earlier times had been designated the Palæolithic or Ancient Stone Period. The implements of the earlier era were of milder construction, and never had their edges ground. These implements had been generally found in the river drift, whence arose the term, the "River Drift Period." Yet a great gulf of time was fixed between these two periods. There was little doubt that the gravels which now capped Hengistbury Head, Barton, and Hordle, 100 ft. above the sea, were originally deposited in the bed of a river which flowed in an easterly direction, and that the Needles at Alum Bay were the shattered and seaworn remains of an extension of the great chalk ridge of High Down, westward from Freshwater. There must have been a time when the chalk downs of Dorset and of the Isle of Wight formed one continuous ridge, and the island of the sea separated from England by any arm of the sea. In those days, the rivers at Poole, Christchurch, Lymington, and Exbury must have contributed to form one river flowing from east to west, which, in the course of time, had widened until it became the Solent Sea and Spitehead. Thus he had shown, though necessarily in an imperfect manner, that the history of man might be carried so far back into a dim past, and even Egyptian chronology, extending as it did over thousands of years, appeared but to cover a small link in the chain of human existence.

#### South Hampstead Working Men's Club

We note that the designs of Mr. Frederic A. Gosling, of 148, Hampstead-road, London, were selected in competition for the new club-house for above, which is about to be erected on the Fleet-road, Hampstead.

## DRUMLANRIG CASTLE.

In 1842 Queen Victoria visited Dalkeith Palace, the Midlothian residence of the Duke of Buccleuch and Queensberry; in 1882 her Majesty does a like honour to Drumlanrig Castle, another of that nobleman's Scottish residences.

Drumlanrig was built by William, first Duke of Queensberry, who was as hateful to the Scottish Covenanters as he was acceptable to Charles II. It was commenced in 1679, and if reliance can be placed on the dates carved on the various portions of the fabric, occupied ten years in building, and so great was the outlay, that the duke wrote upon the bundle of accounts connected with its erection, a sort of denunciation of any of his posterity who should attempt to discover the extent of his folly,—the diction of the curse is strongly characteristic, though far from elegant.—“The deil pyke oot his een [the devil pick out his eyes] that looks herein,” and only for one night did he occupy the mansion that acquired and long retained the name of “The Duke's Folly.” Drumlanrig, in consequence of its resemblance to Heriot's Hospital, Edinburgh, is said by the guide-books to be work of Inigo Jones. Who was the architect of Heriot's Hospital (1628–60)? is a question that has never been answered, and Jones died in advanced age nearly thirty years before Drumlanrig was commenced.\* Any one searching among the records of hygone English architects will find that Colin Campbell designed the fabric, and any one visiting the churchyard of Drnisdeer, the parish in which Drumlanrig stands, will find there a monument commemorating “James Lukup, master of works at Drumlanrig,” dated 1685; he is represented in a wide-skirted coat buttoned up the sides of the skirts, and having very large cuffs, also buttoned, with a cravat hanging down his breast, and with a broad Lowland bonnet (Tam-o-Shanter), from beneath which his hair descends in full flow upon his shoulders.

Defoe, in his “Tour,” writes “Drumlanrig is like a fine picture in a dirty grotto, or an equestrian statue set up in a barn. It is environed with mountains which have the wildest and most hideous aspect of any in all the south part of Scotland.” Then follows a description of the building, which is better rendered by Pennant, who visited the spot fifty years afterwards.—“A square building extending 145 ft. in front, with a square tower at each corner, and three small turrets on each; over the entrance is a cupola, whose top is in the shape of a vast ducal coronet; within is a court, and at each angle a round tower, containing a staircase; everywhere is a wearisome profusion of hearts carved in stone,—the Douglas arms,—every window, from the bottom to the third story, is well secured with iron bars; the two principal doors have their grated guards, and the cruel dungeon was not forgot; so that the whole has the appearance of a magnificent state prison. . . . The apartments are numerous. The gallery is 108 ft. long; it is ornamented with much of Gibbons's carving and some good portraits, and herby hangings tale.—*London Gazette*, Dec. 31, 1745. “Dumfries, Dec. 24, On Saturday last, the 21st, and the day following, the main body of the rebel army came into this place with the Pretender's son: on Monday morning he marched from hence with them, and proposed to lodge that night at Drumlanrig. They shot a tenant of the Duke of Queensbury's for running out of their way and not returning quickly enough at their call,” &c.; that same night the rugged highlanders bivouacked in the great gallery, and with their broadswords nearly huddled in pieces the portrait (a royal gift) of William III., to mark their detestation of “the Glencoe affair.” Sixty years ago the interior of Drumlanrig was in a sad state of disrepair, and the furniture was very meagre and dilapidated. The State chair of the early dukes and duchesses and the family portraits were the only representatives of the former pride and grandeur; but in the autumn of this present year her Majesty, travelling through Nithsdale, famed in song and story, will see the mountains, not frowning upon Drumlanrig with “wildest and most hideous aspect,” but smiling in garments of purple heather and many-tinted foliage; the

\* Mr. John Hill Burton, in his “History of Scotland,” vol. viii., claims as the work of Sir Robert Aytoun, but he gives no proof. “Mr. Walter Balsanquell, Doctor of Divinity and Master of the Savoy,” by the terms of Heriot's will, furnished the plan. Arnott's “History of Edinburgh” is responsible for the Inigo Jones story. † See *Builder*, August 12, 1882, p. 204, note.

iron bars have long been removed from the windows and the grim gratings from the doors; “the appearance of a magnificent state prison” has changed to that of a palace; from the walls of the gallery William III. (completely restored from his encounter with the M'Donalds) and his consort Mary, and Queen Anne with her consort George Prince of Denmark, look no more on tattered tapestry and cobwebbed carvings, and the gardens that found favour in the eyes of Pennant, and reminded Defoe of Chatsworth, with their arbours and stately hedges and banks of flowers, are as pleasant and trim as when the wife of the third Duke of Queensberry, Catherine Hyde, “Kitty ever bright and young,” paced the terraces listening to one who long enjoyed her patronage and friendship, telling how from a London apprentice he became a London poet, and wrote “The Beggars' Opera.”

## ON CRESSET STONES.

A PAPER on this subject was read at the Royal Archaeological Institute, Carlisle, by the Rev. T. Lees, M.A. Mr. Lees said:—

A cresset was a cup of earthenware or metal, fastened to the top of a pole, and containing a light, and so forming a portable lantern. When the pole was fixed in the earth, and so became a stationary light, the whole apparatus was styled a beacon. In heraldry, the beacon was the badge of Henry V., and appears on the frieze within the chantry over his tomb in Westminster Abbey. The Harleian MS. 104, says,—“The cresset with burning fire was the badge of the Admiralty”; and Mr. J. R. Planché, in explaining this assertion, writes that it was probably “founded on the fact that the badge of John Holland, Duke of Exeter, was a cresset. . . . The cresset of the Hollands, Earls of Kent and Dukes of Exeter, was probably derived from the lordship of Wake, such lights being carried by the watch of the Middle Ages; and the motto of the Wakes of Somerset being still ‘Vigila et Ora.’—‘Watch and Pray’” (“Pursuivant of Arms,” p. 251). The Marquis of Northampton bears for his first crest “on a mount a beacon fired.”

But we are concerned at present not with the heraldic use of the cresset, but with the ecclesiastical; for cresset stones, so far as any evidence has yet appeared, were used only in churches and monasteries.

Dr. Johnson (vol. i., 4to, 1786) defines a cresset as “a great light set upon a beacon, light-house, or watch-tower;” and gives the derivation from the French “*croissette*,” because beacons had crosses antiently on the top.” In his anxiety to give a plausible derivation the good Doctor has made more than one mistake. The old French for a “little cross” is *croisette* with one s. The word *croissette*, with two ss, which he uses, means, “a slip of vine for planting,” and is derived from *cruescere*, to grow. This idea that “cresset” is connected with the word “cross” is not borne out, so far as my knowledge goes, by any example of a cresset surmounted by a cross. The cup containing the light or fire forms the top of the instrument, and has nothing above it. These fire-cups were themselves the cressets apart from the handles to which they were fixed. So we find in the “Rites of Durham” (Surt. Soc., pp. 2, 3), in the description of the St. Katherine window—“And in the said window was there a frame of iron wherein did stand nine very fine cressets of earthen metall filled with tallow, which every night was lighted when the day was gone, to give light to the nine altars and St. Cuthbert's ferriture in that part, and over all the church besides, did burne unto the next morning that the day was broken.”

This application of the word “cresset” to the cup containing the light brings us to the derivation of the word. *Cresset* is the middle English word for a cup or vessel containing light fixed on the top of a pole, and comes to us through the old French *crasset*, a cresset; *croiset*, *creuset*, a crucet, pot, crucible (with which last word it seems most reasonable to ally it), from the Old Dutch *kruse*, a cup or pot. This account of the derivation I owe to Professor Skeat's most valuable “Concise Etymological Dictionary of the English Language,” and I believe it contains the true lineage of this much-disputed word.

From the cup, metal-pot, or crock, the word cresset was transferred to a cavity hollowed out in a stone, in which a light was burned. Hence

the stones containing these cavities are called “Cresset Stones.” There were three of these in the church and monastery of Durham, and we find them described in the “Rites”; one was in the church itself, and the two others in the dormitory. The account of the first runs thus:—“Also there is standing on the South pillar of the Quire doors of the Lanthorne, in a corner of the same pillar, a four squared STONN, which hath been finely wrought, in every square a large fine image, whereon did stand a four-squared stone above that, which had twelve cressets wrought in that stone, which was filled with tallow, and every night one of them was lighted, when the day was gone, and did burne to give light to the monks at midnight, when they came to mattens.” The description of those in the Dorter or Dormitory is as follows:—

“In either end of the same Dorter was a four [fair, *Das*] square stone, wherein was a dozen cressets wrought in either stone, being ever filled and supplied with the cooke as they needed, to give light to the monks and novices, when they rose to their mattens at midnight, and for their other necessary uses.”

From the above extracts we learn that the cressets in this case named were not earthenware or metal cups standing on, or inserted in, the stones, but the actual hollows themselves “wrought” in the stone. This, I trust, will prove to you the fitness of the word which heads this paper to describe these simple *Instrumenta Ecclesiastica*. At a meeting of the C. & W. A. S. held at Furness Abbey, August 7th, 1877, I read a paper on the “Probable Use of Certain Stones found in the Ruins of Calder and Furness.” Two of these stones are undoubtedly cresset stones; and since the appearance of that paper I have received information regarding such stones from various quarters. Sir Henry Dryden has shown the greatest interest in the matter, and it is at his suggestion, and encouraged by his advice and kindly assistance, that I now venture to present this subject to the notice of the Institute. The following list contains particulars of all the examples yet brought to my notice. The Swedish ones I know are called “Holy Water Stones,” or “vats,” but this term seems misapplied.

After describing a number of examples known to him, the writer thus concluded:—

*Sweden, Other Examples.*—Besides the above four stones at Stockholm, there are, I find, letters published from Mr. J. Romilly Allen, which mention more Swedish examples of these interesting relics. (1) One at the church of Strio, in the diocese of Sund, of five holes, forming the cushion cap of a pillar, and somewhat like the Swanwick stone. (2) Another which was originally in the church of Nobbolov, also in Sund. “It has,” says Mr. Allen, “six cups arranged in two rows, and measures, 17 in. by 13 in., being supported on a pillar of 3 ft. high.”

On what ground these Swedish stones are called “vigvattens-sten,” holy-water vessels, I know not. I know of no instance where a holy-water stoup is divided into different compartments. Why should it be? One large stoup or basin would serve the purpose far better than a stone block of equal dimensions, hollowed out into a series of cups. For what object these stones were used in England has, I trust, been made clear by the extracts from the Durham “Rites”; and the soot and fire stains on some of them strongly confirm the correctness of the conclusion that these stones have been simply blocks in which lights were burnt, for the convenience of the ecclesiastics at the night offices of the church, or for domestic use in their dormitories. How far their use extended to the lay-folk we have at present no means of judging.

It does not seem as if any symbolical meaning were attached to the number of cressets in each stone; for we find these numbers varying, sometimes three, sometimes five. Six seems a favourite number, and sixteen (in the Calder stone) the highest number yet known. From the “Notes from the Monuments of St. Mary Magdalen College, Oxford, from the Twelfth to the Seventeenth Century,” by D. W. Macray, we learn that in 1365 “a cresset with fifteen holes and four lamps” was maintained in the Church of Chalgrove, Oxon.

The examples brought before you in this paper all belong to Mediaeval times; but is it not probable that our forefathers of the Middle Ages derived their use of hollowed stones for

light-bolders from still earlier times? May it not be that the discovery of the use of cresset stones is a step (and a long one) towards the elucidation of the purposes to which those cup-marked stones were put, which have formed so long a puzzle to the pre-historic archaeologist?

#### THE PRIMARY COLOURS.\*

Of all the interesting phenomena concerning colour, resulting from recent scientific researches, probably the hypothesis that red, green, and violet are the three primary colour sensations attracts most attention, because of its apparent antagonism with the fact that red, yellow, and blue are the three primary colours of pigments.

All colours are really sensations, caused by the action of light on one of the divisions of the retina, the so-called layer of rods and cones. It has only recently been discovered, however, by Professor Max Schultz, that both the rods and the cones have each their peculiar function, and though probably both serve as elements of light, it is more especially the function of the rods, whilst the perception of colour is due, possibly exclusively, to the cones. These cones appear to be divided into three sets: one set, being stimulated by the strongest vibrations of light, produces the sensation of red; another set, acted upon by the vibrations of medium strength, produces green; and the third set, responding to the short and weak vibrations, produces the sensation of violet. Red, green, and violet are, therefore, termed primary colours. Intermediate vibrations affect two sets of cones simultaneously, and, consequently, produce compound or secondary colours. Upon the three sets of cones being excited together, in their proper proportions, the sensation of white is the consequence. If this theory be true, we may assume the existence of a colour-sense wherever we find the cones, and to mark it absent wherever they are absent. . . .

I have shown that the primary sensations of colour,—red, green, and violet,—cannot be produced by the combination of any of the other colour-rays of white light, but that conversely all the other sensations of colour are obtained by these three colours in different proportions. The same may be said of the primary colours of pigments. Red, yellow, and blue cannot be produced by the mixture of other colour pigments; but these colours are capable of producing by admixture almost all other colours. It will be at once evident that the colours of each set are different, the primary green and violet sensations being substituted by yellow and blues as primary colour pigments; and this substitution causes one to inquire whether the remaining primary of light, red, is of the same hue as the primary pigment of that name? It is here desirable to point out the very general idea the names of colours convey to the mind. When we say red, what do we mean? The term red is often applied to a colour that may be almost orange on the one side or violet on the other, green, commonly speaking, may be almost yellow or blue, violet may mean almost pink or blue. I consider that there is as much difference in the primary red of the spectrum and the primary red pigment as there is between the green light and the yellow pigment, or between the violet light and the blue pigment.

Now the primary red of light is a scarlet red; indeed, in some works the term scarlet has been applied to it. The green light is more inclined to yellow than blue, and the violet light is a decided blue violet, and has been named blue by some writers. In pigments we find that the primary colours are the reverse of this. The best red pigment for the mixture with the greatest number of other colours is a crimson red; the best yellow is more inclined to orange than blue; the best blue is of a green hue. When these pigment colours are lightened by the addition of white, there is obtained, perhaps as near as it is possible to obtain with pigments, the secondary colours of light. It would thus appear that the colours which were formerly considered primary colours, are really the secondary colours of light, and therefore, though red, yellow, and blue may be the primary colours of pigments, they are certainly not primary colour sensations caused by the vibrations of light.

\* From a paper by Mr. G. H. Morton, jun., read before the Literary and Philosophical Society of Liverpool.

#### THE FORTH BRIDGE.

IN Section G (Mechanical Science) of the British Association meeting at Southampton, Mr. B. Baker read a paper on the Forth Bridge, in which it was stated that the report of the Anthropometric Committee showed that the average stature of a new-born infant was 19.34 in., while the average height of the Guardsman sent out to Egypt was officially given at 5 ft. 10½ in. These figures had a ratio of 1 to 3.65, and as the largest railway-bridge in this country,—the Britannia Bridge,—had a span of 465 ft., and the Forth Bridge a span of 1,700 ft., the ratio there was also 1 to 3.65. Hence to enable any one to appreciate the size of the Forth Bridge the following simple rule-of-three sum was suggested:—As a Grenadier Guardsman is to a new-born infant so is the Forth Bridge to the largest railway-bridge yet built in this country. Bridges a few feet larger in span than the Britannia had been built elsewhere, but they were baby bridges after all. It was not the physical features of the country, but the habits of the population that rendered the construction of a 1,700 ft. span expedient. The Act for constructing a bridge at Queensferry across the Forth was obtained in 1873, and the contract for the construction of Sir Thomas Bouch's great suspension-bridge in two spans was made, the preliminary works being in progress when the Tay Bridge fell. In consequence of the latter disaster, the directors of the Forth Bridge Company decided not to proceed with the works, and an Abandonment Bill was promoted in the Session of 1881. Different railway companies, interested in securing direct communication with the North of Scotland, objected to the abandonment of the enterprise, and instructed their consulting engineers, Messrs. J. Fowler, Harrison, and Barlow, to report anew on the practicability and cost of crossing the Forth by a bridge or otherwise, at Queensferry or elsewhere. A careful re-investigation of the whole question was accordingly made, with the result that the directors were advised that it was perfectly practicable to build a bridge across the Forth which would comply with the requirements of the Board of Trade and public safety, and that the best place of crossing was Queensferry. The Abandonment Bill, which had passed the Commons, was then withdrawn, and the engineers were instructed to agree on a design. Modifications of the original suspension-bridge were then considered, and Mr. Fowler and the writer of the paper submitted a project for a bridge on the continuous-girder principle. Messrs. Harrison and Barlow, fully appreciating the advantages which would pertain to such a bridge, as compared with a more or less flexible suspension bridge, made independent investigations, and suggested several modifications, and finally the design, a model and plans of which were now before the meeting, was unanimously agreed upon by all to be recommended to the directors for adoption. The directors acted upon this recommendation, and the necessary plans were deposited, and an Act obtained this year for constructing a continuous-girder bridge across the Forth at Queensferry, having two spans of 1,700 ft., two of 675 ft., fourteen of 168 ft. and six of 50 ft., and giving a clear headway for navigation purposes of 150 ft. above high-water spring tides. For this work Mr. Fowler and the author of the paper were acting as engineers. Every one, probably, would concede that a girder-bridge would prove stiffer than a suspension-bridge, but it was not so obvious that it would be cheaper. Careful comparative estimates had, however, proved this to be so in the case of the Forth Bridge. Having explained the reasons which induced the engineers to fix on the length and width and other matters connected with the design of the bridge, the paper stated that the superstructure would be of steel. For the tension members the steel used was to have an ultimate tensile strength of not less than 30 tons, nor more than 33 tons per square inch, with an elongation of 20 per cent in a length of 8 in. For the compression members the strength was to be from 34 tons to 37 tons, and the elongation 17 per cent. In making the tubes and other members, all plates and bars which can be bent cold were to be so treated, and where heating was essential no work was to be done upon the material after it had fallen to a blue heat. The steady pressure of hydraulic presses was to be substituted for hammering where practicable,

and annealing would be required if the steel had been distressed in any way. Having given details in reference to the bridge compared with others, the paper stated that no special difficulty would arise with respect to the foundations. The total length of the great continuous-girder was 5,330 ft., or, say a mile, and of the viaduct approaches 2,754 ft., or rather over half a mile. The piers would be of rubble masonry, faced with granite, and the superstructure of iron lattice girders, with buckled-plate floor and trough-rail bearers, as in the instance of the main spans. The main girders spaced 16 ft. apart would be placed under the railway, and there would be a strong parapet and wind-screen to protect the trains. About 42,000 tons of steel would be used in the superstructure of the main spans, and 3,000 tons of wrought-iron in that of the viaduct approach. The total quantity of masonry in the piers and foundations would be about 125,000 cubic yards, and the estimated cost of the entire work upon the basis of the prices at which the original suspension-bridge was contracted for, was about 1,500,000*l.*, though, owing to the magnitude and novelty of the undertaking, the estimate must be taken as approximate only, as a contract had not yet been concluded for the works.

#### A NEW PAINTING FOUND AT POMPEII.

MR. ESTACE NEVILLE ROLES, in a letter to the *Times*, dated Naples, August 23rd, says:—"An important painting has been found at Pompeii, and was yesterday placed in the Naples Museum among the Pompeian frescoes. It represents the judgment of Solomon, and is the first picture on a sacred subject, the first fragment either of Judaism or Christianity, that has been discovered in the buried cities. The picture is 5 ft. 6 in. long, and 19 in. in height, and is surrounded by a black line about 1 in. in width. The scene is laid upon a terrace in front of a house adorned with creeping plants, and shaded with a white awning. On a dais (represented as being about 4 ft. high) sits the King, holding a sceptre, and robed in white. On each side of him sits a councillor, and behind them six soldiers under arms. The king is represented as leaning over the front of the dais towards a woman in a green robe, who kneels before him with dishevelled hair and outstretched hands. In the centre of the court is a three-legged table, like a butcher's block, upon which lies an infant, who is held in a recumbent position, in spite of his struggles, by a woman wearing a turban. A soldier in armour, and wearing a helmet with a long red plume, holds the legs of the infant, and is about to cleave it in two with his falchion. A group of spectators completes the picture, which contains in all nineteen figures. The drawing is poor, but the colours are particularly bright, and the preservation is excellent. As a work of art, it is below the average Pompeian standard, but it is full of spirit, and drawn with great freedom. The bodies of the figures are dwarfed, and their heads (out of all proportion) large, which gives colour to the assertion that it was intended for a caricature directed against the Jews and their religion. This may be so, but my own impression is that the artist was anxious to develop the facial expression, and to do this, exaggerated the heads. There is nothing of caricature about it in other respects."

#### AN ANCIENT BUILDING CONTRACT.

At a recent meeting of the Berlin Archaeological Society, a description was given by Herr Curtius of a stone tablet which had been discovered in April at the Piræus, containing details of the contract entered into for building a house intended for the reception of naval stores, &c. The details show that at the early period in question the Greeks were careful in such matters. Provision seems to have been specially made for openings in the walls for purposes of ventilation.

The Traffic of Regent-street and Pall Mall is suspended in consequence of the streets being paved by the Asphaltic Wood Pavement Company, Limited. The company has also been entrusted by the Corporation of Leeds with the contract for the repaving of St. Paul's-street and Aire-street in that town.

## THE LATE MR. EDMUND WALKER.

I HAVE looked in vain for an obituary notice in your Journal of the late Mr. Edmund Walker, of Maitland Park, N.W., an artist well known to architects, many of whom will be sorry to learn he passed away on July 9th, aged 68. To his skill in water-colour drawings not a few of the leading architects of present and past days have been indebted for his highly artistic rendering of their perspective outlines; and they could always rely upon him for rapidity as well as excellence. His professional career is full of historical interest. Some forty years ago he had a lucrative practice in miniatures on ivory, and was well supported. The Daguerrotype process, followed by photography, destroyed that connexion. He then visited many of the country seats in England, Chatsworth amongst the rest, and made local and finished drawings of the mansions, whose owners readily purchased them. Prior to 1851 he became connected with the then firm of Day & Son, and executed all those noted large interiors of the Great Exhibition of that year, first in water-colours and afterwards in chromo-lithography. On his judgment and taste the late Sir Joseph Paxton, Sir Digby Wyatt, and Owen Jones largely relied for the effective placing of the principal objects in that exhibition; and the late Captain Powke engaged him for similar drawings for the 1862 Exhibition; but those were not published.

He was commissioned to paint the Opening Ceremony of the Horticultural Gardens, but as the Queen was prevented being present the picture passed into the hands of the Baroness Burdett-Goutts. The first water-colour drawings of the Thames Embankment exhibited by Mr. Bazalgette in the Royal Academy, which all who then saw them will doubtless well remember, were by Mr. Walker, and it was not uncommon in those days for his work to be seen in a dozen or more drawings in a single year in the Architectural Room of the Academy Exhibition. His artistic powers were versatile,—buildings, landscapes, figures, battle-scenes, and any other subjects were handled in a masterly way. All the sketches made by Mr. Simpson during the Crimean War were rendered by Walker as finished productions in chromo-lithography, and afterwards those of the Indian Mutiny, published by Messrs. Day & Son. In the misfortunes of that firm he largely participated, a blow from which he never fully recovered. His gentlemanly bearing, and refined feeling, and honourable dealings, added to his ready apprehension of what was wanted, and his punctuality in keeping engagements, attached many architects to him very closely, and the profession has sustained a loss.

II. J. PALL.

## OBITUARY.

*Mr. James Inman.*—Died, on Friday, the 25th ult., in his 72nd year, Mr. James Inman, long in the employ of Messrs. Crace, of Wigmore-street, and for the greater part of the term their trusted and respected foreman. Mr. Inman was Messrs. Crace's foreman of painters, and had remained continuously in their employ for fifty years and some few weeks at the time of his death, which occurred suddenly on his return home from his day's work. It was later by his boast that he had never, during the whole of that time, been five minutes late in coming to work in the morning; and this was literally true at the time of his death, for he was at his post at six o'clock on the morning of his death, though contrary to the advice of his employers, he having shown signs of ailing the previous day. It is, perhaps, needless to say that he was a most careful and temperate man, and had made his employers' interests his own chief interest. They lost a valued and trusty old friend.

**Sale of Land at Clacton-on-Sea.**—On Monday last, by direction of the Clacton-on-Sea and General Land, Building, and Investment Company, Limited, Messrs. Harman & Matthews, auctioneers, held their second sale this season of freehold building land at Clacton-on-Sea. A large number of small plots, realising in the aggregate about 4,500l., were sold, and a large plot, having a frontage of 400 ft. to Harold-road, was sold for 600l.

## THE EXPLORATIONS OF ROMAN VILLA AT BRADING.

LADY OGLANDER (having acquired that portion which belonged to Mrs. Munns) has granted a lease of the whole site of the Roman villa at Morton to Messrs. John E. Price and F. G. Hilton Price, to enable them to continue the explorations.

As these gentlemen, who formerly acted as executive for the committee that was formed, have now full legal right to carry on the work themselves, the functions of the committee, it is thought, may cease.

It is proposed, therefore, to hold a final meeting of the committee on this Thursday, the 31st of August, at one o'clock, on the site of the Villa, to report the work done and to dissolve. The arrangement certainly does not commend itself to us. It may be all right, but the statement reads oddly.

## THE "NOVELTY" THEATRE.

THIS theatre, as we stated in our last, is approaching completion, and will probably be opened some time in October. The theatre occupies a site on the north side of Great Queen-street, Lincoln's Inn-fields, and has a long frontage to Parker-street. The architect is Mr. Thomas Verity, whose plans have been well carried out by Messrs. Kirk & Randall, the well-known contractors, whose representative on the works is Mr. E. Smith, Mr. H. M. Taylor being the clerk of works. The theatre will accommodate in all from 1,400 to 1,500 persons, thus distributed:—In the pit, 500; in the stalls, 90; dress-circle tier and private boxes on same tier, 150; upper-circle tier and private boxes, 150; gallery, 600. The principal portions of the theatre are approached by a handsome and roomy vestibule, entered from Great Queen-street. The theatre itself is placed at right angles to this vestibule, or, in other words, parallel with Great Queen-street, the stage being at the west end. The private boxes will be provided with movable partitions, so as to allow of two or three compartments being thrown into one when necessary. The whole of the construction of the box and gallery tiers is of iron and concrete, by Messrs. Deunet & Ingle, who have also supplied the iron girder carrying the wall above the proscenium opening, and the girders which carry the flank walls over the private boxes. Behind those flank walls, and over the second tier of boxes, are located dressing-rooms and other apartments connected with the stage department of the theatre; these, however, are quite isolated by fireproof construction from the auditorium. By means of a mezzanine, two stories of dressing-rooms are obtained in the height of the gallery tier at each side of the theatre, the gallery only occupying the central portion of the tier, and not extending over the private boxes. Besides the dressing-rooms already named, there is, at the back of the stage on the side next Parker-street, a tier of six other dressing-rooms. The depth of the stage from back to front is about 27 ft. The width of proscenium opening is 26 ft. 6 in. The whole of the decorations will be in fibrous plaster by Messrs. George Jackson & Sons, of Bathone-place. The sanitary fittings throughout will be supplied and fitted by Messrs. John Bolding & Sons. The sun-burners in theatre and foyer are by Messrs. Strods & Co.; the revolving steel shutters at the entrance to vestibule are by Messrs. Archibald Smith & Stevens, of Leicester-square; and the effective ornamental ironwork in handrail to principal staircase and elsewhere is by Messrs. W. T. Allen & Co. The excavations for the building have been carried down 22 ft. into the blue clay, and this has involved the underpinning of the somewhat dilapidated properties by which the theatre is almost completely hemmed in except on the Parker-street side. The vestibule, which forms the principal entrance from Great Queen-street, is 56 ft. long by 26 ft. wide. This vestibule is on a level with, and affords direct access to, the dress-circle tier, the private boxes being reached by descending a few steps. An extra exit for this tier is provided, opening into Parker-street. The upper circle is reached from the vestibule either by means of the grand staircase leading up to the foyer, or by the upper-circle staircase on the opposite side of the vestibule,—the latter staircase being continued up to the gallery with the view of serving as a supplementary

exit from that portion of the house, should it ever be necessary. There is also an extra exit from the upper-circle tier into Parker-street. The entrance to the pit is from Great Queen-street, by a passage on the east side of the vestibule, leading to a flight of steps going down to the pit. There is another exit from the pit into Parker-street. The gallery entrance is from Parker-street. For every part of the house there is thus provided means of exit in addition to those afforded by the entrances. There are nototrious passages, no winding stairs, and all the staircases are of stone. On each tier there will be provided a refreshment saloon and separate retiring-rooms for ladies and gentlemen. The foyer is a handsome room over the vestibule on the upper-circle level, and looking into Great Queen-street. It will measure 33 ft. by 26 ft., and be 20 ft. high to the ceiling. This will, it is stated, be made into a very attractive picture-gallery. The amount of Messrs. Kirk & Randall's contract is between 10,000l. and 11,000l., but the total cost will be not far short of 15,000l.

## EXTENSIVE ROMAN REMAINS AT BATH.

We have already incidentally alluded to the excavations which have been for some time in progress on the site of the Roman baths, and we are indebted to *Keene's Bath Journal* for some details concerning a bath which is now being excavated. The *Journal* says,—

In the centre of a large rectangular area is sunk a bath, nearly 80 ft. long and 35 ft. wide, its sides formed by six continuous steps. The bath is 4 ft. 9 in. deep. On the north and south sides,—the lengthways of the bath,—are massive pedestals with moulded base, and upon them were built the piers and columns that supported the roof. These pedestals are about 13 ft. apart, and are of a particularly massive character. Midway on the north side is a small reclining figure, which, much to the regret of antiquaries, has been damaged very considerably. In the centre of the figure is an aperture, which probably served as a channel for a pipe which conveyed the water to supply the bath. The steps leading from the figure are "notched," and a small pier of masonry juts out into the bath, and this, it is believed, formed a basin upon which, in all probability, rested a trough or basin to receive the water flowing from the pipe, and thence was allowed to overflow into the bath. The whole of the bottom of the bath is covered with lead, which remains as originally laid on a bed of concrete, and the thorough and complete manner in which the bath was erected may be inferred from the fact that a layer of freestone, about 1 ft. thick, served as a foundation to the whole. At the four corners of the bath are apses (semicircular recesses), and midway on the north and south sides are square recesses; each angle is finished with a pedestal having a moulded base. A portion of the bath was covered in with a light but strong roof of hollow bricks of Roman manufacture. A large number of these bricks have been found among the debris, but some doubt has been expressed as to whether they were used for the purpose of a roof. These hollow bricks, it has hitherto been supposed, were used only in connexion with the conveying of heat from the hypocaust fires, but in the course of the excavations masses of these tiles were met with, which, on careful investigation, and examination, suggested to Mr. Maun (in whose hands the work had been placed) the idea that they were portions of an arched roof.

The stone used throughout is the freestone so plentifully found in the quarries around Bath. The lead in all probability came from the Mendip hills. . . .

Amongst other interesting objects discovered during the excavations is a rude representation of Minerva, which was found nearly at the bottom of the bath. The face and helmet are damaged and the spear-head broken. The owl resting on the shield is also somewhat damaged, but still recognisable, and the head of Medusa as a breast-plate stands out very clear. In connexion with this it may be mentioned that in 1790, under the foundations of the present Pump-room remains of a temple to Minerva were found.

The Antiquities Committee, who have proceeded with the work of uncovering these remains, are to be congratulated upon the

success which has so far crowned their labours. Much, no doubt, remains to be done, and money is needed to enable them to complete the work. We cannot, however, conceive that the learned world will withhold its aid.

Mr. Jerom Murch is the chairman of the Antiquities Committee, and (under the supervision of Mr. Davis, the surveyor of works to the Corporation) the work is being carried out in a satisfactory manner by Mr. R. Mann, the contractor.

#### COMPETITIONS.

*Sculptural Panels for St. George's Hall, Liverpool.*—The committee appointed to consider the designs received in the above competition have decided to recommend the Council to award the premiums as follows:—No. 1, 200*l.*, Mr. Thomas Sterling Lee, Merton Villa Studio, 280*a*, King's-road, Chelsea, London; No. 2, 100*l.*, Mr. J. Milo Griffith, 243, Stanhope-street, Regent's Park, London; No. 3, 50*l.*, Mr. W. S. Frith, 386, Clapham-road, London. The designs which have received the first premium represent Wisdom, Justice, Temperance, Orpheus, Tragedy, Comedy, and Astronomy. The author of these designs remarks that the parts of the building designed for the introduction of the sculpture naturally resolve themselves into four grand divisions or series, and may be grouped thus:—First series: The six panels on the left of the entrance to be devoted to the attributes and results of Justice. Second series: The six panels on the right of the entrance to be devoted to the causes and results of National Prosperity. Third series: The eleven panels at the north or Concert-room end, nine panels of which are on the circular portion, to be devoted to subjects symbolised by the Nine Muses, and the two on the return flanks to be devoted to Orpheus, as symbolical of Singing, and to Tubal Cain, as symbolical of harmony. Fourth series: The remaining five panels at the corners of the building to be devoted to subjects emblematic of the Arts.

*The Ebbw Vale Market Company (Limited),* having offered the sum of 20*l.* for the best design for a new market-house, to be built near the London and North-Western Station, Ebbw Vale, plans from various architects were submitted, and those prepared by Mr. E. A. Lansdowne, of Newport, Mon., finally accepted. The stalls for poultry, butter, basket-fruit, vegetables, clothes, and boots and shoes, will be made to travel on rails to the end of the hall, where they will form supports of the large platform when the building is used for public entertainments, concerts, &c. The butchers' stalls will be open. The main walls will be of blue pennant stone, with Bath stone dressings, and the roofs formed of angle and bar iron. The total cost, when finished, will be about 2,000*l.*

#### GLASGOW MUNICIPAL OFFICES COMPETITION.

SIR,—In making a cube estimate of my design, to which the first premium was awarded in the first competition, I valued the whole at 1*s.* a cubic foot, taking the height in the usual way, from the bottom of the foundations up to half the height of the roof, the result being 150,432*l.* The towers were included in that valuation at the same rate.

Mr. Barry, in his report, said that he considered the estimate insufficient, and that it would require 220,000*l.*, without reckoning the sculpture.

The author of the design now adopted, estimated the basement story up to the ground-floor line at 9*d.* a cubic foot; thence, to half the height of the roof at 1*s.*; and the towers above that level at 1*s.* 6*d.*

Mr. Barry considers this estimate sufficient. I have not seen Mr. Young's design, but from the published descriptions it does not appear to be any less elaborate than mine.

If that is the case, Mr. Barry has evidently modified his views of the cost of building in Glasgow to a very considerable extent.

G. CONSON.

#### TAR ROOFS.

THE German Government has on several occasions pointed out to farmers and others interested in agriculture, that too great an expenditure of capital on buildings is a mistake.

With a view of illustrating the application of this principle of economy to roofing, the *Cologne Gazette* points out that the system of using tar for roofing purposes is at the same time economical and suitable for agricultural buildings, and what is said may serve as an answer to a recent inquiry in our own pages. The framework of the roof can be of relatively slight construction on account of the nature of the covering it is intended to support, and the perpendicular height of the roof can be one-eighth to one-tenth of the entire depth of the building. The distance of the rafters is arranged according to the width of the covering material, the scale being that from the middle of one rafter to the middle of another. The distance should be 2½ in. less than the width of tar roofing sheets.

Immediately above the rafters come boards, and upon these (exactly in the centre of the separate rafters) are placed strong laths, about 2 in. wide and 1½ in. thick, the upper edges being taken off. The roofing sheets are now placed so as to cover the spaces between the laths, and are nailed. Over the laths are placed strips of paper, 5 in. to 6 in. wide, fastened with nails at intervals of 2½ in.

In order to make the sheets lie smoothly upon the boarding, it is suggested, in case they are too dry, to soften them by immersion in water. It is recommended that the workmen should not wear heavy-nailed boots, and also that if the rain comes on, the roof should not be walked upon immediately after. When the entire surface of the roof is covered with sheets, the strips of paper (or caps) already named, as well as the joints, are painted over with a hot mixture of coal tar and pulverised limo. Pure dry sand is at once sprinkled over this coating, and particular care must be taken that all the nail-heads are well covered. When the paint is dry the whole surface of the roof is once more coated with the same mixture, and is sanded.

The object of this careful method of over-laying the roof with several coatings of specially prepared solutions is to preserve in the tar those oleaginous and fatty properties which it soon loses if exposed to the air, and the retention of which is an indispensable condition of its resistance to water. Clay and sand do not afford sufficient protection, as they are removed by violent winds.

Reference is made to various systems of coating the tar roof with protective substances, for the purpose indicated. One of the most successful methods consists of a mixture of cow-dung and thin white-lime, which is spread over the entire surface of the roof. If such a coating is not applied, the tar paint must during the first four years, be annually renewed, which enhances the cost of the roof. If the last-named protective composition is used, and renewed every two years, the coating of tar and lime can be dispensed with. Particular mention is, however, made of a coating of tar, mixed with Portland cement, the tar being well heated and used in the proportion of 111 lb. to 200 lb. of cement. The mixture should be kept well stirred during preparation, and should be applied as soon as made. This particular method has been tried in many cases in Germany, and according to the journal quoted from, its satisfactory results have caused its adoption upon a scale of progressive importance.

#### ST. JAMES'S RESIDENTIAL CHAMBERS.

A VERY extensive block of buildings, called St. James's Residential Chambers, covering an area of upwards of 13,000 superficial feet, is at present in course of erection at the West End. The premises are situated between King-street and Jermyn-street, and have a frontage to Duke-street 110 ft. in length, and one to Ryder-street 119 ft. long. They are faced with Prudham stone, from the quarries near Newcastle-on-Tyne. The two elevations, which are strictly uniform in their architectural character, have three lofty stories above the ground-floor, the third story being surmounted by a bold and richly-carved cornice. The height of the elevation to the top of this cornice is 50 ft. Above rises a high-pitched roof, in which there are two additional floors, the upper floor having pediment dormers. The entire height of the building to the ridge of the roof is 75 ft. The ground-floor of both frontages will consist of shops, each shop having handsome elliptical-headed windows, with rusticated and fluted

pilasters between each shop. At the west end of the Ryder-street frontage there is an arched entrance, 10 ft. in width, to the Turkish Baths in Jermyn-street, the proprietor having a private right of way from Ryder-street to the baths. Above the shops there is an ornamental cornice. The first and second floors have each a range of eight arched and pediment bay-windows, the columns at each angle of the bays being ornamentally carved and paneled. The third-floor windows are three-light. The entrances to the chambers will be in hot streets, leading to spacious and decorated staircases.

The interior of the buildings is well arranged for their intended purpose. The first and second floors will consist of suites of two rooms each, viz., a living and a bed room, each suite having separate bath-room and other conveniences. There will be ten of these suites on each floor. The rooms are all of uniform size,—20 ft. 6 in. square. The third floor will consist of twenty single rooms, each room having a separate bath, as in the suites on the first and second floor. The fourth floor in the roof will be similarly arranged as the third floor. The attic floor will be reserved for the servants. The kitchen and culinary department will be in the basement, from which there will be a lift to the top of the building. The whole of the floors, with the exception of the attic, are fireproof.

Messrs. Jamesson & Wallis, of Great Russell-street, Bloomsbury, are the architects, and Messrs. W. & C. Macgregor, of London and Edinburgh, the contractors. Mr. Lawson is clerk of the works.

#### GREAT TEY CHURCH, ESSEX.

ONE of the most interesting specimens of church architecture visited during the late excursion of the Essex Archaeological Society was the Church of Great Tey, dedicated to St. Barnabas. Mr. G. Golding draws attention to its miserable condition.

The fine Norman work of the eleventh century consists chiefly of the square central tower (all now left), itself well worthy of a visit. It is of pure Norman architecture, having been a cruciform structure, with nave, aisles, two transepts, and chancel; but the state of the interior of the sacred edifice presents a series of Vandalisms happily now seldom met with. The pews are placed facing west in the chancel, which is at the east end, the nave having been suffered to fall into total decay and ruin, and is totally gone. This of a church stated in the Clergy List to be, with vicarage and sinecure attached, of the now value of above 1,050*l.* yearly.

#### THE CHURCH IN SCOTLAND.

SIR,—In your issue of July 1st I observe that you enter among the items of "Dissenting Church Building News" a notice of the new Episcopal church at Keith, Scotland. Now, as a Scottish "Episcopalian" Churchman I protest against our churches being described as "Dissenting." The term is as wrong in fact as it is in principle. The Episcopal Church of Scotland is not in any sense a dissenting church. Politically and historically it is the oldest religious body in Scotland, and was disestablished in 1638 in favour of Presbyterianism. Therefore whatever it dissents from, it cannot be said to dissent from the Establishment. To term Churchmen Dissenters in Scotland would but raise a smile on the face of every Presbyterian who heard it. The term "dissenter" is, however, a purely English one, and is practically unknown in Scotland. In your columns it is clearly used as meaning a Christian community outside the Church of England. Hence the Episcopal Church of Scotland being in full communion with the Anglican Church is manifestly not a dissenter from it. It has already been shown as being no dissenter from the Scottish Presbyterian Church. Therefore in no sense is it a dissenting church.

I would, however, suggest that your division of news of ecclesiastical building into "Church" and "Dissenting Church" is, for a secular journal, an infelicitous one. Rather I would prefer to see all Christian denominations classed in one column, such as Church of England, Church of Ireland, Episcopal Church of Scotland, Established Church of Scotland, Wesleyans, Independents, Roman Catholics, &c.

India, July 30. SCOTO-CATHOLIC.

## BUILDING PATENT RECORD.\*

## APPLICATIONS FOR LETTERS PATENT.

- 3,956. J. H. Johnson, London. Production of artificial stone or marble. (Com. by the Certaldo Marble Company, Paris.) Aug. 18, 1882.
- 3,965. S. Cornforth, Birmingham. Apparatus for punching nail holes in roofing slates. Aug. 18, 1882.
- 3,969. J. Chaffin, Charlcombe. Glazing green-houses, &c. Aug. 19, 1882.
- 3,990. E. Tomlinson, London. Apparatus to facilitate the lighting of fires, &c. Aug. 19, 1882.
- 4,000. A. Keim, Munich. Process for rendering wall-paintings weatherproof. Aug. 21, 1882.
- 4,002. R. W. Crabtree, Leeds. Kitchen ranges. Aug. 21, 1882.
- 4,031. W. R. Lake, London. Heating apparatus. (Com. by M. J. Walsh, New York, U.S.A.) Aug. 22, 1882.

## NOTICES TO PROCEED

have been given by the following applicants on the dates named:—

August 22, 1882.

- 1,828. A. Smith, Huddersfield. Securing and holding sliding window-sashes in a closed or open position. April 17, 1882.
- 2,017. H. J. Haddan, London. Manufacture of mosaics. (Com. by G. Stanley, Massachusetts, U.S.A.) April 28, 1882.
- 3,944. G. J. Dickenson, Albany, U.S.A. Sash-fasteners. Aug. 17, 1882.

August 25, 1882.

- 1,916. T. A. Riggs, Aldeburg. Combination of substances for bricks, blocks, &c. April 22, 1882.
- 1,959. J. Noad, East Ham, and H. Salomon, London. Manufacture of ornamental surfaces for building, &c. April 25, 1882.
- 1,974. J. Henson, Derby. Barns and shelters with rising and falling roofs. April 26, 1882.
- 1,979. J. Beresford, Birmingham. Urinals. April 20, 1882.

## ABRIDGMENTS OF SPECIFICATIONS.

Published during the Week ending August 26, 1882.

237. M. Delmard, Plumstead. Window-sash fastener. Jan. 17, 1882. Price 2d.
- An eccentric cam is mounted on the lower sash, which, on being turned, engages a hooked stud on the upper sash. (Pro. Pro.)
258. B. G. Greig, London. Stoves for heating and ventilating. (Com. by the Detroit Stove Works Company, Detroit, U.S.A.) Jan. 18, 1882. Price 1s.
- The improvements are in a number of details which are not capable of being summarised. The principal one is that a separate shell surrounds the magazine section through which air circulates and is warmed.
261. E. L. Voice, London. Decoration of wall surfaces and ceilings. Jan. 19, 1882. Price 2d.
- The decoration is effected by laying on the finishing coat of plaster with a composition of cement mixed with colouring matter and a small proportion of sand. The ornaments are then cut out of the plaster, and filled in with suitable colour. After drying the surface may then be painted. (Pro. Pro.)
265. J. Westley, Chorley. Rollers and fittings for blinds. Jan. 19, 1882. Price 2d.
- A groove is formed in the roller, and a strip made to fit the groove. When the end of the blind is placed in the groove the strip is forced in and secures the blind. (Pro. Pro.)
276. T. Rowan, London. Ventilating water-closets, urinals, drains, &c. Jan. 19, 1882. Price 6d.
- This is an improvement on Patents Nos. 5,303 of 1880, 162 of 1881, and 545 of 1881, in employing jets of water for producing an induced current for carrying off the foul air and gases.
295. S. H. Terry, London. Water-closets and urinals. Jan. 20, 1882. Price 6d.
- Instead of using a hand-lever for actuating the valves, &c., a pedal lever is employed.
306. G. Smith, Bradford. Application of earthenware pipes for conveyance of gas, water, sewage, &c. Jan. 21, 1882. Price 2d.
- These are embedded in cement or concrete to enable them to withstand the pressure and prevent leakage. (Pro. Pro.)
317. J. Holroyd, Leeds. Sanitary trough closets. Jan. 21, 1882. Price 6d.
- This is an improvement on Patent No. 2,915 of 1879, in making the outlet above the bottom of the trough to ensure a continuous supply of water therein. The bottom inclines

upwards to lead the material to the outlet. The trough is flushed from the other end.

351. J. Holroyd, Leeds. Tanks for flushing and ventilating drains. Jan. 24, 1882. Price 6d.

These are constructed of earthenware pipes, at the bottom of which is the outlet-valve, which is opened periodically. A man-hole on the surface of the ground, covered with a grating, is provided for ventilation, &c.

## CONVICTION FOR BUILDING ON AN ADVANCED LINE OF FRONTAGE.

At the Edmonton Petty Sessions on Monday week, and by adjournment on Monday last, was heard, before Mr. M. Latham and other Justices, a summons, issued at the instance of the Tottenham Local Board of Health, against Herbert Oxenham, of Berwyn House, Finsbury-road, Wood Green, "For that he unlawfully, and without the consent in writing of the Urban Authority of the Tottenham District, did bring forward a certain house forming part of a street there, called Bounds-green, and beyond the front wall of the house on one of the sides of such house, and did continue such offence for three days after receiving a written notice in that behalf from the said Urban Authority to remove the same."

Mr. Crowne, clerk to the Tottenham Local Board, said the defendant was summoned for a violation of the 156th section of the Public Health Act, and that he was liable to a penalty of 40s. a day after a written notice had been given to him that he was committing the offence. The Local Board had not given him the consent to bring out his buildings, and in the month of April last he had a distinct notice that he could not erect his buildings until the line of frontage had been decided upon by the Board.

Mr. De Pape, surveyor to the Local Board, said he had inspected the site on which the defendant was erecting some houses, and those houses next to it, which he knew were erected over six years ago. The frontage of those built by the defendant was 10 ft. 3 in. beyond that of the others. No application had been made for permission to bring out the fronts, nor would the witness have advised the Board to consent to such an application.

Mr. Woodgate, barrister, who appeared for the defendant, subjected the witness to a long examination on technical points, the principal being the meaning of the term, "line of frontage."

Mr. Wilson, inspector of buildings to the Local Board, proved having served the summons on the defendant on the 5th ult. He saw the defendant, and expressed his dissatisfaction with the footings and brickwork of the buildings, and the defendant removed them. It was not his duty to define the line of frontage, and he had no conversation with the defendant on that subject.

The Bench determined, before giving their decision, to view the site and buildings, which they accordingly did.

Mr. Latham, on the matter coming before the Bench again, said they had given a great deal of attention to the case, and had been to view the place, and in the opinion of a majority of the justices, there must be a penalty of 40s. for the original offence, but not a continuing penalty. It was a decision in which he himself did not concur, but a majority of the Court were of the opinion he had stated. He believed the technicality of the Act was not met by the facts of the case.

The defendant said he discontinued the building on receiving the notice.

Mr. Latham said that was the reason they did not inflict a continuing penalty.

An appeal was then asked on the part of the defendant, and at once granted by the Bench.

## WIND PRESSURE.

In the Mechanical Science Section of the British Association meeting at Southampton, the first business on Tuesday last was the reception of the report of the Committee on Wind Pressure:—

Stated that the total pressure on small plane surfaces due to actual winds in high and exposed positions had to a great extent been ascertained with sufficient accuracy for engineering purposes. It must be assumed, for the present at least, that, for engineering purposes, pressures of 80 lb. or even 90 lb. per square foot on surfaces had been correctly recorded in extremely exposed positions, such as the Bidstone Observatory; while pressures approaching the limit prescribed by the Board of Trade, 56 lb.

per square foot, might possibly act on engineering structures in exposed positions. As in the design of marine works, the depth of water and the length of fetch enabled some estimate to be made of the strength of structure required to withstand the heaviest seas to which they might be exposed, so a careful comparison of the wind pressure observed during the height of a gale at various stations where anemometers existed would enable some estimate of the relative exposure of similar places to be made. Exceptionally high gusts of short duration should be excluded from the comparison as being probably limited in area.

In the course of the discussion which followed, Mr. Barlow expressed the opinion that any work made strong enough to withstand the regulation pressure of the Board of Trade would not be in danger from any wind which would ever blow in this country.

The Committee was re-appointed.

## RAILWAY CLOCKS.

Sir,—Having read Mr. Morgan's letter in last week's *Builder* about the regulating of railway clocks, I would ask you to allow me a small space in your paper for a few words on the subject. My excuse for taking the liberty is that I have had many years' experience both in making railway watches and clocks, and in attending to the clocks on the lines.

I quite agree with Mr. Morgan's remarks that railway clocks ought to show, as near as possible, the correct time, and that the present state of railway clocks, and, I may say, of most of our public clocks, is far from satisfactory; but there are difficulties which non-watchmakers are not likely to see. All railway stations shake very much when a train passes or comes to a sudden standstill, and the pendulum is thereby disturbed each time. The pallets of station clocks wear in a remarkable way, and differently from other clocks, showing distinctly the trembling of the pendulum when the trains pass. The temperature, also, is very variable, and many of the stations,—in fact most of them,—are very damp. Some of the above-mentioned difficulties could be overcome to a great extent, but at present they are disregarded altogether. Clocks are fixed in places where it is impossible for any clock to go correctly. Railway clocks may be seen in all conceivable places, some sticking out from the wall like a lamp, others suspended like a trapeze; some are made to carry several sets of hands, and constructed so that it is utterly impossible for the different hands to show the same time. As far as my experience goes, it is a question of expense; the price paid at present for railway clocks and for keeping them in order is much too low to obtain correct timekeeping.

CHRISTIAN LANGE.

## OLD BUILDINGS, YARMOUTH.

Sir,—At a recent special meeting of the Great Yarmouth Lands Committee it was carried "That the old Tolhouse hall and the entire contiguous property be sold, the fixtures, materials, and ground in separate lots; the total amount thus realised to be applied to the funds for defraying the costs of the erection of the new municipal buildings."

Unless some steps are taken at once, or a strong protest raised, the above quaint and interesting old building must rapidly disappear, as in about three weeks or a month the sale will take place.

Your readers may possibly remember the building in Middlegate-street, with its external staircase inclosed with a wooden balustrade, its unadorned and blue-coloured figure of justice holding the sword and scales, and surrounded by the arms of the town; and its high-pitched roof, with gable windows. Herein was the Hall of Justice,—since the time of King John,—and it has been the scene of many trials of pirates and prisoners.

Underneath "the great chamber at the Tolhouse hall," as Manship writes (and it is but a small place after all), are many dungeons and the gaoler's house, in which felons and debtors were, until lately, confined. At the top of the staircase from the street, and also in the pratorium (as it is described), are two beautiful Early English doors, the latter having a double row of dog-tooth mouldings, and being in a perfect state of preservation, and which probably formed a portion of the monastery of Grey Friars, who settled on adjacent property in 1270.

The building is now untenanted, owing to the courts being removed to the new town-hall, but it is to be hoped that such an historical building may not fall into the hands of the despoiler, but may eventually be retained as a museum for the display of much that it is the pride and good fortune of Yarmouth to possess.

E. PRESTON WILLIAMS.

\* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street.

KING'S CROSS TO FARRINGTON-STREET.  
WORKMEN'S TRAINS.

SIR,—In the body of an average working man, what proportion does the width across the shoulders bear to the thickness from front to back? After many experiments, I find it to be as 8 is to 5. The experiments were conducted in this way. Having, some little time back, to carry out a job in the City, I left my lodgings near Russell-square to catch an early workmen's train at King's-Cross Station of the Underground Railway. There are five of these trains between 5.50 and 6.50 a.m. and the first two are almost invariably found to have every seat occupied on arrival at King's-cross, where very few get out, and from 100 to 200 are waiting to get in to be conveyed Citywards. The compartments accommodate five persons on each seat, and as it is essential that the workmen should be at their work, and not standing catching cold on the platform, they crowd into the standing-room between the knees of the sitters, to the extent I have indicated,—five on each seat, and eight standing edgewise between them.

Of course these experiments,—which, doubtless, are being continued,—are very unpleasant for those engaged in them, and are, I believe, contrary to law; and I have sometimes wondered whether the Board of Trade or other proper authority would interfere if it should come to their knowledge.

In the labour list you published on the 12th ult., the rate of wages of plumbers in Birmingham is given as 7d. per hour; it should be 8½d. per hour in town, and 9d. per hour on country jobs, with lodging and travelling money.\*

E. GAMES.

WATERPROOF CEMENT, &c.

SIR,—Before touching the above subject, I wish to ask if it is known where or how a good yellow can be procured that will stand the chemical action of Portland cement when it is incorporated in the body of that material? Also, a black and a yellow to withstand the caustic properties of silicate of soda and potash, separately or combined with the various compounds, cements, and limes? If any of your readers can supply the required information, it would be of good service. In surface decoration it is simple, which is no test proof for the above.

I have long and often used coppers mixed and gauged with Portland cement, oxide of zinc, and magnesia, likewise in other compounds, cements, and limes, and I have found it equal in every particular to their more natural chlorides, and in some respects far superior both with and without the silicates; and when well beaten up or ground when gauged I have never experienced in it a tendency to crack, even though the cement may be too fresh (which is overcome at all times with a small percentage of lime putty). The less lime, of course, is the best; and by reversing this we add a small percentage of Portland cement to any of the lime, say, from 1 to 10 per cent., either of which will greatly improve the limes: the most suitable for brick-laying or pointing, and for plastering,—more so where exposed to the damp of the weather.

To obtain a yellow, I have in the same manner used picric acid with and without ochre, and this I have immersed in strong solutions of coppers; also a solution of picric acid, and the two combined, but the nearest approach to a yellow gained even then has been a dull fawn colour.

Ultramarine blue will stand, and with or without it, by choosing a fine Portland cement, submitted to a bath of either coppers and picric acid, a deep bronze-like green of a metallic cast is produced; a corresponding effect, but of a more varied kind, is obtained with other colours, and where a variety of coloured parts are brought in juxtaposition it has a very remarkable and beautiful effect, some of the lighter colours becoming much changed. These processes, employed with that I have shown and explained to you at various times, if properly developed, would most certainly and fully realise the long-sought quest of the Social Science Congress and other science assemblies, for the artistic, architectural, and horticultural improvements of our streets, town and country houses, from the mansion to the cottage.

EDWIN ROBBINS.

P.S.—Further to improve the colour, and render it still more durable and waterproof, I saturate or coat the same with paraffin and petroleum, as represented by Herr C. Puscher, but in addition I use tallow, and with paraffin and soap dissolved in hydro-carbon, &c., which gives a splendid polish. Yet to further firm, heighten, and protect the same, I coat it with silicate of soda, which I first rub with a cloth slightly dampened with a chloride of lime, which no water will penetrate or stain. This will give a most perfect face to plaster or Keene's cement, as proved in the Marezzo marble by me at various works, the receipt for which I sold for 2l. in 1876.

\* We gave our authority.

PROVINCIAL NEWS.

**Bideford.**—The new bridge buildings recently erected at the western extremity of Bideford Longbridge, overlooking the river, and also facing the Guildhall, are about to be formally opened. The records of the old buildings formerly occupying the site, and which comprised the Bridge Hall, Grammar School, and Free School, are of some interest. The new buildings have been erected at a cost of about 4,000l., the architect being Mr. Brydon, and the contractor Mr. R. T. Hookway, Bideford. On three sides the structure abuts on main thoroughfares, viz., the Quay, Bridge-street, and Allhalland-street. The main front and entrance are in Bridge-street, facing the Town-hall. Along the Quay the buildings extend 60 ft. in length by 50 ft. in height. The Bridge-street façade has similar dimensions, while in Allhalland-street the measurements are,—length, 50 ft.; height, 40 ft. Facing the river are three stories, the first affording accommodation for the Public Free Library and Reading-room, the second throughout its whole length comprising the new Bridge Chamber, while the upper story on this side, together with one or two additional rooms, is intended for the use of science and art classes. The stono used for the walls is from a local quarry, while the window-jambes, mullions, and ornamental portions are of Ham-hill stone. Quite a feature in the exterior of the edifice is the carved work by Mr. Harry Hems, of Exeter.

**Liverpool.**—Mr. G. F. Lyster, engineer to the Mersey Docks and Harbour Board, in his annual report, says of the Mersey Tunnel works:—“On the Liverpool side a second shaft has been sunk in connexion with the Mersey Tunnel, and the drainage heading driven for a length of 355 ft. The tunnel is driven for a length of 490 ft., of which 365 ft. is lined with brickwork. At Woodside the drainage heading is driven for a length of 1,070 ft., of which 645 ft. is lined with brickwork, and the tunnel has been driven for a length of 760 ft., of which 400 ft. is lined with brickwork.”

**Lincoln.**—A new “Coffee Palace” on the High Bridge, Lincoln, has been opened, in premises formerly occupied by Messrs. Fox & Son, ironmongers. The alterations have been carried out by Messrs. Martin & Sims, from plans prepared by Messrs. Watkins & Scorer; and the fittings, &c., were supplied by various local tradesmen.

VARIORUM.

A NEW and enlarged edition of “Elements of Acoustics, Light, and Heat,” is published by Messrs. William Collins, Sons, & Co., and as this is the fortieth thousand, nothing need be said of it. A selection of questions from some of the former Government papers, with their solutions, is given, and will be found useful.—We have before us a new edition of another work on physics of much larger scope and more important character, namely, the “Elementary Treatise on Natural Philosophy,” by A. Privat Deschanel, translated, with modifications, by J. D. Everett, F.R.S. (Blackie & Son, Old Bailey). The fact that a book of this size and character has passed through six editions gives satisfactory indication of the increased study of science.—It is proposed to publish by subscription (Infield, Fleet-street) in a handsome crown 4to. volume, “Bramshill: its History and Architecture,” by Sir William H. Copc, bart. The history will be traced from the eleventh century down to recent times, with notices of its successive owners and occupants, the architecture, external and internal, of the present mansion.—Sir J. H. Ramsay has continued his investigations on the national finances in the fourteenth and fifteenth centuries, and an article on the accounts of Henry IV. (in continuation of a former one on the accounts of Richard II.) appears in the September number of the *Antiquary*.—The publication of a curious collection of the London signs of booksellers, publishers, and printers up to the end of the seventeenth century is commenced in the September number of the *Bibliographer*.—Under new auspices the *Pictorial World* will, on the 2nd of September, appear in a permanently enlarged form, and with every material promise of greatly extended popularity. There is to be a coloured supplement every week, the first series being portraits of the generals commanding the forces

in Egypt. The name of Messrs. Dalziel will guarantee the excellence of the engravings on wood.

Miscellaneous.

**The Water Supply of Leeds.**—Mr. Meysie Thompson, in his paper on the history of engineering in Leeds, recently read before the Institution of Mechanical Engineers, said, on the subject of the town's water supply.—In connexion with the engineering of Leeds, it will be interesting to mention the works, now nearly completed, for supplying Leeds with water. The operations at present in progress consist of the construction of a reservoir at Eecup, about five miles from Leeds, which is intended to contain, when completed, 1,400 million gallons of water. This is about six months' storage at the present rate of consumption; and, as the water will enter in a regulated quantity at one end, and be drawn out at the same rate at the other end, it is anticipated that the purity will be much increased by slow deposition during so long a period. The water is, in the first place, obtained from the moors about twenty miles from Leeds, the area of watershed drained being 25,000 acres. This water is collected in three reservoirs at Lindley Wood, Swinley, and Tewston, about thirteen miles from Leeds as the crow flies, their respective capacities being 750, 900, and 870 million gallons, with a total water acreage of 426 acres. From these reservoirs the water will gravitate to Eecup, through two 30 in. pipes, and from Eecup it will flow through a tunnel under Black Moor, and thence by a 40 in. pipe to the filter-beds at Weetwood, whence it will be distributed to the several parts of the town. The grand total capacity of the four reservoirs mentioned will be 3,980 million gallons. The present daily consumption of water averages 7½ million gallons, the population supplied being about 300,000 persons. It may be stated that the present charge for water collected, stored, transmitted, filtered, and delivered to the consumers in Leeds is 1½d. per ton.

**A Relic of the South Devon Atmospheric Railway.**—Another of the towers, built some thirty-five years ago, when it was intended to work the South Devon Railway on the atmospheric principle, has ceased to exist. A few months ago it was decided to remove the tower standing near the village of Exminster, and it was suggested that dynamic should be used for the purpose. The work was entrusted to Mr. Wilson, clerk of works on the Powderham Estate. A few days since all the preparations were completed, and it was determined to light the fuse as soon as the mid-day express had passed. The greatest care and caution were needed to be exercised, as close on the one side was the railway and on the other a large pond, and Mr. Wilson's anxiety was to prevent the falling *débris* interfering with either. Holes were made in the tower for six cartridges. At the appointed time the fuse was lighted; in about three minutes the explosion followed, and the building, which seemed at first to lift slightly, suddenly collapsed like a house built with cards. The work was carried out with complete success; only about a wheelbarrowful of the *débris* fell across the down line, and this was cleared away in about two minutes. The tower was over 70 ft. high, and in its construction between 60,000 and 70,000 bricks were used.

**Exhibition of Domestic Appliances.**—An exhibition of domestic appliances is now open at the Agricultural Hall, Islington. The show is consequent upon the success which attended the exhibition of March last year, and has been organised by Mr. Chas. Messent, who was also connected with the Furniture Exhibition held last May. The exhibition will continue open until Sept. 7.

**The Welsh National Eisteddfod.**—At the Cymrodorion meeting on the 23rd ult., a paper by Mr. Cave Thomas, “On making the Eisteddfod a greater Institution, and connecting with it Scholarships and Athletic and Military Sports, and having a Permanent Building for it,” excited much discussion, the provision of a movable building being largely advocated.

**Middlesbrough.**—The Church of St. John, Middlesbrough, is about to have added to it a spire. The architects are Messrs. Alexander & Rowland, of Middlesbrough, and Mr. T. Dickinson, of Saltburn, is the contractor for the work.

**Examinations of the Society of Arts, Manufactures, and Commerce.— Programme for 1883.**—The attention of secretaries of institutions and others interested in the Society of Arts' examinations is especially drawn to the fact that important alterations have been made in the examination system. The following are the principal points in which changes have been made since the publication of last year's programme:—1. The examinations in subjects of "Commercial Knowledge" have been renewed. 2. The three subjects, "Clothing," "Cookery," "Housekeeping," &c., will be comprised in a single paper, under the head of "Domestic Economy." The examination in "Health" will be continued under the title of "Sanitary Knowledge." 3. A fee of 2s. 6d. will be required from each candidate in each subject, except Practical Music, for which special fees are required. 4. No prizes will be given in any subject. 5. Certificates in three classes will be given. 6. The restriction as to the age of the candidates has been removed. 7. An examination will be held in any subject of "Commercial Knowledge," in addition to those already in the programme, for which twenty-five candidates offer themselves, provided the Council approve of the subject. The subjects of examination for 1883 will be:—1. Arithmetic; 2. English, including composition and correspondence, and *profs* writing; 3. Book-keeping; 4. Commercial Geography and History; 5. Short-hand; 6. French; 7. German; 8. Italian; 9. Spanish; 10. Political Economy; 11. Domestic Economy; 12. Sanitary Knowledge; 13. Theory of Music; 14. Practical Music. In addition to the above subjects, the Society will provide for an examination in any other subject which may fairly be comprised in "Commercial Knowledge," and of which the Council approve, provided not less than twenty-five candidates are guaranteed for each subject. The examinations in all the subjects, except practical Music, will be held on the evenings of Monday, the 9th, Tuesday, the 10th, and Wednesday, the 11th of April. The complete programmes can be had upon application to the Secretary of the Society of Arts, John-street, Adelphi, W.C.

**The Public Offices Site Bill.**—The protest in the House of Lords against the Public Offices Site Bill (signed by Lords Redesdale, Fortescue, De L'Isle and Dudley, and Stratheaden and Campbell) expresses dissent from that measure because the Parliament-street and Great George-street site has long been considered the proper one for the Admiralty and War Office, and a considerable amount of property on it has been purchased by Government and a large extent of public land left unprofitably vacant for many years on that account; and because, among other reasons, the Bill only gets possession of the Spring Gardens property unaccompanied by any plan of the manner in which the buildings to be erected on it are to be applied to the Admiralty and War Office respectively, or of their architecture and elevation, leaving it uncertain whether the site will afford sufficient accommodation for those two great offices, or how far the aspect of the Horse Guards and Parade may be deteriorated by the new buildings. Further, because if the Admiralty is transferred to a new site, the present Admiralty buildings will give the means of concentrating in an economical manner, in a most convenient situation, a number of small offices now scattered over the town at a great expense and inconvenience.

**Houses in Barnet.**—James Rogers, the secretary of the Maldon Loan Company, London-road, Maldon, Essex, has appeared at the Barnet Petty Sessions to answer a summons charging him with having allowed a house to be occupied without giving to the Local Board the requisite notice. Mr. Rumble, surveyor to the East Barnet Valley Local Board, stated that a row of houses belonging to the defendant's company were being built at East Barnet. The architect was informed that when the houses were finished notice would have to be given to the surveyor so that he could inspect the houses and certify whether they were fit or not for habitation. A few weeks ago witness went to the house and found one of them finished, and persons living in it. The defendant, in answer to the charge, said that the builder of the houses was instructed by him when the houses were finished to give the necessary notice, but this the builder had failed to do. The Bench ordered the defendant to pay 20s. including costs. The fine and costs were at once paid.

**Excavations at Lewes Priory.**—These excavations have been pushed on steadily during the last fortnight, and despite the huge accumulation of *debris*, amounting to as much as 12 ft. in depth in most places, which has had to be cut through, it is now possible to make out more or less accurately the disposition of the buildings whose sites have been excavated. The substructure of the dormitory which occupies most of this area is formed of a number of square chambers communicating with each other by wide single arches or double doorways. Most of these, however, have been filled in at some later period, but prior to the suppression, with chalk masonry, probably on account of some threatened collapse of the Roman work. The walls are in some places still covered with a most perfect coating of plaster, a mode of treatment far more prevalent in olden times than is usually supposed. By kind permission of the London, Brighton, and South Coast Railway Company, excavations have been made in the sides of the cutting through which the railway passes. These were most successful, resulting in the finding of the north-east angle of the refectory and the adjacent angle of the cloister. Behind these was uncovered an ample circular staircase or vice, corresponding in position with the one still existing on the south. It is to be hoped the railway company will cause these to be preserved to view and not covered up again. The line of the east wall of the cloister has been carried across the railway, and the continuation of it which formed the great south transept wall discovered in the bank. Similarly the north wall of the refectory has been opened out near the underground conduit, commonly known as the "barren" or "prison" (l). It is now possible to ascertain the exact site of the cloister, and therefore of the nave of the great church of which a fragment of the west end was uncovered some years ago. Next week we hope to announce further discoveries in connexion with this last most interesting point.—*Sussex Advertiser*.

TENDERS

For works at Salthill, for Mr. G. Hughes:—

	Stables and cottages.	Stops and gates.
D. C. Jones & Co., Gloucester	£1,222 0 0	£50 0 0
Ashford, Slough	1,082 0 0	61 0 0
J. Deverill, Slough	996 0 0	48 0 0
A. L. Oades & Sons, Egham	985 0 0	49 0 0

### The Social Science Association.

THE present Secretary of the Social Science Association, Mr. J. L. Clifford-Smith, has published, as a kind of commentary on the occasion of the twenty-fifth anniversary of the Association, a small book giving an account of the founding of the Association and of the work it has accomplished. Mr. Clifford-Smith has proved himself a most able and energetic secretary, upon whose engagement the Association may be congratulated; and therefore it is not from any want of recognition of his real merits in such a post that we express some dissatisfaction with the little volume in question, which, on his part, is an entirely extra labour, outside of the necessary duties of his office, the good intention of which we fully appreciate. But the account appears to have been compiled under rather a strong bias towards the legal side of the work of the Association,—a bias, perhaps, furnished partly by those who have supplied the author with some of the information and assistance which he acknowledges, and perhaps arising partly from the fact that the plan of the book seems to have been to dwell especially on those portions of the work of the Association which have led directly to special legislation. But this, though it may be the species of work most easily tabulated, certainly does not represent all that the Association has accomplished; and we complain that its sanitary work, and the influence which it has exercised on sanitary improvement, have been far greater and more important than the reader of this chronicle of the Association would be led to suppose; and in so far the said chronicle is unsatisfactory and rather misleading.

The Social Science Association originated, our readers may be reminded, in the house of Lord Brougham, who was president of several of the Annual Congresses, and was, in fact, appointed the first provisional president, Mr. Hastings, the president of this year, being the first general secretary. The specified object of the Association was "to afford to those engaged in all the various efforts happily begun for the improvement of the people an opportunity of considering social economics as a great whole." The advantage of such a generalisation of the subject and of opportunities of discussion was fully acknowledged at the time; and with the continually increasing complication of social life the necessity for this united action and general discussion certainly cannot have decreased, though some part of the work pro-

posed may have been definitely accomplished as far as it is possible for the present to carry it. In regard to the classification of subjects treated by the Association, it may be observed that during the first three years of its existence the classification was under five heads, under the respective titles,—(1), Jurisprudence and Amendment of the Law; (2), Education; (3), Punishment and Reformation; (4), Public Health; and (5), Social Economy. A section for "Trade and International Law" was added to these in 1860; but in 1863 the secretaries were directed to consider and report to the Council "whether any and what alterations are desirable in the designation and business of the departments." A few words from the report presented may perhaps advantageously be quoted here. The questions of "designation" and "business" were taken separately, and in regard to the first it was suggested that:—

"The fundamental conception of the Association was that of a united body dealing with the science of society as a whole, but divided, for purposes of practical utility, into so many divisions as would answer to the leading divisions of that science. The style of 'departments,' rather than 'sections,' was proposed for these divisions, to show that they were intended not to be mere temporary adjustments, but to form a true and exhaustive nomenclature of the permanent heads of Social Science. It was supposed from the first that it might become expedient from time to time to divide more than one of the departments into sections, which might be accommodated with separate rooms at the annual meetings, and have the benefit of separate secretaries and committees. But it was also an essential element of the original idea that the division into departments should be scientific, and therefore exhaustive and final, and that any further development should take place by sub-division, and not by anomalous additions." In pursuance of this idea, the distribution was suggested into the departments of Jurisprudence, Education, Health, Economy, and "Art," or (as the last was defined) "the aesthetic recreative life of the people." These heads, the secretaries thought, seemed to exhaust the entire conditions of society; and it will be observed that the idea of setting apart a department for the consideration of artistic subjects, though only recently adopted, was officially suggested at an early stage in the history of the Association.

This idea of representative "departments," to be subdivided when necessary into "sections," has been adhered to, and the "Society for the Amendment of the Law" having been shortly after this date incorporated in the Social Science Association, the first department assumed the title which it still retains,— "Jurisprudence and Amendment of the Law," with sub-sections for International and Municipal Law and Repression of Crime. The other departments remain as suggested in the above

statement. It was the suggestion at the time that the idea of a department for art should first be experimentally tried by forming a section of the Education Department for the consideration of artistic subjects. This, however, was not done, and the subject dropped until the formation of the Art Department in 1876. We confess we have often had our doubts whether the subjects now discussed in the Art Department might not have been as well and even more suitably classed under a section of the Education Department. The first subject for this year in the Art Department, for instance,—the Royal College of Music,—is really an educational subject; and artistic questions can only be treated in reference to their bearing on popular education or amusement. If the Department proceeded to deal with subjects more directly connected with artistic style and design, it would then be going out of the proper path of the Association, and assuming the functions of a lecturer on art,—a mistake which, in fact, has once or twice been made.

In regard to the two departments with which we are especially concerned, those relating to Health and Art, the questions to be discussed in the former at this year's congress are almost entirely questions of administration, and not of sanitary arrangement or construction; or where they are not merely administrative, they are essentially medical, and therefore touch less upon our special province than is usually the case. Of the questions to be discussed in the Art Department, two are of rather special interest. One of these is on the proposed Royal College of Music, the most important move in musical education in this country which has been made; and though this, as already observed, is a subject which might not unreasonably be supposed to belong as much to the Education as to the Art Department, we have very little doubt that music will receive more intelligent and sympathetic treatment in the latter than it would have been likely to receive in the former department, as at present constituted. The paper on this subject must, however, we presume, be rather one conveying information or making suggestions than raising a discussion, as the establishment of the college is now a foregone conclusion, and probably will, in every way, be advantageous to the promotion of musical education, though it will not necessarily do anything to quicken into new life an art which we fear has now pretty well achieved what it can achieve. The third question, in regard to the limits of conservatism to be observed in the treatment of ancient buildings, deals, we need not say, with a subject which has been botly discussed of late years, and on which some calm and considerate criticism is very much needed; for at present the controversy seems for the most part to have oscillated between vandalism,—the vandalism either of reckless pulling down or of reckless restoration,—on the one hand, and bigoted and unpractical

opposition to all restoration on the other hand. The advocates of the preservation of ancient buildings seem to ignore the present altogether, and to put aside all practical considerations in connexion with the present use of buildings, and all idea of the possibilities of an art of today, in favour of preserving intact every crumbling shred of the art of the past, good or bad; the antiquity of even a century being sufficient to render everything admirable. We are, both by conviction and tradition, as much opposed to wanton destruction or wrong treatment of old buildings as any one could be, but the present has its claims as well as the past, and we hope they will not be lost sight of in the discussion of the subject at Nottingham.

The second question of the Art Department, "In what way can the influence of art be best brought to bear on the masses of the population in large towns?" belongs to a class of questions which have been repeated in somewhat varying terms ever since the Art Department was started, and to which there is little hope of finding a definite answer; though we do not by any means say that on that account it is not worth while to ask the question. It is the repetition, in fact, of the almost hopeless query which arises again and again in the minds of those who contemplate the mass of struggling and unhealthy and unbecoming life in our large towns, how shall we make this mass of human life more good, more beautiful, and less ugly? The more fortunate among us find the contemplation and enjoyment of beauty and of beautiful things one of the chief and highest pleasures of our lives; the sources of this enjoyment are open to us, but they are not open to the poorer masses of the population; and if they were, where is the intellectual culture to appreciate and enjoy them? How are we, without entering on a system of artistic "pauperising," to bring within reach of the poorer class the sources of artistic enjoyment, and how, if we can accomplish that, can we give them eyes to see and heads to understand? The question is continually before us; and, as we have said, no definite answer, no infallible system, seems possible in regard to it; we cannot suggest any special course, and say "Do this, and you will humanise and refine the masses." Hence this class of question is sometimes rather too hastily regarded as vague and unpractical. It is so, doubtless, if we expect definite answers to it, or to find a definite course which will operate as an immediate and certain specific. But each answer given to the question may be one suggestion that may be acted upon by some persons, in some places, and may produce its effect, slowly and imperceptibly very likely; for in such a matter as this we can only expect to progress little by little; but it does not follow that any words spoken on the subject are thrown away because their immediate practical bearing is not very obvious. Let the question be discussed as much and as often as possible, and we shall by degrees get nearer the solution of it. One reason for being less hopeless about it than we might otherwise be is this, that it is after all not so much a question of educating people to understand art, as of bringing art to them to be understood. For art is, to a great extent, her own teacher, and familiarity with works of art has a happy tendency in itself to awaken the feelings and perceptions necessary for their enjoyment.

#### THE ART OF THE CALIPHS.\*

ALLOWING fully for that Eastern exaggeration which must always be taken into account in reading of things Oriental, we have ample evidence of the extraordinary refinement of the surroundings of a caliph of the eleventh century, at a time when our Western civilisation was indeed almost entirely dependent for its luxuries on the East.

In these days, when we hear so much about decorative art, the suggestions for design given by the Arab historian in his relation of the contents of the pillaged caliph's palace are alone sufficient, one would think, to inspire many a work of beauty. Decorative artists, indeed, the Arabs seem to have been born, were it not that we trace in the conditions of their existence the causes of this characteristic feature of their art. With the luxury of the caliphs in Spain, all who have read in Washington Irving or elsewhere of the wonders of the

Moorish rule in the Peninsula are familiar. A passion for dress and ornament pervaded all classes. That of the princesses and ladies of high rank, says Al Kattib, one of their own writers, was carried to a height of luxury and magnificence that bordered on delirium. They wore girdles and bracelets and anklets of gold and silver, wrought with exquisite art and delicacy, and studded with jacinths, chrysolites, emeralds, and other precious stones. The Moorish cavaliers were scarcely less extravagant. Their dress, arms, and horses' trappings were of the most gorgeous description. All this warlike luxury of the youthful chivalry was encouraged by the Moorish kings, who ordained that no tax should be imposed on the gold and silver employed in these embellishments, and the same exception was extended to the bracelets and other ornaments worn by the fair dames of Granada.\*

In their immediate surroundings we have evidence that the Arabs early indulged in the most excessive luxury. The refinement and beauty of Persian art, after the conquest of Persia by the Moslems, influenced the whole of the Mohammedan empire. The passion of the descendants of the original simple Arab shepherds for beautiful objects, and especially precious stones, was insatiable. European travellers as late as the seventeenth century state that they could ensure larger sums for gems in the East than even at home.† Rich as had been the yield during centuries of the mines of Asia, when the New World was discovered, its precious stones soon found their best market in the East, though already Moslem art was on the decline.

Authorities divide the history of the Arab art, or rather architecture,—on which depend, it will be found, throughout all history the decorative arts in general,—into three periods. According to Gwill, the first period stretches from the foundation of Islamism in the seventh century down to the ninth century, the period of Byzantine influence; the second extends to the end of the thirteenth century; and the third to the fall of the Saracen power in Spain in 1492.‡ But these divisions are applicable alone to the Moorish art of the Peninsula. The more recent authority of Bourgoin ("Les Éléments de l'Art arabe," Paris, 1879; and his "Arts arabes," previously cited) divides Arab art also into three periods,—the first extending from the commencement of the religion, the Byzantine period, during which the ultimate style was being formed, and closing with the twelfth century; the second extending from that century to the fifteenth, the Arab period proper; and the third extending from the fifteenth century to our day, the modern period, marked by a gradual decline. This subdivision we may accept as that of a profound student of Arab art.

The earliest monuments of Arab art, the art of the caliphs, do not carry us back further than the seventh century, previously to which time the people whom Mahomet called around him do not appear to have possessed,—or research has not revealed to us,—any architecture of their own. Their simple nomadic life was not one calculated to develop such, for of all arts architecture has been justly considered as that best revealing the habits and manners of a people. The first century of Islamism, one hurried series of brilliant conquests in Syria, Persia, Egypt, Western Africa, and Spain, was scarcely a period for artistic creation, and the few buildings erected are imitations of the Greek and Roman works of the Lower Empire. The first work of purely Arab origin of which history makes mention is the mosque built by the Caliph Omar on the site of Solomon's famous temple at Jerusalem (A.D. 637); to the mosque of Omar succeeded the mosque built at Cairo (now "old Cairo") by Amr or Amrou, the brilliant post-conqueror of Egypt (A.D. 644); then comes in order the mosque at Damascus, erected by the builder Caliph Walid in 705; all buildings, however, that in the course of centuries of repair, have preserved but little of their original structures. As for the famous temple at Mecca, the marvels of which all travellers have vaunted, it may be looked on much as Nelson's old flag-ship, the *Victory*, as a modern antique, so completely has it been rebuilt and restored

at various times, though the original plans have been religiously preserved.

It is unquestionably to Byzantine and Persian influences that the Arabs owe their artistic refinement; their conquering emigration northwards bore back these influences to the heart of the empire. Under Omar, the second caliph, we see entirely predominant,—so De Prangey tells us,—the influence of Persian arts and sciences. These first years of Arab art, the art of the caliphs, like the early commencements of the arts of all people, are, however, wrapped in much obscurity. Debased Byzantine and Persian influences mark deeply their architecture, but these influences, strikingly apparent as they are, we see modified by the exigencies of a new religion, by considerations of time, place, and largely by the important point of the materials which they had the means of "conveying" (in the modern sense of that Shakespearean expression) from the antique buildings. The ogive, or pointed arch, however, by its introduction, adds a fresh mystery to the inquiry, its appearance in the Mosque of Amrou, at Cairo, A.D. 642, being, as Fergusson remarks, "a curious contribution to the much-contested question of the pointed arch."

In its first two or three centuries of existence the art of the caliphs only shows the groping towards its ultimate development, contemporary, interesting to say, with the equally earnest and independent efforts of our own Northern architects to create our exquisite Gothic. No one, however, can fail to regret that the subject of Arab art has not received more study in the mosques of Jerusalem, of Damascus and Cairo, of Kairouan, of Aleppo, of Bagdad, of Persia, and all the countries occupied by the Arab conquerors; it is alone by a comparison of these edifices, combined with an intimate acquaintance with the Christian monuments of the Roman and Byzantine empire, that any definite results can be obtained.

In Sicily we have further traces of the Arabs, left by them during their rule between the tenth and twelfth centuries, a phase of the art of the caliphs of Spain, such as we see it in its more gorgeous development at Seville, at Granada, and Cordova in its famous mosque. Aberlaman, amazed at the grandiose monuments of Roman architecture he saw scattered over Spain, endeavoured to emulate in his mosque the Classic marvels among which he lived; urged on by the beauty of the palace which his brother caliph of the East was contemporaneously building at Bagdad, he erected the wonderful mosque which has so long stood as one of the marvels of the art of the caliphs in Spain. His relations with the court of Constantinople, from which he obtained his workmen,—the Cæsar had sent him as a present a number of rare marble columns,—account fully for any strong Byzantine elements to be found in the work. But the Arab style in Spain, and the art of the Moorish caliphs, if it is not the same as that of Egypt and Syria, which it is not, is one that is strongly marked with the influence of its surroundings, and the character of the Moors, a very different people to the Egyptians. The art of the caliphs of Spain, the art of the caliphs of Egypt, and the art of the caliphs of Bagdad are based on the same lines; they bear a strong family resemblance, but, as must always happen in all artistic creations, they are deeply stamped with the influence of the surroundings in the midst of which they were severally developed; each is a study in itself, rich in suggestive beauties; each is differently gorgeous and refined; each has left on the world the mark of its passage, and the creations of each rank among the choicest products of human skill.

**The Education of Artisans.**—In the Economic Science and Statistics Section of the British Association's meeting at Southampton, Professor Sylvanus Thompson read a paper on artisan education. He submitted that, apart from the question of the real educational value of science, there remained the fact that the teaching of science, at least in its elementary parts, given in a manner capable of illustration by reference to its application to arts and manufactures, was absolutely necessary for our artisan population. He urged that the provisions of the present education code fall far short of the necessities of the case, and directed particular attention to the introduction of manual instruction into the primary schools, a direction in which considerable progress was being made abroad.

### SOME PRACTICAL NOTES ON THE SEASONING OF BUILDING WOODS.

THERE have, perhaps, been as many papers written relative to the seasoning of wood as have been contributed to the discussion of any other purely technical question.

The subject is one to which theorists in particular have devoted a large share of their attention. The matter, indeed, has, for the greater part, been theoretically rather than practically discussed, and whilst an extreme degree of attention has been directed to issues of comparative unimportance, others of material importance have been overlooked. It is hoped by this paper to supply some of the deficiencies which exist.

Commencing upon our inquiries, it is perhaps as well, in the first instance, to inquire what the seasoning of wood really amounts to. It appears to be a prevalent notion that some extraordinary chemical effect upon the juices and saps of wood is brought about by the process of seasoning. Such theories are, however, held by some scientists possess very little interest to those who make use of wood only as a constructive material.

For practical purposes a given effect is required. Wood is required to be seasoned, and what is mainly wanted to be known upon the subject is, what is the best and most economical method of obtaining the desired result? By what is commonly known as seasoning wood is meant nothing more than drying wood.

Wood is to be dried only by the moisture being evaporated from it. It is an elastic material, and in degree as the moisture exudes so it will shrink. It is also by nature somewhat absorbent, and it will therefore, under certain conditions, attract and retain moisture. For instance, if highly dried wood-work be fixed in a thoroughly damp house, the wood will absorb some moisture, and being of an elastic nature, it will re-expand just in proportion to the amount of moisture it has absorbed. When the house has become dry, the wood will also have dried, and the result of the expansion and afterwards of the contraction will be a number of open joints. For these open joints the joiner may receive much censure, although it is highly possible that he may not have been at all in fault. Indeed, if the wood he has used has been highly dried it will, in all probability, have absorbed more moisture than would have been the case if it had only been partially dried, and so when it shrinks again the openings left will in such a case be wider.

Woodwork to be fixed in a newly-erected and, consequently, damp building, should have received a coating of paint before being fixed, as, in such a case, it will not absorb moisture.

These remarks may suggest the inquiry why unpainted woodwork does not continually undergo a process of expansion and contraction. The question is not a difficult one to reply to, although it has not usually been answered in our way.

It is well enough known that wood, in a living state, forms a skin over any exposed portion. Thus, if a branch be lopped off a tree, the injured limb for a time will bleed its sap. Nature, however, supplies its own protection against injury, and a thin skin is soon formed over the injured part, which stays the bleeding. It is the same, to some extent, with deal as with living wood. Flooring-boards, for example, which have been laid down for ten or almost any other number of years, will, if planed over, enter upon a second process of shrinking or expansion, according as they are situated in a dry or humid atmosphere. To season wood, then, is simply to dry it, and that means nothing more than evaporating the moisture from it. For all practical purposes, therefore, we have only to inquire,—

First, what amount of seasoning is required? Secondly, what is the best way to accomplish the seasoning process?

The issues are, consequently, narrowed very considerably.

When we ask ourselves what amount of seasoning is necessary, we must hold steadily in view the requirements of the different purposes for which wood is employed.

And, first of all, it should be clearly explained that foreign-sawn building woods undergo a limited amount of seasoning before they leave the other side of the water. It would not at all do to store green wood into the unventilated holds of ships, for if such a thing were done, the wood would at once commence to "sweat."

In a short time it would become covered with a mildew, and the sap-wood would become permanently discoloured; it would then have depreciated very much in commercial value. To avoid such an occurrence the wood is for a time seasoned abroad under large wooden sheds before being shipped. It is in consequence of being seasoned under sheds that it usually reaches us of such an excellent colour and clean appearance.

The bulk of the foreign building wood imported is used for hearing or joisting purposes. For such purposes it is not necessary that it should be at all seasoned beyond the preliminary seasoning it undergoes previously to shipment. It is a common error to suppose that old wood is in any way better for bearing purposes. A kind of vague idea has generally existed that old wood is necessarily seasoned, and that it is better that it should be seasoned.

In a vague way this view is held to, and yet no one can say in what way bearing wood is benefited by being seasoned. As a matter of fact, it is usually more or less injured by being old.

At the timber-yards, deals are, as a rule, most indifferently piled. They are not generally in any way protected from the weather, nor are they stored in such a manner as will insure any water which falls upon them running quickly off again. If not piled so that air can circulate through them, and if moisture be present, decay will rapidly supervene.

If the sun's rays be allowed to approach the ends and the sides of deals, a splitting process occurs. Should wet weather then follow, these cracks will become filled with moisture. When frost follows upon the wet splitting process continues, and the deals often become in consequence much shaken. Old deals will have endured these contingencies, and it may be taken for granted that they will not have escaped scatheless. Consequently, it is better on the whole to employ perfectly new wood for all kinds of bearing work.

Wood, however, that is intended to be made up into joinery work must be seasoned; and it is left us to inquire as to the best way of accomplishing the seasoning process.

There are two matters to be considered in relation thereto. First, the wood has to be dried. Secondly, it is not to be injured in the process of drying. The injuries that can be done to the material are those to be caused by the sun, rain, and frost, and by the dirt if it be stored in the immediate neighbourhood of a large town. The only sufficient protection against these influences is a suitable shed for the wood to be placed under. The sides and the ends of the shed must, of course, be open to admit of the wind circulating freely through the deals or boards required to be dried. Thus all that is required is a suitable roof. Such a roof should be exceedingly flat, so as to admit of the convenient piling away of the deals or boards under it. It should be made to well overhang so as to serve in the double capacity of a sun-shade and an umbrella to keep off the sun and the rain. It should also be made capable of being raised or lowered at will, so that it can be placed just over any pile. It should be built in the most exposed part of the builder's premises, for no factor is so important in relation to the seasoning of wood as is the wind. If it blows a gale, so long as it does not upset the piles, it is all the better for the purpose of seasoning.

Deals and boards, when placed for seasoning, should alike be separated at regular intervals by evenly sawn strips of wood. It is better that boards should be seasoned when lying in a horizontal position, because they are then less likely to twist or warp whilst being dried. The long and the short pieces should be piled separately, and in no case should a long deal or board be allowed to overhang without any support, or it will be certain to twist. It is worth while taking care in this respect,—as it is only the more valuable qualities,—those intended to be used for joinery purposes, that are required to be seasoned at all.

Flooring-boards will probably have to be seasoned in the open, because room will not, probably, be found for them under the drying-sheds. If such a thing is possible, then it is all the better, but it is a matter of less importance that flooring-boards should be protected from the weather than any other kind of wood that is required to be dried. When flooring-boards are to be dried in the open, it is better that they should be "perched" on their ends rather than laid out in a horizontal or triangular form.

When piled in a triangular form the boards are exceedingly liable to sway at their centres, and thus they will be likely to dry in a twisted form. They also bloat at times a considerable amount of water in such a case. It is a good plan, when stacking flooring-boards on a perch, to pile the boards in pairs with their face sides together, as in such a case the faces of the boards are kept clean, and thus the necessity of replanning the faces of the boards when laid is rendered unnecessary. As we pointed out in the commencing portion of this paper, seasoned boards will enter upon a second shrinking or expansion process if their newly-formed skins be removed with a planing-iron. There are those persons who are in the habit of drying their flooring-boards before passing them through the planing-machines. This is done so as to have a perfectly clean board when laid, but, for the reasons given, the result is not satisfactory, and further than this, clean faces can be preserved by adopting the practice of stacking the boards in pairs to dry.

For certain processes, such as mould-making, for instance, wood must be highly dried, and in such cases "stoving" may be resorted to with advantage. The main reform, however, required to be effected in respect to the seasoning of building wood appears to be the more general erection of suitable and sufficient drying-sheds, having open sides and flat movable roofs. Doubtless the erection of such sheds necessitates the expenditure of a considerable amount of money, but it is as well to bear in mind the admitted adage, that what is worth doing at all is worthy of being done well. There can be no doubt but that most consumers of wood suffer heavily through losses incurred in consequence of the depreciation of stock which has not been sufficiently well cared for. A well-designed and suitably situated drying-shed will permit of the wood which is stored under it being perfectly seasoned, and yet kept free from grit and dust, whilst the havoc which the sun, the rain, and the frost usually commit upon wood that is undergoing the process of being dried will be altogether avoided.

It should be well borne in mind that wood often suffers very much in consequence of its having been stored away in the sale timber-yards without any sort of protection, and it is to be hoped that ere long some protective provisions, in the shape of sheds, will be brought into general requisition by the timber merchants. Until such protective provisions do become generally established we would strenuously advise builders to buy, when possible, newly-arrived stock, and to take care themselves of that portion which they intend to devote to joinery or other similar purposes.

### THE GENIUS OF SIR CHRISTOPHER WREN.

A GREAT deal of misconception prevails, I apprehend, as to the character of Wren's genius.

By the word "genius" I mean a compound of two principal faculties of the mind in their highest perfection: reason and imagination, accompanied by emotion. To these two faculties in combination, the godlike reason, as Shakespeare calls it, and imagination, all the greatest discoveries and enterprises of the world, as well as the great literary and artistic creations, are due. According, however, as one or other of them predominates, genius becomes either scientific or artistic,—the interpreter of nature, or the creator of the beautiful.

As I remarked in a former paper, entitled "Sir John Vanbrugh and his Critics," Wren's career was in the main the very opposite to that of Vanbrugh. While the latter, who was previously a dramatist and poet, was attracted to architecture by its poetic side, Wren, who was one of the greatest geometers of his time, and whose precocious mind had displayed itself not in poetic fancy and fire, but in the abstruse paths of philosophy, was drawn, by the unusual events of his day, towards its scientific side. Their minds had dwelt in two different worlds: Vanbrugh's amid fair ideal forms,—

"Which craft of delicate spirits hath composed  
From earth's materials,"

or contemplating the touching scenes and events of human life; Wren's in that independent world, as Wordsworth has it, created out of pure intelligence, the world of the mathematics; and his ideal of architectural beauty and grandeur was derived chiefly from that

inner realm of precise and regular geometrical forms, and infinity of beautiful curves. Neither of them came into the profession by the door,—I mean, from the feet of a professor. The key to Wren's architectural character, his constructive and scientific pre-eminence, will be found in his mathematical endowments and training. His strength lay in his geometry, which was his dividing rod; and his works are examples of its power in architecture. They suggest that to be a geometer is to be almost an architect, or quite an architectural constructor; and that, like astronomy, building and engineering might be termed mixed mathematics.

It was probably chiefly owing to his general reputation for scientific skill that he was appointed by Charles II., in 1661, assistant to Sir John Denham, the surveyor-general; which was his first introduction to architecture.

What imagination he had received from nature would, of course, be none the worse for his mathematical training. As the imagination must be useful in geometry, which, as D'Alembert remarks, of all the sciences belonging to reason is the one wherein imagination has the greatest share,—in which I may add, thought can scarce move but on its wings; so geometry, which, from a few simple axioms and self-evident principles, leads the mind to the most general propositions and remote analogies, must be a discipline to the imagination as well as to the reasoning powers, strengthening and expanding it for the reception of vast and sublime ideas.

Whether this was the case with Wren or not, geometry dominated and regulated his ideas of beauty both in planning and profiling, and continued to inspire him throughout his career. It manifested itself in his magnificent plan for rebuilding the city after the Great Fire, in his numerous churches, and in both his designs for St. Paul's. It was by geometry and common sense, it would seem, that he solved the problem of adapting his ecclesiastical buildings to the form of worship of the Established Church, for which no precedent existed; maintaining the most characteristic feature of the Church of England, the steeple or spire and lantern, in a style never before applied to it, translating, if I may so term it, the Gothic steeple into Italian.

His churches, which are most of them the perfection of ingenious planning, are geometrical studies, as well as places of worship! St. Stephen's Church, in Walbrook, justly celebrated through Europe as one of the most beautiful pieces of planning ever produced, and a masterpiece of interior composition, draws all its charms from geometry. It is a gem that sparkles among architectural productions like some of the happiest minor efforts of the muse among poems, and leaves nothing to be regretted save that the same principle of composition had not been applied to the exterior, where a like combination of geometrical solids would have been equally satisfactory.

It was through his geometrical propensities, doubtless, that he became enamoured of the peculiar central feature of the plan of Ely Cathedral, and adopted it as the nucleus of his design for St. Paul's, which is no exception to the geometric composition and character of his works. Its appropriation of the octangular centre of Ely renders St. Paul's something more than a development out of St. Peter's, to which, indeed, Wren owed but little, and to which St. Paul's is in some important respects superior. He had as much right as Michelangelo to elevate the Pantheon or temple of Minerva Medice on the Temple of Peace; and combine the grandeur of the basilica and circular temple. After seeing Perrault's colonnade of the Louvre on his visit to France, Wren's geometrical resources, his familiarity with cylinders, cones, and spheres would soon impregnate his mind with the grand form of St. Paul's. But his predilection for geometrical regularity and precision leads him, ashamed of the picturesque clearstory, to disguise it by the false upper façade; and by the circular apse and transept porticos to still farther diminish the simplicity called for by the domed rotunda above.

Again, his fondness for circular forms and skill in arching, leads him to arch all the windows, though square heads would have been more expressive of power, and more in harmony with trabecation. Arches without and niches within, and pendentive domes covering both nave and aisles throughout,—circular or circular-ended chapels and vestibules, octangular vestries, elliptical and geometrical staircases, and niched

windows, all breathe of the geometer, as do also the domes of contrary flexure of the west towers, and the consoles or trusses to the upper entablature surrounding the building. As, to a geometer, an isolated Corinthian column must be a fascinating object, for its susceptibility of receiving subtle lines in its entasis, &c., as well as for its capital, which is a singular instance of beautiful natural forms attuned to the music of geometry in the abacans and volutes, isolated columns play an important part in St. Paul's, in the west front and surrounding the dome, which two features, caught in a certain relative connexion, present one of the finest architectural scenes in existence, and have the advantage of St. Peter's in being seen along with the flanks,—the flanks in the latter being hidden by Bernini's colonnade, which had better have surrounded the church, like the ancient peribolus, or sacred court.

The same principle pervades and governs his first design for St. Paul's, which is singularly geometric in its aspect, both within and without, and seems a product of fancy's loom rather than imagination's,—gravity and solemnity therein being sacrificed to geometrical grace.

It is true that all architecture draws more or less on geometric forms, and that there are other buildings besides Wren's, some of the greatest in the world, which are strikingly geometrical in their composition. The Church of St. Sophia, at Constantinople, which was the model of the Byzantine churches and Turkish mosques, of which the dome and pendentive dome are the chief characteristic, would seem to have had but little other inspiration. But there is no instance, I believe, of this source of inspiration being so clearly manifest throughout the works of one man as in Wren's, which stand out distinctly from all others in the same style, and show themselves diametrically opposite to the wild naturalness of the Gothic, with which he had little or no sympathy.

Such, I think, is the characteristic of the genius of Sir Christopher Wren, which is not more remarkable than it is admirable in itself. His thus sublimating and utilising his mathematical learning and resources reminds me of Milton's use of his historic and literary lore in his divine poem; and proves that he was not without the vital faculty of assimilation,—the power that turns to its purposes whatever material is submitted to it.

This characteristic trait is valuable inasmuch as it contributes to his originality, which is a chief merit of Wren, who throughout his career exhibits an unfolding of himself, and no yielding up of his own peculiar personality to form himself on the model of another. As evinced by his letters from France, he was anxious to enrich his mind and increase his materials by seeing as much as possible of the best work in the style he was pursuing; but, instinctively discerning the true nature of architecture, and proper use of its examples, he poured ancient and modern thought into new moulds, and evermore held an original and philosophical relation to architecture.

In the general conception of St. Paul's he emulated and sought to excel St. Peter's, as well as to embody a broader and more philosophical idea than the Western Medievalists had dreamed of. His choosing the dome, the sublimest of all forms by which space can be covered, as its crowning feature, and surrounding it with the unbroken Corinthian peristyle, the grandest accompaniment it could receive, shows, I think, that he was aiming, as Michelangelo was before him, not to breathe into stone any special or definite expression by which the whole is made to sympathise with man's devotional feelings, and becomes a petrified liturgy, if I may so picture it, but, however vainly, at an ideal, abstract temple, worthy, by its intrinsic beauty and sublimity, to be a dwelling-place for the Most High, which is something like a return to the governing idea of Solon's Temple at Jerusalem.

Such, probably, was the aim, in this his greatest work, of Sir Christopher Wren, who was a true architect, as well as a renowned mathematician and astronomer, and truly great man.

Nevertheless, his acknowledged failure in the designs of most of his numerous steeples, though they are said to be based on principles laid down in his writings, may justify a doubt whether he had the strength of imagination or poetic fancy and feeling to conceive graceful architectural forms independently of his geometrical resources; especially if we consider

that the occasion was sufficient to awaken any faculty that had during his scientific days lain dormant in his mind.

With no vain wish to dim the halo that surrounds, and will for ever surround, the name of Sir Christopher Wren, I confess that I have long been under the impression, induced chiefly by the outlines of his steeples, that his artistic faculties were by no means commensurate with his scientific, which his inventions and discoveries at a very early age, and the frequent association of his name as mathematician with those of Wallis and Newton, would suggest were of the greatest; and that he had not the fire and imagination necessary to constitute an architectural genius of the highest order. There is nothing to weaken that impression in his greatest work, which, though all that I have pronounced it, is, nevertheless, remarkable for nothing so much as its deficiency,—its stopping short of its greatest attribute,—which has caused so much discussion of late years as to its proper decoration, and renders it more than probable that Wren never had a full conception of his great work in his mind,—in all its due and appropriate finish and ornaments, sculptural and pictorial. What was the chief glory of St. Sophia's, St. Mark's, the Alhambra, and most celebrated edifices,—that which, composed of the highest forms of living beauty, gives additional life, and the full expression or speech to a building, whose design offers the greatest opportunity for exercise of imagination and delicate feeling, while it requires a greater knowledge of effect than ought else,—is, for the most part, wanting in St. Paul's. That important element, in short, the possession of which gives to architecture its high place among the arts of design, *with* which it is the highest of them, and *without* which it is the lowest.

Neither this nor any other shortcoming in Wren, it should be remembered, could arise from want of opportunity; for no architect that ever lived had so great opportunities of displaying what gifts natural or acquired, he possessed. He had not to break poverty's unconquerable bar; nor any other bar that we hear of; nor to scramble, like later artists, in the mire of competitions; but during the fifty or more years of his devotion to architecture, uninterrupted by affliction or other casualty, he had commissions for all kinds of public and important buildings thrust on him; and if any wandering muse or spirit of art may be drawn to our service by the enchantments of knowledge, he had it.

My chief aim in these remarks is to enunciate what I deem an important truth, viz., that Wren was not of the highest order of architects, his works not being the perfection of architecture, as is generally, if not universally, supposed by the followers and advocates of the Classic schools,—a truth which, if accepted, cannot but tend to good by removing a false standard of excellence. It is,—

"Only as admiration, hope, and love  
Are well and wisely fed,  
In dignity of being we ascend."

SAMUEL HUGGINS.

P.S.—The above was written before I was aware, through the *Builder's* review (Aug. 26) of Mr. R. G. White's book "England Without and Within," of his attack on the works of Wren. To the just remarks thereon, in that review, I would beg to add, though with strong doubts as to its title to further notice, that it is virtually a condemnation of some of the oldest and most ambitious structures of the critic's own country, as the Capitol at Washington, the State House at Boston, &c., which are domed compositions emulating the grandeur of the metropolitan church of the mother country; while most of the older Classic churches are echoes of Wren's or his pupils'. These and other American structures may, indeed, be deemed, in some sort, like the people, English emigrants, at least, descendants of English builders, chiefly Wren's, which are repeated in a numerous progeny in the older States. For this reason, an Anglo-American attack on Wren's architecture is almost as great a blunder as would be an assault upon the Anglo-Saxon race.

It is absurd, however, irrespective of such consideration: if St. Paul's is ugly, Nature herself, in her grandest phases, is ugly; and if its round windows are ridiculous, then the canopy of heaven, the round earth, and the round human skull, are ridiculous; and the inventions of the arch and dome are mistakes.

S. H.

## THE PROPOSED CRYSTAL PALACE FOR PARIS.

ACCORDING to the Confidential press, the above enterprise is of a comprehensive nature, including permanent exhibitions of collections of various kinds, galleries of painting and sculpture, rooms for gymnastic exercises and scientific experiments, concert-halls, &c. In this international museum of industrial art it is intended to exhibit all new inventions of an interesting character which may have been brought into public notice in other countries, while the concourse of foreign visitors will, it is supposed, be of value to French industry in making its productions more extensively known to the world at large.

The internal arrangements will comprise various groups of subjects, such as the progress of science in general, the productions of art and literature, experimental science, education, the development of the industrial resources of France, &c. The front of the building will look towards Paris, and its situation between the park of St. Cloud and the railway from Paris to Versailles will render it of moderately easy access. The structure will cover an area of about  $1\frac{1}{2}$  acres. The dimensions of the main building are approximately as follows:—Length, 1,640 ft.; height, 165 ft.; width, 460 ft. Amongst the remaining features of the scheme are panoramas on an imposing scale, a large amphitheatre for athletic sports, a model farm, and ornamental buildings of various kinds. It is proposed to erect in the grounds, and thereby preserve to posterity, such monuments of architecture as it may be found necessary to remove from their present sites in any part of France.

## THE BRITISH ASSOCIATION ON THE DRAUGHT OF CHIMNEYS.

A FORMULA AND TABLE FOR CHIMNEY DRAUGHT.

THE attention of the Mathematical and Physical Section of the British Association was, on the 30th of August, called by their president, Lord Rayleigh, to the very humble practical inquiry as to the effect of wind on the draught of chimneys. It would be difficult more aptly to illustrate the true connexion between the pursuit of pure science, and the most everyday annoyances of domestic life (with a view to the removal of the latter), than is afforded by this announcement. As a prime feature in the architecture of dwelling-houses the chimney demands a chapter to itself. And it is well that the basis of this chapter should be mathematical. With regard to draught, we have more than once had occasion to remark that it is a function of the height of the chimney-tubes. We do not, of course, apply the remark without modification to the details of ill-constructed chimneys. Many chimneys smoke from positive ill-construction, having a narrow part, an ugly bend, or a downward portion, in their conduit, which the normal draught is not strong enough to overcome. Others smoke because they form the shortest channel by which air can enter the house to supply the draught of the loftier chimneys. Where there are two chimneys in one room, and the doors and windows are closed, lighting a fire in one chimney will ordinarily cause down-draught in the other, as the readiest mode of maintaining the atmospheric equilibrium. In most cases, however, the addition of a yard or so to the height of the chimney-stack, supposing that to be already above the highest part of the interior of the house which it ventilates, will prove more useful than the addition of any of those curiously contorted and wholly non-pneumatic contrivances, the endless variety of which tortures the eye of the mechanically-minded man as he whirls along the suburban railways.

Apart from the questions of normal draught, and of internal regularity of construction, is the effect of wind on the draught of chimneys. This varies very much with the locality of the house. It may be said to be primarily a question of site. Neither is it a question always to be settled *a priori*, by the architect. The action of wind, although, of course, always determined by physical laws, is so subtle, and so delicately affected by slight causes, that there are cases in which it is all but impossible to foretell it. What is more common than to have a chimney that answers perfectly well, except when the wind is in one particular point of the compass? And why does it then smoke?

To be able to reply to this question is to be able to cure the defect; but how often is the difficulty regarded as insuperable? It may be useful to cite an instance of the deflection of wind in a manner that it is difficult to explain, and that could certainly never have been anticipated. On the lovely plain of Sorrento, sloping towards the Bay of Naples, in the midst of its own gardens and orange groves, stands a stately palace, which, in the days when the name of Nelson was a terror on the seas, was a favourite haunt of the Queen of Naples, and was not unfamiliar to our great sea captain. There are no rocks, lofty buildings, or overhanging trees in the immediate vicinity, and nothing that is apparently likely to interfere with the free movement of the wind, from whatever quarter it may blow. The aspect of the front of the palace is northerly, looking over the Bay towards Naples, and the hills behind it. On a few occasions,—some three or four times, perhaps, in the year,—a strong east wind sweeps across the peninsula, and is clearly indicated as to its course by the straight and level stream of smoke that it drives from the cone of Vesuvius across the Bay. But on these occasions, the current is so deflected by the northern shores of the Bay, fully twenty miles distant, as to drive on the front of the palace; that is to say, in a direction pointing nearly due north, with such force that it becomes necessary to close the *persians*, or outer window-shutters, in order to preserve the great drawing-room windows from being blown bodily in. Full familiarity with the spot does not afford any very satisfactory explanation of the phenomenon, of which, however, we can speak from repeated personal observation.

This, perhaps, may be regarded as an extreme case. Nevertheless, it is typical of not a few instances in which currents may be detected after a house is built, the existence and effect of which the architect cannot be blamed for not having foreseen, but the influence of which on the draught of his chimneys will be, for so many days in the year, at once irresistible and intolerable. There is now absolutely nothing for it, in such a case, but to put out the fires. We do not say that a cowl may not be of use, but, on the other hand, we cannot speak from any experience of the action of a cowl under such conditions.

Here, then, comes in the scientific part of the question as attacked by Lord Rayleigh. What is the effect of a cross current of wind on the draught of a chimney? As the direction of the wind is more and more downward, his lordship replies, the up-draught of the chimney diminishes, but does not turn backwards, that is to say, become down-draught, until the inclination amounts to about  $30^\circ$ . This is an important point at which to arrive. It is, however, obviously necessary to ascertain the precise features of the cases where the experiments were made, before formulating any absolute rule on the subject. The height of the top of the chimney, both above the sea level and above the basement of the house, is one fact needful to determine. The force of the wind is another. Thus, a wind of the velocity of ten or twenty miles an hour blowing downwards at a measured angle would produce a very different effect on the draught of a chimney 40 ft. high from that which it would have on the draught of a chimney 100 ft. high. If our recently published table on wind pressure (*ante*, p. 200) be referred to, it will be seen how important are these data for the solution of the problem.

Again, the maximum up-draught, we are told, is not with a direction of wind vertically upward, but with one making an angle of about  $30^\circ$  with the vertical. This is a result which it is without our experience either to confirm or to question. But it is clear that the cases must be extremely rare, if ever they occur, in which the top of a chimney would be exposed to a wind blowing upwards at a more acute angle than  $30^\circ$ . The determination of the same angle as the limit of downward and of upward efficiency is as elegant as it is unexpected.

A yet more practical part of the subject is the remark of Lord Rayleigh, that "a chimney with a T-piece at the top never produced an unfavourable effect on the up-draught, and only in one case failed to produce a favourable one." Professor de Chaumont thought vertical ends would increase resistance to the up-draught. So do ninety-nine people out of a hundred. We have no hesitation in saying that Lord Rayleigh is right, and that general opinion is wrong, provided, that is to say, that the protection of

the chimney-top be rightly designed. And we say this absolutely and unhesitatingly, because our judgment is based on the two independent and concurrent sources of evidence afforded by observation and by direct experiment. In Southern Italy chimneys, no doubt, are comparatively few, but they exist in many buildings, and no Italian architect would dream of leaving a vertical flue or pipe open at the top to receive the tremendous downpour of rain which occasionally occurs in Italy with almost tropical violence. The aperture of the chimney is always roofed over, the smoke escaping by side apertures. The practice of the master-builders of the world is thus in accordance with the theory of the English scientific noble in this respect.

Experience, we have said, confirms the remark. And here, if we seem for a moment to depart from an admirable rule,—that of not mentioning in a scientific paper anything that may look like an advertisement is deceptive. We have to refer to an admirable invention, which was made and sold some forty years ago under the name of Day's Patent Wind Guard. As to the validity of the patent it is not needful now to inquire, as in any case it must have long since expired. And what we lament is, that so far as we can discover, this admirable invention has been entirely forgotten. In recent inquiries which we have instituted in order to obtain one of these wind-guards for our own use, we have been unable to discover that they are now made, although figured in some old trade-books. It may, therefore, be of much use to give such particulars as will guide any one in constructing an appliance of the kind.

Let us take, for example, the case of a chimney two bricks and a half, or  $2\frac{1}{2}$  in. square, with a flue of 9 in. square. A frame is to be constructed which would lie upon this hollow square, and allow bricks to be built on it to the height requisite to hold it steady. From this frame the guard itself rises as an octagonal shaft. Four pieces of sheet iron, or of slate, each 9 in. wide and 18 in. high, are fixed on the lower frame, 16 in. apart, so as to form four sides of an octagon, and the other four sides are formed of four similar plates, set at angles of  $45^\circ$  with the former, but so much within them as to allow  $\frac{1}{2}$  in. to 2 in. clearance between the edges. These inner plates will just touch the outer angle of the 9 in. flue. A top, of iron or of stone, bolts the upright plates together, and both top-plate and base-plate may be finished with a simple moulding. Sheet iron is perhaps the best material, but it is obvious that the contrivance may be made also in slate.

As to the perfect security which this guard effects from wind, we can speak not only from the testimony of those who have used the plan, but from careful experiment. With models of the wind-guard, made on the scale of 1 in. to a foot, set on small tubes of proportionate size, representing chimneys, which were fed with smoke from the combustion of paper, we have experimented by means of powerful jets of wind driven in various lines of force; vertically downwards on the top of the guard, horizontally at right angles to either side or angle, or in any other direction. In no case have we found it possible to produce down-draught in the chimney by the force of wind. On the contrary, the greater the force the better the draught of the chimney.

The rationale of this action may be illustrated by that of a much later invention, now in common use on our railways,—the steam injector. Let those of our readers who desire to master the subject, and have no more ready mode of doing so, refer to the diagram and description of this appliance which is given by Sir F. J. Bramwell, on p. 335 of a work recently published by Messrs. Longmans, under the title, "Railways and Locomotives." It will there be seen that "steam, escaping at high velocity through a circular orifice, induces a current in a body of water in connexion with that orifice, and carries it forward, at the less velocity corresponding to the increased weights of the combined stream of water and steam, but still at a high velocity." This stream passes into an expanding channel, where its velocity is further reduced, and so into the boiler, which is thus fed with water.

In the case of the wind-guard, the wind striking on the outer plate causes a current of proportional velocity between the edges of the outer and inner plates, and thus creates an

induced current, which comes in aid of the draught of the chimney. The difficulty to be overcome is far less than in the case of the two fluids of unequal specific gravity. But the effect is so much the more powerful. We are familiar with the contrivance mentioned by Professor de Chaumont, which has been used for the protection of lamps from the dash and spray of the sea, as we believe, with admirable results. But it is a much more complicated, and therefore more costly, contrivance than the very simple one which we have endeavoured to rescue from oblivion. And we think that it is purely protective in its action, while the construction that we describe is not only protective, but absolutely aids the up-draught; and, moreover, the cones more likely to become choked with soot. The brush of the sweep can easily ascend into the interior of the wind-guard, in case of any soot lodging there.

We have little doubt that any enterprising manufacturer who will discover one of these old wind-guards (they were made and sold somewhere in Pimlico, in 1842), make some to pattern, and introduce them to the trade, will at the same time do a good stroke of business, and confer a very great benefit, both on the architect who has to build in exposed and gusty situations, and on many a householder who now knows too well, and that to his cost, when the wind is in the east,—or in that quarter, wherever it may be, that is hostile to the good behaviour of one or more of his chimneys.

We are not acquainted with any mathematical formula intended for the guidance of the architect as to the height or draught of chimneys. It may, therefore, be of some service to provide a simple table for the use of the architect and of the builder, stating, in the first instance, the principles on which it is calculated.

The only cause of that upward movement which we call the draught of a chimney is the difference between the weight of the column of air and vapour in the shaft, and that of a column of equal height of the exterior atmosphere. This difference of weight must be enough to overcome the friction within the chimney-shaft and any resistance to free discharge at the top. It is obvious that the ascending volume consists of matter which, at equal temperatures, is heavier than atmospheric air, as it contains soot, or finely comminuted carbon, carbonic acid, sulphur, and other matters naturally heavier than air. Calling attention to the existence of these two sources of retardation, viz., friction and the loading of the column, it will be safe to neglect them in tabulation, as it is very difficult to determine the absolute heat of the ascending column, and a few degrees more or less will amount to quite as much as the elements thus neglected. With this explanation, the formula that regulates draught may be thus stated:—

$$D = (a.t. - a.t.) h.$$

where  $D$  = the draught,  $a.t.$  the weight of a cubic foot of atmospheric air at the external temperature, and  $a.t.$  the weight of a cubic foot of atmospheric air at the mean temperature within the shaft, and  $h$  the height of the chimney. It is obvious from a glance at this formula of how much importance the addition of a very few feet to the height of a chimney must be.

To increase the draught, we must increase either  $h$ , the height of the chimney, or  $t$ , the temperature of its contents. This explains at once the efficacy of the best appliances for increasing draught,—such as the bi-valvular registers, in this country, and the iron blind that is drawn down within the chimney aperture in the wood-burning fireplaces of France and of Belgium. The larger the aperture below,—the greater the quantity of cool air that enters the chimney,—the lower is  $t$ , and the less the draught. The more the air that enters below is compelled to pass through in close proximity with the burning fuel, the higher does  $t$  become, and the more powerful the draught. This is the simple key to the whole theory and practice of draught produced by heat. Of course, in different conditions of the barometric column equal amounts of heat will have somewhat different effects. Hence we can see in a moment why our fires should "draw" so much better in clear cold weather than when the air is warm, or loaded with damp. The weight of a cubic foot of air at 32° Fahr. is 0.080728 lb. avoirdupois.

If the top of a chimney-flue were closed by a flap, or hinged valve (the weight of which

we take as counterbalanced), the effect of the draught, or rather of the downward pressure of the external atmosphere which causes the upward draught, would be to lift the valve in proportion to the force of the current. If at the same time a strong wind be blowing over the top of the chimney (in the direction of the hinged end of the flap), its effect would be to force down and close the valve. The stronger current of the two will obtain the mastery, to the degree of its excess of pressure. This is also the effect, it will be seen, of cross current where there is no valve, but where the two currents more or less interfere with the movement of one another in the way shown by the action of the valve.

It is possible wholly to eliminate the ill effects of this cross current, and even to utilise it in aid of draught, by any contrivance that causes the external blast to produce an induced current from within the chimney; and this, it is easy to see, is the effect of the wind-guard.

In calculating the following table we purposely use round and approximate figures, as quite sufficiently accurate for practical purposes, and as more readily intelligible to many readers than more complicated mathematical expressions. We have also used the pressures proportionate to velocity as allowed by Smeaton, and given in Table I. of our recent article on "Resistance needed to the Pressure of the Wind" (p. 200, ante). Now, assuming, for convenience of calculation, an increase of temperature of 105° Fahrenheit (that is, from 62° to 170°), as imparted by a fire to the ascending column of air that passes over it up the chimney, we shall have an upward pressure of a fraction over 0.04 lb. for every foot of ascent in the shaft. This is represented in the following table of comparative heights of chimney, pressures, and velocities of current, calculated for that rise of temperature.

Table for Calculation of Chimney Draught.

Height of Chimney in feet.	Pressure due to 115° Fahr. in pounds per foot.	Velocity of draught in miles per hour.
30	1.2	16
40	1.6	18
50	2.0	20
60	2.4	22
75	2.8	24
80	3.2	25

It will be proper, in making use of this table, to refer to the table (III.) given in the article, previously quoted (ante, p. 201), showing the increase of velocity of the wind with the height obtained above the ground. Thus, in rising from 15 ft. to 50 ft. there is, as shown on that table, an increase in the local velocity of the same wind from 60 to 70.8 miles per hour. In raising a chimney from 15 ft. to 50 ft. we should obtain an increase of draught pressure of from 0.6 lb. to 2.0 lb. per foot, as against an increase of wind pressure, in a great storm, of from 20 lb. to 27 lb. per foot. The gain is more than threefold,—the loss less than 33 per cent. We mention this, not as a difficulty, but to show that proper consideration must be given to the whole subject.

It is, of course, apparent that if we have an ordinary fireplace, with a chimney 50 ft. high, and with that proportion of fuel and of draught which gives a current of twenty miles an hour to the ascending column of smoke, the aperture at the top of the chimney would be closed by a cross-current blowing at the rate of seventy miles an hour, almost as efficiently as by a valve weighted to 27 lb. per foot. The fire, in fact, would have to be extinguished. But the pressure of 27 lb. per foot, or 0.19 lb. per inch, is very trifling in comparison to the pressure of steam in a boiler; and as the action of the injector by induced current is an ascertained fact, it is plain that it is within the province of the engineer to make the hurricane, blow it ever so wildly, produce an induced current through a chimney, so that the draught shall in no way be reversed by storms. As to, that there can be no doubt, although this may be the first time that the statement has been definitely made. We have given what our own experience has led us to believe to be a simple and effective means of producing this induced current. If any of our readers can recommend a better plan we shall be happy to make it known.

We had put on paper some remarks on one or two other matters discussed at the British Association which appeared to us of striking

industrial importance; but the novelty of a scientific investigation of a subject which most men are accustomed to regard with a hopeless shrug of the shoulder, as well as the importance of a thorough appreciation of a matter which comes so directly home to every householder and to every house-builder, is such that we have thought it well to devote to this question of draught all the space at present available. We think it cannot be too strongly insisted on that when, first, the subject of up-draught, and, secondly, that of wind-protection,—or rather wind-induced draught,—are seen to be thoroughly within the control of science, it will be felt to be unpardonable to be condemned to the great nuisance of a smoky chimney.

#### CONTINENTAL GATHERINGS.

This is the season of the year when archaeology is the order of the day. Archaeological societies are meeting in every corner of the country, and many a quaint district has been invaded by eager excursionists. In the annual obligatory *collegiature* of every family that respects itself an interest in antiquarianism forms a necessary feature; old churches, castles in ruins, and ivy-covered monastic buildings are pried into, sketched and visited, guide-book in hand, and the mysteries of architectural styles become positively familiar,—during a few weeks,—to the more enthusiastic. This eager interest in archaeology, expressed annually during the autumn, the various papers read by kind members, and the learned explanations of local *ciceroni* do not, fortunately, however, represent the sum of the labours of the profession. Its members work in most cases laboriously and modestly, amply rewarded by the humblest find. It is not all of them who have such a field for research as the director of the excavations at Pompeii, who, we hear, has been recently adding fresh stores of information to our knowledge of the buried city. A house has been laid bare in the ninth quarter,—so we learn from the *Zeitschrift für bildende Kunst*,—which, from the nature of the objects discovered, the beauty of the wall paintings and the fountain, must clearly have belonged to some wealthy patrician. Unfortunately, it would appear that the researches in this direction are threatened to be entirely stopped by the presence of a modern villa,—the *Villa dell' Aquila*,—built on the ground which has covered up the classic city. When, a year since, the state of the works was reported in these columns, the villa already promised some difficulties, which, it would seem, have now by any means been arranged. In the meantime the excavations have been resumed in another direction, towards the village of Torre dell' Annunziata, in what is known as the eighth quarter. Here, though the yield of antiquities has been but meagre, some most interesting facts have been brought to light; the neighbourhood was evidently one occupied by the poorer section of the Pompeian population. The houses are small, and in their architecture betray two different styles; from this fact it has been surmised that this portion of the city must have suffered during the first great eruption of 43 A.D., and then was rebuilt only to be totally buried in the final catastrophe of 79 A.D. One most interesting discovery has been made of a baker's shop with a large oven,—not a novel feature, it is true, as others have been found in Pompeii, but in the little room behind the shop were discovered the skeletons of two little children, the first that have been found in Pompeii; unfortunately no east could be taken of the fragments, which crumbled to dust immediately on their contact with the air. A second shop was discovered in the neighbourhood, filled with a large number of beautiful works in terra cotta of Pompeian manufacture. The considerable number of objects in terra cotta found leads to the conjecture that it is a potter's shop that has been laid bare, as most of the objects are of the same form and colour, though of different sizes. But at the potter's the find of the most importance was that of a basket containing coal. Till now it has been held that the Romans alone knew wood as a combustible. The discovery is most curious, and, when made more generally known, is likely to arouse no small amount of interest. In this same quarter a street has also been laid bare, and under the 12 ft. to 15 ft. of ashes have been brought to light the corpses of a woman clutching tightly the hand of a little

ten-year-old child. From the emaciated appearance of the boy it is presumed that he may have been ill in bed at the moment of the said destruction of the city, and the woman by his side had induced the poor little sufferer to endeavour to escape. An attempt made to obtain a cast of the woman proved hopeless, but her jewelry, two gold armlets and two gold rings, one of emerald the other of amethyst, beautifully engraved, have been saved. A cast of the body of the child, though wanting the right hand and left leg, has been successfully taken, and now forms an interesting addition to the curious little museum attached to the excavations; all the more valuable discoveries made at Pompeii going, it will be remembered, to the superb Museo Borbonico at Naples.

Johnson it was, if we mistake not, who, a century ago, remarked that there were very few subjects which could not be found treated by some French writer. True in his day, it is even more so now. Certainly the recently-published translation from the Chinese of a native work on the history and preparation of China, or, as we term it, Indian ink, may be said to supply a fund of information respecting a subject interesting to the architectural profession, about which it would be difficult to find much that has been written. M. Jametel, the translator, knows China well, and having lighted upon a Chinese manual descriptive of the manifold virtues of that indispensable element of architectural production, Indian ink, has considered the little work interesting enough to set into a language which, as Bacon has it, might be more "understanded" of the general public than in the original. The secrets of the wonderful industries of China, laden as they are with traditions of secular antiquity, are not easily fathomed by the European barbarian, so that there is a strong element of novelty about the information we are thus enabled to obtain. The art of writing is traced back by the Chinese to almost fabulous antiquity, the invention of ink being claimed by Tien-Tchen, who lived under the rule of Honang-Ti, 2697 to 2597 B.C. The ink at first was a sort of lacquer, then a black stone ground with water was used to write with, and it was only in the third century before the Christian era, under the dynasty of the Ouci, that, in the province of Kiang-Si, balls were made composed of lamp-black, obtained by the burning of a mixture of lacquer and pine-wood, and glue made either of fish-bones, the horns of oxen, deer, or rhinoceros. It is possible that this process was introduced into China by the Coreans, whose influence on the civilisation of the extreme East modern research has of late revealed. Be this as it may, it was under the dynasty of the Tang, seventh and tenth centuries of our era, that the manufacture of China ink obtained its highest perfection. The name of the great maker of that time, Li-ting-Konei, has been reverently handed down; his products were of such perfection that to this day they have never been equalled. It is not, however, from want of minute precautions that there exist deficiencies, as may be seen by M. Jametel's manual; indeed, it is interesting to read of the extraordinary care, the attention to details, the almost religious formation of Chinese industry. In the country of mandarins and of an antique literature, ink, as may be imagined, plays a considerable part; the Chinese, indeed, regard it as a protecting genius who is subdivided into as many little spirits as there are sticks of ink in the world. M. Jametel cites a work in which we are told that the Chinese conferred in antiquity on ink the title of prefect of black perfume, and that in this position it was to have precedence of the brush, which only ranked as sub-prefect, and over paper, which occupied only the inferior post of head of a district.

It is, perhaps, the character of Oriental art, but it must be admitted by all, even its admirers, that we hardly look upon its creations in that same personal light that it is impossible to avoid in judging of European art. We regard it, as it were, as the spontaneous outcome of a state of existence in which we are disposed to say that everything is beautiful and tasteful, but the East, like the West, has its artists, who have succeeded in attaining an individuality, and whose names are treasured among the worthies of the country. It is a little curious that it has been undoubtedly the Europeans who first brought to the minds of the Japanese the peculiar merit of their national artist, Hokusai. Our Parisian contemporary, the

*Gazette des Beaux-Arts*, in a recent issue, has given a most interesting sketch of the life and works of this great artist, the fertility of whose genius is positively astounding. The name Hokusai is, it would appear, a *nom de guerre*, just as with us we speak of "Phiz,"—poor "Phiz," now no more,—or as the French would speak of "Chan" and "Gavarni." During the course of his long life,—Hokusai was born in 1760 and died only in 1849, at the advanced age of eighty-nine,—the artist appears to have changed his name and signature more than once, a fact which has somewhat baffled his biographers in their researches. England and America may claim perhaps to have been the first to bring before the notice of the Western world the peculiar power of Hokusai's genius. Mr. Dickens, in his "Fujaka Hyakakci," or hundred views of Fuji, a work published in London two years since, gave a most interesting sketch of the life and works of this typical Japanese artist, who at the beginning of this century founded the existing modern school of Japanese art. To Dr. Anderson's writings, again, those anxious to learn more may be referred; as also to a recent article, written by Mr. Edward Morse, in the *American Art Review*. At a moment when we hear that the authorities in Japan have closed the art-schools when they discovered that the pupils were merely preparing to send their works to the annual *Paris Salon*, it is, indeed, refreshing to have brought before one the products of so characteristic an artist as Hokusai. All the quaintest inventions of the weird Japanese mythology he has pictured in the style that has endeared the art of Japan to so many. It was quite late in life, it would appear, that Hokusai came out. His first volume of rapid sketches, "Mangona," was only published in 1810; between that date and 1840 no less than thirteen other volumes appeared under the same name,—"Mangona" means rapid sketches,—together with a mass of other work which he executed. As he drew exclusively for the wood-engravers, his original sketches are of extreme rarity. In Japan the drawing is first made on thin paper, then applied to the block and, naturally, destroyed in the production of the woodcut. A few drawings by the artist exist; there are five, we learn, in the British Museum from the collection of Dr. Anderson, and, if we are not mistaken, we remember to have seen in the little Oriental museum of Munich a small gathering of most interesting rapid sketches made in Indian-ink by the exuberant Hokusai, whose art is the most intensely characteristic that it is possible to imagine. The mastery of touch, the rapidity of execution, the extraordinary understanding of the means at his disposal, and the peculiar possession of that indefinable quality of style, render Hokusai's productions,—though, like all Japanese art, outside the ordinary rules of our æsthetic standards,—master-pieces of skillful design worthy to rank beside the finest creations of our European art. He may be regarded, too, in the history of Japanese art, as its most characteristic embodiment. The art of Japan was originally of Chinese origin, and till the last century was singularly wanting in individuality; it was only about 100 years ago that colours commenced to be largely used in the production of the brilliant woodcuts that we all have learnt so freely to admire. In Hokusai's works Japanese art will be found, as we have remarked, embodied in its most striking features, and the school he founded only now threatens to lose its living character through the influence of European art-teachers. Still it must be remembered that it was we Europeans who first discerned the peculiar genius of Hokusai, who now ranks as one of the great artists of Japan.

The French Government have at length determined to institute a triennial *Salon*, the yearly *Salon* being, it will be remembered, in the hands of the artists themselves. The conditions of the Exhibition were published in the *Journal Officiel* not long since. It is not till next year that the exhibition will be held, from the 15th September to the 31st October; all works are admissible produced since 1878. Foreign artists, it may be mentioned, are invited to send in their works.

**Egypt**.—G. W. Bacon & Co. have published a "Large Print Shilling War Map of Egypt," a rough-and-ready thing, on which you can see at a moment just what you want. It includes, too, enlarged plans of special parts.

## TASTE IN FURNITURE.

THERE have always been some critics who, in the midst of the much-vaunted modern advance in taste and art-matters generally, have expressed sage doubts as to the genuineness of the movement. It has become less difficult, it is admitted, to get really artistic work done than was the case some years since; we do not so entirely rely on foreign aid as formerly, but our captious critics are, we are afraid, only too right when they complain that any such work continues to be alone a luxury reserved to the few,—it is not a matter of course, as in the past. It is true that, in the present day, the love of luxury is far more generally spread than formerly; the increase of public wealth, the rapidity with which fortunes are amassed, the new conditions of a democratic society, as shown in the growing uniformity in dress and surroundings, all favour the spread of what a generation gone by were considered as the luxuries of existence. Fashion has further aided the movement, and, as one of its phases, the passion for the collection of *bric-a-brac*, while widely spreading a love of beauty, has developed a desire for the elegant and the superfluous,—a desire looked on as a sign of a certain intellectual refinement. This being the case, can it be said that art has gained? It is one of the qualities of taste that, as it becomes purer and more delicate, it grows more exacting. Now, is modern work more perfect? Treating the matter commercially, as the consumers increase in number the workmen, we are afraid, it will be found, are forced into hasty production to satisfy customers not only capricious and undecided in their desires, but, above all, anxious to furnish in the shortest possible time.

We hear a great deal in the present day concerning foreign competition. Museums and art schools, it is urged, are necessary to educate our workmen and our artists. The Government has warmly aided the work. Museums and schools, therein lies the remedy. On this point public opinion seems nearly unanimous. But under what form are these museums to be organised? In what manner should these schools give their instruction? It is certain that, in spite of the earnestness of those who have devoted themselves to the task, the results are found to be far from satisfactory. It is easy thus far to see the error; but how is it to be remedied? Museums and schools of design are necessary, but they are not an infallible panacea. As has again and again been pointed out, art is not a flower to be forced by artificial means. There are other modes. If our generation does not show in the productions of its industrial art the same perfection as in the past, what is the cause of this decline?

The first and principal cause is the obstinacy which is shown by a large number of persons of refinement in furnishing their houses solely with old objects, or copies of old objects. Every one is acquainted with friends in whom this love of the past has grown into a fanatic fetishism. None more than ourselves admire the beautiful works of the days when the greatest artists were wise enough not to confine themselves to narrow specialities, but vivified by their influence the whole field of industrial art, and stamped its smallest creations with grace and that indefinable quality of style. None more than ourselves have urged the necessity of the study of the work of those days. But we must not crystallise ourselves in our admiration. Is not the domain of the beautiful essentially a field without limits? And is there not a fear that if, from a distrust of ourselves, or inertia, we cease to excite the productive powers of beauty, they may become sterile, and refuse to yield their customary harvest? The sentiment of the beautiful is scarcely less dependent for existence than human nature on a supply of sustenance, and its stonemasonry is imagination. Now imagination pines and dies when it is not exercised on new objects. Coming to the point, what will be the result of the existing persistent mania which consists in surrounding ourselves only with old-style furniture and more or less servile copies of works of the past?

On the one hand, the designers for the trade seek their motives only from old authorities, and carry out their combinations just as we have machines made, on purely mathematical principles. On the other hand, the manufacturer's aim would lead him to the sole imitation of the old, with the direct result, from want of the creative faculties being

exercised, that the laws on which the old models were produced would be overlooked, or soon become ridiculously harlequined. Before this happens, it is not time to endeavour to prevent the spread of the misunderstanding which exists between the producer and the consumer? The public must understand that a manufacturer is merely in the position, so to speak, of an echo, answering to the call of the bad or the good taste of the purchaser. On the other hand, again, the manufacturer must understand that the public taste largely depends upon him and his satisfying promptly the demands of that taste. As long as he confines himself to producing old style, the chances are that old style will be all that is demanded.

Remains now another question. The time must come, or there will be no progress marked, when the public will understand the manifest superiority of commissioning and possessing for themselves a work of art, a piece of furniture, or what not, adapted, as was the case in the past, to the individual taste of the patron, instead of being a model made common by wide reproduction, however beautiful. Those who earnestly look forward to a real improvement in the taste of the public look forward to the day when what will be especially appreciated in the interior decoration of our houses will be in each possessing an originality of form, an architectural harmony of *ensemble*, a delicate choice of furniture, in keeping with the surroundings. The fashion for *bibelsots* and *bric-à-brac* will have passed away, largely because the *bibelsots* will have become impossible to find,—they will be hurried away in museums, or their gaudiness will be so doubted that the man of taste will avoid the possibility of imposition. Then at last we shall be able to return to the position of our forefathers in the matter of our household surroundings. They never troubled themselves as to whether their furniture was Chippendale or Louis-Quinze, Gothic or Renaissance, if their plate was Queen Anne or Irish. All they exacted was that their surroundings should be elegant, and thus they stimulated and created a race of original artists.

Here, however, an objection presents itself. Admitting that the public will understand the advance of these changed conditions, and surrounded by objects that, instead of diminishing in value with time will increase, as is the case with the works of the past, where is such an ideal public to be found? It can never be anything but very restricted in number. This is where the whole difficulty lies. In the existing state of our industrial arts it is perfectly true that it is alone the possessors of exceptional means who are able to employ artists to design their surroundings or carry out their tastes. This is the evil of the present condition of the industrial art-world, and till some remedy is found we can scarcely venture to vaunt our progress in taste. That eminent critic, the late Charles Blanc, has admirably laid down, in his recently published "Grammar of Decorative Art," that the laws of taste are happily of so elastic a nature that they are perfectly able to accommodate themselves to different conditions, and are applicable to every degree of fortune. Although it is an essential refinement, and a superiority of artistic sentiment has nothing incompatible with the utmost simplicity of condition. Taste, in fact, as has again and again been said, can be displayed as well in a modest habitation as in the most gorgeous palace. Again, it has often been laid down, the beauty of an object may be completely independent of the value of its material; one may produce a beautiful object without its necessarily being costly. This is beyond contest. But is it possible in the present condition of the art-industries to find these conditions fulfilled, always setting aside Japan, which seems to have attained this aim? The cause is only too simple to point out. Take the item of furniture. How is it that the best makers are unable to supply works of special taste at any thing like a price which is within the means of the less fortunate? They will tell you that the mere cost of production, payment of designers, "skilled" workmen, &c., is very considerable. They consequently can only deal with very wealthy customers, and those, even, are not many. As to the public at large, it is simply afraid to think even of such things; it is on the look-out for what is cheap and yet "artistic," and generally finds or contents itself with, what the trade supplies,—furniture which, when not in execrable taste, is of monotonously aggravating

style, clumsily copied from old examples. What else can the public do?

Many years ago, for the question has long been disturbing the thoughtful, the Comte de Labarde,—whose share in the great 1851 Exhibition will by some be remembered,—suggested a remedy for the somewhat hopeless position in which the public and the manufacturers were placed. He suggested the formation of an establishment to produce, not for the public, but for the trade,—a series of designs and specimens of work to serve as models to the manufacturers; to carry out, in fact, the aim intended by the Sevres establishment for ceramics and the Gobelins for tapestry weaving; to introduce art into the smallest objects of existence; and, above all, that they should be suited to the varied uses for which they might be intended.

This scheme, sketched out by an enthusiastic lover of art, a well-known Parisian manufacturer has announced his intention to endeavour to put into action. He has long been preparing the plans, and in its smallest details he has studied the question. He has provided himself with a model of the establishment, and all the estimates are made out. No detail has been neglected. The interests of all employed will be bound up with the prosperity of the institution. A school of apprentices has been planned, and of a most practical nature, the pupils having each day under their eyes the example of their teachers. This is a most important and too often overlooked point.

The theoretical education at present given is certainly in many points good; but in what does it result? Does it form workmen? Does it not rather simply create artists, who are not suited for their work, and who, on leaving school, ignore the most elementary notions of the work necessary in the workshop, for which they should have been trained, or who disdain the manual labour, the use of which it has never been deemed necessary to show them the necessity? Young men will be found who, after passing four or five years of their life in the study of a profession, are incapable of practising it in such a manner as to gain even their bread; and what is the cause of this powerlessness and disdain for manual labour, at the bottom of all the evil? It lies in the fact that the masters in the schools have been able to give to their pupils only theoretical notions of design, without joining practice to example. To each school should be attached a workshop, in which the young people should, after their minds have been exercised, learn the use of their hands and tools. Under these conditions we may hope for a real amelioration of our art industries.\*

#### THE ENGINEERING CONGRESS AT MAGDEBURG.

THOUGH following somewhat closely the Hanover assembly of architects and engineers (see *Builder*, p. 313, ante), the attendance at the above congress was satisfactory as to numbers, and the proceedings throughout were of an interesting character. The business portion of the programme was disposed of on the 27th ult. at a preliminary sitting, so that the time fixed for the duration of the congress itself (28th to 30th ult.) was free for the discussion of various matters of professional interest, and for the festive gatherings which form such a prominent feature of such meetings in Germany.

At the opening sitting on the 28th ult., Herr Wolf, on the part of the Government, congratulated the Union of German Engineers on their assembling for the twenty-third time to discuss matters of interest to the profession. He remarked that in no branch of learning had such progress been made during the last ten years as in engineering, this development having led into new paths many important national industries,—amongst them, those connected with mining, traffic matters, and appliances for lighting purposes.

Herr Born (the Burgomaster of Magdeburg), in a congratulatory address of welcome to the Congress, referred to the fact that the industrial development of the city had been intimately connected with the progress realised during the last quarter of a century by German engineers. Such progress had, he observed, placed the nation on an equal footing with others, which was not the case at one time.

\* The above is a free rendering of an article by M. Victor Champier that appeared in the pages of the March number of the *Revue des Arts Decoratifs*.

Herr Dittmar (of Eschweiler), the president, thanked the previous speakers for the sentiments they had expressed, and spoke of the encouragement the Union received from the appreciation of their efforts at such a centre of technical industry as Magdeburg.

Herr Peters (of Berlin), the secretary of the Union, reported that there were now 4,400 members, 74 per cent. of these belonging to local unions, and 26 per cent. being in direct communication with the central body. One of the entire number, 235 are resident in foreign countries. He alluded to the labours of the various commissions which, during the past year, had been dealing with subjects affecting the interests of members, such as the questions of technical instruction in workshops, and employers' liability for accidents.

The scientific part of the proceedings was opened by Professor Fischer, of Hanover, with a paper on "Heating by the Storage of Warmth." His remarks were in some measure only applicable to the system of heating by means of tiled stoves so usual in Germany, respecting which he stated that the comparative thinness of the materials now commonly employed allowed them to give off heat in more or less exact proportion to the rate in which it was supplied to them. In this respect they differed from the old-fashioned stoves. He then alluded to the system adopted in 1843 by Grouvelle, for the improvement of the heating arrangements at the Mazas Prison in Paris. Heating by means of warm water had been known for a long time, and where storage of warmth was required, had been found to answer the desired purpose, but the want of mechanical power in hot water had prevented its successful application to the heating of large buildings. Grouvelle's principle was the utilisation of the mechanical power of steam in conjunction with the previously-known system of heating by means of hot water. The irregularity of the heat thus given off having been found to be a disadvantage, the efforts of those interested in that branch of engineering had of late years been directed to obtaining uniformity in the supply of heat, and according to the Professor's theory, this end is best attained by the water reservoir being placed in the cellars, the water being there heated by fire from underneath. The insertion of a stopcock provides for the supply of the water to the serpentine pipes leading upwards, and for the regulation of the amount of heat. He remarked that it is without any real influence on the heat given off whether water or steam be employed, but he pointed out that with steam heating a comparatively large quantity of steam is used in the first instance, and hence a boiler of somewhat large dimensions is necessary. In conclusion, he stated his opinion that heating by means of the storage of warmth is only to be recommended where the mechanical arrangements allow of a uniform heat being maintained, if necessary, while also providing for the increase or decrease of the supply, as may be found advisable. He attached particular importance to the storage of heat being arranged in such a way that there should be no difficulty in shutting off the heat from the rooms thus served to any extent which might be found desirable by its occupants, this regulation of the supply of heat being rendered specially necessary by the variable nature of the German climate.

In his paper dealing with "The Technical Application of Electricity" Dr. Zoxner referred to the invention of an electrical machine in 1630 by Otto von Guericke, a citizen of Magdeburg, and claimed for him a priority of discovery in this branch of science. With reference to the electric light and its application to domestic lighting purposes, he spoke of the successful attempts of Herr von Helmholtz to remedy certain imperfections of some systems, such as that by which the extinction of one light used to involve the extinction of the entire circuit of lights. He also spoke of a German invention which permits of the easy renewal of the filaments of carbon in electric lamps, which by their yellowish light seem likely to be more appreciated for many purposes than those which have the white light first known in connexion with electric illumination. He dwelt further on the advantages of lighting railway carriages by electricity, on which subject deliberations and experiments are now being carried on by railway administrations at Frankfurt and Strasburg. The lighting of railway carriages by gas caused an un-

pleasant odour at times in the carriages and on the platforms. By means of the Faure accumulator, there is no danger of the extinction of the light from the stoppage of the train, although the motive force for the electrical apparatus is furnished by the rotation of the wheels. He likewise referred to the trials of transmission of electric force over distances of some magnitude, which will form a feature of the programme at the Munich Exhibition, and which it is expected will be of advantage to the cause of electrical science, particularly with reference to the question of electric railways.

The second day's proceedings were of varied interest, and included papers on "The most recent Improvements in Sugar Manufacture," "Progress of Boring Science during the last Ten Years," and "Salt-mining in the Stassfurt District." In connexion with the last-named subject, an interesting excursion had been organised to Stassfurt.

On the closing day of the congress a number of interesting matters were brought forward for discussion. Herr Peters (the secretary) proposed that the necessary communications should be entered into between the Union and the German Government for the establishment of a fixed remuneration for engineers summoned as judicial experts, on the basis of the scale laid down by the Engineers' Congress at Gotha. This scale was as follows:—4s. per hour at their own houses, or 5s. per hour out of their dwellings, but in the same town. As to matters which involved travelling, it was suggested that the scale of remuneration allowed to attorneys in similar cases should be made legally applicable to technical experts.

Professor Inze, of Aix-la-Chapelle, spoke of the advantages arising from the adoption of normal models for rolled iron. The same member also referred to some length to the measures which the Union of Engineers was taking in conjunction with the Architects and Engineers' Union to bring about the rational utilisation of the water-power of the German rivers. The sanitary advantages of the regulation and purification of rivers were dwelt on by him, and the instance was cited that, in a department of France where such measures had been carried out, the mortality sank from 40·5 to 25·4, and the average duration of life increased from twenty-five to thirty-five years, while the number of recruits who were not up to the medical requirements of the military regulations diminished from 52 per cent. to 9 per cent.

The excursion by boat to the Herrenkrug Park was an interesting feature in the proceedings of the congress. Messrs. Faber, the printers, presented each member of the congress with a large card of welcome, which was printed in presence of those members who visited the works in a body.

#### SALTBURN-BY-THE-SEA.

ONE of the pleasantest, though not the best known, of the bathing-places on the north-east coast, is that of Saltburn-by-the-Sea. It is comparatively new, and, depending largely upon the patronage of the large towns near it, it has felt keenly the depression in trade in the last few years, though its natural attractions are now again drawing numbers to it. It may be described as the extreme north-eastern point of Yorkshire, and is built on a bold bluff that overlooks Huntcliff Foot, one of the prominent cliffs on that coast. Down to a score of years ago there were in Saltburn only the old hamlet, — a few houses scattered around a conical little hill, and noted as the past resort of smugglers. The site was judged suitable for a new watering-place, and in 1863, the Zetland Hotel, erected at a cost of 40,000l., was opened, and the new town shortly afterwards sprang into being. It is built on the top of the cliffs, 150 ft. above the sands, and whilst, on the one hand, these yellow sands stretch uninterruptedly for miles, on the east a deep glen, with almost precipitous sides, has been laid out as pleasure-grounds, and shows a mass of diversified foliage, beds, lawns, temples, and terraces. From the end of this a thick wood extends to the Skelton Castle, the ancient home of the great De Bruns family, and in later years the resort of Sterne. This Skelton Glen, at Saltburn, is spanned by an elegant girder bridge, and the new town, its erections and appliances, point to the aim to fit it for the comfort of pleasure-seekers.

By sea and land its views are stately rather

than magnificent. The gardens, from the seaward entrance to the Spa that terminates them, present many a striking landscape, especially when the hold bluffs of the hills are seen through the leafy screens, or the "iron reservoirs" of Cleveland present their bare peaks to the eastwards, with well-wooded valleys between, and occasional mansions such as that of Rushpool liall striking sharply and clearly out from the steep sides of the glen. Seaward, magnificent views are seen. To the south there are at the little rivulets' mouths ancient fishing villages such as Staithes and Runswick, the abode of a hardy race of fisher folk; whilst to the north-east, clearly and distinctly, the manufacturing town of the north are seen beyond the "golden sands," or across the estuary of the Tees. From these, "beneath their smoky veil," the eye travels along the sandy coast, dotted with one or two abodes of the iron manufacture, till it sees the ancient village of Marske and its now disused church on the higher ground, and then along the sand-banks and the cliffs that grow ruddy until the white-bricked houses of Saltburn glisten, and thence across the glen to red Huntcliff. Little streams brawl noisily down the glens, where thick woods cluster; but beyond these the country has a moorland aspect, and the mining village that dots the rising ground towards the hills gives it unwonted animation. It is a region that was sparsely peopled, remote, and unknown; industry has developed the mineral wealth of its hills, and for the rest and recreation of some of those so brought to the district, several seaside resorts have sprung up, not the least attractive of which is Saltburn-by-the-Sea.

In the past few months there have been indications of improvement at Saltburn, and in the district near it. The last link of the new line of railway that is to connect it with Whitby is just about completed; there has been a considerable revival in the demand for crude iron, and this will give to the iron mining district that helts Saltburn a marked impetus; and after long idleness the whole of the district seems to feel new life. The long-empty houses are filling, and the art of the builder is being again called into requisition. The sanitary organisations are busy, and there are all the signs that in the course of a few months there will be a further marked improvement in the district. The cloud that hung over the commerce of Cleveland has been lifted, and with brighter prospects there are to be expected brighter times for the pleasant health resorts that become barometers of the trade and commerce of the country.

#### THE PRESERVATION OF ANCIENT MONUMENTS IN SWITZERLAND.

THE time when as good as nothing was done in Switzerland for the preservation of ancient monuments of art is fortunately over. There has been a hard struggle for it; but now existing societies do much in this direction, and intended destruction is prevented by prompt action. It looked for some time as if the government of one canton (the town of Basel) were on the point of sacrificing one of the most beautiful churches. It was proposed to take down the Barfüsserkirche at Basel,—dating from the beginning of the fourteenth century, and let in recent years as a warehouse,—and to use the site for the erection of a school. This scheme would probably have been carried out, but steps have been taken, the result of which will be the preservation for future generations of art-lovers of the most imposing and, next to that of Cologne Cathedral, loftiest choir on the Rhine. Basel Minster, also a most imposing edifice, and erected in the beginning of the eleventh century (by Emperor Heinrich II. of Germany), is likewise undergoing thorough restoration. The works are proceeding very satisfactorily; the two beautiful western towers, visible from a considerable distance, have been restored, a great deal of labour having been spent upon them during the last two years and a half. It appears now that the works were highly necessary if the noble building was not to suffer to such an extent as to render later renovation almost tantamount to re-erection. The progress of those works and the rejuvenation of the venerable Basel Cathedral have given a fresh impulse to the work of restoration also elsewhere in Switzerland. At Bern, for instance, the question of

completing the Minster there has been much ventilated. An acting committee has lately been considering a report by Oberbaurath Egler, of Stuttgart, on the possibility of completing the unfinished tower. A Geneva architect (Herr Leemann) has been occupied for some time in executing a large model of Bern Cathedral, as it would appear with the tower completed according to the original plans. The cathedral was begun in 1421, completed in 1573, and restored in 1850; but the tower was never finished, and is at present only 134 ft. high, and covered with a clumsy-tiled roof; but, if properly carried out, it will be of colossal dimensions. The model will not fail to incite the Bernese to exertions in the matter.

#### THE NEW COUNTY PUBLIC OFFICES, FISHERGATE, PRESTON.

THESE buildings have been designed to group with the buildings adjoining, which were erected in 1878 for the head quarters of the county constabulary. The whole pile is now completed, and occupied by the officials connected with the transaction of the county business. The character of the design adopted by Mr. Littler, of Manchester, the architect, is a modification of the style prevailing in the reigns of Elizabeth and of James I., and partaking rather of that known as Jacobean than that of the earlier period. The external facings of the walls are of red pressed bricks, with stone string-courses, cornice, window quoins, mullions, and other dressings. On the stone shields are carved the royal arms of the Duchy, and those of the House of Lancaster. The whole block has a frontage to Fishergate of 180 ft., and to Pitt-street of 184 ft., inclusive of care-taker's house and intervening gateway to court-yard.

In order to utilise to the greatest advantage the area of ground afforded by the site, an open-air court is formed, around two sides of which the offices and other apartments are grouped. The walls of the court are lined with glazed white bricks. A central corridor on each floor gives access to the various rooms and offices, which face the public thoroughfares.

The ground-floor, which is 4 ft. or 5 ft. above the street level in Fishergate, is occupied by the Clerk of the Peace and his staff; and on this floor there are two staircases and two entrances. The principal entrance is from Fishergate, and the first glance of the interior gives the impression that the work is in every respect worthy of the county. Facing the entrance is a long corridor leading to the various offices, the record-room (which is fireproof), and the dining-hall. On the right is the porter's room and the office of the second Deputy Clerk of the Peace; and on the left the office of the Clerk of the Peace, and the Deputy Clerk of the Peace. On the opposite side of the same passage is a room occupied by the clerk to the Clerk of the Peace, and a large general clerks' office. All these rooms are elegantly and substantially furnished. We next pass the way down to the basement, which is lined with white glazed bricks, specially made. In the long corridor, on the right, are the lavatory, the court crier's room, and two rooms occupied by solicitors, who are assistants to the Clerk of the Peace. On the left hand are the library, the stationery room, and large record-room for the Clerk of the Peace.

We next ascend the grand staircase, with tiled walls and wrought-iron balustrade, to the first floor. Here are found similar suites of rooms to those below, which are occupied by officials connected with the financial business of the county. The county treasurer's office is a handsome room, and adjoining it is that of his chief clerk. The next office is that of the county auditor, and on the opposite side are commodious rooms for his clerks. At the end of the passage is a door leading to the constabulary department. The room allotted to the second clerk to the county treasurer is the most handsome one in the building as regards fittings, and no little ingenuity has been displayed in the compactness and convenience of its arrangements. The joiners' work is of pitch pine, most carefully selected, and the markings of the wood are of extreme beauty. Such choice specimens of pitch pine (French polished) as have been used in all the fittings throughout the building are rarely seen; and a timber merchant speaking in reference to the room in question—

where there was a good opportunity for the display of workmanship, said, in expressing his admiration, "The man who has done this deserves to be knighted." Passing down the corridor, on the left, are rooms for clerks to the county treasurer and auditor, and the record-room connected with their departments. On the right is the committee-room, with ante-room and lavatories. At the end of the corridor we reach the large hall, or court-room, for the county magistrates, in which they meet for the transaction of the county business. Here the decorators have had an opportunity for the display of their ability. A pamphlet has been prepared by Mr. C. R. Jacson, J.P., the most active of the county magistrates, descriptive of this room, and the picture-subjects, heraldic devices, badges, and mottoes on the walls and windows. The dimensions of the county sessions hall are 62 ft. by 45 ft., and it is 36 ft. high, with an open-timber roof in character with the style of architecture of the building. It is lighted by a lantern-light in the roof, and by large windows with semicircular heads, having stone mullions and transoms, glazed with lead-lights of suitable design. In connexion with the court is a retiring-room for magistrates, an entrance, and a platform for the public. The court-room fittings are all of pitch pine, darkened to harmonise with the walls; and accommodation is provided for about 200 magistrates, in addition to the county officials and reporters to the newspapers. One of the staircases already mentioned is continued up to the second floor, or attic story, in which additional office room and store rooms are provided.

Descending from the court-room we reach the luncheon or dining room on the ground floor, which is wainscoted with pitch-pine. Every panel in the framing is a specimen of well-marked wood.

The court-room, corridors, and offices are warmed by hot-water pipes, in addition to open fireplaces in the principal rooms, the apparatus in use being that of Messrs. Metcalf & Dilworth, of Preston. The offices are all connected by speaking-tubes, and by telephone to distant parts of the town, so that the officials can communicate with each other, and in any direction, without leaving their rooms. Hydrants are provided on the staircases and corridors, and extinguishers are at hand for the purpose of extinguishing fire. The floors of the corridors and record-rooms are carried on brick arches, and the floors laid with marble concrete of a grey tone.

In the basement are the kitchens, scullery, hoists, stores, hot-water apparatus, and strong-room for the deposit of valuable parchment records. Along the corridors are rooms in which the county registers, election papers, ballot-boxes, &c., are kept for each division of the county. There are rooms for the storage of plans which have to be deposited with the Clerk of the Peace, and documents which are least required for reference. One or two minor officials,—such as the bridge-master and the cattle-plague officer, have quarters in the basement.

Mr. John Walsmsley, of Preston, has been the general contractor for the erection of the building; and Messrs. David Tullis & Son have done the masons' work, as sub-contractors under Mr. Walsmsley. The County Hall has been decorated by Messrs. Shrigley & Hunt, of London and Lancaster, under the supervision of Mr. Hunt, from designs by Mr. E. H. Jovitt and Mr. J. Milner Allen, of London, who have executed the same. The furniture has been made by Messrs. Bell & Conpland, of Preston; and the whole work is done in a satisfactory way, and reflects credit upon the contractor.

The entire cost of the building and site (constabulary offices included) has been 58,000l.

Previously to the erection of this block of buildings, which is within two or three minutes' walk of the railway station, the various public offices were scattered, and documents were stowed away in boxes, cupboards, and drawers, some at one place and some at another, wherever room could be found for them; and the magistrates had to meet at the Court House, more than a mile away. All are now brought together under one roof, which is a great convenience, not only to the officials, but to the general public who may have county business to transact.

To the foregoing general description of the buildings we add some particulars of the decorations. Generally speaking, the scheme of

decoration is as follows:—An attempt has been made to illustrate the history of the county in its relation to the national history by means of picture subjects, portraits, heraldic devices, badges, and mottoes, and to indicate the chief use of the hall by appropriate inscriptions. The history of the county painted is interwoven with the history of England from the earliest period. The legends of the county are found amongst those which appertain to the country at large. The pictorial subjects represented in the semicircular heads of the panels are as follow:—South wall.—Combat between Sir Tarquin and Sir Lancelot du Lac, the Roman Castle of Manchester in the distance. According to Roby, Sir Thomas Mallory, and other writers, these two knights were resident in Lancashire (the one near Manchester, the other near Martin Mere). The shields flanking this subject are, dexter, King Arthur; sinister, King Edmund the Martyr, 2. Alfred dividing the kingdom into shires, hundreds, and tithings,—dexter shield, Alfred the Great; sinister, Edward the Confessor. 3. William I. granting what is now Lancashire to Roger de Poitou (so called from his having married Alwold Poictin), the great Baron of Lancashire, as a reward for the services rendered by his family to the Conqueror,—dexter shield, William I.; sinister, Roger de Poitou. 4. John granting Magna Charta,—dexter, King John; sinister, Simon de Montfort. West wall.—5. Marriage of Henry VII. and Elizabeth; union of the houses of York and Lancaster,—dexter shield, Henry VII.; sinister, Elizabeth of York. 6. Crowning of Henry VII. on the field of Bosworth,—dexter, Queen Elizabeth; sinister, the Duchy of Lancaster. North Wall.—7. James I. at Houghton Tower,—dexter shield, Tyldesley; sinister, Houghton of Houghton, created baronet, 1611. 8. The Defence of Lathom House,—dexter shield, Charles I.; sinister, Stanley.—Lathom. Heraldry.—South wall, in panels (below the historical subjects)—King John, *Comte sans terre*, made Earl of Lancaster by Richard Cœur de Lion; William Radcliffe, sheriff, A.D. 1194; George McCordqudale, present high sheriff; Henry III.; Edmund Crouchback; Edward I.; J. Wilson Patten (Baron Winmarleigh) and Sir Benjamin Heywood, the two last representatives of the entire county; Edward III.; Henry Grismond, first duke of Lancaster; Sir Henry de Haydok, chancellor of the first Duke of Lancaster. West wall.—H. M. Victoria; John o' Gaunt; Richard II.; Henry IV., first monarch of the Lancasterian line. North wall.—Henry VII.; Elizabeth; Edward, Lord Stanley, first lord-treasurer of the county; Molyneux, of Sefton; Gerard le Bryn. The side panels throughout the hall are filled by the rose of Lancaster. South wall.—Returning to the doorway leading to the magistrates' bench, we have portrait illustrations of some of those who by their enterprise, invention, perseverance, skill, and refinement, have contributed to the greatness, wealth, and happiness of the county.

1. Francis, 3rd duke of Bridgewater, representing Enterprise. 2. Sir Robert Peel, 1st Bart., Commerce. 3. Sir Robert Arkwright, Kt., Manufactures. 4. Crompton, Invention. 5. Roscoe, Literature. 6. Whitaker, History. 7. Holker, Jurisprudence. 8. Romney (Pine Arts), from a portrait of the artist by himself, in the possession of John Romney, esq., of Whitestock Hall, Ulverston. The female heads in the picture represent a well-known favourite subject of the artist. 9. Whewell, Science. The hall roof, five panels in height, is decorated with the arms of the Duchy, with the addorsed Talbot supporters, the Lancashire rose crowned, and the motto "Dieu et mon Droit," in the upper and lower two panels, the central band having a blue field on which are the rose, thistle, and shamrock, with the national mottoes, "Dieu et mon Droit," "Nemo me impune lacessit," "Quis separavit," "The panels of the lantern roof are devoted alternately to the feather and the falcon and padlock badge of John o' Gaunt, and the feather entwined with a garter, with the motto "Sovereigne" of his royal son, Henry IV. In the windows are set forth the badges of all the English sovereigns from the Conquest to the present day, as follow:—South side: 1. Norman. 2. Plantagenet. West side: 3. Plantagenet. North side: 4. House of Lancaster, Henry IV. 5. House of Lancaster, continued. 6. House of York. 7. House of Tudor. East side: 8. House of Tudor. 9. House of Stuart. 10. House of Hanover. The east wall, below the spring line of the window-heads, is decorated with the arms of the four

Quarter Sessional Boroughs of Manchester, Liverpool, Bolton, Wigan, which occupy the central spaces between the windows. The two outer spaces contain the principal boroughs (not already named) of the six Hundreds,—Lancaster, in the Hundred of Lonsdale; Preston, in the Hundred of Amounderness; Blackburn, in the Hundred of Blackburn; Chorley, in the Hundred of Leyland; Salford, in the Hundred of Salford; and Warrington, in the Hundred of West Derby. Above the window-heads the wall is diapered with the C.P.L. (County Palatine of Lancaster) alternating with the Lancasterian rose. The shields of the remaining boroughs are disposed upon the west wall and below the corbels on the north and south walls, and the remaining wall space is diapered upon a full green field with the initial letter "L" euseigned with the royal crown. Over the principal entrance of the court are the arms of the county carved in wood. The court is lighted by two gaseliers of wrought brass. It is intended to fill the staircase window with coats of arms, illustrative of the history of the County Palatine.

It was intended that the new County Sessions Hall should be opened on Thursday in the Guild week (7th inst.), by the Duke and Duchess of Albany; but, owing to the illness of the Duke, the ceremony has been postponed to Thursday next, the 14th inst., when the Earl of Derby will open the courts, and deliver the inaugural address, in his official capacity as chairman.

#### THE PRESENT SITUATION OF THE BUILDING INDUSTRY IN GERMANY.

The Union of Master Builders (numbering 4,200 members) has presented a petition to the German Government on the subject of re-introduction of the test-examination for masters. It is urged that the present freedom of admission to the trade is doing injury to it, and is also prejudicial to the interests of the State and of the public at large. The petition goes on to explain that building is an industry which requires all possible assistance from science and art, and that the development of building has at all times been a proof of the general culture of a nation. Thus it is argued that it is unwise to allow persons completely devoid of scientific and technical knowledge to exercise a calling of this nature. It is remarked that the fact of unqualified persons being in the trade imposes upon the public unnecessary trouble and expense in guarding themselves against the dangers of giving work into incompetent hands.

In support of the scheme for a test-examination it is urged that the younger members of the trade are anxious to have a definite object in their studies, and are desirous of having their qualifications vouched for by competent authorities.

In conclusion, it is argued that the proposed restrictions on admission to the building trade are no more a violation of commercial liberty than are the tests which are usual in other callings, of which the unrestrained exercise by incompetent persons would be dangerous to the public safety, the analogous cases of apothecaries, sea-captains, pilots, &c., being brought forward in support of this view of the subject.

**Fall of Buildings.**—An accident that might have been attended by serious results occurred on the 30th ult. at the National School, Mellor, Blackburn, which is being rebuilt. It is stated that a gable had been run up very rapidly to the height of 20 ft. The heavy rains had kept the mortar soft, and some of the stonework fell. The men at work on a scaffold were precipitated to the ground, and one of them had a narrow escape. Two wallers, named Beatrice and Myerson, were injured, one having an ankle sprained and the other being cut about the head. On the same day a joiner named John Woods was working inside the Mason's Arms Vaults, Salford, when he narrowly escaped with his life from a heap of falling building material. The building was being demolished, and two men were engaged pulling down the fire-range on the ground-floor, whilst Woods was pulling up the floor-boards in the second story. They called out to Woods to come and assist them, and he replied, "In about a minute." Immediately they heard a crash, and rushed out of the building, which fell inwards. Woods was buried in the fallen ruins, and when extracted he was found to be suffering from injured ribs.

THE HARRIS FREE PUBLIC LIBRARY AND MUSEUM, PRESTON.—MR. JAMES HUBBERT, ARCHITECT.

W. & A. G. & Co. Printers, Queen St.

THE NEW PROVINCIAL ESTATES HOUSE, HANOVER.—HERR F. WALLBRUCHT, ARCHITECT.

### THE HARRIS FREE PUBLIC LIBRARY AND MUSEUM, PRESTON.

The foundation-stone of this building was laid on Tuesday last by the Earl of Lathom, with Masonic honours. The ceremony was to have been performed by H.R.H. the Duke of Albany. We described the building at some length in a previous number,\* and we now give a view of the proposed building and a plan of the principal floor. For convenience sake, it may be as well to repeat a portion of what we then said, with some further particulars.

The designs have been prepared by Mr. James Hibbert, who was commissioned by the Harris Trustees to visit several buildings of a similar character in this country and on the Continent, the result of Mr. Hibbert's visit and report being that he was appointed the architect to prepare the designs.

The building will be of the Greek Ionic order, and will have four distinct frontages, being completely isolated from the buildings around it. The principal elevation is on the west side, overlooking the market-place, and almost at right-angles with the north frontage of the town-hall. The height of the frontage to the parapet and the apex of the portico is 80 ft., and the extreme height to the top of the central lantern, 112 ft. The portico consists of six massive fluted columns, with bold capitals. It is surmounted by a bold overhanging cornice, and the tympanum is filled in with a group of figures representing Minerva surrounded by Literature, Science, and the Arts. The frontage is 130 ft. The bases of the columns of the portico and its floor level are about 10 ft. above the street level, and the entrance to the building is under the portico by flights of steps on the north and south sides. Immediately under the tympanum of the portico is the carved inscription in large characters,—“To Literature, Science, and Art.” The eastern elevation of the building faces Lancaster-road, a fine thoroughfare about 60 ft. in width, leading out of Church-street, the principal street in the town. It is uniform in length with the Market-place frontage. The north and south frontages are each 170 ft. in length, and will face two new streets, each 50 ft. in width, which are about to be constructed in connexion with certain town improvements intended to be carried out simultaneously with the erection of the Free Library buildings.

The collection of models connected with the industrial arts will be placed on the ground-floor portion of the central hall, with the object of bringing them under the daily observation of visitors passing to and from the leading department and the adjacent reading-room and news-room. The newsroom on the south side, and the reading-room on the north side, are each 29 ft. by 55 ft.; one of the lending libraries is 50 ft. square, and the other 55 ft. by 29 ft. The central hall is 54 ft. square, and is continued, by the staircase, on all the floors, being lighted by the lantern immediately over a central well. The principal floor contains the reference libraries, on each side of the central hall. They are each 30 ft. in width, and 120 ft. in length. The central hall portion of the principal floor will be set apart as a museum of casts and reproductions from the antique. On the principal floor there is also a conversation-room, and a room for chess and draughts. The whole of the upper floor will be devoted to museum and fine-art purposes. The museum galleries are arranged round three sides of the central hall and staircase, one side being devoted to the fine arts, the corresponding side to natural history and physics, and the remaining side between these to the department of general archaeology, ceramics, and the finer kinds of industrial art, and illustrations of ethnology.

Adopting the statement of the architect, for the fine-art galleries time will be required to form a permanent collection that can be considered equal to the objects in view; but meanwhile much may be done in utilising them for exhibitions of the works of living artists and of loan collections. The pecuniary means, however, immediately at command would purchase, for instance, such examples as a complete series of the publications of the Arundel Society, consisting of fac-simile reproductions, in chromolithography and engraving, of paintings in fresco by the old Italian and German masters, which might be framed and placed in the galleries. An historical collection of engravings and etch-

ings arranged in the order of the various schools and masters would equally be attainable. Autotypes, also, on a large scale, of famous paintings in the great European galleries, and characteristic works like the “Liber Studiorum” of Turner, are now procurable. Illustrative examples such as these, though not costly, are of greater interest, and certainly of higher value in educating the public taste than those mediocre specimens of the works of living artists which form the greater part of our annual exhibitions. Modern pictures, that is, those of living artists, can only be very sparingly bought with the endowment fund, and even those only need be purchased which exhibit the best elements of the school to which they belong.

The central hall and staircase are proposed to be devoted principally to works of sculpture after the antique and later schools, and may be rendered, in a degree, somewhat unique in a provincial town. The friezes and metopes of the Parthenon, and the Temple of Theseus at Athens, and the frieze of the Temple of Apollo Epicurius at Phigaleia in Arcadia, may not only be among the models presented of the best Greek art, but can be arranged so as to form the permanent architectonic decoration of these parts of the interior. Some of the finest works of Greek and Greco-Roman statuary, as well as of the later masters, in fac-simile reproductions, may be purchased out of the funds immediately available.

The architect justly observes:—“The character of the design is academical, conceivably the most appropriate. Influenced by studies of Ionian art, its chief features are simplicity and symmetry of plan, truthfulness of expression, and, in execution, refinement of detail. In the plastic arts, as in literature and geometrical science, the Hellenic race has reached the highest standard. If Greek architecture is to be retained in practical service, it is requisite, when opportunity affords, to present new combinations of its forms. For the purposes of a library and museum,—a repository of knowledge, of examples of the arts, and of specimens illustrative of the sciences,—its suitability will be admitted. There are no fashions in architecture, as in most artistic productions of the time. A structure, however, that is fit for its uses, subserves its distinctive functions, and is in harmony of expression with the nature and quality of those functions, stands above the fluctuations of ephemeral taste. Such, in this instance, is the object to be sought and endeavoured, as far as the building is concerned, the production of a work of permanent value, an example of memorial art.”

The design has received the approval of the Harris Trustees, and they have resolved to devote 70,000*l.* of the funds of their trust to its execution, with all the attendant expenses.

### MARINA HOUSE, WALMER, KENT.

We illustrate another of the several houses which have been erected by Mr. Alexander Tod at Walmer, from the designs and under the personal superintendence of Mr. James Neale, F.S.A., of Bloomsbury-square, London.

The house is situated on the beach, and commands uninterrupted sea views, overlooking the Downs and the coast of France. When Mr. Tod purchased the land about a year ago there was on the site a small house, built with outside walls of a single brick in thickness, and cemented, but with a picturesque verandah. To this house it was only intended to build a wing. The wing was well advanced when it was decided to pull down the front of the house so as to get thicker walls and make the old elevation in keeping with the new. Eventually the whole was removed. The various changes somewhat governed the arrangements of the plan. The house is erected as shown on the drawing, excepting a slight change in the treatment of the dormer terminating the bay-window.

The principal story is raised some 6 ft. above the level of the ground, so as to take advantage of the sea views. This causes the basement story to be well out of the ground and thoroughly light.

The house is square on plan. It contains, in the basement, housekeeper's room, servants' hall, kitchen, pantries, larders, water-closets, &c. On the principal floor are five reception-rooms, butler's pantry, and bedroom. There are fifteen bed and dressing rooms, with ample bath-room and the necessary accommodation.

The serving lobby of the dining-room is separated from the principal part of the house, and is supplied with a lift. The balcony-room is intended for billiards and smoking.

Special care has been taken with the sanitary arrangements. Air is admitted into the halls, heated by Doulton's radiating stoves, and circulated through all the bed and sitting-rooms. The house is well fitted; there are water-closets and hot and cold water on each floor.

The verandah in the centre of the front of the house can be approached from either the drawing or dining rooms, and can in winter be glazed so as to give additional warmth to these rooms. The principal entrance of the house is through the glazed conservatory entrance at the side. This leads into a large central hall 31 ft. long by 13 ft. wide. The main staircase is enclosed within an arcading, and forms a picturesque feature.

The external walls are hollow, being faced with Teynham red bricks on the two lower stories. The timbering of the upper story is backed with brickwork one brick and a half in thickness; the timbers are painted a dark combed oak, and the panels filled with pebble dash, collected from the sea shore. The roof is boarded, felted, counter rafted, hatted, and hung with Brossley tiles. The hip and valley tiles have been purposely made to range with the tile courses. The return angle tiles are also purposely made to overlap the fronts of the dormers, and thus prevent the wet penetrating between the timbers and the tiles. The whole of the basement is covered with a bed of concrete. No expense has been spared to make the house comfortable and weather-proof against the driving rains and east winds.

The building has been erected by day-work, excepting the following contracts:—Messrs. Taylor & Sons, of London, for the hot-water and bath apparatus; Mr. G. Harvey, for plastering; Mr. Bartlett, of Walmer, for plumbing; Messrs. Frost Brothers, of Deal, for gasfitting.

On the site of the trees shown on the drawing Mr. Tod is now erecting a large gabled house, which we may hereafter illustrate.

### THE NEW PROVINCIAL ESTATES HOUSE, HANOVER.

ONE of the most striking new buildings of Hanover is the edifice which we illustrate in our present number, the house in which the estates of the province of Hanover meet. It was built in 1879 and 1880, from plans by the architect F. Wallbrecht. Its site is the crossing-point of the Schiffgraben and the Sophienstrasse, in the axis of the latter, and forms for it a monumental *point de vue*. The building stands clear in the centre of garden grounds, and is of a rectangular form, 200 ft. long by 98 ft. deep, with projections in the centres of the four façades. The edifice, of a light grey sandstone quarried at Nesselberg, near Springe (Hanover), Lanba brick being sparingly employed, is in the style of the Italian Renaissance. The ground-story is of freestone; the first story has hard windows framed by Doric columns and corresponding pediments; the second story forms an arcade gallery divided by pilasters. The centre portion of the principal front is adorned on the ground-floor by a wide carriage porch with balcony over it, and in the two upper stories by a large semicircular-headed window, flanked by columns and surmounted by an entablature and pediment. It is profusely decorated with figures in the spandrels over the semicircular-headed window, and with reliefs at the sides. The former, representing History and Poesy, were executed by the sculptors Narten and Dopmeyer, of Hanover. The relief to the left, by Professor Engelhardt, of Hanover, shows Trade and Agriculture under the protection of Hannovera; that to the right, by the sculptor Hartzert, of Berlin, Arts and Sciences under the aegis of Germania. The frieze is adorned with the arms of the seven counties (Landschaften) of Hanover,—Hildesheim, Bremen-Verden, Lüneburg, Kalenberg, Göttingen-Grubenhagen, Hoya-Diepenholz, Osnabrück-Ostfriesland.

The interior execution agrees with the exterior, the principal decoration being concentrated in the centre portion. From a vestibule, the groined vaulting of which is supported by columns of Swedish granite of a reddish colour, the walls being of yellowish stucco marble, the staircase with three flights is reached. The latter, which

\* See p. 233, ante.

reaches through the three stories, is lighted by a large skylight in painted glass, and closed by a surbated vault with ogives. Rich ornamentation, coats of arms, and frescoes adorn the staircase, which in the upper stories opens into grande galleries, by which access is gained in the first floor to the lobby of the "house," in the second floor to the strangers' gallery. The principal meeting-room of the above-mentioned "house" has a height of 36 ft., is 58 ft. long, and 33 ft. broad, and has sitting-room for seventy-nine deputies, the marshal and the president of the province, and the councillors of the exchequer. The hall is lighted from above and from side windows placed high up; its walls are of a sober hue, but enlivened by the coats of arms of the counties and chief cities of the province of Hanover. The principal hall and the lobby are heated by hot air, and connected with a retiring-room for the chief officers of the house, and a cloak-room for the deputies. The rooms to the right and left of the principal hall include, in the first story, another smaller hall, committee-rooms, and official residences. In the second story are the library, committee-rooms, and offices.

The total cost of the building, including the price of the site and the expenses attaching to laying out the grounds, was 75,000*l.*

#### THE FUTURE OF LIGHTING AND HEATING.

FROM the admirably practical and perspicuous address delivered by Dr. C. W. Siemens, F.R.S., as President of the British Association for the Advancement of Science, and upon which we offered some comments last week (see p. 295, ante), we extract the following passages:—

The advantages of the electric light and of the distribution of power by electricity have lately been recognised by the British Government, who have just passed a Bill through Parliament to facilitate the establishment of electrical conductors in towns, subject to certain regulating clauses to protect the interests of the public and of local authorities. Assuming the cost of electric light to be practically the same as that of gas, the preference for one or other will in each application be decided upon grounds of relative convenience; but I venture to think that gas-lighting will hold its own as the poor man's friend. Gas is an institution of the utmost value to the artisan; it requires hardly any attention, is supplied upon regulated terms, and gives, with what should be a cheerful light, a genial warmth, which often saves the lighting of a fire. The time is, moreover, not far distant, I venture to think, when both rich and poor will largely resort to gas as the most convenient, the cleanest, and the cheapest of heating agents, and when raw coal will be seen only at the colliery or the gasworks. In all cases where the town to be supplied is within, say, thirty miles of the colliery, the gasworks may, with advantage, be planted at the mouth, or still better at the bottom, of the pit, whereby all haulage of fuel would be avoided, and the gas, in its ascent from the bottom of the colliery, would acquire an onward pressure sufficient probably to impel it to its destination. The possibility of transporting combustible gas through pipes for such a distance has been proved at Pittsburgh, where natural gas from the oil district is used in large quantities. The quasi monopoly so long enjoyed by gas companies has had the inevitable effect of checking progress. The gas being supplied by meter, it has been seemingly to the advantage of the companies to give merely the prescribed illuminating power, and to discourage the invention of economical burners, in order that the consumption might reach a maximum. The application of gas for heating purposes has not been encouraged, and is still made difficult in consequence of the objectionable practice of reducing the pressure in the mains during daytime to the lowest possible point consistent with prevention of atmospheric indraught. The introduction of the electric light has convinced gas managers and directors that such a policy is no longer tenable, but must give way to one of technical progress; new processes for cheapening the production and increasing the purity and illuminating power of gas are being fully discussed before the Gas Institute; and improved burners, rivaling the electric light in brilliancy, greet our eyes as we pass along our principal thoroughfares. Regarding the importance of

the gas supply as it exists at present, we find from a Government return that the capital invested in gasworks in England, other than those of local authorities, amounts to 30,000,000*l.*; in these, 4,281,048 tons of coal are converted annually, producing 43,000,000,000 cubic feet of gas, and about 2,800,000 tons of coke; whereas the total amount of coal annually converted in the United Kingdom may be estimated at 9,000,000 tons, and the by-products therefrom at 500,000 tons of tar, 1,000,000 tons of ammonia liquor, and 4,000,000 tons of coke, according to the returns kindly furnished me by the managers of many of the gasworks and corporations. To these may be added, say, 120,000 tons of sulphur, which up to the present time is a waste product. Previously to the year 1856,—that is to say, before Mr. W. H. Perkin had invented his practical process, based chiefly upon the theoretical investigations of Hoffman, regarding the coal-tar bases and the chemical constitution of indigo,—the value of coal-tar in London was scarcely a halfpenny a gallon, and in country places gas-makers were glad to give it away. Up to that time the coal-tar industry had consisted chiefly in separating the tar by distillation into naphtha, creosote, oils, and pitch. A few distillers, however, made small quantities of heuzine, which had been first shown,—by Mansfield, in 1849,—to exist in coal-tar naphtha mixed with toluene, cumene, &c. The discovery, in 1856, of the mauve or aniline purple gave a great impetus to the coal-tar trade, inasmuch as it necessitated the separation of large quantities of benzine, or a mixture of benzine and toluene, from the naphtha. The trade was further increased by the discovery of the magenta or resaniline dye, which required the same products for its preparation. In the meantime carbolic acid was gradually introduced into commerce, chiefly as a disinfectant, but also for the production of colouring matter. The colour industry utilises even now practically all the benzine, a large proportion of the solvent naphtha, all the anthracene, and a portion of the naphthaline resulting from the distillation of coal tar; and the value of the colouring matter thus produced is estimated by Mr. Perkin at 3,350,000*l.* The demand for ammonia may be taken as unlimited, on account of its high agricultural value as a manure; and, considering the falling supply of guano and the growing necessity for stimulating the fertility of our soil, an increased production of ammonia may be regarded as a matter of national importance, for the supply of which we have to look almost exclusively to our gasworks. The present production of 1,000,000 tons of liquor yields 95,000 tons of sulphate of ammonia, which, taken at 20*l.* 10*s.* a ton, represents an annual value of 1,947,000*l.* The total annual value of the gasworks by-products may be estimated as follows: Colouring matter, 3,350,000*l.*; sulphate of ammonia, 1,947,000*l.*; pitch (325,000 tons), 365,000*l.*; creosote (25,000,000 gallons), 208,000*l.*; crude carbolic acid, (1,000,000 gallons), 100,000*l.*; gas coke, 4,000,000 tons (after allowing 2,000,000 tons consumption in working the retorts), at 12*s.*, 2,400,000*l.*—total, 8,370,000*l.* Taking the coal used, 9,000,000 tons, at 12*s.*, equal 5,400,000*l.*, it follows that the by-products exceed in value the coal used by very nearly 3,000,000*l.* In using raw coal for heating purposes these valuable products are not only absolutely lost to us, but in their stead we are favoured with those semi-gaseous by-products in the atmosphere too well known to the denizens of London and other large towns as smoke. Professor Roberts has calculated that the soot in the pall hanging over London on a winter's day amounts to fifty tons, and that the carbonic oxide, a poisonous compound, resulting from the imperfect combustion of coal, may be taken as at least five times that amount. Mr. Aitken has shown, moreover, in an interesting paper communicated to the Royal Society of Edinburgh last year, that the fine dust resulting from the imperfect combustion of coal is mainly instrumental in the formation of fog, each particle of solid matter attracting to itself aqueous vapour; these globules of fog are rendered particularly tenacious and disagreeable by the presence of tar vapour, another result of imperfect combustion of raw fuel, which might be turned to much better account at the dye-works. The hurtful influence of smoke upon public health, the great personal discomfort to which it gives rise, and the vast expense it indirectly causes through the destruction of our monuments, pictures, furniture, and

apparel, are now being recognised, as is evinced by the success of recent Smoke Abatement Exhibitions. The most effectual remedy would result from a general recognition of the fact that wherever smoke is produced fuel is being consumed wastefully, and that all our calorific effects, from the largest furnace down to the domestic fire, can be realised as completely and more economically, without allowing any of the fuel employed to reach the atmosphere unburnt. This most desirable result may be effected by the use of gas for all heating purposes, with or without the addition of coke or anthracite.

#### THE NEW PUBLIC HALL, PRESTON.

THE new Public Hall at Preston, formerly known as the Corn Exchange, was opened on Monday last. The alteration and enlargement of the Corn Exchange, from the designs of Mr. B. Sykes, of Preston, will cost the Corporation between 10,000*l.* and 11,000*l.*, which is more than was originally estimated to be the cost. The increase is owing to certain additional structural arrangements, which, as the work has progressed, were found to be absolutely necessary, if the idea originally entertained of making the building one of the largest and finest in the county was to be carried out. The aim has been to utilise to the utmost the space at disposal for the accommodation of the public, without in any way depreciating the effect of vastness and the unity of architectural design, and Mr. Sykes has (according to the *Preston Guardian*) succeeded in forming the interior into a lofty and imposing auditorium, commanding from every seat an unobstructed view of the orchestra. The new public hall exceeds the dimensions of the Free Trade Hall in Manchester. The measurement of the Free Trade Hall is 133 ft. by 77 ft., or 10,241 square feet; and the Philharmonic measures 135 ft. by 102 ft., or 13,770 square feet; and the dimensions of the new Public Hall at Preston are 147 ft. by 95 ft., or 13,965 square feet. Applying the standard regulating the total capacity of the Free Trade Hall and other large buildings of a 1 ft. 6 in. and 1 ft. 9 in. sitting accommodation for each person, the Public Hall will hold 3,564 persons, accommodation being distributed as follows:—Front seats, 524; back seats and under galleries, 1,433; galleries, 807; standing-room being left for 800 persons. The orchestra, which is not included in this calculation, is constructed to hold 250 performers. The main entrance to the hall is from Lune-street, through a tiled vestibule, with a glazed screen. A large crush-room is then entered, to which are attached retiring-rooms for ladies and gentlemen. Passing through a vestibule containing stairs, the floor is reached, which measures 145 ft. by 95 ft., including that portion occupied by the orchestra. The floor is constructed of pitch-pine. The orchestra, which is situated at the other end of the building, in front of the main entrance, is approached from the front on each side by staircases for the band, and from the rear by two doorways for the chorus. The seats, eight rows in depth, are arranged in a semicircular form and in tiers, the front seats for the band being on a level plane. All the steps are movable, so that a clear stage can at any time be presented when the hall is used for public meetings or theatrical performances. In the centre at the rear is the organ, which occupies a chamber measuring 24 ft. by 20 ft. There is a handsome proscenium flanked by bold pillars, with ornamental caps and entablature. The gallery is surmounted by eighteen arches, nine on each side, each having a span from pillar to pillar of 14 ft. It is supported by iron columns and strong pilasters against the walls, which relieve the old walls of the entire weight of the structure. The keystones of the arches are ornamental, with carved blocks and spandrels, and curved ribs in the cove, enriched with ornamental work, and Classic in design. The broad gallery runs round three sides of the building, and has two entrances at the north and two at the south side, and from every seat a good view of the orchestra can be obtained. Beneath the gallery there is a mezzanine floor, and on each side of the gallery there are corridors 7 ft. wide, which connect the assembly-room with the retiring-rooms and waiting-rooms behind the orchestra. Connected with these places there is a large supper-room, measuring 42 ft. by 36 ft., and which communicates with a kitchen in the basement by means of a lift. There is also in the

basement storage room for the hall seats, cooking accommodation, and all the necessary appliances. A pitch-pine staircase has been constructed, in order that there may be direct communication between the floor of the area and the supper room. The height of the building from floor to ceiling is 45 ft. The method of lighting and ventilation is admirable. A series of circular windows of ribbed, reflecting glass, specially made for the purpose, have been fitted into the ceiling. The ceiling is dome shaped, with good wall space. For ventilation, three of Sirode's ventilators, 4 ft. 6 in. in diameter, and six, 3 ft. 6 in. in diameter, have been fitted up. The heating arrangements have been carried out by Messrs. Metcalf & Dilworth, hot-water engineers, of Preston. The building can be illuminated by means of three large sunlights, with 127 jets in each. The hall has a very light and cheerful appearance, the decorations being in a quiet key, and in harmony with the ceiling, the plaster work of which is white through its whole extent. The pillars are painted in light drab, and the caps relieved with gold. The front of the gallery and the cornice is coloured in greens and chocolates of various tones, which harmonise with the general light scheme of colour pervading the upper portion of the building, and it is only underneath the gallery, on the bases of the pillars, that darker tints are used. The walls underneath the gallery, and of the retiring-rooms, have a dado 4 ft. high, of a ochraceous colour, with ornamental border, the other portions being of a creamy tint. The whole of the works have been undertaken by Mr. Robt. Saul, builder, of Preston. The furnishing of the hall and the whole of the interior were entrusted to Messrs. Bell & Copland.

#### MEETING OF THE INTERNATIONAL SANITARY CONGRESS, GENEVA.

The few delegates who, in prudence, came to Geneva a little before date, will have found the time hang heavily on their hands. The principal secretary, Dr. P. L. Dunant, has displayed unceasing activity, and, if he escapes the strain without serious consequences, it will speak well for the vigour of his constitution; but other secretaries, without whose assistance the work became almost impossible, ominously fell ill at the last moment. None of the offices for the congress were, therefore, opened before the 3rd September; that is, on the eve of the commencement of the congress. Further, the Sanitary Exhibition, which should have been ready to receive the public on the 1st of September, remains closed, and admission cannot be obtained before the 4th, and even then the exhibits will be found still in a very confused condition. The organisers of the congress are, however, in no wise to blame for this *contretemps*. The building was not given up to them by the authorities till a fortnight after the date promised. In spite of these little drawbacks,—which, indeed, are characteristic of nearly all congresses,—the meeting promises to be a great success. Names and subscriptions have already been received from no less than 400 adherents, and most of the Governments of Europe have sent special delegates. We have already met Dr. H. Napié and M. Durand Claye, delegates of the Paris Municipal Council; Dr. Louis de Casary, delegate of the Hungarian Government; and Señors Cabello, Montejo, and Vilanueva, delegates of the Spanish Sanitary Society, and the Ministries of War, Marine, and Interior; Dr. Haussier, from the Municipality of Seville; and Dr. da Silva-Amado, from Portugal. These sanitary reformers from the Peninsula for the most part frequent the Hôtel Métropol, the largest hotel of Geneva, and its vast drawing-rooms, staircases studded with divans, supply facilities for lounging and talking highly appreciated by the members of the congress, who have each a special scheme to discuss or system to propagate.

Armed with a special permission, we penetrated the sanitary exhibition, and, clambering over packing-cases, gained a fair view of the display. Practically, it bears the character of a French exhibition, and, being French, it is essentially Parisian. The City of Paris is so far the principal exhibitor that it has printed and issued a special catalogue of its own, independently of the general catalogue. Certainly such a measure is of service, and, to those who are not yet familiar with Parisian administrative matters, this section will prove of very great

interest; while every one will be pleased to note how elegantly, even artistically, are arranged objects that might be considered anything but attractive. Thus there is a trophy of all the brooms, scrapers, spades, &c., used to clean the streets and sewers of Paris, which is so well grouped that it looks absolutely ornamental. Close at hand are all the instruments used at the Observatory at Montsouris for the analysis of the air of Paris. Splendid drawings describe the water supply of Paris, the aqueducts of the Vauve, the Dhuis, and the Canal de l'Ourocq; every system of tap and hydrant; and, finally, a full-size model of a section of a house, showing how the water is distributed and the mysteries of the plumber's work. Under the sink, the pipe is straight; there is no trap or syphon; and this, as a representation of what is done in Paris, is correct enough. But, outside the house, a disconnection is established by allowing the 1-in. lead pipe to flow into the mouth of a 4-in. junction to the rain-water spout. Unfortunately, this is so far from being the general practice in Paris that, though we have visited many houses, we do not remember one instance where any such disconnection was attempted.

Warning and ventilation as practised in Paris are admirably represented by models and drawings of the Hôtel Dieu, the new Hôtel de Ville, where Messrs. Geneste & Herscher's system of ventilation has been adopted, and of various other hospitals, public buildings, &c. Sections of all the Paris sewers, models of the *tinettes-filtres*, for retaining solid matter while the liquid is allowed to go to the sewer, are shown, together with the entire plans of the irrigation farm at Gennevilliers. Under the latter are specimens of gigantic vegetables grown by the aid of the Paris sewage. But all English observers, possessing even only a slight technical knowledge of such subjects, will be surprised, not to say scandalised, by a *vingt-double* picture illustrating the disadvantages of cesspools as compared to sewers. The first half of the picture represents, in a very graphic and telling manner, the interior of a house while a cesspool is being emptied. From the garret to the people walking in the streets every one is seeking to escape from the foul odour. Certainly this rendering of a domestic inconvenience which all Parisians have experienced is familiar and effective. The second half represents the same persons, in the same house, quietly enjoying the evening without experiencing any inconvenience. It also shows that the cesspool has been abolished, and the closets, &c., placed in direct connexion with the sewer. As a means of popularising a generally approved principle, this picture might have been of service; but, as it stands, it is, on the contrary, a triumphant demonstration of the superiority of cesspools over sewers in a country where such profound ignorance of house-drainage still prevails. According to the model in question, instead of improving matters, sewer gas has been laid on throughout the house. It will scarcely be credited that there is not a single precaution taken to prevent the entrance into the house of gas from the public sewer. The drain-pipe ceases under the seat of the highest closet; it is not carried up to the roof for ventilation. It communicates by junctions with all the other closets on each floor, and none of these closets have any traps. It is only when the pipe, passing underneath the house, approaches the public sewer that a bend will be found; but no means whatsoever are shown of ventilating the pipe, or of ventilating the public sewer into which the pipe falls. The house is thus utterly unprotected, and under such circumstances the old cesspool, with all its inconveniences, would be far preferable. It is astonishing that the municipality of Paris should have allowed this drawing, replete with every imperfection, to be presented as a model, and on such an occasion!

Among the private exhibits will be noted some very beautiful drawings of M. Emile Trélat's system of unilateral light for school-rooms, &c., which, at one glance, explain his system. These clearly show how windows can be managed so as to let the light come all from the same direction, thus avoiding the cross lights which distract and distress the eyes, and yet having equal and sufficient illuminating power over each desk or seat. On the opposite side M. Trélat also places windows, but these are shut during class time by venetians or wooden shutters, which, while admitting air, exclude light; thus the "unilateral"

light is maintained. When once, however, the lessons are over and the class-room vacated then the shutters are removed and the light admitted from both sides, but this only for the purpose of purification, for the purpose of giving the schoolroom a bath of sun, air, and light.

Some drawings explanatory of the Geneva system of drainage will surprise many English critics. Geneva admits the principle of draining into the sewer, but it still maintains its old cesspools. These, however, are placed in direct communication with the sewer, and to prevent the nuisance of emptying the cesspools or the danger of accumulations, water is turned on at great pressure by means of stop-cocks accessible in the street, and the cesspools are thus periodically flushed. The violent rush of the water stirs up the heavy matter, and it flows away into the sewer which has its outfall into the Rhone at a point some distance below the town. It is difficult to understand why the cesspools should have been maintained, when once it was determined to admit all matter into the sewer. Also the cost of carrying a pipe across the cesspool to the sewer would have not amounted to the sum now expended in periodical flushing of the cesspools. The dangers that may arise from bringing the water-pipes into the cesspools might also be avoided. In any case, if the inhabitants of Geneva are so tenacious for the preservation of their antiquated cesspools, we would respectfully suggest that these should in future be utilised as intercepting chambers for the purpose of ventilation and of breaking the connexion between the house and the sewer.

Such are a few among the more striking features of the Sanitary Exhibition. There are, of course, numerous health charts, statistical reports of all description, ambulance displays, patent foods, school furniture, chairs for invalids, &c., and, doubtless, many new inventions will be on view in a few days, when the preparations are all complete.

We have every promise of a busy week. Apart from the meetings of the five sections every morning, and the general meetings in the afternoon, every evening is also taken up. On Monday evening an official reception will be held. Tuesday evening Professor A. de Candolle receives the members at his country mansion of the Vallon. On Wednesday there is a similar reception at the hydrotherapeutic establishment of Champel-sur-Arve; while on Thursday the Swiss Government places the steamer *Mont Blanc* at the disposal of the congress. The water-cure establishment of Evian will be visited, and lunch taken at the establishment; then the steamer, crossing the lake, will take the members of the congress to a banquet offered them by the municipality of Montreux at the Kursaal. On Friday there is a reception at the mansion of Madame Eynard, and finally there is a farewell banquet on Saturday.

In spite of all these attractions, we are sorry to note, in conclusion, that the number of English members present is still very limited.

#### THE CIRCULATION OF UNDERGROUND WATERS.

In the Geological Section of the British Association meeting at Southampton,

Mr. C. E. De Rance read the report of a committee appointed for the purpose of investigating the circulation of the underground waters in the permeable formations of England, and the quality and quantity of the water supplied to various towns and districts from those formations, to which was added an appendix, written by Mr. Edward Wethered, on the density and porosity of rocks in relation to the water supply, in which the author set out by averring that a knowledge of the porosity of rocks was important as regarded the water supply, the suitability of stone for building purposes, and in accounting for some of the geological changes often observed in the earth's strata. Though the matter had not escaped investigation, the vast volume of water stored in the rocks had not been fully realised. The density of the old red sandstone was 2.61, the volume of water absorbed by a cubic foot being over 0.707 gallon, and by a square mile, 3 ft. thick, 59,000,000 gallons. The conglomerate beds of the same formation were still more absorbent, being capable of taking in 0.805 per cubic foot, or 67,000,000 gallons to

a square mile, 3 ft. thick. The mill-stone grit which lay at the base of the coal measures varied much in different localities, that found in the Forest of Dean being the most porous, absorbing 66,000,000 gallons to the square mile, 3 ft. thick. Some of the coal-measure grits also stored large volumes of water. The Pennant rock, about 900 ft. thick, in the Bristol coalfield, and extensively developed in Somersetshire, as also around Swansea, was capable of absorbing 12,000,000 gallons in a square mile, 3 ft. thick; and specimens of magnesian limestone taken from the neighbourhood of Bristol, showed a porosity of 86,000,000 gallons, but the carboniferous limestone was quite the reverse, and only absorbed 3,500,000 gallons. Oolites held vast stores of water, and the rock was much used for building. Mr. Wetbered then referred to the relation of specific gravity to porosity, and proceeded to say that shallow well-water had been classed by the Rivers Pollution Commissioners as dangerous, and the deep as wholesome, and there must, therefore, be a purifying process going on during the percolation into the earth. From an analysis of rocks, it was clear that nothing in the chemical composition of the rock could purify the water, and in order to get rid of organic contamination there must be oxidation, and they must, therefore, look to another source for the oxidising agent, which, he thought, existed in the air absorbed by the water, and in the air contained in the interstices of the rock.

#### DISCOLORATION OF "SOUTHAMPTON WATER":

IS IT DUE TO SEWAGE?

In the Section devoted to Zoology (Department of Zoology and Botany), British Association meeting, Southampton,

Mr. Arthur Angell, F.I.C., the County Analyst, read a paper on the brown coloration of "Southampton Water." The writer showed that the peculiar colour of the Southampton estuarine water, which turns to a rusty brown tint in the summer of each year, is due solely to the presence of a small ciliated organism, *Peredinium fuscum*, which is classified by the best authorities amongst the ciliated protozoa, or microscopic animals. This position is generally accepted, but Mr. Angell, seeing that they evolve oxygen, contain chlorophyll, — plant colour matter, — have no mouth or opening of any kind, never contain foreign bodies, have cellulose walls, and, after death, give off an odour of decaying seaweed, is of opinion that they are more plants than animals. He further sought to show that their presence is due to the large amount of sewage thrown into the river at and about Southampton. The seaward margin of the river water is distinctly marked out by the brown colour, and the author noticed that this never leaves the estuarine basin, and pointed out that a measurement of the oscillations of this line provides a true index of the tidal motions, and shows that the water in the river is but very slowly, if at all, changed by the rise and fall of the tides. He showed it was an error to suppose that in tidal rivers and land-locked estuaries a fresh supply of water is given at every tide, and that as a matter of fact the time needed in which a single change in such waters as Southampton Water will take place is dependent more upon the small flow of fresh water and surface evaporation than upon tidal influences. It is not, therefore, safe to pollute tidal waters with sewage; the impression that the filth goes out to sea with the tide is utterly false. The peculiar brown colour gives us an indication by which we can learn that practically a change of the water of the Southampton Water, and therefore of all other similarly situated tidal-river mouths and land-locked estuarine basins, is but very slowly, if ever, effected by the tides. Enough filth is poured into the river to make it in hot weather a stinking abomination, but in accordance with nature's provisions against such unnatural proceedings, a vast army of minute organisms is set to work and the water is kept tolerably sweet. If it can be shown that this creature, which is barely visible to the naked eye, performs the chief functions of plants, — liberates oxygen, and is at the same time an animal, and therefore carries on direct nitrification, it is indeed most wonderfully adapted, by this double set of powers, to keep our sewage-polluted waters as sweet as is possible. Notwithstanding the unsightly colour of *Peredinium*

*fuscum*, we cannot afford to do without it in our river. When the day comes that the authorities of Southampton see fit to keep out the sewage now flowing into its waters so as to free them from such vile pollution, the *Peredinium fuscum*, no longer needed in such vast quantities, will retire into its normal position, become less obtrusive, and leave the water a pure translucent green.

The paper was illustrated by three views showing the enlarged representations of the organism, Mr. Angell adding there was a most wonderful likeness in all the specimens. He had seen them in the Southampton Water in countless millions for years, and had never seen the slightest difference in them, nor had he known an instance of self-division or conjugation, and was perfectly in the dark as to whence the organism comes and whither it goes.

Professor Lawson, M.A. (president of the Department) said the colour of the water which Mr. Angell had described he at first imagined was due to innumerable diatomaceæ of a certain kind which they all knew were exceedingly abundant in estuarial waters; in fact, it was where fresh water and salt water met that it was most abundant. The *Peredinium fuscum* was a creature which, of course, was thoroughly well known, and it made its appearance in large quantities, and he thought it was to that, to a large extent, though not entirely, that the discoloration of the water might be due.

Mr. Shore, jun., said he was sure the members were obliged to Mr. Angell for his interesting paper. As to the nature of the organism, that should be left an open question to be worked out during the resting stage, and when the process of conjugation and division had been watched.

Mr. Angell said the difference of opinion which had been alluded to as to the exact nature of the organism was likely to exist for some considerable time, but he thought they were drifting into circumstances when all would have to admit that no hard and fast line could be drawn between a plant organism and an animal organism. These organisms, however, seemed to him to indicate a remarkable instance of the adaptability of Nature to circumstances, the organism being marvellously well adapted for the double purpose it had to perform. He had a bottle of water taken that morning, but it was not a good specimen of the discoloration; for westerly winds such as were then being experienced affected the colour, but in calm quiet days, the water was quite as thick as good hot brown coffee.

#### THE VYRNWY (LIVERPOOL) WATER SCHEME.

The report of Mr. G. F. Deacon, Water Engineer to the Corporation of Liverpool, on the progress of the Vyrnwy works up to the 30th of June last, has just been issued. Mr. Deacon states that the embankment about to be constructed across the valley of the Vyrnwy will impound the upper waters of that river, and will form, for the supply of Liverpool, a lake at an elevation of 825 ft. above the sea level, having an area of 1,115 acres. The length of the embankment from rock to rock at the water level will be about 1,255 ft.; its height above the original river-bed to the ordinary top-water level about 84 ft., and to the parapet wall of the roadway to be carried on arches along the embankment about 98 ft. It will be formed of rubble masonry set in Portland cement mortar, and will be founded wholly upon sound rock of the Caradoc beds in the lower Silurian formation. This rock extends across the valley and up both sides thereof. The greatest depth of its surface below the river bed, within the area to be built upon, is about 55 ft. Before the works were commenced the rock in that part of the valley across which the masonry embankment is to be constructed, was covered with glacial drift, containing boulders of five or six tons weight, and blocks of rock of forty or fifty tons dislodged by glacial action. Above this drift lay an alluvial deposit, the result of silting up by the rock debris and detritus brought down by the many streams which feed the present river. In times of heavy rain the river Vyrnwy flooded the whole width of the valley, at the site of the intended embankment. Before commencing the present excavations the river was diverted from the left bank of the valley, where the rock is at

a considerable depth below the surface, to the right bank, where it is close to the surface, and the new channel was made of sufficient capacity to pass the highest floods. This work had been completed when the memorial-stone was laid on the 14th of July of last year. Since that time the excavation to the rock has proceeded rapidly. The building of the masonry embankment will be commenced on the rock foundation to the north of the diverted river. The stone for this purpose is being obtained by quarrying at a point in the Cynon Valley about a mile and a quarter distant from the site of the embankment. The rock is of the same nature as that forming the foundation, and the dip of the strata is such that the stone may be obtained at very moderate cost. A tunnel is being constructed from the intended lake to the Hirnant Valley. It will form the first part of the aqueduct. Its length will be two miles 473 yards, and it will be of sufficient size to pass the whole of the water of the three instalments of 13,000,000 gallons a day each.

#### CEMENT, "VULCAN," AND ASPHALTE FLOORS.

A RECENT issue of the *Dasgewerkschaft* contains a communication by Herr Walter Lange on some results obtained by him in the use of cement, a material called "Vulcan," and asphalt for floors in wet and highly-heated rooms. In the extensive rebuilding of the starch manufactory of Herr E. Hoffmann at Salzaufen (near Minden), burnt down some time ago, about 30,000 square yards of flooring had to be laid down. The various uses to which those floors would be put necessitated the employment of various materials. If to this fact it be added that a portion of the floors had to be taken into use as soon as ever practicable, it may well be believed that it was not a very easy matter to make a selection at once as to the proper material to be employed. Experiments had on former occasions been made with different materials, all of which had been unsuccessful. It was especially found that the wear and tear of the floors in the starch factory was very great, owing to the employment of three-wheeled trollies (on the average loaded with 20 cwt. to 30 cwt.), the rapid deterioration of the floors being further accelerated by the fact that they are generally in a very wet or highly heated state.

It was at first intended to use a layer of cement on a concrete bottom for all the rooms (stone slabs could not be employed for the greater part of the rooms on account of the joints), and this was partly laid down when it was found that it would not answer. As above stated, sufficient time had not been allowed for hardening, and then the floors were used at once to such an extent that the cement was broken up in an incredibly short time by the three-wheeled trollies. The front wheel, in turning, leans over on one side, and cuts the upper skin of the cement; and if this was once effected, there was no chance of saving the rest, for the lower layer had not yet attained that hardness which would resist pressure. Water on the cut and bruised surface completed the destruction, for, being forced on to the floors at high pressure, even pebbles in the floor were washed out.

Two methods were employed at Salzaufen for laying down cement floors. Upon a fresh bed of concrete, a layer consisting of cement and sand in equal parts, and from 2 to 3 centimetres thick, was snt, well rammed down, levelled, and then smoothed with a hand iron. This proceeding, compared with the other, has several disadvantages. The second method consists of mixing a concrete of one part of cement, two parts of sand, and four parts of gravel, laying it down, and ramming it until a layer from 1 to 2 centimetres thick appears on the surface without any gravel. This layer is then levelled and smoothed down. Floors prepared by the latter method are much more durable, and resist pressure much better than those laid down by the former. The thickness of the concrete floors depends very much upon the extent to which they will be used, and the resistance of the soil to be covered. If sufficient time is left for the cement floor to harden, — and the longer it is left the better, — it will resist for a very long time any ordinary pressure.

In the drying-rooms of the above starch manufactory, cement floors were also laid down;

but they proved efficient only after having been put down in first-rate style, and left to harden for a sufficient length of time (from four to six weeks). But should they be intended to be used before that time, and subjected early to a high temperature (about 40° C.), it is highly advisable to desist from using cement. In the latter case, a kind of floor is to be recommended which is at present very little known, and is described by the inventor, Herr Oelzner, Ingenieur, of Hagen, Westphalia, as "Vulcan" floor. The mass is poured upon prepared beds to a thickness of 4 centimetres to 6 centimetres, and costs from 3 marks to 3½ marks per square metre (about 4d. a square foot). The "Vulcan" floors are prepared in the following manner. The surface is covered with stone chips, ashes, &c., the height of this bed depending upon their later use. The mass, the composition of which is Herr Oelzner's secret, is made liquid, and poured upon the bed. The liquid mass penetrates the cracks and pores of the rubble, and forms, after solidifying, a hard slab. After having somewhat settled, the mass is beaten with a wooden pestle, and smoothed. This operation is repeated as long as the floor swells after each beating. The floor is smoothed down after each beating. Amongst the advantages claimed for the "Vulcan" floor is its great solidity, which it assumes, however, only after some time. But the hardening of the floor takes place even at a great heat (in the drying rooms at Salznafen, hardening is effected at a continuous temperature of 50° C.). Finally, it must be noted that the floor is proof even against strong acids. Experiments have been made by Herr Lange in which the mass in a powdered state was submitted to the action of concentrated sulphuric acid; the only effect of which treatment was that the mass dissolved and then hardened. Herr Lange likewise observed that old pieces of this floor, after having been immersed for some time in concentrated soda lye, remained perfectly intact. The only drawback is that hardening takes place so very slowly. On the other hand, the mass becomes so hard as even to blunt steel chisels very rapidly. Herr Oelzner's "Vulcan" floors have been very successful elsewhere, even in establishments where very heavy iron castings or forgings are moved over them. Herr Lange says respecting the composition of Oelzner's "Vulcan" mass it appears to him that it contains a large proportion of blast-furnace slag, and that residues of sulphuric acid manufacture and the so-called *caput mortuum* (colcothar) are also used in it.

For such rooms as were already in use, it was found necessary to resort to asphalt. The asphalt, from the Limmer pits, was so-called casting asphalt (*asphalte coulé*). It was melted in the usual way, mixed with gravel, laid on, and smoothed down with wooden spatulas. Concrete of cement, sand, and gravel served as a bed. In some rooms cement and asphalt layers were used together, asphalt being put down in the passages, concrete in the less used parts; a very sharp edge being indispensable for the joints. Of course, asphalt was employed in rooms with wet floors; but it is not suitable in rooms where acids are used, because asphalt peels off in course of time under the influence of acids.

It may be finally added that in Oelzner's starch manufactory several tanks had to be constructed for the reception of acids, the selection of the inner coating causing some difficulties. Cement, if exposed to the direct action of acids, is at once destroyed; asphalt shares the same fate, although not quite so rapidly. It was, therefore, proposed to employ a plaster of cement with a coating of zeidolite, a material consisting of nearly equal parts of sulphur and powdered glass and a trifling addition of graphite. This composition is absolutely acid-proof, but inflammable. Its preparation, moreover, and the laying-on, caused so many difficulties that the use of zeidolite was given up at the last hour. It was determined to employ stone slabs, filling up the joints with sulphur, a treatment or procedure which has been found efficient in sulphuric acid manufactories. Of course, it is understood that the stone slabs used must be acid-proof, and have been tested in that direction.

The Town Council of Oldham has passed a resolution in favour of the construction of the proposed ship-canal between Manchester and Liverpool.

#### THE NETHERFIELD GYPSUM WORKS.

MANY of our readers will remember that when certain scientific diggings were being carried on in East Sussex, between 1872 and 1877, although the undertakers missed a coal-mine they fell upon a mass of pure white crystalline gypsum,—alabaster. A company was formed, and has been at work for some time. An interesting account of the present condition of the works has been given recently by the *Sussex Advertiser*, and many of our readers will be glad to read a portion of it:—

The situation of the Subwolden Gypsum Works is remarkable for natural beauty. The mine is situated in a valley green with forest-wood, in the midst of the mountain district bounding the "the Garden of England." Battle, with its interesting old abbey, is only a few miles distant. The Asbunriah woods are close at hand. Normaulurst, with its spire-crowned walls, towers conspicuously on an eminence in the vicinity. In the wide green forest, rich with a natural flora, the visitor might fancy himself far removed from the habitations of man. Wild strawberries tempt his lips every few steps, wild foxglove blossoms around in rare exuberance. Were it not for the railway-siding and a tramway (1½ mile long) threading its way through the underwood of ash, oak, and chestnut, to effect a communication with the South Eastern main line, the poetry of the "greenwood tree" would be unbroken. Historically and archaeologically the spot is not without interest. The railings of St. Paul's, lately removed, were cast in the neighbourhood. The last cannon made of Sussex iron was likewise cast only a few miles off; and, in 1863, a most interesting find was discovered in a field close by, consisting of solid gold ornaments, which must have belonged to a king or Druid of the Celtic period. The ignorant finder sold the invaluable relic for the paltry sum of 6s. 6d., taking it for brass, and the purchaser was Vandal enough to consign it to the melting-pot, for which,—having defrauded the Crown of its dues,—he was deservedly punished.

A chimney rising high above the trees indicates the site of the gypsum works, and serves as a land-mark around. The works are situated directly over the mine from which the raw material is extracted. The seam now worked is of comparative thickness, and lies some 160 ft. or 170 ft. under the surface. One of the three stationary engines,—of collectively about 130 horse-power,—raises the cage, the descent of which is regulated by a brake. A visit to the subterranean regions is rendered comparatively easy. There is little water to contend with, and the leadings may be traversed dryshod. The gypsum occurs in places in beautiful crystalline forms. The headings are high enough for a tall man to pass along without much inconvenience. At the present depth four headings are being worked. But the shaft has been sunk lower down, and there are headings ready for working in the lower seam. The rock has, of course, to be blasted with gunpowder. To drill the holes Mr. Finlay, whose practical genius is everywhere apparent, uses augers of considerable length, wound in a spiral twist throughout. These augers, worked by hand, are so contrived as to stop automatically when striking upon a hard stone. In the gypsum they will drive 5 ft. in half an hour or less. But for an occasional whiff of gunpowder, the air below is pure. When blasted, the rock is broken up with pick and wedge, and conveyed in trollies to the shaft. The trollies are raised in a cage to about 20 ft. above the surface, stopped on a platform and made to slide down an inclined plane, on rails, to the place where the mineral is sorted and picked. Every piece is examined before use, and, if necessary, any admixture of clay is removed with a hammer. The principal uses to which gypsum is put are conversion into plaster of Paris and cement. The less pure stone is burnt, to serve as a valued manure. Gypsum blocks are also sold in their natural state to brewers, who dissolve them in the water about to be converted into beer. For brewing purposes no ingredient is more valuable than gypsum, to which mineral the Burton water stands indebted for its world-renowned excellent qualities. Fine pieces of gypsum are also sometimes polished as marble for use indoors. Out of doors gypsum is not serviceable, as being soluble in water. Moreover, it may interest smokers to learn that gypsum is frequently used

for a very fair imitation of meerschaum. Indeed, all the cheaper meerschaum pipes and cigar-holders are reported to be made of this adulterated article, which is prepared by polishing hardened plaster, tinting it with a solution of gamboge and dragon's blood, and treating it afterwards with melted paraffin or stearic acid. This process is, however, not practised at Netherfield.

The blocks intended to be made into plaster, having been examined and sorted, are broken up by machinery and then placed in the kilns. There are five kilns for this purpose at Netherfield. The flame is not allowed to touch the mineral, but is carried up to the chimney in flues. The object aimed at is simply the evaporation of the water of combination. The crude gypsum contains about 25 per cent. of water. By desiccation this is reduced to 7½ per cent. Evaporation begins at 175 degrees, and is best effected at a temperature of 230 or 250 degrees. Overheating, say up to 480 degrees or more, spoils the gypsum by making rehydration difficult or altogether impracticable. The kilns at Netherfield hold 10 tons or 12 tons each. Twenty-four or twenty-six hours suffice for drying one kilnful. Being desiccated, the pieces are taken out and tested if sufficiently dried. If they are not, they are put into the kiln a second time. After drying, the gypsum is ground on horizontal stones, having first been "cracked." After that it is sifted, which is really the principal operation in the whole process. All depends upon this. The Subwolden Company have an excellent apparatus for sifting, the construction of which is, however, a trade secret. When sifted the plaster is filled into bags, and stored to cool for ten or twelve days, and then it is ready for use. Plaster, we may mention, is often "hardened" by an admixture of carbonate of lime or gum-arabic, which makes it capable of taking, under further treatment of smoothing and polishing with oil, a marble-like surface.

Gypsum intended for cement,—to be used for internal plaster-work in houses, cornice-mouldings, and the like,—has to be burnt by direct contact with the fire. There are different kinds of cement, three of which are manufactured at Netherfield,—namely, Keene's, Parian, and Martin's. The original manipulation of the blocks is the same in all cases. Keene's cement is made by treating the burnt gypsum with one part of alum to twelve parts of water, at a temperature of about 95 degrees. Having stood three hours, the material is rebaked in the furnace, and then thoroughly ground and powdered. When so treated it requires less water, sets more slowly, and acquires a tenacity half as great again as that of ordinary cement. Parian cement is ordinary plaster hardened with water, containing 10 per cent. of borax, and afterwards rebaked and ground. Stucco is plaster prepared with a strong solution of glue. The blocks intended for cement, of whatever kind, are burnt to red-heat in a kiln set apart for the purpose,—which takes about thirty-four hours,—and afterwards ground and sifted the same as plaster-gypsum.

Netherfield gypsum picked for plaster or cement has, as a rule, a proportion of about 95 per cent. of the pure sulphate. Its advantage, as compared with other English cement, is its freedom from marl and iron, and accordingly from the unsightly red colour caused by these impurities.

#### A HINT TO HASTINGS.

THE urgent want in Hastings (among other wants) of a small fishery pier and shelter harbour, to which we directed attention recently, was forcibly illustrated during the heavy gale of last week, which passed over Hastings and St. Leonard's, doing damage to the extent of between 2,000l. and 3,000l. to the fishermen's quarters. The roadway is almost completely destroyed, and several boat-houses along the beach roadway washed away. Large quantities of nets and gear have been lost, but, fortunately for the poor fishermen, their boats have escaped. The cost, however, of replacing what has been lost will amount to a large sum, and it often spells bankruptcy to a poor boat-owner, and enforces idleness on many of the men assisting in working the fishing craft. Surely, after the present warning, the Hastings authorities ought to bestir themselves in constructing a permanent and efficient roadway along under the East Cliff, and providing a small harbour and pier for the fishermen. We would also again remind

the magnates of Hastings that a better system of groyné work and embanking is needed than what has been hitherto adopted. The life and death interest of the dwellers in, and the bread-winners of, the old town should not be so often and so systematically subordinated to the unimportant and ever-administered-to calls of the fashionable new town. As towns and cities grow from their foundations, they have ever afterwards to be more or less dependent upon them. As it is with towns and houses, so it is with men. What revulsion of feeling is caused by seeing men and women richly attired, or with showy head-dress, while their feet below are ill shod. If Hastings does not wish to cultivate this analogy, and present a glaring exhibition of it, she had better bestir herself at once by manifesting an earnest activity in providing for the wants of the inhabitants of the older quarters of the historic Chique Port.

#### THE GUILD-MERCHANT PROCESSIONS AT PRESTON.

REPRESENTATIVES OF THE BUILDING TRADES.

MONDAY last being "the Monday next after the Feast of the Decollation of St. John the Baptist," the week's celebration of the ancient Guild Merchant festivities was commenced at Preston. It is believed that the custom of holding the Guild Merchant dates back to early Saxon periods, but the first recorded Preston Guild was held in 1320, when Aubert, son of Robert, was mayor. Twenty-three guilds are recorded as having been held since then, and for the past 380 years they have been celebrated regularly every twenty years with quaint ceremony and great festivities. Although successive changes in the forms of local government have deprived the freemen of their ancient privileges, or, rather, removed the necessity for them, the Guild Merchant of today, while chiefly a round of festivities, has some features in common with those of centuries ago. It is still a means of bringing together members of the various trades, though not exactly for protective purposes, as was the case in days of old. Since the Guild Merchant began to change its character it has been a notable fact that each succeeding guild has surpassed its predecessors in magnitude of celebration. So it has been with that of 1852, which will turn out to be the most splendid of all, largely on account of the anticipated though unfortunately abandoned visit of H.R.H. the Duke of Albany to lay the foundation-stone of the Harris Free Library. Triumphal arches span the principal thoroughfares, and many of them bear inscriptions welcoming the Duke and Duchess of Albany,—an incongruity which could not be avoided under the circumstances. In addition to these decorations most places of business are decked with hunting, and the old-fashioned aristocratic town presents a gay and festive appearance. Messrs. J. Defries & Sons, of Houndsditch, were entrusted with the decorations of some of the leading thoroughfares. The streets were lined with Venetian masts, on which were displayed trophies and festoons of flags.

The Amalgamated Trades' procession which paraded the principal streets of "Proud Preston" on Wednesday last included the following representatives of the building trades:—

**Stencemasons.**—Banner of the society from Manchester. Number in procession, 250, wearing wash-leather aprons trimmed with blue silk. Exhibits:—Lurry 1, flower-vases, finished and unfinished; lurry 2, building-stone in process of dressing, and dressed; lurry 3, the operation of stone-laying.

**Ironfounders and Range-makers.**—Two luries, exhibited by Mr. Booth, Derby-street. On one, marble masons and marble polishers were at work; and on the other, range-founders and black and white smiths.

**Plumbers and Painters.**—The men, numbering 350, wore aprons emblazoned with their trade coat of arms. Exhibits:—Several luries, one illustrating the plumbing department, containing a model of the interior fittings of a well-appointed house; another, with a pump and fountain in operation; a third, with men at work on various kinds of painting, marbling, and writing; and a fourth decorated with ornamental wall-paper, illustrating the paperhanging branch.

**Carpenters and Joiners.**—Exhibits:—Lurry containing model of church, with men working; and one with model of a joiner's shop, with men engaged in various kinds of work.

**Bricklayers.**—About 80 took part. Men engaged turning arch on lurry, with trade tools.

**Brickmakers.**—About 150 took part. There were three luries, on which members of the trade showed the various processes of manufacturing bricks, including pressing and burning.

**Faviors and Roggers.**—These were the Corporation *capitals*. Exhibits:—Model street, designed by Mr. Duthie, 13 ft. long by 7 ft. 6 in. wide, and arranged on the scale of 2 in. to 1 ft.; the foot-walks thus representing a width of 12 ft. each, and the carriage-road, 45 ft. The road was paved with stones procured from quarries in England, Ireland, Scotland, and Wales. The borders of the platform were decorated with the royal and borough arms. The weight of the model was about three tons and a half, and was drawn by four of the finest horses belonging to the Corporation, on the largest lurry belonging to the London and North-Western Railway Company. Three apprentices, mounted on the leading horses, carried the Royal Standard. About 80 took part.

**Plasterers.**—Number, about 180, each man wearing an apron bearing the coat of arms of the craft.

This procession was preceded by one illustrative of the textile industries of the town.

#### BUILDING PATENT RECORD.\*

APPLICATIONS FOR LETTERS PATENT.

4,074. D. Jouis, Walton. Heating baths of dwelling-houses, &c. Aug. 25, 1882.

4,077. J. F. Wright and G. E. Wright, Birmingham. Gas stoves. Aug. 25, 1882.

4,090. W. Thornburn, Boroughbridge. Appliances for heating and warming. Aug. 26, 1882.

4,112. W. M. Brown, London. Baths. (Com. by W. W. Rosenfield, New York, U.S.A.) Aug. 29, 1882.

4,142. H. J. Haddan, London. Door locks. (Com. by O. Belger and F. Preller, Hanover.) Aug. 30, 1882.

4,153. E. Edwards, London. Carpet-fastener. (Com. by J. A. Wilnot, Riverside, New Brunswick.) Aug. 31, 1882.

4,165. W. R. Lake, London. Steam and hot water apparatus for supplying heat to dwelling-houses, &c. (Com. by E. F. Osborne, Saint Paul, U.S.A.) Aug. 31, 1882.

#### NOTICES TO PROCEED

have been given by the following applicants on the dates named:—

August 29, 1882.

1,458. L. A. Groth, London. Composition for rendering wood, &c., uninfammable. (Com. by H. R. P. Hosemann, Berlin.) March 27, 1882.

1,975. T. E. Bladon, Birmingham. Ventilators and chimney cowls. April 26, 1882.

2,015. G. Hurdle and W. Davie, Southampton. Opening and closing of window-sashes, &c. April 28, 1882.

2,080. W. Porter, Lee. Apparatus for testing cement, &c. May 2, 1882.

2,829. R. R. McKee, Kirkcaldy. Water supply and apparatus for flushing drains. June 15, 1882.

3,344. W. S. Laycock, Sheffield. Self-acting window-blind apparatus. July 14, 1882.

3,416. T. J. Baker, Newark. Chimney-tops or ventilators. July 18, 1882.

3,486. J. Leather, Liverpool. Ventilating apparatus. July 22, 1882.

Sept. 1, 1882.

3,371. H. A. Williams, Lincoln. Pulleys for window-blind rollers, &c. July 15, 1882.

#### ABRIDGMENTS OF SPECIFICATIONS.

Published during the Week ending Sept. 2, 1882.

324. H. M. Ashley, Knottley. Kitchen-ranges. Jan. 23, 1882. Price 6d.

The bottom and sides of the oven are made of a wared form to allow of contraction and expansion. A sliding door is fitted between the fire and the chimney to send the draught under the oven when required. A passage is made below the hearth to allow air to pass to the bottom of the grate.

344. S. H. Bevan, Neath. Bonding roll roofing tiles. Jan. 24, 1882. Price 2d.

The tile is made approximately square, and the roll is carried up to the overlapping tile. (Pro. Pro.)

353. P. J. Davies, London. Water-closets, &c. Jan. 24, 1882. Price 2d.

Two syphons are so arranged that the water in the pan stands at a higher level than the water in the first syphon. (Pro. Pro.)

355. W. J. Donbleday, London. Bottom gratings or bars of fireplaces, &c. Jan. 24, 1882. Price 2d.

These are fitted in a frame so made as to be able to fall down and allow the ashes to slide off. (Pro. Pro.)

\* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street.

360. W. R. Lake, London. Supporting, balancing, and adjusting window-sashes. (Com. by P. W. Blythe, Boston, U.S.A.) Jan. 24, 1882. Price 6d.

A groove is made in the side of the sash, in which is fitted a tube. Inside this is a coiled spring, one end of which is fixed to the sash and the other to the frame. The dividing leads of the sashes are covered with india-rubber.

379. W. Wright, Plymouth. Flush-cistern for water-closets, &c. Jan. 25, 1882. Price 6d.

A syphon is combined with a ball-valve and a starting-valve and passage. The cistern is filled by the ball-valve, and when the handle is pulled the starting-valve is opened. The rush of water that passes down the discharge-pipe draws with it the air contained in the syphon, and starts the syphonic action that empties the cistern.

413. B. L. Thompson, London. Protecting roofs, walls, &c. Jan. 27, 1882. Price 4d.

The roof or wall is covered with plates of iron or tin which are coated with vitreous material on both sides. Cloth or paper, &c., may be placed between plates and the roof or wall. The plates can be ornamented as required.

438. J. Inray, London. Manufacture of decorating paper. (Com. by A. Cottais, Paris.) Jan. 28, 1882. Price 4d.

The paper is prepared with a layer of fixed white made up with solution of gum arabic. The design, made with coloured fatty ink, is laid on this, and covered with insoluble varnish. Unsized paper is then glued on, and the first paper removed. The design is then applied to the wall, &c., and the unsized paper removed.

449. J. W. Brown, Lemington. Kitcheners or cooking ranges and cooking grates. Jan. 28, 1882. Price 2d.

The ovens are ventilated by perforations in the lower part of the door through which air passes into a box in which it is heated, thence to the oven, whence it escapes through a valve-box in the crown of the oven to the smoke-lue. (Pro. Pro.)

475. J. R. Nottingham, Washington, U.S.A. Composition for the manufacture of artificial stone. (Com. by A. Pelletier, Washington, U.S.A.) Feb. 28, 1882. Price 4d.

Cement or asphaltum is mixed with sand or broken stone, and an oxide and a chloride of any base or metal. These materials are well mixed together while hot.

#### RIGHT OF SUPPORT BY ADJOINING WALLS.

OFFICERS OF ST. OLAVE, JEWRY, T. FINN AND METROPOLITAN BOARD OF WORKS.

This was a motion before Justice Day, sitting as Vacation judge, to restrain the removal of buildings and struts supporting flank walls. The plaintiffs were the owners of the Essex Tavern, and the defendants of the Bull's Head, in the neighbourhood of Houndsditch, and between them supporting struts had, it was stated, stood for forty years. A magistrate's order had been issued under the Metropolitan Building Act for the demolition of the walls of the Bull's Head as dangerous to the public. It had also become necessary to remove the structure, as the Board of Works were making a new street in the locality. The premises respectively were on the City boundary; but the Essex Tavern, being within it, was amenable to the jurisdiction of the Commissioners of Sewers, and could not be condemned until October next, when that body would again meet. On behalf of the plaintiffs it was argued that they had acquired an easement to the support the Essex had had from the other property; that the magistrate's order did not extend to the pulling down of the latter, but only to the making good of defective walls, to the satisfaction of a surveyor, and that whatever the defendants might do must be done without prejudice to the plaintiffs' rights. On behalf of the defendants it was argued that they had no alternative but to obey the order which had been made against them.

Mr. Fischer, Q.C., appeared for the plaintiffs; Mr. Methold for the defendants.

His lordship could not possibly allow the defendants' house to be pulled down under the circumstances to the injury of the other, and therefore granted an interim order to restrain their doing so until the second motion day in November next.

**Statue to the late Alexander Macdonald, M.P.**—At the Miners' Conference held last week at Manchester, Mr. T. Burt, M.P., presiding, it was unanimously decided to entrust the execution of the above statue, which is to be of Sicilian marble, to Messrs. J. Whitehead & Sons, of Westminster, whose model was selected from amongst twenty-four in an open competition. The statue is to be 7 ft. in height, and will, when executed, be erected in front of the Miners' Hall, Durham.

**THE NEW MUNICIPAL BUILDINGS FOR GLASGOW.**

**EXHIBITION OF SKETCH DESIGNS.**

The exhibition of some of the sketch designs submitted in the preliminary competition for the Glasgow Municipal Buildings was opened on Saturday last, and will remain open until the 14th inst. The exhibition has been arranged by the Glasgow Institute of Architects, to whom the Town Council have given the use of the upper gallery in the Corporation Buildings in Sauchiehall-street. Screens have been erected, on which the designs are shown, and in this way, while the work of the architects is properly displayed, the pictures on the walls are not interfered with. In all, forty-nine architects are represented in the exhibition, and as several of them send in more than one set of drawings, these are fifty-four in number.\* Of members of the profession in Glasgow, eighteen have contributed their sketch designs to the present exhibition. London architects are next in strength, their contingent numbering twelve; Edinburgh follows with four, and Manchester with three. Other cities and towns have one representative each, namely,—Alton, Aberdeen, Birmingham, Bradford, Barnsley, Belfast, Leith, Dundee, Halifax, Kilmarnock, Leeds, and Sheffield.

The exhibition is, no doubt, as the *Glasgow Herald* observes, an interesting one, though from the figure of the competitors we see that not half of the promoters of the exhibition, probably because they take our view of the matter, viz., that the decision of the professional assessor (Mr. Charles Barry) having been generally accepted by the competitors as satisfactory, any review of the preliminary sketch designs can now serve no useful purpose.

**THE PRESTON GUILD AND THE OPENING OF A NEW RAILWAY.**

The celebration of the Preston Guild this week has been accompanied by the opening of a new railway between Preston and Southport. The line is designated the West Lancashire Railway, and the opening of the new line will materially reduce the distance between the two towns. The old route is circuitous, and twenty-two miles in length, whilst the distance between Preston and Southport by the West Lancashire route is only fifteen miles, proceeding along the coast of the river Ribble, and bringing the two towns within from twenty minutes to half-an-hour's ride of each other. By a branch from the main line, crossing the valley of the Ribble, a short distance from Preston, the West Lancashire line will be connected with several of the manufacturing towns on the east side of the county, the company having obtained running powers over several portions of the Lancashire and Yorkshire system, extending to those towns. The new line is carried across the River Ribble into Preston by a massive girder bridge in six divisions, and on Friday week the line was inspected by General Hutchinson, the Board of Trade Inspector. The first trial trip over the bridge was made early in the morning. The train, which consisted of first, second, and third class carriages, was drawn by a heavy engine, and amongst the passengers were Messrs. Fox and Brunlees, the engineers-in-chief; Mr. Thursty, the resident engineer; Messrs. Bradlock & Matthews, the contractors; Mr. Gilbert, the manager; and many others. The train returned to Southport, at twelve o'clock, to meet General Hutchinson, accomplishing the distance in half an hour. It shortly afterwards left again for Preston, for the purposes of the inspection. Four large and powerful engines were used to test the bridge over the river Ribble. The engines stood upon the bridge, and ran across it five times at full speed, and the deflection was only a quarter of an inch. The whole of the line proved to be satisfactory, and it was passed by General Hutchinson. It was opened for traffic on Monday, and has daily during the week brought large numbers from Southport, who are attending the Guild festivities. At Preston and Southport two large and commodious stations are in course of erection, both structures being exactly uniform in architectural design.

\* In the competition, 125 sets of sketch designs were sent in, by 110 competitors.

**RAILWAY CLOCKS.**

Sir,—No doubt to the deitzen of the "Empire on which the sun never sets," the sun is the great clock, and "railway time" is simply a mechanical necessity of 1882, from rapid transactions of trade, &c. Any boy knows this who looks up at Bennett's in Cheapside; but railway time affects every social relation of life, like the Post-office does. Two of your correspondents have written on this subject, and it seems the present clocks of all the companies suffer from "draughts," "damp," and "oscillation." I am not an expert, but humbly submit, sir, could not these difficulties be got over? Many would argue that the minimum of oscillation is when clocks, &c., are fixed to walls, &c., or on terra-firma, but would it not be possible (at small cost) to fix every railway clock, wherever placed, in a second strong case of metal or oak, lined with ½-in. vulcanised lining? In this case there might be an apparatus on the hinnaace, "ship-lamp," or "endless joint" principle, the clock itself to be attached above and to this by hook, screw, or otherwise. Railway train or "oart tremor," or such like, would surely not affect this arrangement as much as a firm fixture,—that is, of course, always provided that the pendulum proper is not affected by this isolated or pendulous treatment. I apprehend not. Then if this minimises the shaking, the double case and lining will cure the draughts and damp.

*En passant*, that picture discovery from Pompeii is simply marvellous! (the "Solomon's judgment on the true mother,") because a few years ago the religious world feared science, but Biblical knowledge has been strengthened by science. LAKEMAN HERBERT.

**FOG SIGNALS.**

Sir,—Will some one of your readers give me particulars as to the cost of fog-signalling on the railways in this country, as I am unable to procure sufficient particulars from their balance-sheets? LECTOR CONSTANS.

**SCHOOL BOARD SCHOOLS.**

*Felling and Felling Shore (Heworth).*—Three groups of schools are at present in course of erection to meet the deficiency of school accommodation in the Heworth School Board district. Two have been completed, and were opened on Monday last, whilst the third, which is being erected at Windy Nook, will be completed in the course of a few months. The Felling schools are arranged to accommodate 725 children. The building is in two stories, and the characteristic features of the interior are the large number of class-rooms provided, with the facilities that exist for easy and direct supervision by the heads of departments, and the means that are provided to enable all the children to approach and leave their several class-rooms without noise or disturbance to the rest of the scholars. Mr. G. Waddell, of Edinburgh, was the contractor for these schools, and the cost of their erection has been 3,461l., or 5l. 5s. per scholar. The schools at the Felling Shore are for infants only, and the work has been carried out by Mr. Alexander Thompson, contractor, of Gateshead. Messrs. Oliver & Leson, of Newcastle-on-Tyne, are the architects for the three groups of schools.

*Lambeth.*—A new school in the Lambeth Division of the School Board for London, situate in Mina-road, Old Kent-road, has been opened. The school is built to accommodate 420 boys, a like number of girls, and 558 infants, making in all, 1,398. The site comprises 19,213 square feet, and the cost of the building, independently of the site, is 13,130l., or 9l. 7s. 6d. per head. The builder is Mr. C. Wall, of Chelsea, and the architect is Mr. E. R. Robson. The building has a spacious playground at the back, part of which is covered in with an iron roof, to enable the children to take their exercise during wet weather. The playground is the largest open space within a considerable area, and it is hoped that the Board will see their way clear to allow it to remain open to the children of the neighbourhood for a reasonable time after school hours.

**Builders' Benevolent Institution.**—The dinner in aid of the funds of the above-named Institution will take place at the Freemasons' Tavern, on Thursday, the 2nd of November, Mr. J. T. Chappell, president in the chair.

**Books.**

*Practical Organ Building.* By W. G. DICKSON, M.A., Precentor of Ely Cathedral. Second edition. Crosby Lockwood & Co. 1882.

This is one of the "Weale's Series" of books, and is intended to afford practical information and instruction to those who wish to follow the very interesting employment of building an organ for themselves. The writer, of course, does not, in a book of this kind, go into all the refinements of mechanism adopted in modern large organs, such as pneumatic lever action, pistons, &c. These are not necessary in a small organ, and cannot be satisfactorily made without more elaborate mechanical resources than an amateur can usually afford to have at his command. The action shown in the diagrams is the usual action adopted in ordinary organs of moderate size, and the parts are sufficiently shown in the diagrams to enable any one with a capacity for using tools and understanding drawings to work from them. We can hardly say the same in regard to the pipe diagrams and descriptions, which are not by any means so clear as might be; and we doubt whether any one coming to the book with no previous knowledge of the principles and practice of making organ pipes would be able to make one from the information and illustrations here given. The diagrams are too small in scale, and do not explain themselves sufficiently. We are aware that the low price put on the "Weale's Series" books renders elaborate diagrams impossible, in view of economical considerations. The publishers have done what they could, no doubt, but it is hardly sufficient for the purpose. But in one or two cases there is a defect in the method of drawing also, as in the section of the foot of a wooden pipe (fig. 3), where portions which are separate pieces are drawn in section as if they were cut out of the solid.

In the main, however, the author seems to be well up in the practical part of his work; but, after all, the end and object of organ-building is a musical and not a mechanical one, although we have observed that with not a few persons who indulge in private organ-building the mechanical interest seems entirely to obliterate the musical object of the work. Those who go into amateur organ-building on this ground, of course, have their reward; but to those who look also to the musical ends for which organs are supposed to be constructed, our advice to those about to build small organs would be in the same brief terms as *Punch's* well-known advice to those about to marry. The genuine qualities of the organ as a musical instrument are, to our thinking, never realised except when the instrument is on a tolerably large scale. Little organs bring into prominence all the characteristic defects of the organ and minimise its beauties; and if small organs for sitting-rooms are built, some of the recommendations made by the precentor of Ely (whose musical notions seem as old-fashioned as those of cathedral precentors almost proverbially are) should be carefully eschewed. We will mention, however, one in which we are disposed to support him, the rather because it is one in which, as he himself says, he is likely to find very few persons to agree with him,—that is, in the recommendation that when, in small church organs, only two keyboards can be afforded, the second keyboard should be not, as usual, a "swell" organ, but a "choir" organ. Variety of tone and the highest qualities of organ effect are far better attained by the bright and varied tones of the pipes standing free in the usual form of "choir organ," than by shutting up pipes in a box and letting them sound through shutters occasionally opened and closed. The swell is an expressive adjunct to the organ, but its importance has been much overrated in England (where it was invented) and its use much abused; and we are glad to support Mr. Dickson in his suggestion on this head. But in other points his recommendations are painfully old-fashioned. He speaks of stops being made to draw in halves, treble and bass, a proceeding which is utterly useless, and which none but a hopelessly middle-headed builder would ever think of adopting nowadays; it is found only in old English organs, built when people knew no better. But, still worse, the author not only recommends the system of "grooving" one stop into another, but even speaks of it as if it were the natural and inevitable way of building small organs. Grooving, it may here be explained, is an operation used when there is

supposed to be not room enough or not money enough to have some particular stop complete, and so the lower octave of pipes, perhaps, which should belong to that stop, is omitted, and the lowest octave of sounds is borrowed from the pipes belonging to another stop, which are thus made to do double duty. Now, we beg to point out (and we speak with the advice of those who are competent judges of the subject) that this practice is, from a musical point of view, simply detestable, and is one of the worst of the old prevalent vices of English organ-building, which are now happily getting disused. To any persons possessed of ordinary common sense it must need only very slight musical knowledge to perceive that such a process not only breaks the continuity of tone in a stop, but it leads to the result that when the stops are used together, the lowest octave, which ought if anything to be the strongest and firmest in tone, is the weakest, having only one set of pipes against two in the upper octaves. Every one who looks at an organ,—or, we should rather say, listens to it,—from a musician's point of view, would, we are assured, tell Mr. Dickson and his readers that it is far better to omit a stop altogether than to make up a sham list of stops by such a wretched makeshift as grooving; and it is a pity that any book on the subject should have been put forth recommending such a practice, unless the object of organ-building, in the author's view, is merely to exercise a talent for joinery, without consideration of the ultimate musical result.

We fear the frontispiece, also, which gives a view of a small organ built by the author, suggests other criticisms more directly from our own point of view. The organ is represented as placed under a low arched organ-chamber, the front pipes only projecting from the mouth of the cavern. This, as has been more than once pointed out in the *Builder*, is the worst position that an organ can be placed in. An organ ought to have free space all round for the sound to develop; nothing militates against its tone so much as cooping it up in a closet in this way; and, besides, it is very desirable that it should be in a position where there is plenty of light, for darkness means the unseen accumulation of dust and dirt, and increased difficulty in inspection and repairing. This, again, ought to seem a matter of more common sense; and yet architects and clergy go on smothering organs in what they call "organ-chambers," as this was the only orthodox way of treating the instrument.

*A Hand-Book and Guide to Preston.* By Wm. POLLARD. Preston: H. Oakey, Fishergate. 1882.

CARE has been taken to provide the large number of persons visiting Preston this week with an inexpensive and compact little hand-book. Mr. William Pollard has done his work very satisfactorily, and has given a history of the town as well as a clear and comprehensive account of the various buildings and the environs.

#### VARIORUM.

MESSRS. LONGMANS, GREEN, & Co. announce the first number of a new Magazine, to be continued monthly, under the title of *Longman's Magazine*, each number consisting of from 100 to 128 pages, price 6d. The articles will in most cases be signed by the contributors, and the editor will be personally answerable for the opinions of the anonymous writers only. A strong list of writers is given.—"The Footsteps of St. Paul in Rome" is an admirable little memoir by S. Russell Forbes (of Rome), treated from an archeological point of view. It is published by Thos. Nelson & Sons, London.—The September number of *Belgravia* is a good one. The serial story in it, "All Sorts and Conditions of Men," by Walter Besant and Jas. Rice, increases in interest.—In the *Gentleman's Magazine*, a chapter headed "An Author at Home" gives some account of the private life of Mr. Charles Reade, and shows him to be of a liberal turn of mind.—Cassell & Co. have commenced the issue of a pictorial edition of "The Arabian Nights Entertainment," to be completed in sixteen sixpenny parts. It will contain 400 illustrations by Gustave Doré and other well-known artists, and promises to be a remarkable book of its kind.—From "Our Homes and How to make them Healthy" we get the following paragraph on "Sanitation in the Eighteenth Century":—

Though it is somewhat difficult to arrive at any very precise estimate of the sanitary condition of the great towns at the commencement of the eighteenth century, sufficient records exist to show that a steady increase must have taken place both in personal and public cleanliness. The average of deaths from colic and dysentery decreased with remarkable activity, so much so that in the last decennial period of the century the annual average of deaths from these causes was little more than a tenth of what it had been in the first one. The cause of this decrease is attributed by a writer at the beginning of the present century to the improvements which took place in all the great towns, in the manner of living, but particularly in respect to cleanliness and ventilation. In many provincial towns, however, the sanitary arrangements were but little in advance of those in the Middle Ages. In the year 1855 Mrs. Mary Bartlett, aged 105, described to Mr. Edwin Chadwick how, within her own recollection, it was dangerous to walk the streets of Exeter after dark "for fear of being befouled by what was thrown out of the windows, and during rain by the water-spouts from the unuttered houses." The old custom of strewn the floor with rushes also survived until the middle of the eighteenth century. In seaside towns sand did the work of rushes. Brussels carpets were introduced from Tournay in 1745, and by the year 1760 the floors of all respectable houses were carpeted. The subject of ventilation appears to have received little or no attention in this country until the close of the seventeenth and the early years of the eighteenth centuries.

#### Miscellanea.

**Disfiguring Buildings.**—The Canterbury magistrates have been called upon to investigate a case in which the Dean and Chapter of the Cathedral prosecuted a visitor to the city for an act of wanton mischief in the nave of that building by scratching his name on one of the piers. It was stated that it was a very common practice among strangers who visited the cathedral to write or scratch their names upon the columns and other conspicuous parts of the stonework, but hitherto the authorities had been unsuccessful in their attempts to make an example of one of the offenders. The present defendant was caught in the act by a gentleman who had undertaken the part of amateur detective to the Chapter. Mr. H. G. Austin, the cathedral senechal, said the Chapter did not press for a heavy penalty, but desired merely a conviction as a warning to others. A great amount of damage had been done in different parts of the cathedral, especially in the north-west transept, and the authorities were determined to put a stop to it. The Bench fined the defendant 1l. 8s. 6d., with the alternative of fourteen days' imprisonment. It is to be hoped this incident will act as a warning to other foolish people.

**Appointment of Surveyors and Architect for Ripon Diocese.**—At a meeting of the archdeacons and rural deans of the diocese of Ripon, held under the presidency of the bishop, at the Palace, Ripon, it was resolved that Mr. Ralph Nicholson, of 55, Parliament-street, Westminster, and Mr. C. R. Chorley, of Headland-buildings, 15, Park-row, Leeds, be elected diocesan surveyors of dilapidations for the Ecclesiastical Dilapidations Act, 34 and 35 Vict., c. 43, and that they continue in office for three years from this date on the same terms as heretofore. It was also resolved that Mr. J. Oldrid Scott be elected diocesan architect for the diocese of Ripon, in the place of the late Mr. G. E. Street, at a salary of 50l. This resolution is subject to confirmation by the general meeting of the society next spring.

**Fleet-street Improvements.**—On Tuesday, says the *City Press*, tenders were received for erecting the new building in Fleet-street (at the corner of Chancery-lane) for Messrs. George Attenborough & Son, from the designs of Messrs. Archer & Green, of Buckingham-street, Strand. Those sent in are as follow:—Messrs. Mowlem & Burt, 11, 962l.; Messrs. Perry & Co., 11,000l.; Messrs. Colls Brothers, 10,697l.; Messrs. Holland & Hannen, 10,680l.; Messrs. Bywater, 10,123l. The latter tender was accepted, and the works will be forthwith commenced.

**The Parkes Museum.**—The Council of the Parkes Museum have just acquired new premises in Margaret-street, Cavendish-square, to which the museum is to be removed from University College as soon as the alterations and additions which are now being made, under the direction of Mr. Mark H. Judge, A.R.I.B.A., are completed. The new museum will consist of a central hall, suitable for meetings and lectures; a library; and corridors, all lighted from the top, and well suited for exhibition purposes. The meetings and lectures on sanitary and other matters connected with the health of the people, which were only occasional while the museum was at University College, will form a permanent feature of the institution when it is re-opened in Margaret-street. Capt. Douglas Galton, C.B., F.R.S., presided at the last meeting of the Council, when a letter was read from Mr. Thomas Twining, of Twickenham, offering to contribute a special donation of 100l. towards the expenses incidental to the change of quarters. It is expected that the museum will be re-opened before Christmas.

**Burnley.**—The Burnley Board of Guardians, on the 31st ult., adopted the plans of Mr. T. Bell, architect, for the new cottage-homes and schools at the workhouse. The plans show four cottage homes, capable of accommodating twenty-six children each. These cottage homes are to be erected on the plot of land now used as a meadow, in front of the main building. The school will be erected between two cottage homes, and will be capable of accommodating 110 children. The boys will occupy the home nearest the turnpike road, and the girls will be placed on the Infirmary side. Each home is intended to be under the superintendence of a "mother," and the children will do the whole of the work in connexion with each block, except the washing and baking. On the ground-floor there are to be day-room, dining-room, kitchen, scullery with pantry, lavatory, and store-room. On the second floor there will be two dormitories,—one to accommodate 16 and the other 10 children, and the nurses' bedrooms are so placed as to overlook both dormitories.

**An Achievement.**—Mr. S. C. Hall, F.S.A., recently entertained a number of ladies and gentlemen in Plymouth with a discourse on the remarkable men and things he has known. Admission was by invitation ticket issued by the Mayor, and such was the desire to hear Mr. Hall that more tickets were issued than would fill the room. All were not able to come; but as many came as rendered the room uncomfortably warm. The Mayor (Mr. C. F. Burnard) presided. After a most interesting address, delivered in a strong audible voice, and extending in delivery over two hours and a half, Mr. Hall concluded by expressing his great interest in the Plymouth Free Library, and his desire to promote its usefulness. A cordial vote of thanks, moved by Mr. I. Latimer, and seconded by Mr. R. C. Serpell, followed by a similar recognition of the Mayor's services in presiding, brought to a close an entertainment which gave great pleasure to those who were present.

**Another London Theatre Burned Down.**—Early on Wednesday morning the Philharmonic Theatre, Upper-street, Islington, was completely destroyed by fire. The theatre was closed about twelve o'clock on Tuesday night, and at ten minutes to one o'clock a policeman on duty saw smoke issuing from the main building. By about three o'clock the whole of the theatre,—stage and auditorium,—was nearly burnt out, and most part of the roof was burnt off. The property and dressing rooms, which are apart from the main building, were not materially damaged. The cause of the disaster has not been ascertained. The theatre has not been originally built as a music-hall, and was opened about twenty-two years ago. If we mistake not, it had only lately undergone reconstruction to a material extent.

**A Pastoral Staff.**—A pastoral staff, prepared by the diocesan architect, has been presented to the Bishop of Bath and Wells. It is designed to illustrate the histories of Glastonbury, Bath and Wells in their connexion and independence, the main imagery of the crook applying to the name of Wells. The plan of the crook is heron-goual. Engraved upon the staff are the words "Thy rod and Thy staff comfort me." The Earl of Cork made the presentation, and Archdeacon Denison presented an address. The Dean of Wells and Mr. R. H. Paget, M.P., also took part in the proceedings.

**The Borough Surveyorship, Swansea.**—At a special meeting of the Swansea Town Council, on the 30th ult., the election of a borough surveyor took place. From the large number of 100 candidates for the appointment, the special committee had selected seven, as follows:—Mr. George Bell, aged 32, assistant engineer to the Swansea Corporation for the past seven years; 2, Mr. P. B. Coghlan, aged 40, engaged under the London School Board and in private practice; 3, Mr. W. A. de Pape, aged 35, Tottenham; 4, Mr. J. M. Thomas, 32, assistant surveyor to the Swansea Corporation; 5, Mr. W. H. Wardle, 32, assistant surveyor, Bolton; 6, Mr. Winter, chief assistant surveyor, Liverpool; 7, Mr. R. H. Wyrill, aged 31, of Leeds, in private practice. It was arranged that the candidates should be called into the chamber *seriatim*, the testimonials of each being read before he was seen. This being done, all the candidates being called in and questioned, with the exception of Mr. W. A. de Pape, who was not in attendance, and so was disqualified, the result of the voting was as follows:—For Mr. Wyrill, 14; for Mr. Bell, 5; for Mr. Thomas, 3. On the motion of Mr. Cadry, seconded by Mr. Burnie, Mr. Wyrill was elected.

**New Clock and Carillons for Bombay University.**—A native of Bombay, Mr. Premchund Rogchund, having munificently provided the necessary funds for a large clock and carillons for Bombay University, the India Government entrusted the work to the following firms:—The bells to Messrs. John Taylor & Co., of Loughborough, Leicestershire, founders of the new ring of twelve bells for St. Paul's Cathedral, and of Great Paul; the iron bell-frame to Messrs. Westwood, Baillie, & Co., and the clock and carillon machinery to Messrs. Lund & Blockley, of 42, Pall-mall, by whom the whole of the work has been erected and put in operation in London, preparatory to its shipment to Bombay. The bells are sixteen in number, in the key of C (twelve consecutive and four half-notes). The largest weighs about three tons, and the whole peal about twelve tons, and they are contained in a wrought-iron bell-frame, weighing about seven tons more.

**Modern Mosaics.**—At the cost of Mr. Bateson de Yarbrough, the reredos of St. Paul's Church, Hestington, has recently been richly embellished by the introduction of a series of beautiful mural decorations carried out in Venetian glass mosaic. The work in question comprises the decoration of nine panels at the east end of the church, and the subjects represented in the four principal panels are full-length figures of the Evangelists, with emblematic devices and inscriptions. The figures are in colour, and stand out prominently from the rich gold background which surrounds them. The smaller panels are treated with foliated designs, and the central panel contains an ornamental Maltese cross. The work, which has given great satisfaction, has been carried out by the well-known Venice and Murano Glass and Mosaic Company, of 30, St. James-street, London.

**Electric Lighting.**—At the last meeting of the Fulham District Board of Works, the seal of the Board was affixed to an agreement with the West Middlesex Electric Lighting Company, empowering the company to lay wires enclosed in pipes under the footways, throughout the parishes of Fulham and Hammersmith,—the distance of roads in the district being thirty-seven miles, and containing 29,000 houses. It is proposed to erect, at suitable points, central stations upon a large scale, within the two parishes, for the purpose of generating electricity. Gramme dynamo machines will be used for this purpose. For street lighting Brocchi's arc lamps will at present be fixed, and for shops and private houses, the Improved British Incandescent Lamp.

**Boring Operations with Bort.**—A correspondent writes:—"In the course of some boring operations which have recently been carried on by the Government of the Capo of Good Hope in the search for coal, it occurred to the geologist in charge to make trial of native bort in lieu of the Brazilian carbonado, which had, until then, been employed. The experiment proved a complete success. The first six crowns used were of 3 in. diameter, set with bort. It was found that these bored through 1,100 ft. of sandstone and shale, part of it exceedingly hard, being indurated by contact with intrusive rock. The average boring per crown was therefore 183 ft., and the last row is nearly as good as new."

**Proposed Municipal Buildings at Hyde.** At a meeting of the Hyde Town Council, on Monday night, a memorial, signed by 2,262 ratepayers, was presented, urging the Council, in consequence of the unsatisfactory termination of the public meeting lately held to discuss the scheme for erecting municipal offices for the borough, at a cost of 800*l.*, to reconsider and abandon the scheme, a large majority of the constituents being opposed to it. The Council, however, were of opinion that it would be to the interest of the present and future ratepayers that the scheme should be proceeded with. Mr. J. W. Beaman, Manchester, has been appointed the architect, and Greenfield House will be taken down to make room for the new building.

**The Coalbrookdale Company** have taken premises at Nos. 43 and 44, Holborn Viaduct, as London showrooms, for their well-known manufactures, and purpose to keep there a selection of the principal articles in grates, stoves, ranges, gases, railings, &c., made at their foundry in Shropshire. The rooms will be under the charge of Mr. Henry Ch. Eyres. The Coalbrookdale Company, as among the very first of the manufacturing firms who, after the Great Exhibition of 1851, sought to bring in art to the elevation of their works, well deserve a warm recognition at our hands.

**Dorking Sewerage.**—At a meeting of the Dorking Local Board, held on the 29th ult., a report was received from the Sewerage Committee, stating that the Committee had examined the report of Messrs. Smith & Ansting, the consulting engineers to the Board, for the sewerage of the town, and recommending that the same be approved and adopted, and that the engineers named be instructed to proceed with the preparation of the working plans and sections. This was agreed to.

**Art in Liverpool.**—On Saturday last, over 1,500 persons attended the "private view" of the collection of pictures and sculpture in this season's autumn exhibition, held in the Walker Art Gallery, under the auspices of the Liverpool Corporation, and ninety-one pictures were sold, realising 1,328*l.* The collection comprises 826 oil paintings, 741 water-colour drawings, and 38 pieces of sculpture. Sir F. Leighton's "Phyrrus" occupies a prominent place in the exhibition.

**Royal Commission on Technical Instruction.**—The members of this Commission have not been idle during the past month. Considerable progress has been made in the collection and arrangement of the vast amount of information collected by the Commissioners during their visit to France, Germany, Austria, Switzerland, and Italy. They have recently been engaged in pursuing their investigations here and abroad.

**Newport (Mon.)**—The clergy of Holy Trinity parish, having held services for years past in small rooms lent or hired for the purpose, feel it desirable that a permanent and commodious building should be erected. A central and very suitable site has been promised by the Trade-gar Wharf Company, and plans, prepared by Mr. E. A. Lansdowne, of Newport, have been approved by the committee. The total cost will be from 2,500*l.* to 3,000*l.*

**The Jahlochkoff Electric Light Company** have taken large premises on the Albert Embankment, to be used as a manufactory for their carbon candles, as a warehouse, and as a lighting centre. They are also about erecting a building on the Victoria Embankment for the purpose of more effectually carrying out their contract with the Metropolitan Board of Works.

**The Tyde Union Sanitary Authority** have obtained designs from several civil engineers for sewerage the town of Poulton, and the districts of Breck, Skippool, and Little Poulton, and the scheme of Mr. Alfred M. Fowler, Manchester, has been accepted.

TENDERS

For the erection of warehouses and timber store, Bunhill-row, for Mr. W. Walker. Messrs. Davis & Emanuel, architects, 2, Finsbury-circus, City. Quantities by Mr. Frost, Downing, 7, Whitehall-yard.

Alcock	4,740 0 0
Harris & Wardrop	4,699 0 0

For blue brick paving and kerbing and channelling at Loughborough. Mr. Frank Baker, C.E., Town Surveyor.—

Gibbons, Leicester	£1,012 0 4
Lee, Leicester	953 4 4
Barker, Loughborough	948 5 4
Brown, Nottingham	929 3 1
Knight, Loughborough	911 11 5
Cordon, Nottingham	897 15 0

Mr. Knight's tender has been accepted for the blue brick paving, and Mr. Cordon's for the kerbing and channelling.

" Tavern, Storey's Gate.—In the list of tenders for rebuilding the Storey's Gate Tavern, Westminster, published by us last week (p. 229), the tender of Mr. Thos. Spearling, of Beaneley-road, Wandsworth-common, which amounted to 3,237*l.*, was, by the inadvertence of our correspondent, omitted.

TO CORRESPONDENTS.

T. H. (the clause may be got over by facing the chimney breast with 9 in. work instead of 4 in.).—A. P. d'Or.—A. T.—T. G. B.—W. S. B.—A. F.—E. H. L. B.—W. H.—D. K. & Son.—C. H. G.—E. H. M. A.—E. M. U.—W. L. M.—W. L. P.—L. P.—B.—A.—W.—F.—D.—T. & S.—M. & L.—W. W.—S. W. H.—Mr. B.—T.—S.—C.—H. G.—S.—W. N.—J. St. C. M.—S. & A.

All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication.

We are compelled to decline pointing out books and giving addresses.

Not.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.  
Six lines (about fifty words) or under ..... 4s. 6d.  
Each additional line (about ten words) ..... 0s. 6d.  
Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competition, Contracts, Sales by Auction, &c. may be obtained on application to the Publisher.

FOUR Lines (about THIRTY words) or under ..... 2s. 6d.  
Each additional line (about ten words) ..... 0s. 8d.  
REPLIES TO ADVERTISEMENTS.

Addressed Box.—Office of "The Builder."  
Cannot be forwarded, but must in all cases be called for, and the Office Receipt produced.

THE CHARGE FOR A BOX IS AS UNDER:—  
For "Situations Wanted" Advertisements ..... 8*s.* per Week.  
For all other Advertisements ..... 6*s.* per Week.  
PREPAYMENT IS ABSOLUTELY NECESSARY.

\* Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to  
DOUGLAS FOURDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY. TESTIMONIALS, &c. left at the Office in return for advertisements and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 19*s.* per annum, FREIGHT. Remittances payable to DOUGLAS FOURDRINER, Publisher, 46, Catherine-street, W.C.

**Best Bath Stone.**  
WESTWOOD GROUND,  
Box Ground, Combe Down,  
Corsham Down,  
And Farleigh Down.  
RANDELL, SAUNDERS, & CO., Limited,  
Corsham, Wilts. [ADVT.]

**Box Ground Stone.**  
Is the best for use in all exposed positions, being a well-known and tried weather stone.  
50,000 feet cube in stock.  
PICTOR & SONS,  
Box, Wilts. [ADVT.]

**Doubling Freestone and Ham Hill Stone**  
of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Ilminster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [ADVT.]

**Doubling Freestone,** supplied from their own Quarries and Kilns by SPAFF & HAYS, Stoke, Ilminster. Agent, Mr. E. CRICKMAY, 4, Broad-street-buildings, Liverpool-street, London, E.C. [ADVT.]

**Asphalts.**  
Seysse, Patent Metallic Lava, and White Asphalts.  
M. STODART & CO.  
Office:  
No. 90, Cannon-street, E.C. [ADVT.]

**Asphalts.**—The Seysse and Metallic Lava Asphaltic Compound (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [ADVT.]

**Immense quantities of**  
DRY WAINSCOT,  
DRY MAHOGANY,  
DRY WALNUT,  
in all thicknesses.  
B. J. HUDSON & SONS,  
Whitefield-st., W., and Great Peter-st., S.W. London. [ADVT.]

"Lightning."—An accident to buildings would be unknown if J. W. GRAY & SONS' Patent System of Conductors, as fitted to the Houses of Parliament, the Royal Palaces, Principal Churches, Cathedrals, and Public Buildings, were universally adopted.—Estimates free on application at 58, Fenchurch-street, London, E.C.—[ADVT.]

**MICHELMORE & REAP,**  
Manufacturers of  
CHARLES COLLINGS' PATENT.  
COLLINGS' PATENT HINGES,  
LEVER, SCREW, & BARREL BOLTS,  
Self-Acting "FALL DOWN" GATE STOPS,  
and IMPROVED GATE FITTINGS of every description,  
36A, BOROUGH ROAD,  
LONDON, S.E.  
Discount to Builders. Illustrated List two stamps.

**ZINC ROOFING.**  
**F. BRABY & CO.,**  
LONDON, LIVERPOOL, GLASGOW.  
**VIEILLE MONTAGNE BRAND.**  
**NO SOLDER.**  
**NO EXTERNAL FASTENINGS**  
PARTICULARS ON APPLICATION. CHIEF OFFICE: 360, EUSTON ROAD, LONDON.

### Economic Science, and the State Purchase of Railways.

#### THE PRACTICAL KEY TO THE PROBLEM.

THE discussion, on August 29th, by the Section for Economic Science and Statistics of the British Association, of Mr. Watherston's paper, "A Plea for Unity of Administration of Railways," is hardly calculated to support the claim of an annual occasion of the kind to produce work more striking or more valuable than that which, week after week, is brought

forward in the columns of the scientific press. It would be difficult more pregnantly to illustrate the difference between the steady worker, kept in the groove by a sense of public, although unnamed, responsibility, and the brilliant or the hasty essayist, than was afforded by the debate in question, whilst the great public interest taken in the subject has been insisted on, and ably enforced, by the *Manchester Guardian*. With the starting-point taken by Mr. Watherston, and with his views of what is desirable, —if only it were possible,—we fully agree. But we regret that the question of feasibility should not be put in the first rank, as this precaution would effect a great saving of time and of argument. Captain Douglas Galton touched upon the first points to which we have to refer, but was not prepared to go into them with that precision which is requisite in order to obtain definite results. How much railway capital, he inquired, is debenture or preference stock? Let us see.

That theoretically railways "ought to be public property," we hold to be indisputable. It is quite another thing to ask whether, after Parliament has authorised the spending of 745 millions by private companies on the construction of 18,000 miles of line, it is feasible to make the change; and further, if feasible, would the public be the gainer?

In the first place, out of the 728,000,000. of railway capital existing at the end of 1880, 182,000,000. has been raised by loans and debenture stock, and 276,000,000. by guaranteed or preferential capital. This leaves only 270,000,000. of ordinary capital,—a consideration of no little importance in attempting a practical view of the question. On the whole capital of 728 millions, the interest divided amounted to 4.38 per cent. This, then, is the

value of the property to be acquired by the nation in order to carry out Mr. Watherston's plan. If converted into three per cent. stock, it would represent an amount of 1,062 millions sterling; and the annual interest for which the State would thus become responsible would be nearly 50 per cent. more than that now paid on the National Debt! But this is allowing nothing to the shareholders for compulsory purchase,—a feature of some importance in the case. Again, out of the 458 millions of loan, debenture, preference, and guaranteed capital, very little more than 13 millions now pays less than three per cent. interest. The bulk of the remainder receives between three and five per cent., and small sums run up to as much as 10 and even 15 per cent. It is thus evident that the Government would require more than the present net earnings of 32 millions to save themselves from loss by the transaction; probably considerably more. And this being so, from what source is any abatement of tariff to be made up? Either the railway customers, or the nation, would have to pay, and that no inconsiderable sum, for the mere transference of the property. Thus the first financial requisite, that of the lowering of rates and taxes, would be defeated by the charge made in order to secure it.

As to saving in working expenses, Captain Galton remarked that it could not possibly exceed some 500,000. or 600,000. out of a gross expenditure of 34,000,000. sterling. It has yet to be shown that any saving whatever would be effected by the change. The only direct experience bearing on the question is that of the French, Belgian, and Italian railways, and that is to the effect that Government management is at the same time the most costly and the least efficient. Some paid chairmen and directors would, no doubt, disappear; but it is not to be thought that these gentlemen are paid for doing nothing; and how far their duties, whatever they may be, would be more cheaply and efficiently discharged by Government officials, has to be shown. As far as our own knowledge extends, we should say that the railway servants of the United Kingdom are as industrious, efficient, and as far from over-paid a body of men as can be found anywhere in the world, and we think there is every reason to expect that the substitution of Government management for that of the representatives of shareholders, interested in the cheap working of their lines, would be a steady and notable rise in the wages of every department of the great system, as compared with the work done.

At the same time, we would be the last persons to throw cold water on any serious discussion of the subject of the ultimate freedom of our railways. It is only when the question is approached without a full view of the magnitude of the difficulties that attend it that we have anything to say as a protest. For the State to purchase the property of the railway

companies we hold would be a ruinous mistake. And this opinion we share with those French and Belgian statesmen who have studied the subject with clear and impartial intelligence, and at the same time with a knowledge and command of statistics that are not attainable as to English railways. But the prospect of the continuance of the English railway system as a source of mercantile profit to the capitalists who have found the money for making the lines is one that is attended by grave menace to the country. Within a short time the manufacturers of France and of Belgium will be able to command water-carriage at cost price, and railway carriage at very little more than cost price. To pay the modest 4½ per cent., which is only the net earning of our railway capital,—double freights and fares,—how will our manufacturers hold their own against those of the Continent who have only half as much to pay for transport as they have? This is a question not theoretic, but practical; not a long way off, but at the door; not to be brushed aside with the policy of the ostrich, but to be looked in the face.

Take one example, to show how the matter comes home. The value of coppers is less than 30s. per ton. Large works for the manufacture of alum and of coppers exist at Manchester. The rate charged by the railway companies for conveying this cheap undamagable material, in large quantities, from Manchester to Liverpool, or to Garston, is 7s. 6d. per ton,—more than a fourth of the selling price! But for conveying it to Glasgow, it is no less than 21s. 8d. per ton; while at the same time sugar, which is worth 20l. per ton, is conveyed for the same distance for 13s. 4d.! The distance is 225½ miles. The cost of conveyance by canal would be about 6s. 3d., if a line of canal existed; and the cost by canal to the Mersey, and thence by sea to Glasgow, would probably be less. We think it probable that if the railway charges were based on the two elements of actual cost of transport and proportionate profit, from 16s. to 19s. per ton would be a fair charge to Glasgow, and something under 3s. a ton to Liverpool, as against 1s. by canal. The manufacturers in this case naturally complained before the Select Committee on Railways (Rates and Fares) as to inequality of charge. But there is something even more serious, as far as the country is concerned, than this inequality. It is the fact that the railway companies have closed the old routes from Manchester to Liverpool and from Manchester to Birmingham by water, while at the same time they cannot themselves (with justice to their shareholders) carry the material in question for the longer distance at a price that it can afford. To stop water-carriage from Manchester to Glasgow is to shut up chemical works at the former spot, in so far as sale at the latter spot is concerned. It is this injury done to the manufacturers, without any corresponding benefit

to themselves, that forms the real nut which the English public has to crack with the English railway companies.

Not a week passes without some fresh indication of the vivid interest which this question of the cost of transport is exciting among all branches of industry. As to its intimate connexion with the welfare of the building trade we have already spoken on former occasions, and also of that displacement of the centres of activity of this trade which has been shown in consequence of the improvement of the free waterways of the Clyde, the Tyne, and the Wear. On the other hand, we hear from one of the Conservators of the Thames that the transport on that river above the Thames now amounts to little more than one-tenth of what it was twenty years ago; and that notwithstanding the outlay of 100,000*l.* by the Conservators on that part of the river. How far continued activity of the Conservators is called for, the destructive floods that have devastated this fair valley not so very long ago bear witness. But the income of the Conservators depends on the traffic. The traffic has been strangled by cutting off the through communication, which was formerly afforded by the Oxford, the Coventry, and the Birmingham canals, between the Thames, the Trent, and the Mersey. The control obtained by the London and North-Western Railway over the once rich and active Birmingham Canal, and the purchase of the Ashby-de-la-Zouch Canal by the Midland Railway, have blocked the connexion between these rivers. The income of the two former canals has fallen, in consequence, to about one-fourth of what it was in 1830. The Thames itself is a fellow-sufferer. And of the enormous increase which we lately chronicled of building on the banks of the northern rivers, how much, let us ask, has been driven by the obstruction of the waterway from the valley of the Thames?

The physical advantages which England offers to the manufacturer are, first, her mineral wealth, in which she is not unrivalled; and secondly, the easy maritime access to her numerous ports, in which she is without a competitor,—speaking, of course, of the whole United Kingdom. For inland railway carriage England is, and probably always will be, at a disadvantage as compared with many parts of the Continent. Her railways have cost half as much again to make, and cost considerably more to work than most of the Continental lines. Thus, as far as railway carriage is relied on, the Continent has the advantage. But in so far as we can bring the sea inland, make our rivers and canals free, or carry the imports from our coasts inland at the least expense,—in so far do we strengthen the natural economical defences of the kingdom, and fortify a position which is in some respects unique.

Most unfortunately the railway managers have taken a view of the mode of working their lines which is diametrically opposite to the idea that her maritime facilities are the great stronghold of England. When contesting trade exists between two points also connected by railway, the companies carry between such points at fares calculated to compete with the sea passage, although it is certain that little if any profit can be thus obtained. But where a town is some little way inland, and is dependent on railway communication, then they strain their charges to the utmost legal limit. It may be questioned whether this is really a paying policy for the railways. It is certain that it is a losing policy for the country.

To meet this great difficulty by the purchase, on the part of the State, of from seven to eight hundred millions worth of railway capital, is, we hold, quite out of the question. But there is another step which is within our power, and to which we think that the efforts of reformers might be successfully directed. Eight hundred millions would not be enough to purchase our railways. But twenty millions would be enough to purchase our canals, and, when the key lines are held by railway companies as before indicated, that sum would also provide for the construction of new links of water-way, in lieu of the obstructed lines of junction. The construction of from thirty to forty miles of new canals would at once put in connexion the Thames, the Severn, the Nene, and the Trent. A return to former prosperity would at once commence. So certain is this, that we do not doubt that it will be before long taken in hand. But what we are anxious to see cared for, is not the canal interest (except as a means to an end), but the productive interest. We want to see the canals

not only navigable, but free. The present is the moment at which to take this in hand. If the canal companies, aided as they will be by the Chambers of Commerce through the country, fight the battle high-handed, there will be the spoils of the victory. When dividends rise from 2*½* to 25 per cent., there will be all the stronger disinclination on the part of the canal companies to part with a property of such enhanced value. It is now that the bargain is to be made. It could be made by the assent of the parties interested, instead of, as in the case of the railways, by compulsory purchase. Let a great central committee, with a large guarantee fund, be formed for the purpose of opening our inland navigation free for ever to the public. The success of such a body in removing the obstructions now caused by the railway companies might be delayed, but must be ultimately certain. The Railway Commission, if the recommendations of Mr. Ashley's committee be carried out, will have power to enforce it. There will be the alternative of the new canal lines, if the contest be unduly obstinate. But as a part of the bargain, let the canal owners fix now the price at which they will sell the property. The influx of traffic will be certain to provide the means of purchase, on the behalf of the committee, for the purpose of free navigation. But if the bargain is deferred till the canals are actually open, the nation will have to pay five times as much to obtain the permanent freedom of its water-ways as would now be joyfully accepted by the proprietors of our canals.

The main question between ourselves and those railway managers and advocates who have come forward in defence of the present system, including low mineral freightage, and low rates wherever sea passage competes with railway passage, lies in a nutshell. They say, a little profit is better than none. We say, that entirely depends on what is the preliminary expenditure incurred for the purpose of securing this little profit. Take a line which has cost 26,000*l.* a mile, and which has a gross traffic in passengers and goods of 2,000*l.* per mile per annum. Such was the case of the French railways in 1877. Bring upon that line an extra traffic of 800*l.* per mile, carrying a net sum of only 80*l.* per annum. It cannot be done if it consists of a traffic running at a much slower rate than the existing traffic. The passenger and goods traffic, no doubt, might be increased by 800*l.* per mile per annum, earning 400*l.* per mile net profit, to the manifest advantage of the proprietors. But that is not the question. The question is the introduction of another kind of traffic, conveyed under different conditions, and earning a low return. This can only be done, either by driving off a part of the existing traffic, paying it 50 per cent., or by increasing the accommodation and the capital cost of the line. This latter course we have taken. In 1877 our passenger and mineral earnings were just 2,000*l.* per mile per annum. But we carried besides this 800*l.* of slow mineral traffic. And what was the result? Perhaps,—it is not sure,—we carried 80*l.* per mile net profit more. But it is certain that our railways cost 39,500*l.* a mile instead of 26,000*l.* per mile. That is an indisputable fact. Is there any rational doubt as to its real import?

The growth of railway capital has long been made a subject of complaint and of alarm by many writers. The subject should be looked at with proper discrimination; a growth of capital that brings with it an increased volume of paying traffic, and an increased percentage on the same, as in the case of the French railways, is a growth of both public and private wealth. A growth of capital to the amount of 20 per cent. in cost per mile in nine years, accompanied by a decline in net earning power of capital from 5.56 to 4.67 per cent., which has taken place on the aggregate of seven of the great English trunk lines, is a loss of property, public and private. Any compulsory transfer of railway property would increase the capital (or the annual dividend) by at least 16 per cent., or to 856,000,000*l.* up to the end of 1881. But any operation, involving the transfer of perhaps 20,000,000*l.* of property, that tended to provide England with free inland waterways, would not only allow of the transport of minerals and heavy goods at cost price,—which it is the true profit to secure,—but, by arresting the unprofitable growth of railway capital, would afford the only hope that is conceivable of a future reduction of fares and freights. To open our canals will be to cheapen railway transport,

as well as to provide means of transport with which railways only compete to their own disastrous loss.

#### THE SELECTED DESIGN FOR THE GERMAN IMPERIAL PARLIAMENT HOUSE.

The design of Herr Paul Wallot has been selected by the almost unanimous vote of the jury from among those of 189 competitors, who sent in upwards of 2,000 sheets of drawings. Such is the information as to the result of this great competition which has already been recorded in the *Builder*; there also it has been read that the best German critics agree that in point of originality of character the design of Herr Wallot surpasses all that were placed in competition with it, and that the whole evinced satisfactory national progress since a previous contest in 1872. If the Germans themselves are satisfied, what other nationalities, it may be said, are so far concerned in the matter as to have a right to complain? Perhaps we may reply, most other nationalities, if there is reason for complaint at all. A structure which must needs be imposing by combined magnitude and dignity of purpose in the imperial city of United Germany is an object which will attract the attention and interest of all students and lovers of art, who will always be drawn sooner or later to Berlin by the accumulated treasures of the national museums. It is by no means matter of indifference to such visitors whether a prominent work of architecture which cannot be escaped from is a constant cause of irritation, an offensive obtrusion, or as constant a source of delight. It is a still more serious consideration whether the success in competition of a faulty design may not blind to its demerits in too many cases, and misdirect emulation in other instances, even when it does not vitiate taste. We cannot conceal from ourselves that the authority of success has an influence which is constantly independent of any particularly cautious appreciation or analysis of its conditions. It marks the direction of fashion, at least, if not of good taste; and if good taste will ever survive in the long run, the shorter period of an individual career may seem more prudentially adjusted to the shorter career of even whims of which the vogue will last its time. The services of Germany to science, to learning, to at least the archæology of the arts, have been so pre-empted that it becomes a duty to be jealously watchful lest a not very unnatural assumption of consequent superiority in the practice of the arts should be admitted with the tameness which, we believe, has ascribed too liberal a value to German criticism, not only in the arts, but in literature, ancient and modern.

These observations will not read like an introduction to a very highly-pitched note of appreciation of the design which is at present in question; nor are they meant to be such. Sooth to say, with every desire to welcome a great achievement,—“Trojan or Tyrian,”—with an earnest anxiety, indeed, for an opportunity to greet with disinterested applause the successful improvement of still one more of the great national opportunities that within a generation can scarcely count up beyond the place of units, this accepted design for a structure which should be the symbol of some of the mightiest aspirations,—of the progressive achievements of our time,—seems (must the word be said?) unsatisfactory in the last degree; crude and commonplace when it does not deviate into originality to become hopelessly incongruous.

It is, perhaps, right that it should be understood that the present enunciation is purely from the point of view of the architectural critic,—of the devotee of admirable architecture,—so far, at least, a representative of the most numerous class whom architecture concerns. As regards the distribution and assignment of apartments on the chief floor for particular purposes, various apparent anomalies have already received notice; some of these may have their justification in peculiar national habits, and others are open to easy correction, and may be expected to receive it. The separation of reading and writing rooms from the library at the greatest distance possible from each other, appears strange; and scarcely less so the remoteness of the *restaurant* from the hall of session and cloak-rooms for the sake of interpolation between the two most spacious

committee-rooms. Its position also as ranging with the Hall of Session, Ceremonial Hall, grand staircase, and state entrance upon the transverse axis of the plan, and occupying the very centre of the chief front on the principal floor, is a little suggestive of bathos. Full allowance, however, must doubtless be made for the conditions imposed by the form and limitation of the area at command, and criticism must be content to attach to particulars in respect to which the architect could exercise unshackled judgment and taste.

We are scarcely in the position to form a definite opinion respecting what should naturally be the principal aspect of the building from comparison of the plan with the elevation from the point of view provided. The western front, which is not shown, should be the true façade, though the eastern, of like magnificent extent, has also a claim to be treated with special if subordinate dignity. Central on the west, and facing the site of the future Imperial palace, is the entrance of state, which admits to the grand staircase, and thence on the transverse axis of the building to the Hall of Ceremony and galleries of the Hall of Session. The predominant importance of this axis is manifestly emphasised by the cupola over the Sessions Hall, and then by two other ornamental erections surmounted by colossal sculpture, the least and lowest being central. It is very difficult to understand how these could tell effectually, even at an oblique view from the front,—how they could compose harmoniously with each other, and then with the violently contrasted square towers at the angles. In what manner appropriate dignity is given to the main entrance, opposite to the palace, and blended with exceptional treatment of the windows which light the restaurant above it, is not to be deduced from the materials before us.

As regards the general design, a degree of solidity is given to it by the continuous lines of the basement, only broken by the interruption of carriage-entrances, and this expression is strengthened by the continuous bands between the two lower stories and the channelled masonry of both. But we must demur most strongly to the meanness of the square windows of the ground-floor, which seem utterly inadequate to light the wide intervals between them, and to be not only confined but crushed. They give offence, or, rather, perhaps, challenge pity in the curtain between the towers; but what shall be said of the suggestion of cellar-like obscurity within, which is intimated by the single opening of these distressing proportions in the full breadth of the angle towers, which are indulged above with exaggerated provision for illumination?

The long eastern front of the building has a projecting centre equal to half its entire length; it is marked sufficiently as not being the true or principal façade by the absence of a central gateway or entrance, in which respect, indeed, it is marked, intentionally or not, as subordinated to the composition of the two ends. In perfect consistency with the internal arrangements two large and co-ordinate portals indicate provision for admission of the outer world in two distinct streams to communicate with diverse classes of the necessarily multifarious offices. We are therefore plainly at the back of the building, and only at the back could the dead flank walls of a projecting centre be otherwise than repugnant to our sensibilities. And yet does this projecting centre receive such exceptional treatment as to imply an anxiety and an endeavour to mark it with distinguished emphasis. The line of general cornice of the building is broken for once to introduce columns flanking a large window opening, rising as high as its corona, and sustaining an independent entablature and thereon a pediment. This feature,—a pedimental form,—unknown on other sides of the building, is introduced again over the window below, and also over each of the side portals. Variety, at least, is proffered to us by segmental pediments attached to the quasi-cupola above, which comes most closely into composition with this front. Finally, at each angle of the plan of this cupola rise piers of channelled masonry, which certainly claim kindred in distribution with the great angle towers, but they are surmounted by pinnacles or pyramids or obelisks, which neither in function nor outline manifest analogy to any other feature whatever in the entire building.

The general cornice which, but for one surprising interruption, seems to run entirely round the building, does its very best, and

certainly contributes importantly to promote a semblance of true structural coherence, but not without provocation of a protest. It shows consistent relation to the lofty windows of the towers and intermediate centres as expressing a well-proportioned height of the apartments so liberally lighted; but as it is continued it throws us upon a perplexing doubt as to what can be the interior application of the dead interval above the smaller windows which far more than equals them in height. Does it really represent the height given to the rooms between top of window and ceiling? If so, they will be of very anomalous proportions indeed. If this incongruity is avoided, how else is the space disposed of? Let it be disposed of as usefully and ingeniously as it may, the offence to the spectator from without remains the same; the design fails to explain itself to him lucidly and satisfactorily. This is an aggravation of a general failure in harmony of composition or something more,—of a violent breach of that well-ordered gradation which is as essential to dignity as to grace,—most of all indispensable when, as in the present case, the requirement is for dignity to assert itself under the conditions of gracefulness and sympathetic combination.

Free columns will always dominate pilasters with which they range, but surely they might be more bappily introduced than as we see them on either side of the large windows of the angle towers, raised upon advanced rustic piers, then mounted on pedestals and surmounted by a segment of entablature, and owing an excuse for their existence after all to a statue at top, some 70 ft. above the eye.

The side fronts of the building, so to call them, on its longer axis, are treated so similarly, and in themselves so symmetrically, as to present themselves as proper fronts composed of centre and uniform wings; they give, in consequence, no intimation whether the true front of the great structure is to be sought to the right of the spectator or the left, or whether, indeed, the true front may not be already before him.

The wide and lofty windows of the towers at the angles range and correspond in proportions with those of the central division of the intermediate curtain over the gateway, an agreement which inevitably suggests a certain correlation,—but a suggestion that is as immediately banished. The quoins and channelled courses of the towers which are continued from the basement to the general cornice give an appearance of a solidity which is not greater than demanded by the extraordinary superstructure, but which oppresses and threatens to reduce to triviality the intermediate screen,—the central compartment included.

The four smaller windows on either side of this are in such sudden contrast in respect of size, that, whatever their sufficient absolute dimensions, they seem only worthy to light passages of communication between such apartments as the three great windows imply,—apartments which, it must be said, even so present an appearance of unsocial isolation. When we refer to the plan of the chief story, we find that the two small windows to right and left of the centre do, in fact, belong to the apartment which is lighted by the large window, and the suppression of any intimation of that fact on the exterior seems gratuitous sacrifice of an opportunity for expressive composition. On the north front three of the four windows on either side combine with the large central window to light the library, but apparently their treatment is the same as on the south.

It cannot be said that the range of smaller windows possesses any dignity that would be materially affected by reduction of multitude. Each series of four has an allowance of only three pilasters, with the result that a terminal window at either end seems crowded into its corner against the angle of a returned wall to the great impediment,—real or apparent, it matters little,—of its function of illumination. The omission of a pilaster also in this position,—the open avowal that it may be dispensed with,—conveys an imputation on the member of worthlessness, if we should not say, is a simple confession of fictitiousness in its employment throughout. It is but rarely, indeed, that the pilaster is employed, or capable of being employed, externally with true artistic effect, and of all its forms the pilaster on a pedestal is surely the most obnoxious. A pedestal so employed is the high-heeled shoe of architecture; as derived from the most unlucky innova-

tions of the Roman architects, it pairs off with their broken architraves, which we shall meet with here also before we have gone far. An isolated pedestal has inevitably the appearance of coming to the assistance of a short column that would have done without it if it could. It is interesting to observe in the churches at Cologne, and on the Rhine generally, how the better taste of the Romanesque architects dealt with these sophistications before handing them on for still further modification by the masters of proper Gothic. It is not difficult to trace, by comparison of examples, how a set of mouldings which seem to constitute a superabacus are, in fact, the remnants of the all but suppressed segment of the Roman entablature. The pedestal is less drastically dealt with, but no less effectively; it is unceremoniously shorn of its cornice, and instead of being admitted as a contrivance to eke out or lift up a column, it is made part of it,—is taken into its proportions and finished with base mouldings, which happily repeat those of the proper base on another scale. The transformed pedestal is thus, as the evolutionists would say, *differentiated* to constitute a fully-developed base, which is peculiarly effective as the dignified support of a cluster of columns or a compound pier.

So little, then, does this design appear to us to be worthy of a noble,—it may be said a secular,—opportunity, that we should be unwilling to accept it as the best that the contemporary German architect is capable of; we would willingly ascribe its selection rather to a previous error in the selection of a committee of judges. Opinions with which we have nothing to do here are at variance as to the position and the promise of the constitutional system of which a German Imperial Parliament house is a natural symbol,—whether it is already in the vigour of youth or scarcely beyond the precarious stage of a hopeful but still imperilled germ. But there can be no difference of opinion as to the momentous historical importance of the events which have culminated in the requirement, to whatever ultimate end, of a seat of concentrated legislation for Germany. It is not, however, as a monumental reminder of the proceedings and sacrifices and achievements by which the union of Germany was brought about that their Parliament House will ever appeal to Germans; far more reverentially will it be regarded as the sacred hearth of those aspirations and energies which realise, by due adjustment of self-assertion and self-control, "the act of order in a peopled kingdom." It is, no doubt, much to demand of an architect that in his conceptions for a work prescribed he should not merely bear in mind the past and present, but even anticipate history, and so provide a structure which shall appear to future generations to have been designed under a consciousness of the diversity yet consistency, the detail yet comprehensiveness, the intellectual vigour, and the moral dignity of the work that was to be carried on to happy completion within it; and yet it is possible in architecture, as in other arts, for "old experience to attain to something like prophetic vein." Reluctantly, we must confess that our hope for the harmonious consolidation of Germany by Parliamentary action would be but weak if the design before us is to be accepted in any degree as a worthy symbolical embodiment of the self-consistent energy and harmony to be expected from it.

**The Lime Process of Getting Coal.**—At a monthly meeting of the South Staffordshire Institute of mining Engineers, held at Dudley, on the 5th inst., Mr. W. Farnworth, who presided, explained that the Council of the Institute had been that day to Canock Chase and witnessed some experiments with the new lime process of getting coal. Mr. Sopwith, of the Canock Chase Colliery, said the man in the employ of the patentee had been down the pit, and had offered to them the shallow seam to experiment upon. They chose a fair specimen, and, without going into details, he might say that after the lime cartridges had been put in, and the expansion had taken place, some 40 or 50 tons had come down in a solid block. So far as he was able then to say, the trials had been as successful as could be desired. The cost of drilling, &c., would have to be carefully worked out in reference to gunpowder. The coal came down so quietly that the only slack to be made would be that in breaking up the coal for the tubs.

### FURTHER MUSINGS ON THE MERITS OF SOME STYLES OF ARCHITECTURE.

FINDING it impracticable within the limits of one evening to say at the recent meeting of the Architectural Association all that was wished on the above subject, and baving in consequence left out some matter which I had written and intended to then bring forward, I have been tempted to supply the following additional observations in your journal.\*

Before proceeding with the consideration of any individual style; let me say a few words generally. Mediæval architecture has such a wonderful versatility, that it is difficult to trace to the end the many ramifications into which the several European styles spread in the Middle Ages. To instance only one of its leading features,—groining, the outcome of the parent,—the plain, ribless, quadripartite Roman vault, a form of construction which was carried on into the Anglo-Norman,—this alone is remarkable to contemplate. The children of its maturity may be called the ribbed quadripartite and sex-partite vaults, and, ultimately, the intricate hermes of the Late Decorated period, culminating (as far as mere elaboration went) in the magnificent fan-vaulting of Henry VII. In the South of France the early barrel and domical vaulting, though thoroughly harmonising with the architectural surroundings, lacked the finish of the late developments.

In Italian architecture there is much variety in the surface of the vaulting, whether in relief or colour, as, for example, in the celebrated stanze of Raffaele in the Loggia of the Vatican. But, short of the domical and barrel forms, there is not much else to choose from.

Turning to the Gothic treatment of vaulting, there is the indescribable charm of the play of light and shadow, caused by the various sharply-expressed angles of the groining. The style can be most legitimately treated with such freedom as to suit every want, and to adapt itself to circumstances. In another feature the mutability of Mediæval architecture is found,—in wall arcades, sometimes one behind another, sometimes trefoil-cusped, sometimes cinquefoiled-cusped, or in other examples with plain well-moulded arches, or in arches of ornamentally-erived forms, practically in one order, but not cusped, as at Durham, Wells, &c.

Or, again, in a window, doorway, a capping to a tower, or a wall diaper, observe the large number of changes each of these features undergoes. It is not only a variation in surface ornament, or a little alteration in the mouldings, but is equally shown in outline, form, and construction.

Mere caprice or eccentricity I except. The Mediæval men were too faithful to the true principles underlying all that wondrous manipulation of the vernacular architecture, as I may truly call it, to often diverge into such paths. And this versatility extends through those great English Mediæval styles which may broadly be called the Early English, Decorated, and Perpendicular, though the latter of these three has more sameness than the architecture of the two earlier periods.

In the timber roofs is another great charm of the Gothic era; first, the rafter-tie-beam construction, then the trussed rafters, the king-post, the magnificent hammer-beam treatment, or the moulded and cambered tie-beams with rich perforated panelling over, or the cradle ceilings of Somerset and Devon. I cannot but just mention a few other details in which a like beautiful variety exists: the fonts and pulpits, for example, particularly noticeable in the former, of which so many interesting specimens have fortunately been handed down to us, after having been the appointed means of inducing so many babes into the Christian fold; or in the tabernacle work of shrines, tombs, and niches; in canopies to stalls; in the plan of piers; in that beautiful Gothic feature, the flying buttress, with its useful as well as elegant pinnacles; the carved spurs in Norman and Transitional bases; the crocket and finial exquisitely carved; the gable crosses, the barge-boards, the pierced parapets of many a different design, the corbel tables, the brick moulded chimneyshafts. All these features present to us many beautiful changes, but yet do not represent a tithe of the wealth of resource in Mediæval work.

In the smaller, though none the less important, details, such as, in churches, the sedilia, the ambray, the credence, the piscina, it is rare

to see one like another. In our modern work, probably owing to less time being bestowed on it, there is much more sameness.

Although, as that sagacious authority, Mrs. Malaprop, has remarked, "Comparisons are odorous," I cannot resist jotting down some few notes on the idiosyncrasies of Classic architecture. I have not yet mentioned window tracery in the foregoing remarks on Mediæval architecture, undoubtedly one of the finest characteristics of its best period, where the Italian style is notoriously at a disadvantage. But, of course, in the Veneto-Italian style, to be presently noticed, some of the palaces exhibit the yearning after this lovely feature, which, however, never developed further than the simple principle of two semicircular-headed lights under a semicircular arched window carrying a circle. The Piccadilly front of the Museum of Economic Geology is a good example of this; in fact, the whole building is an illustration of chaste Veneto-Italian design, severe possibly to a fault, but how superior to much of the bastard stuff foisted on the public (who, I fear, like it only too well) nowadays as "Free Classic," of which the reputed mother, which produced a Michelangelo, a Palladio, a Scamozzi, would have felt ashamed!

There is an elegant feature in Italian architecture, if skilfully treated,—the Venetian window. But supposing the same idea were attempted to be carried out in a Gothic moulded window, the effect could scarcely be satisfactory,—that is to say, in Domestic work. In fact, I hardly remember a Mediæval example where the cornice light is wider than the others, though in ecclesiastical architecture, in the case of traceried windows, it is not so unusual, and is sometimes of advantage for the working in of the tracery design of the head.

In the more severe phases of Italian work there is not much variety in the balustrades. There seem to be about three species:—(1), the ordinary bulbous form; (2), the double-bellied baluster; (3), the baluster square on plan, though bulbous in elevation. But in Renaissance work a little more play of fancy in this particular respect is found. There are miniature pilasters in the place of balusters, or geometrical devices consisting of circles, lozenges, frets, &c.; but, like window tracery, the mutations are very limited as compared with those of the great Gothic field. The rustication of the basement or lower stories of a building is one of those details of Classic architecture for which we search in vain among Mediæval examples,—it does not seem to exist, the parallel is wanting. The courses of masonry may be deeper, the surface less finished, the reveals of windows and doorways more profound, the openings narrower and smaller, the mouldings plainer,—in a word, the whole construction more massive. But in other respects the distinction of treatment between the lower and upper portions is not so great.

There is one detail in the later developments of Italian architecture in which it is difficult to see any force or any object,—far less beauty. I mean the box-like blocks of stone, sometimes vermiculated, "hung," so to speak, round detached columns. To a man who reverences Mediæval architecture the notion is given of the work being half done and left unfinished, or as if a square block, called in the euphemistic language of Chambers "a rustic cincture," had had a round hole cut in it, and the attempt made to slide it over the cylinder, but with so little effect that it stuck half way. How it ever can have been considered a recognised and legitimate feature in the style seems a puzzle. The Gothic zone or band has, in this respect, a great superiority. In Italian and Gothic architecture it is remarkable how very different in proportion are the columns. In the more severe Italian their height is "cut and dried," and it is only in the Renaissance and Elizabethan times that less rigorous came to be observed. Consequently, bands or zones were never actually required, though sometimes added, and then the length of the column beneath them fluted, or decorated with sculpture. But it is not my intention to traverse the whole ground of Classic detail, and I must briefly conclude this branch of the subject. There is a certain coldness and staidness in Italian architecture which seems naturally to appertain to its symmetrical order of things. Whereas Mediæval work is warmer, less formal, on account of its not infrequent irregularity, though when occasion demands it, it can, as we know, don very stately robes, and be a match to its severe elder sister. Mediæval

architecture is home-like, as may be well illustrated by studying the effect of a labourer's cottage carried out in this style. In Italian architecture it is difficult to conceive any building less humble than the entrance-ledge to some gentleman's park.

The many beauties of the Italian-Gothic style have been ably treated of in the "Brick and Marble Architecture of North Italy," as well as in Ruskin's well-known works. Yet, happily there still remains much that might be said about that style. Among its conspicuous merits I may certainly instance the natural treatment of terra-cotta and brickwork; the extensive use of various beautiful native marbles in decorative features; and last, not least, the glorious enrichments in mosaic and fresco. The employment of alternate bands of warm-tinted stone and brick, and a like treatment continued in arch voussoirs, gives much variety of tone and colour to Italian-Gothic work, having a special charm to the traveller from a less sunny land. So, when the passion for this style was raging a few years back, this characteristic of North Italy was translated, only too frequently with but indifferent success. For the colours of the two materials ought, to a great extent, to be assimilated and so brought into harmony, and thus prevent a "bizarre" look. In these Mediæval examples, too, the gentle hand of Time has done much to bring into tone the diverse tints, not only in Italy but in many other countries. If a clumsy yellowish-looking stone is used, with a good deep red brick (not bright red), the effect is good and harmonious. The contrast must not be only in one place, but spread over a large area, so as to give "breadth of effect" and avoid "spottiness." It is unfortunate the English language does not contain better words to express what is meant in this respect, so I have no resource but to explain myself by the usual cant phraseology.

The same principle prevailed in Italy as existed in our Late Perpendicular period, where large surfaces are monotonously, whilst ornamentally, panelled. Yet this great repetition of panelling actually looked less fussy than in other buildings, where there was abundance of plain wall surface, but no judicious manner of utilising it. While on the subject of panelling as a means to sometimes break up and greatly enrich a plain surface of wall (a thing often desirable, as at the east end of a church), I would instance, as very suggestive, the effective treatment that exists in the apse of the Duomo, and also at San Fermo, Verona. In this case diaper-work would have been too rich, and the long narrow pilasters of shallow projection which occur are scarcely further apart than the width of each pilaster. These support semicircular arches, but it is almost needless to say that the pointed arch is as equally applicable as the round for such features. There is a beautiful object in North Italian Gothic work which does not exist in old English architecture, the stone balcony supported on boldly-moulded corbels or cantilevers. The balcony exists in many modern Gothic examples, as in the new buildings, Christchurch, Oxford, the style of which, however, is decidedly very suggestive of Italian Gothic. It is difficult to understand why, in Mediæval times, the balcony was not adopted. Though our climate is unfavourable for sitting or standing out of doors for any length of time, there are yet days when it would be a pleasure to thus make use of a balcony, especially to those who like a whiff of the fragrant weed. At any rate, flowers or shrubs, with an æsthetic blue pot or two, could be put here with excellent effect, both pictorially and architecturally. When the sun shines an agreeable shadow would be cast, giving a sparkle and crispness of effect to the elevation or façade, preventing any appearance of tannous or flatness. It is easy to guard against undue shadow to the windows beneath by making them rather larger, or, perhaps, by obtaining a greater amount of light in other walls. Such an adjunct suggested by North Italian architecture could be very suitably made use of without any misgivings.

The Certosa, near Pavia, is one of those buildings which an architectural purist might, in cold blood, condemn, if he only judged of it from illustrations. But let him see the wonderful façade and general ensemble under a deep blue Italian sky, with all the beautiful variety of different coloured marbles, delicate arabesques, and decorative sculpture.\* What, then,

\* See vol. xlii., pp. 610 and 659.

\* See view published in the *Builder*, p. 208, ante.

becomes of his strictures? Judging from my own experience, I can speak feelingly, and opine that one's condemnation is very prone to vanish! Nevertheless, it cannot be denied that a cardinal rule of true composition has been transgressed in the principal façade, where the lower stages are more ornamental than the upper. The Englishman, accustomed to the greater ruggedness of our Northern architecture, and finding the surroundings of the Southern clime so different, is very apt to treat as a matter of course this and other divergences from the rules laid down as proper in architecture, forgetting that such axioms are equally applicable in every country, and that it is dangerous to give way to licence. History is said to repeat itself, and one of the worst blemishes in Italian Gothic is continually now being introduced in another very different but, alas! debased style, the so-called "Queen Anne." I allude to the way in which architectural features, whether structural or ornamental, are stuck on to a building, instead of being bonded into it. Late Perpendicular work was bad enough in this respect, as can sometimes be seen even in counties like Somerset, where splendid building stone was to be had almost at the door. But in those localities where freestone was scarce, there is, but too often, hardly any bond at all, and a width of only 2 in. or 3 in. at most between the termination of the mouldings and the end of the face of the stone. In the Perpendicular period, however, the further enormity, now so common in the "Free Classic" style, of projecting architraves and other members attached to a building just like joiner's work, was rarely perpetrated.

The use of coupled shafts is not peculiar to North Italy, but is, perhaps, a more characteristic feature there than in any other country. There are two modes in which they are arranged, *i.e.*, either side by side, their axis parallel with the face of the wall; or with the axis at right angles with the thickness of the wall. The west façade of San Zenone, Verona, contains, in the curious "wheel-of-fortune" window, a good specimen of the first named treatment. It appears to me that in those instances where a substantial wall is desired, and the walls, perhaps, are thin, owing to want of funds, the former treatment answers well, and takes away any semblance of poverty-stricken architecture.

In the interesting Church of Santa Eufemia, Pavia, there is a pretty though not very common feature, that of the shafts set at the angles of the octagon turret or tower, which in effect help to carry the corbel course, thus pleasingly and most appropriately connecting it with the sub-structure. The shafts in this instance project, the rest of the panels, as at San Gottardo, Milan. In the latter instance, however, column rests on column, but there are corbels between the upper range. The columns in the second range (counting from the top) rest on a set-off. The angle shafts are detached, but need not necessarily have been so.

Another very characteristic North Italian, as well as German Romanesque, feature is, of course, the arcade following the rake of the gable. In Milan and its neighbourhood, it is a feature of the tile-covered spires to be elongated cones, or circular in plan. From a practical point of view, this has the advantage of having no angles, or weak points for rain to get in; but, on the other hand, the octagonal spire, or the square-planned pyramidal capping, has much more vigour, and certainly better suits our climate. How fortunate that during the rage for Italian Gothic architecture, no enthusiast ever thought of transporting this to our country!

There is a peculiar detail in this same style of architecture which also, curiously enough, exists in another very different country,—Ireland,—the return of the jamb mouldings round the window-cill: an irresistible reminder, as it appears to me, of an Italian (Classic) door or window panel. For many reasons it is advantageous to have a deeply-splayed, or at least a flat-weathered, cill, to throw off the wet, something which shall not harbour dust, or water to be frozen up,—something firm and substantial, on which the jamb mouldings can plant themselves. There is yet another advantage in the plain splay—the pretty way in which the mouldings die into it, and elongate their sections—a feature which is also effective in jambs where the arch-mould stops on it in what is termed a "discontinuous" manner.

In concluding this short review of this particular style, I must not forget to mention the remarkable intarsia woodwork of the latter part of the fifteenth century, which is of great beauty. There really seems no reason why such a species of ornamentation should not be more used in England, as has been essayed with much success by the late Mr. Burges in Worcester College Chapel, Oxford. But great care must be taken not to introduce this parti-coloured ornamentation into a building where the walls are left uncoloured, the roof or ceiling undecorated. In such cases the inlaid woods would appear out of place, out of harmony and tone with the surroundings. I believe that the variety of different colours in Tunbridge ware is from the tints of various naturally-coloured woods found in that neighbourhood. Owing, however, to their generally being squares, the effect has neither the variety of mosaic tesserae, with their irregular cubes and thick joints of cement, nor that of the intarsia work of North Italy, where the inlay is in all varieties of curved, straight, or other forms, and of every size.

Since the use of distemper, mosaic, or tiles has become so usual in England, while the ceilings are coloured by artistic hands, and while Roman mosaic or handsome encaustic tile pavements cover floors, why should we be content with only oak or walnut fittings,—I speak more particularly of churches?

By no means let the characteristic features of well-moulded bench-ends, &c. be abandoned. Let them remain so, with the addition of employing different coloured woods, or inlay, as the case may be. Such examples exist among us, but might, I venture to think, become more common.

The last style which I propose to treat of may be said to be almost the mother of Gothic architecture. In the East, where the sun rises, and where true believers consider the very earliest historical memories spring, from near the garden of Eden, from the East, appears to have sprung the germ of that grand style which, apparently founding itself on Classic models, stayed not there, but went to an earlier source, and with such nurture produced the magnificent and never-to-be-eclipsed works of the Middle Ages.

Fergusson\* has drawn attention to the remarkable Gothic feeling of some of the work in Hindostan, which he attributes to the fact of the natives, some time after the Mahometan conquest, imitating the architecture of their conquerors. Few architects, however, have been able to travel there and investigate the matter for themselves, and their judgment has probably been formed by having seen some of the fine photographs published by the Government, or by other illustrations. There is, however, a very good substitute for a journey to India, and that is a journey to South Kensington, to the India Museum. The magnificent and extensive collection there is apparently not so much frequented as its very interesting contents deserve. At present the interior rather deters people from going in; and when one enters at the so-called principal entrance, such a series of tortuous passages, some almost underground, and so many twists-about, make a visit to the collection a tiring one, as the objects to be looked at are so far away to reach. No doubt, in time, when some grand building springs up to shelter it, the public will find out the Museum more easily. Casts, though not giving the time-worn colour and texture of the original details, have yet the merit of affording an absolutely faithful reproduction of the contour of the actual work. A drawing may not be truthful; a photograph, owing to the particular light or focus in which the view was taken, may not exactly give a right impression; and in either a photograph or drawing, *scale*, with the exact relief, cannot be represented. Casts have none of these disadvantages, and both in the Architectural Court at the South Kensington Museum and at the India Museum they exhibit exact copies of some of the largest details. The "bracket" capital, which is considered to be of a very early period, far before the development of the generally-recognised capital, is a great feature in Hindoo archi-

\* I shall have occasion more than once to refer to this great authority on Hindoo art, but will just premise that what I write was not suggested by Fergusson's work, but is merely the opinion of one who has not made this style a study. So I can only pretend to lightly skim over its surface. Indian architecture is certainly distinct and widely different from other styles.

ture. There are some good specimens of it in this Museum. A large part of the ornamentation is barbarous and overlaid, with scarcely an inch of plain flat surface, so that much is frittered away in crowded detail, giving the third eye no rest. A characteristic specimen of this kind of thing exists in the magnificent entrance archway to the great gate at Sanahi. There is no attempt, apparently, at any real architectural composition, but only an array of superimposed detail, in which, by-the-bye, the relatives of Jumbo figure very largely in all kinds of attitudes, the elephant being in the East one of the most important animals for many purposes, whether for regal state or other uses. On the other hand, as has been not infrequently remarked, how much exquisite refinement and delicacy is found in this Indian architecture and sculpture! The ornamentation of the Runic, the Romanesque, and the Norman is fore-shadowed when we examine some specimens from the Ambarath Temple, for example. Of the latter type there are some very beautiful examples in the temples at Bhuvanavara (commencing with the seventh century A.D.) of ornament designed in a serpentine manner, teeming with animals and birds. In fact, in these temples there is much most worthy of attention, if one can form an opinion from these excellent casts. In the ruined city of Saitu is some foliated ornament (of about A.D. 1100) which is quite Renaissance in character, while some of its detail more resembles Flamboyant work. In specimens of Hindoo architecture of the tenth century, the characteristic ornament of our English Decorated style, the four-leaved flower, occurs most unmistakably; and in examples of the eighth century, the Tudor rose, four-leaved or petalled, has been anticipated. One wonders how it came to pass that, while the ornamentation is frequently barbarous and rude, there is never any vulgarity. I suppose the best reply is that the Oriental imagination had an innate spirit of greater refinement in architecture or art than that of the inhabitants of Europe. The female figure, always draped, is very frequent in these Indian sculptures, posed in attitudes which are apparently meant to be very attractive.

At the ruined city of Saitou Rajpootana is a freely-treated example of an ornamental arch, sept-foil cusped, of about 1100 A.D. Fergusson, I may say, remarks on the trefoil arch in Hindostan, and appears to think it is indigenous, not copied from elsewhere. There are also some casts from the Ambarath Temple, Bombay, which are extremely Mediaeval-looking,—a patera or boss, for example. In the architecture of Cashmere there is a strong Greek feeling, so that we seem to find characteristics of many styles in India. The magnificent temples and tombs of Indian potentates are proverbially famous. As happens in hot climates, where water is so grateful and precious, much attention was paid to conduits, wells, and baths. There is an extraordinary model in the India Museum, to a large scale, of the grand staircase, or rather series of flights of steps, leading down to a well, which is quite a magnificent architectural feature, most unlike anything existing in Europe. In pavements, the encaustic and glazed tiles are, in texture and general appearance, much like Mediaeval ones, though in the general tone of colour green is more predominant, rather than red and buff.\*

B. EDMUND FERRY.

#### PROGRESS OF THE MINOR ARTS IN ENGLAND.

WRITING upon the subject of the progress of the so-called minor arts in England of late years, Herr Zimmermann, a German critic, gives, upon the whole, a very favourable report. He is more particularly struck with the changes that have been taking place in the style of fitting up of the ordinary sitting-rooms of English dwelling-houses. It is, he says, an undeniable fact that, within the past fifteen to twenty years, a lively interest has been awakened in this country in all the arts contributing to the adornment of our living-rooms. Upon this subject many books and treatises have been written, many lectures have been delivered, and numerous models published to the world within that period. The rooms of English dwelling-houses, almost without exception, show a total change, and on the whole it cannot be denied that their interior has been

\* To be concluded.

considerably improved. Not so very long ago there was no room left for free choice in the character of our internal fittings and ornamentation, but now it is quite within our power to indulge our personal tastes, to carry out new practical ideas, and to gratify our desire for variety. The walls of our rooms are no longer, as formerly, pasted over their entire surface with one and the same pattern of paper. Who does not remember the unpleasant effect that used constantly to be produced by the repetition of the same glaring or tasteless wall-paper perpetually forcing itself upon the eye,—a pattern which had been known ever since paperhangings had come into existence, and which had to be endured from the difficulty of obtaining anything better? This, which was formerly a necessary evil, is so no longer. In England we have at length arrived at the conviction that wall-paper ought to be regarded simply as background. Hence we have softened its tones; we have made the figures upon it less distinct and less prominent, and we avoid the mistake of making the colours of the ground and of the figures different or inharmonious. Patterns with a white ground have almost disappeared, and dark-toned blue and green are more and more coming into vogue. But this is not all. A new arrangement is now made with the surfaces of walls—they are divided into two divisions horizontally, and the lower portion is decorated differently from the upper. The original idea in this division appears to be that of the old panel,—that is, a protective covering for the lower parts of the wall by wood or some other material not easily injured,—and such, in fact, is the object the new arrangement is calculated to attain. For this purpose, matting of various patterns and colours, consisting of plaited straw or cocoa-nut fibre, is very popular. Another frequent material is pressed leather and various imitations of it. If these imitations only prove durable, they may be regarded as perfectly adapted to their purpose. If they turn out to be, not simply in appearance, but also in wear and quality, at all comparable to leather, they will be sure to gain ground. This material, which is a kind of oil-cloth, avoids the ordinary defects of oil-cloth, and is not covered with mosaic or carpet-like patterns of figures. It is produced in simple colours, quiet and pleasing to the eye, and deserves to be more generally used. However, with regard to the lower portion of room walls, it is commonly the fashion, although many artistic authorities place their veto upon the practice, to cover it only with paper of a pattern different from that on the upper half. It is still a matter of dispute whether such an imitation of a panel or dado in a dark tint does not offer a practical advantage, and whether, apart from this consideration, it is not artistically defensible on the ground that it serves to break the monotony of a large surface of wall. With regard to walls of small dimensions, however, it cannot be disputed that they would be better without any such break or division. Unfortunately, the builders and decorators of small houses are precisely those who are most inclined to a slavish imitation of the prevailing fashions, and so the panel-like divided walls are seen almost everywhere in small rooms.

With respect to the woodwork in the interior of houses, a considerable improvement is to be reported. Instead, as formerly, of endeavouring to impart to it a painfully-elaborated similarity to some more valuable kind of wood, woodwork is now either painted so as to harmonise with the wall-paper, or it is simply stained and varnished. The mouldings and surroundings of the fireplace are now almost always in wood, and in many houses are also painted or stained. The fashion of staining wood instead of painting it is gradually leading to the adoption of better kinds of wood, while formerly deal was exclusively used. The beauty of the natural grain of different kinds of timber is being more and more recognised. It is certainly a sign of progress that the practice is of the decrease of painting one kind of wood so as to resemble another, of making mortar look like marble and oil-cloth like mosaic work. Still the change is only going on so gradually that the observer, when he sees the odious old patterns constantly turning up again, often feels tempted to believe that their supposed decrease is only imaginary.

The custom of covering floors with fixed carpets, which was formerly universal in England, is now no longer invariable. The innovation, to which an exaggerated importance is attributed

by the writer, as contributing to health and cleanliness, has, of course, necessitated greater attention being paid to the quality and appearance of the wood of floors. Carpets are now being employed of designs adapted to the apartment, and the English eye is becoming accustomed to the patterns prevailing in Oriental carpets. This improvement in taste is also producing its effect in the carpet factories of the country, and the harsh and glaring contrasts which once prevailed are giving way to more harmonious patterns and more appropriate combinations of colour. Although, as part of the wooden flooring is now allowed to be visible, more attention is paid to the timber employed, yet oaken and inlaid floorings are still rare. The ordinary deal planks, of course, look poor, and they are accordingly being stained, and inlaid work is being introduced, of elegant and durable workmanship.

The changes which have of late taken place with regard to fireplaces and mantelpieces are even greater than those in the floors and walls. Low square grates, a covering of glazed tiles, and a low simple fender, are now used in place of the old high round grates, with black or black-leaded sides and high fenders. The glazed tiles are in every way to be recommended. They are, or might be, pretty. They are easily cleansed, and they throw the heat back into the room. Like everything made by the hand of man, however, this form of decoration can easily be made ugly. Not a few of the so-called artistic tiles used in new houses might serve as examples of what ought to be avoided in this department. The low and simple fender is worthy of all praise, whether it consists of brasswork or of a stone border. The reintroduction of wood as the material for the chimney-piece has produced a sort of revolution in large houses. Artistic decorations, often models of the fifteenth and sixteenth centuries, are everywhere to be seen, and they are often of such dimensions as to reach many feet above the chimney-piece itself. Of course, the value of these productions is very various. Very recently they have begun to be overloaded with ornamentation, a fact that is not altogether satisfactory.

In the case of curtains and blinds, the same change of taste is making itself felt as we find in the carpets and paperhangings. The figures are less prominent, the tones of the colours are less glaring or definite. Pale green or brownish nuances have taken the place of white. This replacing of the glaring white by other and softer tones in the new fabrics is a characteristic mark of the change of taste in the decoration of rooms. The furniture in the English living-rooms that have been thus revolutionised likewise exhibits a different character. What is most noticeable in it is its greater simplicity, a larger variety, and a departure from the rigid symmetry of former days. The heavy table that used to occupy the middle of the room was first pushed to the side, and finally got rid of altogether. The return to old forms, and a suddenly awakened interest in the products of Japanese art, have resulted in producing an immense multiplicity in the forms of chairs and tables. Wooden chairs are now straight and square. Arm-chairs, or easy-chairs, are now formed of every conceivable shape. Basket work is increasingly patronised, and *chaises longues* and small work-tables and tea-tables are becoming more numerous. Instead of the unavoidable old chimney, elegant hookcases and cupboards are now to be found. In their chief lines they are mostly simple, but if, as frequently happens, they are imitations of Japanese original work, their two sides are often dissimilar. The panels are sometimes adorned with paintings, but the latter are subject to a modification or transformation, which is likewise attributable to Japanese influence. The idea hitherto prevailing in Europe of a regular pattern placed in the middle, which has been handed down to us, not from Greece, to which it is often attributed, but from the Byzantine style, which, of course, itself sprang originally from Greece, is diametrically opposed to the Japanese principle. The art of Japan shows an aversion to symmetry and repetition. For example, instead of decorating a plate or tea-cup with the traditional wreath of flowers round the edge, and with a single flower placed uniformly in the centre, it will ornament such articles with an irregular end of a twig or branch running across from the circumference on one side to the other, and suddenly breaking off at the boundary line. This new idea has been taken up with avidity,

and there are few branches of English art in which its influence is not to be traced. Fortunately it has not extended to the carpets and paperhangings, for, as these are naturally only background, figures of the kind we have described would be entirely out of place in them. Upon the whole, the Japanese influence has been most salutary, particularly from the fact that it has diminished the inclination to ostentatious mechanical reproduction,—a tendency which has been fostered by the high estimation of symmetric form, coupled with the development of machine work. Japanese taste, however, like Byzantine, has its dangers, and the English artist and workman, although subject to both influences, has not yet attained to the well-proportioned achievements of the Greeks, whose products observe the due mean between total disregard of all symmetry, on the one hand, and a mechanical uniformity on the other.

The cause of this interest in everything Japanese which has been awakened in England simultaneously with the revival of fashions prevalent here a century ago is to be found in the introduction of the Japanese wall-screens. This, perhaps, more than all the other changes, has contributed to give the new character to our dwellings. By help of a high movable screen we can produce numerous changes in the appearance of a room. The form of it, the light, and its fitting up may all be modified by a change in the position of the screen. The monotonous quadrangular form of most modern rooms is advantageously broken up by these intervening walls. They offer the charm of snug and cozy corners. Next to the banishment of the large central table that used to take up far too much space, nothing has so greatly contributed to render reception-rooms comfortable as the introduction of these wall-screens. Moreover, their own surface affords room for tasteful decoration, which in importance is hardly second to that of the room-walls themselves. In most cases the screen surface is made of some textile fabric, but sometimes of paper. Very recently the fields have been occasionally formed of wood-carvings in open-work designs. This latter species, which reminds us of Moorish wood and stone work, is often very effective in appearance, but the object of the screen to protect from the heat or draught cannot, of course, fail to suffer much under this style of ornamentation. For small screens, colored glass has often been employed of late. With appropriate colours, like the deep blue of peacock feathers, which is mostly chosen, these screens look very well, but their weight tells against their general adoption. The prettiest, and at the same time in every way the most handy, screens are those consisting of a bamboo, cane, or some other light frame hung with Turkish silk. Few articles would, ten years ago, have filled an ordinary decorator with greater astonishment.

Considerable as has been the deviation from the old paths in regard to the furniture and fittings of our living-rooms, the new tendency is everywhere far more observable in the case of objects of a purely ornamental character. Pottery in particular has developed itself in England to a degree never yet attained in Germany. The Lambeth firm of Doulton has founded a new branch of this industry. In this pottery-ware articles of all degrees of quality are represented, from the commonest stone jugs to the finest and most splendid vases. The articles for which the firm in question are celebrated consist of a finely-glazed earthenware, whose ground colour is blue or brown, which in most cases is not uniform, but in various shades. This ground is ornamented either with figures incised, or in relief, and sometimes with a combination of both. The forms are exceptionally pure and classical, and the lines of the ornamentation are mostly worthy of the form. Amongst the most charming are the outlines of animals on a brown ground. As we hear, they are from the hand of Miss Barlow. The elevated ornamentation consists frequently of lines formed of fine pearls, which describe exceedingly pleasing arches and patterns. Sometimes the reliefs represent shells, flowers, or animals. Some of the larger articles decorated in this way remind one, though with important variations, of the strange Japanese vases only recently imported into England, upon which birds and flowers are represented in the strongest high relief with the most perfect fidelity. The art products of Messrs. Doulton are by no means limited to the earthenware articles bearing their name. Glazed tiles are

also manufactured at Lambeth, and some of them are very beautiful models. Paintings on porcelain and tombstones are also among their productions. The plates of the latter, painted by hand, are not up to the level of the other art products of the establishment. The generally high standard it has attained is in no small degree attributable to the influence of the Lambeth School of Art, where many of the artists employed by Messrs. Doulton were educated. This firm, on principle, allows the greatest practicable freedom to the individual taste of those who furnish the drawings, some of whom, like Miss Barlow and Mr. Traverth, have acquired a well-deserved reputation of their own. Their terra-cotta tablets in high relief have for several years taken a place in the exhibitions of the Royal Academy. Terra cottas form an important branch of the manufacture carried on at Lambeth. The distinguished place held by these products of the potter's art is in the main due to the Doulton ware, and their most characteristic quality is their colour. Nevertheless, that which forms their strength, threatens also to constitute their weakness. The defects of the Doulton ware result simply from the tendency to overdo the ornamentation and colouring; that is, they arise from an absence of repose. All these objects, however, are marvellous examples of artistic skill; but as works of art those are the most admirable which are least marvellous or surprising.

Porcelain-painting has for a number of years past acquired in England the character of a fashionable amusement, and many ladies devote their leisure to it. It cannot yet be affirmed that the efforts of the *dilettanti* in porcelain-painting have produced many works of great artistic value, a fact which is probably attributable to the general ignorance of the fundamental principles of art prevailing amongst the ladies taking up this amusement. But where, as has been increasingly the case of late, this branch of art has been taken up by genuine students of art, the results have often been excellent, and articles have been produced which have been extensively purchased and have contributed to that improvement in porcelain-painting which is everywhere making itself felt.

The artistic products of the needle in England have likewise undergone a similar improvement. There is a special school for this branch at South Kensington, where the work of the ladies there engaged is constantly exhibited. Many of these samples will compare advantageously with the best of the older class of articles. In some cases the strict limits of art have been transgressed, but such instances are rare. The achievement of the special school for needlework show best upon screens and curtains, but it is beyond the field of an exhibition that they celebrate their greatest triumphs. This triumph arises from the fact that they have completely extirpated that barbaric kind of wool-working which was formerly the pride of English women. To the influence of this Institute we must attribute both an improvement in the material and in the colours employed in artistic embroidery. We are also to it the preparation of copies of extraordinary design.

Another branch of ladies' work which has of late begun to be cultivated in England is the Gobelin painting. At first it aimed at copying the Gobelins work with the brush. But to copy at second hand the pictures after which the original Gobelins were executed appears a very unfavourable course of procedure. However, it has already been abandoned, and in place of copying the worked tapestry a sort of durable painting on rough fabrics for curtains, &c., has been substituted. Whether this young branch of art has a future before it, it is impossible as yet to predict. Such, then, are some of the fields in which art has in England made astonishing progress in recent years.

**Building in Leyton and Leytonstone.**—About three months ago we had occasion to complain of the bad building in this district. We are now informed that a great change has occurred, owing to the action taken by the Local Board and their surveyor. The Model By-laws of the Local Government Board, we are told by those who know, are being strictly carried out. All private connexions to sewers are now made by the Board's contractor, under efficient inspection. Certificates are granted on completion, and the building materials, with few exceptions, are of good quality.

#### FORTIFIED CHURCHES ON THE NORTHUMBRIAN BORDER.

Along the Northumbrian border, at intervals of a few miles' distance from each other, are several ancient churches that possess strong, stalwart stone towers, evidently intended for defence in Mediæval warfare, or as places of refuge for the inhabitants of the districts in which they are situated when alarmed by enemies. They are not always of the same date as the rest of the structures of which they form part; for, in some cases, they have been added after the rest of the fabrics have been in use for two or three centuries. Nor are they lofty, like landmarks; but low, square, sturdy, and inscrutable. There are also a few instances in which churches have been fortified in a similar manner in Cumberland, facing the same borderland, notably at Great Salkeld, Dearham, Newton Arlosh, and Burgh-by-Sands. The abbey church at Holme Cultran, also, in a plea for its maintenance in old times, was alleged to be the only place of defence for the inhabitants against the marauding Scots. The examples in Northumberland are more numerous.

One of the most interesting examples of a Northumbrian church thus constituted, "half-house of God, half-castle 'gainst the Scot," is at Ancroft. This village is about midway between "Norham's castled steep" and Holy Island. In the old days, when there was a monastery on Holy Island, Ancroft was one of the five chaptries on the mainland that belonged to that establishment, and which were served by priests appointed and paid by the priors. The little church has the same characteristics, in miniature, that the remains of the famed monastic buildings on the island still possess, including the low semicircular arches to doorways and windows that denote Norman workmanship. The accustomed eye can see it was, at first, a small Norman building consisting of a nave and chancel, lighted by small Norman window-openings, and entered by a small doorway, which still exhibits the low soft curve of the old Norman builders. The masonry consists of rows of small stones as nearly as possible of the same size, which, as time and weather have softened down their edges and left interstices between them, have a beadlike regularity. On the western end of this little ancient edifice Plantagenet masons built a strong tower. They took off as much as was necessary of the roof, and, on the Norman walls, raised two upper stories, firm, square, and compact. The manner of building with small regular stones in even courses had passed away, perhaps because there were then cleverer contrivances for lifting, and better appliances for removing, larger stones from the quarry; and we may see the Edwardian builders used larger stones in a more irregular manner. Here and there, when they found a stone was too small to keep the level of a course, they filled in the space with a smaller one, in some places; although they preserved a general aspect, as well as certainty, of massive strength. Worn with sea-fret and the storms of five hundred winters, their work still stands intact and upright, though much of the rest of the original building has been taken down and removed to make way for modern enlargements. A Plantagenet tower has also been built on the west end of a Norman church at Ponteland, near the Tyne.

There is another warlike Edwardian tower at the west end of Ingram church. This stands in a wild country on a bend of the flat pebble-paved shore of the river Breamish, in the hilly district of the Cheviot range. There are hills in every direction, with their sloping sides strewn with great grey lichen-spotted boulders, and bright with heather and mosses; but between these hills there are valleys that must have afforded every facility for the operations of moss-troopers. The builders of Ingram Church, therefore, beheld themselves of a strong tower. "Go to," they may have said, "we will build us a tower." If there ever was a more ancient building on the site, but little use was made of it, for this fabric is built from beginning to end in the lighter manner that was in vogue after the Norman style was discontinued. Every arch is lofty as well as light; every window is long, narrow, and acutely pointed like a lancet. The chancel arch has the same delicate and venerable beauty, and at the west end rises the evidence of the insecurity of the district at the time of its erection. The plan of this tower is square. It has three stages,

whereof the lowermost is lighted only by arrow-slits, the second by small square-headed openings, and the uppermost by double lancets of similar dimensions. It has a double chamfered base, and midway between it and the projecting parapet there is a "set-off" or sloping line of masonry, marking a slight reduction in the size of the topmost stage.

These fine old towers have another comrade at Ilderton. Only two stages of this one are left. The third has been rebuilt, with large window openings and a flimsy embattled parapet. All the rest of the church has been likewise rebuilt in the same poor unsubstantial fashion. But we can see there was originally Norman work in the edifice, for the masons who have rebuilt it have used up rows and rows of the Norman stones they found ready to their hands. They dealt in a very rough-handed way with the Plantagenet tower, as we have seen. Further, they broke an arched doorway through it, which is now the only entrance for the congregation. This tower is but 18 ft. square. In the south-west angle of it there is a winding stair in the thickness of the wall.

The tower of Eglington Church has about the same dimensions as that at Ilderton, but it has not been so ill-used. It still stands its full height, looking across the wide sweep of country extending from the Cheviots on the one hand to Alnwick on the other, with its masonry intact. It is lighted with double lancets, just as the barbacan of Alnwick Castle is lighted, and the only entrance to it is from the interior of the church. The second, or central, stage bears traces of having been used as a chamber. There is a small opening in the east side of it through which the services in the church could be observed, and on the north side is an ambry or cupboard. The church suffered in the seventeenth century, when a Scottish army, under General Leslie, left it in ruins; but this tower must have looked down upon the war-wasted building comparatively unimpaired, and, sentry-like, guarded the site till better times came round, and masons were set to work to repair the dilapidations. Within the last few years a chieftain among the antiquaries of the North has been at the cost of capping it with a high pyramidal roof, and causing careful repairs to be given to it.

Midway among the heathery and mossy moors that stretch from Alnwick to Rothbury, and close to Edlingham Castle, stands Edlingham Church. The castle does not date much further back than the Restoration, therefore the inhabitants of this district, remote from towns and help, fortified their church in earlier times. It was a small ancient Saxon edifice, one of the first built in the days of the Saxon Evangelists. A sombre tower was added to the west end of it in Plantagenet days, with no external entrance, and no windows below the height of a man. There were plenty of stones at hand on the surrounding moors; they only required fashioning. We may note the long quoins made to suit them. We may note, too, that the doorway, which opens from the interior of the nave, is furnished with receptacles for a strong har on the outer side, as though persons had sometimes been imprisoned in this tower.

Every Northumbrian church-tower is not of this military character, it must be observed. Some have great doorways into them, easily forced; some are capped with spires; and the lovely lantern of St. Nicholas, Newcastle, is an architectural feature with which most people are familiar. There is a very fine tower, for instance, at the west end of St. Michael's Church, Alnwick; but it has not the warder-like features of those just described. It has not been built for defence, for it has grand bold step-buttresses at each angle, from its base to its parapet, whereby a nimble man may easily climb to the top of its three stages; and wide traceried window-openings of the same ornamental fifteenth-century workmanship as the rest of its masonry. At the east end of the same church, however, there is a peculiar turret that has evidently served some purpose in Border warfare. It is on the south-east angle of the chancel. It has a winding stair in it, and an embattled parapet, and gives access to the roof, upon which are traces of a small chamber. Here may have been lodged a sentry, or guard, when extra danger called for extra vigilance. The turret may have held a beacon-light, or it may have protected the guard whilst displaying signals and taking observations. Below the embattled parapet is a moulded stringcourse, and below this again, here and

there, are tiny slits to give light to the stone stair within. Now only used as a means of access to the leads upon the roofs, it stands hasking in the sunshine of its southern aspect, acquiring with each summer's sun a deeper richness to the tints of its amber masonry.

One of these old Border church-towers has been nearly lost by fire within memory. The conflagration in question occurred in the Church of St. Peter, at Long Houghton, and was so considerable as to involve rebuilding the uppermost stage of the tower. It was then observed that the walls of it are 4 ft. thick, and 23 ft. long by a width of 22 ft. Its stalwart, sturdy comrades are not always quite so large. There is something more about Long Houghton tower worthy of note. It stands on the site of an old Saxon tower, and has the original Saxon tower arch incorporated in it. We can gather from the evidence of the stones that the church built by the first Saxon teachers consisted of chancel, nave, and tower. After standing 300, or, perhaps, 400 years, it was rebuilt all but the chancel arch (which must have been considered sound enough to be retained), and the arch and piers of the tower, which were also deemed sufficiently strong to serve as the beginning of a fortress that Scottish raids and moss-trooping customs rendered necessary for the safety of the surrounding population.

There is another of these towers, sea-bleached and wind-worn, at Newhiggen, yet with its fine strength apparent in every line of its honest masonry. The great sea comes almost up to the churchyard sward on which it stands, lazily lapping the sands, or raging and beating upon them, ever changing, but the gloomy grey tower, unscathed, unmarred, stands, an unvarying testimony to the needs of the troubled days of old. It is now surmounted by a spire.

A grand grave tower, with corbelled-out parapet, still stands at the west end of the Church of St. Mary Lesbury. This is very stern and rigid-looking. Lesbury was once the ecclesiastical centre of a large district, for in the twelfth century there were three chaptries attached to it,—Alnwick, Long Houghton, and Almonk. As time passed by, changes were effected that made the head-quarters of the Percies, Alnwick, of more consequence than the parent church, and the sufficient safety of the district was secured by the creation of the strong tower in question attached to the church.

There is historical testimony to the fact that Warkworth Church was the scene of a great slaughter when the Danes landed in its neighbourhood, and finding the inhabitants had taken shelter in the little Saxon church, surrounded it, and massacred them every one. About 100 persons are thought to have been slain on this occasion. A century after this outrage, one of these martial towers, 23 ft. square, was built at the west end. In a later century, probably after Warkworth Castle was built, when the tower would not be required to defend the inhabitants any longer, a spire was placed on the top of it, which still ornaments the structure.

There is a fine tower to Bolam Church, still more ancient than those before mentioned. It stands on the ridge of a slope looking over the wide domains of the warriors who held Bolsay, Bolam, Meldon, and Mitford in the days of yore. Like the rest, it has three stages, and is only to be entered from the interior of the nave, as it has no external doorway; but it has the additional interest of a great antiquity, for close up to the parapet is a course of herring-bone masonry, marking its Saxon origin. Through the intervening centuries, when Norman masons took down the rest of the Saxon building, and Plantagenet masons afterwards took down nearly all the work they substituted for it, and wind and weather so wrought with this newer work, with its elegant detached columns and dog-tooth ornament, that it became old and grey and worn in its turn, this tower has held its own. The lowermost window openings have been tampered with and enlarged, but the uppermost stage still preserves in their integrity the Saxon openings, with the massy recessed haluster that divides each into two lights. Whittingham Church, in a neighbouring vale, still preserves the two lowermost stages of a fine Saxon tower. At Long Houghton there was probably a tower similar to these, but, as indicated, the Norman masons did not spare it, but took all of it down except the tower-arch. It is possible, too, there was a Saxon tower at Ingram, and that the arch still stands in the present Edwardian structure. Woodhorn

Church, also, has preserved a Saxon tower arch. The Saxon towers appear to have been about 12 ft. square, and those of the Plantagenet period about 20 ft., more or less.

We learn, therefore, that on the Northumbrian border, in Saxon and in Plantagenet days, the parish church was not only the scene of the baptism, marriage, and funeral service of the parishioners, and the centre to which they all gathered for worship on the Sabbath, but the literal stronghold to which they resorted when menaced by their enemies, and in which they placed their wives and children for safety when alarmed by the approach of enemies. After the great catastrophe of the Norman Conquest we may conclude there were fewer apprehensions, for the small Norman churches or chapels in the district have no towers. As time passed by, and the strength of the new strong hand relaxed, aggressive grew. The Scots became rivals, and towers were again in request.

Just as every nobleman had his castle, and every gentleman his pele, or tower, in this border country, when Edward was marching his great armies Scotlandwards, many parish priests likewise lived in towers within a stone's throw or so of their churches. In some parishes there is still a tower to the church, as well as a tower in the vicarage-house, as at Embleton and Ponteland, whilst in others where there is a tower in the "manist in the vicarage," to use the old phraseology, there is none to the church, as at Elsdon and Shilbottle. In fine, clergy, noble, gentle, and simple, from Plantagenet times down to the days of the Tudors, alike acted upon the impulse of the prophet, "I will stand upon my watch, and set me up upon the tower, and will watch to see." We may assume a system of correspondence by signals was maintained from tower to tower, which increased their utility, and reduced the necessity for patrol.

#### THE INTERNATIONAL SANITARY CONGRESS.

A BRILLIANT assembly gathered in the Aula of the Geneva University to witness the opening of the Sanitary Congress.\* The room, small in size, yet with its three galleries capable of holding a great many persons, was admirably adapted to the purpose. The feeblest voice could make itself heard. Every sanitary reformer is not of necessity gifted with powerful lungs.

Dr. Lombard, of Geneva, occupied the chair, and enthusiastic applause broke forth when Dr. Pasteur took a seat by his side. The speeches of welcome were, of course, pronounced by the Swiss local authorities, the first to speak being the Councilor-General, M. Scheuch. He remarked that Switzerland was the country of all countries for international congresses, especially if their motives were calculated to be of general benefit to humanity. The preference which Geneva enjoyed was due not merely to her geographical situation, but to the ready sympathy of her population, and the ardent champions any good cause would find amid the Swiss people. It was to Geneva that the honour of the International Treaty for the succour of the wounded in war belonged, and at Geneva a great war had been prevented by the arbitration with respect to the Alabama claims. Switzerland having much to learn was particularly eager to welcome the Sanitary Congress. Her death-rate was not 17, but rather 25 per 1,000, and, therefore, the country was eager to accept good advice.

The delegate of the Council of State of Geneva, M. Hiridier, urged that hygiene would tend to do away with war, as the Red Cross Convention had already mitigated many of its horrors. Its strength rested on the spread of education, and Jean Jacques Rousseau, a citizen of Geneva, had been one of the foremost promoters of the cause of education. In ancient Greece, Rome, and Egypt hygiene held a high position. The ignorance of the Middle Ages alone caused its tenets to be neglected, and Europe was punished by appalling outbreaks of the plague.

M. Le Coindre, of the Geneva Municipal Council, insisted that the Town Corporation would be the first to benefit by the good advice of the congress, and invited a frank exposition of all local defects. The Swiss were a proud people, but they wanted light everywhere, and on everything, knowing that progress was always possible.

Dr. H. C. Lombard, as president of the Committee of Organisation for the Congress, in offering his welcome, remarked that the members, though they could not expect a royal reception, might count on a cordial greeting. He then described the improvements already realised at Geneva. It was not the present generation but their ancestors, who were to blame for the narrow streets. Formerly the one large street used to be crowded with the stalls of a permanent market. Now this had been swept away, and ractitism was no longer constantly visible amid the population. To an American, named Church, they were indebted for the introduction of the first steamer on the lake, and when navigation became popular they were obliged to improve the unsightly water-side. The unwholesome sewers emptying from nondescript hovels into the lake were now removed, and beautiful embankments constructed in their stead. Afterwards, and as a more important improvement, came the destruction of the city walls, which hid air and light from the town. The handsome building where the congress was now united stood on the site of the ancient city moat. The population was not half so crowded, and there were large gardens both inside and outside the town. Geneva was built on an amphitheatre freely swept by the prevailing winds, notably the cold north wind. This might tend to increase inflammatory systems, but it carried away the germs of disease, and to this cold wind was attributed the cessation of the great cholera epidemic. The water drunk in the town was also remarkably pure,—one of the purest water-supplies of Europe, according to Professor Tyndal. The workmen of Geneva eat abundantly of meat, soup, and vegetables, and this contributes greatly to maintain the health of the population. Further, the visitors will have seen that the schools are built like palaces,—palaces not for the dwelling of kings, but for the education of the youths who are to become the sovereign people. Yet, if much has been done, still more remains to be accomplished.

The Secretary-General, Dr. P. L. Dunand, then read his report, from which it appeared that the Governments of France, Italy, Spain, Roumania, Hungary, Holland, Servia, Sweden, Mexico, Portugal, Prussia, Bulgaria, Canada, Switzerland, and Belgium had sent special delegates. Further delegates were sent by the municipalities of Rheims, Bucharest, Geneva, Paris, Lansanne, Neuchâtel, Rath, Seville, Lisbon, Nancy, Turin, and many other towns. A number of societies and academies from all these towns and countries had also sent official delegates.

Dr. Paolichetti, Senator, president of the Turin University, and of the Third International Congress of Hygiene, which was held two years ago at Turin, then delivered a most eloquent speech, proposing that Dr. Lombard should be president of the present congress. We wish we had space to reproduce the poetic charms of this discourse. It was the most telling speech of the inaugural sitting, but an abbreviation would not do justice to this passionate exordium. Switzerland was the holiday land of all Europe. Here overworked and broken constitutions came to seek health, recreation, and happiness. It was the land of those who loved, and of those who had loved to well. Both gained strength in the contemplation of its beauties, and became wiser and happier. While war was raging in Egypt, and all Europe was aching, the Swiss were discussing hygiene. They were a truly happy people, and if Europe could follow their example it would become a vast Switzerland.

This allusion to Victor Hugo's dream of the United States of Europe was greeted with enthusiastic applause.

After some formal business, the first sitting of the congress was closed, and the members went home to prepare for the official reception held the same evening at the theatre by the town authorities.

The Trades Union Congress will be opened on the 18th of this month at Manchester. The principal business brought before it will most likely have reference to the amendment of the Employers' Liability Act. On this subject the trade unions and the miners' organisations of the country may be said to have fairly made up their minds. A Bill to carry out their wishes was, it will be remembered, introduced at the beginning of this year by Mr. Burt.

## FROM GERMANY.

*New Astronomical Observatory at Bamberg.*—Dr. Carl Romels, of Bamberg (Bavaria), lately bequeathed to his native city a sum of 20,000*l.* for the erection and maintenance of an observatory. The amount devoted to the erection of the structure will be 9,000*l.* A sum of 7,500*l.* will be invested to form an endowment fund for the payment of the astronomer who will be appointed to the observatory, and of the other officials, as well as for keeping it in repair. The remainder of the amount will be devoted to the purchase of instruments. The testator has, however, left the observatory a number of instruments as well as the money referred to.

*The Munich Electrical Exhibition.*—Following in the track of France and England (whose displays at Paris and Sydenham opened a new era in the development of electrical science), Germany has been preparing at Munich an exhibition of a similar character, the opening of which has been fixed for September 16th. In addition to numerous examples illustrative of the progress of electricity in various branches of technical research, its practical application to public and private uses will be shown upon a scale of importance commensurate with the position this branch of the subject now occupies in domestic and industrial economy. Amongst the features of the exhibition are the following:—

1. Free lectures by eminent men of science.
2. A free library, containing technical works as well as periodical scientific literature.
3. A well-arranged catalogue and a guide to the exhibition written in a popular style.
4. *Viva voce* explanations of the objects exhibited by a number of young scientific men, who will take it in turn to attend at the building, and will give the visitors all needed explanations.

The exhibition will be open until October 16th, according to the arrangements made in the first instance. Doubtless the object of limiting the time has been the probable difficulty of attracting many visitors from a distance at a late period of the autumn.

*New Bridges at Berlin.*—The Berlin Municipal loan of 1878 placed at the disposal of the authorities a sum of 4,000,000 marks (200,000*l.*) for the building of new bridges of a solid character, and designed to accommodate the present increased traffic. The works already executed and still in progress represent an expenditure of nearly 300,000*l.* To meet the deficiency and to provide for further works of the same kind, a second loan of 200,000*l.* is being raised. Should the deepening of the bed of the Spree take place (according to the present intention of the Prussian Government), the bridges still to be built can be on a level with the thoroughfares adjoining, or at a slightly higher level, without the navigation of the river being impeded. This would allow of the estimated cost of the new bridges still proposed (varying from 23,000*l.* to 45,000*l.* each) being materially reduced, the approaches having hitherto formed an important proportion of the total cost in each case.

*Pavements in Berlin.*—The Berlin police authorities, in their decennial report, speak unfavourably of asphalt pavement as compared with good granite pavement, so far as the safety of traffic is concerned. In addition to the numerous cases of horses falling, it is remarked that it is difficult to stop or turn horses quickly on the asphaltic. Wood pavement is also found inferior to granite in this respect. It is stated that even on the worst stone pavement, fewer horses fall than on wood or asphalt. These assertions are based on actual observations.

*The Berlin Hygienic Exhibition.*—The active co-operation of the German Government in the exhibition is considered in well-informed circles as being rendered certain by the fact that the director of the Imperial Sanitary Department has recently joined the committee. The competition for the building of the new structure is confined to six firms. Twenty-two leading firms were invited to tender, but sixteen of them declined to do so on account of the multiplicity of their present engagements.

*Gothic Architecture in Hungary.*—According to a recent treatise from the pen of Abate Lublich (custodian of the Agram Museum), there is in Hungary an older monument of Gothic architecture than any existing in Germany. The instance to which he refers is that of the church at Topuzsko (or Topics), the ruins of which point to its having been designed

in a pure Gothic style. The date assigned to it is about 1205, and the site would seem, by records still in existence, to have been granted by King Andrew II. to the Cistercian order, some members of which had come from the French Abbey of Clairvaux towards the close of the twelfth century, and settled in Hungary. The clergy were in those days their own architects in many cases, and the fact of the Gothic style having been adopted in this instance, goes to prove (according to the arguments adduced) that France was the home of Gothic architecture at an earlier date than Germany.

## AN OCTOGENARIAN ENGINEER.

THE *Army and Navy Journal* of New York, of the 19th of August last, contains a reference to the fact that in that month the venerable Nestor of the profession of civil engineers, Captain John Ericsson, K.V., entered on the eightieth year of his age. We claim, on behalf of the civil and mechanical engineers of England, an interest in the health, wealth, and fame of Captain Ericsson. It is only due to one of those minor events,—accidents, as we ignorantly call them,—on which the turning point of human life so often depends, that we have not had to congratulate the father of the ironclad on keeping his eightieth birthday in London, or in Manchester. On the Liverpool competition in 1828 there is no doubt that Ericsson's engine, the "Novelty," was the best on the ground as regarded design. It was not of such stout and sturdy workmanship as the "Rocket" of Stephenson, and, breaking down more than once, the prize was adjudged to the latter. But no one who stood, on that memorable day, beside Ericsson on the foot-plate of the "Novelty," and saw the change that came over the face of Mr. Stephenson as the competing locomotive shot by his own on a parallel pair of rails, would ever forget it. As it was, Stephenson knew how to hold the lead that he had worthily acquired as a workman, rather than as an inventor, and Ericsson, thus failing to become the first man in the profession here, went a few years after to America,—without prejudice to his being regarded by those who knew him as the first engineer in the world. Now that age has put his silver crown upon him he is that, and without a second.

The *Army and Navy Journal* refers with appropriate respect to the labours of Captain Ericsson during the last two years. These comprise (1), the reconstruction of his original calorific engine (which was completed about 1834), and its application to pumping. The success that has attended this reconstruction is attested by the sale of upwards of a thousand of the engines by the Delamater Works within the last two years. Second, we place a high-speed steam engine for electric machinery, with a single steam cylinder of 5 in. diameter, and 3 in. stroke, making twenty-one revolutions per second, under steam of 55 lb. pressure on the valve; the Prony friction brake shows that a 12-horse-power is obtained. Thirdly, a solar pumping engine applies, by a method long since perfected by Ericsson, the rays of the sun to heat atmospheric air, and thus replaces such contrivances as the old windmills of the fens by a costless and mighty, if somewhat variable source of power. The fourth invention is the application of hydraulic training gear for changing the direction of the torpedo boat, the *Destroyer*, as to which we reserve any further remark. And the last is one which, although called forth only for the service of this last of the ocean children of the inventor of the *Monitor*, is capable of very wide application in war no less than in peace. It is the application of a reflector to the wooden backing of the *Destroyer*. By means of this, the helmsman and commanding officer, while standing on a grating placed so low in the vessel that their heads are 2 ft. below the top of the armour plates, are able to see both sea and sky forward of the vessel, and thus to approach the enemy while protected from his guns.

When we consider how small an elevation gives a commanding view over the flat level country, especially when the air is dry and clear, we cannot but think that a very small balloon, by no means adequate to carry an aeronaut, might be fitted with reflectors, and so managed by silken cords as to give to our look-out in Egypt very precious information as to what is going on behind the sand rampart of the enemy.

## SELF-SUPPORTING RESEARCH.

HOWEVER successfully the scientific men may be able to combine, as they certainly seem to do in the present day, their well-directed studies with the principles of lucrative commerce, it can scarcely be said that the archaeologist has as yet turned his delightful pursuit to any pecuniary profit. Happy student! like Agassiz the naturalist, he has no time to make money. It is alone his dependence on those sinews to carry on his war with the action of time, which are so requisite in every struggle that ever leads him to disturb a public who unfortunately he only too often finds indifferent to his appeals. His demands are never exorbitant. Of the millions ungrudgingly voted to be squandered on costly and not infrequently useless experiments he would shrink from demanding even a tithe for his use. A few hundreds he finds the utmost difficulty in raising in a country where private fortunes are enormous. We are afraid the chief interest he finds awakened by his appeals in favour of his pursuit is,—as we remember to have heard the American sculptor, Horatio Greenough, say of his artistic appeals to the Senate of his country,—chiefly an antagonistic one. Subscription slowly supplies the sums requisite. It is sad to think how many are the directions in which the researches of the archaeologist might be pursued were it not for the monetary difficulties that invariably hinder all consecutive study.

The plan of making antiquarian excavations self-supporting is admirable, and has been wisely adopted by the Italian Government. For some years past the system has been found to work well. It is true that in Italy there exists, as in France, a commission that watches over the historic monuments of the country. In spite of the efforts made in this direction, we seem almost as far off as ever from this consummation in our country.

The Italian Government derives a very considerable income from the admission of visitors to the national historic monuments, among which are numbered the museums. The traveller now is admitted through a turnstile, on the payment of a franc, to the Uffizi Gallery at Florence, the Brera at Milan, the Museo Borbonico at Naples, the Vatican at Rome, the local museums, such as those at Siena, and elsewhere; in fact, all the art galleries of the principal cities; and, greatest surprise of all (to those who remember Italy in the past), one enters Pompeii as one would the Crystal Palace or the South Kensington Museum.

By means of the funds thus collected, the Italian Government is able yearly to devote a handsome sum to the purchase, the restoration, the protection, and maintenance of existing historic monuments, and to continue its archaeological researches, foremost among which come, of course, those in the buried cities at the foot of Vesuvius. All the old system of uncertain fees to *custodi* is abolished, and an agreeable branch of the Government administration has been organised throughout the country.

We have been reminded of this skilful settlement by the Italians of the monetary difficulties that so constantly beset archaeological research, by the adoption of the system of self-support in the interesting Roman villa discovered now two years since at Brading, in the Isle of Wight. As we announced in these pages not long since, the ground on which (or, perhaps, rather, under which) the villa lies, has now, after having belonged to two separate owners, become the sole property of Lady Oglander. The tiresome difficulties which for some time had hindered any further research, having been now arranged, a turnstile has been set up, and the funds having accumulated,—thanks, also, to the aid of some generous subscribers,—work has just been resumed on the eastern side of the villa. Whether, however, the present proprietors are justified or not in their belief that still greater treasures are likely to be unearthed, we ourselves have some doubt, but that they are certain to discover other portions of buildings there can be no question whatever, numerous Roman remains having, it would appear, been found in the neighbourhood.

The discoveries so far made have been of such importance and exceptional beauty that it is alone the most sanguine who could hope to find any further work of equal merit to that already laid bare. What is at present placed before the public is of sufficient interest to hold out to the proprietors ample promise of a positively remunerative return for their efforts.

We foresee the villa near Brading becoming in time as much frequented as Pompeii. Not only the antiquaries, but the excursionists from the remotest parts, are paying Brading and its Roman villa a visit, and well may they do so, for, although the British Museum is filled with treasures of the greatest periods of antique art, there is no spot within four hours of London where may be seen, as they have been reposing now for hard on 2,000 years, such specimens of the art of antiquity as are to be seen in the Brading mosaics. It is not until the traveller should reach Pompeii that he would be able to see, apart from the interest attached to the residence of a refined Roman, a piece of mosaic work so grandly conceived and composed as that which covers the floor of the largest chamber in the villa.

Roman villas are no rarities, but villas containing works of art such as the pavements of the Brading villa are indeed rare. Those who in their visit to the Isle of Wight have the opportunity of comparing with this treasure the villa which has long been one of the attractions of Carisbrooke, where the few interesting remains of the home of a former Roman resident nestle under the walls of the famous old castle, can see at a glance, without requiring the erudition of the antiquary, the value, artistic and archaeological, of the villa discovered at Brading.

#### IMPORTED IRON.

ALMOST unnoticed, a startling change has during the last few years, taken place in the metallurgical world. The iron manufacturers of Great Britain have come to depend in very great degree upon foreign nations for a large part of their raw materials. If we look back twenty years we shall find that the iron that was made in Great Britain was made almost exclusively of that smelted from our own ores; but this is far from being the case now. A few figures will show how great has been the growth of the demand for iron ore from other parts. In 1861 we imported 23,408 tons of iron ore, all, except a few hundred tons, being brought from Spain. Taking the importations in the total for periods of five years from that date, we find that by the year 1866 the importation had risen to 49,360 tons, and by the year 1871 to 335,033 tons. Again, in 1876 it was 673,235 tons, and in 1881 it was 2,450,636 tons; so that, roughly speaking, it doubled itself in every year named, except that in the last of the periods there was an increase much more than threefold. And it is worthy of note that Spain still supplies the great bulk of the ore thus brought in, for last year 2,227,486 tons were imported from that country, Italy and Algiers sending in the bulk of the remainder. Sweden used to send us large quantities of iron ore, but for the last seven or eight years it has sent us none; and Norway, once a large source of supply, sent us only 118 tons last year; so that it is from the countries of Southern Europe and Spain that our supplies are drawn.

This growth of the use of imported ores is due to one cause,—the increase of steel-production. Until the basic process was commenced it was tolerably clear that the great bulk of the iron ores of Britain were not suitable for use in the steel manufacture; and thus as the use of steel grew, there was an inevitable use of ores that were so fit. The rich districts of Furness and that of West Cumberland had ores that were so usable, and there was a continuous growth of the production of these; but there was a call beyond that that they could supply. And, moreover, many of the works that were on the coast could bring ores from Spain by sea cheaper than they could bring those by land, so that there arose the vast demand for ore that has caused the swelling of the imports shown in the figures above given, and that seems likely to continue, though probably not with such rapidity. There is now a systematic attempt to utilise our own ores by the basic process, and this will allow a portion of the steel that we use to be smelted from our own iron, and thus will at least lessen the rapidity of the growth of the imports of iron. But the fact that we use about 2,500,000 tons of ore from other nations, and that they cost with the carriage probably 1,500,000*l.*, is one that should be a very great inducement towards the further development of any and every system that will allow of the increasing use of our own resources, and that would retain a very large amount of money in this country. It is not to be expected

that any such change will be very rapid. The imported ore and its product has made itself well known; that made by the basic process from our own ores has yet to win its way in many quarters. But whilst there has been only one large extension, that of Eston, where the process has been in use, there is now in course of construction one that will be equally large, and that will, in the course of a very few months, materially add to the production, whilst in the Shropshire and Staffordshire districts new works are in course of construction or in contemplation, and by those the basic process of steel production will be much extended, and the use of our own ores in the steel manufacture will be extended. It remains to be seen what effect the extension will have on the importation of ores; in the past that importation has been affected by political events in Spain, and that cause alone should induce as much as possible the substitution of our own ores for those the continuance of the supply of which has been broken at times.

#### COURTS AND COURTS: A REVERIE.

THE Long Vacation is drawing to a close, and we fall a-thinking in this wise:—The probabilities of a visit to London by Macaulay's New Zealander are yearly growing less; but if in A.D. 2068\* a single aboriginal should be left between Cape Maria Van Diemen and Port Pegasus, and, prompted by curiosity, he should take a trip to the Thames and wander along the Strand, his attention will doubtless be arrested by the Courts of Justice, and he may criticise the design as sharply as has already been done, and may continue to be done even to the time of his arrival.

How few of the million passers-by,—home-born or strangers,—as they look up to arch and spire, will, or can, picture to themselves the thirty-three streets, lanes, courts, and alleys that formerly covered the seven-and-a-half acre site of the new building. In a short time the Majesty of Justice will occupy her new palace, and law reign over the spot where but lately lawlessness was rampant. Never were courts and alleys inhabited by a motlier set. At the Punch Bowl, in Hemlock-court, the original Jack Ketch refreshed himself after his dreary work at Tyburn, or in the Strand, or wherever duty might call him. At the Bear and Harrow tavern, which stood close to the Strand entrance to Clement's Inn, died Nathaniel Lee,—“Mad Nat,” the dramatist. The Assembly Rooms were in Star-court, and thither, two centuries ago, flocked the gay lords and knights and their ladies from Lincoln's Inns, the Strand, and the streets around Clare Market. In Crown-court the Crown Tavern occupied the site of the palace of the Bishop of Bath and Wells; and Gully, who overcame Cribb in a pugilistic encounter for the “Championship,” and represented Pontefract in Parliament, was host of the Plough Tavern, in Plough-court. From Boswell House, Boswell-court, in 1589, Gilbert Talbot wrote a letter of London gossip to his father,—Queen Elizabeth's doughty Earl of Shrewsbury. In this same court for a few years abode Lady Raleigh, widow of the famous Sir Walter. Hither also came Sir Richard and Lady Fanshawe. “In his absence,” she writes, “I took a house in Boswell-court, near Temple Bar, for two years.” In Ship-yard lingered a dreary memory of Admiral Sir Francis Drake. In 1654 were published the banns of marriage, “in Newgate Market, upon three several market days, between William Paythorne, squire, and Judith Grant, daughter of Henry Grant, of Michael's, Cornhill.” Not long after the wedding the pair moved into Ship-yard.† But of all the vanished network of buildings Shire-lane was the most remarkable. It was so named, says Stow, because it divided the City from the Shire. It was the birthplace of Sir Charles Sedley, who sang to please an audience that did not place purity high among the virtues. Here at the Griffin Sir John Denham, another poet, while a student of Lincoln's Inn, would madden himself with drink and rub into the Strand to amuse and terrify the passengers. On May 1st, 1670, Antony à Wood, antiquary and biographer of famous antiquaries, writes, “Dined with Mr. Ashmole,”—a brother in ancient lore,—“at his house in Sheer-lane, near Temple Bar.” Roque, in his map (1736), names it Sheer-lane. Some-

time previously to 1678, Andrew Marvell, in writing of a bonster, said “he sounds another trampet than that in Sheer-lane.” The Trumpet tavern, which stood half-way up the lane from the Strand, had under the first-floor window a small sign-board, on which was depicted a trampet, and was one of the oldest licensed houses in the metropolis. The “Tatler” frequently “marched down Sheer-lane at the top of which I lodge,” to the Trumpet, and from it he dated many of his papers, and it had for its landlord Christopher Katt, in whose parlour Tonson, Steele, Addison, Walpole, and other bright spirits were wont to assemble. But who knows not the story of the Kit Katt Club? Not far from the Trumpet lived Hooe, the translator of Tasso, who had for almost daily visitors Dr. Johnson and Dr. Warton. These are pleasant scenes in the tragi-comedy enacted on this stage of seven and a half acres, but there were others, alas! in which the woman lost to shame, the thief, and the murderer played their parts. In every court and alley there was a larger percentage of poverty and vice than could be found in any similar amount of space in London. Newcastle-court, up to the day of its demolition, was a synonym for all that is blackest in the schedule of crime. Strange anomaly that the Bible public-house in Shire-lane should have been the rendezvous of the unlovely families of the Jack Sheppards and Moll Flagons.

Over this tragi-comedy the curtain has fallen to rise on a new drama, in which the misery and suffering of hope deferred and the law's delay may flit across the scene, but no parts shall be assigned to loathsomeness and horror.

#### SURVEYORSHIP ITEMS.

**Conington.**—On the 4th inst., a meeting of most of the members of the Conington Town Council and of the Borough Bench was held in the Council Chamber of that town for the purpose of presenting a silver tea and coffee service to Mr. W. Blackshaw, the Borough Surveyor, on the occasion of his leaving Conington for Stafford, to which town he has been appointed Borough Surveyor. The presentation was made by the Mayor (Mr. T. G. Sheldon), who, on behalf of the subscribers and the Council, expressed their sense of the value of Mr. Blackshaw's services and their best wishes for the success of his future career.

**Darlington.**—At a meeting of the Darlington Town Council on the 7th inst., the first business on the agenda was a motion of Mr. Wharton, “That three months' notice be given to Mr. Smith, the Borough Surveyor, and his staff; also to Mr. Armitage, Borough Accountant, and his staff; and that a General Purposes Committee be called by the Mayor within one month to take the question of the salaries into consideration, and to re-arrange the above staffs.” The motion found no supporters. Mr. Smith's salary is 350*l.* per annum, and he has three assistants.

#### BUILDING IN PARIS.

ACCORDING to recent statistics, the number of houses in Paris is 82,352, against 71,873 in 1871. It appears, therefore, that within five years 10,479 new houses have been built. In 1876, the average number of inhabitants per house was 26; it has since risen to 27, a greater increase of the population having taken place than in house accommodation. Over-building does not seem to be in progress in Paris.

**The Great Eastern Railway Company's New Quay at Parkston.**—Owing to the enormous increase in their Continental goods traffic, the Great Eastern Railway Company have opened their new quay at Parkston for the landing and shipment of merchandise somewhat earlier than they contemplated. The quay is so far completed that three berths are available, with a depth of water alongside of from 16 ft. to 27 ft., according to tide. One of the warehouses on the quay is also completed, and part of the station-building. During the past week two extra vessels,—one from Antwerp and one from Rotterdam,—with full cargoes, have been discharged and loaded at Parkston. The company intend running two extra boats a week from Rotterdam, and extra boats as required from Antwerp during the present pressure of traffic.

### REREDOS, LADY CHAPEL, CHICHESTER CATHEDRAL.

The reredos and altar-table we illustrate in our present number were set up in the Lady Chapel of Chichester Cathedral as a memorial of Miss Franco, Messrs. Carpenter & Ingelov being the architects. The reredos includes some very good carving.

### PROPOSED NEW LUNATIC ASYLUM FOR THE CITY OF EXETER.

For some years the Corporation of Exeter have had in view the erection of an asylum for pauper patients, to obviate the trouble of sending them to the Fisherton Asylum at Salisbury, and to provide a certain amount of accommodation for the surrounding parishes. At length they secured a fine estate near Heavitree, about two miles and a half from Exeter, overlooking the estuary of the Exe towards Exmouth, which, being approved by Her Majesty's Commissioners of Lunacy, conditions of a competition were issued on the 31st of January, 1881, by the City Corporation, for an asylum for the reception of 300 pauper lunatics, with facilities for enlarging the same at some future time.

The competition was to be divided into two stages, viz., a preliminary one of sketch designs, and a final one with elaborated drawings. In the first one, plans of each floor, an elevation, transverse and longitudinal section, all to a scale of 20 ft. to an inch, were asked for, and a perspective view taken upon a picture-line indicated upon the block plan, in which the building should occupy about 1 ft. in length of a drawing to be 18 in. by 12 in. in pen and ink without colours, but etched or tinted in Indian ink. The geometrical drawings were to be tinted to indicate the various dormitories, day-rooms, infirmaries, kitchen and washing departments, and medical officers' rooms, and premiums of 100*l.*, 50*l.*, and four of 25*l.* each, were offered. On the 12th of April, thirty-three sets of designs were sent in, and Professor Hayter Lewis (who was retained by the Corporation) adjudicated on the designs, and after having put aside such as were exceptionally extravagant, or more especially worked out in disregard of the Commissioners' instructions, and after carefully weighing the merits and defects of the remainder, he reserved fourteen as being superior to others. Of these he returned eight for the second competition (for which additional instructions were issued), and further detailed drawings and specifications were made and sent in on the 12th of May.

In this final competition the original sketch-plans were allowed to be again submitted, with amendments, if any, made on "flies," and the plans now illustrated were treated in this way. Therefore, the one half differs from the other, the one being the amended plan shown in the final competition, the other being the plan sent in the first competition. Additional elevations and sections were drawn in detail to a scale of 8 ft. to an inch, illustrations of which are shown to a larger scale than the general drawings, and some  $\frac{1}{2}$  in. scale sections were also required showing details and the system of ventilation. Professor Hayter Lewis again examined the eight sets finally sent, and reported to the Corporation on the 22nd of June, 1882, that "after carefully reconsidering the prominent features of the several designs, I have no hesitation in recommending the design of 'Stet' for the first premium."

This design, which was prepared by Mr. R. Stark Wilkinson, A.R.I.B.A., of 14, Fumival's Inn, London, who has been appointed to carry out the same by the Corporation of Exeter, we this week illustrate, giving in fac-simile portions of the various sheets of drawings sent in. The general plans, elevation, and section have been treated by the author in the full spirit of the conditions of competition as sketches sufficient to show his intentions to a professional assessor, the larger detailed drawings being more carefully worked out for the second competition.

In his report, the author states that "the designs were prepared so as to fulfil the recommendations of the Commissioners as set forth in their published pamphlets, and with a view to the convenient placing of the executive department, of sufficient size for future accommodation, and to the proper arrangement of day-rooms and dormitories, so as to ensure facility in the overlooking and visiting of the wards by the

medical officers with the introduction of as few corridors as possible. The plans, as arranged, give all the day-rooms and dormitories the full advantage of a good south-east aspect, and are capable of extension at the ends in the same line, or by returns.

The day-rooms combine the wide corridors which, at intervals, extend into rooms having through light and ventilation, and attendants' and single rooms as required are arranged at the back of the corridor; while on the first floor, the corridor of access to the dormitories (which are placed out to the front) runs along the back wall over the single rooms. Corridors and staircases are of fireproof construction, as is the whole of the first floor. All w.c.s are entirely isolated from the wards by ventilated lobbies. The recreation-hall is placed centrally, and projecting from the front, divides the male from the female airing-courts, which are all placed in the front of the building on gently sloping ground. A covered recreation-ground is provided under the hall, advantage having been taken of a dip on the site for the formation of the same and of terraces in front of the wings. Seen in perspective, the projection of the hall will obviate the seeming depression in the centre of the principal façade.

The patients enter by separate entrances on either side of the executive block, and are passed from a reception-room into the wards by a corridor, at the end of which is a general bathroom adjoining the wards. The general excess of female over male patients is provided for in a detached building, consisting of day and attendants' rooms and dormitory, water-closet, &c., which adjoins the laundry-yard, and which would accommodate the patients employed in the laundry. A corridor (shown in the amended second plan) connects this with the kitchen departments, and can be used by quiet patients on their way to the dining-room, without passing through the acute ward.

Separate dining-rooms are shown well lighted by side windows, and conveniently placed for serving from the kitchen; but if economy is desired, the recreation-hall can be used as a common dining-room, though the author recommends that it be kept solely for recreation purposes.

Workshops for male patients are provided in the rear of their wing, and adjoining a yard and sheds, which will be planned in connexion with an existing farm and outbuildings now proposed to be incorporated for the use of the asylum.

In the basement a corridor traverses the length of the wards, in which is a small tramway for supplying the wards with coals and stores from the central executive block.

The general stores adjoin the kitchen-block, and close to them is placed the steward's office, and a goods entrance from the roadway. A Turkish bath is arranged next the bakery. The chapel is detached, and is placed near the principal entrance.

The medical superintendent's residence is also detached, and is placed to the west of the building, with a covered corridor of communication. An assistant medical officer has living-rooms on the first floor of the entrance-block.

In the amended plan for the second competition, as shown on the half-plan on the female side, the infirmaries are arranged entirely on the ground-floor, the dormitories having large day-spaces embodied for the use of infirm patients just able to leave their beds for a few hours.

In the original plan, shown on the half-plan on the male side, the infirmaries are arranged on both ground and first floors; the first-floor ward being for those patients entirely unable to go out of their room, and an isolated ward is shown adjoining the infirmary for the reception of cases which might prove contagious, and the author states it is open to discussion whether the original or the amended plan is the better. A detached mortuary for each infirmary is provided at a little distance from them, adjoining the yards.

Water-towers are provided at the ends of the executive block and of the principal wings, of sufficient height to dominate the roofs in case of fire.

The rain-water is collected and stored in underground tanks, and the drainage is kept separate and carried to sewage-irrigation tanks at the lower part of the farm.

The warming of the wards will be chiefly by open fireplaces, protected where necessary with strong wrought-iron projecting eaves.

The corridors will have hot-water coils at intervals. Toin inlet-tubes will be fixed in all

rooms. Wards and dormitories and extract-shafts will be arranged from the ceilings and upper parts of walls, carried thence by separate flues into the chimney-shafts. Certain large extract-flues will have gas-pipes burning in them.

The water and gas supply will be brought from existing mains to the asylum buildings.

It is proposed to build this asylum of red bricks, with terra-cotta dressings and green slate roofs. The elevations have been kept plain and free from useless detail, and economy of construction has been studied throughout.

The estimated cost of the whole of the buildings is 44,000*l.*; for the asylum buildings proper (as shown on the accompanying engravings), 33,711*l.*

### MONUMENT TO PARMIGIANINO.

This small but graceful monument, which has been erected by Francesco Mazzola, known by the name of Parmigianino, at Parma, and which we illustrate in our present number, has been raised in the centre of the Piazzola della Steccata. The statue of the celebrated painter stands upon a square pedestal of three tiers resting upon a plinth, and adorned by cornices and mouldings, the highest one of which serves as the base for the statue, while the lower two form a public fountain. The plinth, which is a square, measures 9 ft. 9 inches on each side. At the eastern and western faces, just above the first tier, are supported two light and elegant basins, in the form of shells, for receiving the water flowing from the mouths of two female heads, sculptured in half-relief. The other two faces bear, in similar plans, the following inscriptions:—the north side, "Il comune eresse"; the south side, "Contribu alla spesa l'Ord. Costantiniano." The arms of the municipality of Parma are sculptured upon the eastern face of the pedestal; those of the Order Costantiniano di San Giorgio, who contributed towards the erection of the monument, on the western face. Upon the northern side of the pedestal is carved the inscription, "Al Parmigianino"; upon the southern, MDCCCLXXIX.

The statue of Parmigianino, 7 ft. 3 in. high, rises from the pedestal at an elevation of 12 ft. 6 in. from the base. The figure of the painter is in the attitude in which we illustrate it. The left foot rests on the step of a kneeling-stool (known in Italy by the name of *genuflessorio*), upon the outer face of which is sculptured the winged head of an angel. The painter holds in his right hand a brush, in his left the palette; the latter arm rests upon the top of the kneeling-stool. He is dressed in the costume of his time (Mazzola was born 1503, and died 1540),—long stockings, under-waistcoat, and wide and long robe (*zimarra*). The expression of the face is reproduced with great fidelity in our illustration. The design of the monument is by Professor Giovanni Cherici, a Parnese sculptor. The monument is in Carrara marble and granite, the latter being chiefly employed for the fountain arrangement. The cost of its erection was ridiculously low, only 9,000 lire (300*l.*); but this is explained by the fact that the marble was gratuitously supplied by the Accademia di Belle Arti di Parma, with the exception, however, of that for the statue, which was provided by the sculptor at his own expense.

### LEEDS ARCHITECTURAL SOCIETY.

On Saturday afternoon last the visit of the society was to Halifax. The party were met at the station by Mr. John Leeming, of the firm of Leeming & Leeming, architects, &c., Halifax, and conducted over the principal parts of the town.

Amongst the buildings visited were the parish church, recently restored by the Messrs. Scott at a cost of about 20,000*l.*; Square-road Congregational Chapel, recently restored by Messrs. Leeming; the Higher Board School, Prescott-street, erected at a cost of about 6,000*l.*, from plans by Mr. R. Horsfall, of Halifax; Heath Grammar School, erected at a cost of about 10,000*l.*, by Messrs. Leeming; Haugh Shaw Board School, also by Messrs. Leeming, and which cost about 6,800*l.*

The town-hall was the last building visited, when the opportunity was taken on the part of the visitors to express their thanks to Mr. Leeming. It is the intention of the society to again visit Halifax, as many buildings were necessarily left unseen, owing to the shortness of the visit.

## NEW SCHOOLS AT ST. ALBAN'S.

THE new school buildings erected by the School Board here are now in use; they afford accommodation for 250 boys and 300 girls and infants. The new boys' school is in the Hatfield-road, and is about 60 ft. north of the old school belonging to St. Peter's parish, which was handed over to the School Board when the latter was formed. A playground extends on the north of the new structure up to St. Peter's Churchyard,—the average size of this ground being 110 ft. by 130 ft. The plan of the school is so arranged that accommodation for an additional 100 children (making 350 in all) can be provided at a future time without disturbing the present buildings to any extent. The site not being a prominent one, the architects were instructed to make the building of good outline, but very simple in detail. The walls externally are faced with a greyish-coloured brick obtained from Peppercrook; the roofs are covered with red plain tiles. A shelter-porch, under which the children may assemble before school-hours in bad weather, gives access to the school-porch, from which the schoolroom and the class-rooms are reached. The schoolroom is 62 ft. by 22 ft., 14 ft. high at the eaves, and about 20 ft. from the centre. There are also large recesses for cupboards, &c. This room will accommodate 130 children. The principal lighting is by a range of windows in the north wall, and there are also windows to the east and south. This arrangement, by which the principal lighting is derived from the north, applies to the main rooms in all the three schools. Each class-room is intended for sixty children, and is 29 ft. 4 in. by 22 ft., and of the same height as the schoolroom. The entrance to the building can be reached from each of the rooms without it being necessary to pass through any other room. The cloak-room and lavatory are sufficiently large to provide for the total number of 350. Wood-block floors, laid herringbone-wise, have been used for the school and class rooms of all the schools, both for upper and lower floors. In the upper floors the blocks are 20 in. long, so as to suit the joists, and bedded on dry pugging and fine sand. On the lower floors they are laid on cement concrete, finished with a floated face of cement. The latrines consist of six water-closets for the boys and one for the master, and a range of urinals with ribbed slab slate channels, foot paces, divisions, and wall linings. The closets have louvres in the front enclosures, and are covered with skylights, and in them Messrs. Bowes Scott & Read's patents have been applied,—the glazed earthenware tubes being jointed with Stanford's patent joints. Flushing is arranged for by means of Field's self-acting annular syphon, each flush being 100 gallons. None of the floors in the school and class rooms are graded, but the desks are of different heights. The "Invincible" school-desks, made by Messrs. Philip, of Atlas Works, Liverpool, have been used in this school.

A site on the west side of the Alma-road was purchased in order to erect schools for girls and infants, much wanted in the large neighbourhood which has grown up between the Marlborough-road and Midland Railway Station. As the surface of the ground was considerably below the level of the Alma-road, the infants' school was put at the lower level and a girls' school over it. Both the playgrounds are reached by sloping ways, so that there are no external steps. The houses in the Alma-road are of a good class, and the Board, therefore, directed that a good-looking building should be erected, which would be an ornament to the neighbourhood. Box-ground Bath stone has been used for stone sills, mullions, and lintels to the windows. There are also moulded stone string-courses, water-tables, &c. The bricks are of a dull red. Plain tiles cover the roof, with barge tiles and finials. The playground for infants, in the northern portion of the site, is about 35 ft. by 100 ft. At the west end of the building is a play-shed for infants, 20 ft. by 22 ft., which will also serve as a shelter-porch. The schoolroom for infants is 44 ft. by 19 ft., and 14 ft. high. It is fitted with a gallery of raised seats at the west end, providing accommodation for sixty children; there are also desks for the elder children. South of the schoolroom is a babies' room, 17 ft. by 18 ft. On the upper floor is the girls' school, the schoolroom being 68 ft. by 19 ft. 9 in. There are also large recesses for cupboards, desks, &c. It is 14 ft. high at the eaves and 19 ft. in the centre. The class-room is on the south of the schoolroom, over

the babies' room. This school is reached from the playground level by a stone staircase constructed in the most approved manner with short flights between the flights. The girls' playground is on the south of the buildings, and is about 40 ft. by 120 ft. It is reached from the Alma-road by an inclined path. The sanitary arrangements of these schools are especially adapted to their requirements, but are in principle much the same as those in the Hatfield-road school.

The heating in all the schools and class-rooms is by Shorland's Manchester grates. Fresh air is also supplied to the rooms by what are known as Tobin's ventilators, fitted with perforated zinc, and with valves and lids for regulating and shutting off the supply. The spaces above the collars of the roofs form ventilating chambers. There are also extraction-flues in the chimneys, Boyd's iron flue plates being built in next the smoke-flues. All the rooms, staircases, &c., are lighted with gas.

The accepted tender for the Hatfield-road school amounted to 2,210*l.*, and that for the Alma-road school to 2,483*l.* The Board, however, have incurred further outlay in order to secure greater perfection in regard to the heating, ventilating, and sanitary arrangements, &c. There have besides been the fittings to provide for.

The contractor for the Hatfield-road School is Mr. D. Ireson, of Waterloo, Northampton, his representative on the works being Mr. F. W. Austen, and the foreman Mr. Samuel Bayes. For the Alma-road School the contract of Mr. C. Miskin, of St. Alban's, was accepted, his foreman on the works being Mr. Henry Hilliard. All the buildings have been designed and superintended by Messrs. John & S. Flint Clarkson, of London and St. Alban's, the architects to the School Board.

## EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY ARCHITECTURAL COMPETITION.

QUESTIONS open to serious consideration relating to the above competition resolve themselves into grave and complicated difficulties, some of which cannot too soon be made public to restore the confidence to so many able and generous minds who have placed a host of wealth and genius into the hands of the committee of management in good faith that justice and merit would be the reward.

The conditions given, or rather sold, out to the competitors or those who desired to take up the invitation, were clear and pointed in their requirements, with certain equally clear and prominent stipulations as to the way such drawings were to be prepared and to be received in competition; with equally precise and strict points which should disqualify any transgressions being made or attempted. Such being the case, no doubts could exist in the intentions put forth to regulate the order and comparative character of the works when submitted.

Any one acquainted with the conditions could not fail observing at the first glance into the convenient rooms and looking at the magnitude of drawings sent in and exhibited, that a grave breach of faith had crept into them,—I allude to the colours on the plans and sections as violating the conditions which alone should disqualify those who took such liberties.

The conditions state:—"The geometrical elevations to be without colour or shading of any kind, except a flat tint of Indian ink to the door and window openings, and on the roofs if desired. *The walls, &c., of plans and sections to be shown in Indian ink.*"

The words italicised, in justice to the many competitors who sent in untinted plans, should be a safeguard that they alone could be dealt with in the competition. See 7th section, schedule B, of the conditions. The above is clear and decisive, and should be a protection, not a snare; for there cannot be the slightest doubt a plan deftly tinted puts those not tinted at a discount, and, though equally worthy, they do not get so carefully looked into, nor are they so readily impressed upon the minds of others. This should have been so treated by the assessor beyond a doubt, or otherwise his judgment is null and void.

The competitors may have been advised that such liberties would be allowed, but in the name

of love of justice, with such conditions in print, who has the power to say ay or nay to such a privilege without the full knowledge of all concerned? They have acted, presumably, upon the slender, though courted, compliance, for I cannot believe any one would run the risk on his own responsibility. By such acts they rightly deserve exclusion for taking such advantage, well knowing it must be to their gain and attraction if passed over. I venture to think the faithful ones should have the protection which I hope it is not too late to give.

I will next refer to the premiated designs 1, 2 and 3, all of which should lie out of the competition for "violation of conditions" on the first ground alone, but I will go further as to their merits, looking into their fitness for such an institution, and I am sure it will be clearly seen that the assessor must have treated the conditions as waste paper, and overlooked the special requirements of a hospital for sick and infirm patients. All of the three premiated designs have the out-patients' department in the basement. As one accustomed to hospital work for twenty years, I know such an arrangement is fatal to any proper working of such a department. What proportion of patients are able and fitted to go up and down stairs? It is as much as many can do to crawl, if I may use the expression, and many others have to be supported or carried.

Another defect in No. 1. The children's wards have no water-closets but by crossing a wide main corridor, leaving their wards, of course, and thus being exposed. There are only two bath-rooms on each floor, and those very small, to accommodate thirty-eight patients, mixed together,—that is, adults, children, and dirty cases; this should be enough to condemn the plans at once. The wards are fairly well arranged, but at the sacrifice of the working part.

There are but two nurses' rooms to six wards, one on each side, which have to serve all purposes,—quite insufficient. There are some good points in the plan, but had are sufficient to condemn it.

Premium No. 2 goes to a very industrious aspirant, who actually sends in no less than three complete sets of designs, all tinted, but without much else to recommend them, as they contain a mixture of bad points. The rise of the ground 19 ft. appears to have been forgotten, and not seen, as there are numerous windows on the ground-floor opening into earth, from which there is no possible chance of gaining any light, as the ground would be 5 ft. above the first-floor level. Where was the assessor? Could he have been prompted by charity at others' expense? The areas at the back are all close and confined, making, as it were, dark wells for the admission of light and air. The kitchen arrangements are absurdly small. The *post-mortem* and dead house are placed in the front, next to White Rock-place, exposed to the full sun and public gaze, and obliging all bodies to be conveyed into and through the basement. The arrangement of wards is incomplete, having no water-closets connected with them, and only four to thirty-nine patients, without any separation, except the sexes, for each ward and children, and to get to them the patients must leave their wards, cross main corridors, and then have some distance to traverse before they reach them. This is most painful to contemplate, and more so when it is qualified with the second premium. The baths are equally small, two to thirty-nine patients, all mixed,—that is, for general use to adults, children, dirty, and contagious cases. Nurses' rooms,—small and inconvenient, I think,—one to four wards. Staircases poor and cramped.

Premium No. 3.—The out-patients' department is in the basement; the patients have to get down stairs, and after treatment perambulate a circuitous route upstairs into the hospital for medicines. This is a violation; the "out-patients were not to enter the main building," it could never work, as not eight patients if ten could do it. Wards, baths, and water-closets are badly arranged. Dark corridors ventilated through water-closet,—jobs at each end. *Post-mortem* in the basement, and a very dark approach. This plan is a shade better than Premium No. 2, but has much the same character of faults.

Finally, their cost, which must not exceed stipulated sum more than 10 per cent.—a very ready test, you will say, and I to that agree.

First premium estimate, 25,000*l.*: a modest sum, considering that at 9*d.* per foot cube, fo

which possibly it might be built, but not for less.

Second and third premiums, both very low, 15,000l. and 17,000l. thereabouts: a startling difference, even with the 10 per cent added, and the buildings themselves are more pretentious than in the first design, and certainly quite as expensive.

All these points, faulty and unjust as they are, are combined in the three premiated designs. What about the others?

They comprise a wealth of ingenuity not met with in the foregoing, though I regret that many, which have some excellent points, utterly fail in making a building fit for sickness and infirmities. I, however, believe there are some few most worthy designs to choose from, and which will be found nearly approaching the name of the conditions, and should not be overlooked. I allude to untried plans of the highest merit, embodying most of the best features of a modern hospital.

I will not venture to direct attention to these, for if the conditions are regarded they can be readily seen; but merely for the love of fair play and justice to those who are so unfortunately to be shifted, but not beaten, I make known the facts, in the hope that it will be followed by restriction of rights to those more worthy.

FAIR PLAY.

THE NICHOLSON INSTITUTE, LEEK.

The site of this building, which is quite central, lies upon the north side of Stockwell-street, and comprises a ground area of more than 10,000 ft. including the space occupied by an interesting stone house of the seventeenth century, which it was fortunately found possible to retain without detriment to the convenience and utility of the new edifice.

A quadrangle is thus formed between the edifice and the street, in which the hum and rattle of the outer world will lose the track of the tormented student seeking sanctuary in the Institute. This space may receive, too, such treasures of hoary vestiges and wrecks and waifs of time as cannot well be offered "logement à pied on à cheval." By taking down a portion of an adjoining modern block of buildings ground is obtained for a spacious entrance with foot and carriage gates of wrought iron, supported by massive stone piers.

The plans of the Nicholson Institute promise a building of a severe Classic Renaissance character. The materials adopted by the architects are thin hard-fired local bricks and red Roche and Aston stone, with brown Broseley tiling upon the roofs. All the floors will be of wrought-iron girders and cement concrete (covered with wood block paving), quite impervious to fire, noise, or other risks.

The leading feature of the principal front, which faces south into the quadrangle, is the tower, containing the portico and staircase, and rising to a height of 100 ft. from the street. Its domed roof will be entirely covered with copper. In the upper stage it has large oval windows, enclosed by carved pilasters and swags of foliage, and the lower stage is filled by the richly-carved entrance-doorcase and the pedimented window upon it, together 40 ft. high. To the left of this front we have the main gable, 70 ft. high, curved in outline, and with a carved pediment, in harmony with the tower decorations, flanked by two small turrets, terminating in stone domes. At the foot of this gable is the large bay-window of the committee-room and rooms beneath. The remainder of this façade, between the tower and the gable, contains large windows lighting the hall, &c., and bearing upon four large medallions under a carved pediment the effigies of eminent writers or painters. The eaves are finished by an open balustrade surmounted by urns.

The windows are of ample size, transomed and mullioned, and glazed with clear glass in lead quarries. The other fronts are simply treated to follow the general lines of the south front.

Internally the building has three floors, the central one being some 9 ft. above the street; the ascent is made partly by steps and partly in the incline of the approach.

On the lower floor is placed the school-of-art accommodation, entered separately from the east side; also the library basement and the stoker's, storage, lavatories, &c. Sloping north lights are secured for the art class-rooms.

The central floor comprises the entrance-hall, &c., reading and news rooms and committee-room, and the library, which runs up through both stories, and is lighted entirely by a large domed glass roof. The manifest advantages of this position for the library are that none but the attendants have actual access to the book-shelves and presses, which are carried upon open iron galleries round this lofty room; the attendants' and readers' respective occupations do not clash; and the books themselves are isolated and preserved from the damage caused by the vitiated air which must accumulate near ceilings before it can be drawn off by ventilation. Mr. Conell (the Liverpool librarian) stated at the annual meeting last week of the Library Association that "the money value of replacing bindings of books,—attributable to the effects of gas,—was enormous." The library, with its contents, can be fully seen from the other portions of the building through lofty openings, fitted with glazed screens.

On the upper floor are the picture-galleries and museum, with landing and cloak-room. The major picture-gallery is to have a platform for chamber concerts or lectures, upon which occasions chairs will be sent up to the room from the storage by a lift. All this floor will be lighted by clearstories at a suitable height, to obviate any danger of glare on the pictures from the incidence of the light, this method of lighting being regarded as more comfortable and substantial in appearance than the glass sheds roofs frequently make use of.

The following is a list of the accommodation and its extent:—

	Width.	Length.	Height.	Area.
Large picture-gallery	25 ft.	66 ft.	32 ft.	1,650 ft.
Two smaller galleries	16 ft.	19 ft.	22 ft.	698 ft.
Museum, &c.	25 ft.	56 ft.	32 ft.	1,490 ft.
Reading-room	25 ft.	50 ft.	15 ft.	1,250 ft.
Newsroom	25 ft.	20 ft.	15 ft.	750 ft.
Library	20 ft.	40 ft.	45 ft.	800 ft.
Committee-room	18 ft.	23 ft.	15 ft.	450 ft.
Hall	17 ft.	52 ft.	15 ft.	881 ft.
Elementary art school	25 ft.	37 ft.	13 ft.	925 ft.
Second ditto and master's stores	20 ft.	37 ft.	13 ft.	710 ft.
Advanced art school	24 ft.	23 ft.	13 ft.	690 ft.
Entrances, lavatories, library basement, storage, &c.				2,900 ft.
Total super.				11,707 ft.

The works are being carried out to the plans, &c., of Messrs. W. Sugden & Son, architects, of Leek, and under their superintendence, by Messrs. Inskip, builders, Longton; Mr. Philips, plumber, Leek; and Messrs. Haden, engineers, Manchester.

The amount of Messrs. Inskip and Philips' contracts (exclusive of cost of site, heating, and ventilation, and all fittings) is 8,633l.

RESTORATION OF THE MANOR HOUSE, EVERLEIGH, WILTS.

THE Manor House, Everleigh, the ancestral home of the Dugdale Astleys, and traditionally a residence of the old Saxon King Ina, whose hunting-lodge is said to have stood near the Sidbury encampment, was totally destroyed by fire at Christmas last. Fortunately the billiard-room, ballroom, orangery, conservatory, and an extensive range of servants' offices and stables were saved, although considerably damaged. This mansion (for the original Manor House is now a comfortable hostelry and hunting quarters) is supposed to have been built by Sir Ralph Sadler, to whom the lordship was granted by Henry VIII. Sir Ralph was afterwards falconer to Queen Elizabeth. His portrait and all the family pictures, with one exception, were preserved, and will have a place in the new building. The old drawing-room,—a handsome and spacious chamber, with carved oak panelling, and a decorated ceiling in the style of the period,—was totally destroyed. The romantic and picturesque surroundings of the house, which nestles in a well-sheltered and secluded spot in the vicinity of Stonehenge, Tedworth, and Savernake Forest, invest the place with charms which but few possess.

The work of restoration was commenced in February last. The new building presents a façade of about 110 ft. by 56 ft. in depth. The reception-rooms, which are all on the ground-floor, are spacious and conveniently placed on each side of a corridor, 8 ft. wide, extending the full length of the building, and comprise dining-room, large and small drawing-rooms, library, morning-room, study, business-room, lavatory and gentlemen's water-closet, house-keeper's-room, butler's pantry, back stairs,

brushing-room, lamp-room, &c. The entrance-hall is in the centre of the façade; it is entered from a portico, having an inner lobby and screen, and is shut off from the corridor by an elliptic-heated screen, in three bays, the side bays being filled with panelled and moulded framing to agree with that in the hall. The principal staircase, which is of oak, having a panelled oak dado and soffits, with carved and moulded newels, is in the rear of the entrance-hall. The hall is open to the roof, is finished with a richly-panelled and coved ceiling, and is lighted from the roof, in addition to windows on the landings. The principal rooms, corridor, and staircase have panelled and moulded dados, and the large bay windows in the dining and drawing rooms are finished with pilasters and panelled and moulded elliptic arches. The chimney-pieces are specially designed, those for the principal rooms being of an elaborate character, and the ornamental ceilings of these rooms are being executed in fibrous plaster by Messrs. Jackson. The family and guests' bed-rooms, bath-rooms, water-closets, housemaids' closets, upper servants' rooms, &c., are on the first-floor, and the bachelors' bed-rooms are placed in the attics. The works have been carried out with great energy and despatch by Mr. Stanley G. Bird, of Upper George-street, Edgware-road, under the direction of Mr. John Birch, architect, of John-street, Adelphi.

UNIVERSITY COLLEGE, BRISTOL.

WE would direct the attention of our readers to the prospectus of this college, which has been published in our advertising columns. It will be seen that, like the similar colleges at Manchester, Leeds, Birmingham, &c., the lectures comprise all the branches of a liberal and scientific education. The erection of new buildings, which will be completed before the close of the current year, will give increased facilities for the study of science. The chemical department now contains accommodation for nearly fifty students, and is thoroughly equipped with the latest improvements for teaching which are in use in this country or on the Continent. Lectures are delivered on pure chemistry, as well as on certain branches of applied chemistry. The physical and engineering departments are also provided with facilities for laboratory work. A special feature of the engineering department is the arrangement by which students attending lectures at the college during the six winter months are enabled to gain practical experience during the summer months, when they work as pupils in the offices and workshops of leading engineering firms in the neighbourhood. The instruction in experimental physics is kept abreast of the rapidly-increasing requirements of the age, and arrangements are now perfected for the thorough training of students as electric engineers,—a profession for which the recent development of electric discovery opens good prospects.

CASES UNDER BUILDING ACT.

FLUES.

AT Hammersmith, Frederick Davis, a bellhanger, was summoned by Mr. Knightley, the District Surveyor of Hammersmith, for cutting away a portion of a flue contrary to the rules of the Building Act. Mr. Knightley said that on the 25th ult. he went to Bute House, Brook-green, and found, on removing the skirting-board near the chimney-pieces, that a vertical chase had been cut in the plaster to admit the tube for the wire for the bell. It was a very important matter, as he found that workmen often destroyed the plaster and so endangered the safety of the fabric. He would be satisfied with a nominal penalty, in order to show workmen that it could not be done with impunity. In the present case the external "rendering" or plastering had been cut down to the brickwork, which was left exposed. In the event of the sweep's brush, passing through the flue and rubbing off the mortar, the brass would be endangered. The defendant denied interfering with the plaster, and said it was all right when he left it.

Mr. T. Chamberlain, the builder, was called by the defendant, and he stated that Mr. Knightley was correct to a certain extent, but he submitted that the Act did not apply to the case, and that he ought to have proceeded in another way.

Mr. Knightley referred to the rules, and contended that the act done amounted to the cutting away of a portion of the flue, which the Act prohibited. Mr. Paset thought the Act did apply, and fined the defendant 5s., with 2s. costs.

Salford	94.3	111.4	82.4	101.8	100.8	104.8	116.5	98.5	99.0	97.6	102.3	82.6	100.9	99.1	11.8
Sheffield	106.2	113.3	104.2	103.0	107.3	89.4	87.0	82.2	106.2	91.4	91.4	84.4	105.5	94.5	11.0

Sir.—In reference to the recent discussion as to the death-rate of certain English towns, I was led to calculate the above table.

The mean death-rate of each town by itself for the whole period is put equal to 100, and the yearly death-rate then calculated as a percentage on that basis.

The table would, therefore, read thus:—In 1870 the Birmingham rate was 97 per cent. of the twelve years' mean, but next year it rose to 105.5 per cent., falling again in 1873 to about the rate of 1870. At the end of the table the years are grouped in two periods of six years each, and we find, taking the average of the first period, the Birmingham rate was exactly the same as it had been in 1873; when the second period is, however, taken, the average of the six years is less than at any time during the first period. The difference between the two periods is expressed in the last column, showing that the rate has been reduced in every case; and the amount, however, varying considerably, the basis of calculation being throughout the twelve years' mean of each town by itself.

The population of these towns varies so much, and with regard to Manchester an actual decrease has taken place in the time covered by the table, that in the following table the population of the smallest town and its "difference" are each put equal to 100, and the others reckoned as percentages:—

	Population.		Improvement.
	1871.	1881.	
Birmingham	371.8	371.9	118.6
Brighton	100.0	100.0	100.0
Liverpool	423.8	513.6	116.3
Manchester	379.8	317.6	85.0
Salford	155.0	167.1	20.9
Sheffield	259.5	264.5	127.9

Thus we see that Liverpool, though containing more than five times the population of Brighton, shows a rate of improvement somewhat higher, and not much less than six times the rate of improvement in Salford.

OWEN ROE.

COMPETITIONS.

**Walsall Public Buildings, Blonwick.**—At a meeting of the Walsall Town Council on the 4th inst., out of the plans submitted by four architects for the proposed public buildings at Blonwick, comprising police-station, reading-room, and stabling and cart-sheds for the sanitary department, the General Purposes Committee submitted for the decision of the council those prepared by Mr. S. Loxton and Mr. F. E. F. Bailey respectively, each set being within the settled cost of 1,200l. Alderman Lindop proposed, and Councillor Beechey seconded, the adoption of Mr. Loxton's plans. Alderman Brewer expressed his preference for Mr. Bailey's, but declined to move an amendment, and eventually the proposition was carried, ten members voting in its favour.

**The Wallace and Bruce Memorial, Edinburgh.**—The members of the Treasurer's Sub-Committee on Properties, of the Edinburgh Town Council, met on the 8th inst., in the Waverley market, for the purpose of inspecting a number of competitive designs for the memorial to Wallace and Bruce, proposed to be erected with a sum of money bequeathed to the Corporation by the late Captain Hugh Reid for the purpose. Captain Reid's will (according to the *Scotsman*) provided that 1,000l. should be placed at interest in the Royal Bank of Scotland, which interest was to be paid to the testator's widow during her lifetime, after which the principal and interest should accumulate as a fund for twenty-five years, to assist in erecting some memorial to the two national heroes. The will further suggested that the monument should take the shape of "an ornamental piece of water in the North Loch, with a fountain in the centre, and colossal statues in bronze of each

hero in conference." The stipulated twenty-five years posterior to Mrs. Reid's death having elapsed, the Corporation intimated that they desired to receive, in open competition, designs of the figures for the memorial, and among the conditions imposed on the competitors were the following:—That the sum to be allowed for the completed work shall be 2,000l.; that the competitors whose designs are second and third in order of merit shall receive, out of the city's common good, premiums of 30l. and 15l. respectively; but in the event of no design being accepted, no premium will be awarded; that the figures of the memorial shall be colossal, not less than 12 ft. in height, and that those in the competitive models shall be of the uniform height of 3 ft.; and that, while following generally the indications given by Captain Hugh Reid as to the site and character of the memorial, the treatment of the designs in detail, as well as the suggestion of the most suitable site within the locality indicated by the terms of the bequest, shall be left to the discretion of the competitors. Seven sets of figures have been put forward for competition, and, while varying considerably in style and in merit, the majority are creditable pieces of sculpture. In most cases the warriors are represented as clad in mail and armed, the Knight of Elderslie with his famous double-handed sword, and his comrade with the short battle-axe wielded with such deadly effect against the English knight at Bannockburn. Meanwhile, the names of the respective artists have not been disclosed, the models being merely distinguished by numbers and notices. After the committee had inspected the designs, it was decided to adjourn the meeting without coming to a decision, and to invite the members of the Council to make an inspection and express an opinion regarding the merit of the several designs.

**The West Cumberland Liberal Association, Workington Branch.**—The committee having advertised for plans for buildings comprising a large hall to seat 2,500 people, a club-house, a post-office, shop, and offices, the designs sent in by Mr. T. Lewis Banks, of 23, Finsbury-circus, London, and Whitehaven, have been selected.

STONE-DRESSING BY STEAM POWER.

ACCORDING to the *Daugetwerkszeitung*, the use of facing stones of terra-cotta will, in future, experience the competition of natural stone dressed by steam power. The new invention of Herr Schmidt has apparently been proved by trials to combine simplicity of mechanical arrangement with economical and rapid working. Former attempts in this direction have been based on the idea of imitating stone-dressing by hand, and the machinery has been devised for the purpose of producing a smooth surface by the removal of all uneven portions; but Herr Schmidt has worked on a different plan. He has applied the principle of a saw with as great a power as can be obtained, to the production, at the same time, of two surfaces ready for use. The inventor seems to have been, to some extent, influenced by the stone-boring machine, which was the means of accomplishing the gigantic tunnelling works of St. Gotthard and Mont Cenis. He seems to have reasoned, that by the judicious application of the principle of this machine it ought to be a matter of no insuperable difficulty to produce a stone-dressing machine able to supersede manual labour.

A provisional machine, of limited size, was constructed, in which a small steam cylinder imparted a vertical striking motion to a pair of steel chisels of equal width. A stream of water was used in conjunction with this appliance, and as the chisels penetrated the block of stone, two regular and even surfaces were produced. This trial was made with the hardest syenite granite.

An ordinary stone-dresser, working with a

hand saw, can produce in a day of eleven hours, according to the journal named:—

Square feet of cut surface.
4.30 to 6.45 in sandstone.
1.82 to 2.15 in marble.
0.21 to 0.32 in granite.

The smallest machine on Herr Schmidt's principle, with one small steam cylinder, can produce in the same time 43 to 65 square feet of cut surface of granite, and, therefore, represents the daily labour of 200 workmen. It is the same thing to the machine whether hard granite or soft sandstone is given to it to cut, but the quantity of work done varies, of course, according to the hardness of the material. The machine is, therefore, a reliable test of the exact comparative hardness of various descriptions of stone.

The piston only requires a limited stroke of 1 1/2 in. to 2 in., and gives about 1,000 blows per minute without the chisels heating, as a continuous stream of water serves the double purpose of keeping them cool and of carrying away the minute particles of stone, &c., which are constantly accumulating. This is a considerable gain to the workmen from a sanitary point of view, as there is no stone dust thrown off. There is provision made for the stone dust being deposited by the water which flows away, in such a manner that it can be easily removed. It is used in the ceramic industry, and is, therefore, of some value.

The inventor delayed bringing his machine in a prominent manner before the industrial public until it had been subjected to the most difficult tests.

SEWERAGE AND DRAINAGE WORKS.

**Nottingham.**—At the meeting of the Nottingham Town Council on the 4th inst., the Beck Valley Sewer Joint Committee reported to the council as to the scheme for dealing with the storm waters in the Beck Valley district as follows:—The committee report that, pursuant to the order of the Town Council made on the 3rd day of April, 1882, they have again seriously considered the question of providing for the carrying away of the storm waters in the above district. The committee having had before them the particulars of the rainfalls which have occurred during the past summer, are compelled to come to the conclusion that some scheme for dealing with the floods should be carried out without further delay. Your committee refer to the council their previous report on this matter, dated March 1st, 1882, in which it was stated that a scheme for dealing with 1 in. of rainfall per hour would cost about 32,000l., and that a scheme for dealing with 2.8 in. per hour would necessitate an additional outlay of 9,000l. Considering that by the expenditure of the extra 9,000l. nearly three times the amount of rainfall would be carried off, your committee feel bound to recommend the council to carry out the scheme capable of dealing with the largest recorded rainfall of the district, which is estimated to cost about 41,000l. During the illness of the borough engineer, your committee called in the advice of Mr. Tarbotton, and asked him to report generally on the whole scheme. He has reported to your committee, and has also made a thorough inspection of the line of route in company with the borough engineer. Your committee, having fully considered the matter, recommend the council to adopt the scheme drawn up by the borough engineer, the plans of which are now laid before the council, and that your committee be authorised to carry out such scheme at a cost of 41,000l. The report was adopted.

**Burton-on-Trent.**—At a meeting of the Burton Town Council on the 6th inst., the Highway and Sowers Committee recommended that giving of notices to treat for the land schedule in the provisional order for the works of sewage disposal be deferred for the present, and that Mr. E. Daniels, of Needwood-street, should be appointed clerk of works in respect of the construction of the engines, boilers, &c., for the sewage works. In moving the adoption of the report, the Mayor referred to the question of the drainage of Stapenhill and Winhill. The matter had not been neglected since the last meeting, but the committee had given it consideration, and had devoted considerable time to the inspection of the most difficult places. As to the lands required for sewage works, the committee recommended that the Estates and General Purposes Committee should proceed

with the purchase of the 300 acres for which they obtained an Act of Parliament, and that the purchase of the additional land for which they obtained a provisional order should stand over for a time. From a letter which they had received from Mr. Mansergh, the engineer, it appeared that 300 acres would be as much as could deal with for some time, and they thought it was desirable they should wait to see how things turned out before they proceeded further. Alderman Wardlo said he could not vote in favour of the report as it stood with reference to the taking of land for sewage works. The committee had come to the determination that some 450 acres (he forgot the exact figures) were absolutely necessary for the work, and he argued that it would be more economical to secure the whole of that area at once. The report was, however, agreed to.

**Shirley (near Southampton).**—At the meeting of the Shirley and Freemantle Local Board of Health, on the 6th inst., a letter was read stating that Lady Mill would not sell the land required by the Board for the proposed sewerage works in any terms, and that every means would be taken to oppose the acquisition. The chairman (Major-General Lewis) said the only way, then, to get possession of the land was by exercising compulsory powers. They could not do anything until they had plans of the proposed works laid until the scheme was sanctioned by the Local Government Board, and then they could take the necessary steps to get possession of the land. Subsequently the Chairman stated that Dr. Sampson and himself, who were appointed a deputation to Hertford, to see the sewage works, went there on the 19th ult., and they had drawn up a report which had been submitted to the Sewage Scheme Committee. He might mention that they were of opinion that the process in use there was an efficient one, the chemical agents being crude sulphate of alumina, oppera, and lime. Whether the system would be adapted to the Shirley and Freemantle district would be dependent upon the cost at which these materials could be procured. With Mr. Sampson, he (the chairman) was of opinion, indeed they could procure them at a reasonable cost, and they would require at Shirley a lower degree of purity than at Hertford, at least the process would suit the Board very well. On the proposition of Mr. Stewart, seconded by Mr. Inder, it was decided to leave the matter in the hands of the Sewage Committee to find out the cost of the alumina, and to get the Engineer to the Rivers Purification Association to report on the subject.

**BUILDING PATENT RECORD.\***

**APPLICATIONS FOR LETTERS PATENT.**

- 4,219. J. B. Shaw, Tunstall. Decorating bricks, &c. Sept. 5, 1882.
- 4,232. J. Hudson, Bolton. Apparatus for holding and releasing cords for venetian blinds, &c. Sept. 6, 1882.

**NOTICES TO PROCEED**

have been given by the following applicants on the dates named:—

- Sept. 5, 1882.
- 2,097. R. Guelton, Brighton. Producing artificial marbles, &c. May 4, 1882.
- 2,120. W. McGill, London. Urinals, &c. May 5, 1882.
- Sept. 8, 1882.
- 2,121. T. W. Holliswell, Brighouse. Water-proof basins and means of flushing the same. May 5, 1882.
- 2,209. L. J. J. Kolly, London, and C. B.indsay, Blackheath. Graining and ornamenting surfaces. May 10, 1882.
- 3,614. T. Hyatt, London. Illuminating stings, &c. July 31, 1882.

**ABRIDGMENTS OF SPECIFICATIONS.**

Published during the Week ending Sept. 9, 1882.

- 424. M. Ingram, Manchester. Apparatus for preventing waste of water from lavatories and fhs. Jan. 27, 1882. Price 2d.
- A three-way tap is used on the water-supply pipe, which fills a receiver of the required size, and when the tap is turned to fill the bath, &c., no more water will enter the cistern. (Pro. Pro.)
- 437. J. Inray, London. Effecting fireproof partition of the stage and proscenium in theatres. (Com. by K. Pfaff, Vienna.) Jan. 1, 1882. Price 4d.

Compiled by Hart & Co., Patent Agents, 28, Newgate-street.

The curtain consists of horizontal strips of sheet iron bent to a curved shape, the concave sides of which are towards the proscenium. These are riveted together, and the lateral edges are supported by vertical bands. This curtain travels in a wide groove. (Pro. Pro.)

468. F. Wilkins, London. Apparatus for sustaining sliding window-sashes, &c. Jan. 31, 1882. Price 2d.

In each side of the frame is a recess, in which is pivoted a tongue-piece kept projecting towards the sash by an india-rubber pad. Above this is a roller which, when the sash commences to fall, jams in between the tongue and the side of the sash, which is thereby sustained. (Pro. Pro.)

469. J. Parkinson, Caton. Boilers and furnaces for heating greenhouses, &c. Jan. 31, 1882. Price 6d.

These have water-spaces all round, both sides, front, back, and top. Above the crown of the fire-box are three arched water-shelves alternately connected to the front and back water spaces, so that the products of combustion pass backwards and forwards between them on their way to the chimney. The flow-pipe passes vertically through and communicates with the centre of each of these water spaces.

482. E. R. Wethered, Woolwich. Latches and locks. Jan. 31, 1882. Price 6d.

A weighted lever handle is used to project the bolt forward. A notch is formed in the bolt, in which a stud engages when the bolt is withdrawn, and when the door is shut the fore-end of the bolt is lifted by an incline on the sticking-plate, which forces it of this stud, and the handle presses forward the bolt.

544. G. Otway, Brixton. Apparatus for cutting or dividing bricks, tiles, or slabs from plastic clay. Feb. 4, 1882. Price 8d.

The stream of clay is cut as it passes on to the cutting-table into the exact lengths required to form a certain number of bricks. This is effected by a rack with two number of teeth, to which the pusher is attached, which slides in a pair of parallel guides. The rack is set to the required length, and pushes the required quantity of clay beneath the cutting-table.

2,302. J. Mitchell, Paris. Manufacture of decorative transparencies for windows, &c. May 16, 1882. Price 2d.

These are made of thin sheet gelatine of different colours. The several pieces are joined together by strips of dark coloured paper attached thereto by glue, &c.

**"WHAT IS PROPORTION?"**

Sir,—It is essential in discussions of this kind that the words used should have a precise value, a definite meaning. When it is said that a work is proportioned, it is meant that it is well "proportioned"; but the word "proportioned," connoted with the prefix badly, is also applied to the unsymmetrical both in nature and in art. "Symmetrical" is probably the word which ought to be used for the aesthetically or beautifully proportioned; this word, however, is unfortunately generally misapplied, in discussions on architectural matters, to balanced repetition on either side of a medial line, as observed in the features of the human figure, and to regularity in geometrical configuration. Everything in existence is either well proportioned or ill proportioned, i.e., exists in either right or wrong quantitative relation. It is idle, therefore, for any one to talk or write upon the subject of proportion who has not conceived it mathematically.

Before the subject of proportion can be firmly grasped, we must be able to clearly discriminate between aesthetic proportion and proportion in relation to constructive fitness. The science of aesthetic proportion treats only of those proportions which, quite irrespective of any other purpose, are opposite to taste. The adaptation of proportion to taste is a distinct section of study, which may be pursued abstractly and independently of any consideration touching the conformity of proportion to any other end. In fact, the adaptation of proportion to constructive purposes is ruled by quite other considerations, by the necessities of the case, and cannot be formulated as a science. Aesthetic proportion, however, is founded on human experience as to what proportions, in the combinations of forms, colours, and musical notes, are opposite to taste, to the senses of sight and of hearing; and not upon any vague *a priori* notion that some ratio  $a : b$  is a beautiful ratio. Half-educated persons in these matters would appear to think that to call proportions either mathematical or geometrical must necessarily determine them to be beautiful; why, every quantitative relation, every proportion, good, bad, or indifferent, is mathematical, and every configuration of surface, and every form of solidity, is geometrical. In the course of my studies connected with the subject of proportion in general, I have formulated the science of aesthetic proportion, and have demonstrated that the music of form, colour, and sound are based upon identical quantitative

relations; that the same ratios which are opposite to the ear are also opposite to the eye. I have shown, moreover, that there is a corresponding effect produced by the same combinations of ratios on the auditory and optical senses,—possibly on all the senses.

Proportion in the concrete, or in reference to constructive fitness, is quite another consideration. Neither on *a priori* nor on aesthetic grounds could the proportions of either a column or a doorway be determined. The proportions of these may be decided by reference to some constructive end; by the Greeks it was probably determined by reference to human proportions, for the column of 8 : 1, with interval of 4 : 1, conforms to the general proportions of typical human form, sideways and full front. The interval of 4 : 1 is, therefore, a consistent ratio for an intercolumniation, for an entrance, a doorway. There is a tradition, indeed, that the variations in the proportions of the column and its interval, in Greek architecture, were decided by reference to certain characteristic human proportions. The proportions of either a factory chimney or of a steam-engine are not determined by any aesthetic considerations, but by constructive necessities; and this is why constructive fitness of proportion is not necessarily beautiful; rigorous constructive fitness of proportion commends itself to the judgment rather than to taste. But the proportions which are adapted to a constructive purpose may sometimes coincide with proportions which are opposite to sense, to taste; as, for instance, those of the perfect human form, the egg-shape, &c. Although we all know perfectly well that the horse, the gazelle, the leopard, the hippopotamus, the elephant, and the lion, are all equally admirably proportioned to their several ends, no one would be able to convince us that their forms are all equally agreeable and opposite to the sense of sight. Sensitive aesthetes will often insist that the ugliness of constructive fitness should be garnished by something beautiful, *appliqué*, which appears to me about as reasonable as it would be to insist that the hippopotamus should be made pretty.

There can be no doubt that the general effect which a building or a chamber makes upon us may to some extent be dated from ourselves, from the relative magnitude of the observer to the building, just as we are differently affected by the magnitudes of hill and mountain, the different scale of natural scenery, in comparison with our own dimensions.

W. CAVE THOMAS.

**STAINED GLASS.**

**Debden.**—The east window in the chancel of the parish church at Debden, near Saffron Walden, has just been filled with stained glass. It is a three-light window, and has "The Crucifixion" forming one subject, running through the three openings, the background being a deep ruby, panelled upon a foliated ground of roses and carefully-drawn foliage. The tracery of the window is filled with weeping angels, and the bases of the lights with appropriate symbols of the pelican feeding its young, and the Alpha and Omega. The window is the gift of Mr. R. S. N. Barthropp, to the Vicar, and is the work of Messrs. Gibbs & Howard, of London.

**Handborough.**—An improvement has just been effected in the church at Handborough, by the filling of the three-light east and west windows with Munich stained glass, by Mayer & Co. The former represents the angel appearing to the women at the sepulchre, and the latter contains rich and chaste ornamental designs. The whole has been erected in memory of the wife of the Rev. R. P. Nowhouse.

**Miscellaneous.**

**Railway Plant for Victoria.**—It is stated that the Government of Victoria, Australia, have just placed a further order for 30,000 tons steel rails and fish-plates. Competition was very severe between English and Continental manufacturers, but the *Ironmonger* states the order was secured for Belgium through De Paula & Co., London. The foreign houses were able to compete on close terms for the extended deliveries specified in this instance.

**Maidstone Local Board.**—Mr. Anscomb, C.E., who has held the appointment of Borough Surveyor of Maidstone for upwards of eight years, has resigned the appointment in favour of private practice.

**The Latest Excavations at Pompeii.**

The Naples correspondent of the *Daily News* writes:—"The last house excavated at Pompeii in Isola V., Regione VIII., is of an anomalous kind. It is situated at the south side of the isola. Its construction is quite unusual, as it possesses no proper atrium. On entering the doorway you find on your right a small stove in the corner of the passage, and on the left is the kitchen proper, with a room for slaves. Then to the right is a row of columns, forming a rectangular space, in the midst of which is the triclinium, with the reclining bed formed of masonry, and in the centre a cylindrical table covered with slabs of marble geometrically arranged. The wall-paintings of this open space are not of great value: there are heads of Medusa, hypographs, and fantastic birds. Returning into the passage, there is on the left next to the kitchen an exedra, with walls ornamented with white and yellow squares, divided by columns, decorations, and festoons, all in fresco. At the entrance of this room are two strange figures; on the left, an infant surprised at the sight of a large rat issuing from a trap, and on the right the same infant trying to catch the rat. On the left wall is a medallion with a small figure, two Cupids and two flying geniuses, one with a pastoral staff in the left hand, and a bunch of grapes in the right; the other with a staff in the right hand, and the left supporting a basket on the shoulder. The opposite wall is in a bad condition, so that nothing can be distinguished but the faint traces of a similar medallion. This room was covered, and above it and the kitchen was a second story, and which access was had by a staircase at the end of the ground-floor passage, and by a similar passage above. Behind the exedra (always to the left of the passage) comes an enclosed garden. A window into this garden gave light to the staircase. At the extreme end to the right is another small room, with a window opening into the triclinium. This room had this upper room with the others on the left was by means of the passage on the second floor. Many vases, shells in bronze, several gold rings with engraved stones, and amphore, were found in this house, and six skeletons. A walled-up door on the left wall of the exedra makes it probable that the house was once a portion of some other larger dwelling, and that it, like so many others, had been sold separately, and undergone various changes."

**The Drainage of Cannes.**—M. Gazagnaire, the mayor of Cannes, sends to the *Morning Post* some information as to the sanitary works now being carried out in that town:—"He says the contract for one portion was taken on the 17th of August, and the works were begun on the 21st. This portion consists of, first, the sewer of the Boulevard de la Croisette from the Rue d'Oustinoff to a large receiving sewer which already exists; and, secondly, the portion of the Rue d'Antibes from the passage on the level to the Boulevard de la Croisette, running by the Rue d'Oustinoff and the Rue Dubouys d'Angers. The system of sewers will need three contracts for its entire completion. According to the scheme, the flow from the sewers will be conducted to a point, say the mole of the port, where an elevating-machine will raise and empty them into the Gulf of Napoule, near the opening of the Canal de la Siagne at the Trou de l'Ancre, where the depth is from eight to ten fathoms, and there are currents which will carry everything away into the open sea. The authorities are also engaged in elaborating a plan for the complete drainage of the low-lying grounds. This will be commenced with Chatignier."

**An Appointment at Swansea.**—A correspondent writes to say that in our issue of August 5th there appeared an advertisement for an Estate Superintendent under the Swansea Town Council. The advertisement stated that applications were to be sent in "not later than the 7th prox." On the 6th inst., our correspondent sent in an application, together with testimonials, and by return of post had them returned, accompanied by a letter from the Town Clerk (dated Swansea, September 7th), stating that the application came too late, as "the selection had been made"; and further stating that "the appointment would be made early in the following week." Some further explanation appears to be needed.

**Another Theatre Burnt Down.**—The Beriot Theatre at Louvain was destroyed by fire on the 11th inst. No lives were lost.

**The Value of Sunshine** has been strikingly exemplified since the 4th of August, when it may be said the summer commenced. It has arrested the progress of potato disease, rendered the harvesting of grain possible, and made a fair finish of the hay crop in the late districts. Still more strikingly has the influence of solar light on vegetation been displayed in the flower garden, for with the brighter days there came a perfect flood of flowers; and yet the sunny days have been divided by chilly nights, and the thermometer has on several occasions very nearly touched the freezing point. But tender plants seem able to endure without harm a temperature lower than we should dare to subject them to by intention, provided they are well-established in the ground, and are brought to their full development in a dry healthy air under continuous sunshine. We cannot make sunshine, but we may, and must, take note of its action with a view to accommodate all our out-door work to the necessity that it is so amply demonstrated. When we plant strawberries on terraces, and potatoes on ridges, and stone fruits on walls, we are complying with the direct teachings of nature in respect to the powers of solar light, and it may be that we have much yet to learn as to the utmost advantageous appropriation of a power that we can never influence directly, and to only a small extent indirectly. As regards the possibility of indirect influence, we have but to compare the country with the town. In the country the light is strong and pure, and vegetation rejoices in it; in the town it is weak and impure, because we have ourselves loaded the air with smoke and dust, and the adulterated sunshine produces a weaker plant and a weaker man than that of the open country, where there are no fumes from chimneys, and no unwholesome exhalations from sewers and rubbish heaps, which are equally obstructive of sunlight and poisonous to all forms of animal and vegetable life.—*Gardener's Magazine.*

**Fire at a Builder's.**—Between ten and eleven o'clock on Sunday morning a fire broke out on the premises of Messrs. Ashby Brothers, builders, No. 24, Bishopsgate-street. The property is approached by a gateway next to the fire-brigade station, and runs some distance back, abutting on the rear of the houses in Devonshire-square. The firemen were the first to discover the fire burning in one of the upper workshops, and the hose was instantly brought out of the station and attached to a street hydrant, whence a good supply of water was obtainable; but the flames developed themselves rapidly. Other engines were brought to the scene. The superintendent's report represents the damage occasioned as follows:—"A brick and timber building, of three floors, about 45 ft. by 30 ft. (used as workshops and stores), second floor and contents burned out, and roof off; rest of building and contents and stock in open yard severely damaged by fire and water." We understand that Messrs. Ashby Bros. have also premises in the Kingsland-road, which will enable them to carry on their business with less difficulty than they would otherwise experience.

**Beneficial Results of Sanitary Measures.**—On the 7th inst. the eighth annual meeting of the Sanitary Association of Scotland took place in Greenock. Mr. Mackay, Sanitary Inspector, gave an interesting sketch of sanitary progress in Greenock. He said that when, in 1876, the local authorities got Parliamentary powers for carrying out a scheme of town improvement in many closes in the lower part of the town, the mortality averaged from 40 to 57 per 1,000, while the general mortality was higher than in any other town in Scotland. Between 1855 and 1873, the mean death-rate was 30.24; while for the five years ending 1880, since stringent regulations had been adopted, it was 24 per 1,000.

**The De Lank Granite Quarries,** now called the Eddystone Granite Quarries, are in full work again, the proprietor, Mr. Shearer, having secured from the Trinity House contracts for the supply of granite for the Bishop's Rock Lighthouse, and from the Admiralty for a dock at Haubowllie, in addition to other large works in hand. The fact that these quantities supplied the stone for the new Eddystone Tower in six months less than the contract time testifies to their capabilities.

**Chard Parish Church.**—The restoration of the parish church of Chard, in Somerset, at an estimated cost of 5,000l., has been commenced.

**"The Wall that Jack Built."**—The correspondent of the *Standard* at Alexandria gives the following account of the entailing which is being made through the sand-hills between the sea and Lake Mareotis:—"It is intended to raise the level of the lake and so flood a wide tract of sand, now dry, so as to form a protection to our right flank. A large body of natives were at work deepening the moat under the western walls of the fort, while at each end working parties of blue jackets from the *Inconstant*, under Lieutenant Scott, were engaged in blasting the dams. In three days the indefatigable sailors have built up a wall 4 ft. high, 12 ft. broad, and nearly 200 yards long, to prevent the inflowing water from wasting itself in the western section of the lake beyond the disused railway embankment, which has also been pierced to allow the passage of the water into the eastern section. The work is now nearly complete, and this morning the tars erected a triumphant placard, "H.M.S. *Inconstant*. This is the wall that Jack built."

**Burnley.**—On the 2nd inst., the memorial-stones of a school-chapel, to be erected in Hinfing-lane, Burnley, for the Wesleyan denomination, were laid by the mayor (Alderman Fielding), the ex-mayor (Alderman Howarth), Mr. John Butterworth, J.P., and Miss Butterworth. The building will consist of a large room, to seat about 300 persons, and four classrooms, and is estimated to cost about 1,500l., towards which sum 1,000l. has already been raised. It is the design of Messrs. Waddington & Sons, architects, Burnley. Land has been taken for the erection of a chapel adjoining the proposed building, to be erected when required.

**New Assembly Rooms,** adjoining the King's Arms Hotel, Wood-green, were opened last week, and a want long felt in the neighbourhood has been supplied by 35 wide and 19 ft. high, will seat comfortably 750 persons and has cloak and retiring rooms attached. The approach is by a wide stone staircase, and the rooms are lighted by a white stone staircase, and special attention having been given to the ventilation. Mr. Henry Stone is the architect, Mr. John Bell the contractor, whilst Mr. Cawdron acted a clerk of works.

**New Workhouse School, Oldham.**—The premiums in this competition have been thus awarded by the Guardians:—"First (50l.), Mr. Thomas Mitchell (motto, "Charity"); second (30l.), Messrs. Will & Collinge ("Olive Twist"); third (20l.), Mr. Alexander Bank ("A.R.A."). All the competitors are Oldham practitioners. The other competitors received vote of thanks as a "consolation prize."

**Darlington.**—New printing and publishing offices are about to be erected in Crown and Quebec streets, Darlington, for the North-County Constitutional Newspaper Company (Limited), from the designs of Mr. G. C. Hoskins, architect, of that town.

**TENDERS**

### Compressed Air as a Transmitter of Motion.

THE account which was given to the Mechanical Section of the British Association of the working of a tram-car by compressed air at Nantes attracted so much attention, that it may be well to give a caution as to an important condition of the use of compressed air as a motor power, which does not appear to have engaged the consideration of the section. Of course it is known to all who touch the subject that it is incorrect to speak

of the air, when expanded, for caloric. This fact lies at the very foundation of the ventilation of such works as the St. Gothard Tunnel by the use of perforators driven by compressed air. In the case of the South Devon Railway, after the line had been laid out with gradients suitable for stationary power, and powerful pumping machinery had been erected for the exhaustion of air from the pneumatic tubes, it was found necessary to abandon the scheme. The ports of the air-pumps became almost red hot, and the escape of caloric, not only in the pumps, but along the whole line of the pneumatic tube, was so great as to put a stop to a very elegant mode of traction, which had the great advantage of doing away with the weight of the locomotive.

The loss in a condenser such as that fit for a tramway or other locomotive engine is, of course, not so rapid as that in a long line of pipe. But the experience gained in the one case may be applied, *mutatis mutandis*, in the other. It is within the means of science to say how much heat,—that is to say, how much motive power,—may be lost in the process of filling a condenser of a given volume, at thirty atmospheres, or any other stated pressure, and how much will be the subsequent loss, by conduction, per hour. Before recommending the introduction of this convenient and elegant mode of transmitting power, the engineer is bound to calculate the cost,—the cost per unit of its own force,—of the loss by condensation.

The product of the pressure and the volume of atmospheric air, or of any gas, is proportionate to the absolute temperature. Thus, when the temperature is uniform, the product of the pressure and the volume of a given weight of gas is also uniform. If gas can be so compressed or expanded within a cylinder of non-conducting materials, the curve of expansion is called an adiabatic curve, and the general expression for the values is thus given:—

$$VP = 53 \cdot 15 T$$

V being the volume of the gas, P the pressure in pounds per square foot, and T the absolute temperature of the gas, that is to say, the temperature in Fahrenheit degrees, plus 461°. This subject has been worked out with great, but, as it appears to us, very useless, accuracy. So utterly impossible is it for an adiabatic state, or a condition in which loss of heat by conduction is prevented, to exist in nature, that it seems something like laborious trifling to calculate by formulae and equations what are the different phases of an impossible process. Where pressure is constant, the fraction of expansion for every degree of Fahrenheit by which temperature is raised is  $\frac{1}{461}$ . In the same way the abstraction of 1° Fahrenheit from the temperature, reduces the volume (under unchanged pressure) by  $\frac{1}{461}$ ; or, if volume is constant, pressure is raised or lowered at the same rate, viz., by the  $\frac{1}{461}$ -th part for every degree of Fahrenheit raised or

lowered. Thus, in condensing air we have the two elements with which to deal of the quantity, that is to say, the weight, of the air forced into the condensers, and of the resisting power of heat lost or overcome in the process. Now, if we take the rule "to find the pressure of one pound of air, of a given temperature and volume," from the admirable "Manual of Rules, Tables, and Data for Mechanical Engineers," by Mr. D. K. Clark (a book that no student should be without), we find it to be, Divide the absolute temperature by the volume, and by 27074, the quotient is the pressure in pounds per square inch. But suppose we force 30 lb. of air into the space occupied by 1 lb. of atmospheric air under ordinary pressure, how much heat will escape in the process? We know of no reply to the question; and, in the absence of one, of what use is it to work out an equation in which temperature is an essential element? Supposing the thermometric heat of the atmosphere to be 62°, the absolute heat is 533°. But in the forcing into the same space of thirty times the volume of air, the temperature will be raised in the same proportion,—minus the escape of heat in the process. Each atmosphere of increased pressure is equivalent to an increase of 461°. Is it conceivable for a moment that thirty times 461°, that is to say, 13,530° Fahrenheit, has been attained? No material could resist such fierce heat. And the higher the temperature attained, the more rapid would be the loss of heat by conduction, radiation, or in whatever mode it would most readily escape to restore the equilibrium of nature. A pound of air, at the absolute temperature of 0°, that is to say, at -461° Fahrenheit, has, according to the formula, no elastic force. If so, 30 lb. at the same zero would have none. The expansive force of the 30 lb. is thus entirely due to the amount of heat contained within its volume; and from the commencement of the compression to the period at which equilibrium was established, there will be a constant flight and escape of heat, that is to say, of imprisoned energy, from the condensed air. Of course it is not to be supposed that a pressure of thirty atmospheres involves the condensation of thirty volumes, or, rather, weights, of air. But it is just because the resistance to compression depends, in part, on the weight of air, and, in part, on its temperature, that we regard the rules that are based on the adiabatic theory to be of so little practical use. There are no means known to us of either preventing or gauging the loss of caloric under compression.

Ingenuity of all kinds may and has been directed to eluding the prime physical difficulty. It has been sought to heat the air as it expands. But this, though probably about the most economic and productive application of heat possible in the present state of science, is still the addition of power, and of cost. If the principle of Ericsson's caloric engine could be

of compressed air as a motor power in the true sense of the term. It is, more correctly, a transmitter of power. To condense a certain volume of air, as in the present case, to a density of thirty atmospheres beyond the ordinary pressure,—that is to say, to a resistance of 450 lb. per square inch,—a force of that amount, plus friction and loss in delivery, must first be exerted. It is quite possible that circumstances may render this a desirable mode of, so to speak, bottling up force. But the worst of it is that, in the process, the force escapes from the bottle. It is not possible so to imprison and to condense a given volume of air as to allow of its yielding the same amount of force by its expansion that was exerted in its condensation. We speak not from scientific data alone, but from discussion of the practical experience gained by two of the first men in the profession of the civil engineer who, now some thirty-six years ago, spent much time, and unfortunately lost much money, in acquiring a dear-bought experience. These men were Isambard Kingdom Brunel and Eugène Flachet. The thief that ran away with the power was one who was unsuspected, but as to whose action, when once detected, no manner of doubt is possible. The name of the mischief-maker is Conduction. The reason why so many volumes of condensed air will not, as an elastic spring, give out the force exerted in compressing them is, that during compression, and to some extent after it, heat escapes from the compressed air. It escapes in a ratio proportionate to the amount of compression; that is to say, the more convenient and portable the form of the receiver or accumulator into which the charge is put, the higher the pressure obtained, the greater in proportion is the loss of heat in the process. The less will be the expansion, and the greater the capacity

thoroughly applied,—if the heat escaping under compression could be stored up within the apparatus, and restored to the cool expanding air,—the loss might be obviated; but when we are speaking of high-pressure, which means high temperature, it is obvious that it is idle to talk of any such compensation.

It is somewhat remarkable that considerations of so elementary a nature were not brought forward in so congenial an atmosphere as that of the Mechanical Section of the British Association, where marvels and mountains were announced as to the use of compressed air as a motor power. Compressed air is not,—cannot be,—a motor power. And as an accumulator or transmitter of motive power, it is, we think, theoretically about the worst and most costly medium that can be desired. We hear all testimony to the extreme ingenuity that has been devoted to the study. We can recall instances where pressure and power are low, in which elegant and, no doubt, useful results have been obtained by the transmitter; as, for example, in the working of the gold weighing-machines in the Bank of England many years ago, one of the most delicate and magical of operations; but we are very much disposed to fear that the language applied by the *Manchester Guardian* to the discussions of the Economic Section of the British Association are not without some justice if applied to other discussions than that on Mr. Watherston's proposal to triple the national debt. "The section has in recent years lost caste by indulging in merely wordy discussions on merely wordy papers."

#### DRAINAGE IN FRANKFORT.

CIRCUMSTANCES led the writer of this paper to pass some months at Frankfort-on-the-Maine during the summers of 1881-82. He was much struck by the cleanly appearance of the town, as well as by the entire absence of all odours both inside and outside the houses. This led him to investigate the sanitary system of Frankfort, and as it simply acts perfectly, both as regards the healthiness of the population and the rapid removal of the drainage, he has thought well to publish an account of it. In some respects it differs from the system prevalent in England, reference to which will be made later on. The whole of the drainage works were carried out under the direction of the eminent firm of engineers Messrs. Lindley, from whose report much of the information now published is obtained.

In the year 1863 a commission was appointed by the municipality of Frankfort to decide upon a system of drainage suitable for the town. The commission, after a thorough investigation, decided upon a system of sewerage of which flushing was to be the leading feature. The town and suburbs were divided off by intercepting sewers into hands of land, and the course of these sewers was parallel to that of the river Maine from east to west. Following the contour of the land, two networks of drainage, independent one of the other, were undertaken, and called "the upper" and "the lower" system.

The upper network, as regards outlet, is independent of the water level of the river; for in time of floods it can be shut off from the lower network, and disposes of its drainage as will hereafter be stated. The lower network, on the contrary, is affected by the Maine, rendering it necessary in floods to lower artificially the water level.

The drains are so constructed as to carry off at once all house-water and water-closet discharge, as also the rain-water and land drainage water. At the same time, they are so arranged as to prevent sand, gravel, or anything of mineral origin getting into the sewers.

The construction of and slope given to the sewers are such that there is no possibility of any lodgment occurring under ordinary circumstances; but in order to be secure, sluice-gates have been placed at certain distances enabling the drains to be flushed by their own water whenever desirable. In addition, a reservoir has been made specially for the purpose of flushing.

The street sewers are constructed below the ground-floor of the cellars, with the view of draining the soil, as well as of removing the refuse water from every part of the houses. Although the rapid and continuous removal of the sewerage before decomposition has taken place prevents the formation of sewer gas, care

has been taken to prevent the entry of any bad odours into the houses, and a perfect system of ventilation by inlets and outlets has been carried out for the whole network. All house-owners desiring to make use of the system are obliged to have all the arrangements made under the direction of the administration.

With regard to the execution of the work, a commencement was made in 1867, and as quickly as funds permitted it was carried on. In 1876, about sixty miles of sewers of various dimensions had been completed. The greatest care was taken as regards materials,—the municipality supplied cement, bricks, the inverts, &c., to the contractors, in order to insure the best quality in everything. The cement was constantly tested during the progress of the work to the extent of 25,000 trials, and artisans employed by the municipality mixed the mortar. Only the actual labour was entrusted to the contractors. The constant overlooking of the work caused it to be completed in a manner so efficient that left nothing to be desired. The drains and sewers were constructed with glazed pipes, or built in an oval form with bricks, and, for the most part, with inverts glazed,—the sides being built in mason work, with Portland cement. Care was taken to make these sides perfectly smooth, without covering them with cement. The principal sewer has a height of 6 ft. 6 in., and a width of 5 ft., and the secondary sewers vary between 6 ft. by 4 ft. and 3 ft. by 2 ft. For the small streets with good slope pipes of 12 in. and 15 in. diameter have answered admirably. Fifty per cent. of the work has been done in sewers of 3 ft. by 2 ft., and seventeen per cent. has been done with pipes. The slope varies according to situation and circumstances, but where the slope is steepest, glazed pipes have been used, while the sewers with the lesser slopes have been made so that people may pass through them. The depth of the public sewers below the level of the streets varies from 10 ft. to 33 ft. In the streets of the ancient city of Frankfort the depths have been found down to 22 ft. In general it has been sought to make it from 13 ft. to 20 ft., and the average is about 16 ft. to 17 ft. This great depth was necessary to ensure the drainage of the subsoil and all the cellars, and in consequence most of the public sewers are below the water level or in impermeable clay. This prevents most thoroughly the escape of drainage water, and any infection of the subsoil. All junctions of house drains and secondary sewers with the main sewers, are made at an acute angle with the flow, so that there is no possibility of any deposit or lodgment.

The rain-water gratings are placed at the sides of the streets at 36 yards apart from one another, and all unpleasant odours are prevented by hydraulic traps. Catch-pits are made with 20 in. glazed pipes placed vertically to a depth of 7 ft., furnished with a movable bucket with handle. The sand and small stones, &c., carried down by the rains are received into this bucket, which is, from time to time, raised, emptied, and replaced. These deposits of mineral matters are never offensive, as all putrefying matter is carried off in solution into the main sewer.

For flushing purposes, 320 flood-gates and 200 slides have been provided. In addition forty cast-iron slides, which are ordinarily used to separate the upper from the lower network of sewers, can be used for the same purpose. To carry out this system of flushing, as well as to facilitate the inspection of the public sewers, 700 side entries have been made at distances of 180 metres apart, opening from the foot pavement.

In order to carry out perfectly the flushing system, collecting galleries have been made at the highest point of the system of sewers, which hold about 2,500 cubic yards of water. This water comes from the land drainage and some surface water, and is used, when it is thought advisable, to flush very completely.

Under ordinary circumstances, all the sewerage is made to empty by the main sewer into the river Maine at a distance of nearly two miles from the ancient bridge, and far beyond any habitations belonging to the town. The pipe, 4 ft. in diameter, is carried out in the middle of the current, some 50 yards from the shore. This outlet, being situated in the bed of the river, and in the line of the quickest flow, has the effect of causing the sewage to be carried off so rapidly as to give no grounds for fear of any deleterious influence to the

health of the neighbourhood. In addition, the refuse matters are so dissolved in the water as to show no trace of their existence. It is, however, intended to carry the main sewer about a mile lower down the river, and by means of settling tanks to remove all matter deposited before the water is allowed to enter the river. This deposit will be used for manuring purposes.

The main sewer is constructed so as to take a certain quantity of rain surface-water in addition to the sewage, but in times of very heavy rains there are means by which a large quantity of the rain-water can be diverted and sent direct into the river Maine at once. These rain-water conduits pass by means of syphons under the intercepting sewers running parallel to the river. It is also easy, in time of floods, to lower the water level in the lower network by using a natural channel or depression in the land running parallel to the river Maine for the surface-water, and so causing it to discharge itself near the village of Nied at a point where the water level is 10 ft. lower than at the ancient bridge in the town.

As regards ventilation, the system employed at Frankfort is a combination of outlets and inlets. Wherever an escape of air from the sewers would be hurtful or disagreeable, it is prevented by traps used, as before mentioned, in the receptacles for surface-water by the foot pavements. But wherever an outlet can be had allowing a free escape of air, it is used. Thus, all down pipes of rain-water gutters, when not below or very near windows, are pressed into the service, whether they belong to the town or its inhabitants. The water-closet pipes are carried up through the roof, and are open at the top, so that each house in the town, by means of these pipes, and the down rain-pipes, contributes to the ventilation of the public sewers. In addition, at two of the highest points of the drainage system, and away from dwelling-houses, two large towers, one having the appearance of a huge chimney, over 100 ft. high, have been erected, and through which the sewer air is constantly escaping. Advantage has also been taken of factory chimneys as ventilators. So much for the outlets. It now remains to describe the inlets. These are placed in the middle of the roads and streets, and consist of 9-in. pipes on end with a grating. If needful, disinfecting agents can be placed in these pipes, but a constant inspection proved that, owing to the system of outlets above described being so complete, they acted entirely as inlets, and in no case was air found to be issuing from them, or any unpleasant odour discovered.

The principle that has been the mainstay of the entire project is that every householder wishing to take advantage of the drainage system is compelled to have the connexion carried out under the direction of the town engineer, who will see that all the sinks, closets, &c., are of the proper kind. Not only is this obligatory, but the engineer's authority over all private drains joining the sewers is as complete as it is over all public works. He applies certain standing rules, accompanied by explanatory plans and models, showing the necessary conditions of this sanitary work. The advantages that have been realised in comfort and health by the inhabitants of Frankfort are due to the conscientious observance of this principle.

The inhabitants are not bound to connect their drainage with the sewer system, but their recognition of its advantages has been such that the administration has been fully employed in making the connexions with private houses ever since the work commenced. Thus, in 1875, 884 houses, representing 2,958 families and 3,977 water-closets; in 1876, 687 houses, containing 2,012 establishments, and 2,517 water-closets had been connected with the sewers; while, at the end of May, 1877, Frankfort contained 3,547 houses, representing 10,333 establishments and 14,349 water-closets that had been joined to the new drainage system. A large proportion of the houses is let in flats, and, therefore, each, including several families, accounts for the numbers of establishments and closets stated.

Up to the end of 1876 nearly 100,000 yards of sewers had been completed, and the sum expended amounted to nearly 300,000 sterling. The results obtained by this sewer canalisation have been highly satisfactory. First, the complete drainage of the cellars and subsoil has been attained, and the water so obtained

## SOMETHING OF CAIRO.

WHEN, a few hours after the reception of the first news of our recent victory at Tel-el-Kebir, it was learned that Cairo had been quietly occupied by English troops and its old forts manned with our red-coats, it is no exaggeration to say that a feeling of relief was experienced by all who had watched with any interest the Egyptian campaign. A beautiful and famous city was saved from sharing the fate of Alexandria, a fate which had more than once been dreaded as likely to befall Cairo. Ever since the commencement of the troubles which have carried our troops into the heart of Egypt, the constant fear has been expressed that the hazards of war might at any moment lead to the destruction of Cairo. These fears were felt not alone because Cairo is the capital of Egypt, or because it is in importance, after Constantinople, the second city in the Ottoman Empire. Its antiquity, the beauty of its monuments, its peculiar artistic interest, which have so often excited the descriptive powers of travellers,—English, American, and foreign,—have long rendered Cairo familiar to the West as the ideal of an Oriental city such as the "Arabian Nights" has described, and the theatre and a few painters have successfully brought to the general mind.

Apart from any contemporary interest that may be attached to Cairo at this moment, Cairo, as the pure creation of the Arab conquerors who, now twelve hundred years ago, seized Egypt, holds a place in artistic history such as has long surrounded it, in the eyes of the refined, with a peculiar halo of romance. Till within recent years this romance has been, as it still is to a great extent, fostered by the large share of mystery which enwraps all things Oriental. Travellers' tales have been accepted for want of definite information, and our acquaintance with the Arabs has been made far more through the doings and creations of their kinsmen, the conquerors of Southern Spain, than through the original stock who people the Egypt of to-day.

The architectural interest of Cairo has long been known,—since, that is, the commencement of this century; but the research in a field of the utmost promise has been narrow. From an artistic point of view, we may look with some satisfaction on the recent result of our armed invasion of Egypt, if it is to make us more familiar with the art of the Arabs, the relations of which with our Gothic art is a study of the utmost interest. We shall now, it is to be hoped, become more familiar with Cairo and its architecture, and learn that our admiration for Arab art, as shown in the Alhambra, has led us to overlook its purer and earlier creations in Cairo, where almost the whole development of Saracenic art can be studied.

How much has yet to be learned of this chapter of artistic history may be judged from the very short account which is devoted to the art of the Arabs in Mr. Fergusson's "History of Architecture," and even in this short account there exist statements which more recent research is able to correct.

In some previous papers on the subject,\* we have endeavoured to lay before our readers a slight sketch of the nature and origin of the art of the Arabs, an acquaintance with which will be found indispensable to the full understanding of the rise and formation of our own Medieval art.

It may unquestionably be accepted that the great movement of the Crusades contributed not a little to arouse the West from the torpor which had come over it after the fall of the Roman Empire, by bringing us Northwards into contact with a refined and brilliant civilisation. That civilisation we have seen developed entirely under the influences of surrounding circumstances. The Sinitic races were anti-artistic; they conquered country after country each in possession of an art and artists the creation of long generations of tradition; of these the Arabs immediately availed themselves; they adopted at first, as we have seen, the old art, gradually grafting on to it the features of the new style, which was eventually to possess so marked a character of its own, and into which the Persian influence was to infuse that peculiar elegance and decorative grace which mark so indefinitely all Saracenic art.

In Cairo and its monuments the development of this art can be traced from its earliest manifestations through its most brilliant period down

to the present day. With the aid of Fergusson and a guide as competent as M. Prisse d'Avennes,—whose superb and recently-published work on Cairo, "L'Art arabe, d'après les Monuments du Kaire" (Paris. 1875-77. Folio), may be looked upon as one of the most sumptuous artistic productions of the present day,—we shall pass in review some of the artistic features of a city concerning which we may expect for some time yet to hear a great deal.

The Arab historians have exhausted their descriptive powers in the story of the foundation of El Kahirah, or, as we term it in its Italianised form, Cairo. The city which we know by that name is in reality the creation only of the tenth century, the portion known as Old Cairo, or Fostat, being the town which tradition states was built by the first Arab conqueror of Egypt, Amr, on the site of the tent,—Fostat means tent,—he had occupied previously to his famous capture of Alexandria. From A.D. 640 till 969, when Egypt was conquered by the Caliph Moer-ou-Din-Illah, Fostat remained the capital of Egypt. In the latter year the conquering caliph built the existing city of Cairo. For two centuries the new capital slowly spread in size, since when, till within the last fifteen to twenty years, it has remained, to all intents and purposes, the Cairo of the Middle Ages.

There stand to this day, and our troops passed under their old arches, as the French did at the beginning of this century, the gates of the line of fortifications erected by the great Saladin, the courteous rival of our own stout-hearted Cœur de Lion; and our red-coats have occupied the citadel which was built by the same great Sultan. Cairo possesses in reality seventy-one gates. Architecturally, however, there are only two worthy of attention, the Bab-el-Nasr, or gate of success; and the Bab-el-Foutouh, or gate of victories. The former of these, a massive construction, is formed of two square towers, broken only by some graceful mouldings and sculptured heraldic scutcheons; in appearance, as may be seen by any representation, nothing could be less Arabic. The inspiration of its design is clearly Christian; it is only the inscriptions and the delicate balustrade that show to the observant eye that the work is Saracenic. The Bab-el-Foutouh, or gate of conquests, has round, or rather, elliptical, towers; heavier in construction than its companion, the mouldings are more numerous, and the style generally, in fact, is more Arabic. Of the fortifications themselves a great portion remains, the section of the walls nearest the Tombs of the Caliphs being in the best preservation. There still exist the covered way and machicolations exteriorly. In connexion with the fortifications the citadel deserves mention; built, as we have above stated, by Saladin, in the twelfth century, it still serves as the strongest point of the city. With the now destroyed fortifications of Alexandria, the walls of Cairo form the sole existing specimens in Egypt of the military architecture of the Arabs. There remain in the city a few private palaces which retain their Mediaeval modes of defence in the shape of loopholed and machicolated walls, to show us how the Eastern life of those days resembled that of our own more turbulent North; but the interest of Arab architecture does not centre in the remains of its military strength. It is the religious architecture of Cairo which affords the chief field for study, and it cannot be said to be barren or unpromising. There exist in the Egyptian capital over 400 mosques of every period,\* by means of which the development of Saracenic art may be traced almost step by step.

Each dynasty of rulers, from the time of Amr down to the Turkish Conquest, early in the sixteenth century, vied in adorning Cairo with sumptuous buildings. With the appearance of the Ottomans this beautifying process stopped; ruin, injury, and neglect are all, we are afraid, that mark their presence in the land which has owned so many masters.

It is almost always in the capital of a country that the chief elements for the study of its architecture are to be found; there, usually, the first efforts are made, and there it is that the accumulated wealth creates the finest buildings. In Cairo the oldest edifices are religious. The greater part of the mosques contain tombs,

\* In Cairo proper, 387 mosques; at Boulak, 51; and in old Cairo, 10; total, 448. Built often side by side,—through the vanity or caprice of their founders,—and bristling with minarets, the appearance of the city can be more easily pictured than described.

\* See ante, pp. 202, 231, 297, and 326.

has been applied to the cleansing of the sewers. Secondly. The cleansing of the public sewers is effected solely by flushing, the work of which is performed by a foreman and four labourers. The greater part of the sewers cleanse themselves by their ordinary flow, while the remainder are flushed from time to time, so as to remove all deposits, mineral or otherwise. Thirdly. The ventilation has succeeded perfectly, so that the outer air has free circulation throughout the sewers; consequently, the sewer air has been so free from noxious odour that there has been no occasion to have recourse to the disinfectants originally contemplated.

The amount of liquid discharged by the network on the right bank of the river Maine amounts to 470 cubic yards per hour, while the amount of water running under the bridge is 650,000 cubic yards per hour. Although the quantity of sewage entering the river is small in proportion to the volume of water in it, the question of its different disposal must be entertained ere long.

Such is the history of the Frankfort drainage, and as its working clearly proves that it is most efficient, so does the reduction of the death-rate to little over 18 per 1,000 prove the town to be one of the healthiest in Europe. It should also be noted that, owing to its charities, an unusual number of aged and sick people are drawn to the town. The fact that a portion of the town is built upon what was formerly the bed of a lake is additional evidence of the efficacy of the drainage. As the system followed is not the same as that most prevalent in other countries, it will be well to notice in what the difference lies. (1.) As before said, the power of the engineer over the house connections and the apparatus of closets and sinks is absolute, and (2) the system of ventilation. To carry this out efficiently, it has been found necessary to forbid any house-drain being trapped from the sewer or disconnected. Every sink and closet drain has its own special trap, which has been found sufficient, always remembering that the pipe is carried through the roof and has the top open. Thus the sewer air, having a ready outlet, makes no effort to force the traps to find a way of escape. The effect is that the open gratings in the centre of the roadway, instead of sending up noxious odours, as is the case in some of England's health-resorts, act as air-filters only, and are quite free from smell. The sewer air, being warm, will readily rise to the highest point if encouraged. An inspection of the sewers at the lowest, a central, and the highest points, which necessitated a considerable time being spent inside them, showed that there was no smell of putrefaction whatever. Any person in ordinary health might pass hours in the sewers of Frankfort without any unpleasant effects. The rapid rush of the water, the absence of all deposit owing to the branch sewers and house drains joining at an acute instead of a right angle, and the perfect ventilation before described, all contribute to this satisfactory result. Nothing could be more complete as regards the removal of the drainage.

One cannot say so much as regards its disposal, although the enormous flow of water in the river Maine makes 600 cubic yards of drainage-water per hour a mere bagatelle. It is, however, matter in a wrong place, and must be dealt with. This is intended to be done by means of settling-tanks, the water eventually finding its way into the river. It would be well if this even could be avoided; but in a country where it rains on 120 days in the year it is difficult to do so. It has been found necessary in England to separate the surface from the drainage-water, in order to prevent farms under sewage irrigation becoming swamps. On the other hand, an occasional flushing with extraneous water is an important aid to the efficient working of the sewers; but to all who are interested in sanitary works no better advice can be given than to do what many have already done, viz., visit Frankfort-on-the-Maine.

**The Lower Memorial.**—On the 9th inst. the foundation-stone of a memorial to the life and work of the late Rev. Charles F. Lowder, the vicar of St. Peter's, London Docks, was laid, in the presence of a large number of friends, by Earl Nelson. The site of the memorial is immediately in front of the church, on a piece of ground in Old Gravel-lane. On this spot it is intended to erect a substantial clergy-house, for the use of the mission clergy of the district. Mr. Bowes A. Paice is the architect.

contrary, curious to say, to the special injunction of Mahomet, who, with a foresight which it is to be regretted Christian countries have not equalled, forbade, in one of his *hadiths* or traditional sentences, the burial of the dead in the mosques.

Previously to enumerating the more important mosques of Cairo, it may not be out of place to briefly sketch the general character and arrangement of a Mahometan mosque. In the first place, the mosque is not a temple occupied by a god; it is, to use a strictly Biblical expression, a "house of prayer," of contemplation, in which the believers meet to adore the Divinity. What may be termed "worship" does not exist in the Mussulman religion. Mahomet, it must be remembered, preached to barbarous tribes whose forms of worship entirely concealed the Divinity. The rites are of the simplest: an annual festival, ablution and prayer five times during the day, with no other dogma than the belief in a creating and remunerating God. All images are suppressed, from a fear that they might tempt the feeble imagination, and convert the mind to culpable adoration.\*

The enclosure termed a mosque (from "Medjid," place of adoration; in Arabic, "Djami") has no form determined by the religious law. It may be square, octagonal, or round, covered over, or open to the sky. We find at Cairo mosques of almost every possible plan. The oldest, it is true, affect a large square, with porticos; those of the later period afford a Latin cross, and those erected under the Turkish rule are often round, after the plan of Santa Sophia. The sole condition required by the law is that the principal interior wall, which is faced during prayer, should be turned towards the east, in the direction of Mekka, considered by the Mussulmans as the house of God and the centre of the universe. The mosque is separated into two distinct portions: one, the outer, which may be entered without the ceremony of removing the shoes, and corresponding in a manner with the *narthex* of the early Christian churches; the other, the inner portion, a species of raised dais, ascended by several steps, and regarded as of the utmost sanctity. Recessed in the wall facing Mekka will invariably be found in every mosque the so-called *mihrab*, or *kiblah*, towards which the applicant is turned during prayer. The first *mihrab* built was that of the mosque of Medina during the lifetime of the Prophet. In every mosque it is the portion on which the utmost splendour of decoration is lavished. Elsewhere in the mosque, but always on the eastern walls, will be found other smaller *mihrahs*.

To the right of the *mihrab* is placed the pulpit, termed *minbar*. The South Kensington Museum possesses an interesting specimen, taken from a mosque demolished in Cairo some years ago. This pulpit on festivals is covered with rich draperies, but is invariably itself richly decorated with carved and inlaid work. The *minbar* dates back also to the time of the Prophet. In the seventh year of his mission he improvised, it would appear, a small pulpit ascended by two steps, previously to which he had simply leant against the trunk of a palm-tree while delivering to those about him his sacred sermons. In some mosques,—in Cairo, those of Teyloun and El Azhar,—a cupola or baldacchino, supported by four columns, rises above the *mihrab* and the pulpit at its side.

Opposite the *mihrab*, and at a certain distance, is the *dekke*, or tribune, supported by columns and reached by steps; in this the priest, previously to the sermon, delivers to the congregation the rules to be observed, together with a slight sketch of the discourse about to be given. In the mosque proper it may be observed that there are two kinds of *maqsourah*, or reserved enclosures,—one general, the other special. The *maqsourah* is that portion of the mosque surrounded by a wooden railing, and containing the *mihrab*, the *minbar*, and *dekke*, above referred to. In this only persons of a certain rank are admitted to recite their prayers. There formerly existed in the mosques a special tribune,—*Tekasser*,—reserved for the women, but these no longer exist; in Cairo the custom had been borrowed from the Byzantine

\* The Koran, it may be further stated, is founded on seven essential principles; on a belief in a single God, of whom Mahomet was not the son, but the vicar; on penalties and recompenses in another life; on prayer; on alms; on fasting; and, lastly, on the pilgrimage to the Kaabah, an institution of antiquity even in Mahomet's time, and which he skilfully incorporated into the new religion. Those familiar with Arabic state that no religion possesses prayers to the Deity more exquisite and beautiful than the Mahometan.

churches, and to this day such tribunes are to be found in some of the old houses; in the Mosque of El Aghsa, at Jerusalem, the tribune is still used.

The *sahn*, or *impluvium*, is generally square and open, confined on the Mekka, or eastern side, by the *maqsourah*, and on the three other sides by walls constantly to be found provided with porticos, called *liwans*. In the Mosque El Azhar,—which is, at the same time, the great theological university of Islamism,—the porticos are each set aside for the students of the different provinces and nations who have come to Cairo to be initiated into the mysteries of the religion.

The *musalla*, or oratory, is situated by the side of the *meidaah*, or place of ablution, a square basin filled with water; and here exist also, for purposes of purification, other basins termed *magtas*, often repeated, like the Scriptural Pool of Siloam, for their supposed healing powers; but those who object to the stagnant and not too clean water of the *meidaah* use the *hanafiyah*, in which the water is constantly flowing. Access to the mosque is forbidden, not only to every unbeliever, but even certain portions are forbidden to Mussulmans themselves when not in a state of absolute purity, that condition being regulated by precisely similar laws to those of the Mosaic code, and doubtless from the same motives.

The number and position of the minarets,—*maadneh*,—is entirely a matter left to the taste or caprice of the founders and the architect. It is not alone, as is generally stated, the mosque of Mecca which enjoys the privilege of possessing seven minarets; the chief mosque of Herat, one of the most beautiful in Central Asia, possesses no less than nine. When there is only one, it is usually placed above or beside the principal door. The number of galleries or balconies on each minaret is again entirely left to the architect. The name of the founder and the date of the building are invariably to be found recorded in some mural inscription, in picturesque Koufik characters, and thus made a suggestive piece of decoration. As a last detail the ornaments which surmount the minarets and domes are usually in the form of a crescent. This custom dates from the fifteenth century, in which Constantinople was captured by the Mahometans, the symbol of that city being a crescent. Sometimes the termination is varied, as we see in the case of the dome of Iman Chafey, in which it is a ship, symbolic of the ship of faith.

With these general facts respecting the plan and distribution of the Mahometan mosque, its difference from the Christian temple, church, or cathedral will be at once seen.\*

#### THE USE OF STEEL FOR CONSTRUCTIVE PURPOSES.

At the recent Architectural and Engineering Congress, in Hanover, the above question was treated at some length by Professor Inze, of Aix-la-Chapelle. He attributed the limited employment of steel by architects to their reluctance to depend upon a material which had not been fully tested with reference to the purpose named. Recent improvements in the manufacture of steel have been of such a nature as to bring in a prominent manner before the attention of the profession the question of the comparative qualities of steel and welded iron. Concurrently with this improvement in steel manufacture, the requirements for constructive purposes have been, to a certain extent, modified; hardness being now deemed of less essential importance than strength and toughness. One convincing proof of the position which German steel manufacturers have now attained is afforded by the fact that exports have been made to England for Admiralty purposes.

The trials made in 1875 and 1876 by the Dutch Government of steel girders manufactured at the Harkort Bridge-building Works, were singular in their results. The material of which the girders were composed should have been capable of resisting a strain as great as 38½ tons to 41½ tons per square inch, but when the girders were tested they were found to be far inferior to this standard, their strength being, in some instances, as low as about 7½ tons per square inch. The sample bars cut out of the girders were, however, found, on testing them, to be fully up to the requirements

\* We shall continue the subject on a future occasion.

of the contract, so that the inferiority of resisting power must have arisen from causes connected with the putting together of the girders themselves. They could not be rejected, and the disappointment of the Dutch engineers may be imagined. According to Professor Inze's statement, however, they had not been without some warnings on the subject. Taking as a basis the work produced on previous occasions, they had imposed more stringent conditions as to strength, with the idea of arriving at a greater degree of presumptive safety. The removal of the rolling-mills were considered as being prompted by interested motives, and the so-called safety was dependent on the breaking strain without reference to elasticity or toughness.

Elasticity is, however, a most important point in judging a composite structure, as the different degrees in which this property exists in its component parts preclude a strict uniformity in this respect, and the attaining of the expected degree of strength is prevented. The unfavourable results of the trials of punched and riveted steel girders, as compared with the full satisfaction given by those which were bored and fastened with bolts, indicate, the speaker remarked, that more attention should be given to the material used being of a uniform character, really extensible, and not influenced by the process of manufacture, than to the attaining of any degree of safety represented by figures.

After referring in detail to the tests now applied to steel by marine and railway engineers, Professor Inze dwelt on the advisability of the results of any experiments being diffused as widely as possible, with the view of giving confidence in the use of steel for constructions where a high standard of resistance is necessary. He alluded to the theory which English engineers have founded on recent trials, that soft steel is less injuriously affected in manufacture than iron. He also spoke of the trials lately made at Königsberg, in which composite girders of soft steel fully proved the uniformity and reliability of that material. Trials in England as to rust showed that flowing steel is affected by rust to a greater extent than welded iron, but the homogeneous quality of the former causes the rust to develop itself evenly on the surface, while experience shows that it penetrates more or less rapidly into the interior of welded iron.

While a closer and more uniform texture is obtained by the casting of flowing steel and fused iron than is possible in the case of welded iron, it is considered by many that the rolling in the sizes now usual in section iron will be of considerable difficulty in the case of flowing steel. Some steel works have, however, expressed their hope of being able by the judicious formation of the ingots to obviate this difficulty, and in some instances to arrive at a lower cost than is at present possible. Some descriptions of work can, according to the statements of steel manufacturers, be executed in steel at an increased price of only 15 per cent. as compared with that of iron, but the difference in relative cost is more marked in the case of  $\Omega$  iron,  $\Sigma$  iron,  $\square$  iron, and  $\Gamma$  iron. Another estimate gives 25 per cent. as the average difference.

In conclusion, Professor Inze remarked that the use of steel for the purposes indicated, while being on the whole preferable to that of iron, was not likely to cause any difficulties of a serious character to such manufacturers as took up the matter seriously.

#### RESTORATION IN VENICE.

A PAMPHLET has been recently published in Venice, with the title of "The Future of Public Buildings in Venice," which is of interest as showing that there is not that unanimity among the Italians with regard to the work of restoration going on in Italy that was recently represented to be the case. It is evident, from a perusal of this pamphlet, that there exists a party in Venice which, although it may be in a minority, does not approve of the refacing of the Cathedral of St. Mark, and must have hailed with delight the action of the English St. Mark's committee in protesting against the proposed rebuilding of the west front of the basilica.

The following extract reads like a paragraph from one of the publications of the Society for the Protection of Ancient Buildings, and shows that the principles of the society are making progress on the Continent:—

"Restoration means the entire destruction of a building,—a destruction which leaves no remnants to be gathered up, a destruction which is accompanied by a false description of the thing destroyed. Do not let us deceive ourselves upon this important question. It is as impossible, as much impossible as it is to raise the dead to life, as to restore whatever has been great or beautiful in architecture. The unity of its life, the soul that is given by the hand and eye of the artist alone, cannot be recalled. Another soul may be given by another epoch, and a new building evoked; but the soul of the artist of the past cannot be recalled and made to direct the hands and thoughts of the workmen of to-day. To produce a direct and simple copy is an evident impossibility, and in any case, no matter how accurate or elaborate the imitation may be, it will only be a frigid imitation of such parts only as can be copied by the help of conjecture.

And now let us talk of restoration. The whole thing is a lie from beginning to end. You may make a copy of a building, but the ancient building is destroyed, and that more completely, more cruelly, than if it had been allowed to crumble into a heap of dust or had become dissolved into a mass of clay. Nineveh the desolate is more eloquent than Milan as rebuilt.\* It may be urged that the need for restoration may arise sometimes. Agreed. Let us look this necessity well in the face and understand what it means. It is the necessity of destroying. Accept it as such, pull down the building, disperse the stones of which it is built, make them into ballast or lime as you will, but do this honestly, and do not put a lie in the place of the truth. Reflect on this necessity before it occurs, and prevent it by taking care of your buildings. Take care of them tenderly, reverently, assiduously, and many generations may be born and die under their shadows. The evil day must come at last, but let it come openly and truthfully, and do not act in such a way that dishonour and misrepresentation deprive them of the funeral offices of memory."

We believe that in the sixteenth century, in which so many Medieval buildings were lost to us, the assertion so often repeated that this or that building was a ruin or threatened to fall was suggested by nothing more than the classic vision of a Greco-Roman temple of a certain order and a certain proportion, which was proposed to be proudly erected upon the foundations of its predecessor. A new style was substituted for another of a different kind, and little care was wasted upon the old building, seeing that a new one was being given to the world, which, not having the charm, the beauty, the colour of the old, was yet a new and living specimen of the artistic world.

This, however, only partly justifies the rebuilding, and does not excuse the fact that the builders frequently only consulted the exigencies of the moment. For instance, Guido da Polenta erected a monument to Dante, which is thus described by one who had seen it:—"Epyreio atque eminenti tumulo lapide quadrato et amissum constructo compluribus in super egressis carminibus inciso insignitumque." It was added to by others; but, says Foscolo, "somebody not more than half a century ago, reconstructed it with wonderful magnificence, according to the description: an opinion which is not shared by those who look upon it, and reflect upon the vanity of men who, for the sake of adding their miserable names to a monument which appeals to eternity, could alter and obliterate a relic sacred to history."

This reminds one of the exploits of Benson with regard to the tombs in Poets' Corner in Westminster Abbey. Benson restored these monuments, taking care that his share in the business should not be forgotten.

"On poets' tombs see Benson's titles writ."

says Pope, in the "Dunciad."

The authors recall the proposal with regard to the ducal palace at Venice made by Palladio,

\* When the Rebecchino, the old street that encumbered the Piazza del Duomo at Milan, was swept away, the following epigram was written:

"Tedeschi imperatori di di restate,  
Apporter di stragi, e di suenura  
Di Milano atteravano le mura.  
Al sol di libertà ora nipote  
Per placidare a un Germanico Sorzano,  
Mura e contrada ahattano a Milano."

[In ancient days, German emperors, the hangers of carnage and misery, threw down the walls of Milan. Today, in the full light of liberty, their descendants, to please a German sovereign, sweep away both wall and street.]

who was called in to advise as to the steps to be taken after the great fire of 1577. "Considering," says the great architect of the Revival, in his report, "that the columns are slender, and that the wall over is very thick, that the number of capitals split is thirty-two, and that, even if these were replaced, they would split again, that nature has made man with slender legs in order that he may transport himself from one place to another, it follows that the buildings should be stable! . . . I have come to the conclusion that it will be necessary to underpin the fabric of the palace with very wide pilasters between the windows from top to bottom, and to rebuild the wall above the arcade, which is injured by the fire, and is out of plumb." . . .

All the lesser stars of the Classical Renaissance (Renaissance) naturally swelled the chorus; these proposals are full of Ionic and Corinthian colomades, together with allusions to the harbarous style of the edifice, "on account of the ugliness of the orders as well as of their weakness, deformity, and insecurity, we recommend that the whole building be taken down to the foundations, which will enable a new palace to be built, which, for solidity and beauty, will be the wonder of the world."

This was the opinion of the architects of the sixteenth century; happily their advice was not followed by the Municipality, thanks to the opposition of a cultured few, foremost among whom we must name Gian Antonio Rusconi, who attached no importance to the circumstance that the capitals of the columns were in two pieces, seeing that they were still able to do their work, and attributed the want of perpendicularity in the wall over the upper loggia to an optical refinement similar to that which has been recognised to have been practised in the Parthenon and other Greek buildings.

"We do not believe," continue the authors of this manifesto, "in the general insecurity of those buildings, which, having escaped the hands of the renovators, remain to this day; the principle, 'Let us neglect in the present in order that we may restore in the future,' explains more certainly the cause of their actual bad condition. Instead of redoubling their care for their preservation, they restored them; now increased care means energetic means for their preservation; and we accept these as necessary as a surgeon accepts amputation when other methods fail, an operation which is at once distressing and painful, but to which recourse must be had if we wish to save the rest of the body."

J. H.

#### FURTHER MUSINGS ON THE MERITS OF SOME STYLES OF ARCHITECTURE.\*

DEPARTING from ancient Hindoo art, and coming down to a much later period, some beautiful specimens of Mogul work, of about the date A.D. 1570, may be observed in the India Museum. They are casts from the Sultan's apartments at Fâthpur Sikri, near Agra, and much resemble the Moresque type of the Alhambra. Some of these floriated designs could very readily be transformed into wall papers à la Morris. They possess one of the first essentials of a good diaper or wall-paper, that of pretty equally covering the field of decoration. These ornaments appear to have been originally executed in plaster, and are certainly exceedingly well suited to the correct treatment of that material. In the Moorish buildings at Toledo, Spain, is a rather similar style of ornamentation. For sgraffiatura, also, it might very well be adopted. One is here tempted to quote the words of the Preacher, "There is no new thing under the sun"! For it seems rather remarkable that so many thousands of miles away architectural features exist almost as much akin to our vernacular as in those European styles so much nearer our shores.

The examples of trellis-work, filled in with talc, for windows, which are exhibited in this Museum, of severe, straight-lined, geometric devices, such as interlacing squares and lozenges, closely resemble some of our Elizabethan work. Other far less formal patterns of perforated window-screens, some executed in sandstone, some in lime cement, are essentially Gothic in feeling. They are to a certain extent geometric, and remind one of the Decorated window tracery of England, or the perforated stone on trellis-work

in the windows so characteristic of the Perpendicular towers of Somerset. In Egyptian, in Algerian, and in Moorish work, this beautiful feature of the pierced window-screen much impresses those who live in a colder climate where the sun is seldom powerful enough to render such protection necessary. In this style, and in all Oriental art, whether in furniture, jewelry, pottery, carpets and shawls, or costume, how intrinsically artistic were they in form and skilful in harmony of colour! There is in this same building an elegant door of carved teak, with square panels and metal mounts. Pretty geometric and flowery devices of very refined character fill in the panels. The whole treatment is very suggestive to modern wants where no particular limit as to cost is imposed on the architect.

The conclusion that I have come to, after this brief review of Indian architecture, is that in the detail much is to be learned. Probably in a few years' time it will be as common for English architects to travel through India, sketch-book in hand, as it now is to wander through France, Germany, or Italy, such are the increasing facilities for travelling about inexpensively and with celerity. In Assyrian architecture there is in some of the details a mixture of Greek and Gothic feeling, if one can legitimately name the latter in this manner when in reality it had not commenced its existence. In the basement of the British Museum are two examples of very effective incised stone pavements, the one from the Palace of Sardanapalus III, the other from the North Palace, Koyunjik. Both are elegant designs, the honeysuckle ornament appearing to be of a bold character, and not so delicate as in the Greek type. By a very few strokes of the pencil, it would be easy to render either of these pavements into a Gothic thirteenth-century design. It seems to me that here one of the inestimable charms of Gothic work is exhibited. It is so natural,—the outcome of a common-sense treatment of art, fettered by no unreasonable chains.

I do not intend to further consider the merits of any particular styles of architecture, but rather to generalise. We are living in an age of great restlessness, but vast progress, nevertheless. The Queen Anne movement, notwithstanding all eccentricities, has at least had one advantage,—the far more extensive employment of self-coloured building materials. This has had the effect of fostering commercial enterprise and bringing into the general market many materials which before were scarcely known. For example, the want of a stone to harmonise, yet slightly contrast with, red brick had been felt, and the Dumfriesshire, more suitable in many respects than red Mansfield stone, very well supplies this requirement.

Another material, which is not new, but a revived one,—Roman mosaic for pavements,—has brought a beautiful substance to our aid, with its elegant store of Classic patterns and quiet subdued tones. Without depreciating the merits of Mediaeval encaustic tiles, the new advent of Roman mosaic ought to teach us the lesson of reticence in tints.

Gorgeous patterns for tile pavements in little village churches look incongruous as compared with the simplicity of the surroundings. Alas! in time past I have sinned in this way, but now know better. In the churches designed by Wren in the city of London the floors generally have seldom more than a kind of chessboard arrangement of black and white squares of stone or marble, the whole scheme of the unobtrusive paving possessing little variety. It is curious in metalwork how little difference there is between the examples of various styles when a really natural smith's treatment of the material is essayed, i.e., twists and curls, or such forms as iron is readily shaped into. Classic and Gothic, Elizabethan and Queen Anne, almost meet here on an equal footing.

In plaster used internally for decorative purposes, the Mediaevalists of the North of Europe were, one may say, "nowhere." The material was only employed because it was a convenient vehicle for the application of tempera painting, and can never have been intended, as a rule, to be left plain and unadorned. For flat surface decoration in plaster itself we must go elsewhere,—to the Moresque of Spain, to Algeria, or to the elaborate work in relief of the Renaissance period. There are, I am aware, a few examples in England of what is called parqueting work,—in Kent, particularly in the neighbourhood of Broadstairs. But such work

\* See p. 369, ante.

is local and exceptional. Some forty years ago "truth in construction" was one of the great watchwords of the Gothic revivalists, but since then some of these ideas have undergone very important modifications.

For example, in most public buildings at the present day, the floors are constructed so as to be fireproof. But as a general rule what is there to view in the ceilings to show that such floors are anything more than ordinary ones? Or, again, in one of the grandest decorative works of modern times, the Albert Memorial, it is notorious that a considerable amount of concealed ironwork was introduced in the interior of the lofty canopy to counteract what would have been the enormous thrust on the four angles. A tyro in architecture must realise that according to all rules the weight above would force out the angles, unless tie-bars at the springing line of the arches had been introduced, as one sees so commonly in Italy, even in the smallest arches. I presume that, as the Albert Memorial was the design of Scott, the great enthusiast and exponent of Mediaevalism, he saw no objection to this course, and was glad to get rid of permanent tie-bars which would certainly not have added to the ornamental appearance of the structure.\*

In an example lately in my cognisance, it was necessary for a purlin in a roof of considerable span, and resting on a lofty clearstory, to have a bearing of 17 ft. without any intermediate support. There was not height enough between the panelled ceiling and the outer roof to contrive a trussed purlin. A rolled iron joist, however, answered every purpose, but was an awkward thing to exhibit, as the lower part of it would have been visible below the wood ceiling. To have cased it would have looked ugly. The way out of the difficulty was thus solved: the rolled iron purlin was moved slightly, set in such a way as just to clear the ceiling line and he above it, so it cannot be seen from the floor of the church. I expect that if the first principles of the Mediaeval revival had been adhered to, this "sham" would have been considered altogether bad and most reprehensible. The gradual change which comes over men's minds in these questions of taste or fashion is very curious, but has been patent over and over again.

The New Zealand Chambers in Leadenhall-street, when first erected, seemed very odd, but time has accustomed us to much more remarkable specimens of revived old-world architecture. We have relegated stucco and graining to the limbo of shams, but do not object to painting iron, plaster, or stone with a flat tint, so that they might be any material whatsoever. Neither is it considered essential that a church roof should be "honest" and open-timbered, and so it is more usual to have a wooden barrel or otherwise panelled ceiling.

It has been left to the able reviver, or, I should rather say, adapter of an earlier style than Gothic, the Byzantine Romanesque of Italy, to take yet another line and boldly display construction without a shadow of concealment. I allude particularly to the new Natural History Museum, where in the great central hall the arched trusses of iron are left with plain unornamented square-edged soffits, which, possibly may be destined to receive colouring some day, but are clearly not otherwise intended to have *appliqué* ornament. Now, the iron being in immediate contiguity with terra-cotta of the most massive and substantial description (rather recalling to mind the solemn grandeur of the Norman nave of a cathedral), it must be apparent that the two materials, the character of each being so very opposite, do not well agree together. This can the more readily be appreciated by comparing the excellent effect of the great arch occurring before the last bay (to the south) of the hall, which is of terra-cotta. I do not think a better illustration of the principle I venture to advocate could be found. At Westminster Hall, as in numerous other Mediaeval examples, the splendid open-timbered roof rests most naturally and appropriately on the stone walls. Or take a modern example, the enormous roof of the Midland Station at St. Pancras. The effect of the pointed arch trusses set on solid red brick walls, with the accompaniment of freestone dressing, is more successful (my remarks apply solely to the different materials

\* It will be remembered that tie-bars were introduced at first, and left for some considerable time after the work was done for precaution's sake, so that it might take its bearings, which led to an unfounded rumour that they were indispensable and must always remain.

so far as concerns the comparison of the two buildings) than at South Kensington. The span is so vast, the surroundings so different, whilst the hustle and general noise, the roar of the trains, and steam of the engines, all these heterogeneous elements combine in inducing one to realise the wisdom and advantage of employing an iron truss. For, even supposing it could be executed in stone or brick arches, how terrific the thrust would be! The foundation and abutment, too, would have to be of extraordinary and almost impracticable strength. At St. Pancras the glass suits the iron framework. But glass in the roof does not equally harmonise with such a building as this great hall at South Kensington. I presume it was inevitable that there should be top-light, notwithstanding the windows at the sides and north end of the hall.

In this same portion of the Museum much honesty of construction is displayed by the soffits of the rolled iron joists under the great staircase being shown, as well as the non-concealment of the soffits of the stone steps; elsewhere in the building, where iron joists for constructional reasons are necessary, they are shown. All this severity of treatment answers admirably in a museum of natural history, where the leading decoration ought surely to be that of the objects of interest, or the specimens hung on the walls. All the examples must be Nature's handiwork; we do not look for conventionalities. But proceed further, and how very different it is with, for example, a picture-gallery, a concert-room, or other public building, or a private house. There a less austere rule may prevail. Paintings need some more finished accessories around them, and though the opposite mistake has been sometimes committed of making the shell too beautiful, and so detracting from the kernel itself, a building decorated to the pitch of the new rooms at the National Gallery is more appropriate, and harmonises better with the priceless treasures of art around, than the cold, bare rooms of the old portion. But to return to the Museum. The employment of terra-cotta as the material for the internal lining of the walls was a most happy idea, admirably suited to the purpose of the building. The variety, too, afforded by the occasional bands of a bluish grey terra-cotta is very pleasing. For a London atmosphere terra-cotta thus used is much superior in effect to the chilly look of stone, which, owing to its absorbent nature, soon collects dirt, or to brick, which must be necessarily more or less porous, and has not the finished look of its grander sister, terra-cotta. Plaster (except, possibly, polished Parian) or encaustic tiles, mosaic, fresco, or tempera, walls covered with mirrors having gilded frames, how far less would they suit the store-house of natural history objects! Terra-cotta seems exactly to supply the want. In London, where it is necessary to go a long way for stone (unlike Paris, where splendid building stone, easy to work, but soon hardening by exposure, is found at the very threshold of the city in profuse abundance), the use of terra-cotta or moulded brickwork, the constituents of which are as near to London as freestone is to Paris, is very suitable, and in many ways better adapted to the atmosphere of a great city. I cannot but think that cutting of brickwork is a mistake. In the first place, I believe it is a waste of labour and strength to hew about a material which had been made plastic; and then, again, the cutting takes off the hard outer skin formed during the baking. Though I will not pretend to say the inner part is soft, it must necessarily be more porous. It is, I admit, difficult for moulded brickwork to be burned quite true, but any little irregularity does not come amiss, as it is a natural result of the process employed. Much of the work where cut brick is employed could have been more cheaply worked in stone.

For many years it has been again and again declared how absurd and ridiculous and wanting in common sense architects must be to design elegant and costly structures with elaborate and minute mouldings, and carving, in a material like stone, which soon gets dingy and black, the pores choked up with soot and dust, finally corroding away to decay and premature death. It has been asked, why not use glazed bricks, tiles, or even majolica, if the cost be not too great, when not only would cheerful tone and colour be given, but there would be a material easily cleaned by the fire-hose, and unaffected by the gases of the

atmosphere? Small attempts have in consequence frequently been made in this direction, but as yet in no building of any great importance. I need scarcely say that I leave out of the question the piecemeal employment of polished materials, such as inlay, or granite and serpentine for columns or piers. In fact, it seems a mistake to put polished and dead-looking materials side by side in the same building; they do not well harmonise or consort together. It seems curious that a compromise is not more often made by applying a semi-polish instead of a full polish. This would brighten up the marble without producing a metallic appearance. There are several materials, incomplete marbles or padding-stones, like Draycott stone from Somerset, or magnesian limestones such as Hopton Wood, which take a slight polish, and would fulfil the required purpose.

Polish practically abolishes shadow, and thus diminishes that sharpness and crispness of light and shade which one so well sees in a stone or brick building when the grand cumulus clouds of an April or October day suddenly roll away, and a brilliant hot sun bursts forth in a clear atmosphere guiltless of fog or mist. Again, no building constructed entirely of glazed materials (not even polished Carrara marble) would ever have the variety of effect which an unpolished surface gives. The former undoubtedly looks more cheery than the latter on a dingy wintry afternoon near the date of St. Thomas's Day. But wait till spring time comes, with sharp showers and fitful gleams of sunshine, then I make bold to say the quieter building of the two would have the advantage. The glazed substances alter little by age; they do not become venerable. There cannot be much difference between a building just put up and one built fifty years ago. In Italy, where unpolished marble has been used, it acquires a beautiful tone or "patina" by age.

Such, I fancy, are some of the causes which have prevented architecture in glazed materials becoming popular. But internally, when no direct external light can be obtained, or in kitchens, public dining-rooms, buffets, &c., these polished substances have obvious advantages and many uses.

In concluding this brief review of some styles of architecture, it would appear to my mind that the balance, after the scales of the merits of respective styles have been fairly weighed, inclines heavily towards Mediaeval architecture. I can say this with all truth, and without avowing myself exclusively an admirer of this and no other. Great freedom is attainable, even in the most severe thirteenth-century work; there are no shackles to gall, but, rather, subtle cords of elastic. When we get to the fifteenth century, still greater freedom becomes possible, without degenerating into mere whims and conceits. In the Queen Anne style, rule or law there appears to be none; architectural details with no meaning whatever are piled up one over another in a happy-go-lucky fashion. Perhaps they happen to look picturesque, perhaps they do not. No one can tell or foresee the result. It is like a game of pitch-and-toss. Buildings like the new schools at Oxford, Renaissance in character, are very different, and show great skill and study on the part of the architect. Though many may regret the style was not a pronounced Mediaeval one in this case, yet the originality, without eccentricity, of this great pile obliges the critic to acknowledge how exceedingly well it is done, certainly as far as the exterior goes, all that the public now sees. In plain words, though Renaissance in detail, and severe Classic in its symmetrical plan, &c., the structure is Mediaeval in spirit.

There is one structural feature in Gothic architecture which no other style can equal or approach. I allude to the pointed arch. However much opinions may differ as to the relative beauty of the semicircular and pointed arches, there can be no question as to the superiority of the latter as regards strength to carry weight, the material reduction of thrust, and consequent saving in abutment; there is likewise the advantage in vaulting where it is necessary to contrive ribs of different spans, but the same height from the spring to the crown. There is also a charm and variety in the pointed arch, owing to its having a strongly-marked centre and consequent lightness of effect.

The class recently formed at the Architectural Association for the study of Mediaeval architecture, with the excellent examples of which England is so thickly studded, is a wel-

come sign to those who have been faithful to their old love, and a signal to those who have departed from their former allegiance, to come back! We have lately lost two giant architects in this style. How can we better evince our respect and regard for their memories than by following on in their footsteps, and showing that the remembrance of the teaching they inculcated by their buildings has not died with them, but will remain green and flourish for many a long year to come?

B. EDMUND FERREY.

#### ANCIENT ARCHITECTURAL AND FURNITURE DETAILS IN THE BRITISH MUSEUM.

AMONG the immense collection of articles in the upper rooms of the Antiquities Department of the British Museum, we come upon a good many items which are of interest and significance in their relation to architectural style and architectural history. In the new Etruscan room, in the Egyptian rooms, in the Greek and Roman "vase-rooms" (as they are called), we may find among odds and ends of sepulchral memorials and furniture, and in the numerous paintings on the Greek vases, curious examples of ornaments which seem like the first hints of details familiar in their complete form to every architect. Sometimes we are struck by finding, in the archaic work in two different rooms, and belonging to two different peoples, details of remarkable similarity, and which seem to betray the close relationship of the art of the two countries in their archaic period; just as we find, in old German and old English, words which were nearly similar in both languages originally, and have assumed more diverse forms as each language has developed its own idiosyncrasies. At times, too, we may be surprised by the remarkably modern appearance of some detail amid work which is otherwise far removed from any similarity to modern art,—a phenomenon tending to show how the same class of article for practical use sometimes suggests the same kind of treatment to artificers as far apart from each other in time and general circumstances as can well be imagined. To those of our readers who are either not within daily reach of our great national collection, or who may feel grateful to those who will pick out for them things which they have not time to pick out for themselves, it may be of interest to see a few collected examples occasionally of the curiosities of architectural and quasi-architectural detail which may be picked out from the "anticks," as Edie Oebiltree would have called them, in the said collection; and we give sketches of a few such in the present number (see p. 407).

Since the removal of the Egyptian mummies and other remains into their new rooms, from the present Greek vase-rooms, where they were formerly to be seen, sundry pieces of Egyptian furniture have been collected into two cases, where they are more accessible for inspection than they were in their former position; and a very curious collection these make, partly illustrating very good qualities of design, partly showing how very old are some of the special tendencies and idiosyncrasies of furniture design. The chair front which occupies the principal place in one of those cases, numbered 1 in our illustrations, is known to many of those interested in furniture design, and has, we believe, been engraved, but it is very probably new to many of our readers, and is worth calling attention to as an admirable specimen of simple and effective furniture design. The legs and framing are of ebony and ivory, the ivory being used solid in the small tie-bars between the seat and the horizontal rail, and also in the two ends or caps of the horizontal rail where it is fitted into the legs; at the top portion of the legs, and at the neckings of the horizontal bar, the ivory is an inlay. In front of the legs, just above the moulded portion, is a small panel of white ivory with a red centre. The lower part of the legs is moulded in very small mouldings commencing as shown at C, and then continued in a repeating group of two square fillets with a rounded bead between them, each group separated by a slight hollow, down to the foot. For good taste and effectiveness this is almost a model piece of furniture; it is, however, curious, even in this instance, to see how the prevalent details of the architecture of the period reproduced themselves almost unconsciously in the furniture, just as they have

done in other periods; for the form of the ends of the horizontal bar in this case is obviously that of the Egyptian capital, with its hollow bell and its striations at the necking, repeated on a small scale, and turned horizontally instead of vertically. A more curious example of this imitation of architectural forms is the Egyptian bottle, sketched as figure 8, which is little more than the model of the column and capital executed in glass, except with the variation that the lines of the necking are spiral instead of being horizontal. The design is not unsuitable for a bottle, if we did not know the form first as that of the Egyptian column; but, to those who made it, it evidently was the column in miniature, and comes, therefore, under the same kind of category as the jewelry in imitation of larger and different kinds of objects, which is so common in shops at the present moment, and is usually considered (and rightly) to represent a vulgar taste. The Egyptian example of this false taste is not nearly so objectionable as many modern examples, for the very reason that it is slightly altered so as not to be an entirely realistic imitation of the original object; but it shows, as many other things in antique art remain to show, that some of the prevalent forms of had taste in our day are not so exclusively modern in spirit as we are sometimes told.

The cross-legged chair, figure 2, from the same room as the other, is so different in style that we may well believe that the two belong to a period a considerable distance apart from one another, or else that changes in taste were as rapid in Egypt as they are now; which latter would, however, be an improbable or impossible conclusion, seeing the decisive evidence to the contrary which Egyptian architecture affords. The method of producing the ornament is, however, similar, in one respect, to that of the last example; it consists partly of ivory inlay in wood, the eyes and long stripes behind the heads being formed in that way, though the wood in this case is not ebony, but a dark brown wood. The ornament at D is produced by inlay of apparently another wood of very red tint and lighter than the ground. This chair illustrates a fashion which seems to have had its turn in every country at some time or other, of using animal forms as a portion of furniture design. It is not very easy to identify the animal which has formed the model in this case: it is a bird of the duck species, apparently. The fancy is a piquant one, but the bird's bill grasping the bottom rail is not a very fortunate fancy for the purpose, as it looks very weak just at the point where strength is required. No. 3 is another example, and a much better one, of the adaptation of animal form, from a portion of a wall-painting in the Egyptian Court on the ground-floor of the British Museum. Mr. Lawson, the sculptor, appeared to have used this form for the seat for his "Cleopatra," exhibited at the Royal Academy last year.

But the most curious fact in this collection of remains of Egyptian furniture certainly is, that the forms sketched in figures 4, 5, and 6, should have found among the work of the same people who have left the chairs just spoken of behind them. These chairs, No. 1 especially, are eminently antique in spirit, quite removed from the forms and fashions of the present day; but the fragments, figures 4 and 5, might actually be parts of the legs of a common-place modern table or wooden bedstead. They do not seem to show anything analogous to what we generally understand as Egyptian work; they show pretty plainly that wood-turning was practised in ancient Egypt, and they suggest the conclusion that there is something in the process of turning which naturally leads the workman who carries it out to adopt somewhat the same kind of outline and character in his work, independently of his special period and surroundings. In figure 6, which is cut square and not turned, there is a more special character; but the other two might have been the work of a joiner in our own day. No. 7 is another example of the introduction of architectural features into cabinet work; a half of a lotus capital cut in wood, and evidently originally *appliqué* as a part of the exterior design of some piece of cabinet-work, just as Classic pilasters are often applied in cabinet-work at present.

The tendency of objects which are turned to take somewhat similar forms at whatever period they are executed receives another illustration in a bas-relief representation of some article of furniture which occurs on one of the long panels

of the Etruscan terra-cotta monument which formerly stood at the top of the Egyptian Court in the British Museum, and is now transferred to the centre of the new Etruscan room. This bas-relief, sketched in figure 13, shows just the same character of design as has been found in modern turned work so frequently, and reminds one in general outline of some specimen of a Roman or Renaissance candle-brush, with its marked horizontal discs dividing it into sections. The remaining sketches, except figure 19, come from the Etruscan room, and show curious examples of rough forms of Greek and Roman work. Figures 9 and 10 are from that same sculptured Etruscan sarcophagus from which No. 12 is taken; they form the terminations of the angle pilasters, two of which are finished as No. 9, and two as No. 10. There seems to be a great deal of architectural history hinted at in these two details. The rough form of the honeysuckle ornament is obvious at once; but the most remarkable features are the single and double capital, which seem between them almost to supply a connecting link between the Corinthian and Ionic capital, or at least to suggest that there may be such a connecting link, and that the two forms might have had something more like a common origin than has been usually supposed. The form in figure 9 represents the Classic capital of the so-called Corinthian type *en bloc*, the leaves growing from the base of the capital, and the volute at the angle; it is, in fact (more curious still), almost exactly like some specimens of transitional Gothic capitals. But the form in figure 10, which consists simply of the fig. 9 capital continued downwards the reverse way, results in a form very closely resembling the main features of an Ionic capital set vertically instead of horizontally. It has been suggested, by Mr. Ferguson, that the Ionic capital was derived from a Persian vertical form of the same kind; these two forms, occurring on the same object, serve at least to show how naturally the Ionic form may be related to the more common form of the Corinthian type. The Ionic feature in its horizontal position is roughly shown in the small capital from a sepulchral coffer, fig. 13; but we confess this example looks more like a corruption of Classic work than a forerunner of it, and probably belongs to a much later period than the sarcophagus before named: it is interesting as showing an unusual combination of the volute ornament with a kind of repeated scallop ornament, like the lower termination of a series of flutings. This latter ornament is shown the reverse way (the way it was generally used in Roman detail) on the right hand side of fig. 9, where it runs along the upper side of the bas-relief panel of the sarcophagus, from pilaster to pilaster. In this form it is almost a pure Roman ornament, or rather became so subsequently. In fig. 14 we see its employment on both cornice and base of an Etruscan sepulchral chest (about 2 ft. square). It is impossible not to feel that there is some connexion between this and the radiated scalloped ornament over the head in fig. 11. Here it represents evidently a kind of crown or diadem. Is that the origin of the form, and was it used as a straight cornice ornament subsequently? It might seem not unnatural to suppose so; but in the present instance the mask with its curved diadem is probably not so old as the sarcophagus from which Nos. 9 and 10 are taken. The mask,\* with its curious side ornaments (so exactly in the shape of a well-known feature in Cashmere stuffs) belongs to a set of relics discovered by Signor Castellani at Capna, and collected in one case in the Etruscan room, but apparently of very different dates. A considerable number of them strongly resemble archaic Greek work, while one or two seem to belong to the complete Classic period, and to be Roman imitations of Greek work. The one given in figure 11 may be midway between the older and more recent contents of the case in question, which may have been found at the same time, but certainly cannot be all of the same date. The painted ornament on the base of this example marks it as archaic in character; it is

\* In this and other similar masks in the same case it is curious to observe that the ears are sculptured not as they would be seen in a front view of the head, but as if spread out laterally from the head; an incident which is altogether to the treatment of the eye in painting by people who had not come to their perspective. The Egyptian painter painted a full eye in a profile face, because he could not represent the eye sideways; an Etruscan sculptor seems to have represented a full ear on either side of a front face in bas-relief, because he could not carve an ear as seen from the front.

in fact, an inchoate and disjointed form of that Pretean ornament, the square fret pattern, which takes almost every imaginable form. All the terra-cotta masks of the same character, in the case of Capuan terra-cettas referred to, have an ornament painted along the front of the slab or abacus which forms their base, and these painted ornaments are very interesting in the various forms in which they present well-known types of Classic ornament. Four others are given in Figures 15 to 18, all painted in the same position as that at the feet of figure 11, either in black or in black and red on the terra-cotta ground; the solid colour in the drawing representing black, and the shaded portions red. No. 15 looks like another early form of square fret pattern; No. 17 is an exceptional form; No. 18 shows the guilloche pattern painted on the flat in thick lines, with a dot in the centre of the eye. No. 16 shows a more elaborate, but still defective, form of the square fret, in black and red; defective because the interior red parallelograms have no connexion with the flow of the ornament, but are only stuck against the margin of the space. In the manner of putting the ornament together there is some resemblance between this and the purely Egyptian form shown in fig. 19, from a mummy-case of the Roman period in Egypt. Both of these, though not ineffective ornaments, are imperfect as compared with the true Greek type, because their parts are only arbitrarily put together, whereas the perfected Greek fret is a continuous and self-generating ornament.

There is more to say on the subject, to which we hope to return.

#### SITE OF ROMAN POTTERIES ON THE BANKS OF THE MEDWAY.

My researches on the site of Roman potteries, on the south bank of the Medway, have extended over many years, and are yet in progress; for the district is very extensive, and only accessible at low water. I was introduced to them by Mr. Harrison, who, at the same time, brought me acquainted with the Rev. John Woodruff, of Upchurch, who had collected a large number of specimens of the fictile vessels fabricated in the potteries in the low land to the north of Upchurch, now called the Upchurch Marshes. With him I was ever on most friendly terms up to the time of his death. One of his latest acts of kindness was the entertainment of a party of the more enthusiastic members of the Congress of the Archaeological Institute at Rochester, whom I conducted to the marshes, and then to inspect his collections, now inherited, together with his antiquarian taste, by his son, Mr. Cumberland Henry Woodruff, F.S.A. Having thus made good my footing in this somewhat out-of-the-way district, I paid many visits, from time to time, on foot, from Otterham Creek, beyond Lower Rainham, to Lower Halstowe and to the marshes leading to Sheerness, which enabled me to judge of the wide extent to which the land had been worked by the potters; and also, to discover traces of what I conclude were some of their habitations.

At the same time, Mr. James Hulkes, through Mr. Humphrey Wickham, placed his yacht at the service of myself and friends. It was under the command of Mr. Henry Coulter, whose acquaintance I renewed when I came to reside near Strood, finding in him a warm-hearted and generous friend, whose loss to me cannot be replaced. His death was accelerated by one of the periodical overflowings of the Medway, on which I have much to say. By means of the well-provisioned yacht, armed with probing rods and light spades, and mud boots, we never failed to extricate from the creeks large quantities of pottery, which for some flaw or imperfection had been thrown aside by the makers. Of almost infinite variety in shape, dimension, and pattern, the pottery has generally such a marked character in colour and ornamentation that it has acquired the name of "Upchurch Pottery," although it is not to be supposed that it was made nowhere else; yet, such was the extent of the manufactory, that it must have been sent to various parts of the province, the situation being well adapted for conveyance by water.\* Like modern pottery, the manufacturers of the

ancients can often be recognised by certain distinctive peculiarities, as, for example, those in the district of the New Forest, at Ewell, and at Caister; each has a very marked character, and all are different from the Upchurch fabric.

These marshes are an interesting study for the geologist as well as the antiquary. When the Romans inhabited and worked the land it lay high and dry, and the Medway must have been confined within comparatively narrow limits. It was probably some time after the Romans had left before the sea began to make inroads and submerge hundreds of acres. There was time enough for the earth to accumulate 2 ft. or 3 ft. over the *débris* of the kilns ere the creeks formed and washed the remains into their beds where we now find them. As wide tracts of good land have been lost within the memory of man, it is probable that the serious change did not take place before the Middle Ages; and it is too certain that in modern times the inundations are rapidly increasing. The Romans understood embanking, as their noble works on various parts of the sea coast demonstrate, and they regarded the public health and safety, the *salus populi*. On the western bank of the Medway, where the land is yearly submerged, Roman funeral interments are found, and the same at Strood. Here we have clear evidence that in the Saxon times the floods which are yearly allowed to carry with them, desolation, disease, and death, were then unknown. The Saxon cemetery adjoined the Roman, and both were secure from any apprehensions of deluges. History and science warn in vain. A rich corporation in a cathedral town with a large population, year after year, placidly permits a ruinous watery devastation which common engineering skill could stop for ever in a very short time. With land, houses, and streets periodically standing 3 ft. and 4 ft. in salt water, impregnated with pestilential matter, it is the height of irony and mockery to hear talked about, as being actually in existence, a Medway Conservancy Board and a Corporation.\*

#### INTERNATIONAL SANITARY CONGRESS, GENEVA.

FROM beginning to end the congress has been one long success. Nothing has occurred to mar the general harmony, and the representatives of no fewer than twenty-four different countries have met day after day, and in spite of all the differences of opinions, politics, interests, and nationalities, no unpleasantness has arisen. The common object held in view sufficed to unite all these heterogeneous elements; and, were it but for this motive, such congresses should be encouraged. Yet, out of more than 400 adherents, we only recognised fifteen English names, and did not meet more than ten Englishmen.

It was no easy matter to follow the transactions of the congress, divided into five sections, and meeting each in different rooms, particularly as it was in these sections that the subjects which interested us most were generally debated. At the general meetings, held in the afternoon, the subjects of debate were scarcely so well selected as at previous congresses. The opening *séance* was given over to congratulatory addresses, which we have already described;† but, on the second day, an unusual crowd gathered to hear M. Pasteur, who had reserved for the special benefit of the congress the statement of the results attained by his most recent researches. These related to the virus of hydrophobia. M. Pasteur had discovered a special microme in the saliva and blood of persons dying from this fearful poison. By cultivating the microme, and reducing its virulence, he hoped to compose a vaccine that would protect animals, and perhaps human beings, against the dreaded danger of hydrophobia. This, together with many other facts and experiments, sufficed not merely to elicit the applause of the medical members, but was listened to with equal interest by the architects, engineers, and the general public present. In the evening, a brilliant party was given at the country residence of Professor A. de Candolle, the son of the celebrated botanist.

On Wednesday the subject of discussion, relating to the contagious nature of phthisis, was of more special interest to us; for, while the doctors disagreed as to the poisonous effects

of the *Bacillus*, in determining tuberculosis, every speaker admitted that the prevalence of consumption would be reduced by improved sanitary measures. To architects and engineers, by securing the better ventilation of dwellings and the exclusion of sewer gas, appertained the all-important task of reducing the prevalence of consumption. Indeed, an English speaker suggested that experiments should be made with the *bacillus* found in the sputa of consumptive patients and sewer gas and sewer water. If it was found that sewer gas favoured the development of this animalcule, it would greatly accentuate the necessity of sanitary improvements in drainage matters. The same afternoon, Dr. G. Varrentrapp, Sanitary Councillor at Frankfurt-on-the-Main, described the institution of holiday colonies in Germany, by which the feeble children of the poor were sent for several months in the country, and gave some conclusive statistics to prove the very marked and favourable influence such measures had produced on the health of the working classes. In the evening an excursion was made to see the water-cure establishment of Champel-sur-Arve, where refreshments and music greeted the members of the congress. But Thursday was the great holiday. The splendid saloon steamer, *Mont Blanc* conveyed nearly 400 members of the congress first to Evian-les-Bains on the southern side of the lake, and then to Montreux on the north side. Lunch at Evian, and a banquet at the Montreux Kursaal, were the more welcome, as the long enjoyment of the pure air in the lake had stimulated even the most sluggish appetites. The Municipality of Montreux had provided the banquet, and after the feast was over, the inhabitants of the entire neighbourhood vied with each other in the display of fireworks and illuminations. From Villeneuve to Vevey the entire coast was ablaze with Bengal fires, long garlands of Chinese lanterns, and the bright display of rockets. Every now and then the valleys re-echoed the boom of the guns fired in salute to honour the members of the congress. This startling demonstration took every one by surprise. The fairy-like appearance of the coast, the heart-felt sympathy that this spontaneous demonstration betokened, deeply moved the admiring and wonder-struck guests of the Swiss Republic. Loud were the cheers, enthusiastic the waving of hats and handkerchiefs, as finally we steamed away from this Venetian fête organised in our honour.

The general meeting, held on the Friday, brought forward M. Paul Bert, member of M. Gambetta's Cabinet, as one of the speakers, and he was followed by Dr. W. Marcet, member of the Royal Society. The subject discussed was the hygienic and therapeutic influence of mountain air, and it was agreed by all that a moderate altitude, that is from 3,000 to 5,000 ft., was calculated to restore strength, even to increase the size and capacity of the thorax, and was admirably adapted to revive the intelligence and energy of professional men who had lost tone through overwork. In the evening there was another reception, this time within the town itself, at the mansion of Madame Eynard, where many of the *élites* of the Geneva society met to greet the members of the congress.

Finally, at the general meeting of Saturday the prevalence of blindness was the topic for debate. The opening paper was read by Dr. Hilttenkoff, followed by Dr. Roth, who represented the London Society for the Prevention of Blindness, and maintained that two-thirds of the cases of blindness could have been prevented. There were 300,000 blind persons in Europe, and this represented one to the thousand of the population. Then came the farewell speeches, the votes of thanks, and finally the resolution, carried in response to a cordial invitation, to hold the next International Sanitary Congress at La Haye, in 1884. We may, therefore, as well, at once, give notice that communications relating to the next International Congress, which will be held two years hence, may be now addressed to Dr. van Overbeck de Meyer, Professor of Hygiene at the Utrecht University. Thus the members of the English professions connected with the preservation of public health will not be able to urge, as an excuse for their absence, that they have not been warned in time. Holland is easy of access from England, so that we shall hope to meet a far larger number of our fellow countrymen two years hence.

Needless to say, that the farewell banquet, held after the congress had finished its work,

\* I have printed in the sixth volume of the "Collectanea Antiqua" an elaborate account of the site, together with engravings of the leading types of the pottery.

† From vol. i. "Retrospections, Social and Archaeological," by C. Roach Smith (now printing).  
† See pp. 349, 363, ante.

was a most enthusiastic gathering. The foregoing brief sketch of the general meetings gives but a feeble idea of the labours of the congress. The most important work, especially in what relates to architecture, was done in the sections, and to this we may return when we have collected and studied the documents. For the moment, we were merely anxious to give a general idea of this most important and successful meeting; and above all, to at once express our gratitude and high appreciation of the cordial welcome received.

#### LARGE EXPENDITURE IN RAILWAY AND TRAMWAY WORKS.

AN analysis of the railway, tramway, town improvement, and other Bills for the construction of public works which have received Parliamentary sanction during the session which has just closed is of an exceptionally interesting nature, as showing the immense increase which is going forward in the number and expenditure of these several undertakings. The entire number of private Bills introduced into Parliament during the late session was 303, of which 228 have now become law.

The number of these applications has been increasing year by year, more especially as regards railways proposed by existing and new companies, as the subjoined figures will show. During the session of 1882 the Bills promoted by existing companies were 104 against 85 in the session of 1881, and the length of proposed new lines by these existing companies in the present year was 591 miles against 381 miles in 1881, the amount of capital required for these undertakings of 1882 being 36,663,798*l.* against 21,700,496*l.* in 1881. The railway Bills promoted by new companies in 1882 were 60 against 34 in the previous session. These proposed new lines showed a length of 789 miles against 433 miles in 1881, and the amount of capital to be raised was 45,798,593*l.* against 11,941,856*l.* in 1881. Combining the existing and the new railway companies, their Bills in 1882 numbered 164 against 119 in 1881, the total length of proposed new lines 1,380 miles against 814 miles, and the amount of capital to be raised 82,662,307*l.* against 33,641,829*l.* in 1881, or an increase of nearly 49,000,000*l.*

Of the total number of 164 railway Bills which have been investigated during the present year, 92 have received Parliamentary sanction. Of this number, 34 were Bills in connexion with amalgamation, purchase, and other arrangements. Of the remaining Bills promoted by existing companies 36 have become law. These several Bills are for the construction of an aggregate length of 396 miles of additional railway and other works by the respective companies, the capital required for which is 25,178,833*l.* Amongst the largest items are 3,200,000*l.* for the construction of 32 miles of new railway by the Hull, Barnsley, and West Riding Junction Company; an expenditure of 2,141,000*l.* by the South Eastern Company in new railways from the Charing-cross Station, and other works; 2,000,000*l.* by the Great Northern Company; 2,000,000*l.* by the Midland; 1,832,000*l.* by the North-Eastern; 1,750,000*l.* by the Caledonian; 1,666,600*l.* by the London and Brighton; 1,333,000*l.* by the London and South-Western; 1,280,000*l.* by the Lancashire and Yorkshire; 1,000,000*l.* by the London and North-Western; 820,000*l.* by the North British; 800,000*l.* by the London, Tilbury, and Southend; 733,000*l.* by the Great Western; 641,066*l.* by the Great Eastern; and 560,000*l.* by the Wrexham, Mold, and Connah's Quay Company. The Didcot, Newbury, and Southampton Company's Bill likewise authorises them to expend 1,330,000*l.* in the construction of 45 miles of new railway.

The number of Bills sanctioned, promoted by newly incorporated companies for the construction of entirely new railways, is twenty-two. These Bills authorise the construction of 271 miles of railway, with a capital expenditure of 19,280,333*l.* Some of these undertakings are of unusually great magnitude, the heaviest being the Regent's Canal, City, and Docks Railway, 19 miles in length, the proposed capital for which is 10,490,000*l.*, including 1,600,000*l.* to be expended in the purchase of the Regent's Canal. The next undertaking in order of cost is the Metropolitan Outer Circle, 29 miles in length, with a capital of 2,666,600*l.* The Mersey Overhead Dock Railway, 7 miles in length, is estimated to cost 650,000*l.*; the

Glasgow and City District line, 3 miles in length, 733,000*l.*; the Tilbury and Gravesend Tunnel Junction, 4½ miles in length, 600,000*l.*; and the Wimbledon, Merton, and West Metropolitan, 3 miles in length, 200,000*l.* The Charing-cross and Waterloo Electric Railway is also amongst the number of the new undertakings. The length of this proposed line is about three-quarters of a mile, and the estimated cost is 133,000*l.* From Charing-cross the line is to pass in subway under Northumberland-avenue, the river Thames, College-street, and Vine-street, to a point adjoining the London and South-Western Railway terminus.

The entire length of new railways sanctioned to be constructed by existing and new companies, is thus 667 miles, and the amount of capital to be expended in their construction is 44,459,166*l.*

The number of Bills sanctioned during the session for the construction of new tramways was twenty-one, authorising 120 miles of tramway at a cost of 1,217,500*l.* Of this number seven of the Bills authorised the construction of 30 miles of tramway in different parts of the metropolis, the capital for which is 837,500*l.* The metropolitan companies which have obtained these various powers are the London Southern Tramways Company; the London Street Tramways Company; the North London Suburban Tramway Company; the North Metropolitan Company; the Norwood and Crystal Palace District Company; the Peckham, East Dulwich, and Crystal Palace Company; the South London Tramways Company; and the West Metropolitan Tramways Company. In addition to the above there were twenty-seven applications to the Board of Trade for Provisional orders to construct an aggregate length of 124 miles of tramway, at an estimated cost of 517,611*l.*

The number of gas and water Bills passed was thirty-one, in addition to twelve applications for Provisional Orders. The proposed capital for the works under the several water Bills sanctioned is 1,609,000*l.*, in addition to 342,708*l.*, the estimated cost of gas and water undertakings under Provisional Order applications. The capital for the intended new waterworks at Bristol is 400,000*l.*; 400,000*l.* are also required for similar works at Manchester; 187,500*l.* for further works at the North Essex Water Company; and 181,250*l.* for extended works at Windsor and Eton.

Amongst the other Bills passed during the session were twenty-two in connexion with dock and harbour works, and thirty-five town improvement and sanitary Bills.

#### MARBLE WORK AND OTHER DECORATIONS AT THE DUBLIN EXHIBITION.

THE high degree of excellence attained by Irish artisans in the department of artistic marble work in Ireland has given a stimulus to the genius of Irish architects and artisans engaged in the designing and execution of such work. The country supplies some of the most beautiful kinds of marble from those of her quarries that are now worked. The display of artistic marble work at the Dublin Exhibition includes many kinds of ornamental sculpture and carving used in churches and in private houses. The chimney-pieces are mostly of Irish marble (Middleton red and Galway), exhibiting taste in design and goodness of finish. The most important work exhibited is a pilpit executed by Messrs. O'Neill & Co., of Dublin. It is of large size, and stands upon nine polished marble pillars, resting on a base of white granite. The eight outer or smaller pillars are of Irish green of the same material. The capitals are of mottled marble, carved, presenting a beautiful contrast with the grouped figures in the panels. Another specimen of ecclesiastical sculpture is a high altar by Messrs. Pearce & Sharp, of Dublin. Imported white marble being the principal material used, it presents a very chaste appearance, the carving, polishing, and tracery exhibiting much artistic skill. All the coloured marble used is Irish, and the labour expended upon the entire work has been that of Irish sculptors and artisans. The altar is from a design of Mr. G. C. Ashlin, architect, and it is intended for Kilmanno Church, county Limerick. A collection of chimney-pieces of Bardella and other marbles is exhibited by Mr. J. Chapman, of Dublin, who also shows a

number of circular tables inlaid with Irish and other marbles of different colours. A baptismal font of Irish and Italian marbles is also included in this collection. Two highly-finished chimney-pieces, with fenders attached, made entirely of Irish marbles of various colours, are shown from the Kilkenny Marble Works. Three marble chimney-pieces in Carrara, Italian, and Irish marbles are exhibited by Mr. John Coates, of Dublin. Mr. W. Birney also exhibits a collection of mantel-pieces of different coloured marble,—Irish and foreign. Two of them are entirely of Irish marble. Two Italian statuary marble chimney-pieces, well carved, are shown by Mr. W. Haliday, of Dublin. The spandrels are perforated and relieved with the background of Middleton (Cork) pink marble. An interesting collection of marble work is that of Messrs. Ryan & Sons, of Dublin, comprising three carved and inlaid mantelpieces in Irish and Italian marbles of beautiful pattern and finish, a polished urn of variegated marble, and marble crosses.

#### PROPOSED TESTS FOR MATERIALS USED IN DRAINAGE CONSTRUCTION.

THE *Deutsche Bauzeitung*, of Berlin, has lately called attention to the importance of special tests for the materials used in drainage constructions, in view of the increasing adoption of the modern system of sewerage in the various cities of Germany. It is remarked that the tests used in connexion with the construction of open water-courses are of no practical value when applied to drain-pipes, even when materials of an analogous character are employed. This arises from the nature of the liquids carried through sewer-pipes, which contain, in most cases (although in a very diluted form), a certain percentage of alkalis and of different acids,—the latter being found in greater abundance in the sewage of industrial towns. Thus it is suggested that the tests of the materials used in constructing drains should be conducted with a view to determine their properties of resistance to muriatic, sulphuric, and nitric acids.

Some time ago Dr. Kämmerer, of Nuremberg, instituted a series of tests of this description, with special reference to the drainage works of that city. Pieces of the various substances to be tested were left for a certain length of time in a solution of one per cent. of sulphuric, muriatic, and nitric acid, or ammonia, and their loss in weight was accurately observed.

The results arrived at showed that ammonia exercises an effect of such slight importance that its action can, as a rule, be disregarded. The destructive properties of muriatic and sulphuric acid were, however, fully demonstrated. In the various kinds of brick the loss was from '02 to 23.50 per cent. The losses in the instances of concrete and cement pipes varied from 13.94 to 37.11 per cent. Glazed pottery-ware pipes withstood the influence of the acids better than any of the other kinds tested, their loss only being from 0.13 to 0.17 per cent.

These tests, which were made in 1878, were noticed at the time in various technical journals, and although they led to the prohibition of the pouring of the refuse water from chemical factories into the sewers of Nuremberg (mostly built of cement-concrete), they have not been regarded to any appreciable extent in the smaller towns in Germany. Cement-concrete and cement pipes do not, however, seem to be used in the more important drainage operations in the principal German capitals.

In connexion with the destructive influences of certain acids upon substances containing lime, silicate of lime, and more particularly carbonate of lime, it is remarked that mechanical causes also act in an injurious manner. When the lower part of the drain is attacked in such a way that a cavity is formed, solid matters sink into it, and in smaller drains a stoppage may after a time result.

The expense of excavation and other labour bear such a heavy proportion to the total cost of drainage operations, that a slight difference in the outlay for the materials used does not seriously affect the entire expenditure. Works of this description occasion such disturbances of traffic, and are of such vital importance to the public health, that it is with justice remarked that only such materials should be used as promise the longest period of service without need of repair. Thus any partiality to local industry may lead to the most troublesome results in the end.

### ANCIENT MONUMENTS IN IRELAND. DUBLIN ANTIQUARIAN SOCIETY.

At the monthly meeting of this society, held on the 12th inst., Mr. J. P. O'Byrne, who was received with loud applause, said that it was matter for great regret that the many noble monuments of antiquity which were strewn all over the land were fast mouldering away. The stranger to our shores would be led to believe that Irishmen were indifferent to the ancient glories of the past. Do not you meet the Druid's altar and the mystic round tower in every barony, and Ogham stones in many a sequestered spot? While every other nation in Europe jealously guards and studies the remains of what it once was, shall Ireland let all go to ruin? If Ireland were in national health her history and antiquities would be familiar by hooks and pictures, statuary and music, to every cabin and shop in the land; her resources as an agricultural, manufacturing, and trading people would be equally known. It is quite useless to ask the English Government to patronise the efforts we are making to save the ancient edifices of Ireland from the fast-mouldering band of time. Nevertheless, it is the duty of all good governments to preserve the ancient remains of a country. No do not a small sum was voted some years ago, which only went half way in patching up the thousand monuments which adorn our island. That venerable and celebrated relic,—the Coronation Stone of Destiny on Tara Hill,—stands in the open air unprotected, and is being constantly subjected to worse than Pagan usage. There was once civilisation in Ireland; and yet, with all our boasted nineteenth-century enlightenment, what do we know of Ireland or Irish history beyond a catalogue of names and a few marked crests? He trusted the members of the Antiquarian Society all over the country would do all in their power to preserve the monuments of Ireland. And so say we.

### FACING BRICKS.

BUILDING in brick has been resorted to in this country for a long time. Not so on the Continent, where brick has come into more extended use only in recent years. The taste for brickwork is spreading everywhere, not only in districts poor in quarry stone, but all over France, Germany, and Switzerland, where, even for buildings of some architectural importance, rough masonry work was the prevailing mode. In Switzerland especially, where the workmen have had little experience, building with brick is looked upon as expensive and luxurious. In consequence of the prevailing tendency of combining the beautiful with the useful, facing bricks of various sizes are now manufactured in Germany and Switzerland, by the employment of which builders are enabled to erect walls for nearly their whole thickness of bricks or cement slabs, even partially of quarry-stones,—which may be obtained everywhere at very low rates, especially now,—and to face them afterwards with a finer description of bricks. Bonding is preserved in the usual manner by joining the inner bricks in such a manner as to use for facing alternately  $\frac{1}{2}$ ,  $\frac{1}{4}$ , or  $\frac{3}{8}$  bricks. This way has the advantage, besides cheapness, of permitting the facing bricks to be put in afterwards, so that they cannot be soiled or damaged.

The greater the distance of the building site is from the place of manufacture of the facing bricks the greater is the saving by a reduction of carriage, the charge for which is very high in Switzerland especially, and tells so much with heavy materials. The bricks are, therefore, made hollow, and, in order to secure a better hold for the mortar, provided at the sides with ribs and grooves. It is evident that, for the manufacture of facing bricks of the description indicated, only clay which in burning becomes hard and compact, and acquires a nice colour, is suitable. Bricks which are brittle, porous, of an inferior colour, are not adapted for elegant and durable building, are consequently lower in price, and will not bear increased expensive working. Architects who have visited recently Northern Germany, and in Southern Germany, especially Frankfurt and neighbourhood, will have seen numerous instances of the application of partial facing bricks. At Amsterdam, the new railway station is being built with those bricks. In Switzerland, as far as we know, those bricks have been used only in two instances, at Basel and at Geneva. In Switzer-

land, they are made in dark red, yellowish white, and various shades between those two colours. The bricks are said to be of very great hardness, and of close grain, carefully made, and well burnt. There can be no doubt that these facing bricks will find a more and more extended application.

### THE SWISS NATIONAL EXHIBITION BUILDING AT ZURICH.

THE most remarkable feature at present noticeable in the construction of the above building is the Machinery Hall. A great part of the hall is now covered in, and its carpentry work is nearly complete. This hall (which is expected to be one of the most attractive portions of the exhibition) is composed of two wings which intersect each other at a right angle. One is about 420 ft. in length, and the other about 320 ft. The width is about 80 ft., and the height about 60 ft. There will be a gallery looking out upon the river Sihl. The transmission of steam power will be effected by means of an underground passage, so that visitors will not be in any way incommoded. The Machinery Hall will be, it is said, larger than any which has lately been seen at any district exhibition, and even compares with the similar portions of the recent national exhibitions.

In one spot an octagonal structure is being erected, surmounted by a tower, from the summit of which a view of the city and its romantic environs can be obtained, as well as a general idea of the exhibition building and its surroundings.

### THE MUNICH INTERNATIONAL ELECTRICAL EXHIBITION.

This exhibition was opened on Saturday evening, the 16th inst., by Duke Charles Theodoro of Bavaria (as representative of the king), in the presence of upwards of 1,000 guests.

Dr. Von Beetz, the president of the committee, opened the proceedings by referring to the comparatively modern period in which the science of electricity has attained the important position it to-day occupies amongst the various branches of human knowledge. He likewise alluded to the important advances lately made in the storage of electric force and in the application of electricity to various mechanical purposes. He remarked that the astonishment we now feel at the marvels of electric science is similar to that sentiment with which our forefathers regarded the invention of the steam engine, and its adaptation to purposes of locomotion. In conclusion, he referred to the international character of the exhibition and to the advantages which the cause of science would probably derive from the display of what various nations are now doing in this important branch of technical knowledge.

Duke Charles Theodoro then declared the exhibition open.

### DRINKING-FOUNTAIN AT ST. JUDE'S, WHITECHAPEL.

THE drinking-fountain which we illustrate this week, executed by Messrs. Doulton, from the design of Mr. Statham, was alluded to in our notice of the last Building Exhibition at the Agricultural Hall, where it formed the centre object of Messrs. Doulton's exhibits. It now stands in its place against the wall of the tower of St. Jude's Church, Commercial-street, Whitechapel.

The materials employed are the result of a desire to use something which would present an indestructible surface without the expenditure on mere raw material which would have been incurred by the use of granite, the material adopted by the Drinking-Fountain Association for their street fountains. Doulton presented such a material, with the opportunity of obtaining a certain amount of elaboration both in modelling and colour, at a cost less than that of the plainest and most uninteresting granite structure on the same scale. The steps are made of the Eureka Concrete Company's material.

The cost, including the steps, was 32*l.*, the whole being presented to the district by Mrs. Barnett, the wife of the Rev. S. A. Barnett, the Vicar of St. Jude's, as one means of contributing towards the ornamenting and improvement of the neighbourhood. The effort must certainly be considered successful.

### HÔTEL DE VILLE, PARIS. HALL OF FÊTES.

IN a recent volume we gave an external view of the Hôtel de Ville, Paris, as rebuilt under the direction of Messrs. Ballu & Depertbes, architects, with a very brief sketch of its history.\* The view showed what is known as the Façade Boccador, from the name of the Italian architect who is believed to have designed it, and which is an exact reproduction of that part of the building as it existed before its destruction in the time of the Commune, 1871. The competition which resulted in the present building took place in 1873.

In July of the present year a portion of the interior of the Hôtel de Ville was opened on the occasion of a splendid fête; as we had previously shown, however, a large amount of work remained to be done to complete the interior.

In our present number we publish a view of the Hall of Fêtes, in which was given the inaugural banquet, and we shall be able on a future occasion to add some descriptive particulars.

### DERBY SCHOOL: NEW MASTER'S HOUSE.

This building, which is now nearly finished, is being built in the Kedleston-road, adjoining the school cricket-field, and within a few minutes' walk of the school buildings. The facing bricks are red Coalville, and the tiles dark-coloured Broseley. The work is being well carried out by Mr. C. Bass, builder, of Leicester, for the sum of 1,500*l.* The architect is Mr. E. J. May, 3, Great James-street, London.

### HOUSE ERECTED IN THE CLAPHAM- ROAD, LONDON.

IN our present number we give an illustration of a house which has been recently erected near Clapham Common for Mr. Hunter, organ-builder.

The house is built of bright-coloured stock and rubbed red brickwork, with a Portland stone balcony and cantilevers under; the gable of the house in the lower part is tile-hung, and the cove and upper part are finished in plaster work, carved and stamped by the architect. The roofs are covered with red tiles. The whole of the window-frames are shown outside, and have a moulding round where they meet the brickwork, the upper lights of windows above the transoms have lead glazing in, and all the woodwork throughout is painted white.

A pleasing feature has been introduced at the side of the house, where a window which lights the upper staircase is brought between the two chimney-stacks with an arch over.

A large organ-factory has been erected at the back of the house, from which it is separated by a court-yard, and the archway at the side is made so that carts can have access to it. There is a large show-room above the archway nearly the whole depth of the house in length.

In the interior there are some turned newels, balusters, and other woodwork, in old-fashioned style.

The chief aim in all the work has been to keep close to the homely English brick style, which prevailed in the last century.

The whole of the works were designed and superintended by Mr. Sidney R. J. Smith, A.R.I.B.A., Belle Vue House, Lansdowne-road, Clapham. Mr. Copp was the foreman who had charge of the work.

**Electrical Cutting of Glass during Manufacture.**—At present, large glass cylindrical vessels for scientific and commercial purposes are cut during manufacture by surrounding them with a thin filament drawn out from the molten glass, and then cooling them suddenly by contact with a cold substance. According to *Iron*, a more sure and perfect method has been devised by Herr Paht, of Dresden, who surrounds the glass vessel with a copper wire, connected by binding screws with the two poles of a galvanic battery, and made red-hot by forming contact. The rough edges are then rounded off by turning the object in a blow-pipe flame; and, to prevent any unequal contraction of the parts subjected to this action, a slight annealing is effected in the furnace.

## GLASGOW MUNICIPAL BUILDINGS.

## SKETCH DESIGNS EXHIBITION.

Str.—Upon the supposition that the rejected designs in the Glasgow Municipal Buildings Designs Competition were contract ones, and that there was no new light among them, your view that the exhibition of sketch designs was superfluous is, perhaps, correct enough. But there might have been new conceptions or new combinations displayed in them which were worth showing; and when architects have spent days in drawing and nights in dreaming over a plan, they are apt to imagine that there is something in their production of a promising kind, and to wish for an opportunity of exhibiting it to the town. Besides, are there no lessons to be drawn from such an exhibition,—no beauties to be discovered, no defects to be pointed out? There were many neat and ornamental designs exhibited. Were any of them,—it might be asked, for instance,—perfectly appropriate to the situation,—sufficient for the position and purposes of the building? One great thing to look to is that the building should cover the ground well, be elegantly spread upon the surface, with a sufficient number of handsome ins and outs on the plan. Another thing of moment is, that the façade should have that largeness of appearance which is not got when the picture of it fills the eye at once, or when it has the appearance of a small building erected upon a large scale. It seemed to me, on a cursory view, that some of the designs would suit an academy or normal seminary better than municipal buildings, so neat and self-contained were they. Some of them were as pretty as ivory tectonics, or a new-born cherub that had come into the world with its wig on.

A building of the kind required should be spacious and square, and be all glancing and gleaming like a battalion of soldiers at the present on a field-day. The grand is always above expectation, and when the building had its walls brought up to their height and level, and completed and finished with cornices and balustrade, and urns and statues, and all keeping, that another tier should suddenly and gracefully spring up in bows and curves and arcs, with trellis and hood, and filigree and stars and stripes; and that the work of splendour should begin at the very point where it appeared to be at an end, would please the eye and the imagination; then, that over and above that, and in the background, the spires and domes, and minarets and peaks and pinnacles, should rise, and pierce, and flash in blue sky, and all in due proportion, would satisfy the severest taste.

There is no such view as that perspective one required in the competition by the assessors to be got in the case of most large and imposing buildings. Nor could such a view of the building in question, when erected, be obtained. The flanks of mostly all large buildings in towns rest in perspective on the smaller and obscurer buildings which surround them, and in the country on banks and groups of trees: and properly so. Whether the building when completed will shoulder it finely in the town remains to be seen. But with regard to the putting the competition sketches out of sight, I do not see that there is any obligation to do that, or that it should be expected to be done. If these designs, or any of them, or one of them, have anything original in their composition, there is no cause that they should merely strut and fret their little hour upon the stage, and then be seen no more. On the contrary, if this is rather a case when being beaten in one city the disciple should shake the dust off his feet and flee to another. As a personal matter, my own design (by the way, the town from which it hails is not mentioned among others in the *Builder*), furnished up, may yet appeal to lovers of art in London or in Paris. As it is, I have the consolation that it was approved in Edinburgh. An architect of great experience and very considerable taste told me that "the roof was well broken up, and that the front would have a grand appearance." And on the strength of this I have gone on and will go on.

W. Y. B.

\* \* \* We had no intention in the note referred to by our correspondent to express any objection to the exhibition of the sketch designs; our objection was simply to any reopening of the first competition by review of the sketch designs which had been put aside. Exhibition is at all times desirable so that the greatest educational advantage possible may

be obtained from a competition, and that all desirable publicity may be given to the merits of competitors. We add what appears to be at present scarcely a list of the authors of the ten designs selected from the first open competition:—

- "Viola," Mr. Young, London.
- "St. Roman," Messrs. Hall & Taylor, London.
- "Semplice," Mr. Lynn, Belfast.
- "Gauntlet," Messrs. Worthington & Elwood, Manchester.
- "Ars Regia," Messrs. Leeming & Leeming, Halifax.
- "Aurea Medicaria," Mr. G. S. Aitken, Dundee.
- "Civis," Mr. F. T. Baginall, London.
- "Peradventure," Mr. F. Stirrat, Glasgow.
- "Tea," Mr. Higgins, Glasgow.
- "Trident," Messrs. Cox & Robinson, London.

## CARPENTRY AT CROYDON.

Last week a meeting was held at the Public Hall, Croydon, for the purpose of distributing the prizes and certificates to those members of the Croydon Technical Carpentry Class who had been successful at the examination recently held. Dr. Alfred Carpenter, J.P., presided, and in opening the proceedings said that perhaps there was no place which more showed the necessity of technical training in carpentry than Croydon. During the past year, according to the report of the Local Board of Health, more than 1,200 new buildings had been erected, and he was sure that any one who had noticed houses in course of erection in Croydon would admit that in their construction there was shown a great want of knowledge on the part of the carpenter. At present there was a great difficulty in regard to carpentry, in consequence of the action of the contractors, who did not seem to care how the work was done so long as it was done cheaply. The system of apprenticeship was dying out; contractors did not care to teach apprentices. The carpentry classes supplied the deficiency thus created. Any one attending these classes, too, would be able, when necessary, to turn his attention to other kinds of work to that on which he might be specially employed. They, in fact, would become good workmen, and do their work at less cost to the masters and greater benefit to themselves; for they would be able to do it in a smaller amount of time.

The Rev. Henry Solly, the founder of the classes, read a letter from the Drapers' Company, regretting that they were unable, through absence of members of the Court from London, to send a deputation to the meeting. Mr. Solly then delivered an address, showing, by many practical illustrations, the great advantages of a technical education generally, and particularly as regards carpentry.

Mr. C. T. Millis, hon. secretary of the Artisans' Association for the Promotion of Technical Education, also addressed the meeting. He urged that in addition to the practical value of technical education in making men better workmen, it had another, a moral, value in causing men to think, and so making them better men. Particularly he advised a thorough knowledge of practical geometry, and said he believed that men would find it to their advantage to join these classes even if they had to "lose a quarter" to do it. In Mr. Staynes they had an excellent teacher, possessing just the kind of knowledge required to teach such a class.

Mr. Staynes, the teacher of the class, in his report, said the class had increased from sixteen to thirty-six during the last two years, and that the members attended more regularly than last year. He strongly recommended all carpenters to learn the elementary principles of solid geometry. It would enable them to do their work more quickly and accurately, as it acted as a check against error.

Mr. Fraser, artistic carpenter and designer of art furniture, and a donor of one of the prizes, bore testimony to the superiority of the workmen under him who had attended the technical carpentry class over those who had had no such training.

Dr. Carpenter then distributed the prizes and certificates as follows:—Mr. A. D. Reynolds, first-class certificate with prize for practical plane and solid geometry (elementary stage); first-class certificate with prize in the elementary stage technical carpentry; also first prize for home work. Mr. F. Shopland, first-class certificate with first prize, elementary stage technical carpentry; second prize for home work. Mr. J. E. Mead, first-class certificate with prize, elementary stage technical carpentry. Mr. Wippeny, second-class certificate, advanced

stage technical carpentry; first prize for applied work. Mr. Hayward, third-class certificate, advanced stage technical carpentry; second prize for applied work. Mr. S. Hughes, third-class certificate, elementary stage, technical carpentry; prize for an extra paper.

Mr. Knight (furniture manufacturer) proposed, and Mr. Bailey (builder) seconded, a vote of thanks to the Drapers' Company for the pecuniary assistance they had given to the class. The resolution was carried with applause.

## THE TRADE UNIONS CONGRESS IN MANCHESTER.

THE fifteenth annual congress of trade unionists was opened in the Co-operative Hall, Ardwick, Manchester, on Monday last. The following were among the societies represented by delegates, viz., the Operative Bricklayers' Society, Carpenters and Joiners of England and Scotland, Amalgamated Society of Engineers, Operative Stonemasons of England and Wales, United Operative Masons' Association of Scotland, Amalgamated House Decorators and Painters, Manchester Operative House Painters' Association, Metropolitan Society of Operative Painters.

Mr. T. Birtwistle, chairman of the Parliamentary Committee, took the chair, and in introducing the business of the congress, he expressed a hope that the deliberations of the delegates might not only tend to the improvement of the moral and social condition of the working class, but strengthen and promote the true principles of trade-unionism.

Mr. Robert Anstyn, Amalgamated Engineers, Manchester, was elected president of the Congress; Mr. John Burnett, London, treasurer; Mr. Kelly, Manchester, secretary; Mr. J. R. Smith, London, vice-president; and Mr. Shorrocks, Manchester, and Mr. Sedgwick, Leicester, auditors.

On the motion of Mr. Shipton, a resolution was passed recording the appreciation of the congress of the valuable work rendered to the cause of trade-unionism by Mr. Daniel Guile, and their best wishes for his long and happy life in retirement from his official duties as secretary to the National Society of Ironfounders.

The Parliamentary Committee's report was read by Mr. Broadhurst, M.P. It began with a tribute of respect to the memory of Mr. A. Macdonald, M.P., and the next subject noticed was the Employers' Liability Act Amendment Bill, with which no progress had been made during the past session. "In the meantime," it was added, "many families are suffering injustice by the sharp practice of some employers, who, when an accident befalls a workman in their employ, have, by paying the injured person his full wages for six weeks thereby induced him not to begin an action at law within that time. Payment is then discontinued, and the injured person has lost his right to sue for damages, as the notice required by the Act has not been given. The energy of insurance companies, in their endeavours to induce men to contract themselves out of the Act, has considerably increased during the year. We have had occasion to notice the plausible proposals of an insurance company who are establishing, in connexion with their general business, an 'accident fund,' to which employers and workmen mutually contribute. For a small weekly payment by the workpeople and the employers, they propose certain benefits in cases of accidents for which the employer is not liable under the Act; but it is to be known that the employer is 'not liable under the Act' for all cases insured without the decision of a Court. We are at a loss to understand this, and we hope that the workpeople will not be caught contracting themselves out of the Act by this specious mode of putting the case. Our advice to workmen is that they should hold fast to the law. If they want greater insurance against sickness and accidents, let them join the unions established for that purpose and managed by their fellow workmen. For injuries received through the neglect of their employers they should claim compensation under the law given by Parliament for that purpose, but we cannot advise them to throw in their lot with companies of which they know little or nothing, and thus harter away the rights and protection which have cost us so much to obtain. During the past session Mr. Burt and your secretary succeeded in striking out of the Huddersfield Corporation Bill a clause having for its object the contracting out of the Act of

the employes of that Corporation. A return moved for by Mr. Norwood, intitled 'County Courts Plaints,' shows that during the year 1881, 126 causes under the Employers' Liability Act were entered in County Courts. Twenty-two of these resulted in the recovery of damages to the amount of 1,533l. 18s. 6d., being an average of 69l. 14s. 6d. in each case. Six had yet to be tried in 1882, and twenty-two had been withdrawn and settled out of court. In the remaining cases either the juries could not agree or the result was a verdict for the defendants or a nonsuit. We have no doubt that during the current year the number of cases will show a great increase over that of 1881, and will further demonstrate the great advantages, notwithstanding its shortcomings, derived by the working classes from the Act of 1880. We have no doubt that during the next Session of Parliament Mr. Burt will do his utmost to press forward the Amendment Bill. In this difficult task he is entitled to, and will, we trust, receive, the energetic assistance of those whom it is intended to benefit.

"The general trade of the country has not been so brisk during the past year as we could have wished. Exception to this general quietness must, however, be taken in the case of the engineering and iron shipbuilding trades. In these branches we believe that the demand for labour is fairly good. In the iron shipbuilding trade it has never been equalled, and, as far as union purposes are concerned, the men appear to be laying by for the proverbial rainy day. We hope they are also as thrifty in their private stores, as it is impossible for so extraordinary a period of prosperity to continue, and nothing would more surely steady the inevitable fall in wages than for each workman to be in a position to warehouse his labour, if we may use the term, in times of threatened reductions consequent on scarcity of employment."

The President, Mr. Austin, delivered his inaugural address on Tuesday. Commencing by giving a retrospective glance at the history of this annual congress, he said he found that during the fifteen years of its existence there was much trade unionists might pride themselves upon. Their position at the present time was far different from what it was fifteen years ago. Their funds were protected now by registration, and the Criminal Law Amendment Act had repealed the Master and Servant and the Conspiracy Acts. The Mines and also the Factory Acts had been amended, and the Employers' Liability Act had been passed. This last Act would come before them for amendment, in consequence of the evasions of some of the employers, and the decisions of the lawyers. When the second congress meeting was held in Birmingham in 1869, there were present 44 representatives of trade unions and trade councils, the number of members they represented at that time being, he judged, about 150,000. At the present meeting there were upwards of 150 delegates, representing more than 500,000 members, being an increase of 300 per cent. in representatives, and the same number in members,—a very satisfactory result. He trusted that before the congress had been twenty-one years in existence the members represented would reach the number of 1,000,000. At the time when the first congress was held the trade unionists and trade unions were undergoing the ordeal of examination by Royal Commission, and if they did not come out of the searching inquiry exactly like gold out of the hands of the refiner, they came out of it in such a manner as to show that trade unionists were not so bad as they were painted, but were very much like other people. In connexion with the repeal of some of the unjust and unequal laws of past days, croakers had prophesied that injury would accrue to persons of property. They had, however, never heard at all of such injurious results since the repeal of the laws which trade unionists at one time suffered under. Trade unionists simply asked for fair treatment. They were and always had been law-abiding citizens, prepared to follow out those dictates of common sense and reason which should guide every man and woman. A great deal yet remained to be done, and he trusted that by their united efforts they would go persistently on and never rest contented until they had placed on the statute-books of Great Britain and Ireland the whole of the seventeen propositions on the programme for consideration at that meeting. The first proposition was one relating to the amendment of the Employers' Liability Act, 1880. It was not

necessary for him to tell them what the Act referred to, or what was its intended operation. Suffice it to say that every conceivable advantage had been taken of the defects in the Act by unprincipled employers and large companies, so as to render the Act practically of no use. It was for the congress to say whether they would rest satisfied with that state of things or not. In fact, those who were entrusted with the administration of the law had in many cases been hostile to the claimants, who were mostly helpless in the matter. The amendment of the Act deserved their most earnest and serious consideration. They must do all that they possibly could by every legal means in their power to induce their representatives in Parliament to vote that this law should become what it was intended to be, namely, a real benefit to men injured through the negligence of their employers. They asked for the same conditions for the working man as were granted to the general public. He found from the last report of the Employers' Association that it was stated that so far as the Iron Trade Employers' Association of Great Britain and Ireland was concerned, that Act had not brought that ruin to many which had been predicted, and they found that they could meet all their liabilities for a sum of 330 per cent. less than the sum at which the insurance companies had agreed to contract them out of their liabilities. There was evidence which proved that more care was now exercised than was the case before, and that the insurance companies' calculation for taking the risk were based upon the evidence of the past.

Among the other topics touched on by Mr. Austin in his address were factory inspection, the prevention of steam boiler explosions, and the patent laws.

#### THE DEMOLITION OF KENSINGTON HOUSE.

THE final sale of the materials of Kensington House, preparatory to the erection of new buildings on the site, took place on Monday and Tuesday last, when the carcass of the building, together with the massive ironwork, consisting of numerous box-girders and columns, also the flooring-boards and joists, the whole comprising nearly 300 lots, was sold. Included in the sale was also the west half of the grand marble staircase, the whole of which was purchased at the June sale, by Madame Tussaud & Sons, for 1,400 guineas, with the intention of introducing it into their new building now in course of erection in Baker-street. It now appears that the staircase in its entirety will not be required for the new premises, and hence the resale, which produced 480l., or nearly 50l. less than the moiety of the staircase was sold for in June last. Six pairs of Italian marble fluted Corinthian columns, which were likewise disposed of at the June sale for 100l. per pair, were now again sold, realising 74l. per pair. The total sum realised by the stone and brickwork of the main building was 760l., the portico over the principal entrance, supported on six polished Aberdeen granite columns, and two polished pilasters, being sold for 140l. The total proceeds of the two days' sale amounted to 2,389l.; but, in estimating the sum which the whole of the materials and fittings of the building have ultimately realised, 924l. must be deducted, the amount produced by the second sale of a portion of the staircase and the marble columns, leaving the net produce of Monday and Tuesday's sale at 1,465l. This, added to 8,450l., the result of the four days' sale in June last, brings up the aggregate produce of the sale of the materials of the building to 9,915l., its original cost having been variously put down at 180,000l.

Workmen are now busily engaged in constructing the sewerage on the estate, preparatory to the commencement of building. Mr. Mears, of Hammersmith, is the contractor for this portion of the work.

#### A New Industry for Middlesbrough—

On the 5th inst., at a meeting of the Streets Committee of the Middlesbrough Corporation, plans were submitted and passed for the erection of new works on the Marshes at Middlesbrough, for the manufacture of Scotch and Ganister firebricks by the Middlesbrough Firebrick Company. It is expected the works will give employment to between 50 and 100 hands.

#### FALL OF A BUTTRESS AT ST. PATRICK'S CATHEDRAL, DUBLIN.

ON Thursday, the 14th inst., shortly after noon, one of the buttresses on the north side of the chancel of St. Patrick's Cathedral, Dublin, fell to the ground with a terrific crash, the force of which smashed the fallen masonry into a great heap of debris. The adjoining portions of the building were considerably damaged. We regret to say that the catastrophe involved the death of three persons,—a young girl and two boys.

The buttress which fell so suddenly was nearly 70 ft. high. It and three other buttresses supported the north wall, which runs alongside Patrick's Close, a wide thoroughfare, occupied almost entirely on the side opposite the cathedral by small shops for the sale of second-hand furniture and articles of a very miscellaneous description. The side of the street nearest to the cathedral has no houses erected upon it, and beyond the narrow footway are the iron boundary railings of the cathedral grounds. Inside these railings on the north side the grounds are not wide,—probably about 15 ft. or 20 ft. from the railings to the bases of the buttresses. These were built of solid masonry, each being topped by a heavy pinnacle in cut stone, weighing many tons. The buttress which fell spread across the entire space between its base and the opposite shops.

The *Freeman's Journal* says the cathedral is built upon the lowest ground in the city, and almost since its partial re-erection after fire in the latter part of the fourteenth century its base was subject to the disastrous effects of water lodging around the foundations. The Poddle River, which runs beneath the building, is the cause of this lodgment of water, and frequently causes an inundation of the grounds. The excessive damp which, spite of all efforts, could not be overcome, made it absolutely necessary that steps should be taken to strengthen and preserve the foundations, and at the beginning of last June the cathedral was closed and placed in the hands of contractors for the execution of the necessary improvements. Messrs. Dockrell, Sons, Martin, & Co., undertook a contract for the laying down of encaustic tiles throughout the floor, and Mr. Stephen Adams, of Bishop-street, undertook excavations for the purpose of laying down suitable heating apparatus. His contract was completed last month. Mr. J. H. Pile, of Great Brunswick-street and Abbey-street was entrusted with the contract for underpinning and concreting the endangered foundation. A moat had been dug along the north wall. The excavations were carried to a depth of a few feet below the base of the foundations. Mr. Pile's workmen, it is said, commenced underpinning the first of the buttresses a few days ago. On the day preceding the accident, this buttress, they state, gave indications of not being safe, and on the morning of the accident, five or six of Mr. Pile's workmen applied props to the foundation, and then proceeded as expeditiously as possible with their concrete work. Shortly after twelve o'clock, the men being in the excavated moat, their attention was attracted by a trembling motion in the buttress, and seeing, when they looked upwards, the nature of the occurrence that was about to take place, they jumped out of the moat, with a shout of alarm, and rushed into the graveyard. The next moment supplied ample proof that their escape from death was narrow and providential. Down fell the buttress with a dreadful crash. The base of the masonry sank into the excavation underneath, but the main portion of the column, without perceptibly losing any of its solidity until the crash occurred, spread across the iron railings and the street. A section of the iron railings was smashed, and the dwarf of the falling stonework. Two enormous masses of stonework and mortar lay in the centre of the street. The topmost part of the pinnacle fell upon the roof of a one-story house on the opposite side of the Close and hurst through it into the yard at the rear, fortunately without injury to any person. Near this house the heavy entrance-gate of a yard was smashed by other portions of the descending pinnacle. Here two children who had rushed to the shelter of the archway lost their lives, their bodies being almost crushed into pulp; and a girl named Sarah Egan, in whose arms was a child two years old, was also knocked down and died a short time afterwards.

from her injuries. The infant was not killed, but received very serious injuries,—a fracture of the skull and several bruises on the body. An arch, shaped like an ellipse, which sprang from the buttress to the north wall of the building, fell almost simultaneously with the buttress, and crashed through the slated roof beneath, but the ground arched below the roof proved sufficiently strong to sustain the weight of the debris, and thus saved the grand organ.

Soon after the accident, Mr. Park Neville, City Engineer, made a careful inspection of the foundation of the fallen buttress and of the foundations of the buttresses adjoining, as some apprehensions were expressed lest the calamity should be repeated. The foundations of the whole of the northern flank walls of the cathedral are exposed in the excavations which are being made with a view to carrying out necessary improvements in the drainage of the building. Mr. Neville expressed an opinion that it would be well to put up supports to the buttress next to that which has fallen.

On the 15th inst. Dr. Whyte, the Dublin City Coroner, held an inquest at the Morgue on the bodies of the deceased. Evidence of identification having been given,

William Egan, 17, Patrick-street, was examined. He said,—the deceased, Sarah Egan, was my sister. She was a servant-maid, and her age was 16. She last resided at 76, Patrick-street, in Mr. Mooney's house. I was one of the workmen employed in the building, and was engaged at the time being out on the wall.

The Coroner.—Can you say anything of your own knowledge as to how the accident occurred? That morning before the accident, just after breakfast, I took notice of a small crack in the building. I was working about 16 ft. down from the pathway.

Michael Goggins, 29, New Bride-street, examined.—I was employed as foreman mason of the works,—the repairing of St. Patrick's Cathedral. I was there when a portion of the building fell. I was standing quite convenient to it, on the bank formed by the earth thrown up.

The Coroner.—What first attracted your attention?—I first saw one of the pinnacles separate from the wall.

Was there any noise or warning?—I heard none. It came out quite clean from the wall. Did it fall in a solid mass?—Yes; across the Cathedral-yard into St. Patrick's-close. At the time two masons were underpinning the buttress, and two labourers were bringing them stones; they had just time to get away.

They were actually engaged working when the masonry began to give way?—Yes.

What was it gave the warning?—A little bit of mortar fell down when the masonry began to give way, and alarmed them, and then they ran. The buttress stood out quite straight after parting from the wall, a minute or so before it fell.

Are you satisfied that all your men escaped?—Yes, I am; there are none missing.

When did the work commence?—My work commenced about three weeks ago. The greater part of the excavation around the cathedral was then completed. I had to superintend the excavations at the place where the accident occurred.

Do you know what those excavations were for?—Yes. They were being done to build a boiler-house to supply hot water to heat the church. I had completed the excavations at the spot.

Had all the buttresses undergone the process of underpinning?—No; only one.

Which one was that?—The one next to the one that fell had been partially underpinned.

How much of the underpinning had you completed of the one that fell?—The whole of it.

Then it was no safeguard in doing it?—No, sir, it was not. There was no connexion between the buttress and the wall of the church at all.

A Juror.—There was no tie?—No tie.

The Coroner.—That was a defect in the original construction?—Yes.

It was the excavation that brought about the catastrophe?—That is my opinion.

If the buttress had been properly constructed the excavation would not have had that effect?—No, sir.

Were you notified that morning that there was a crack in the buttress?—I was, sir.

And you saw it?—I did, sir.

What did you do to meet that?—I did not think the crack would be any harm, sir.

Supposing you did, could you have done any

more?—Nothing more than that we might try to stop it up if we could.

Did the foundation of the buttress settle in any way?—No; not an inch.

Nor of the building?—No, sir.

Mr. Law.—The buttress projects from the church wall?—About 7 ft., sir.

What is the breadth of it?—About 4 ft.

When you were underpinning that did you go in under the whole of it?—No, sir. I began at one side, and went a foot under the mason work, and then built up from the bottom.

Did you cut away any mason work that was not sound or good?—I did, sir.

Did you pin it up in a proper mason-like way?—As well as it could be done by the hands of man.

How much of the work had you done when it fell?—I had the face and the third side.

As regards the buttress, is it a rough or a smooth wall? Does it appear as if there had been an older buttress there?—Yes.

Could you when you went there see a crack between the buttress and the main wall?—No.

And there has been some "facing" down there?—Yes.

Now at what point did the buttress break off? Is it at the juncture of your work?—At the juncture of my work and the old, about 4 ft. above where I was working.

The part that is still up against the wall, is that much above where you were working?—About 3 ft. or 4 ft.

A Juror.—Did you shore up any of this place?—Yes, I did. I thought the buttress was constructed in the ordinary way, and was properly tied. It never occurred to me that it was not tied.

After some further evidence, the inquest was adjourned until the 21st inst.

#### THE LONDON AND NORTH-WESTERN COMPANY'S NEW HOTEL AT PRESTON.

THE magnificent new hotel erected on the high ground, and the crossing of the Venham Park, at Preston, by the London and North-Western Railway Company, has just been completed and opened. A view of the building, together with a general architectural description, has already appeared in the *Builder*. It is in the Renaissance style, of red brick, with red sandstone dressings, and covered in with red Staffordshire tiles. The most prominent feature of the building is a lofty tower, at the top of which is a tank, capable of holding 2,000 gallons of water, from which the hotel will obtain its supply for domestic and sanitary purposes. Below is a spacious apartment for the use of visitors, who are here afforded a most extensive and charming view of the valley of the Ribble and the surrounding country. The hotel is approached from the island platform of the railway station by a covered way, having an open-timbered roof the entire length. That portion crossing the line has a wooden floor, and is lighted on either side by plain white glass. This section ends in a spacious hall, from which the way is continued to the hotel. This portion of the structure has a striking and handsome appearance. The floor is covered with artistic octagon tiles, having an ornamental border, and the windows are glazed with tinted cathedral glass. The covered way has a total length of 180 ft. It is intersected by a 24 ft. cab-way at the back of the hotel, after crossing which it leads into the principal vestibule of the main building, which is paved with Milton's tiles, and is well lighted by an ornamental lantern light. This leads into the large hall, where the bar is situate. From this point run a series of corridors, ornamentally tiled. To the front of the building, facing the Park and the country around the valley of the Ribble beyond, are coffee-rooms, sitting-rooms, smoking-rooms, drawing-rooms, and private suites of apartments, whilst on the opposite side of the corridor are a number of bedrooms. The walls of the corridors and upper floors are lined to a height of 4 ft. with different coloured tiles, forming artistic panels. Above the tiles the walls are faced with the material known as "Lincrusta Walton." It is of a pale green colour, having a pretty embossed surface, and has a highly ornamental appearance. A wide stone staircase leads to the upper floors, on which are suites of apartments, and a number of separate sitting-rooms and bedrooms. Some of the suites are arranged

for entire families, and comprise sitting-room, two bedrooms, dressing-rooms, bath-room, and lavatory. Every part of the building is well lighted and ventilated, the ventilating, heating, and sanitary arrangements having been carried out by the Sanitary Engineering Company, of Victoria-street, Westminster. In front of the hotel is a promenade, 400 ft. long and 18 ft. wide, and below this is a new public promenade, and the hotel is connected with the sloping park beneath, to which visitors have direct access. The grounds belonging to the hotel are being tastefully laid out as a garden.

The general contractors for the hotel, of which Mr. Mitchell, of Manchester, is the architect, are Messrs. Neill & Sons, of Manchester; and Messrs. Benham & Co., of London, have supplied the furniture. The total cost of the hotel and furnishing is estimated at 50,000.

#### COMPETITIONS.

*North-Eastern Counties' School, Barnard Castle.*—At a meeting of the Governors of the North-Eastern Counties' School, held at Durham, it was resolved that the school be erected on land near the Bowes Museum, on the east, and Mr. Watson, Canon Brown, and Mr. Richardson were empowered finally to purchase or exchange land necessary for a square enclosure twenty acres in extent. A long discussion took place with regard to the employment of architects, and the proposition to throw the design open to public competition was negatived, as were also motions to limit the number to six, and even one. Several names were mentioned, and eventually it was resolved that three architects only be invited to compete, and were thereupon allotted for, namely, Messrs. Giles & Gough, London; Mr. Armfield, Whithy; and Mr. Johnson, of Newcastle-on-Tyne. It is hoped that the foundation-stone of the school will be laid on Lady Day next. The successful architect will receive no premium, his remuneration being the usual percentage on the cost of the building. The two unsuccessful architects will be awarded 40*l.* each. A writer in the *Darlington and Stockton Times* criticises the limitation of the number of competing architects to three, observing that two of the three gentlemen nominated to compete are diocesan architects.

#### MASTERS AND MEN IN THE BUILDING TRADE.

SIR,—The public will think, when reading Mr. Potter's letter in the *Times*, that there are at this moment, or likely to be, severe differences between the employers and employed in the building trade. It may, perhaps, be a relief to some to hear that we have never dwelt more peaceably together than now, and, as far as we can see, there is no prospect of a rupture.

It is quite true that a National Association of Master Builders does exist. It is also a fact that it was constituted soon after the last great masons' strike. Its object is to protect the masters against unjust demands from the men, either as to increase of wages or, what is often almost as important, "rules of working." This object, if faithfully carried out, is to the general benefit of the community. Since the establishment of this association there has been no serious general strike in the building trade.

It may be that it is unfortunate that such a society should be necessary, but in the case of a builder, where any one of the many trades employed may, by means of a strike, stop the whole proceeding of a building, it is impossible, with any degree of comfort, and without great risk, to carry on business without such means of protection, to be used in case of necessity. It so happens that, for some years past, labour in all branches has been abundant, and if the public were aware of the circumstances of the trade they would be inclined, I think, to commend the master builders for not having endeavoured to reduce the wages, as they might have made an attempt with good chance of success. But they have taken no step in that direction. I trust that the good feeling now obtaining in the trade may not be disturbed.

A BUILDER.

"Heaton, Butler, & Bayne."—In consequence of the death of their senior partner, Mr. Clement Heaton, his son, Mr. Clement John Heaton, who has for some time taken an active part in the business, has been taken into the firm.

## BUILDING PATENT RECORD.\*

## APPLICATIONS FOR LETTERS PATENT.

- 4,287. S. C. Jervoise, Torquay. Open fire-grates. Sept. 8, 1882.  
 4,315. M. J. O'Riordan, Cork. Boilers for heating water and cooking, &c. Sept. 11, 1882.  
 4,353. H. Pearce, London. Apparatus for opening and closing fan-lights, casements, sashes, &c. Sept. 13, 1882.  
 4,369. W. A. MacLeod, Birkenhead. Window-sash-fasteners. Sept. 14, 1882.  
 4,383. F. Bander, Venezuela. Construction of walls, &c. Sept. 14, 1882.

## NOTICES TO PROCEED

have been given by the following applicants on the dates named:—

September 12, 1882.

- 3,783. B. D. Healey, Brighouse. Asphalt apparatus. Aug. 9, 1882.

September 15, 1882.

- 2,266. W. Newell, Birmingham. Combined letter-box and name-plates. May 13, 1882.

## ABRIDGMENTS OF SPECIFICATIONS.

Published during the Week ending Sept. 18, 1882.

326. O. Seefeld, London. Stamped metal roof filing. (Com. by H. Kleho, Baden-Baden). Jan. 23, 1882. Price 4d.

This filing is made of sheet metal, stamped out with a curved lip, whereby each plate overlaps the next. (Pro. Pro.)

519. G. W. von Nawrocki, Berlin. Fire-places. (Com. by R. Müller, Berlin). Feb. 2, 1882. Price 2d.

Above the grate is placed an iron box, round which are flues, the air passing through which is heated, and mingles with and thus consumes the smoke. (Pro. Pro.)

556. E. Verity, J. M. Verity, and B. Banks, Leeds. Windows. Feb. 4, 1882. Price 6d.

The sashes are made with double frames. The outer one slides in the ordinary grooves in the window-frame, and the inner one, which carries the glass, is hinged to the outer frame. They are secured together by a cam action.

558. G. W. Wigner, London. Gas-fires. Feb. 4, 1882. Price 2d.

The pipe which constitutes the burner is fitted to the shape of the grate, and one end is plugged, while the other projects beyond the grate, and when the gas is lighted draws hot air into the interior of the grate. The bottom of the grate is covered with sheet metal, and the back is filled with a mixture of clay, saw-dust, and water, with silicate of soda. (Pro. Pro.)

566. T. Redmayne, Sheffield. Fire-places. Feb. 6, 1882. Price 4d.

The front bars are suspended upon a transverse bar, and the bottom bars are arranged to rise or fall as required. When the fire requires replenishing the front bars are turned inwards, so as to lift the coal off the bottom bars, which are then allowed to fall and fresh coal is put in, when the bars are replaced.

568. C. D. Abel, London. Chimney-cowls. (Com. by H. Hahn, Berlin). Feb. 6, 1882. Price 2d.

Several conical funnels are placed in the mouth of the cowl, one inside the other, to create a draught. (Pro. Pro.)

623. H. Leggott and E. Marsh, Bradford. Cooking-stoves. Feb. 9, 1882. Price 2d.

The smoke is made to pass from the bottom of the grate through a flue, past the oven, &c., to economise the fuel. (Pro. Pro.)

625. J. Winfield, Derby. Fire-grates. Feb. 9, 1882. Price 2d.

The air passes under the grate and up behind the back, and then out through perforations in the upper part thereof to prevent the formation of smoke.

634. T. Brindle, Southampton. Veneering or facing walls, &c. Feb. 9, 1882. Price 6d.

The front bricks are taken out of the wall at intervals and replaced by shoddies having dovetailed faces. Stone or ornamental slabs are secured on these shoddies.

647. C. Slagg, Leeds. Preventing the fouling of vertical soil-pipes. Feb. 10, 1882. Price 2d.

A concentrator is used consisting of a tapered pipe inserted in the vertical soil-pipe to prevent the fouling of the sides thereof. (Pro. Pro.)

652. J. Stainer, Heckmondwike. Lifting apparatus for stones, bricks, &c. Feb. 10, 1882. Price 2d.

A rope is passed over a pulley on the scaffolding, each end of which has a basket. One is filled with material, and the labourer gets into the other; his weight lifts the full basket. (Pro. Pro.)

654. T. Fraser, Aberdeen. Lining for venturals or chimneys. Feb. 10, 1882. Price 6d.

The lining is made of red clay or fire-clay, but, instead of being smooth, has annular corrugations or ridges.

658. A. McLean, London. Slabs or panels

\* Compiled by Hart & Co., Patent Agents, 28, New Bridge-street.

for decorative purposes. Feb. 10, 1882. Price 4d.

These slabs are formed of cement in moulds, with any raised decorative pattern impressed thereon. When dry they are secured to the walls or ceilings.

663. J. F. Williams, Liverpool. Sliding windows. Feb. 11, 1882. Price 2d.

The bottom of the sash is fitted with runners, which fit into grooves in the side frames. The top of the sash has hooks, which take into openings in the side frames and support the sash. (Pro. Pro.)

666. H. J. Haddan, London. Bricks, tiles, &c. (Com. by F. Caucaon, Rouane, France). Feb. 11, 1882. Price 2d.

The clay is pressed through a perforated plate, and these round strips of clay are again formed into an compact mass, from which the bricks are moulded. (Pro. Pro.)

671. J. S. Willway, Bristol. Combined doormat and scraper. Feb. 11, 1882. Price 2d.

This consists of a series of parallel flat bars on edge, tied together a certain distance apart. (Pro. Pro.)

681. J. W. Pitt, Liversedge. Hinges for doors. Feb. 11, 1882. Price 2d.

A recess is cut in the joint of the hinge, in which is secured a coiled flat spring to close the door. (Pro. Pro.)

786. J. M. Lamb, London. Ventilators and cowls. Feb. 18, 1882. Price 6d.

The wind vanes are fixed between a series of cones rising one above another. These are all mounted on the usual spindle.

889. J. C. Mewburn, London. Water-closets. (Com. by J. E. Boyle, Brooklyn, and H. Huber, New York, U.S.A.). Feb. 23, 1882. Price 6d.

A pipe is led from the air-space between the two traps of the basin up through the flushing-tank, thence to the tank to the flushing-chamber and fills it, driving the air out. When the seat rises the water passes from this chamber into the bowl, producing a partial vacuum in the chamber and siphoning the water from the bowl. After this has been repeated several times the vacuum is broken by the admission of air to the flushing-chamber, and the water gives the bowl a thorough after-flush.

## NEW BALL CASTOR.

HAVING occasion to design some heavy moveable furniture, &c., for which the ordinary form of castor seemed too weak, I at first thought of using the ordinary ball-casters, but found that these do not work well except with light weights. The form of castor shown in the accompanying sketch then suggested itself to me, and on trial I find it answers admirably; in fact, the greater the weight the better it rolls. The sockets and screw-collars are of brass, and

the balls of gun-metal, but cast iron or phosphor-bronze might perhaps be used with advantage for the halls; but if any metal harder than that of the socket be used, it would probably be advisable to insert a ring of steel wire over the top of the smaller ball (as is done in the one-balled castors), so that, if any wear takes place, it may be in the upper balls only, and these can be replaced without much trouble or expense. I trust others of your readers may find the idea of service to them.

Melbourne.

J. B. COHEN.

**Charterhouse Science and Art School and Literary Institute.**—The winter session of this, the largest science and art school in the United Kingdom, will, under the presidency of the Rev. Henry Swann, M.A., commence on Saturday, the 10th of September. During the late session about 700 students availed themselves of the privileges afforded by this institution, and of this number nearly 500 presented themselves for examination, and were successful in obtaining no fewer than 125 Queen's Prizes and twenty honour certificates, awarded by the Science and Art Department of the South Kensington Museum.

## SIR CHRISTOPHER WREN.

Sir.—I have read with considerable interest the article [p. 327, ante] on "The Genius of Sir Christopher Wren," by Mr. Huggins.

I agree with much that is there stated, but, here and there, there is room for some difference of opinion, notably in regard to his observations upon St. Paul's Cathedral. I will not, however, trouble you with these, but proceed to say that I do differ fundamentally from Mr. Huggins when he goes on to state,—"Nevertheless, his [Wren's] acknowledged failure in the designs of most of his numerous steeples, though they are said to be based on principles laid down in his writings, may justify a doubt whether he had the strength of imagination or poetic fancy and feeling to conceive graceful architectural forms independently of his geometrical resources." In regard to the last part of the clause, I would remark that no true architect, worthy of the name, ever did, or should ever, "conceive graceful architectural forms independently of his geometrical resources," or, if he did, it would be wise to confine them to his sketch-book. We are familiar with "graceful architectural forms independent of geometrical resources" in the backgrounds of the paintings of some of the old masters, but fortunately these have only been constructed upon canvas.

With regard to the first portion of the clause I have quoted, I have recently devoted considerable time to the study of Wren's "Towers and Steeples," and it was a surprise to me to read that "most of his steeples were acknowledged failures." On the contrary, I have no hesitation in saying that most of his steeples are acknowledged successes, and I think I shall be borne out in my statement by most of your readers. It is only necessary for me to run over the names of St. Mary-le-Bow, the campanili of St. Paul's, St. Bride's, St. Vedast; Christ Church, Newgate; St. Michael's, College Hill; St. Stephen's, Walbrook; St. James's, Garlick-hill; St. Magnus, London Bridge; St. Margaret Patten; St. Martin's, Ludgate; the towers of St. Michael's, Cornhill, and Christ Church College, Oxford; the destroyed spire of St. Antholin's, and many others, to bring before your readers' minds a host of noble, graceful, and clever conceptions.

Were I not fearful of encroaching upon your space it would be easy to show how most of Wren's minor examples are eminently fitted and suited for their positions and circumstances. It will be sufficient for me, I think, to quote the words of that distinguished and lamented Gothicist, the late Mr. G. E. Street, R.A., as conclusive on this matter. He said in an address at the Royal Institute of British Architects, "When I return from some foreign travel . . . I feel a pride in the architectural beauty of the City of London. . . . And to what, may I ask, is the beauty of this view owing? There is a magnificent river and a sublime bridge, but beyond and above these, a cluster of towers and steeples of so much variety of design, so skillfully treated, so picturesque from every point of view, as to afford unending delight."

I will not take up more of your valuable space, except with a word in reference to Mr. Huggins's concluding sentence, in which he says he has this "important truth to enunciate:" that "Wren was not of the highest order of architects, his works not being the perfection of architecture." If the "perfection of architecture" (supposing we knew what that was) is the standard by which we are to judge, I know not where to look for an architect "of the highest order," ancient or modern; but judging, as ordinary mortals have to do, by manifested strivings after perfection, he who comes within measurable distance of that has a claim to be enrolled in the highest order of architects, and such a claim I unhesitatingly make for Sir Christopher Wren.

ANDREW T. TAYLOR.

**Traction-Engine Disaster.**—On the 15th inst. a fatal accident occurred at Harriets-ham, near Maidstone. A traction-engine was drawing a thrashing-machine up Stede-hill, a steep ascent, when, owing to the slippery state of the road, some of the machinery got out of gear and the engine ran backwards. William Parker, who was engaged as a labourer to the machine, was instantly killed, another man named Butler, being badly injured.

OBITUARY.

Mr. Joseph Pettitt, the artist, died on Saturday, at Balsall Heath. As a young man, Mr. Pettitt, who was a native of Birmingham, was engaged in the paper-matched trade. His earliest efforts in landscape, exhibited in the rooms of the Birmingham Society of Artists, gave promise of excellence, and attracted for him the support of the late Mr. Joseph Gillott, for whom he painted a considerable number of views of Swiss scenery, and whose friendship and society he enjoyed until Mr. Gillott's death. Mr. Pettitt became a member of the Society of Artists, and afterwards, on removing to London, he became a regular exhibitor at the Gallery of the Society of British Artists, in Suffolk-street, and at the Royal Academy.

Mr. W. B. C. Fyfe died at his residence, Abbey-road, St. John's Wood, on the 8th inst. While he was still very young his crayon portraits attracted considerable notice by eminent Scottish celebrities, including that of the then President of the Scottish Academy, and were sought for far and wide. At the age of fifteen he became a student of the Royal Scottish Academy. In 1861 was exhibited his picture, "Queen Mary resigning her Crown at Loch-even Castle."

EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY COMPETITION.

Sir,—After a careful examination of the drawings submitted in this competition I cannot help expressing my concurrence in the main with your correspondent, "Fair Play" [p. 380, ante]. I consider that grave injustice has been done to certain of the competitors who evidently strove to adhere to the spirit of the "conditions," by the premiums having been awarded to authors of designs who not only flagrantly ignored the conditions, but who failed even to evince any knowledge of the simplest elements of hospital planning.

What the arbitrator would say if asked why he too ignored the conditions, upon a reasonable interpretation of which competitors depended for success, I am at a loss to conceive; but it is evident that Mr. Alfred Williams paid but little regard to the feelings of the authors of those designs who sought honestly to win the competition,—indeed, it is evident to any one conversant with the subject that the assessor has showed want of knowledge on the subject. To premiate designs for hospitals of six stories in height without proper ambulance lifts,—indeed, in which lifts are depreciated (I suppose, because there was no place for them); with a bad-house within the main building; a whole story underground; rooms planned to look into the ill; wards lighted one story only with corridors between; water-closets and baths, for mixed classes, away from the wards in out-of-the-way places, at the rate of one to twenty, is sufficient evidence of want of knowledge, and must be very provoking to the authors of creditable designs planned with a fair knowledge of the subject.

The estimates, too, are mysterious. The first premium plans will cost 25,000*l.*, or 250*l.* per bed, whilst one set of the other premiated plans could only cost 150*l.* per bed,—certainly sufficient, in my opinion. The names of several gentlemen were submitted to the committee, any one of whom would have commanded confidence and assessor. It seems to show that biased finances were at work somewhere. It would be interesting, at least, to see the arbitrator's report. It may not be generally known that the estimated cost of preparing the forty-five designs submitted in this competition is 1,300*l.* All there were 270 drawings, some of which were hung in dark passages, some not hung at all, but placed on the floors in confusion so that they could with difficulty be seen or read.

Well may the question be asked, How are competitors to be satisfied, or can they be? Only one way of securing satisfaction occurs to me, and that is, to leave to them the selection of the arbitrator. If each competitor had the privilege of naming, say, six professional gentlemen, and the gentleman whose name had the greatest number of nominations were selected to act in that capacity, I believe the result would be met.

JUSTICE.  
\*Too late for attention we received several letters to the same effect, and one very long communication from the author of the

second premiated design, Mr. Lansdell, denying the correctness of some of our former correspondent's statements.

HAMMERSMITH BRIDGE.

The Board of Works for the Fulham District have presented a memorial to the Metropolitan Board, with reference to the proposed rebuilding of Hammersmith Bridge. The memorialists call the attention of the Board to the statistics collected by them of the traffic across the bridge, and point out the complete inadequacy of the scheme for providing for this traffic by means of ferry-boats. In the course of six days of the present month the day traffic amounted to 54,434 foot passengers, and 8,705 vehicles, and the contention of the Fulham Board is that, taking the working hours of ferry-boats of the description and capacity specified by the Metropolitan Board at twelve hours and a half per day, that being the period from sunrise to sunset, they would have conveyed in the six days above referred to, 10,800 foot passengers only, leaving 43,634 persons unprovided for; while no provision at all was made for the 8,705 vehicles passing during the same period. It is necessary to add that the specification provides that the two ferry-boats shall each be capable of carrying twelve persons, and shall cross the river every ten minutes between sunrise and sunset, unless prevented by thick fogs or floating ice. The prayer of the memorialists is for the erection of a temporary bridge.

We trust sincerely that this will be listened to. The notion of closing the bridge as proposed strikes those who are aware of the traffic constantly passing over it as so extraordinary that they can scarcely conceive how such a proposal could ever have been seriously entertained by the Metropolitan Board of Works. Unless the Board comply with the prayer of the memorialists, a most grievous calamity will be inflicted on the district.

RAILWAY CLOCKS.

Sir,—I am glad that the two letters published in your paper have caused the more correspondent to write on the same subject. My principal object in writing is an attempt to awaken some public interest in the matter.

From what we see around us, and from what I know from experience, neither the Government nor the railway companies take much interest in public timekeeping.

Mr. Lakerian Horbert's suggestion to have double cases for railway clocks, lined with vulcanite, would do very well; but double cases and vulcanised linings would not make bad or common clocks go correctly, and railway companies will not pay for first-rate clocks.

The knowledge of clocks and watches is, of course, very limited, to say the least of it, but the same rule holds good of them as of other things; if we want first-rate work we must pay first-rate prices. People seem to think there is a mystery about clocks and watches, that it is all a chance, it does not matter much what is paid, except as regards the outside. The same strange ideas also prevail with regard to the length of time that clocks can last. Railway people can understand that the permanent way, the rolling stock, &c., must be renewed, and that they do not work so well when old as when they are new; but not so with their clocks: they must not want much repair, and as for sometimes having new clocks altogether, instead of the old ones, that would be considered out of all reason. It is only clocks that are expected to work as well when they are old as when new. Other things in this world, human beings included, are allowed to be a little shaky and unpunctual as they get old. Not so with clocks: many years working night and day must show no effect,—clocks must enjoy everlasting youth, and, very limited, to say the least of it, but the same rule holds good of them as of other things; if we want first-rate work we must pay first-rate prices. People seem to think there is a mystery about clocks and watches, that it is all a chance, it does not matter much what is paid, except as regards the outside. The same strange ideas also prevail with regard to the length of time that clocks can last. Railway people can understand that the permanent way, the rolling stock, &c., must be renewed, and that they do not work so well when old as when they are new; but not so with their clocks: they must not want much repair, and as for sometimes having new clocks altogether, instead of the old ones, that would be considered out of all reason. It is only clocks that are expected to work as well when they are old as when new. Other things in this world, human beings included, are allowed to be a little shaky and unpunctual as they get old. Not so with clocks: many years working night and day must show no effect,—clocks must enjoy everlasting youth, and, as I said in my last letter it is all a question of money. We have plenty of clever men who know what to make, and how to make it; but as long as they are beaten down to the last shilling they cannot do the best work; and the worst of it is, if we go on much longer the same way, we shall not be able to get first-rate work at any price.

I know for a fact that American clocks have been bought and used on the platforms of a large London railway, and I am told that Government have bought American watches for India. What would people say if our soldiers were supplied with bad guns, only because they were cheap?

CHRISTIAN LANGE.

The Duke of Albany.—We understand that H.R.H. Prince Leopold, Duke of Albany, has consented to accept the Presidency of the Parkes Museum, which is about to be re-opened in Margaret-street, Cavendish-square.

SMOKY CHIMNEYS.

Sir,—My attention has been called to an article in your paper respecting the cause and cure of smoky chimneys; and I am glad to find a section of the British Association is about to make practical experiments with a view to the abatement of the nuisance. Such an inquiry must of necessity be useful and interesting; but I fear the practical result will not be very satisfactory. The cause and cure bristle with difficulties. As an engineer, I have paid great personal attention to ventilation and smoky chimneys for many years. I consider these two sciences, if I may call them such, are nearly akin.

I am daily called on by some sufferer to give my advice and provide a remedy, but I must confess I am often sorely puzzled. I may perhaps I never undertake a cure unless I can do whatever I please. My first duty is to find out if there is a down-draught in all weathers, or only when the wind is in a certain quarter. After getting all information at my disposal, I commence my careful examination at the bottom, and trace the course of the brick or pipe flue up to the chimney-pot. I also pay a visit into the false roof, and frequently find a defect there. To save money, very often the chimney-stack here has never been plastered, and there is a suck of cold air through the defective brickwork; this would cause any well-constructed chimney; this would cause any well-constructed chimney; this would cause any well-constructed chimney (no pipe) often smokes badly, while in the same house a perfectly straight chimney draws well. I go a little further on, and find just the reverse,—the crooked chimney pulls well, but the straight one will not go at all. Sometimes I fancy a tree in the immediate neighbourhood causes mischief. Against this theory, I find a great many chimneys situated far away from trees or buildings smoke badly, although the houses enjoys an elevated position. I have a theory that on a stormy day the wind current may strike a house at a certain angle, and make the chimneys smoke; but, strange to say, while on these stormy days one chimney refuses to act upwards, all the rest draw powerfully, and I have known all these peculiarities occur in wall-built chimneys. If the door and windows of a room are air-tight, then the room may try to supply itself with fresh air down the chimney. A good plan in such a case is to put in a Robin's ventilator; but there are many chimneys which refuse to act with both windows and door open. I have known smoke emitted from a chimney carried across a wide street by the wind, and when it reached the houses on the other side of the street, it was sucked down a chimney, and the room was partly filled with smoke. There was no fire in this room. I have tried it, and raised the chimney, and the nuisance did not occur again. As I mentioned before, I do not allow any restrictions as to cost, because if I did I should mostly fail in my object, as others do. I see that the grate is properly constructed; if it is not, I alter it or condemn it; if the latter, I recommend an Abbot's Grate. Great care is taken in setting all grates, and none but thoroughly experienced men should set them; there should be no flat coverings over for the smoke to kick against, nor any unbuilt corners behind the grate for the lodgment of cold air,—another friend to a smoky chimney. The backing up of a grate should be solid and gradually gathered up right into the throat of the main flue. Having made all right at the bottom, and assured myself that the upright shaft is free from obstruction (built straight or dog-legged, I do not think it matters much which), I examine the chimney-pot and frequently find the outlet very much contracted; here is danger, because the sweep, finding his brush tightens, considers he is at the top, whereas his brush has not gone through by 2*ft.* or 3*ft.* This, repeated every three months, rams the soot into a solid mass, and eventually closes the smoke-vent. I come across many such cases. I prefer the outlet being a little wider than the main flue. Generally I have come to the conclusion that theory will not cure smoky chimneys. A man undertaking these duties must be experienced and painstaking, and not afraid of soot. I seldom fail. I cured four of the worst description last week. I have registered a simple top made of galvanised iron, which has proved so far a success in every case. It is not a spinner. I do not like them; the latter often provoke the smoke nuisance.

JOHN PINDAR, C.E.

DAINGEROUS BUILDING: OVENS.

MR. CARTER, West Kent Coroner, has held an inquiry, at the Prince Arthur, Arthur-road, Beckenham, on the bodies of Henry Baily, aged thirteen, of 8, Oak Town-terrace, Arthur-road, and George Hobbs, aged fifteen, of 48, Arthur-road, Beckenham, who were killed by the falling in of the roof of an oven on Thursday, the 31st of August. The evidence showed that on the day named his two boys, with a third, named Blizzard, were engaged in deslating out an oven on the premises of George Blick, baker, of 12, Arthur-road, in order to prepare it for baking, the oven having been built about ten days previously by a bricklayer named Charles Coomes, of Hoxton-street, Hoxton, for a contractor, named Alexander Paul Cuming, of Albert-road, Old Ford-road. Whilst the boys were so engaged the roof of the oven fell, burying the three lads under the fallen brickwork. Blizzard was rescued alive after the lapse of about fifteen

minutes, being pulled out by the legs, and he managed to walk home; but some time elapsed before the other two boys could get out, and then they were dead.

Coomes said he had no drawings by which to build the oven, but took verbal instructions, Cuning inspecting the work as it proceeded, and expressing his approval of it. The three boys in the oven had a light to work by, but the job had only been given to one boy, and he did not know how the other two came to be in the oven. He had been told the boys had been jumping on the top, and any oven would have fallen in after that. The outer walls had been built about six weeks, and it would take a month for the mortar to dry.

Mr. Carlton, surveyor to the Beckenham Local Board, said the crown of the oven did not correspond with the plan submitted to the Board. The ring of the arch was simply 4½ in., and any kind of rubbish had been placed between the bricks. Witness had no opportunity of going to see the work in progress, as the plan had only been passed three days before the accident. The building should not have been commenced without the sanction of the Board, and he should have condemned it. The bricks were adapted to the purpose, but the mortar was very inferior. Mr. C. A. Pope, harrier, who attended for Cuming, called Mr. H. Lefevre, engineer, to prove that the work in the oven was good, and that question occupied the attention of the jury a considerable time. Ultimately the jury returned a verdict in both cases of "Accidentally suffocated by a baker's oven falling in," and the coroner severely censured Cuning and Coomes for the scamping work and bad material in building the oven.

#### CHURCH-BUILDING NEWS.

**Plymouth.**—The new spire at St. Jude's Church, Plymouth, is now all but complete, and the scaffolding having been cleared away, its satisfactory effect is apparent. It has been designed by Messrs. Hine & Odgers, architects, Plymouth, from whose plans the church itself was erected some few years ago. The tower and spire are built entirely of worked limestone with Portland stone dressings, boldly buttressed. Mr. Blowey, of Plymouth, was the builder, and Mr. Harry Hems, of Exeter, has executed the stone carving, &c.

**Whitby.**—At a recent meeting of the committee appointed to negotiate for the construction of a new church on the West Cliff, Whitby, the rector (Rev. George Austen) in the chair, a letter was read from Sir George Elliot, bart., M.P., in which, reverting to the promised subscription of site and 2,000*l.* towards the fund, he reminded the committee that, in appointing Mr. Arnfield as architect, they had forgotten the conditions attached to the gift, namely, that he should be consulted as to the appointment of architect. After some discussion, it was agreed, with some expression of sorrow, to rescind the resolution referred to, and Mr. Johnson, of Newcastle, was unanimously appointed architect.

**Seaton.**—The foundation-stone of a new church at Seaton, Cumberland, has been laid. The church will be in the Gothic style, and will comprise a nave and chancel, with open-timbered roof. The interior fittings will be of pitch pine; on the north side there will be a small bell-tower, 50 ft. high. The chancel will be apsidal in shape, and will be lighted with three lancet and two tracery windows. In the nave there will be seven windows, and at the west end two lancet windows and a rose window. The church will seat 240 persons. The architect is Mr. George Watson, Penrith, from which place the various contractors come.

**Preston.**—St. Paul's Church, Preston, was reopened on the 27th ult., having been closed since the early part of the year for purposes of cleaning, extension, and alteration. A new chancel has been erected, extending 18 ft. beyond the line of the old building, and fitted up with clergy and choir stalls, the organ having been removed from the west end of the church to a new organ-chamber at the south of the chancel. The walls, ceiling, and roof of the church have been coloured, and the space previously occupied by the organ has been fitted up with 150 free seats. A large arcaded baptistery has taken the place of the old vestry, and in this is to be placed a memorial font of white marble, presented to the church by Mr. J. Huntington, of Cleveland, Ohio, U.S.A. Another memorial is a stained-glass window, representing the "Ascension of our Lord," and presented by Mr. James Hall, of Preston, in memory of his late wife. A pulpit of oak has been promised, but is not yet placed in the church. The organ has been cleaned and altered by Messrs. Jardine & Co., of Manchester,

The amount of the contract for the extension and cleaning of the church was 2,029*l.*

**Pensnett.**—St. Mark's Church, Pensnett, has been re-opened for worship, after being closed for two months, during which period Messrs. Hardman & Co., of London and Birmingham, through the instrumentality of Mr. Pippet, have been busily engaged in decorating the church. In the body of the edifice the walls have been coloured and painted a vellum tone, and when the work, which is yet incomplete, has added to it the finishing touches, Scriptural texts will be inscribed upon the walls all round. It is, however, the chancel upon which the greatest amount of work has been bestowed. The roof has been treated in brown and white, the rafters being left their natural colour, and relieved with repetitions of the letter "M" in white, signifying St. Mark, the patron saint of the church, whilst the principals are picked out in vermilion and white. The upper part of the walls have been powdered with an emblem of St. Mark, treated in a heraldic manner, and inscribed with a motto of the saint. The north and south walls of the chancel will, when finished, have painted upon them subjects representing St. John Preaching in the Wilderness, and Mary Magdalene at the tomb. On the south side of the chancel is Lord Dudley's private chapel, and this, it is stated, his lordship intends to have decorated at his own expense. Upon the four panels of the pulpit are let in representations, painted upon canvas in oil, of the four Evangelists, with St. Mark in the centre. This portion of the decorations was the work of the Rev. C. H. Dicker, one of the curates of the church. Altogether the cost of the work has been about 400*l.*

**Seaford.**—At a public meeting just held in the town-hall, Seaford (Sussex), plans for the restoration of the fine old tower of the parish church were considered. Mr. Lee (Lee & Son, architects) stated that the tower dated back to the time of the Normans, and was remarkable for the symmetry and elegance of its proportions. The total estimated cost of the work is nearly 1,000*l.*, and it was decided to adopt the plans and carry the work out in sections, if the requisite amount for the whole work cannot at once be raised.

#### DISSENTING CHURCH-BUILDING NEWS.

**Rock (near Horrabridge, Devon).**—On the 23rd ult. a new Bible Christian Chapel was opened here. The structure adjoins the old chapel built in 1866, and provides sitting accommodation for about 170 persons,—the old structure having been retained as a schoolroom. The architect was Mr. J. Crocker, Exeter, and the builder, Mr. Blowey, Matley. It is built of local stone, with granite quoins, the ceiling, like the seats and rostrum, being of pitch-pine and white deal intermixed. The flooring of the aisles is of Minton's tiles, and the walls internally are stuccoed above the dado rail, which is about 4 ft. above the floor. The style is Gothic. The cost has been about 300*l.*

**Colwyn Bay.**—The corner-stones of the chapel, schools, and minister's manse, which are now in course of erection at Colwyn Bay, have been formally laid. The buildings will complete a scheme set on foot by the Rev. Dr. Morley Punsdon to provide for the spiritual wants of English Wesleyan Methodists resident in or visitors to North Wales. The memorial church, which is dedicated to St. John the Divine, is erected in honour of the late Dr. Punsdon's intimate connexion with and zealous support of the movement, and out of respect to his memory the cost of the tower and spire is being defrayed by the ladies of Bristow, and that of the pulpit by the ministers of the Connexion. The materials used in the construction of the chapel and schools are Yorkshire stone, with local stone dressings. The style of the buildings is Decorated. The chapel will accommodate about 700 persons. The architect for the whole of the works, which are being executed by Messrs. Foulks & Son, Colwyn Bay, is Mr. Robert Curwen, London and Liverpool, the amount of the contract being about 6,000*l.*

**Wednesbury.**—Spring Head Wesleyan chapel, Wednesbury, was re-opened on the 9th inst., having undergone transformation at the hands of Mr. J. J. Trow, painter and decorator, from designs prepared by Mr. C. Newman, architect. The decorations are in the Corinthian style. The whole of the woodwork has been stained

and varnished. The organ has also been repaired. The pipes of the organ are elaborately decorated in marone, green, and drab, with gold bands.

**Harrogate.**—A new Baptist church is in course of erection here. The building is Decorated in style, and comprises, in addition to the church, two vestries, a lecture-room, classrooms, and attendant's dwelling, erected upon two sides of the present school chapel. The church consists of a nave—without aisles, transepts, and chancel; the latter contains the baptistery, which will be of white marble. The roof will be a hammer-beam and arched roof in pitch pine, finished with boarding instead of plaster work. The seats are also of pitch pine,—open benches, calculated to seat 600 persons. The exterior is in stone, Burley stone being used for dressings, and Pateley Bridge pitched faced stone for walling. The entrance-doors will be deeply recessed and elaborately moulded with red Corshill stone shafts, with carved capitals. At the south-west corner there will be a tower and spire, together about 130 ft. in height. The roofs will be covered with blue Welsh slates in green bands, finished with ornamental red terra-cotta ridge. The lighting will be by gas, Benham & Sons' ventilating globe light being adopted for the purpose. The lecture-room has an octagonal end, and can be divided into two rooms by a revolving partition, erected by Messrs. Salmon, Barnes, & Co., of Ulverston. The architect for the work is Mr. Wm. Peachey, of 36, Coney-street, York. The following are the contractors for the various kinds of work:—Brick and stone work, Mr. Matthew Wilson, Headingley; slating, Messrs. Watson, Worsnop, & Co., Leeds; plastering, Mr. Charles Fortune, Harrogate; carpenter and joiner's work, Mr. R. A. Raworth, Harrogate; plumbing and glazing apparatus, Mr. S. Rushworth, Shipley; glass work, Mr. Hodson, Stonegate, York; painting, Messrs. Knowles & Son, Harrogate; stone carving by Messrs. Thorpe, of Leeds. The Clerk of the Works is Mr. G. Fletcher, of Manchester.

#### SCHOOL-BUILDING NEWS.

**Otley.**—New Sunday schools were opened here on the 6th inst. The schools are in plain Gothic style, built in a substantial manner of idle wallstones, with local ashlar dressings. The large school-room is 73 ft. 6 in. by 31 ft. The entrances to this room are by two porches in the front; and four class-rooms, average 14 ft. by 16 ft., are arranged on the south side of it, with communications to each from the large room. The inclination of the ground has enabled the architects to obtain under the class-rooms a large room (53 ft. by 14 ft.), intended for use of boys; also a tea-room, which may be used as an additional class-room if required. An internal staircase connects the two floors, and an outer door is provided for lower rooms, level with yard. The large room is calculated to seat, when used for concerts or entertainments, nearly 600 people, and is exceedingly lofty, and provided with Boyle's patent air-pump ventilators. The works have been carried out under the superintendence of Messrs. Fairbank & Wall, architects, Bradford and Otley; and the contractors have been as follows:—Masons, Cordingley & Wildmar, of Idle; joiner, Wm. Hartley, of Idle; plumber, Squire Farrand, of Otley; plasterers, J. & W. Chaffer, of Otley; slater, James Smithies, of Bradford; and painter, G. R. Forster, of Otley. The iron railing and gates have been provided by Exley & Son, of Otley. The cost, including site, has been about 2,000*l.*

**Shibden (near Halifax).**—A new wing, containing a large and commodious school with two class-rooms, a spacious dormitory, and several store-rooms, &c., has been added to the Shibden Industrial School. It is about twelve months since the foundations were laid. The building is a three-storied one. Leading from the stair case in the basement is a room where a warming apparatus has been fixed. In the basement swimming-bath has been constructed. Over the bath is the new school, which is capable of seating 400 persons. This room is wall lighted and lofty, and is fitted up with hot-water pipes, whilst at one end are two large class-rooms, wide staircase leads to the new dormitory to contain eighty beds. The new premises have been carried out under the supervision of M. John Lister. Mr. Simpson, of Bradford, has been the architect; and Mr. Cordingley, of Halifax, the builder.

VARIORUM.

AMONG the cheap books,—the wonderfully cheap books,—now appearing we would mention Carlyle's "Heroes and Hero Worship," at 6d., and the "Life of Richard Cobden," by John Morley, at 1s., both issued by Chapman & Hall (Limited). They are well printed on good paper.

Miscellanea.

**The Valuation of Shoreditch.**—The annual report, just issued, by Mr. Enoch Walker, vestry clerk of the parish of St. Leonard, Shoreditch, shows a remarkable advance in municipal wealth which is being made by the parish, the rateable value of which will presently receive a heavy addition by the assessment of the new goods station of the Great Eastern Railway Company in Shoreditch High-street. The valuation list shows a gross rental of 731,301l., and a rateable value of 588,989l., being an increase during the past year of 0,134l. and 8,578l. respectively. The rateable value of the parish includes the following items:—Railways, 50,085l.; Gas Companies, 28,341l.; Water Companies, 7,350l.; Tramways, 2,500l.; Tugboats Canal, 738l.; Board Schools, 5,412l.; Tuxton House Asylum, 1,900l.; theatres and taverns attached thereto, 3,322l.; the townhall, 1,000l.; assessments of 500l. and upwards, including model dwellings of that value, 5,875l.; the workhouse and infirmary belonging to the Holborn Union, in the City-road, is by local Act rated at only 19l., and the remainder on ordinary assessments under 500l.

**Fatality to a Carpenter at Westminster.**—On Wednesday evening, at the Sessions House, Westminster, Mr. Langham held an inquest in the body of Charles Goddard, a carpenter, aged 48. The deceased was in the employment of Mr. Joseph Lewsey, a builder, and on Tuesday, the 12th inst., was engaged with other men in repairing the premises belonging to the Institution of Civil Engineers, Great George-street, when a rope attached to a piece of timber, which was being hoisted at the time, gave way, and the deceased, who had hold of the rope, was thrown on to some spiked railings beneath, a distance of several feet, and received a severe puncture of the right thigh. The deceased died on the 16th inst. from exhaustion, consequent upon blood-poisoning. It was found necessary to amputate the limb. A verdict of "Accidental death" was returned.

**Association of Municipal and Sanitary Engineers and Surveyors.**—The programme of the Northern District Meeting of this Association, to be held at Tynemouth, on Wednesday next, the 27th, is before us. The members will assemble at 1.30 in the Council-chamber, North Shields. The following papers will be read and discussed:—*Resumé of Discussion on Paper on Private Improvement Apportionments*, by Jas. Hall, Borough Surveyor, Stockton; "The Operation of the Canal Acts," by E. C. B. Tudor, C.E., Surveyor of the Goole Local Board. During the day the w. Coble Dene Dock Works and Pier Works, at the courtesy of Mr. P. J. Messier, the engineer to the River Tyne Commissioners, will be visited.

**Messrs. R. W. Winfield & Co.,** of Birmingham and Holborn Viaduct, have acquired the well-known stained-glass business of Messrs. Mum Brothers, of High-street, Smethwick, at Birmingham. We learn that they intend fully to develop the various branches of the business, which will, for the present, be carried at the same premises at Smethwick, and they have retained the services of Mr. T. W. Mum and the same staff of assistants as heretofore. What Messrs. Winfield & Co. do they naturally do well.

**The Papier Mache Company.**—This Company, long established in Wellington-street, Strand, have lately published two useful additions to their issue of trade books; one "Shiny Pieces," manufactured by the company; and the other, "Architectural Ornaments," among which are many tasteful designs. The company are successors of the well-known Jelfeld & Co., established as long ago as 1816.

**Brighton.**—The ninth annual exhibition of den pictures in oil, 1882, will open on this morning, September the 21st, in the Royal Victoria Gallery. The private view took place on Wednesday, September 20th.

**A Plea for Tree-Planting in Ireland.**—"A dreary treeless waste" will shortly be the appellation of our otherwise justly favoured island, as we have lost the homestead law and timber-planting mania of our forefathers. We ought to learn from the tree-planting lairds of Scotland, where the Duke of Athole can boast of 27,000,000 trees, covering 15,000 acres. The vast woods and plantations exist for use as well as ornament, and the Duke plants annually from 600,000 to 1,000,000 trees. During the past planting season, 2,000 acres were laid out, and the once desolate and bare region, the Dunkeld Hills, are now a place of beauty. The plantations consist of every variety of timber, but recent nurseries are set with white willow trees, as they are in popular demand, and the wood is worth 1s. 6d. per foot for cricket-bats and other purposes. Clean and best quality huts of 9 in. diameter fetch from 2s. 6d. to 3s. 6d. per foot in the London market. These are planted in marshy tracts, where they thrive and grow rapidly from stumps and cuttings. We think our rural industries could be further stimulated by tree-planting, as the season is fast approaching. Ozier culture pays as high as 10l. per acre in the moist grounds of the North and South of Ireland.—*Freeman's Journal.*

**The French Archaeological Society.**—This society is on the eve of holding its forty-ninth annual session, with a very full and highly interesting syllabus of operations. These begin at Avignon on Tuesday next, the 26th of September. Excursions are laid out to Ville-neuve, Orange, Carpentras, Vaison, Aubune, Gigondas, and Vénasque, all abounding in Roman, Medieval, and Renaissance curiosities. The Avignon session, which closes on Saturday, the 30th, is to be supplemented by a four days' visit to Fréjus and its neighbourhood, La Tourrahe, Le Pont des Eclappes, St. Raphael, Boson's Mine, and the Gail's camp at Arlesque. The semi-centenary of the society will be celebrated next year at Caen, at the foot of the statue of its founder, M. A. de Caumont.

**The Law on Ancient Monuments.**—One of the last Acts passed in the recent session (45 & 46 Vic. c. 73) was for the protection of ancient monuments. The law is now operative, and may shortly be enforced. Power is given to constitute the Commissioners of Public Works the guardians, and any owner of an ancient monument may by deed place the same under their guardianship. The Commissioners are empowered, with the consent of the Treasury, to "purchase ancient monuments," and inspectors of ancient monuments may be appointed. Penalties by fine or imprisonment to be imposed for injury done to ancient monuments in a summary manner in the United Kingdom.

**The Royal Institution, Manchester.**—On Saturday last Mr. T. C. Horsfall personally conducted a number of workpeople and representatives of the working men's clubs through the various rooms of the Manchester Royal Institution. Two hours were well spent in describing the beauties of the art-treasures, and great interest was manifested by the members of the party.

**New Route to the Continent.**—The Hundred of Ho Railway, a stretch of thirteen miles, from Gravesend to Port Victoria, Isle of Grain, is now complete, and the first passenger train from the new terminus at the entrance to the Medway to the metropolis was run on the 11th inst. The works at Port Victoria are being pressed forward with unremitting energy.

**Raffaello.**—To celebrate the fourth centenary of the birth of the great painter, a committee, under the presidency of H.M. the King of Italy, has been formed with the view of erecting a monument at Urbino, his native place. Besides a statue of Raffaello, allegorical statues and bas-reliefs may form part of the design.

**The Social Science Congress at Nottingham.**—was opened on Wednesday last, when the president, Mr. G. W. Hastings, M.P., delivered an interesting address, in which he treated of questions concerning the ownership and tenure of land, food supply and population, the poor law system, and education. We shall next week report some of the papers and discussions likely to interest our readers.

**Proposed Roman Catholic Cathedral, Westminster.**—The proposal to build a cathedral adjoining Cardinal Manning's present residence in the Vuxhall Bridge-road, at a cost of 100,000l., but which was temporarily abandoned five years ago, has been again revived.

TENDERS

For alterations and additions to Marsh-street Schools, for the Walthamstow School Board. Mr. W. A. Long, architect. Quantities by Messrs. J. & E. Goodchild.—

### Bristol going ahead.

To ascertain the part of the world from which the megalithic blocks which formed the prehistoric sanctuaries and fortresses of Stonebengo and Avebury were derived is the object of a problem not unfrequently alluded to in our columns. Before the birth of the science of geology, indeed, little curiosity was felt on the subject. Stones, it was thought, were stones. There they were, and that was all that was to be said about it. A little later, when the investigations set so efficiently on foot by Cuvier were chiefly regarded in this country in relation to their supposed theological, or anti-theological, bearing, a clerical writer on Avebury gravely propounded the theory that the "sarsen stones" with which the tourist over the Wiltshire downs is so familiar, were "excreted from the chalk by the action of the deluge."

Not feeling altogether convinced by the arguments of the reverend gentleman to this effect, we yet felt disinclined to adopt the theory, which is that of what we will call geological orthodoxy, i. e., that these stones were transported on ice-floes, and dropped on the melting of their sustaining blocks over the surface of what became afterwards the downs of Wiltshire. To our minds the theory (like many others), if admissible, only puts off the day of reckoning. If carried by ice the stones must have come from some original quarry or mountain face, no less certainly than if transported by human or by gigantic labour; so that, in fact, the geological explanation only added a second difficulty to the first. How they came was, no doubt, a question; but it was one which it would be more convenient to discuss when we knew whence they came. Nor could the ice-transportation theory throw any light on the distribution of the sarsen blocks, in some places on the highest parts of the downs, and in some (as near the Devil's Den), in lines and cross lines, that bear the strongest resemblance to the plan of a tow.

A professional visit to Bristol, however, recently shed some light on the matter, by showing the "sarsen stone" used in the construction of a comparatively recent, and very magnificent, warehouse in the very heart of that ancient city, and at the side of the dock. Unmistakably there is to be seen the same stone of which the wandering "sarsens," as well as the gigantic circles of the ancient sacred capitals

of the district, consist, a millstone grit (we venture to think), as superior to granite for building purposes as granite is to ordinary sandstone. The building in which we found it is called the Counterslip warehouse, and was erected as a sugar refinery, with a prodigality of cost, and an excellence of workmanship, which it is rare, as far as we know, unexampled,—to find out of a Government dockyard, or the like locality. Four substantial floors are supported on iron pillars. There are chimneys on which experiments, such as those recently cited in our columns, might be satisfactorily repeated. And throughout is the trace of the sound workman unstinted as to cost, so that his work is what it ought to be. And here, as quoins and lintels, we recognised the sarsen stone.

For any student who has the opportunity to undertake an excursion that might associate his name with one of the most interesting problems that regard prehistoric England, here is a good opportunity. Let him trace the quarries whence the stone for this refinery was brought. It cannot be an impossible, nor, we should think, a very difficult, task. Bounding our own observation to what could be seen from railway, road, river, or tramway, we saw fine outcrops of stone, which we will not venture on such slight acquaintance to identify with this stone, but from which it did not seem unlikely that blocks as large as those of the Avebury *cella*, 18 ft. square, and 2 ft. or 18 in. thick, might have been procured. At all events, this is the vicinity in which the stone exists. That is one step, and, we venture to think, an important one. And whatever may have been the means of transport commanded by the ancient builders, a degree of strong human interest attaches to the fact that it is not necessary to have recourse to the services of imaginary icebergs as carriers from Norway, or from the mountains of the moon. Those who could build Stonehenge and Avebury,—and our own opinion has been before expressed that they were masons, and that the great stones were wrought,—could have found means of transporting their materials from the mouth of the Avon, which probably was a much better or, at all events, a much fuller, waterway in their time than it is at present.

Not that we would speak with any disrespect of the navigation of the river Avon, as it is at the present moment. Its seven locks are of the noble dimensions of 108 ft. long, and 18 ft. 6 in. wide, with an average fall of 9 ft. And Avonmouth Dock, which is called the Bristol Port and Channel Dock, is certainly one of the finest in this or in any other country. It is 1,400 ft. long by 500 ft. wide, affording about 16 acres of water. Its entrance into the Severn, close to the King's Road, is by a lock 454 ft. in length and 70 ft. in width; and the depth of water over the sill of the lock, in equinoctial spring tides, is 42 ft. At ordinary springs the depth is 38 ft., and at ordinary neaps 26 ft. The

retention of a mass of water of this height by a single pair of gates of 70 ft. opening is an achievement of which the engineer, Mr. Brunlees, may be justly proud,—no less than of the perfect ease with which, on the moving of a lever, and with a preliminary subterranean rumble of loose chain, the great gates slowly roll back, with the apparent ease of a drawing-room door.

The dock is in connexion with the inland railways by means of branches to the Great Western and the Midland lines. But it is more likely to attract attention as being the English Port Said which has been selected as the base for the great campaign for the free opening of our waterways. The enterprising directors of the dock are putting themselves at the head of a movement for restoring the activity of that noble system of water-carriage which, linking together the Severn, the Thames, the Trent, and the Mersey, was the original basis of the great prosperity of English manufacture and commerce at the beginning of the century. We are not about to imitate a well-known example, and endeavour to measure how far this prosperity was due to one cause, and how far to another. Among the names of what we may call the great physical benefactors of the human race the palm may, perhaps, be accorded (with a reserve in honour of Jenner) to James Watt. But even the invention of Watt would have done comparatively little for us, without the aid of Brindley and of Arkwright. All concurred. The steam-engine enabled man to use heat instead of manual or animal labour, and this was, indeed, the mother invention. But the inventor of machinery set the mighty, though beneficent, demon thus raised to execute a work more profitable, if less interminable, than that of twisting ropes out of the sand of the Solway. And Watt's pistons, and Arkwright's spinning jennies, would have had but a restricted field for their activity but for the opening afforded for the transport of their produce by that which always has been, and always must be, the cheapest of communications,—the waterways.

It should be remembered, alike by those who would attribute the chief influence on national prosperity to legislation, and by those who would attribute it to railways, that our first spring, and, indeed, our most rapid proportional advance, was made before any one had dreamed of either "liberating legislation" or locomotion at sixty miles an hour. The first source, condition, and measure of national increase in wealth and productive energy, is the increase of population. It was in 1737 that the Royal assent was given to the first Act of Parliament for the Construction of the Bridgewater Canal. This Act was followed by successive Acts for the same work, in 1759, 1760, 1762, 1766, and 1795; and the completion of the canal, at the cost of upwards of 220,000*l.*, out of the private means of Francis, Duke of Bridgewater, was perhaps, in its consequences, the most splendid

gift with which any Englishman ever endowed his country. True, it brought in to the Duke a revenue of 130,000*l.* a year; and did he not deserve it? He ran near the verge of beggary in proving his faith in the genius of Brindley, and met with the recompense. We wish his mantle would fall at this moment on the shoulders of a worthy successor, for the work has to be done anew. Not done, be it remarked, under the disadvantage of fear of failure, but under opposition acting from the fear of success. It is no longer a question whether a canal is not the necessary attendant on the factory, or whether its service can be replaced, at equally low cost, by any other method of transport. But it is a question how far those who have embarked large sums of money in another series of noble enterprises, which, rightly viewed, ought no more to be regarded as competing with canals than the navy as competing with the army, shall be allowed, alike to their own loss and to that of the country, to lay greedy fingers on a traffic which can be carried on by canals at a profit at less cost than by railways at a heavy loss.

By 1737, according to careful abstract of our legislation as to canals, made by the Freiherr von Weher, in his book, "Die Wasserstrassen Nord-Europas," thirty-eight Acts of Parliament had been passed for the regulation of our inland river navigation; the earliest of which, in 1423, temp. Henry VI., related to the Thames. By the close of the eighteenth century the number of such Acts amounted to 116, many of which were for the construction of canals. Here was the base which fed the increase of our population, from 1800 to 1840, at the rate of 05 per cent. for the whole period, or a little over 14 per cent. per annum, a growth altogether without precedent before the establishment of inland navigation, and greatly diminished since its recent discouragement.

The year 1840 is one which may well be taken as a turning-point, not only from convenience of calculation, but as marking a time when canals were at their zenith, not yet strangled by the railway companies, and when the latter were also at their best, and on the road to the ten per cent. dividends which they obtained before they meddled with the canals. The average passenger and goods receipts on the London and Birmingham Railway for 1840, '41, and '42, were 789,652*l.* per annum; the working expenses were 222,879*l.*—less than 30 per cent. The first direct attempt on the part of a railway company to obtain possession of a canal was in 1845, and by that year the London and Birmingham Railway divided ten per cent. on its original shares. The fatal work of canal acquisition, unchecked by Parliament, though admittedly in defiance of public policy, rapidly proceeded. In 1845 railways acquired control over five canals, in 1846 over ten, in 1847 over seven, in 1848 over three,—the twenty-five canals in question being the very keys of the through navigation of the country. And it is matter for serious inquiry how far that collapse of industry which we have been accustomed to refer to the "Railway Mania" of 1845 has been caused or exaggerated by the mischievous policy adopted with regard to canals; mischievous in two ways,—first as murder, and secondly as suicide,—first as blocking from the canals the traffic which they could carry cheaply at a fair profit, secondly as throwing on the rail a traffic which it costs three times as much to transport by rail as by water. Let it be noted, moreover, that as soon as a railway attains a fair amount of trade, every slow cheap train displaces at least three quick and lucrative trains. At all events, the concurrence of the two conditions of activity in canals and of increase in prosperity is indispensible. Railway dividends have declined in proportion to the extension of the mineral traffic on trunk lines. The canals, which formerly paid 20, 30, and, in one well-known instance, 128 per cent. per annum, are reduced to comparative penury; and the country is doubly the sufferer,—first by the loss of this great item of natural wealth, and secondly by the high rates of transport imposed on all places to which there is no water competition.

However we measure the increase of the national wealth, it is certain that it has undergone a very material check since the seizure of the canals by the railway companies. From 1800 to 1840 the increase of population in the United Kingdom was 66 per cent. From 1840 to 1880, it was only 30 per cent., or at less than half the rate attained during the canal period,

From 1800 to 1854 (we are obliged to take the closest dates given in the returns of the Board of Trade), the yield of our coal mines, which measures the activity of our steam power, was multiplied by six and a half, being an increase at the rate of a little over 34 per cent. per annum, year after year. This rate continued unchanged to 1872, since which it has sunk to 2 per cent. per annum, or three-sevenths of the former rate. From 1800 to 1840, during the canal period, the tonnage of vessels cleared outwards from our ports increased at the average, and enormous, rate of 8 per cent. per annum,—year by year, note!—for forty years. From 1840 to 1872, the increase has been 44 per cent. per annum, and from 1872 to 1880 only 4 per cent. And in 1881 there was a decline of 750,000 tons from 1880. Without attributing this altogether to the stoppage of canal transport, there can be little doubt that this was one of the causes of the decline. And the decline from 1872 to 1880 of 34 per cent. in our cotton exports, of 46 per cent. in our wool exports, of 34 per cent. in our silk exports, and of 30 per cent. in our flax exports, throws a very lurid light on the policy, avowed before the Select Committee on Railways, of charging the highest available rates of freight for carriage on railways, where no water competition exists, and of carrying cheaply only where there is already a cheap sea or other water transport. The difference between the canal cost of 3*d.* per ton per mile, and the lowest rate at which a railway can remuneratively carry, is enough to keep rails, castings, and every kind of heavy goods out of the market, and is the reason for that migration of our industries to the seaboard and the valleys of the navigable rivers, of which we have recently given such striking examples.

It is thus with extraordinary interest that Manchester, Wolverhampton, Birmingham, and other great inland centres of industry will watch, and no doubt will aid, the movement now set on foot in Bristol for restoring to the inland districts that free water communication which nothing can rival in cheapness and in convenience. It is a curious remark,—and in making it we desire to acknowledge fully the immense benefit conferred on the world by the introduction of railways,—that in two signal instances among our first great railways the children have shown strong partricial instincts. Manchester made the first English railway, and Manchester is now so barred from the sea by what, in the language of Mr. Peter Spence, she calls the "Railway Ring," which charges 7*s.* 6*d.* for transport that can be effected by common road for 6*s.*, and by canal for 1*s.*, that she contemplates bringing the sea inland, and probably will carry out the bold intention. Bristol was the cradle of one of the most magnificent works that ever sprang from a human brain, the Great Western Railway as designed by Brunel. And Bristol, according to the evidence of Mr. Wills before the Railway Rates Committee of the present year,—evidence that every one should read,—appears to be the object of what he considers a spiteful persecution by the Great Western Railway Company. That such is intentionally the case we do not believe. But that a portentous blunder underlies the policy of carrying cheaply only where there is competition, and charging as much as possible everywhere else, we have not the slightest doubt. Nor have we any more doubt that the adoption of a sound mercantile policy, based on a scientific analysis of full debtor and creditor accounts, such as that established by Mr. Rae, and his successor Mr. Goodchap, on the New South Wales Railway, would enable the Great Western Company to raise its dividend to six, to eight, and probably to ten per cent.

Under these circumstances,—the truth of which it is easy for any one who will take the trouble of studying the statistical returns of the Board of Trade to verify,—we are happy to welcome and to chronicle the revival in Bristol of that sound old mercantile spirit,—bold and yet safe, lucrative and at the same time patriotic in its outcome,—which made London what it is, and which, from the days of Sir Richard Whittington, was the proud characteristic of the British merchant. We do not wish to say anything uncivil to those who have, after all, done so much for England as her railway directors. But it is impossible to deny the fact that the policy, as stated before the Committee on Railway Rates, and as defended in the columns of a contemporary by Mr. Farrar, is a purely selfish policy. Not, we observe, a policy of

enlightened selfishness, for that, in the long run, respects all interests; but a policy of giving to those who have much, and of taking away from those who have little: of charging prices that do not pay to towns that have a choice of sea carriage, and of making up the loss by disproportionate charges on those towns that have no alternative but to pay. This is not our picture of the case; it is plainly, not to say cynically, avowed in the pages to which we have called attention. Now, this, if a lucrative, is not a patriotic policy. To our eyes, it is as sure to be a losing one in the end to the companies themselves as it is injurious to the country. The man, and the association, that enriches itself while serving the country, is, like the famous portrait of Shakspeare, "twice blessed." A truly sound mercantile policy "blesses him that takes and him that gives." A policy that is founded on ill-advised competition must be, to speak out honestly, a policy of extortion, and we believe that its natural result is ruin.

It is a remarkable proof of the depth to which the sense of the importance of securing the cheapest mode of transport has penetrated the manufacturing and mercantile classes of society in England, that we see, at the same moment, in two such different localities, Manchester stretching her hands towards the sea, and Bristol preparing to push her water transport into the heart of the Midland district. Bristol, once the second port in England, is now the eleventh in the order of her tonnage. Will she ever regain her former pre-eminence? More unlikely things have occurred. It is not attempting to prophesy to say that that port, or that city, which adopts and enforces the sound principles of true mercantile policy which have made England what she is, will thrive and grow, while those cities and ports that hug themselves on a selfish and short-sighted policy will dwindle and decline. As to command of coal,—the main-spring of industry,—Bristol is no whit behind hand with Liverpool. The imports and exports of the latter port amounted, in 1880, to 1914 millions sterling, those of London itself being only 194 millions. Bristol comes after with only 10 millions sterling of trade. But during the last twenty years, while the shipping of Liverpool has increased by 53 per cent., that of Tyne has increased by 85 per cent., and that of the Clyde by 103 per cent. Is there not a warning in these figures? Proud, and justly proud, of her quasi-metropolitan dignity, Liverpool seems to have forgotten that a port must have two legs to stand upon. Her command of maritime trade, except for purposes of coal and of re-shipping, can do her little service unless she has equal command of the free channels of internal traffic. It is of no use to receive food unless it be distributed through the system. The facts which have been recently brought to light as to inland transport from Liverpool are of extreme gravity. Whether as large holders of railway property, or as a great corporate body, the merchants of Liverpool have the deepest interest in being able to send their imports inland, and to receive their exports from, inland Lancashire and Yorkshire by the cheapest possible route. How far this has been lost sight of we have seen. Manchester now meditates a blow, which, if delivered, will deprive Liverpool at one stride of half her wealth. And Manchester, it is only fair to say, only meditates this blow as a measure of long-suffering and long-provoked self-defence. We have before expressed the opinion that, on general grounds, the location of ports on the seaboard, with canal communication for heavy, and railway communication for light, inland traffic, is the true mode of developing to her utmost the natural resources of a country. The recent decision of the Provisional Committee shows that they have given full attention to the considerations we suggested (vol. xlii., p. 763, and vol. xliii., p. 58). But if the port neglects, or even aids, in choking up her inland outlets, the case is widely altered. Mr. James W. Harvey, in a letter to the *Manchester Guardian* of the 11th current, calls attention to some serious difficulties (apart from those caused by the railway companies) in the way of an adequate canal service between Liverpool and Manchester. His arguments have great weight. If Liverpool only cares to increase her dues, and neglects to keep open her inland outlets; if the combined five railways and two canals between Manchester and Liverpool, instead of emulating one another in the cheapness and convenience

with which they can supply the great centre of consumption, Manchester, from her present great centre of maritime income and outlet, Liverpool, only combine to keep up extortionate rates, neither Liverpool nor the railways will prevent Manchester from turning herself into a seaport. The engineering science of the day can overcome what is the true difficulty in this case,—the construction of low-level docks at an enormous cost. For the difficulties of navigation to Manchester, they reduce themselves to one,—that of the purse; and at that, unless we are mistaken, Manchester can afford to laugh.

France and the United States are rivaling one another in the enormous sums which they are expending in perfecting their inland navigation. And the reason is, that men of business, in France and in the United States, have quickly put to themselves the question, "How shall we secure the cheapest possible inland transport? Through Belgium extends a network of 1,250 miles of inland waterway, the dues on which are not more than enough to maintain the safety of the canals. To that we must come in England, if English manufacture is to hold its own in competition with that of countries provided with free inland water carriage. Manchester regards, and wisely regards, her own need in this respect. Bristol, looking at the need of the inland district, will enrich herself in supplying that need. But all England is interested in the possession of a free inland water communication,—costless, except for its own maintenance. And it is our opinion that those localities which first bestir themselves towards attaining this great national desideratum will be the first participants in the wealth which they will thus aid the nation to acquire.

#### WANTED! AN OPERA HOUSE.

It is a strange enough fact, not perhaps quite easy to fully account for, but a certain one, that there is, in so vast a city as London, filled as it is with all that the highest civilisation can afford, but one opera-house. True it is that efforts have been occasionally made to add another to this one; but, as it would seem, only to fail. How this is, with so very many theatres round and about us, it might be hard to say, for so many considerations crowd on us in the endeavour to account for it. That it is a fact is certain. And not only is this so, however to be accounted for, but the "season" for the one only is for so short a time, a few weeks only, that there is but small,—if, indeed, any,—chance of even the upper world of London seeing or listening to many of the most famous of the great compositions of the gifted few who have had it in them to write those unique works. A rare combination of facilities and endowments would seem to be needed to write an opera, and to bring so much of that which is purely mental and musical thought and inventiveness to what may almost be termed a practical purpose. The men and women in an opera must needs talk and act for a time in music, and the very music itself must tell the story of what is going on, and how. Operas are thus quite apart from the usual "stage" business, as visible and listened to in "plays."

Operas and operatic performances being so exceptional, and demanding so much in those who invent, and in those who realise them to the public ear and eye, it would seem that no amount of cost and art-thought would or could be well spared in providing a due and proper place for the representation and rendering of a fine opera. In listening to so magnificent a creation as the "Don Giovanni" of Mozart, or the "Fidelio" of Beethoven, all must needs feel, who at all care for such things, that it would be impossible to over-estimate them, or to wonder too much at them, or at the powers displayed by their authors in the planning of them, and in the working out of their details. The subject is a very complicated one, and we can here touch on but one or two aspects of it which seem to us to call for more especial attention, and which, if thoughtfully taken into consideration by those who have the management of such things, might, as we cannot but think, do some service. Operas are artistic works, and call for not a little from artists of many kinds and degrees of power. Nothing, perhaps, in the whole range of art demands more: there is the author of the libretto, the composer of the music, the actors and singers, and the instrumentalists, and what most con-

cerns us here, the house in which the performance takes place; and the scene-painter, and we can but add it,—for he has, as things are, not a little to do,—the artist who should regulate the lighting of both house and stage.

We have been led to some thoughts on operas and operatic performances and requirements, from contrasting the music of the "Don" with the place in which it is now necessarily given to the world, and in the hope of in time seeing a something better provided. It would, perhaps, be difficult to contrive a place less happily adapted than the present Covent Garden Theatre for such a purpose as this of opera music. We go to hear, as well as to see; to hear, more especially and emphatically, and also to hear and see that nothing shall distract the attention of either eye or ear from the stage and music. But how are matters here? In all theatres we are looking at the stage, and not at the house, yet at Covent Garden so brilliant is the light from the huge and ungainly chandelier of glass suspended from the roof that it all but hides the stage from those who otherwise can but see it, but are supposed to see the stage un-interrupted from the gallery and the gallery stalls and even upper boxes. This may, perhaps, have been unnoticed by those who can so readily mend such matters; and we can but hope it will be, for we do not hesitate to say that very much is and must needs be lost by it, even by those who witness the performance from a lower, and in many ways more, favourable point of sight. But it is to the ear that opera more particularly addresses itself, and this gains by distance, for the instrumental music is thus softened, and is made to so impress the ear as to seem to come in its unity from the conductor's baton.

We may here, perhaps, usefully say a few words on this world-famous opera, the "Don Giovanni" of Mozart, and on the special way in which it is presented or not presented to the public ear and eye at Covent Garden many times during each opera season, and on the scenery and the special architecture which are made to do duty, and thus to aid and support the music of it; for in spite of the brilliant splendour of the house and the absorbing attractions of the music, it is impossible altogether to be blind to the scenery of this famous opera. Anything duller or less suggestive, or indeed dingier, is scarcely to be imagined. No attempt whatever would seem to be made to harmonise the different scenes, or to make them in any way suggestive of the time and place in which the action may be supposed to have taken place. Anything, indeed, in stock would seem to do for the "Don," and so bad and incongruous is it, that all sense of unity and continuity is utterly lost. It is a pity, indeed, that this is so, for one at least of the elements of opera, which no less a celebrity than Rousseau declared to be an essential, is even worse than absent. A something is in the place of it which had far better be absent altogether. A room utterly bare, or an empty vault, must be better, thus leaving the dramatic music to do the whole work and to tell of what is going on.

Mozart composed this greatest of operas in 1787, for, as he said, "himself and his friends." It found its way into England in 1817, when we are assured that it was performed in a way that has not since been equalled. And we thus allude to it in the hope that effort will in time be made,—shall it be in the next year?—to improve a little on what is now done. We dare not go into details, but it is hardly to be estimated how great is the art loss, and perhaps must needs be when no architect, or even upholsterer, has been consulted as to the unity and fitness of the scenic details, and no painter's eye has been brought to bear on the glare of the house, painting out, as it needs must, the very stage itself, its scenery, and the action on it. The very "constituents" of opera are, according to the great authority we have just quoted, the poem, the music, and the "decorations," or scenery, and to those we would venture to add the place, or "house," in which all goes on, and its fitness for its special purposes, and perhaps, we are disposed to think, as much as anything the method of its lighting. On the poor way in which this is now managed at Covent Garden might need be said, further than this,—that it could hardly be more destructive of all scenic and pictorial and dramatic effect. The purpose of the "decorations" is to provide fitting objects for the eye to dwell on, and to aid the dramatic effect, and thus to add to, and not to mar, the work of the music.

We would fain say a word on the music of this great opera and on the singular fact, for fact it is, that but for the "Italian opera," as it is termed, there would needs be a vast gap and a want which it would, as we can but feel, be impossible to fill up. We speak of the fine instrumental band which, but for it, would hardly have existence either in numbers or quality. Right well does it do its work, and would do yet better if the house were better or at all adapted for such work, and how worthy of all effort and painstaking the rendering this music of "Don Giovanni" is none need to be ever reminded. That the illustrious composer was at his best, and was indeed inspired, when he wrote it, is certain. Its glorious and ethereal tones never pause or flag for a moment from beginning to final ending; from the first bar of the overture to the last note, as from the abode of the lost, there is nothing wanting. It is all but perfect work, and is on a level, as a work of the very highest art, with the "Hamlet" of dramatic art, and the music of it is so essentially dramatic that it takes the place of words in power of description. Such a work evidences the power of sound, as it does the wonderful inventive powers of its author. It is worth a house built of real and solid materials, thus to add to the power of the band and voices, and to their interpretation of so magnificent an art-thought.

#### WHAT ARE THE PROPER LIMITS OF CONSERVATISM IN REGARD TO ANCIENT BUILDINGS?\*

We live in an age of what are sometimes called "movements." We can all particularise a considerable number of such movements in the regions of politics, theology, and social life. We have had the reform movement, the evangelical movement, the ritualistic movement, and the women's rights movement, and other smaller intellectual and social upheavals of the same kind. The world of art has conspicuously shared in this general tendency of the mind of the day. Five-and-twenty years ago lovers of painting were scared by the pre-Raphaelite movement; more recently lovers of music have been scared by the Wagner movement. Almost all such movements have two characteristics in common. They are almost always taken up by a large number of persons who know not why they give their adherence to the particular standard set up, but who follow a fashion, without logic or reason, because it is a fashion, and because they are gaping for novelty; and all of them tend (more especially in art and literature) to give rise to a counter movement, a swing of the pendulum in the opposite direction.

If we keep our eyes open to this general tendency of the day, we shall probably conclude that the particular movement we are considering this morning is not an abnormal phenomenon, but is only one example of the prevalence of rapidly-changing fashions which is to be observed in the world of art as much as in that of politics and of society, and has the usual characteristic of movements arising out of fashion,—viz., that many persons follow it without knowing why. Numbers of people are at present exceedingly excited about, or rather against, the restoration of ancient buildings; but it may be doubted whether nine-tenths of them have ever seriously considered the subject, or are even acquainted with the main facts of architectural history; and the vehemence of opinion entertained and expressed in the matter seems, as far as my observation has gone, to be usually in inverse proportion to the knowledge of the subject on the part of the anti-restoration zealot. And, as in the case of other movements, this somewhat extravagant zeal is the result in great measure of a reaction against an opposite extreme. Let us see if we can get at the balance of truth between the contending parties.

The movement against which we are now "re-acting," the restoration movement, did not grow up alone; it was closely connected with, if it did not actually arise out of, the High Church movement. With the idea that a new life was to be infused into the Church by a revival of pre-reformation theology and ceremony, came naturally the idea that the buildings also should be revived, that they should be raised from the state of neglect and disfigurement

\* By Mr. H. Heathcote Statham. Read in the Art Department at the Nottingham Congress of the Social Science Association.

into which many of them had certainly fallen, and that where possible they should be restored to something of their ancient beauty. The Ecclesiological Society, under the motto, *Donec Templum reficiamus*, gave the cue, and the restoring of churches became one of the watchwords of educated society; and he who admired un-restored churches, or who objected to giving his mite towards restoring them, would have been called a "Philistine," had that expression been in common use in this country at the time. How church committees and architects acted under this régime we all know; how they swept away galleries, laid down Miuton's tiles, and inserted Mediaeval metal work from Southampton-street; and how they ceased the exterior with new stone, scraped the old stone, imitated the old mouldings where decay had gone too far for scraping up; put in stained glass "by the most eminent firms," and made the whole as good as new. By such proceedings were deans and committees covered with glory, and architects' pockets filled with bank notes. The reverse of fortune began when first a few people, and then an increasing number, began to find out that some of the artistic significance and a good deal of historical value was eliminated from churches that had been restored; that the new work, however carefully worked in accordance with the old details, was not like old work in one sense,—had not the same feeling, was not interesting to sketch; and that it was too like old in another sense, seeing that to future generations it might remain somewhat difficult, after time should have reduced old and restored work to much the same texture, to say which was the genuine Mediaeval Gothic and which the nineteenth-century imitation. This negative feeling against restoration seems to have been strengthened at the same time by a positive feeling in favour of much work which the Mediaeval restorers had swept away as uninteresting and "Pagan." The revived Gothic being only an imitation art after all, palled on people after a time, and they got up another imitation,—that of eighteenth-century architecture,—as a change; and thus the old pews and galleries which the Gothic restorers had made conscience of clearing away, came now to be regarded reverentially as objects of artistic as well as of historic interest. Lastly, the reactionary party having come to the conclusion that there was and could be no real architecture in the present day, the impulse and spirit of architectural art, being dead (a conclusion which it must be admitted many of the buildings in the now fashionable style amply justify), laid it down that it was an artistic crime to meddle with, alter, or add to any existing building, or part of a building, in any way; that "whatever is, is right," to the extent, at least, that whatever has been put up for a certain number of decades (not quite defined yet), however ugly, inconvenient, or useless for present needs it may be, has, by its mere existence, acquired a right to remain; that no one ought to touch a stone or a timber of an old building in the way of destruction; that to attempt to restore that which has wholly or partially decayed is a foolish and wicked sham, since no work done in this century can really reproduce the spirit of a former period; that the only right thing to do with any old building, however large and important, is to prop it up as long as possible with brickwork and shores, and reverently to contemplate its decay; and, generally, that any one who would take any other and more active course must be either a hopeless Philistine or an unprincipled person inspired by the worship of "Five per Cent." Society, to a great extent, has, for the present, taken up this way of looking at the matter, as the last novelty in taste; and thus we have the absurd contrast that, while five-and-twenty years ago it was considered a mark of stupidity, and of being below the level of average culture, to be indifferent to the restoring of old buildings, it is now supposed that to be a restorer or an advocate of restoration is an indubitable mark both of stupidity and vulgarity.

That seems to be about the creed of the anti-restorer of the day, as expressed in an often very defiant manner, through the mouth of its representative Society and its supporters in the press, some of the latter of whom carry on their attacks against any architect who may have ventured to pull down a dilapidated and useless building, with a rancour and an apparent disregard for common fairness which are very discreditable. We might, if we liked, amuse

ourselves by picturing the aspect which one of our churches or cathedrals would have assumed by this time, had it been left to the custody of the anti-restorers; what a picture its interior would present, filled with all the heterogeneous furniture which different churchwardens at different dates had placed there; its roof-timbers handgaged with iron and propped in places from the floor, and the crown of an arch, which had hopelessly settled, held up by a brick column built up under it,—"reverently," of course. But the first thing to say in the way of serious criticism, in regard to this theory of the treatment of old buildings, is this, that it is something absolutely novel, it is the assumption of a principle which has never been recognised, or acted upon in the whole previous course of the history of architecture. In every period hitherto men have not hesitated to sweep away a building which was in their way, which they did not want, or on which they thought they could improve. Had the Mediaeval architects not done so, many of the most beautiful specimens of Mediaeval architecture would never have come into existence. There is hardly a cathedral in England parts of which do not stand on the foundations of an earlier building, pulled down without scruple because the later builders preferred to build in their own style. William of Wykeham, one of the most honoured among the few names that are known in connection with Mediaeval architecture, did perhaps more wickedly than this, for he caused the whole Norman nave of Winchester with work in the style of his own day. Had the "Anti-Scrape" Society been in existence then, William of Wykeham would almost have been hounded out of the country; the *Times* would have been filled with letters about his enormities; no name would have been bad enough for him, that reply to such an instance will probably be, that we have no architectural impulse now, no power of building well. Those who assert this so strongly probably know their own deficiencies, but they might at least be content to speak for themselves. It is certain that this age is not pre-eminently an architectural age, as the thirteenth century was; it is pre-eminently a scientific age; science is its peculiar mission. But that therefore no original architecture worth having is in any way possible, is a rash and somewhat pusillanimous conclusion. At all events, it is quite certain that we shall not produce any by propping up old buildings and watching them with our hands folded; and it might, perhaps, be suggested that if as much trouble and energy were expended in applying the mind to the problems of modern architecture as in mourning over ancient remains, our present condition might be better than it is.

It is, however, equally true that restoration, as it has been recently practised among us, is also a system almost entirely modern and unknown to former epochs of architecture, for the very reason that its opposite, the superstitious veneration of old buildings because they were old, was also unknown. At any period previously to the present century, when a building or a portion of a building was dilapidated, the natural course was to pull it down and to build a new and better one, or what the new builders fully believed to be a better one. The builders of the Mediaeval cathedrals appear to have done this with as little hesitation, and as little doubt that they were doing the right thing, as a modern engineer would feel in regard to pulling down an old viaduct or station and replacing it with one more ample and more scientifically constructed; and even the Georgian architects, who placed a Classic pedimented veredox in front of an old Mediaeval one, had not the slightest doubt that they were improving the architectural appearance of the building. The result in regard to the Mediaeval buildings has been that most of our cathedrals form an agglomeration, highly picturesque and historically significant, of various styles, each portion expressing the taste and artistic power of the generation which built it; and that, on the same principle exactly, Westminster Abbey has been crowded with monuments in a style utterly alien from that of the building, but nevertheless carried out in perfect good faith by the men who designed them, and which the late Dean of Westminster regarded as a most interesting exemplification of the modern spirit in art, "awkwardly struggling into life." We can realise better the distinction between either of the other two methods we are considering, by endeavouring to imagine for a moment what would have been the aspect of our cathedrals if

either of the two systems, the restoration system or the let-alone system, had been systematically applied to them, since the Norman foundation (leaving Saxon foundations out of question for the moment). On the restoration system we should now have a considerable number of buildings in the Norman style throughout, a large proportion of which would be probably imitation of Norman work made in the fourteenth or fifteenth century, when the buildings would have begun to require repair, and perhaps further imitation of those imitations made in the eighteenth or nineteenth century. If the let-alone method had been used, we should now have the remains of a set of Norman cathedrals, all genuine work as far as they were left, but with the details nearly obliterated in many places, and the walls upheld by shores, brick piers, and iron handgages, where the foundations had given or the masonry had otherwise failed; and as the Norman buildings were mostly timber-roofed, they would nearly all be roofless. On the whole, the restoration method would have the best of it, as the buildings would at least be available for practical use, which, after all, is one object of a building.

It is this latter fact which seems to be entirely forgotten by the excited opponents of all restoration whatsoever. The mistake which the anti-restoration zealots make is in regarding buildings solely from the point of view of their historical interest. There are, in fact, three different ways of regarding an ancient building, three different values which may attach to it, viz., its historical interest, its architectural beauty, and its practical utility; and it depends upon the relative preponderance of these values in any particular case, which we should adopt of the three possible courses, that of restoration, of removal, or of mere preservation in its existing state. We are speaking, of course, of buildings which have become more or less dilapidated, so that the question is necessarily raised as to what should be done with them. It appears to me that there is only one class of ancient structures to which the doctrine of anti-restoration in its purity can be applied; those, namely, which are already what are usually classed as "ruins," partial remains of structures, all practical usage of which has long been discontinued. These are almost certain to have historical value, and in many cases they have also high artistic value from the remains of beautiful architectural detail which they present. To restore the missing portions of such buildings would only be to add the imitation to the reality, the false to the true; it could add nothing to their value in any way, but rather detract from it: the one thing to do in such a case is to preserve them as carefully as possible, so long as their preservation does not interfere with really serious present interests, which is a possible though a very exceptional case. But the problem is not by any means so simple when we have to deal with a building which is in the main complete, and which is in present practical occupation.

It seems to be necessary to remind people nowadays that architecture is not *only* a form of historical record, but also a form of artistic design; and that the more complete and homogeneous such a design has been originally, the more it will be rendered imperfect by the delay and loss of any of its parts or details. When a building is in that state that a great portion of its mouldings and other details are worn away, I am unable to see why it should be an act of vandalism to replace these by new details following the indications left by the old ones. There need be no pretence made that they are old works; they are simply the repair and reconstruction of features necessary to the architectural expression of the whole, and which had become worn out, although the main portion of the building may be solid enough to last a long time. To say that they cannot have the precise look and surface of the old work, is quite true; why should they? Let them appear as what they are, the necessary restoration of details essential to the architectural ordinance of the building, and which had unavoidably perished in course of time. I would draw a line between purely architectural detail, however, and such additions as figure subjects in sculpture and mosaic. Those are not part of the architectural design, but separate designs added to or framed in the architecture, the value and expression of which depends entirely on the "personal equation," so to speak, of the individual artist. If these are so

far decayed that little or nothing can be made out of them, and that they have ceased to be artistic adornments to the building, let them be, if possible, preserved in a museum, and their places filled up with work of a similar class, not imitative, but representing the best ideas and work of modern artists, unless it be preferred to leave their places vacant. But purely architectural details, which all have a relation to the whole, and are chiefly valuable through that relation, stand on a different footing. Take such an instance as that of a series of traceried windows, of which the greater part of the tracery has decayed, but enough is left to show the original design,—why are such windows to be left melancholy, broken, and dilapidated? To object to their restoration is to be at variance both with architectural fitness and with common sense; to restore them is to restore the originally contemplated architectural design of the whole; and the same reasoning holds good in many similar instances.\* Again, there are cases in which the interior of a Medieval building, let us say, has been utterly spoiled by the insertion of totally incongruous and badly designed accessories, such as the pews, galleries, and Classic reclosets of what may be called the "churchwarden era." When the ecclesiological movement began, there was a greatly-exaggerated depreciation of everything that was not Medieval, and all relics of the "Pagan" Renaissance were to be trampled under foot. This, of course, was absurd. But equally absurd is the new idea, that all the preposterous lumber that may have been put into a church is to be left there for ever, because it was once ignorantly put there. A good Medieval building is an illustration of a special architectural style consistently carried out. Even good work in the Renaissance style is at variance with the artistic feeling of a Gothic building, and had much better be removed, if a good and more suitable one can be found for it elsewhere. But the feeling of the modern zealot does not stop at what is good. He would have us religiously retain an ugly and unnecessary gallery, a hideous quasi-Classical recloset, which are absolute blots on the main architectural design of the building, because some blockheads put them there a century ago. Had the said zealot and his Society been in existence then, they must, on their own principles, have protested vehemently against these additions to the building as acts of vandalism. If any one will give me any logical reason why an addition, which was vulgar and tasteless when it was made, should become an object of enthusiasm because it has been there for a hundred years, I shall be very glad to hear it.

This latter point is partly connected also with the practical view of the subject, as regards buildings which are in present occupation. That our cathedrals and churches are buildings in present occupation is a fact which seems by some people to be entirely forgotten. If it is to be laid down that those using the churches are never to repair or re-furnish them, never to clean away whitewash and cobwebs, or to lay a new tiled floor, I suppose the same argument applies to old houses, and that the man who has the misfortune to live in an old Elizabethan house has no right to have his rooms repainted or re-decorated, or to have any new furniture of any kind, on pain of aesthetic damnation. If it be true that cleanliness is very closely connected with godliness, it might be supposed that even on that ground it was on the whole a pious work to clean and scrape and redecorate the interior of a church or a cathedral occasionally. To my perhaps perverted mind it seems that even architectural effect is aided by an aspect of cleanliness and renewal of interiors at least. I have read in the æsthetic papers lamentable outcries over the spoliation of Tewkesbury Abbey by restoration. I first saw Tewkesbury when the interior restoration was half finished, down to the first bay of the nave, and a screen divided the restored from the unrestored part. There was some coarse and glaring gilding introduced on the bosses of the vaulting, the effect of which was vulgar and over-prominent; but with that exception, the restoration chiefly consisted in scraping off

whitewash dingy with the dirt of years, and cleaning the whole thing up generally. On the western side of the screen were dirt, whitewash, and general untidiness, on the eastern side cleanliness and order and repair; and if any one had seriously told me that the architectural effect of the restored portion had been injured by the change, I should have regarded him as a person too silly to be worth arguing with.

In connexion with the practical part of the subject comes the question of the stability of an edifice which is in use. Upon this head the scepticism of the new æsthetic party is most remarkable. No representations will induce them to believe that a building is really too rickety and dilapidated to do any good with. It is all the malice of the architect, who wants to have a commission to build a new one. It is desirable that the general public should be decisively warned against believing all the assertions which are made in such cases, often by people who have absolutely no means of judging of the truth at all. Let me put on record one example about which I happen to know something. There was a furious paper warfare some time since about the proposal to put a new roof on the nave of St. Alban's Abbey. The proposal was denounced by members of the anti-restoration party, who had never seen the roof for themselves, as absolutely scandalous; they had been assured on good authority that it was perfectly possible to repair the existing roof, &c. I was one of those who did see the said roof, which was in such a condition that the wonder was that it had clung there so long, and that it had not been down in the church long before. Then there was a solemn appeal made in one of the papers (*The Athenæum*, I think) about the painted ceiling of the nave, or rather an expression of incredulity that any one could dream of touching *that*, as if it were a sort of sacred thing. Now there is one portion of painted ceiling at St. Alban's which is good and original Medieval work; but the ceiling of the nave aforesaid was what appeared to be a had and rough imitation of the general effect of the older part; it was a design of the most commonplace character, such as an architect's pupil might make the first time he got a pair of compasses and a paint-box in his hand, and it was roughly painted in black and red on wood little thicker than a band-box, and so rotten that you could almost crumble it in your fingers. And I think any one who had first read the outcry in the papers about this roof, and then gone up the ladders and looked at it, would have made the same memorandum that I did, not to believe everything that he was told about the stupidity and vandalism of restoring architects.\* The latter have, no doubt, done some things they should not have done; but I venture to think that in nine cases out of ten they know better what they are about in these matters, and can better judge how to reconcile the claims of archaeology with those of practical architecture, than their very pertinacious instructors of the anti-restoration clique can teach them.

This very strong and exaggerated feeling about touching ancient buildings, even in the way of reasonable repair and refurnishing, which has made itself heard lately, is only one form of a prevalent false note in the life of today, consisting in a disbelief in and discontent with everything in the present, a continual sentimental yearning over the life of the past, or after some impossible æsthetic millennium of the future. Nothing done to-day is good; everything good was done a long time ago; and, conversely, everything that was done a long time ago was good. This unwholesome sentimentalism has affected the judgment of many persons in regard to all the artistic side of life, as well as in regard to social conditions; and one form which it takes is this exaggerated worship of old buildings, quite irrespective of the merits or defects which a calm critical judgment might see in them; the natural conclusion from which state of mind is, that there is no limit whatever to conservatism in regard to ancient buildings; that, however dilapidated, however useless to us at present, however really bad in style they are, they must be preserved till they come down of themselves, because they are relics of the past, and we poor creatures of the present can do nothing. It is vandalism even to decorate an old build-

\* This must not be taken to imply any sort of satisfaction with the treatment which St. Alban's is now undergoing,—not, be it observed, at the hands of an architect.

ing in any way; and one eminent decorative artist lately made public his determination to put no more stained glass into any old building. One cannot but respect the heart of an artist so conscientiously sticking to his principles in opposition to his own professional advantage; but this must surely be at the expense of our respect for his head! Another characteristic of this superstitious worship of old buildings is that it puts aside all questions of public convenience or public improvement, all questions of mere utility in fact, as trivial and beside the mark. Thus the outcry about the removal of one or two of the City churches in London has been more serious than the nature of the cases really warranted. It is out of the question that churches which, owing to various social changes in the locality, have fallen almost out of use, should necessarily all stand for ever, where land is so much wanted for the immediate purposes of life, because they were once put there; especially when their architectural merits are certainly in some respects over-rated. For it is one result of this over-acted conservatism that all critical judgment is subordinated to an uncritical, and what may be called a sweeping admiration for the past; otherwise it would surely be seen that Wren's churches, even where they are admirable for their plan and construction and a general largeness of style, are so in spite of much exceedingly bad and even vulgar detail. The absurdities to which this kind of superstition may lead people are notably exemplified in the statement which has been solemnly made, that the undulation in the pavement of St. Mark's at Venice was intentionally made by the builders, and constitutes one of the special beauties of the edifice. Persons who would say that would probably say anything. But those who are not entranced in this kind of sentimentalism will regard architecture as an interest of the present quite as much as of the past, and as a subject which has its practical as well as its sentimental side. They will recognise that those who are officially or professionally in charge of ancient buildings have something else to do than prop them up and watch them crumble away; that it is worth while to keep the architectural design of a building intact by occasional renovation of its details before they are worn out of all recognition; that it is no artistic desecration to clean and redecorate a building once in a century; and that where a building is actually in occupation or usage, to neglect or refuse to do this would simply be to range ourselves on the side of slovenliness, dirt, and decay, besides the evil of deliberately shutting out one means of stimulating and encouraging the artistic design and art workmanship of our own day. That is one merit which has certainly to be credited to the Gothic revival and the restorationists. They sometimes overdid restoration deplorably, and made some great mistakes which cannot now be named; but they did a great deal to stimulate architectural study, and to give a new life to architectural art in this country. The Gothic revival and the restoration movement constituted a kind of "craze," no doubt, and did mischief in some ways, while doing good in other ways; but the anti-restoration craze does neither evil nor good; it would avoid mistakes by doing nothing; it means architectural stagnation and death.

**A Cathedral for the Isle of Man.**—A meeting for the purpose of promoting the erection of a cathedral in the Isle of Man was held at Peel on the 20th inst. Bishop Hill presided. A scheme was produced for making the new parish church of Peel, now nearly complete, into a cathedral. This could be done at a cost of 2,000*l.*, but the scheme was opposed on the ground that the cathedral, to be of utility, should be established in Douglas, that being the centre of the population, and the chief resort of many thousands of visitors to the island. If, however, Douglas was chosen as the site of the proposed cathedral, the cost would not be much less than 50,000*l.* An amendment was proposed by Mr. E. C. Farrant, that an architect should be employed to report on the cost of so altering one of the existing churches in Douglas as to make it suitable for the purposes of a cathedral. This amendment was not seconded, but the bishop expressed himself in favour of a new cathedral in Douglas, if some means could be devised for raising the necessary funds.

\* Since this was written, I have met with some remarks in a paper in the August number of the *Cornhill Magazine*, by the talented lady who writes under the name of "Yerona Lee." In respect to the restoration of ancient statues, which bear upon and support the view. Speaking of the case of a beautiful head of which the nose was gone, she asks whether any modern restoration of the feature could possibly be so injurious to the statue as this ghastly scar in the centre of the countenance. The same argument applies to what we may call the architectural countenance of a building.

## AN INTERNATIONAL DEBATE ON DRAINAGE.

THERE were no fewer than fifty-one subjects inscribed for discussion by the five sections of the International Sanitary Congress.\* But of all these questions, that which attracted the most attention, elicited the greatest number of speeches, the strongest display of feeling, was the problem of dealing with the sewage of towns. The authorities of Geneva are themselves somewhat perplexed by complications in this respect that become more and more serious every day as the population and number of visitors increase. Several town architects and engineers, therefore, took an active part in the discussion, and though the section had no less than nine subjects to deliberate, it devoted three out of its four sittings to this one topic. The debate was opened by M. A. Durand-Claye, chief engineer of the Paris Ponts et Chaussées, professor at the Ecole des Ponts et Chaussées and at the Ecole des Beaux-Arts. As one of the principal authors of the irrigation farm at Gonnevillier, M. Durand-Claye's eloquent and witty speech was devoted to the defence first of draining into sewers, and then of disposing of the sewage by irrigation through cultivated fields. Cesspools he justly qualified as barbaric contrivances, and proclaimed himself the uncompromising advocate of what is known in France as the principle of "tout à l'égout." The arguments in favour of this principle are so familiar in England that we need not repeat them. The real points at issue were what should be done with the sewage when collected, whether there should be a separate sewer for rain and surface water and another for sewage proper, and whether the latter should empty itself by the force of waterflow and gravitation, or by pneumatic suction.

Dr. P. Bronardel, from Paris, Professor of Forensic Medicine, delivered an earnest protest against the dangers of draining into sewers. He described the visits he had paid to the Paris sewers; how in the sewer of the Rue Montmartre he found the deposit of filth more than a foot deep, and how in this mud he had discovered dead dogs, &c. If to such foul accumulations were added the germs of disease, an epidemic must inevitably break out. It was all a question of the germs, and in large towns the germs must sooner or later find their way to the sewer; and sewers, working so badly, apt to stagnate and collect filth, were well suited to develop the germs and spread the disease. Typhoid fever had undoubtedly been traced over and over again to the sewers, and the present epidemic in Paris was in all probability due to that same cause. During the sieges of Metz and of Paris in 1870, every condition known to favour an outbreak of typhus existed, and yet this dreaded disease did not make its appearance. At Metz, the case was more remarkable than at Paris, because there were soldiers ill of typhus fever among the Germans. Fortunately the French made no prisoners; the germs were, therefore, not introduced into the besieged city, and hence, in spite of all the predisposing circumstances, this fever did not attack the inhabitants. So in Paris, and in every large town, there were thousands of persons who, from time to time, became predisposed to certain diseases, yet these persons escape the illness if they have the good fortune not to come in contact with its specific germ. Dr. Bronardel's experience of Paris sewers, however, led him to believe that they would bring the germs to the door of every house. He therefore hesitated before approving the abolition of cesspools and the mingling in the public sewer of the dejections from every household. If, nevertheless, this was done, then the sewage should be received in pipes hermetically closed with no possibility of any sewer-gas escaping either into the street or the houses. In other words, Dr. Bronardel was evidently an advocate of the pneumatic system of drainage.

M. Émile Trélat, the eminent architect, whose name is already familiar to the English reader, at once rose to oppose the conclusion of Dr. Bronardel. He protested that the matter had now become no longer a question for doctors to decide, but for engineers and architects to deliberate. The doctor was no longer the operator; he now occupied the position of the patient. It had been decreed by doctors, chemists, and men of science generally, that all organic matter

must be at once removed from the neighbourhood of dwellings; that if such matter remained stationary even for a few hours it might endanger public health. In a word, removal before mischief has time to arise was the solution of the problem. It was a doctor's business to arrive at this conclusion, but, in the carrying out of this principle, he was no longer a competent judge. He compared Dr. Brouardel's language to that of a patient before an operation, who insisted on examining the surgeon's instruments, criticised his mode of proceeding, and complained that he might perhaps hurt him. M. Trélat was well aware of the imperfections in the Paris sewers, but this only proved that the sewers had been badly built and must be rebuilt. In Paris matter coming from the farthest branch of the sewers should not take more than six hours to reach the outfall; and in answer to the danger of typhoid fever from sewers he would quote the statistics given at Berlin during the recent epidemic. In 1879 there was one case of typhoid fever in every sixty-five houses draining into the sewers, and one case in every seventeen houses draining into cesspools. In 1880 there was one case of typhoid in every forty-five houses connected with the sewers, and one case in every nine houses not connected.

Dr. J. Teissier was the next speaker, and he gave the details of a most interesting experiment he had made at Lyons, where cesspools are still used by most of the inhabitants. The hospital of the Charité, however, drains entirely into the sewer. In spite of this the scavengers of Lyons always prefer descending into all the parts of the sewer communicating with the hospital. They declare it is free from bad odours, and the easiest to clean. Dr. Teissier, collecting some water in this sewer, found it so clear and free from odour that any one ignoring whence it came would not have hesitated to drink it. He then proceeded to inoculate some guinea-pigs with a strong solution from a cesspool. The animals were none the worse after the operation; but the guinea-pigs inoculated with the clear water from the Charité hospital sewer died in seventy hours. Dr. Arnodid, who assisted at these experiments, found microbes in all the tissues of the dead guinea-pigs; and by inoculating other guinea-pigs with the blood of the first victims, the poison in passing through various guinea-pigs became so intensified that ultimately death resulted in ten hours. The apparent cleanliness of sewer water was not, therefore, a proof of its purity. Yet he recognised that the sewer water of towns where cesspools were still maintained, contained nearly as much nitrogen as those which received the entire drainage. He also recognised the experiments made by Doctors Simon and Emmerrick, which proved that human dejections, diluted and injected into animals, would not harm them if fresh, but that the same solution, even when administered in a smaller dose, would produce death if allowed to stand for a few hours. He therefore could not deny the importance of the immediate removal of sewage. But while sewage, if promptly removed, could not, as a rule, be injurious, and would not create germs of disease till it had had time to ferment, still, if it should be impregnated from the very first by specific germs coming direct from patients, he thought that no amount of cleanliness and freedom from odour could disguise the fact that, at such moments, sewers were dangerous, and carried the danger far and wide.

Dr. Vidal then followed with some remarks as to the risk of sewers communicating with the outer air, and related how an epidemic had broken out at Croydon by the accidental contamination of the water main with sewage.

This speech, and it was a lengthy one, ended the first day's debate, which imparted a general impression that whatever was done would be badly done, and that the building of sewers in particular was fraught with incalculable danger.

M. Duverdy opened the next day's debate by protesting that too much had been said concerning the dangers of sewers, and nothing about the disposal of sewage. He was willing to recognise that the experiments at Paris and Berlin proved the possibility of rapid transit of matter in the sewers; but the first of all questions was to settle what would be done with the water thus transported. He then proceeded to give a vivid account of the sewage farms near Berlin, describing them as sloughs of despond,

where cattle could not graze, but sank up to their knees in mud. The farms were not nearly big enough. For the 300,000 inhabitants of Berlin, no less than 2,017 hectares of farm land would be required. In Paris, with its 240,000 cesspools, 14,000 to 15,000 hectares would barely suffice if all the sewage was to be thrown on to the land.

Dr. G. Varrantrapp, the medical officer of health at Frankfort, then delivered so thoughtful and practical a speech that we are tempted to translate almost verbally the greater portions of this discourse, which, in fact, was received with the utmost attention and applause. The learned doctor urged that local observations, however accurate and authoritative, did not justify our adopting general conclusions. The sewage question was a question of principle. It had become an international question, and must not, therefore, be lowered to the level of a mere parish squabble. The results attained at Paris certainly presented great interest to us all. But the experience acquired at Paris does not touch the question. "I am very willing to allow, for the moment, the imperfections of the Paris sewers—imperfections that are the more easy to understand, as the town attempted to unite old with new sewers. If there is stagnation,—if there are deposits in the Paris sewers, this is highly regrettable, but it does not prove that these defects are inherent faults of the system of sewers. The question is, whether it is possible to construct sewers where these deposits will not occur? For my part, I confidently affirm that it is possible. I will not speak of the experiments made at Hamburg, Dantzic, and Berlin, where I have visited the sewers, and found no deposits or stagnation, but I will speak of Frankfort, where my observations have been made from day to day. We have real sewers, that is, sewers receiving everything that comes from the houses. These sewers were commenced fifteen years ago, and have now reached a length of 130 kilometres, fed by 25,000 water-closets, which householders are now compelled to use. Never during these fifteen years, excepting at the period of construction, has it been necessary for a workman to descend into these sewers with a broom or any other implement for the purpose of cleansing. The cleanliness is maintained by the household water, of which 15,000 to 18,000 cubic metres are daily employed. So great is this incidental flushing of the sewers that a special discharge of water direct into the sewers is rarely if ever required. Yet, in spite of this, there have never been any deposits, either in the little or the big sewers, though the main sewer has only a fall of 1 in 2,000. He challenged the members of the congress to come to Frankfort at any time they chose and to descend any part of the sewers they might select, and he defied them to find any deposits or stagnation. They would further find that the sewers were free from odour, or, at least, they would not be able to detect the odour of human dejections. The water travelled from the farthest water-closet to the sewer outfall in about one hour and a half. Frankfort deems that she has proved the possibility of constructing effective sewers. I will now examine the statistics, which are so often misquoted, that accurate figures lead to inaccurate conclusions. Our statistics since 1850 are very precise in their character. During the first period of five years we had eighty-five deaths from typhoid fever for every 100,000 inhabitants per annum. Then the figure decreases from 1866 to 1868 to 6.1, 1869 to 1871, 7.9. Thus showing an increase after the construction of the sewers, but when, in 1875, the water supply which formerly had been insufficient was added, the figure fell to 2.8 from 1875 to 1877, and to 2.0 from 1878 to 1880. Let these figures be compared with those of Paris, where typhoid fever has increased tenfold within the last few years! This good result is not due entirely, but in part, at least, to the Frankfort sewers. We must remember that modern typhoid fever cannot be compared with the typhoid of thirty years ago. Throughout Europe it has decreased, but other maladies, such as diphtheria, have increased. At Berlin we can establish a comparison between houses that are connected and those that are not connected with the sewers. During the last few years the progress of canalisation has been very rapid, with the effect of reducing the mortality from typhoid fever in the houses connected with the sewer to the extent of one-third; while in the house not connected no reduction whatsoever has taken

\* See pp. 349, 363, 384, 407.

place. The experience acquired at Hamburg and Dantzig points to the same conclusions. An outbreak of typhoid occurred in this last town ten years after the building of the sewers, but this was due to a defect in the construction and the insufficient ventilation of the sewers. This is no more a reason for condemning sewers than an accidental gas explosion would be for condemning the use of gas. At Croydon faults of construction once remedied reduced the mortality to about the lowest in Europe, that is, from 11 to 15 per 1,000. Eminent doctors at Glasgow and elsewhere believe that by increasing the number of water-closets the number of cases of diphtheria also increases. But we must not look at the details of a few houses. The question must be judged on a broader basis. The Registrar's return for Scotland shows that during recent years deaths from diphtheria in rural districts have been more frequent than in towns, and yet the cottages in villages have neither water-closets nor sewers. Throughout Prussia diphtheria is more prevalent among the rural populations. But here is another example. From 1862 to 1866 there were about 10,000 deaths per annum from diphtheria in England, but in 1870 to 1880 there were only 3,000 to 4,000 (?). Have the number of water-closets and of sewers been reduced during that period? The Governments of Podolia and Ukraina in Russia had about three times as many deaths from this cause as England; but, how many miles of sewers are there in England as compared to Podolia? Let us be prudent in coming to general conclusions after a partial study of figures." Finally, it had been remarked that it was only the human *dejecta* that poisoned the sewers when these began to ferment. Do not kitchen-waters ferment? Does not kitchen-water give a more offensive odour than that of water-closets? Other speakers wished to divide the waters. Do they not know that Pecten-koffor and many other able chemists have demonstrated that there is no difference in these waters? If we tried to separate the waters what would become of the morbid dejections of the 80,000 or more houses that crowded the streets of the great capital. Then the linen coming from a patient, and which often contained the most dangerous of all matter, has to be washed, and the water would go into the ordinary and not the special sewer. Such questions required serious and comprehensive study, and the conclusion would be that everything should go to the sewer, but above all that there should be no stint of water.

Following on Dr. Varrantrapp, one of the few English speakers insisted on the necessity of ventilation of sewers and disconnection between house and public drains, and denounced in no measured terms the barbaric condition of French towns.

Dr. Overbeek de Meyer, Professor of Hygiene at the Utrecht University, found that M. Durand-Claye had committed many errors. To begin with, he spoke principally of the Paris sewers. Now, this was the very worst example he could give us. There were three means of applying the English system,—the first was what we saw at Paris, large sewers with domed roof and side sewers opening without valve or any impediment on to the large sewers, and communicating with the houses by pipes that were not trapped. These sewers received a large quantity of organic matter and greasy matter that stuck to the sides and refused to float away. Deposits were the natural consequence, and these remained bare when the falling of the water level after rain disclosed what adhered to the sides. An army of sewer men, more than 800 in Paris, were required to scrape these sides of the sewers. Now, this form of sewer is condemned by all competent men living outside Paris. Mr. Rawlinson, the eminent sewer engineer in England, has declared that if the sewers of Paris had to be made over again it would be necessary to adopt another system. It would effectively have been more logical not to have allowed all the solid matter to enter the sewers when it was so difficult to get rid of it that it had literally to be pushed along by men till it reached the outfall. The second application of the English system is best illustrated by the town of Frankfurt. For there main sewers have been constructed under Dr. Varrantrapp and Mr. Lindley, with every possible care; the sections not being too large, with syphons to protect each house and each branch drain. By means of powerful flushing at regular intervals, cleanliness is well maintained, and he was

obliged to confess that he could not find any deposits when he visited these sewers. Yet the system is not perfect, for the ventilation of these sewers carried germs, perhaps above the roofs of the houses, but the currents of air could bring them down again into the streets, especially where the houses are not all built on the same level. One of the speakers stated that sewer gas always went to the highest point. This is a mistake. M. Rosshagegi has shown that this was not always so; the course taken by the air must depend on barometric pressure, &c. He further doubted the water-tight properties of the Frankfurt sewers. Accidental fissures must occur, and these are very large in the Paris sewers, at least according to the official reports. Thirdly, we have the English sewer applied by means of a separate system. This means one sewer for house and closet water, and another for rain or surface water. In the former, flushing by automatic syphons is established. The separate system, qualified as tolerable where nothing better can be had by M. Durand-Claye, is, on the contrary, the best of all systems. It is advocated by the most eminent English and American engineers. Mr. Robert Rawlinson would like to apply it to the towns of London and Paris, and it is now actually working admirably in the towns of Penzance, Carlisle, Dover, Chelmsford, Ely, Rugby, Reading, Oxford, and in America at Lennox, Cumberland Mills, and Memphis. The statistics quoted often showed an improvement, but this was due frequently to improved water supply rather than the building of sewers. Thus at Croydon, during the epidemic of 1875 (April and October), 950 cases of typhoid and 87 deaths occurred in 10,456 houses with water-closets, while only nine cases and three deaths occurred in 1,070 houses without water-closets. Alluding to the Liernur system, he remarked that it admitted the use of five litres per head per day in the closets, while M. Alphonse demanded for Paris only three litres. He was aware that the Paris engineers demanded more (M. Durand-Claye, "40 litres"), but evidently this was not required for the sole purpose of cleanliness. This quantity was not necessary for cleanliness, but as a motive power to push heavy substances along in the sewers. But M. Liernur did not demand any such help, for he produced a vacuum in his pneumatic sewers. If foul matter did get into the other sewers it would be an exception, and, as such, would not stagnate. The municipality of Amsterdam had answered to the inquiries of the Prago municipality that (1) the Liernur system, tried for eleven years, had worked thoroughly well; (2) cost but little, and paid good interest; (3) the metal pipes remained absolutely water-tight. The rare impediments were caused by abuses, never by any fault in the system, and were easily removed; (4) the estimates of Captain Liernur deserve every confidence, the expenses being, if anything, over-estimated; (5) the system is superior to all systems known from the hygienic, financial, aesthetic, and technical point of view.

Dr. Loisean, member of the Paris Municipal Council, then delivered a lengthy speech, aimed at his electors rather than at the members of the congress. It was difficult to discern what the honourable councillor's opinions might be, but he admitted the necessity of water, the danger of germs, the success of the irrigation farm at Gennevillier; in a word, he recalled the typical reply of M. Prudhomme on being presented with a sword of honour,— "This sword is the happiest day of my life; I will use it to defend our Government and national institutions, and, if needs be, to combat them."

During the third day's debate on these questions of sewage, the speakers from Geneva took a leading part. M. Armouardier, town contractor, explained how Geneva was drained and the drains flushed, from which it appeared that a sort of receptacle placed where the cesspool used to be, and where all the house-drains united, was periodically flushed from the water main, which was placed within the sewer, and communicated directly with the branch sewers or house-drains, and with the taps whence was drawn the drinking-water! On objections being raised by the English present, the only answer was the old argument that the pressure of water prevented the sewer-gas entering the water-main.

Another speaker insisted on the necessity of maintaining the water at the same level in the sewers. At Rheims, 30,000 cubic metres of

water passed through the sewers in twenty-four hours,—28,000 cubic metres during the day time, when all the wool-carding factories were at work, and only 2,000 cubic metres at night. As a natural result there were horrible smells at night. This, indeed, explained the prevalence of smells, so general at night in towns. Under such circumstances sewers were always dangerous, however well they might be constructed. The great problem was how to maintain the water level always at the same height in sewers.

Dr. C. W. Covertan, member of the Ontario Board of Health, described the measures taken by the public authorities in Canada, the appointment of Government engineers to see that drains were properly laid, trapped, and ventilated to the top of the houses, and various other eminently practical efforts that redounded to the honour of the Canadian sanitary administrators.

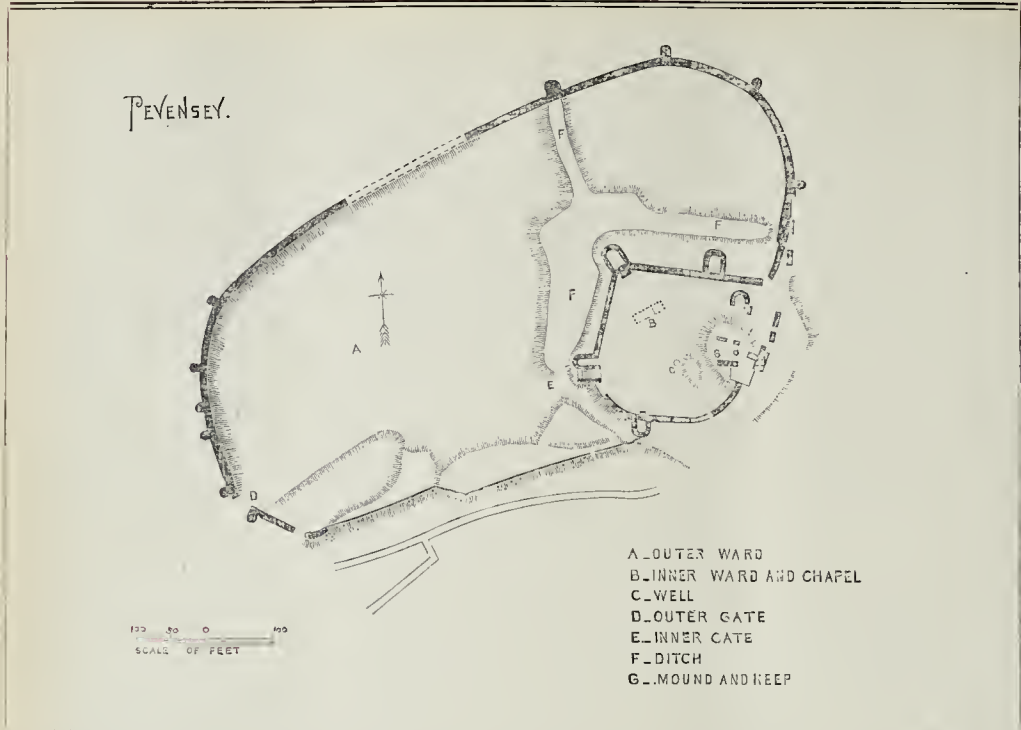

Dr. Hauser, of Seville, followed, and presented an elaborate and most carefully-calculated work on Seville, with maps, showing the death-rate for each quarter of the town, and, as compared with the state of the sewers. This led to the conclusion that the lowest and best-drained districts were the most healthy. The patients in the hospitals contracted the diseases special to the quarters where the hospitals were situated. Altogether, this remarkable study, too replete with facts and figures to hear condensation, concluded in favour of the principles generally accepted in England with respect to the draining of houses.

M. H. Bourrit, architect, Geneva, then delivered an optimistic speech on the condition of Geneva, in which he boasted that the sewers were not ventilated at all, and that no complaints were possible. As a matter of fact, complaints are possible, and were very freely uttered during our stay in Geneva. The sewer months are all trapped by syphons, and there are syphons between the house-drains and the sewers. The confined sewer-gas is, therefore, highly dangerous; and when, in spite of water-seals, it makes its escape, the results are anything but pleasant or safe. Also, when we think that it is in these unventilated sewers that the drinking-water is conveyed, the prospect that an accident to the pipes suggests is anything but pleasant. Still, M. Bonritt and the other speakers of Geneva seemed quite satisfied with the present state of affairs, and their only anxiety was to know whether or not they should create a sewage-farm or continue throwing all the sewage into the Rhone.

At last, this long debate was brought to a close by M. Durand-Claye, who very adroitly pointed out that all opponents to the "tout à l'égout" principle came from towns where it was not practised, but that no one from the numerous English, German, and American towns, where everything went to the sewer, had come forward to advocate a return to the cesspools as of old. The great point urged was water. No system was perfect that did not allow the poorest person to deluge his family with water. Movement, movement of water as of air, was the only means of cleansing our sewers as of ventilating our rooms. The man who wants to be clean washes himself; we must wash our sewers, not so much by direct flushing, as by great volumes of water going through the houses first. M. Durand-Claye further defended the large-sized sewer on the ground that in it the water met with less friction and therefore ran quicker. Finally, he invited all the members of the congress to visit the sewage farms at Gennevillier.

Altogether, it seemed pretty evident that the majority were in favour of allowing everything to go to the sewer, but opinions were much divided as to the advantages of the Liernur and Berhez systems of pneumatic drainage and the ordinary process. The German, Dutch, and English speakers alone seemed acquainted with the practical problems involved in the question of trapping and ventilating sewers and house-drains; and to Englishmen the debate seemed confined too much to general principles, and did not deal sufficiently with those details of application which, if neglected, compromise the best of theories.

The Baroness Burdett Coutts has acceded to the invitation of Mr. W. Busbridge to deliver the Queen's prizes to the students of the Metropolitan Drawing Classes. The ceremony will take place at the Guildhall, on Thursday, October 12th. The Lord Mayor will take the chair at eight o'clock.

#### PEVENSEY CASTLE.

PEVENSEY is, in some respects, the most interesting place in the South of England. Not only is it closely associated with English history during the eleventh and twelfth centuries, but its ancient and present names, and a part of its material remains in masonry and earthworks, connect it closely with the British, Roman, and early English occupation of our island.

It was, without doubt, the chief place in the great forest of Anderida, which, in remote times, extended over the south of Sussex and the Weald of Kent, and of which the not infrequent remains are seen in the very numerous and wild parks found in these districts. The British name, both of forest and town, is preserved in its Roman form, and the site of the latter is still indicated by its Roman walls and towers, which compare with those of Porchester in extent and completeness, and, like them, have been incorporated into a later fortress. The Romans probably left Anderida in good repair. One of the chief strongholds of the "Comes litoris Saxonici" was not likely to have been neglected, and it appears, from the Saxon Chronicle, that the Britons were well aware of its value, and held it against their piratical invaders with fierce but unavailing valour. Late in the fifth century it was besieged and taken by Ælle and Cissa and their followers, and every Briton within it was put to the sword. Possibly to this period are due the marks of undermining still to be seen along the exterior base of the Roman walls, and to some period between the original construction of the wall and additions by the Normans are to be referred the slips of the soil by which the foundations have been weakened, so that the wall, unsupported, has given way along the south front.

Andredes-ccaster or Andreceaster, from a Roman and British, became an English fortress, and, by slow degrees, the Forest of Andredes-weald became encroached upon by cultivation. The change of masters also brought a change of name, and the island or "eye" in the marsh became the property of a supposed "Peofn," whence its present name is thought to be derived.

Under the English rule, law and order and the divisions and names denoting property were gradually introduced, and Pevensey became the chief town of a Rape, an honour it shared with Chichester, Arundel, Bramber, Hastings, and Lewes, in each of which the town was distinguished by early earthworks, and at Chichester by Roman walls. Each of these Rapes, divisions thought to be of Jutish origin, had its town and fortress, and each town was placed upon a river. That of Pevensey rises in the wooded ridge about Penshurst and Dallington by a number of streamlets which meander athwart the marshy level of Pevensey, until a little above the castle they form what is still known as the old Haven, and which was in use in the twelfth century. As late as 1317 a grant by Edward II. mentions the marshes as overflowed by the sea, and as in no man's tenure. The castle then stood on the margin of the sea, from which it is now more than a mile distant, and the whole area of the level, many quarters in extent, seems to have been an impracticable morass, covering the fortress towards the south and east, and in some degree to the north. The knoll must so have presented itself to Julius Cæsar, if, as generally supposed, he here landed, and so, with the addition of the Roman walls, it was certainly seen by Ælle and his followers, and 500 years later by Duke William when he landed between Eastbourne and Hastings, and selected the higher ground to the east of that castle for his march inland to give battle. "Mare transitiv," says the Bayeux tapestry, "et venit ad Pevensæ," and the chronicle of Battle says he landed "prope castrum Pevensel dictum," whence the soldiery went to seek victuals at Hastings. Here, then, it was, beneath these very walls, that the Conqueror took seizin of his yet unconquered kingdom.

Pevensey, under the Normans, became once more a place of consequence, and one of the havens through which the sovereigns kept up their communications with Normandy. It was hence that the king embarked on his return to Normandy in 1067. William granted it to his half-brother of Moretaine, who is said to have built a castle there. What he actually built is unknown, and the only existing masonry that can possibly be of his date is the broken superstructure of one,

or perhaps two, Roman towers, and some rude repairs executed on the face of one of them. But whatever he did he held, and continued to hold the Roman castle till his death, and he so held it against William Rufus, in 1088, being supported and encouraged by Bishop Odo of Bayeux, and by the hope that Duke Robert would come to their relief from beyond the sea. This hope was fallacious. Rufus having stormed the mound of Tonbridge, laid siege to Pevensey. The garrison was brave, the Earl Bishop and his brother Count were skilful generals, the walls were high and strong, and for six weeks the king, at the head of a numerous army, assailed the place in vain. A tardy force sent, not led, by Duke Robert, strove to land beneath the castle wall, but, though the king's English soldiers were thus placed between the double attack from the castle and the ships, they overcame and, for the most part, slew the invaders. The castle was surrendered, and Odo, transmitted under a guard to Rochester, contrived to enter that castle, and to encourage its garrison to hold out.

Pevensey next comes under notice in 1101 as the muster place of the army led by Henry I., to repel this expected invasion of Duke Robert. He was so far successful that the invaders were driven to land at Porchester. Either under Earl William of Moretaine, who was taken at Tenebri and lost his lands, or under his successor, Gilbert de L'Aigle, the Lewy of Pevensey was erected into an Honour, and finally became the Honour of the Eagle, "Honour de Aquila." In 1144 the castle was attacked by Stephen, and defended by Gilbert de Clare, then holding it for the Empress, to whose son Henry it had been granted by Henry I. It next came to King Stephen, and about 1216 became the property, under the Crown, of William de Warren, and after various confiscations and restorations, was finally lost to the De Aquila family in the reign of Henry III. John, Earl Warren, took refuge here in 1264, after the Mise of Lewes, and in the following year it was held by Peter of Savoy for the king against the younger De Montfort. Very little of the present Mediaeval masonry could have been standing during these various sieges. The strength of the place must have then mainly depended upon the Roman

exterior wall, furnished, no doubt, with a Medieval parapet, and dominated by the early English mound, with probably a shell keep, of timber or masonry, upon it.

About 1269 it fell into the hands of Prince Edward, and remained a while in the Crown. In 1300 it was in a ruinous condition, "Contractum et male custoditum," Edward I. having declined to repair it. It must have been soon after this, judging from the evidence of the existing masonry, that the present additions were made, that is, either at the close of the thirteenth or very early in the fourteenth century. The towers are attributed to Edward II., in 1309.

Pevensey, "La Ville et la Lowce de Penense," was included in the extensive grants made by Edward III. to John de Gaunt, under whom and the Duchy of Lancaster the Pelhams became hereditary constables. In 1399 Lady Pelham distinguished herself by holding the castle for Richard II. against the combined gosses of the counties of Kent, Sussex, and Surrey. After this event it was mainly used as a state prison. Edmund, Duke of York, was confined here in 1405, and in his will bears testimony to his good treatment; and here also were imprisoned James I. of Scotland in 1414, and in 1419 Joan of Navarre, the last queen of Henry IV. In 1650 the castle had a narrow escape from the claws of the Parliament, the materials having been sold for building purposes.

The history of the building, though aided by passages in the public records, is mainly to be established by the study of the material remains. Those of the Roman period have fallen under the searching and very accurate notice of Mr. Roach Smith; the present paper deals mainly with the Medieval additions both in earthworks and masonry.

#### DESCRIPTION.

The Roman fortress is in plan a rounded oblong, 220 yards north-east and south-west by 115 yards, and contains from  $8\frac{1}{2}$  to 9 acres. It is included within a wall strengthened by towers, and here, as at Lyme, the outline of the plan was evidently governed by that of the ground on which the castle stands, and which rises 8 ft. to 10 ft. above the sea level and that of the surrounding marsh or meadow. The wall is from 10 ft. to 11 ft. thick throughout, and at this time from 20 ft. to 30 ft. high. The length in circuit is about 530 yards. At the head of the enclosure, towards the south-west, is the main entrance, preserving, very nearly, its original form. Two half-round towers, 28 ft. apart, and 20 ft. diameter, with produced flat sides, giving them a depth of 30 ft., and 30 ft. high, project 20 ft. from the curtain, and were connected by a cross wall, of which only the foundation remains, and in which was the outer gateway. These towers are not quite parallel, but their longer axes radiate slightly outwards. They are solid and have no internal projection, but from each of them a wall ran backwards 18 ft., terminating in a cross wall, in which was the second gateway, the foundations of which show that the base had an opening of 9 ft. This rectangular gatehouse must have resembled those of Porchester, and, like those, had evidently been altered to suit the Norman entrance, of which there remains one jamb of the outer gateway.

Besides the towers flanking the entrance are eleven others upon the curtain wall. These also are solid, of the height and age of the curtain, and without internal projection. They vary from 14 ft. to 20 ft. in breadth, and from 14 ft. to 16 ft. projection from the wall. They stand at irregular distances of from 14 to 35 yards. Besides the thirteen standing towers there are two displaced and broken down, and the fragments of two others, making seventeen in all. They are closest along the north-west and north fronts, where the ground outside is highest. Towards the south and east there are but few, the shallow muddy sea and the marsh being found a sufficient protection. Besides the main entrance there were three posterns, of which that to the north-east is still in use. That to the north is broken down, but its remains show it to have passed obliquely through the wall. The southern postern was probably a water gate. In the south wall the mouth of a sewer, about 18 in. square, and opening towards the sea, has been laid open. Although the wall is for the most part thickly covered with ivy, it is pretty evident that in parts it is still capped by a later battlement, and one of the northern

towers, originally 32 ft. high, bears a superstructure of 18 ft., which, from a window in its side, appears to be of the Norman period.

The wall has been breached on the north front for 65 yards, and its mass, thrown forwards, still encumbers the ground outside. To the south is a much longer breach, at least of 200 yards. This seems to have been produced by a slip of the soil, by which the foundations have been moved forward bodily several feet. At the east end also the wall has been broken down, but here its fragments, which are of considerable bulk, are mixed up with others of later date in wild but not absolutely inextricable confusion. Most of the north wall has been picked into to a considerable depth, at the ground level, but the foundation remains uninjured. This is more probably the work of the Northmen than of those who, in later days, laid siege to the Norman garrison, for these latter would have worked below the surface of the earth, and have inserted props of wood beneath the base of the masonry to be set on fire, and so to have caused the destruction of the whole superincumbent mass. No gunpowder has here been employed.

It is evident that there was formerly a ditch at the foot of the wall on the south front, full of water, where, indeed, it may still be traced. Along the north, west, and east fronts, the wall is bordered by a road, to make which the ditch, probably never very wide or deep, has been filled up. There can be no question as to the authors of the exterior *excavate*, both wall and towers. They are all of one, or very nearly one, date, and distinctly Roman, and, which is not always the case, the towers are hinged into the walls. The substance of the masonry is very rudely-coursed flint-rubble, chiefly composed of flints and pebbles from the adjacent sea-beach, mixed with angular fragments of stone, the whole held together by mortar very freely employed. This mortar is remarkably white in colour, and contains numerous small pebbles, little if any broken tile, and a preponderance of sand. On the whole the mortar has set firmly, and holds well together the rather heterogeneous mass of materials. The face of the work, both inside and outside, is composed mainly of squared stones from Eastbourne or Beachy Head. They are generally about 6 in. by 4 in. on the face, but sometimes as large as 12 in. by 6 in. The lowest courses at the ground-level are composed of darker and far larger stones, and in the wall above are occasional double hands of tile, and sometimes of stone nearly of the colour of tile. A good deal of the facing at the lower part of the wall has been stripped off, but inside this stripping is confined to the part of the wall just above the ground-level, which is raised artificially higher than the level of the natural soil. In some places this addition is high enough to convert the lower part of the masonry into a retaining wall. It has been thought that the earth thus employed was derived from the inner ditch, an Early English work. It may be so, but more probably the contents of this ditch went to form the mound, and it is possible that the raised soil may be derived from the ditches of a British camp preceding the Roman occupation.

The Romans, who constructed the outer walls, seem to have been content with a single line of defence; but the Northmen treated the whole area after a different fashion. Within the area, at its eastern end, a mound was thrown up, table topped, and about 30 ft. high; this, though within the area, was upon its margin, and rested against the eastern wall. The material for the mound seems to have been derived from a ditch which surrounded about two-thirds of its circumference, extending from wall to wall, and which thus isolated it from the remainder of the Roman area. This ditch has been filled up, probably to give space, but its line is still marked by a slight depression in the soil. By this means a strong place would be formed very nearly in accordance with the Early English practice, having a mound or bank, with its proper ditch, and an appended court. The only peculiarity would be that the court was walled, and thus the ditch of the mound would be traversed by the masonry, and the outer side of the mound supported by it.

The Normans, who at once saw the value and took possession of Pevensey, probably were for a time content with the Roman walls as they stood, and with the palisaded citadel of the mound. At least, there is no certain trace of any very early Norman masonry. Indeed, the only masonry of Norman date at all now to be seen

is a fragment of wall with a window, the remains of a superstructure upon one of the northern towers, and some patchwork in flints, and a few courses of stone laid herring-bone fashion, by which the face of another of the Roman towers has been repaired. Had the Normans of the eleventh or twelfth centuries constructed any eastern walls, gatehouses, or mural towers within the court, some trace of them would probably remain. The chapel, indeed, judging from its dimensions, was probably Norman, and the base of the font decidedly so, and it is possible that the shapeless fragments of rubble masonry which encumber the top and slopes of the mound may be of the same, that is, of late Norman date. In truth, the castle, as the Normans found it, was a very strong place. The walls only needed a battlement, and even if this were surmounted, the entrenched and palisaded mound would be perfectly defensible so long as provisions held out.

At this time, however, the Roman *excavate* contains the remains of a strong and tolerably perfect Medieval castle. This, as usual in such cases, takes the form of an addition to the defences of the mound, shutting it off as a citadel from the rest of the works. Advantage was taken of the broad and deep ditch extending from the east to the south wall, 210 yards in length, curved westwards or outwards, and which shut off the mound, and a part of the great area within it, and thus formed an inner ward, of about an acre and a quarter, containing the mound or keep. The ditch, which was probably supplied with water from the sea at its south end, gives off a branch northwards towards the Roman tower, called the watch-tower, and this cuts off the north-east corner of the ground, which thus forms a sort of small middle ward between the forks of the ditch. Behind the ditch is a curtain wall, near the centre of which is a gatehouse of some pretensions, and three large drum towers, of which two flank the gatehouse, and one is placed to the north of it.

The gatehouse points to the west, opposite to that of the Roman area, now the outer ward, at a distance of 184 yards. In front of it are the two solid piers of the drawbridge, 14 ft. wide, and approached from without between curved wing walls. The piers were faced with ashlar, now stripped off. The space between them is 12 ft., and may have been 10 ft. The gatehouse is composed of two half-round towers, produced backwards to contain the entrance passage. Outside, these towers somewhat resemble those of the Roman or outer gate, which may have served as their pattern. Their loops are of unusual length, one being 15 ft. long. The vents of two garderobes are seen, opening flush with the wall. One seems to be the lower end of a loop. They contain a basement, a ground, and an upper floor, looped towards the field, not vaulted, and only provided with garderobes. The north tower, faced with sound, though rather open-jointed, ashlar, is still standing, though mutilated. In its ground-floor is a fireplace. The south tower is quite broken down. The entrance passage is tolerably perfect, although the gateway at each end is gone, as is the upper chamber for working the portcullis, of which part of the grooves remain. The passage, 12 ft. broad and 35 ft. long, was vaulted with a segmental vault, strengthened with plain broad chamfered ribs, now broken away, and in the vault, a little behind the portcullis, is a large square central hole or "meurtrière" for the defence of the passage. In either wall is an arcade of two arches, a larger and a smaller, low pointed. The larger are closed, the smaller pierced by doors opening into the ground-floors of the gatehouse.

Flanking the gatehouse, at a distance of 33 yards north and 54 yards south, are two round towers, each capping an angle of the curtain. The north curtain has a base or plinth slightly huttering. The wall is vertical. There is no cordon between them. The north-west tower is 30 ft. diameter and has a basement, ground, and upper floor. The basement, though below the inner ward level, is on the level of the ground outside. It is arcaded, having six arches in its rounded sides, and one in its flat end or gorge. These arches have a drip of the double-scroll pattern, and between each pair springs a moulded rib, and one from each of the two right angles, eight in all. They are broken away, but their profile is seen, and the plan of the vault may be inferred. The entrance to this chamber is by a straight staircase from the inner ward, and at the foot of the stairs is a lobby on the

left or west side leading to a postern doorway placed at the junction of the tower with the curtain. In the gorge wall is a fireplace the hood of which seems to have been of timber. It is difficult to understand what this chamber can have been intended for, with its ornate details, and a fireplace, and yet half under ground.

The ground-floor is entered from the inner ward by a separate entrance, in the right or east wall of which an opening passes into an oblong mural chamber, vaulted, and contained within the curtain. This chamber has a water drain, and above it, in the wall, three bold corbels, and above these a small segmental-headed doorway, now blocked up. This is a very peculiar arrangement, and it looks as though there had been a wooden structure, perhaps a garderobe, bracketed out upon the face of the wall, over the ditch, at about 10 ft. from the ground. The upper floor of the tower was entered from the battlements, the tower rising above the wall. Only the basement floor was vaulted. Each stage is lighted, or rather ventilated, by loops, towards the field. The southern flanking tower is nearly upon the pattern of that last described, save that the basement is not areaded, and none of the floors vaulted.

The third tower, in the north wall, 36 yards from the north-west flanker, is of the same pattern, with the same exceptions. The staircase into the basement has a side door opening upon a postern in the east wall, with a segmental head, and from the ground-floor entrance there opens, westwards, a long mural chamber, the counterpart of that described as attached to the north-west flanker, having also brackets and corbels, and a small door in the wall, 10 ft. above the ground, as though for a timber garderobe. These are all the regular towers, but in the south wall, where a tower might be expected, is a postern, which pierces the wall at its junction with the Roman wall, and outside and in front of it is a fragment of a Roman tower, which has slipped forwards a few yards, and forms a sort of bulwark concealing and protecting the postern. It is evident that the displacement of the tower is older than the Norman period, and was taken advantage of by the later builder. In the north wall of this inner ward, between the north and north-west towers, is a large fireplace, perhaps that of a hall. The kitchen was probably in the north-west tower, and the large mural drain connected with it.

The mound which occupied the east end of the castle and carried the keep, remains tolerably perfect, though much encumbered with ruins produced evidently by gunpowder. Against its east side, and supporting the mound, is a Roman tower, which was worked into the keep, its solid top being battlemented. The mound has a spur of earth towards the north, probably connecting it with the north wall, but nothing definite can at present be ascertained, though the foundations upon it, if laid open, would probably disclose something.

As the Medieval castle is placed within the eastern end of the Roman area, its eastern side osenlated with the Roman boundary, which is here common to both areas. About four-fifths of the enclosing wall of the castle is Medieval, but the remainder, that towards the east, is Roman, which is thus common to both fortresses. Commencing at the south postern, where the two walls are in contact, to the great disadvantage of the masonry of later date, the Roman wall extends, partially propped up by a later buttress, until it reaches a Roman tower that connected it with the keep mound. Beyond this, passing southward and eastward, to where the Medieval wall springs from the Roman *enceinte*, the Roman wall has been left to support the mound, but about 6 ft. in front of it a Medieval wall, 9 ft. thick, has been built, probably to afford more space above, and to assist in supporting the earthwork. The castle has been attacked on this side, or else those who dismantled it, thinking this the strongest part, have mined and blown it up, for the glacis for many yards is covered with enormous masses of masonry, which have evidently been displaced by gunpowder, exploded in large quantities. At one part, abutting upon the Roman tower, the two walls are seen. About 20 ft. of the Medieval wall, 9 ft. thick and 10 ft. high, stands undisturbed, though above this height its superstructure has been blown off. Behind it is the Roman wall of about the same height, not only reduced in height by the explosion, but

tilted forward. This is what has happened in this quarter, and the history of it is clear, even in the midst of so great a confusion.

Within the Medieval or inner ward an excavation shows the position and plan of the chapel, with a nave 40 ft. by 8 ft. or 9 ft. broad, and chancel of 12 ft. by 11 ft. A fragment of the front has been preserved. The chapel is, no doubt, of Norman date, and older, therefore, than the castle in its present form. There is also a rude pillar piscina, or perhaps a holy-water stoup, such as is now and then found in Norman buildings. There are one or two in Glamorganshire. The free chapel in the castle is mentioned in the grant of John of Gaunt. The well also has been discovered at the foot of the mound. It is cylindrical, 7 ft. diameter, and lined with ashlar to a depth of 52 ft., below which it is square and lined with timber.

The Roman works at Pevensay have been explored and examined with great skill and success by Mr. Roach Smith. Unfortunately the Medieval castle has been less fortunate, and has not been accurately described. A short but complete and brilliant description of Pevensay, and a notice of the part it played in the campaign of 1066 will be found in Mr. Freeman's "Norman Conquest." It also plays a conspicuous part in his recent life of the Red King. G. T. C.

#### THE EXHIBITION AT TRIESTE.

THE city of Trieste is now celebrating the five-hundredth anniversary of its annexation to the Austrian dominions by an exhibition, which has for its purpose the display of products of Austro-Hungarian industry in various branches. Matters relative to navigation are treated with a completeness which gives the exhibition in this respect almost the character of a special nautical display. Thus codes of signals, rules for avoiding collisions at sea, nautical calculations, maps, instruments, books of reference, &c., are shown in a systematic manner. Submarine electric illumination also forms a subject of illustration. The hygienic arrangements of the port are designed with a view to prevent the introduction of epidemics from the Eastern countries between which and Trieste important trade relations exist, and the various official bodies connected with the sanitary inspection of Austrian vessels have placed in the exhibition various interesting records of their activity in the cause of sanitation.

The display of Oriental furniture is well arranged, and the mineral wealth of the Austro-Hungarian monarchy is exemplified in a very complete manner. Sections of the woods grown in Croatia are exhibited, and form an interesting display.

One notable feature with respect to the exhibition is the absence of art from the subjects illustrated. As, however, there has recently been at Vienna an exhibition of art, the Trieste display may be considered as appropriately following it up. The situation of the exhibition on the seashore is in harmony with the general character of the display. The Milan pavilion is spoken of as being specially effective, being built of elegant ironwork on a solid stone foundation. The view of the exhibition and its surroundings from the sea is said to be very picturesque, the grounds being laid out in artistic style.

#### THE STATE OF WORDSWORTH'S GRAVE.

THOMAS DE QUINCY records that on the 23rd of April, 1850, Wordsworth was "buried in the green churchyard of Grasmere, between a yew tree of his own planting and an aged thorn." In this "churchyard among the mountains" beneath "a plain blue stone, a gentle dalesman lies"; the stream of the Rothay murmurs near his grave in the valley under the shelter of Fairfield,—Faarfell, the mountain of the sheep,—and the crag where Sidrophel and the Ancient Woman,—

"Dread pair that, spite of wind and weather,  
Shall sit upon Helm Crag together."

In this churchyard are also laid the poet's wife, "the phantom of delight when first she gleamed upon my sight," his sister, "impassioned Dorothy, the gift of God," and his daughter Dora. "To this resting-place of a family that were 'lovely in their lives, and in their death were not divided,' pilgrims have flocked, as to a holy shrine, from all the continents of the world.

We visited the spot last week. After viewing a marble medallion bead of Wordsworth, in St. Oswald's Church, a strange old building, very rude and rough, with a roof that recalled the architecture of a Highland cottage, we went in search of his grave. Though one of the finest of country churchyards, we had actually to ask a woman, who lived at the gate, to tell us where the grave was. We saw a path among the grave mounds, about 1 ft. in width, and followed it, and it led to a dirty dark corner, where several blue-black headstones of slate stood. Could this be the resting-place of Nature's tender lover? It was; and we felt a chill come over us. The day was beautiful: the sun was shining in a cloudless sky, but everything round the spot we had come to seek seemed decayed and withered, like a grave in the centre of a dirty smoky town, not in beautiful Grasmere. No green grass was there, all was dull, dank, and depressing. The poet's corner must be badly drained, for we could scarcely get near enough to read the inscription, in consequence of an accumulation of water that formed a trench at least an inch deep at the base of the stone curb that held the iron rails surrounding the grave. The contrast between the sunlit mountains and the gloomy surroundings of his grave who sang of them so lovingly and well was extremely painful. Must Wordsworth's grave become an "ancient monument" before something will be done for its preservation?

#### THE NEW ROYAL ST. ANNE'S ASYLUM, REDHILL.

THE accompanying design for the New Royal St. Anne's Asylum, Redhill, was one of the two submitted in competition by Mr. A. Hessel Tiltman, M.R.I.B.A., architect, of 7, John-street, Bedford-row. The plan attached will describe the general arrangement of the main building. Accommodation is provided for 260 boys and 140 girls, together with the necessary apartments for the officials attached to the establishment. The chapel is placed, as shown in the view, immediately in front of the building, and the head-master's house immediately to the right. The infirmary is at the north-eastern part of the site, well isolated from the general building, and with a southern aspect. Immediately adjoining is the cricket-field. Attention, it is claimed, was directed to the proper sanitary arrangement of all parts. The lavatory blocks in the centre of the boys' court are placed mid-level between the ground-floor and the level of the playground, so as to be conveniently accessible from either. The author claims for this plan great simplicity and compactness of arrangement, together with easy intercommunication between all parts for the officials. The amount to be expended being but small, no attempt was made to gain effect at the expense of ornamental features, the author relying entirely upon the grouping of the various parts, and the colour of the materials used. The cost of the design, cubed up at an average of 7d. per foot, was estimated to be 35,820*l.*

An alternative scheme was submitted also, interpreting the conditions less liberally, and capable, consequently, of being executed for a somewhat less amount.

**The Railway Appliances Exhibition.**—The arrangements for holding the exhibition of improved wagon-couplings and other railway appliances at Darlington on the 3rd of October and four following days, under the auspices of the Amalgamated Society of Railway Servants, and in connexion with their annual congress, which will open on the same day, have been reported to the London committee at the chief offices of the society, City-road, as progressing satisfactorily. Many applications have been made by inventors and patentees for space; and, from the nature of some of the applications, it is believed that in improved signalling arrangements and modes of electric communications between guards, passengers, and drivers, the exhibition will be particularly interesting, not only to railway employes, but to the travelling public. It was reported that in order to have the improved wagon-couplings practically tested, the North-Eastern Railway Company have consented to provide wagons for the competitive trials, which will take place at the Great Northern sidings, Bank Top, on Thursday October 5.

THE GERMAN IMPERIAL PARLIAMENT HOUSE.—The Design by Herr Friedrich Thiersch.

### THE COMPETITION FOR THE HOUSE OF THE GERMAN IMPERIAL PARLIAMENT.

HERR THIERSCH'S DESIGN.

As we have observed on a previous occasion, no fewer than 189 designs, with about 2,000 sheets of drawings, were the result of the second competition, which was to give to United Germany the long-desired House of Parliament. With comparatively few exceptions, those designs represent a performance which calls forth the respect of those able to judge. But, as we have already pointed out, it is open to question whether the selected design in its exterior form is at all a worthy symbolical embodiment of the ardent aspirations of generations of Germans. The mistake, however, may be explained by the unusual nature and magnitude of the work which German architects were called upon to undertake. If, amongst all the designs sent in, there is not one which fully corresponded to the requirements of genuine monumental art, the reason is to be sought in the difficulties which beset the execution of the task. Architects were expected, as is too often the case, to make the best of a site offered to them, no matter whether its nature was at all in consonance with the conditions which the erection of such a monumental edifice imposed upon them.

It is necessary to recapitulate some of the instructions which were to guide competing architects in working out their designs. The portion of the Königsplatz set apart for the Imperial Parliament House forms a parallelogram 446 ft. long and 312 ft. deep, the limits of which were by no means to be exceeded. The two longest sides of the building are to face on the west towards the Königsplatz with the triumphal column, and on the east towards the Sommerstrasse. The northern and southern sides are bounded respectively by the line of street and the paths of the Thiergarten leading to the interior of the city. It is evident that this position points to the Königsplatz as the direction towards which the dominating principal front with a wide portico was to face. But as the traffic will flow towards the building from the other sides, it was impossible to place the regular approaches in its western front. As might have been expected, in not a few of the designs the Königsplatz façade was chosen for placing the principal portal, as being most suitable for displaying the most prominent architectural features of the edifice. Although this view may be more or less justified by the purpose which such a portal would serve on special occasions or as an approach for the court, it appears contradictory that the principal entrance should not be on that side of the building in which the most immediate and principal business of the house is carried on. But quite apart from this consideration, and whether the principal entrance be in its western or eastern façade, the architect had to meet another obstacle, the comparative narrowness of the site, which placed great difficulties in his way in freely developing his design on a comparatively short axis. In order, therefore, to obtain the required space for the prescribed covered vestibule, with adjoining cloak-rooms, the great sessions-hall, which would naturally be sought in the centre of the whole edifice, at the intersection of the two axes, and for the hall which is to serve as the lobby for the members and as a festal hall for special occasions, or for large committee meetings, many of the designs placed the principal entrances in the short façades of the building, preference being given to the southern side, that facing the Brandenburg Gate. The advantages of such an arrangement, again, are counterbalanced by the great drawbacks which are as difficult to avoid in placing the rooms along the longitudinal axis of the building as by their partial grouping in its transverse axis.

We have already freely criticised in these columns the design of Herr Paul Wallot, of Frankfurt; but we refer to it here again because we wish to compare it with that of his rival, Herr Friedrich Thiersch, of Munich, whose design, as we have on a former occasion indicated, received also a first prize, but was not deemed worthy of the honour of execution. We give a perspective view of Herr Thiersch's design in the present issue of the *Builder*. The two designs are different, both in exterior form and ground-plan, and yet they have several features in common. They are both wanting in a portal having a claim to archi-

tectural importance, its place being supplied by plain semicircular-headed openings,—entrances they can hardly be called,—distributed over the four fronts, and cut, as it were, into the ground-story. This mode of dealing with a difficult subject, arises from a desire of obliterating, to some extent, the inferior position accorded to the Königsplatz façade. The place assigned to the sessions-hall at the intersection of two wings, by which disposition four courts are formed in the parallelogram occupied by the edifice, is the same in both designs. The latter also agree in assuming the principal entrances to be in the narrow fronts of the building. But only in the design of Herr Thiersch the entrance of the south front is, at the same time, the point whence the grouping of the rooms proceeds, while Herr Wallot proceeds in reality from the Königsplatz. To the two entrances of the narrow fronts, Herr Wallot adds here a third opening, direct into the vestibule and upon the principal semicircular staircase leading from it. Three open arches, in the centre one of which it is proposed to place the equestrian statue of the emperor, connect it direct with the festal hall. Passing through the latter, the sessions-hall, the "house," is reached, while the galleries behind lead to the refreshment-hall, placed in the Königsplatz front, wide corridors to the right and left establishing communication with the other parts of the building. One of the principal objections raised against this arrangement is that it lowers the festal hall to a mere passage, and shifts the sessions-hall from its proper position, the centre, towards the east, to where the cupola is placed. The latter is intended to supply light by day, while at night the hall is to be illuminated by the electric light throwing its rays also outwards. Something more imposing seems to be wanting on the western façade than the figure of Germania rising on a broad base, to counterbalance the cupola on the east.

In contrast to Herr Wallot, Herr Thiersch develops his plan, as already remarked, in the direction of the longitudinal axis. Upon the entrance on the south front follow spacious stairs, and upon the latter a hall, both of square form. On either side of the hall follow in the transverse axis, first a semicircular room lighted from above, and next an oblong room receiving its light from three large circular-headed windows, serving as reading and refreshment rooms, while, in proceeding from the hall in a straight direction, the sessions-hall, ending in a semicircle, is reached. This mode of grouping the rooms assigns the most important position to the festal hall, in the centre of the edifice, with the cupola above it, the "house" occupying a secondary position. The latter is shifted to the north, to a position in the building which outwardly is the least striking, the part of the façade inclosed by the centre and corner projectures. This arrangement evidently did not find much favour, but, in other respects, it seems the more preferable one. Herr Thiersch's design shares with that of his successful competitor this disadvantage, that, being placed central and lighted exclusively from above, no direct ventilation is possible. In both designs, the sessions-hall of the Federal Council, which, ideally at least, corresponds with that of the Reichstag, is relegated to the north-east corner of the building, which, in the case of that of Herr Thiersch's, is justified to some extent by the nearness of the "house," but in that of Herr Wallot's appears to be chosen perfectly arbitrarily. In consequence of taking up more space for vestibule, stairs, and central hall, Herr Thiersch proposed two stories above the ground-story, which is treated as sole, and thus his building would have been of higher elevation than that actually chosen. His design may be less attractive, but it appears to us that the sober earnestness of its forms agrees well with the compact features of the whole edifice.

**The Polytechnic, Regent-street.**—The syllabus of the evening classes now open here to the public is issued. Attention should be called to the practical trade classes, and also to the proposition to grant an "Industrial Diploma" to tradesmen who pass through a course of study combining both theory and practice, extending over three years. How this will work we do not exactly know. We are bound to confess we do not look with any particular favour on the self-created examining bodies which are bringing themselves forward.

### THE DOMED CHURCHES OF CHARENTE.

THE "SHARPE MEMORIAL" VOLUME.

SHORTLY after the publication of this volume we gave a careful account of its aim,\* finding it "honourable to those who have executed the memorial, and to him in whose memory it has been done." We also gave an account of the twelfth-century architecture of Charente, which is so well illustrated in the volume,—an architecture in which we find stone domes used instead of the cross-vaulting met with elsewhere at the same date. The book is the memorial of the Architectural Association to one of its members, who did good service to the world at large, and in the later years of his life conducted a number of members of the Association to different fields of architectural study, shared and directed their labours; and led the members to put their measured drawings, sketches, &c., into shape to be used, in the first place, as lecture diagrams, and afterwards, when reproduced by photo-lithography, as book illustrations. The plates in the volume are reproductions of the drawings used at the lecture delivered by Mr. Sharpe in June, 1876,—that is to say, of some of them, for the profusion of drawings put upon the walls that evening was such as has rarely been seen at an architectural lecture. A selection was made when the sixty plates of the volume were prepared. Some of the material as yet unused appears in the two pages of illustrations given in this number of the *Builder*. These illustrations will show our readers the class of work which was prepared after Mr. Sharpe's excursions, and the kind of plates they will find if they possess themselves of copies of the volume.

A few remarks may appropriately be made with reference to:—

1. *Plan.*—The churches are, for the most part, without aisles, and sometimes without transepts. Roulet is one of the most elegant of those which have a series of domes. A longitudinal section of this church is given in the work, and an interior perspective, &c. The tops of the domes appear to be worked to an even face, as though they had been intended to be seen externally, as seems to have been the case at St. Front, at Périgueux; usually in Angoumois they are rough, and covered by timber roofs. Domes were used for covering the centres of crossings earlier than as vaulting to naves. This, in the older churches, is of the barrel-vault form, either semicircular or pointed. Passac is another example of a church without transepts. It is a church of a remarkable kind in many ways; the apse, the tower and spire above the dome, and the west front are very characteristic examples of the special features of the churches in this district. The spires are not steep, and are formed of stone, shap'd so as to give the appearance of scales, presenting the idea of a fir-cone or pine-apple, and have thus obtained in France the appellation "*en pomme de pin*."

Berneuil is a fine example. A solitary dome is put at the crossing, barrel-vaults being used elsewhere. The various modifications of the type of general plan in this church are given very effectively in the parallel of plans which forms plate 2 of the volume: a dozen plans, all to the same scale, appear there. At Puyperoux and Mouthiers are to be found examples of a direct communication between transepts and chancel, towards which there would seem some approach at Berneuil. At Puyperoux the idea of such communication is carried still further,—the north and south respond piers at the crossing are also isolated,—passages run behind them leading from the transepts into the nave. The plan of Berneuil calls to mind another feature seen in splendid development at Coudéon and Barbezieux. At Coudéon, some of the buttresses added to the earlier church are 12 ft. wide with 20 ft. projection, which, in a church of very moderate size and height, presents a very strange appearance. The large buttresses in this and several other churches were added at a period subsequent to their first erection to counteract the great thrust of the barrel-vaults. In the volume, a well-drawn view of the picturesque, but much altered and dilapidated, west front of Berneuil is shown. The very elegant original design of the twelfth-century west front is strangely modified by the addition of great buttresses at the angles and along the nave wall.

2. As to the domes, the reader must be referred

\* See vol. xlii., p. 728.

to the volume itself for a painstaking account of their structure, and a recital of the various conjectures with reference to their erection in this particular province. In the interior view of Mouthiers the dome is just seen, a very perfect dome slightly elliptical in plan. The arches are pointed, but very slightly so; this form of arch introduces a modification of the true Byzantine pendentive, which requires for its simplicity of form semicircular arches. The interior view of Cellefrouin (cellam Sancti Protinii, as the editors do not fail to note) shows a domical vault at the crossing springing from slightly cut-off corners supported by squinches; and the section of Châteauneuf shows a vault octagonal on plan, supported by squinches and corbels,—resembling Mouthiers, shown by a view on plate 17. The squinches, carrying true circular domes, indicate early date; the pendentives proper are of later introduction.

This church of Châteauneuf alone, among those of Romano-Byzantine type visited during the excursion of the Association, has side aisles, and the arches are acutely pointed; a section is given, plotted from measurements, on plate 3. From the sketches in this number, the stately simplicity of some of these churches can be judged. Cellefrouin is a fine masculine specimen of rather early Romanesque; Mouthiers is for the most part of the late Romanesque or early Transitional periods,—all the arches of construction in it are pointed, whilst those of decoration are semicircular.

3. Two *west fronts* are shown in our illustrations. The greater part of the church at Chillac is practically ruinous. The barrel-vault of the nave has been too heavy for the walls, and the cupola of the crossing is cracked. The west front is without the original termination, which has shared the fate of several other upper stories in the churches visited. The church at Chalais has a really magnificent lower story,—a large central portal with five orders in jamb and arch, and arches at each side of it; but the rest of the front is a blank wall. Chalais has several plates devoted to its illustration. The fronts appear usually to have marked the completion of the work, and to have received the greatest share of ornamentation. Usually the capitals are richly adorned, with figures or foliage, and across some of the fronts is carried a rich, broad frieze, continuous with the capitals of the ground-story arcade. At Chillac the second story is divided from the ground story by a fine corbel table. At Dirac, about seven miles south-east of Angoulême (the headquarters of the excursion in 1875), the west front is of the same type as that at Chillac, but with differences of detail. All the fronts of this type suffer from the smallness of the angle piers. In the other type of treatment, of which the very beautiful desecrated Cistercian Abbey Church of Châtres (near Cognac) is an example, the mass at the angle is somewhat increased by large vertical shafts being carried up from the ground to the string-course at the starting of the gable. The fine front of Lanville also has large shafts, which are repeated on each side of the central doorway; and from these shafts arches are thrown across in the upper portion of the second story of the front. The details and general form of this front render it a very interesting one, but the angles, albeit strengthened by the shafts, do not gain the quality of solidity which is of much value always, especially when wall surfaces are well filled with arcades.

4. The illustrations of the *ornamentation* fill a goodly number of plates in the volume, and are most of them admirably drawn, some drawings being really exquisite in touch. "The extraordinary richness of the ornamentation in the province," said Mr. Sharpe in the lecture before referred to, "is a most remarkable characteristic. It is of two kinds, firstly, figures of men, animals, and birds, and nondescript compositions of all three; and secondly, of foliage only. The first kind is more or less barbaric, the latter very rich and pure. As regards the *chapiteaux historiés*, although there may be some deeper meaning in them than at first catches the eye, they more probably indicate the familiar struggles of the inhabitants in battle or in the chase than any allusions to Biblical texts." The stag-hunt and battle-piece given in plate 41 may well have been in the mind of the lecturer. The small capital with the bird in our illustration is from the apse of Plassac, of the exterior of which there is a good drawing in plate 25. The other capital is from the Church of St. Hilaire, at Poitiers, brought in

here as a reminder of the similarity in general expression between the Romanesque capitals there, and those further south, at Cellefrouin (plate 13), &c.

We may add to our previous notice that the "Sharpe Memorial" is 12 in. by 10 in., and that, of the sixty plates, eighteen are devoted to measured drawings, plans, sections, and elevations, nine to exterior views, six to interiors, and the remainder to details. A map of the department is prefixed to the text, which extends to forty-eight pages,—that is, the text with reference to Charente. The purely "memorial" part of the volume is put at the commencement, and terminates with a very careful and complete list of Mr. Sharpe's publications, filling eight pages, in itself a memorial which might be reproduced with advantage for insertion in copies of his works. We remember with some satisfaction the assistance given by the *Builder* by publishing the list so that it might have the advantage of critical testing when improvement was possible. Messrs. Birdsall & Son, of Northampton, deserve mention for a very refined piece of book-binding, with coloured inlays and admirable tooling, both blind and in gold. The subscription price of the volume is a guinea and a half, and there are still a few copies beyond those subscribed for by members of the Association.

The honorary treasurers of the publication fund,—Mr. John Quilter, of 10, Brunswick-square, and Mr. S. Flint Clarkson, of 36, Great Ormond-street,—will no doubt be glad to see the remaining copies reach public libraries or the hands of students. The task, commenced fully five years ago, will then have been well completed in all respects.

#### ART AND ITS INFLUENCE ON THE MASSES.

IN the Art Department of the Social Science Congress at Nottingham (presided over by Mr. G. Atchison, A.R.A.), one of the special questions for consideration was, "In what way can the influence of art be brought to bear on the masses of the population in large towns?" The first paper read was that of Mr. T. C. Horsfall. In the course of his remarks, the speaker contended that a strong love of beauty was, as a rule, gained only by those who, in childhood, habitually saw beautiful things, had many pleasant associations with them, and were taught to perceive their beauty by persons whose opinion they cared for; and of those who had gained sensibility to beauty, many lost it if they ceased for a long time to see beautiful things and to think about their beauty. Many of the children who live in large towns had no chance of becoming familiar with birds, flowers, grass, ferns, trees, or any other beautiful things; but most town children saw such things occasionally, and as they saw them chiefly on holidays, probably they had some pleasant associations with them. If love of art was to be common among the people of large towns, the slight acquaintance with beautiful things thus gained must be increased by the help of art. Good coloured pictures of common birds, flowers, trees, butterflies, country lanes, farmyards, coast scenes, that is, of the beautiful things and places which town children saw in town parks and when they go out of town, should be placed in every school, and the attention of the children should be directed to the pictures by brief addresses and by labels containing brief explanations, so that when they saw any of the things represented they might look at them more carefully, and come back to the pictures with more interest for having seen the things. There should also be pictures of historical incidents and places mentioned in the children's lesson-books. To induce attention to, and interest in, art-methods, coloured plates and good woodcuts of the same objects should be placed side by side, and the differences in the modes of representing form and colour in different arts should be pointed out. Full descriptions of wood-engraving, etching, and other processes, with all the appliances used in the processes, should be placed in an art gallery in the town, and the fact that they can be seen there should be stated on the labels attached to the woodcuts, &c., in the school collections. Each collection should contain a few examples of well-shaped jugs, cups, &c., which should have labels stating that they are well shaped, and each school should have a large glass case for growing plants, and at least two casts from

sculpture, showing what the bodies of men and women ought to be like. When chromolithographs were used in school collections, each should have a label referring to a good picture of the same subject in the art gallery. The central art gallery ought to be opened on Sundays, and, to induce workpeople to come to it often, music ought to be given in it on one or two evenings every week. As good art was essentially right beauty of appearance, if we wished busy people to care for it, we should show it to them applied to things which they cared for. One principle of great importance was almost entirely disregarded by managers of art galleries. To make people take a keen interest in art, we must show them things that really interested them. Judging from the language of many people, one would think they placed the greatest value on things the most worthless. Success in bringing the influence of art to bear upon who knew the importance of art, and of the right appearance of the whole life, which was of more importance than what was usually called art. Rightness of appearance was of far greater importance than things which did not deeply influence human feeling. In the art gallery there should, therefore, be a model small house, to show how a small house in town can be made to look pleasant, which should contain all the things which are needed in such a house, all well made, of good form and colour, and it should have on its walls a few good pictures. The gallery should contain a small collection of casts from the best Greek sculpture, and good examples of the products of all the industrial arts. Each should have a label stating that it is good, and, if this be possible, explaining why it is so. Some of the pictures in the gallery should represent the most beautiful places near the town, the most interesting buildings in and near it, interesting events in its history, the trees, flowers, birds, butterflies, &c., to be seen near it. Of pictures of this kind copies,—photogravures, etchings, good chromo-lithographs,—should be made. Framed examples of the pictures should be shown in the gallery, and the price of a copy and of a frame should be stated on a label. Similar labels should be attached to other good etchings, engravings, &c., in order that workpeople may learn how many kinds of good art can be obtained at a small cost. Every picture should have an explanation of its subject, and if the subject be one which is not familiar to most people, its connexion with familiar things should be pointed out. To encourage study of art-methods pictures should be placed side by side with etchings and other copies of them, and groups should be formed of representations by different kinds of art of the same subject. Mr. Horsfall, advertent to the subject of female dress, urged that ladies should be induced to dress more neatly, and with a truer sense of beauty. When appearing in public they should wear a dress which could be obtained by poorer women. As comparatively few people saw the need of the objects for which they were working, it necessarily fell on a smaller number of persons. By the masses of the population acquiring a knowledge and love of art, we would obtain more and better designers. It was surely unquestionable that the knowledge and love of art was indispensable to our population. Religion was one of the strongest motives to resist temptation, but it behoved them to declare the truth that thousands must be incapable of just feelings unless they first felt the influence of art, unless by the help of art the beauty of the world could be brought within their reach. The masses required more interesting recreations for their leisure time. Till then he did not think any great change would take place in the way they spent their time. The speaker concluded by urging that the work should be undertaken by all who desired the welfare of the working classes of the country.

Mr. Judge (in the unavoidable absence of the author, Mr. Hodgson Pratt), read a paper on the same subject, strongly advocating the opening of museums and art galleries on a Sunday.

The President having invited discussion, Mr. Statham said they must have been struck with the exceedingly practical way in which the question had been handled by Mr. Horsfall's paper. There was one idea in his paper which was also touched upon in that of Mr. Pratt, and that was the great effect of bringing objects of art before the people as a means

of cultivating their taste. With regard to the remark that a knowledge of art was necessary to the cultivation of religion, he suggested that the two things might go together. History might be quoted against them to show that the most artistic periods were the most immoral that ever existed. Why, he could not say. They heard a good deal of affording the people the sight of well-shaped objects, but, he asked, how were they to decide what were well-shaped objects and what were not? It could only be done by people accepting a certain style as to the right thing. He strongly advocated the cultivation of a moderate knowledge of drawing. Nothing would be of so much influence as increased facilities for the teaching of drawing in primary schools.

Mr. Hill, in stating his objection to the opening of museums on Sundays, said it would have been desirable if the question had been put down on the paper. His objection was that the Sunday opening was not necessary. Working people had been able to obtain the Saturday as a half-holiday, and one great argument in favour of the half-holiday was that the museums, &c., were closed on Sundays. Supposing they were open on Sundays, employers would say "You can go on Sunday to the museum. You don't need to leave work." Working men felt that if the museums were opened on Sundays they would be inflicting injuries on the masses of the people. Taking Nottingham, for instance, would any one say that any considerable number of people could not on the week-days avail themselves of the opportunities given them for the inspection of art-treasures? He argued that the feeling of the working classes was wholly against the opening of museums on Sunday.

The President drew Mr. Hill's attention to the fact that the question raised by him was a merely accidental one, and not the question under discussion. He would ask him to be as curt as he could on the question of Sunday opening, and touch upon the influence of art upon the people.

Mr. Councillor Jacoby inquired whether, if the question of Sunday opening were discussed, he would have the right of reply.

The President had no objection to the speaker making remarks on the question when the previous speaker had done.

Mr. Hill, resuming, thought the question should be fairly ventilated, as there were two papers on the subject. Why, he asked, should they stop at the opening of museums on Sunday? Why should not the Crystal Palace be open? (A Voice: It is.) Why not the Polytechnic, the opera, the theatres? Our day of rest would be like what prevailed on the Continent. That was the tendency of the movement.

Mr. Councillor Jacoby said that having made the Sunday question his own, and having brought it two or three times before the Nottingham Town Council, he could not allow the remarks of the last speaker to pass unchallenged. All who endeavoured to make museums popular with the working classes found that Sunday was the only day on which they could go to institutions of that character. They found that they had most leisure on the day that they left off work. As to employers endeavouring to rob the working classes of the Saturday half-holiday, he would leave the trade unions to look after that. In regard to their own Castle Museum, the attendance had exceeded their most sanguine hopes. In Manchester the experiment of opening institutions of this kind on a Sunday had been attended with the greatest success.

Mr. T. C. Hino urged that an improvement of street placards would tend to the cultivation of beauty. In regard to the two papers which had been read, the object was to show how the eye of the beautiful could be influenced for good.

Mr. Rathbone strenuously advocated the opening of museums on Sunday, from that being the only day the working classes could enjoy them. He contended we had no right to close museums to that portion of the working classes who made use of them. He ridiculed the objection raised by Mr. Hill as the eternal "thing of the wedge." The answer in this case is very simple. If it were asked, if we are to open museums, why not shops? the reply was that the majority of the nation desired a day of rest. If one man opened his shop on Sunday it would necessitate other men opening theirs. The minority would, therefore, force the majority

to do what they wished. There was no compulsion in the matter of the opening of museums. Those who did not think it right need not go.

After some remarks from Mr. Wright, who advocated the development of illustrated newspapers,

Mr. Horsfall moved "That this section recommends that the Council request the Science and Art Department to seek to acquire the power of preparing and of selling at cost price to persons or societies interested in education, representations of trees, birds, and other beautiful natural objects, good in respect both of fidelity to nature and of artistic quality."

Mr. Judge, who seconded the motion, spoke warmly in favour of Mr. Horsfall's paper. He contended that if the influence of museums was good it should be extended as wide as possible, and that it was not sufficient that they should be open to working people on Saturday afternoon.

Mr. Horsfall, briefly replying to the remarks made, said he did not say that a knowledge of art was necessary to religious feeling, but people could not be expected to have healthy and just feelings unless they gained knowledge through art. He did not think it possible for people to form an idea of the utter ignorance which prevailed among working people as to healthy views of life.

The President, in a few closing remarks, said it was of the highest importance that we should endeavour to give to every person as much pleasure as possible in the walk of life which he had to fulfil. He thought we could do a great deal more. We must devote a certain portion of our time to earn our living. We might reduce that, and he hoped to see the time when a similar portion was devoted to art. It was very important that young persons should have their eyes cultivated to perceive forms of beauty. The Greeks, who were the greatest artists the world ever saw, took the greatest possible care that people should be surrounded with objects of beauty, and he thought we should do more in that direction. There were few objects in nature which caused repulsion. In conclusion, the speaker suggested that we might combine pleasure with utility by teaching children to draw simple things they saw before them.

THE PRESERVATION OF LIFE AND HEALTH.

SANITARY INSTITUTE AT NEWCASTLE-UPON-TYNE.

The address of Captain Douglas Galton, C.B., as President of the Congress, contained a large number of valuable facts, and deserves the greatest consideration. The host of congresses which are being held at the same moment makes the space scanty that we can afford it. We print, however, a small portion of it towards the close:—

The death-rate affords to some extent an index of the disease-rate in the community. It is, however, very difficult to ascertain with any degree of accuracy the disease-rate of a community, as compared with the death-rate.

If we take the army as a criterion, it would seem that there are more than a hundred men admitted to hospital to one death, whilst the number constantly sick averages from four to six times the number of deaths. No doubt in the army many an ailment has to be treated in hospital which in ordinary life would allow the sufferer still to pursue his vocations.

The sickness of the population is not registered, and it is very difficult to obtain any data respecting it. It has been generally stated that there are on an average twenty cases of sickness to one of death, of which four cases out of five are of children. I find, however, from a return of an unsanitary district in St. George's-in-the-East, that with a death-rate of 31 per 1,000, the sickness-rate was 270 per 1,000, or nine cases of sickness to one death. But in the worst parts of the same district the sickness-rate amounted to 620 per 1,000, which gives twenty cases of sickness to one death.

Mr. Nelson, who has recently examined the records of the Ancient Order of Foresters, shows that at thirty-five years of age there are on an average twenty-two cases of sickness to one death, and that is in a body of men which it must be borne in mind are selected men so far as health is concerned. From the same record we find that at twenty years of age the loss of time from sickness amounts to 1.5 per

cent. of the whole time; and at forty years of age it amounts to 2.6 per cent.

The value of a single premium paid at 20 years old (calculated on the 3 per cent. tables) to insure 1*l.* a week during sickness, for the whole life, is 40*l.*

I sought, but failed to obtain, definite statistics on this subject from some of those who are working amongst the poor, both in the east and west end of London.

An East-end clergyman remarked that "the poor go on living wonderfully in wretched places, but that they have so much ill-health. They are perpetually on the fringes to the hospitals with their bad chests and bad legs, and get patched up again and again, and live on." Our London hospitals and dispensaries cost, according to Mr. Burdett's statistics, nearly 600,000*l.* annually to administer. The average number of out-patients treated at the various institutions in a year is about 1,000,000,—that is to say, more than one out of every four inhabitants of the metropolis becomes an out-patient in the course of the year.

This expenditure is incurred mainly for the purpose of patching up the wretched poor, who have been injured by bad drainage, want of ventilation, darkness, &c. Though drink may be one of the immediate causes of many hospital cases, yet the tendency to drink is created and fostered by the wretched dwellings of the very poor. But besides the time lost by the sickness itself, there is the large amount of time wasted by the poor in going to and waiting at hospitals, which would be spent by healthy poor in labour.

There is, moreover, the great amount of lassitude and idleness in the low-class poor, which Dr. Richardson traces to want of ventilation, in their own and former generations.

I think we may safely assume that if you can, by preventive arrangements, bring down the death-rate of the wage-class to the standard afforded in good sanitation, you would reduce the sickness-rate in a similar proportion at least. By means of this item alone the wage-earning power of the industrious classes would be enlarged by some millions of pounds, and their comfort correspondingly increased.

You would effect, in addition to the savings under this head, certain other distinct economies. For instance, it is certain that the need for much of the accommodation in our prisons, reformatories, and workhouses arises from evils incident to unhealthy circumstances and crowded dwellings.

We shall probably be led to appreciate more fully the advantages of good sanitation if we can arrive at putting a money value upon some of the more direct results of sanitary improvements.

In the first place, the community derives a direct advantage from adopting such a system for the removal of refuse as will enable it to be applied directly to improving the cultivation of land. For whilst, on the one hand, the rapid removal of refuse from the neighbourhood of dwellings by the efficient sewerage of towns results in improved health, the application of sewage to land by the irrigation of growing crops affords both a means of fertilising the land, and of cleansing the fluid, so as to place it in a fit condition to pass into the streams.

My friend Mr. Chadwick asserts that where the sewage is undiluted with rain-water, and where it is utilised at once, and carefully applied under favourable conditions, an acre of land ought to absorb the sewage of 100 persons, and that the crops on this area should feed five cows; or, if put in another way, that the produce of ordinary cultivation being represented by 1, and market garden produce by 3½, the produce of sewage cultivation should be represented by 5.

I have obtained some recent facts on the direct application of sewage to land which, although they do not show such high results, deserve attention.

Mr. Brundell, who has the management of the Doncaster Sewage Farm, states that during nine years he has never applied any other manure than sewage. That this year the crops are the heaviest that have been produced, and the land remains just as capable of receiving the sewage as it ever was, and does not "fire." Mr. Collett, of the Bedford Farm, says that their produce is generally much above the average of the neighbourhood, and that the crops are as good or better than they were seven or eight years ago; and the land under sewage treatment has improved in quality. . . .

In the next place, the diminished death and sickness rates, and the greater length of life entailed by good sanitation, afford direct pecuniary advantages.

Let us apply this reasoning to the population of the improved artisans' dwellings in London. These now accommodate about 11,000 families.

In many of the districts which are now covered by these improved dwellings, the death-rate in the wretched homes which have been removed varied, as I have told you, from 35 to 40, and even 50 per 1,000. Mr. Gatliff shows that there are nearly five in a family, on an average, in model lodging-houses. There has thus been a saving of life to the extent of at least 20 per 1,000, by the erection of these dwellings, on the 50,000 persons inhabiting them, or about 1,000 deaths annually. And if we take the estimate of sickness which I arrived at above, there would be a reduction in the number of cases of sickness which occur in the population of these dwellings of at least from 15,000 to 20,000.

The cost of the improved dwellings appears to have averaged a little over 170*l.* each, or about 1,900,000*l.* for the 11,000 families.

By the light of these various data we may obtain some idea of the actual pecuniary advantage to the community which results from the improved health of the occupants of such dwellings. The cost of funerals has been stated to average 5*l.* apiece. Under this head, therefore, the saving may be taken to average 5,000*l.* a year; the diminished loss of the sickness of the 11,000 heads of families alone may be assumed to average another 5,000*l.* a year; and in addition to this there would be the saving in time and money, in seeking medical attendance, of the wives and children who make up the remaining population of the dwellings, as well as the increased power of earning wages afforded to the mothers of families from the diminished sickness of the children.

Hence the money benefit to the community thus made up, which is caused by the diminished death-rate and sickness-rate, would form an appreciable item in the percentage of interest paid on the 1,900,000*l.* capital expended in the construction of the dwellings.

But there is another way in which we may estimate the economy to the community resulting from the increased health which has been obtained in these dwellings.

The analysis of the mortuary rates for Westminster showed that the mean age at death of the males of the wage classes in Westminster, who had survived the period of youth, and died after 20, was 47*·*6 years.

The rate of mortality in the Improved Dwellings is from 14 to 16 per 1,000. The rate of mortality in the rural parishes of Northumberland above mentioned, in the years 1877-81, was 15·3 per 1,000; and in Dover in 1880, it was 16·7 per 1,000. It will not be unfair, therefore, to take the mean age at death of the males who died over 20 in the rural parishes of Northumberland and in Dover as a standard, which may be reasonably expected, for the duration of life of the males who die over 20 years of age in the Improved Dwellings. This was, for the rural parishes of Northumberland 60·9 years, and for Dover it was 57·8 years. That is to say, from 10·2 to 12·3 years, or a mean of 11 years additional duration of life may be expected for the heads of families occupying the Improved Dwellings, beyond that enjoyed by the wage classes who do not live in such favourable surroundings.

Therefore, we may assume as a profit to the community the increased earning power of the occupants of these dwellings, due to this increased expectation of life. It would appear from Mr. Neison's tables that six per cent. would be a full average deduction for sick time between 47 and 58 years of age; and we may, therefore, safely take the increased earning power as that due to an additional 10·4 years of life.

If, in order to form a rough estimate of the money value of this, we assume that each of the heads of the 11,000 families receives as a present on his admission to the dwellings a grant of ten years more life, and calculate its money value on the earnings of only 1*l.* a week, we find that upon a four per cent. table the present value of ten years of increased wage earning power at 1*l.* per week would be for 11,000 heads of families 4,640,000*l.*, or nearly two and a half times the cost of the property.

By considering the question in this way, we

arrive at an understanding of some of the direct pecuniary advantages which accrue to the nation from those sanitary improvements which lead to a decreased death-rate and sickness-rate; and we see that, however large may be the cost of the removal of bad dwellings, and the substitution in their place of healthy well-planned dwellings, the actual money gain to the community far exceeds the expenditure in money.

But it is not as a money saving alone that the question must be considered. Its social and political bearings are even more important.

The nation is made up of individual items. The goodness and the happiness of the nation depend upon the individual. Well-regulated family life does more to make up individual happiness than any other form of life. But family life is impossible in the wretched homes which have been permitted to exist in most of our large towns, and many of our rural parishes. These wretched homes drive the population into the streets, and into the gin-palaces, and into the public-houses. They engender sickness, which entails poverty, and they foster crime.

The improved dwellings, on the other hand, ensure improved health, and by thus affording a security for the more continuous earning of wages, create the possibility of a comfortable home. I was much struck, when in the United States of America, with the fact that the artisan and wage classes, in many manufacturing towns, lived in very comfortable houses, in which each family had their parlour, with appropriate furniture, pictures, and often their piano. They had come to look upon these things as a necessity; and this is an evidence of the general civilisation which pervades American society. By civilisation I mean the education and the general well-being of all classes.

In this country our most advanced sanitarians have long endeavoured to impress these doctrines on the public, and I am happy to think that at last they are beginning to bear some fruit; for, in order to develop morality, contentment, and happiness among a people, it is essential that they should be provided with healthy and comfortable homes.

#### HEALTH QUESTIONS AT THE NOTTINGHAM CONGRESS.

The Health Department of the Social Science Congress at Nottingham was presided over by Sir Rutherford H. Alcock, K.C.B., who, in the course of his address, said he doubted if there was a word in the language of so deep a meaning as the word "health." On it depended not only the duration of human existence, but the power of active exertion and enjoyment, often more highly valued than life itself. "Health" was a term difficult to define, but for all practical purposes, however, they might, perhaps, be content with knowing that it implied a state or condition which allowed full play to all the organs and component parts in due subordination and harmonious action. Yet few precious things were so persistently neglected, so rashly imperilled, or so wantonly thrown away. And as regarded whole nations or communities, few objects of public interest met with so little attention. How was it that the history of all sanitary progress in this country was that of a continuous struggle against prejudice, ignorance, and vested interests, separately or collectively opposed to the measures best calculated to safeguard and promote the public health? The antagonistic forces to be met were not difficult to define, and they might be ranged under a few heads. Putting aside such exceptional cases as those of the Peculiar People or the Anti-Vaccinationists, they might reduce the ranks of the opposing force to those who objected to the sanitary legislation required, either on the ground of a distrust in the average mortality, which they believed was regulated by laws beyond man's control, or on the ground that any compulsory legislation would be an undue interference with the personal liberty of the subject or the rights of property and vested interests. The liberty of the subject had always been used as the stalking-horse of the opponents of reform and improvement, and might be pleaded for the liberty of carrying a lighted torch among neighbors' hay-ricks, or an open lamp in a coal-mine, or smoking a pipe in

a powder-magazine, or, in fact, any other act of insanity or recklessness, or the imminent danger of a whole community. In itself it was an argument of little value. So long as the health or life of an individual alone was concerned, as in diseases which were neither infectious nor contagious, each one might claim some large discretionary right to decide whether either the one or the other be worth preserving, and refuse to the State or to others any power of deciding. But even as regarded that the State did assume, in the case of suicidal acts, both the right and the power to interfere with the individual. But it was a wholly different matter when a person was attacked by an infectious and death-spreading disease endangering the health and lives of others, and the interests as well as the safety of a whole community. The adoption of compulsory measures of isolation and disinfection became then an act of self-preservation and public policy which no pleas of public liberty could be allowed to stand in the way of, or otherwise prevent the most prompt and effective action; for the multiplication of centres of infection gravely compromised the health and lives of a whole community, and with it the wealth and prosperity of the country. Mr. Edwin Chadwick had recently told them that he always found in his local inquiries that the seats of epidemic disease—the results of bad sanitary conditions,—were the seats of irritation of disturbance, and of crime. The indissoluble connexion between the physical and moral law was fully demonstrated in the origin and progress of epidemics. A population crowded into dilapidated houses, ill-drained and ill-ventilated, not only grew feeble and enervated, and predisposed to receive infection, but by the same process they became demoralised in body and mind, and dangerous subjects. Mr. Chadwick, dealing with the economic aspect of the question, in his paper read at the meeting of the Association in Dublin last year, said that the total loss to the wage-earning class by the loss of work through sickness had been estimated by Dr. John Watts, who had had great experience in friendly societies, at 13,000,000*l.* in the course of a working man's life, and referred to the report of the Local Government Board for 1880-81, in which it was stated that the death-rate of England and Wales had fallen during the last decade by nearly 4½ per cent., showing by a rough estimate that about a quarter of a million of persons were saved from death who would have died if the death-rate had been the same as in the previous thirty years. Thus, if twelve cases of serious but non-fatal cases be reckoned for every death—and the early estimate was greater,—it followed that about 3,000,000 persons, or over one-ninth of the population, had been saved from a sick bed by some influence at work in the past decade, which had not been in operation previously. As regarded our Navy and Army, which cost us about one-third of the whole revenue raised by taxation, it would be found that far more were struck down by sickness than fell by the sword. There was to be found within seventy-four pages of the Registrar-General's annual report, condensed in tabular form, a record full of instruction and of absorbing interest, giving the sum of all the ills to which the flesh is heir from disease or violence. In looking over those returns he could not but come to the conclusion that though many of those ills were irremovable, others were certainly preventable. Of the first class, at the head, stood endemic diseases, or those peculiar forms of disease which arose spontaneously, as it is termed, in a country or particularly locality, of which goitre in mountainous countries was perhaps the most striking example, existing, as it did, in every quarter of the globe where the mountains were physical features, and the agues in all marshy countries, and the plica in Poland. Yet sanitary science could materially alter these, and so effect what medicine could not. Cesspools and sewage might be removed, and sewers might be ventilated and flushed, and all the foul and deadly gases generated in them diverted from inhabited houses by trapping and other means. But placed at the head of all the specified causes of death, were those of the zymotic class, that is, diseases which prevailed among a large number of the people of a country, raged for a certain time, and then gradually diminished and less appeared to return again at periods more or less remote. From that group came all the epidemics from which we suffered from time to time. The whole group constituted a class of

diseases which might be distinguished as essentially preventable. Upon the cardinal point of the power of isolation to arrest the spread of infection the evidence was absolutely unanimous, showing that such isolation almost invariably answered its purpose. In order to insure such isolation, legislation was needed, and the compulsory notification and isolation of those infected must form essential provisions of any effective legislation. Nothing short of this could suffice.

One of the special questions for discussion was, "What Reforms are desirable in the administration of Hospitals?" Dr. T. Gilhart Smith read the opening paper, in which he indicated many changes which he deemed to be desirable, and said that, having regard to the complications and difficulties which surround this question, and to the necessity for efficient reorganisation, there could be but one opinion, namely, that a full, wide, and searching inquiry into all its bearings can only be obtained by the appointment of a Royal Commission.

Mr. F. S. Powell moved, and Dr. Cameron, of Dublin, seconded:—

"That this department, deeply convinced of the necessity of reform in the administration of metropolitan hospitals and other institutions for the medical treatment of the sick, requests the Council to continue their exertions to obtain the appointment of a Royal Commission, with the view to obtain reliable data upon which reforms should be based, and make such recommendations as may appear desirable."

After some discussion the resolution was put and carried.

Sir J. Pope Hennessy made a short statement on the Chinese system of collecting sewage and placing it on the land. The advantage was the freedom of the Chinese from typhoid and the diseases generated by sewage-gas. The disadvantage was that it was not pleasant to be in the fields at the time the nightsoil was being distributed. A conversation followed, in which Dr. Little, of Liverpool; Mr. Tarbotton, of Nottingham; Alderman Ford, of Nottingham; Dr. Hill, of Birmingham; and Sir R. Alcock took part.

Smallpox epidemics, as affected by the states of war and peace, were discussed in a paper by Dr. William A. Guy, F.R.S. A series of curves accompanied the paper, in which the leading facts were represented; and attention was specially directed to the figures and curves of the years 1796 and 1871,—years in which Paris (our near neighbour) was suffering from the worst effects of war, aggravated by domestic discord. War was rather an aggravation of evils already existing among the peaceful populations from which its fighting men were drawn, than a thing altogether *ex nihilo*. The progressive decrease of mortality by smallpox, so characteristic of the nineteenth century (for no such decrease had occurred previously) was not occasioned by the transition from war to peace, but it began in the years of war, and continued during the years of peace. As the seventeenth and eighteenth centuries afford no other example of a decreased mortality so progressive and so considerable, we are forced to conclude that some new and powerful cause, or combination of causes, acting continuously and with ever-increasing force, must have come into operation in the early years of the nineteenth century. Vaccination replacing inoculation, and extending its protective influence to an ever-increasing section of the population, is the only force which fully meets the conditions of the problem.

DAVOS-PLATZ.

The Frauenkirche at Davos has little to mark a date except an apical east end. The body of the church is said to date from 1240, and the miniature tower and wood-shingled spire of the same date yet remain at the north side.

About 1560-70, i.e., some years after Zwinger's tower at Zurich, a large tower with shingled spire was added, and forms the only architectural feature of value in the landscape of this Alpine valley. In point of size it is out of proportion to the little church of which it forms a part, and was probably built to mark the freedom from Austria of the little Davos district.

I must call attention to the beauty of the spire. It is not twisted bodily like Chesterfield one on the Continent, but has to each face singularly graceful surface-spiral, or, rather, portion of one. In colour and texture of

shingle it is equally beautiful. Tower and spire together have a certain Khenish character, mainly produced by the steep gables which terminate the tower walls.

There are two bells, one 3 ft. 3 in. diameter, the other 4 ft. 3 in. The latter is a tenor of singularly fine tone, cast at Poschiano in 1681, as its inscription testifies, "Pavio Antonio Gaffori von Pushhof." It bears also the arms of Davos,—a species of Robinson Crusoe with a spiked Swiss club.

The name of Buol occurs in Davos history in the sixteenth century, and a descendant of the family still keeps the hotel which bears his name.

The place itself is 5,105 ft. above sea level, with a singularly fine, dry, clear, bracing atmosphere, and is becoming a great winter resort for invalids. Seeing what a harvest Death the Reaper has lately garnered of the leading English architects, I commend it as a holiday resort to those who survive.

EDWARD ROBERT ROBSON.

Innsbruck.

BISHOP STEERE.

As one who knew the late Bishop Steere intimately from the time we were school-fellows together, and as one deeply interested in the new building called the Cathedral at Zanzibar (the bishop always called it "Christ Church"), having made all the designs for it myself, I feel impelled to add a few words to the excellent statement of his life and work which appeared in the *Times* of the 19th inst. The bishop is there spoken of as a "bold man" because he was his own architect, and it is added that he felt himself equal to the task. I think I alone can fully appreciate this, inasmuch as the bishop came to me as an old friend with his original ideas, and, bringing his crude sketches before him, asked me to undertake the task of designing the building therefrom, putting the whole into a proper architectural form. This was done, and, therefore, the boldness referred to was less than the wisdom which sought and accepted help in the form which was needed. Subsequently, the bishop himself superintended the whole of the work on the spot; had put together, under his own eye, the centering for the vaulted roof which I had caused to be made and sent from England, as well as the marble work for columns, &c., stained glass for windows, font, and altar-piece of marble and mosaic.

These sketches I have referred to were no surprise to me, as we had gone together in small church-hunting excursions many years ago, he studying the glass and such internal details, while waiting for the conclusion of my architectural study of a building, neither of us dreaming how, in after-life, such studies would blend together in forming a distant edifice,—a church on the slave-market at Zanzibar,—and scarcely less so when, on his first appointment to the living of Little Steeping, he called on me to build his parsonage, and subsequently the schools, after his first visit to Zanzibar.

C. FORSTER HAYWARD.

PROPOSED TIDAL BATHS AT BRIGHTON.

At the meeting of the Brighton Town Council, on the 20th inst., the Works Committee submitted a special report with reference to the improvement of Madeira-road (the road which skirts the beach at the foot of the Marine Parade). It comprises a report to the committee by the surveyor, a recommendation, a form of advertisement, and particulars of the proposed improvement. The report of the surveyor (Mr. Philip C. Lockwood) says:—

"In pursuance of your instructions I beg to submit to you herewith a plan of the beach and foreshore from East-street to Black Rock, with reference to the improvements which have been suggested on the Madeira-road, and in so doing I wish to point out that, in addition to the proposed improvement between the Chain Pier and Paston-place, it is also very desirable that the base of the slope at Duke's Mound should be defended by a sea-wall extending from the groyne opposite Paston-place to the Kemp Tewn slopes, and that the lower roadway should be extended from the north end of the concrete groyne to the gap at Black Rock, as proposed by me in 1872, a plan of which I also present herewith."

The committee recommend that premiums be offered for designs for the erection of Public Tidal Baths for men and women, with suitable

adjuncts and conveniences, embracing tepid swimming-baths and private baths, on the beach, off or near Adlingworth-street, and that the premiums be 200*l.* for the best design, 100*l.* for the second, and 50*l.* for the third. The committee also recommend that the form of advertisement and draft conditions for the competition, appended to their report, be approved of and adopted. The form of advertisement states that the Town Council desire to improve that part of the sea frontage called Madeira-road, extending from the Chain Pier to the concrete groyne opposite Paston-place, by the erection of public tidal baths, with terraces, sheltered seats, summer-houses, and other public conveniences, and invite architects and engineers to give designs for this purpose. The drawings and designs to which premiums are given are in each case to become the property of the Town Council, who will not be bound to employ any competitor in or about the execution of the work, or otherwise, nor to make any payment with regard to any of the designs, except the three premiums above mentioned. The designs are to be sent to the town clerk on or before the 1st day of February, 1883. Particulars, for the information of engineers and architects sending designs, are also appended, and from these it appears that the baths are to embrace a tepid swimming-bath with a water-area of about 200 ft. by 50 ft. for men, and a swimming-bath, with about half that water area, for women; about fifty private baths for men and thirty for women, and suitable adjuncts and conveniences. Careful arrangements, the particulars continue, must be made for filling and emptying the baths, and for heating them without making smoke. Ample public conveniences for men and women, and spacious places for promenade and recreation, should be provided in connexion with the baths. It is not intended to make provision for shops or for the sale of goods, but only for the sale of newspapers, light literature, and refreshments; and there should be accommodation for attendants. It is also proposed to construct such other terraces, promenades, embankments, summer-houses, sheltered seats, grass slopes, or the like, as may be conducive to the improvement of the roadway as a place of public resort, and to the pleasure and comfort of visitors, and the designs are to show the best means of approach from the Marine Parade and other adjacent roadways to the site of the proposed improvements.

The report of the Committee was adopted.

EXTENSION OF THE BRITISH MUSEUM.

On Saturday last the corner-stone of a block of buildings connected with the south-eastern side of the British Museum was laid by Mr. Edward A. Bond, Principal Librarian, in the presence of the chief officers of the Museum and others. Mr. Bond took advantage of the occasion to make it known that the new buildings, consisting of a frontage to Montague-street of 120 ft., with two sides carried up to the museum walls, were being erected from funds bequeathed by Mr. William White, a gentleman who had resided in the neighbourhood, and who, at his death, in the year 1823, left the reversion of a sum of 93,941*l.* to the trustees of the British Museum, to be used at their discretion, but with the expression of a hope that it would be expended on an extension of the Museum buildings. The actual terms used by the testator are as follow:—

"The money and property so bequeathed to the British Museum I wish to be employed in building or improving upon the said institution; and that round the frieze of some part of such building, or, if this money is otherwise employed, then over or upon that which has so employed it, the words 'Gulielmus White Arm. Britannia dieavit 18—' be carved, or words to that import. It is a little vain of no harm, and may tempt others to follow my example, in thinking more of the nation and less of themselves."

The bequest fell in early in the year 1879. By payment of the legacy duty,—rigorously exacted by the Government,—it was reduced to 57,572*l.* Of this sum about 11,000*l.* has been expended in the erection of a new gallery for Greek sculptures, between the Elgin and Assyrian galleries, and in other works connected with it. The remainder is now being spent on the new block of buildings. It was further explained that this would give accommodation on the ground-floor for the rapidly-increasing collection of newspapers, which has outgrown the space

designed for it in the library, together with a convenient reading-room in which they could be consulted, and, on the two upper floors of the front and north side, rooms for the department of prints and drawings, with space for exhibition.

The plans of the building have been furnished by Mr. John Taylor, surveyor to Her Majesty's Office of Works; and the contractors are Messrs. John Mowlem & Co. It is expected that it will be completed within about twelve months from the present time.

THE SANITARY CONDITION OF BERLIN.

THE question of sanitary reform has long been a prominent one in technical and official circles in the capital of the German empire; but an opportunity has now presented itself of obtaining a ready insight into the progress really made in that city. This is afforded by Dr. Skrzeczka's report to the Imperial Government, from which it appears that much work of a really useful character has been done at Berlin of late. Party differences and occasional diversity of views between the state officials and the municipal authorities have been merged in the successful efforts to promote the health of the population.

The purity of the air has occupied attention, with special reference to the necessity for new building regulations, framed with a due regard to the exigencies of the public health. According to the estimate of Herr Böckh, the population of Berlin is more numerous, in proportion to the ground covered by the capital, than is the case in any European city. It is remarked by the *National Zeitung* that this evil has increased of late, and has had a direct influence upon the spread of epidemic diseases. The unfavourable situation of Berlin, together with the unsatisfactory condition of the dwelling accommodation in many parts of the city, exercise a confined effect upon the mortality amongst children in a special manner.

The efforts to find better sources than heretofore for the drinking-water of the population, and the due carrying out of the filtering arrangements, have been matters of special moment to the various administrations affected.

There seems to be a general opinion that the system of drainage introduced into Berlin of late years has exercised a beneficial effect upon the public health. The frequency of the occurrence of typhus fever is usually considered a reliable standard for estimating the sanitary condition of a city. The report of Dr. Skrzeczka points out that the result of the adoption of drainage in certain districts was a progressive improvement of the health of those portions of the capital and a gradually decreasing number of typhus cases.

THE GENIUS OF SIR CHRISTOPHER WREN.

SIR,—A letter appears in the *Builder* of September 23, signed "Andrew T. Taylor," commenting on some points in my recent paper on the genius of Sir Christopher Wren; but so void of argument and so incoherent that, but for fear my silence might be misconstrued, I should leave it unnoticed.

In his haste to contradict me, the writer mistakes and misrepresents my meaning in the passage he refers to. The doubt I expressed in reference to Wren was whether he possessed, in strength of imagination, higher resources and inspiration than what geometry yielded him; not whether he had power to design independently of his geometrical resources, which no man has; and my object was to suggest that geometry is not the only fountain of architectural beauty,—that architectural designing is something higher than a geometrical operation, or the construction of regular solids,—and that, though based on geometry, architecture can soar into the pure haunts of imagination.

I now contend that though the great majority of architects do not conceive graceful architectural forms independently of, or beyond, their geometrical resources, the man who cannot do so is not, in the high and true sense of the word, an architect, imagination being the vital quality in all art-work.

I have only to add that Mr. Taylor's quotation from the late Mr. G. E. Street, R.A., whatever it may be to his own mind, is by no means conclusive to mine; and, as Mr. Street had no

monopoly of critical judgment, I take the liberty, without the least feeling of disrespect to his memory, to differ from him on the subject; and whether the failure of the steeples in question has been acknowledged or not, to reassert it on my own responsibility. The very natural and touching remarks of Mr. Street in his address to the Institute are, however,—rightly read,—but little at variance with my position. Whether I am right or not can only be judged by those few who are capable of designing or imagining superior compositions of the class. To those few I appeal. Wren's steeples will doubtless be perfection to him who can see nothing higher and brighter beyond them.

SAMUEL HIGGINS.

PROPORTION IN PRACTICE.

SIR,—The series of papers which have lately appeared in your journal on the subject of proportion in architecture are specially valuable in the light of present-day practice. With the revival of the picturesque in architecture and the extent to which it has been developed, there is a tendency to value it exclusively for its own sake, and to ignore the just and fundamental claims of proportion. It is difficult to define what proportion is, and much injury has been done to the cause of good architecture by propounding theories which are purely mechanical in their basis. Excellence of proportion is the result of many qualities; it will commend itself to the intellectual and æsthetic faculties, and therefore be the product of both combined, and not of either separately, but the result of this combination must in turn be tested by experiment and practice. Hence an advantage in studying good models of the best styles of architecture, so that we may, if possible, ensure some advance on what has been already done. Much good work is being accomplished in this direction; old forms with their refinements are recombined and re-proportioned, new creations of beauty are the result. But danger may arise from satiety; even good forms repeated are apt to pall on the mind; when that occurs, there is then a tendency to change their proportions with a view to new effects. This is sufficiently evident in much of modern practice, and, while regrettable, is in a certain measure excusable. The architect has a story to tell, and prefers to do so in his own way, and it may, though crude, lead perchance to fields and pastures new, and, provided it does not violate good taste, he accepted with thankfulness as a new rendering in art.

Modern practice is diffuse, and the cases are rare where a man devotes himself to one branch of architectural art, each succeeding effort surpassing that which went before. Even assuming such a case, it would require to be multiplied by many contemporaneous instances, as no one mind is capable of eliciting the whole truth; it must be the work of several, each sharing with each that aspect of it which commends itself to his own individuality. We can never again have that unity of architectural effort which characterised what men are pleased to call the Dark Ages.

It has been the theory of many people that geometrical proportion pervades the architecture of those times, and your esteemed correspondent, Mr. Cave Thomas, alludes to it in your issue of the 18th inst. [p. 383, ante]. But as this subject is an interesting one, and may be regarded from another standpoint, I venture to say that in the various qualifying circumstances with which actual practice is invested, the theory becomes of doubtful applicability. Take some normal architectural form, something possessing unity, and which may have been operated on by various minds during many generations, and therefore likely to embody the quality of good proportion in its fullest measure,—the Gothic cathedral, for instance.

Imagine, in the first place, each part of that edifice a gem of art, carefully related in height, width, and detail; this accomplished, take the next step of uniting these parts together, and you have, up to that stage, a merely mechanical combination. Something else is required to encompass it within a higher principle: it may be desired to impart the attributes of dignity, aspiration, or mystery, but all these elements are so far independent of good proportion that their evolution may require the modification of those proportionally-related parts.

Besides all this, the effect of a building is modified by the standpoint of a beholder, so

that what might be satisfactory in one aspect may be quite otherwise from another. Fore-shortening, with its transmutations, for instance, is a condition which must be taken into account. Or again, the whole effect of a building may be changed by the nature of its situation; and, be it peaceful valley or rugged hill, proportion will inevitably need adaptation to different surroundings.

Is Mr. Cave Thomas right in covering construction from art in its claims on proportion? May construction in satisfying the judgment not also gratify the æsthetic faculties? The flying buttress is essentially constructive, and, whilst, one of the most beautiful conceptions of Gothic art. Even the factory chimney referred to has its latent capacity for development into good, if not graceful, proportion. Moreover, the material we have to deal with may further demonstrate this view of the case. If a column be of iron we adopt an entirely different ratio of diameter to height than in the instance of stone, and either of these two modes of construction will satisfy the taste and judgment of any person cognisant of their respective qualities.

If there be, therefore, any connexion between construction and art, it seems reasonable to expect that by satisfying the claims of the one the interests of the other are not neglected.

G. S. AITKEN.

"WHAT IS PROPORTION?"

SIR,—Your correspondent, Mr. Cave Thomas, [p. 383, ante] in dealing with this subject, concludes very justly that "every quantitative relation, every proportion, good, bad, or indifferent, is mathematical, and every configuration of surface and every form of solidity is geometrical," and in consequence that constructive fitness need not of necessity be symmetrical. He apparently overlooks the difference between *aliquot* and *aliquot* proportion. During a practice of thirty years as an architect, I have given this subject considerable attention, and have found that well-proportioned rooms, for instance, are only to be obtained by the following rule of geometrical relation, which may be varied to any magnitude, taking the height as the standard of measurement:—

Height of room, 18 ft.	Length.	Width.
The cube .....	18 ft.	18 ft.
Cube and a half .....	27 ft.	18 ft.
The double cube .....	36 ft.	18 ft.
The subduplex, 4, 3, and 2 .....	36 ft.	27 ft.
Ditto, 5, 4, and 3 .....	30 ft.	24 ft.
Ditto, 6, 4, and 3 .....	36 ft.	24 ft.
Ditto, 3, 2, and 1 .....	54 ft.	36 ft.

All these relative proportions, and many others, varying with the standard height, produce what has been termed the harmonic proportions of rooms, and in practice, I have always found them satisfactory in construction. Writing on this subject more than a hundred years ago, an old writer says: "Nature has taught mankind, in music, certain rules for proportions of sounds, so architecture has its rules dependent on those proportions, or at least such proportions which are in arithmetical harmony; and those I take it to be dependent on nature. The square in geometry, the unison or circle in music, and the cube in building have all and inseparable proportion; the parts being equal and the sides and angles, &c., give the eye and ear an agreeable pleasure." The same natural law may be noted in the regularity of the progressive strain brought upon a lattice girder as represented by numerals, a regularity by which all the laws of creation are distinguished, and through which they have been interpreted by such men as Newton, Herschel, and Darwin.

The only means by which an accurate reproduction of the proportions of the old Classic temples of Greece and Rome can be obtained, is by quantitative relation. The diameter of the base, divided into modules and minutes, is the standard scale by which the depth and projection of the smallest member is regulated. Mr. Thomas may argue that the beauty which is the undoubted result of these proportions is the effect of custom, but if they had not been originally pleasing custom could never have established them at all.

Mr. Thomas doubts those who differ from him on this question as half-educated persons, but by these rules such buildings as the Parthenon are to be judged, and were applied before men

were educated up to the standard of Mr. Thomas's conception, and before the word æsthetic, as used in the modern parlance of the day, brought art into contempt.

I may add that the width of the windows has always been considered by architects as regulating the height on every floor. A good proportion for a window on the second floor is obtained by squaring the width and taking the diagonal as the height.

BYNG GRAUD.

FROM BIRMINGHAM.

The lighting of the Birmingham Town-hall for the evening performances during the Musical Festival was entrusted to Messrs. Winfield & Co., of Cambridge-street, and they adopted the Swan incandescent lamps fitted to cluster pendants of their own manufacture, arranged around the hall so that each plaster above the galleries had on the sides of the hall a cluster of twelve lights, and on the ends of the hall a double cluster of twenty-four lights each. Lamps were also arranged in pairs under the galleries, and chandeliers in the committee and artists' rooms, and an arc light of a nominal 10,000 candle power suspended over the entrances in Paradise-street. These all gave great satisfaction. The whole of these fittings the Messrs. Winfield now offer to the Corporation as a present to the town. The electricity was derived from some twelve Crompton-Burgin dynamo-machines, set up in the works at Cambridge-street about a quarter of a mile away, and transmitted through wires laid down in pipes through the streets to the hall. The firm now offer to supply the electricity to light the hall when required at the rate of 8l. per six hours for inside the hall, and 2l. per six hours for the arc lamp outside the hall, provided the Corporation purchase from them the pipes and wires laid down in the streets. These terms are generally considered onerous and excessive, and are some 40 per cent. more than the present cost of gas.

Another meeting of the Dawson Memorial Committee has recently been held, and an announcement made which has given great satisfaction in the town. The committee find themselves no longer able to contend against the almost universal convictions of the subscribers and the public as to the utter want of artistic merit in the present statue; and as it has been recently discovered that the figure was suffering from a broken nose,—done by a workman during its erection,—a fact which, to the writer's knowledge, has been an open secret ever since, they recommend that a new statue be obtained, and the present one removed. As a considerable sum of money remained in their hands after paying all expenses of the present statue, the contractor and the committee have made it up to 800l., a sum which Mr. Williamson is willing to execute a new statue for, and his offer is accepted. A very warm discussion is now going on as to the desirability of removing the very pointed Gothic canopy, and re-erecting that and the statue over the grave in the cemetery. The general feeling seems to be, that if the new statue is to be a standing figure, the canopy ought to be removed and the canopy cast in bronze; but if the canopy is to remain, then the figure may be of marble, but should be sitting. E. G.

ELECTRICITY AND VENTILATION OF BUILDINGS.

The dynamo-electric machine has already been shown, in the able papers of Dr. Hopkinson, to be a most economic transformer of energy; in fact, there can be room for little improvement in a machine which, when used for heating or lighting, actually transforms nine-tenths of the power applied to it into actual work, exclusive of friction. By connecting the terminals of the dynamo-machine, to which power is applied, with those of a similar machine, a certain portion of the power can be re-obtained, independently of the distance between the machines. This power varies with machines of different construction. With the Siemens machine, which is particularly well adapted for the transmission of force to a distance, the best actual results seem to be 49 per cent. of returned energy. In ordinary cases the loss is too great for power to be transmitted in this matter, unless the original source is ob-

tained for nothing, as in the cases of utilising a waterfall, or the rise and fall of the tide. Where the electric current is laid on for lighting purposes, as in a theatre or workroom, for instance, advantage may be taken of the application of the power by utilising it to work the apparatus for ventilation when not in use for lighting. The great drawback of mechanical ventilation hitherto has been the necessity of having a steam-engine. With the introduction of the electric current this will be got over, and wherever a building is lighted by electricity a means will be provided for thoroughly purifying and renewing the air when the light is not being used. More than this, it would be possible to utilise the surplus energy of the current supplying each arc lamp by causing it to work small electro-motors, placed either in the main or in the shunt circuit of the lamp; or, if several fans were to be worked, a special separate generator could be used. These motors would actuate small exhaust-fans fixed in the air-ways in the places hitherto found most difficult to ventilate.

The author has found by experiment that as long as the power thus taken off is practically constant, no irregularity is noticed on a light working on the same circuit. It is for this reason that it would be better to cause the fans to exhaust air rather than to supply under a pressure which might vary from time to time. Where a system of electric mains has been laid down, the introduction of power for the purpose of working every class of light machinery will become general.

Hoists can be worked, sewing machines, lathes, and looms have already been driven by small electro-motors, sailing at the present time for about 30s. each and upwards, and which, from the absence of complicated working parts, will cost, for renewals and repairs, less than the oil consumed in the gas engine they are destined to supersede at an early date.

KILLINGWORTH HEDGES.

THE FALL OF A BUTRESS AT ST. PATRICK'S CATHEDRAL, DUBLIN.\*

THE inquest on the bodies of the three persons who lost their lives by this disaster was resumed on the 21st inst.

Mr. R. M. Carnegie, in answer to the Coroner, said,—I am verger in St. Patrick's Cathedral. I was standing in the choir with Dean West when the buttress fell. It was at a quarter to twelve in the forenoon.

To Mr. Collins (who appeared for the Dean of St. Patrick's and the Cathedral Board).—The pinnacle that fell was not one of those interfered with or renovated by the late Sir Benjamin Lee Guinness. On the back of this pillar, under the flying buttress, there were stones on which were cut the words, "Rebuilt by Henry Kingsmill, 1845." Before it fell it was never suggested to me that the buttress was in a dangerous condition, nor that any imperfection existed in it.

Mr. James F. Fuller, architect to the Board of St. Patrick's Cathedral, deposed, in reply to Mr. Collins, that he had been twenty-five or twenty-six years in the profession. He was architect for eight years under the late Ecclesiastical Commissioners, for a large district extending to nine counties. His duties as such architect were to superintend the erection of churches, of additions to churches, and the execution of repairs on churches. He was architect in the restoration of Limerick Cathedral, and was one of four architects to the Representative Church Body.

By the Coroner.—Was the work of excavation being done under your direct supervision?—As a matter of fact, I was absent when the excavation was made at the buttress that fell, but I do not think it would be fair, on a technical point of this kind, for me to shirk any responsibility.

Do you assume the responsibility of saying that, as far as you saw, the work was well done?—I did not see the excavation at all.

Well, it was done by your direction?—I saw the work after it had fallen.

Have you examined the place thoroughly since?—I was there about an hour after the accident, and have been there every day since. I have thoroughly examined the place.

Did you find the work done well?—Yes, I should say decidedly.

Was there any part of it that you thought unsatisfactory?—The only point I could find fault with was that my orders had been disobeyed.

In what respect?—In the use of mortar instead of cement in the underpinning.

What was the effect of being set in mortar?—The effect we usually apprehend is subsidence at the joints.

Was this effect manifest in the case?—I could not judge that, because of the shaken condition of the masonry which was standing.

If a subsidence had not taken place, would you anticipate the fall of the buttress?—I would not.

I suppose by subsidence you mean what is ordinarily called "settling"?—Yes. I may state that in underpinning we depend more upon the proper wedging up of the work than upon the mortar or cement.

Would you be able to form an opinion as to whether the stonework was well done?—It was. Have you formed any opinion that would guide us, Mr. Fuller?

I maintain that this old buttress (pointing to a model), which was cased up in 1845, separated from the wall years ago; it may have been centuries ago.

Do you think the persons engaged at the work in 1845 could have seen that crack?—I think they could.

This rotten state of things was undiscovered, according to your evidence?—It was.

But something must have formed the climax; something must have immediately led to the fall. Can you give an opinion as to that?—It is almost impossible to answer that question.

This is the question upon which we ask your opinion?—Coggin himself stated in his evidence, I think, that it must have been caused by the excavation under the pier, but he stated also that in any case it would have fallen, and that is my opinion.

Is there any other thing you wish to express an opinion upon?—There is one point upon which I wish to express a clear and decided opinion. I have been asked out of court whether before the operations commenced at this buttress if, suppose I had been asked, would I have recommended it to be shored, and I wish distinctly to say that, taking into consideration the fact that the buttress was supposed to be bonded to the wall, and that the pressure for which the flying buttress was originally built had been removed, I certainly would not have directed it to be shored. If I had been asked by Mr. Pile whether there was any necessity for shoring it, I should decidedly have said not.

You spoke of Mr. Pile as the contractor?—Yes.

Had Mr. Pile any contract for carrying out any late works on the cathedral?—No, he was working on a schedule of prices, and was paid for what he actually did.

A Juror (Mr. Rafferty).—Had not he articles signed?—Yes, but he was working on a schedule of prices.

Mr. Law.—If he had been told to shore up this buttress would it not have paid him better?—Yes.

And, as a matter of fact, working with cement would have been more profitable to him than with mortar?—Yes, according to his schedule of prices.

And, therefore, he had no motive in using mortar?—According to the prices of the articles it would have paid him better to use cement.

Edward O'Reilly, 65, South Circular-road, examined by Mr. J. O. Byrne, said,—I am a builder and contractor. I know these buttresses for the past fortnight. I saw the one that fell while the works of excavation, &c., were going on.

Did you see anything the matter with the buttress that fell?—I did. About the 5th or the 6th of September, in passing down, I observed a sinking in the arch of the flying buttress to the extent of 1½ in. The same thing was visible in two other arches near it.

Mr. Byrne.—Did you point that out to anybody else? I pointed it out, first to Mr. Conway, a builder, and again to Mr. Brodigan, another experienced builder. I saw how the foundation of the buttress that fell had been excavated, and I thought, having regard to the sinking of the flying buttress, that before the excavations went far it should have been shored with heavy balk timber. I did not see any indication of danger at that time, but on the

\* See p. 410, ante.

day I brought Mr. Conway (about the 5th or 6th) I thought they were excavating without proper trussing or shoring.

The Coroner, having summed up, the jury retired, and after half an hour's absence the foreman announced that twelve were for holding Mr. Fuller and Mr. Pile responsible. The remaining juror was only for holding Mr. Fuller alone responsible.

The Coroner.—But you are agreed that it was an accident?

The Foreman.—Yes.

At the request of the jury the coroner then drew out the verdict in legal form.

The jury again retired to consider the terms of the verdict, and after a short absence the Foreman announced that they were unanimous in the following:—

"We find that Sarah Egan, John Ward, and James Bolger, were crushed to death at Patrick's Close, on the 14th of September, 1882, by the accidental fall of one of the stone buttresses of St. Patrick's Cathedral, and we consider that the accident was due to the culpable negligence of Mr. Pile, the builder, and Mr. Fuller, the architect, then engaged in works at the said cathedral."

#### THE INSPECTION OF FACTORIES AND WORKSHOPS.

This subject was discussed last week by the trade unionists assembled in congress in Manchester.

Mr. A. W. Bailey (Preston) moved:—

"That, whilst acknowledging the great and beneficial results to the factory and workshop population of the United Kingdom conferred upon them by the legislation of the past half century, this congress is of opinion that a vast amount of juvenile and female labour is still carried on under conditions entirely opposed to the intentions of the factory and workshop laws, and in a manner most detrimental to the physical and moral well-being of the workers engaged, and in many cases producing great danger to the public health. This congress is therefore of opinion that, in order to the better enforcement of these laws, the united trades should continue to urge upon the Government the great and pressing necessity which exists for such an increase of practical working men and women as sub-inspectors as would meet the constant extension of factory and workshop industries, and thus to enforce the observance of the law upon many who now evade it, to the disadvantage of those honourable employers who faithfully carry out the intentions of the Legislature."

He said he did not wish to speak in disparagement of the present inspectors, but it was impossible for them adequately to perform the work entrusted to them. Any one with a practical knowledge of the great increase not only of factories but of domestic workshops, would say it was simply a farce to think that fifty inspectors for the United Kingdom were sufficient. It was the duty of the Government to make such provision as would meet the requirements of any Act they might pass, and he believed that congress would be able to supply the Government with fifty or 100 practical men and women well qualified to act as sub-inspectors.

Miss Wilkinson, upholstress, London, seconded the motion. She said there was nothing so bad as to make a law and not carry it out, and to give men work as inspectors which they were unable to perform was not likely to create respect for the Act. She could not understand the argument against lady inspectors. If a place was fit for a female to work in, it ought to be fit for a female to inspect.

Mr. McLean (Edinburgh) said that they had felt very strongly indeed on the subject of inspectors. It was not so much an increase in the number that was wanted as a change of the class of men. The present inspectors had no sympathy with them because they did not belong to the same class. He thought the congress did well in asking for an additional number of inspectors at a low salary. Had they asked for an additional number of men to be appointed at large salaries, it would have looked as if they were trying to boost some of their best men into good positions. Their intention, however, was not to get big salaries, but to see that the law was efficiently carried out, in order that their lives, those of their families, and the general public might be protected.

Mr. Bloor (Burslem) said he thought the resolution did not entirely cover the question. There were different degrees of danger among different employments, and what was wanted in connexion with this movement was a thorough

searching inquiry, by a commission or Parliamentary committee, in large centres of industry where females and children were employed, to see how far their labour in certain departments was injurious to health.

Mr. Simmons (Maidstone) said the administration of the Act had done a great deal of good towards purifying the brickfields of both juvenile and female labour. It was impossible, however, that inspectors could get through their districts more than twice or thrice in the course of a year. Unless the attention of the inspectors was called to special cases of infraction of the law, they knew that several months in the year. He considered that there was the greatest necessity for additional inspectors.

Mr. Drummond (Glasgow) moved, as an amendment, "That the proposal to appoint women as sub-inspectors should be struck out of the resolution." He did not question the ability of the ladies, but he thought it would be better to get half a loaf rather than none. If they sent their representatives to the House of Commons with their case, before women's rights had been acknowledged in that House, they would get nothing like the increase of inspectors that they wished.

The amendment was not seconded, and the resolution was put and carried unanimously.

#### THE SANITARY CONDITION OF BAKEHOUSES.

At the Trade Unions Congress, held in Manchester last week, a resolution was submitted by Mr. Jenkins, of Manchester, instructing the Parliamentary Committee to use their influence with the Government to promote a measure as early as possible to prevent bakehouses being constructed underground, and to insure that bakehouses should be inspected the same as factories, workshops, and mines. He stated that many of the bakehouses were in such a disgraceful condition that they were not fit for the purpose of preparing food, and he called the attention of the delegates to a recent report of a Government official on the state of the London bakehouses if they wished to know what it was that required to be done. The contrast between the inspections of corporations and Government was of the most astounding character, and it was absolutely necessary, if any improvement was to be made, that they should demand more efficient and more regular inspection.

Several delegates suggested that the improvement was a matter rather for corporations than for the Government, and that regulations should be insisted upon when the bakehouses were being built, which would remedy all objection to the charge of their unsanitary state.

Some delegates gave examples of the filthy state of bakehouses, and also the habits of the workmen, and said there were scores of bakehouses in all large towns which, if only the public could see them, they would at once move in this matter in such a determined way that a change would soon be brought about.

Mr. McLean, of Edinburgh, moved an amendment, extending the proposal of the resolution to all trades carried on underground, which Mr. Stevens, Glasgow, seconded.

The resolution was carried.

At the Marylebone Police Court on Saturday last Alfred Alford, baker, Willow-walk, Fortess-road, Kentish Town, was summoned by Mr. James B. Lakeman, Inspector of Factories, for, on the 7th and 8th inst., neglecting to keep his bakehouse in a clean state. There was a further summons for neglecting to affix on his premises the prescribed abstract of the Act 41 Vict., c. 11.

Mr. Lakeman said that the responsibility on the owner of a bakehouse was now much greater under the Act than formerly. The defendant had on his premises two bakehouses, one below the other, and on the days mentioned the lower one was found to be very dirty, and was not thoroughly ventilated. At the foot of the stairs, covered over with sacking and loose boards, was a well about 3 ft. long and 2 ft. wide, and filled with water 7 in. in depth, and at the bottom there was a deposit of matter. The liquid had overflowed the floor of the bakehouse, and stood above 1 in. deep about the ovens.

Alfred Blake, the principal baker in the defendant's employ, said the water in the well was rain-water which had come from adjoining premises. It sometimes overflowed the floor of the bakehouse, and they got "rid" of it by pushing a cane into the

sewer, or dipping it out. The kneading-trough was about 2½ ft. from the well.

Captain Armstrong, one of the Factory Inspectors, stated that on the 8th he visited the place with Mr. Lakeman. A portion of the soil was taken out of the well, and it consisted of black mud and stones. Effluvia arose from it, and it had sewage matter mixed with it.

The magistrate, in the hope that the case would be a warning to other master-bakers, imposed a penalty of 20s. in the first summons, with the costs, and the defendant must pay the costs in the other summons; and the well must also be removed and the place limewashed.

#### DRAINAGE IN FRANKFORT.

SIR.—At p. 388 of the *Builder* of September 23rd, 1882, is a description of the new main sewerage and house-drainage systems carried out by the Messrs. Lindley at Frankfort. The writer does not seem to be aware that the system is, with some exceptions, essentially the "English system," as advocated and taught by myself. The resident engineer, from the first to the completion of the main sewers, was Mr. Joseph Gordon, who went from my works at West Ham, to Frankfort, under Mr. Lindley, and I have been in constant communication with the Messrs. Lindley throughout the whole of their works. I do not desire in any degree to disparage the Messrs. Lindley; I only wish to claim an English origin for the works. Mr. Lindley, sen., had, it is true, sewerage Hamburg before any work was commenced at Frankfort, but I think he will admit that he very much perfected his Frankfort works through Mr. Gordon, and by a study of what was being done in England. At this moment I, however, know of no better works of main sewerage and house-drainage than the works of the Messrs. Lindley at Frankfort, either in England or abroad.

ROBERT RAWLINSON, C.E.

\*Too late for insertion, we have received several long letters on the same subject, notably one from Mr. James Mansergh, complaining of the omission of Mr. Gordon's name in the article referred to, and one from Mr. Gordon himself, giving a history of the undertaking. The latter we will print next week.

#### BUILDING PATENT RECORD.\*

##### APPLICATIONS FOR LETTERS PATENT.

- 4,402. S. S. Hellyer, London. Supply and waste valve for baths and lavatories, &c. Sept. 15, 1882.
- 4,423. W. R. Lake, London. Composition for the preservation of wood, stone, &c. (Com. by A. Bugolich and T. K. Smith, Victoria.) Sept. 16, 1882.
- 4,430. J. Imray, London. Water-closets, &c. (Com. by R. H. Lecky and J. Hay, Pittsburgh, U.S.A.) Sept. 18, 1882.
- 4,437. L. C. C. Currie, London. Fastenings for blind-cords or wires. Sept. 19, 1882.
- 4,438. J. W. Andrews, Whitelesea. Blind-roller furniture. Sept. 19, 1882.
- 4,449. W. G. Stevens, Bristol. Combined range and register-grates. Sept. 19, 1882.
- 4,462. J. McPhail, London. Chimney-tops, &c. Sept. 19, 1882.
- 4,466. E. Edwards, London. Apparatus for closing, &c., window-frames. (Com. by A. Descaves and D. Halut, Paris.) Sept. 19, 1882.
- 4,479. W. McNicol, Leith. Appliances for securing windows, &c. Sept. 20, 1882.
- 4,491. W. H. Cooper, London. Drip-course bricks for weathering to brick wall, &c. Sept. 20, 1882.
- 4,495. W. R. Lake, London. Manufacture of bricks. (Com. by H. E. Dickison, Hamilton, U.S.A.) Sept. 20, 1882.
- 4,509. T. H. Noot, London. Drain-pipes. Sept. 21, 1882.
- 4,514. J. W. Cook, London. Forming temporary partitions in class-rooms, &c. Sept. 21, 1882.

##### NOTICES TO PROCEED

have been given by the following applicants on the dates named:—

September 19, 1882.

- 2,275. T. Wellon, London. Bedsteads, couches, and chairs, &c. May 15, 1882.

\*Compiled by Hart & Co., Patent Agents, 23, New Bridge-street.

2,498. A. M. Clark, London. Door-fasteners. (Com. by C. A. Crougery, Detroit, U.S.A., and G. W. Busch, Walkerville, Canada.) May 23, 1882.

September 22, 1882.

2,346. G. H. Haywood, London. Over-mantels for chimney-pieces. May 18, 1882.

2,377. H. Kelly, London. Gullies. May 20, 1882.

2,556. G. L. Reynolds, Oakland, U.S.A. Window-screens. May 30, 1882.

ABRIDGMENTS OF SPECIFICATIONS.

Published during the Week ending Sept. 23, 1882.

445. J. Jaffrey, Manchester. Domestic fire-grates and stoves. Jan. 28, 1882. Price 6d.

The bottom and sides of the grate are of solid fire-clay, &c. The smoke, &c., passes through an opening in the back down to a chamber below the bottom of the grate, where it is met by heated air and consumed.

505. J. D. Brunton, London. Apparatus for dressing, turning, and moulding stone, &c. (Partly com. by F. H. J. Frier, Boston, U.S.A.) Feb. 1, 1882. Price 10d.

The circular rotating cutters are placed at such an angle to the stone that they abrade it away, instead of splitting or abrading the surface.

715. R. M. Chevalier, London. Venetian blinds. Feb. 14, 1882. Price 6d.

These are made of very thin wood, which, when newly cut, are saturated with glutinous matter, comprised of glue and shallic, dissolved in highly-refined spirit, to make them tough and pliable. The latter are slung in the usual way, but when drawn up are wound round a roller.

755. R. Weaver, London. Sanitary appliances. Feb. 16, 1882. Price 6d.

The trap and bend of the closet discharge pipe are so formed that there is always some water retained in the bottom of the pan. The same kind of trap, &c., can be applied to gullies. The pan is ventilated by a pipe rising therefrom before the seat to the roof.

769. T. A. Weston, Stamford, U.S.A. Attaching door-knobs to spindles. (Com. by B. H. Lockwood, Stamford, U.S.A.) Feb. 17, 1882. Price 2d.

The knob-shank has a longitudinal slot extending from the spindle-socket radially through the wall of the shank, and also a transverse slot intersecting the longitudinal slot. A sleeve fits over the shank, and is made slightly eccentric. When the knob is put on the spindle the sleeve is turned, and the shank is gripped tight on the spindle. (Pro. Fro.)

770. E. Latham, Birkenhead. Bolt fastenings for doors and windows. Feb. 17, 1882. Price 2d.

Two bolts are attached, one at each end of a lever, which has a central sliding fulcrum. When the fulcrum pin is pressed forward the bolts of the lever enter the recesses in the sash. (Pro. Fro.)

781. A. Ashwell, London. Indicating door-fastenings. Feb. 17, 1882. Price 6d.

On the sliding bolt that secures the door on the inside are teeth which gear into a pinion, on the spindle of which, on the outside of the door, is a disc with the word "engaged" on it. This is enclosed in a case, with an opening so arranged that when the door is closed and bolted this word shows.

810. A. S. & C. Buxton & F. O. Ross, London. Ventilating-valve for preventing the bursting of water-pipes during frost. Feb. 20, 1882. Price 6d.

The outlet-pipe of the cistern is fitted with a valve. Beneath this valve a small air-pipe enters the outlet-pipe. The valve can therefore be closed and the water entirely drawn out of the outlet or service pipe without wasting all the water in the cistern.

THE SANITARY EXHIBITION AT NEWCASTLE-ON-TYNE.

In connexion with the Sanitary Institute's Congress at Newcastle, elsewhere mentioned, an exhibition of sanitary appliances has been opened on the premises of the Tyne Brewery in Bath-lane. There are five classes of exhibits in all. The classes are divided into sections varying in number from six to eleven each. The work of erecting the temporary buildings and of joining them to the main portion and far north end of the brewery has occupied some time, but under the superintendence of Mr. Poggin, the contractor, it was all satisfactorily completed a week before the exhibition opened. The task of arranging the space was supervised by Mr. E. L. Box, the curator of the Sanitary Institute.

Class I. consists of constructive materials, paints, and other protective substances, wall-papers, decorative materials, machinery adapted for sanitary purposes, and washing-machines. The firms exhibiting include Messrs. W. E. Rendle & Co., London; W. B. Wilkinson & Co., John Ismay & Sons, the Sanitary Paint Company, London; the Art Tile Company, London; E. H. Andrews & Co., Stockport; Thos. Bradford & Co., Salford; Maurice Gandy, London; Manlove, Alliott, Fryer, & Co., Nottingham; the Turner Gas Co. (Limited),

St. Allan's; J. & H. Harrison, Kirsop & Co., and Jas. Mitchell, Newcastle. Messrs. Bambridge & Ormston, Gateshead, exhibit a pair of wrought-iron entrance-gates which gained a prize at the Paris Exhibition last year. The gates are decorated in black and gold. The Whitburn Coal Company have erected a pair of gate pillars with limestone from Marsden. The little structure is ingeniously built of channelling, caps, kerb-stones, and paving blocks. A little further down in the same avenue, Mr. White, of the Great Western Works, Abergavenny, has on view the "Hygeian rock-building composition." A brick structure is here provided, and the strength afforded by the composition is shown by a number of heavy weights suspended from a girder of brickwork, which they fail to break down. An interesting feature to many will be the display of artistic wall and ceiling papers made in this department by Wm. Woollams & Co., of London. The Albissima Paint Company have at the head of the first avenue a cabinet containing samples and show-cards.

Class II. includes sewerage and water-supply fittings, water-closets, dry closets, urinals, sewage treatment, traps, sinks, baths, and lavatories, cisterns, &c. The exhibitors include Messrs. Wm. P. Buchan, Glasgow; Doulton & Co., Lambeth; Harriman & Co., Blaydon; John Fell & Co., Wolverhampton and Newcastle; Hayward, Tyler, & Co., London; Mather & Armstrong; Tyler & Sons, London; H. Watson & Sons; British Sanitary Company, Glasgow; A. T. Angell, London; J. & M. Craig, Kilmarnock; Hugh Stowell Crocson, Bromley; Dinning & Cook; Rimington Bros. & Co.; Thomasson & Key, Worcester; John Mill & Sons; Wm. White, London; Maguire & Son, Dublin; Straker & Love; and R. Thubron. Messrs. John Fell & Co., Wolverhampton and Newcastle, are the largest exhibitors in this class. Their stand is a most extensive one, and is filled with baths, water-fountains, lavatories, pumps, and chandeliers. Henry Watson & Son show flush-tanks and waste-preventers, by Adams, of York; the "Westminster" steam-pump for raising water, leather hose, with copper standpipe and hydrant, and other articles, many of brass. John Mills & Son exhibit Winn's patent acme syphon cistern for lavatories, &c. Dinning & Cook show improved stable-fittings for stall and loose box, with ventilating-panel door. Maguire & Son, Dublin, exhibit a couple of Dr. Scott's hot-air disinfecting houses. The interior is provided with baskets for the disinfection of clothing, and, by a very ingenious arrangement, any temperature can be obtained. A structure at this part is formed by the fire-clay bricks made by Messrs. Staker & Love.

Class III. comprises heating apparatus, cooking apparatus, smoke-preventing appliances, lighting, including electric lighting and ventilation. Messrs. Dunning & Co., Percy Works, Newcastle, have secured one of the best stands, and show cast-iron chambers and over-mantels. They have also exhibited a stove, "The Nautilus," in the form of a shell. The mouth of the latter forms the front of the fire, and the products of combustion pass up into the centre or axis, whence, with a spinning motion, they fly out on each side into vertical flues. A warming and ventilating stove from Dresden, intended for churches, schools, and public halls, is exhibited in this class. W. S. Forrest, Grey-street, Newcastle, exhibits the alcho-carbon light in all its varieties. The most extensive article in this department of the exhibition is a single-acting Norton ventilating apparatus, worked by a two-horse gas-engine. It is the invention of Captain Norton, of the United States Navy, and consists of two cylinders, each 5 ft. in diameter. It has already been adopted on board the steamer *Salisbury*, built at Sunderland in 1872; on board the *Warwick*, built by Messrs. Wigham Richardson & Co.; in the Chamber of Deputies at Berlin; in one or two of the London hospitals; and at other places. It is claimed for the ventilator that it exhausts 240,000 ft. of air in an hour.

Class IV. is devoted to personal hygiene, foods, and disinfectants; and Class V. to miscellaneous exhibits.

The Exhibition will remain open until the 21st of October.

**Sydney Exhibition Building destroyed by Fire.**—A telegram from Sydney says that the Exhibition Building was totally destroyed by fire on the morning of the 22nd inst. The loss is estimated at 500,000.

APPRENTICESHIPS AND OVERTIME.

At the Trade Unions Congress, last week, Mr. J. S. Murchio, Manchester, moved the following resolution:—

"That, in the opinion of this congress, the system of working overtime is injurious to the health of the workers, and detrimental to the general welfare of labour; and that it is the duty of every trade unionist to endeavour to minimise the practice by enforcing such extra rates of payment as would prevent systematic overtime. It is also a matter deeply to be regretted that a growing tendency exists among employers in many trades to discourage the employment of indentured apprentices, thereby deteriorating the quality of skilled labour and inflicting serious damage upon our industrial progress."

He said the resolution differed very materially from most motions which had been submitted to the congress during the week, because they did not ask either the Parliamentary Committee or Parliament itself to do anything for them. The resolution pointed out something which they ought to do for themselves. His object in bringing forward the proposition was to get from the meeting some expression of opinion.

Mr. Sodgwick (Leicester) seconded the resolution.

Mr. Drummond (Glasgow) said he thought it to the interests of apprentices in some cases not to be indentured. The remedy was to make the pay for overtime double.

Mr. Evans (Manchester) in following, said that the overtime system as adopted in Manchester had broken down the benefit of the nine-hours system.

Mr. Buckley (Sheffield) said if we were to maintain our prestige as a manufacturing country we should look well into and consider the matter, and

Mr. Jack (Glasgow) said he was of opinion that the subject should be taken back by the delegates to their own districts, there to deal with it.

Mr. Anderson (Manchester) said that it should be the object of every trade unionist in the room to abolish this most abominable system.

Mr. J. Burnett (London) proposed, as an amendment, that the words "trade unionist" in the resolution should be altered into "trade union," and that, instead of minimising the practice as suggested, the following words should be made to follow on after "union," "to endeavour by special restriction or absolute resistance to abolish the practice."

Mr. Mark (Oldham) seconded this amendment, and, upon a vote being taken,

Mr. Burnett's proposition was carried by fifty-six votes against twenty-five given for the original motion.

BREACHES OF BUILDING BY-LAWS AT FINCHLEY.

A QUESTION OF OWNERSHIP.

At the Highgate Police-court on Monday last, Messrs. Henry Goodwin & Walter Graham, architects and surveyors, of Air-street, Piccadilly, were charged on nine summonses, before Mr. G. Plucknett and Mr. G. N. Minto, as owners of ten houses in Manor Park-road, Finchley, with various breaches of the by-laws of the Finchley Local Board of Health, in connexion with the construction of the said houses.

The case was a peculiar one on the question of ownership, which was the point at issue, and had been adjourned for a month for the production of further evidence on the point, it not being admitted or denied that the defects existed. Considerable trouble had been caused to the Local Board by this property, the original builder of which, a man named Butcher, was summoned at this court some time ago for breaches of the Board's by-laws. Fines amounting to about 30l. were then inflicted, but Butcher disappeared without paying the money. It was asserted on the part of the Board that Messrs. Goodwin & Graham, who had been acting as architects, and "financing" the builders, then became owners; but Mr. Graham at the last examination denied on oath that he or his firm were "owners," and gave the name of Mr. Ashwyn, a solicitor, of the Temple, as the representative of the mortgagees, who, he contended, were the owners.

Mr. Ashwyn was now called by the Board, and gave a history of the "financing" of the estate, on which some 2,000l. or 3,000l. had been advanced by his clients, himself, and Mr. Graham respectively, their claims standing in the order given. Mr. Graham, he said, was "the owner," and would

receive the rents of the property if any were coming in.

The Bench held Messrs. Goodwin & Graham to be the owners, and imposed fines and costs amounting to 29l. 8s. upon them.

#### THE "HYGEIAN-ROCK" BUILDING COMPOSITION.

SIR,—We note an article in your issue of the 9th inst. [p. 350, ante] on "Cement, Vulcan, and Asphalt Floors," in which it is mentioned that great difficulty is experienced in finding a material wherewith to construct tanks for the reception of acids. Our "Hygeian-Rock" building composition has been most successfully used by several firms in the Midlands for this purpose, and has been tested and conclusively proved to be acid-proof.

ARTHUR CHARGE.

#### SYNAGOGUES.

SIR,—Can any of your readers tell me if there is any Jewish synagogue in Europe having a spire to it? I believe there is one at Poonah, in the Bombay Presidency, but want a European precedent. Also, if such exists, where could I obtain a photograph of it?  
AN OLD CALCUTTA SUBSCRIBER.

#### CHURCH-BUILDING NEWS.

**Newton Heath.**—The new Church of St. Anne, Newton Heath, is approaching completion, and will shortly be consecrated. It will consist of nave, north and south aisles, chancel, organ-chamber, and clergy and choir vestries, the cost of erection being between 4,000l. and 5,000l. The foundation-stone was laid on October 1st, 1881, by Mrs. Fraser, wife of the Bishop of Manchester, the church being intended to serve that part of All Saints' parish lying nearest to Manchester, and which has for some years been known as St. Anne's district. Sitting accommodation is provided for 600 worshippers. Mr. A. W. Smith, of Manchester, is the architect.

**Lindley (near Huddersfield).**—The Parish Church of St. Stephen was re-opened for public worship on Sunday, the 3rd inst. The whole of the old pews in the nave and west gallery have been taken out; new floors, seating in best pitch-pine, and new gallery-front have been substituted. A new porch leading to the western tower has also been added. The cost of the whole has been about 600l. All the woodwork has been executed by Messrs. T. Taylor & Son, of Salems-street, Bradford, with local men for the other branches. Mr. James N. Crofts, of Liverpool, was the architect.

#### Miscellaneous.

**Exhibition at the Manchester School of Art.**—An exhibition has just been opened at the Manchester School of Art, consisting of works from the whole of the schools of the United Kingdom to which prizes have been awarded by the Science and Art Department, South Kensington. The works exhibited cover all the twenty-three stages indicated in the Science and Art Directory, and the collection includes drawings and paintings of the human figure, ornaments from the east, and original designs, as well as studies of examples, from various museums, and the South Kensington Museum in particular. It is, we are informed, the first exhibition of the kind which has been held in Manchester for the last eighteen years. Entrance to the exhibition is free, and there have been crowded attendances.

**Telephonic Appliances during Storms.**—The *Deutsche Bauzeitung* gives publicity to an official report, according to which the telephonic connexions (which in Berlin are carried over the roofs upon iron standards) did not suffer any damage during the violent storm which swept over the German capital on the 15th day of August. Although the lightning struck many projecting portions of numerous roofs, such as chimneys, flagstaffs, sandstone figures, &c., the telephonic appliances escaped, notwithstanding the fact that these were, in some instances, quite close to places where the lightning struck. The total length of the wires which have been placed in position in Berlin is about 1,450 miles, and the number of iron standards is 2,450.

**Proposed Street Improvements South of Fleet-street.**—At the last meeting of the Court of Common Council, Mr. Wheeler (chairman of the City Lands Committee) presented a report with reference to the vacant land on the Thames Embankment. The committee proposed:—1. That the Corporation should give up to the Commissioners of Sewers, for the purpose of throwing into the public street, a piece of land on the south side of Temple-street and Tudor-street, containing about 10,283 superficial feet; 2. That a wedge-shaped piece of land on the north side of Tudor-street, and containing about 1,225 superficial feet, be appropriated by the Corporation when the leases of the premises adjoining upon it expire, or the houses are rebuilt; 3. That the line of frontage next Whitefriars-street be set back by the Corporation; 4. That the valve-house on the south side of Tudor-street, belonging to the Gas Light and Coke Company, be set back to the proposed line of street at the expense of the Corporation; 5. That the Commissioners of Sewers continue the widening of Tudor-street by setting back the house between the land belonging to the Corporation and Water-street, the Corporation contributing to the expense thereof the sum of 1,000l.; 6. That the Commissioners of Sewers widen the approach to Bouverie-street by taking down the house at the corner of Fleet-street and the north-west end of Bouverie-street, and throwing the same into the public way. With regard to the valve-house, the architect (after conferring with the Secretary to the Gas Light and Coke Company) has estimated the expense of setting back at between 4,500l. and 5,000l. The Commissioners estimate the cost of effecting the improvement in Bouverie-street and setting back the property in Tudor-street, next to Water-street, at about 13,000l. In moving the adoption of the report, Mr. Wheeler said he believed the Corporation would be more than recompensed for the piece of vacant land they would give up to make Temple-street 40 ft. wide. They would open new and important lines of thoroughfare from Fleet-street on to the Thames Embankment, and would relieve the overgorged traffic of Fleet-street. The report was adopted by 55 votes to 12, but notice of motion to rescind the resolution arrived at was given.

**A New Curtain for Theatres.**—Subsequently to the burning of the Ringtheater at Vienna, inventive genius has been greatly stimulated in exerting itself to provide for the safety of a theatre-going public. The iron curtain is a most important and valuable arrangement, but it is somewhat cumbersome, and, above all, expensive, and thus only suitable for large theatres. Its unwieldiness has led to the design of an apparatus which may, in some instances, replace it. The new curtain, which we briefly describe, is formed of a double layer of canvas, between which a large meshed net of stout cord is placed and quilted to the canvas. If at the moment of danger water is made to flow from a pipe which carries the curtain, the latter, as experiments have shown, remains intact, even if exposed to the greatest heat. One of the principal features of the invention is that, by the weight of the water pouring in, the curtain descends automatically, and thus by simply opening the watercock its descent and incombustibility are ensured, and further danger is at once prevented. The expense for such a curtain, moreover, is, as against an iron curtain, comparatively low, and small theatres are thus enabled to provide an efficient protection against fire.—*Iron.*

**"Plans and Planning"** is the title of the public opening lecture of Professor Roger Smith's courses of Architecture, Construction, and Professional Practice, at University College, London. The lecture, to which admission is free and without tickets, will take place on Wednesday evening next, the 4th of October, at six p.m. It will be fully illustrated. The regular work of the classes, as may have been learned from our advertising columns, begins the following week.

**Leakage of Gas-pipes.**—As much attention is now being devoted to the generation of diseases caused by the leakage of gases from the sewers, and which has, to some extent, threatened the character of Brighton, it is interesting to know that the South Metropolitan Gas Company have just had the ground opened in several places to see if any leakages arose from the joints of the pipes laid in 1879, and they have found them perfectly tight. The material used for this purpose was Spence's metal.

**The Proposed Tower Bridge.**—At the last meeting of the St. George's East Vestry, the chairman (Mr. Collyer) asked Mr. Fairclough, of the Metropolitan Board of Works, if he could give the Vestry any information as to the intentions of the Metropolitan Board in reference to the provision of a bridge across the Thames below London Bridge. Mr. Fairclough said he was not in a position to state anything definitely. The engineer to the Metropolitan Board had reported on the subject, and had foreshadowed three alternative schemes, viz. for a subway, a high-level, and a low-level bridge. The report was to be printed, and no doubt it would be presented at the next meeting of the Board, and then be put before the public. In view of the circumstance that it was not yet public, he (Mr. Fairclough) thought it would be hardly correct for him to make any further statement regarding it. He might say, however, that the members of the Board seemed anxious to do something, and as the negotiations with the Corporation had fallen through, the Metropolitan Board would have to act independently. Mr. Willey wished to know if any site had been suggested for the bridge. Mr. Fairclough replied that the site suggested was at the Tower. Mr. Willey said that in his opinion a crossing from the Minorics would be far too near London Bridge, and do very little good for the East of London. As there was to be a fishmarket at Shadwell, a communication lower down than the Minorics would help that and the East of London at once. Mr. Fairclough replied that, speaking with considerable knowledge of the traffic, he was convinced that at the Minorics would be the best point for the bridge, as that would be easy of access, and would relieve the enormous traffic over London Bridge.

**The Crystal Palace Electrical and Gas Exhibition.**—This exhibition will be opened on the 24th of October, and active preparations for the display have commenced. Electricians will be largely represented, although they will be mostly those who did not appear on a former occasion. A few, however, of those who did well in the last display repeat their show in new form, and amongst these are the British Electric Light Company, who will illuminate the Egyptian Court; the Pilsen-Joel and General Electric Light Company, who will light up the Renaissance and Byzantine Courts and the orchestra; Messrs. Guard will take a part of the great transept; and Messrs. Strode a portion of the northern nave. Amongst those who were not in the last exhibition, to whom the most important is Mr. Werdermann, to whom the Alhambra Court has been assigned. The advocates of gas will not be less powerfully in force. The gas interests are taken in charge by a general committee, under the chairmanship of Mr. George Livesey, whose reports as a gas engineer is well merited, and the gas-lighting of the south nave will be undertaken by them, under a plan which will secure the due representation of the various systems of gas-burners. There will be also an important display of gas-stoves.

**Theatres.**—At the meeting of the Metropolitan Board on this, Friday, the 29th, will be considered a letter from the Lord Chamberlain, forwarding a list of the theatres (twenty-seven) in his jurisdiction, the managers of which have applied for a renewal of their annual licence from the 23rd instant, and requesting to be favoured with the opinion of the Board, whether, with reference to the structure of the theatres in question, and the safety of the public, his licence should be issued for them.

#### TENDERS

For alterations at the Greyhound, Fulham-road, for Mr. R. Dean. Mr. H. L. Newton, architect, 27, Great George-street.

Bendon .....	£280 0 0
Forman .....	207 0 0

PREPAYMENT IS ABSOLUTELY NECESSARY.

\* \* \* Stamps must not be sent, but all small orders should be remitted by Cash in Registered Letter by Special Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 10s. per annum PREPAID. Remittances payable to DOUGLAS FOURDRINER, Publisher, 46, Catherine-street, W.C.

Best Bath Stone.

WESTWOOD GROUND, Box Ground, Combe Down, Corsham Down, And Farleigh Down.

RANDELL, SAUNDERS, & CO., Limited, Corsham, Wilts. [Adv't.]

Box Ground Stone.

Is the best for use in all exposed positions, being a well-known and tried weather stone. 50,000 feet cube in stock.

PICTOR & SONS, Box, Wilts. [Adv't.]

Doubling Freestone and Ham Hill Stone of best quality, in blocks, or prepared ready for fixing. An inspection of the Doubling Quarries is respectfully solicited; and Architects and others are CAUTIONED against inferior stone. Prices, delivered to any part of the United Kingdom, given on application to CHARLES TRASK, Norton-sub-Hamdon, Minster, Somerset.—Agent, Mr. E. WILLIAMS, 73, Charlotte-street, Portland-place, W. [Adv't.]

Doubling Freestone, Of best quality, supplied from their own Quarries and Kilns by STAPLER & HANN, Stoke, Minster, Agent, Mr. E. CUNREAY, 4, Broad-street-buildings, Liverpool-street, London, E.C. [Adv't.]

HAM HILL STONE, BLUE LIAS LIME (Ground or Lump), [Adv't.]

Asphalte. Seyssel, Patent Metallic Lava, and White Asphalts. M. STODART & CO. Office: No. 90, Cannon-street, E.C. [Adv't.]

Asphalte.—The Seyssel and Metallic Lava Asphalte Company (Mr. H. Glenn), Office, 38, Poultry, E.C.—The best and cheapest materials for damp courses, railway arches, warehouse floors, flat roofs, stables, cow-sheds and milk-rooms, granaries, tun-rooms, and terraces. [Adv't.]

Immense quantities of DRY WAINSCOT, DRY MAHOGANY, DRY WALNUT, in all thicknesses. B. J. HUDSON & SONS, Whitfield-st., W., and Great Peter-st., S.W. London. [Adv't.]

"Lightning."—Accidents to buildings would be unknown if J. W. GRAY & SONS' Patent System of Conductors, as fitted to the Houses of Parliament, the Royal Palaces, Principal Churches, Cathedrals, and Public Buildings, were universally adopted.—Estimates free on application at 58, Fenchurch-street, London, E.C.—[Adv't.]

J. L. BACON & CO., MANUFACTURERS OF IMPROVED STEAM AND HOT-WATER APPARATUS, FOR WARMING AND VENTILATING Private Houses, Churches, Schools, Hospitals, Manufactories, Greenhouses, &c. OFFICES AND SHOW-ROOMS:—No. 31, UPPER GLOUCESTER PLACE, DORSET SQUARE, LONDON, N.W. Illustrated Pamphlet on "Heating" post free.

### Some Recent Discoveries on the Art of the Etruscans.

HERE must be few of the reading public who have not been charmed this season with the work of one of our popular novelists, the scene of which is laid in the all but deserted Maremma. The portion of Italy which lies between Leghorn and Civita Vecchia has always possessed something more than an ordinary interest for the traveller and the archaeologist. The melancholy and fever-stricken Maremma, and the neighbourhood of the classic Lake Trasimene, have long been regarded by the antiquary as a prolific field for research; and it scarcely required the imagination of the romancer's art to add in any degree to the interest that attaches to that portion of Italy known as Etruria. But in spite of the innumerable relics which we possess of the civilisation of the Etruscans, notwithstanding the wealth of every European museum in Etruscan antiquities,\* research has been singularly baffled for three centuries that the great necropolis of Central Italy has continued to supply its yield of archaeological treasure. We have learned more of late years of Egypt, Assyria, Chaldea, Asia, America, and the pre-historic races than of the story of the early inhabitants of the classic peninsula with which we have for generations past been made familiar. So little, indeed, has been discovered concerning the Etruscans and their tombs with the quaintly smiling figures filling case after case in our great museums, that there are not wanting those who urge the uselessness of further research in this direction. But fortunately archaeologists are a happy race, not to be deterred by ill success from the prosecution of their studies. In the research which has now for so many generations been carried on to acquire some definite information respecting the Etruscans, fortune may be said finally to have blessed the efforts of the antiquaries.

Etruria, till the days of "the iron way" a difficult and even dangerous portion of the country to penetrate, is now comparatively easy of access. But though modern activity

has facilitated the approach to the Maremma, the district still remains, fortunately, almost as little invaded by the omnipresent modern traveller, as it was in the days when Dennis wrote his fascinating and familiar volumes. And yet the district possesses an interest more than common. This interest may be said especially to centre round Corneto, where within the last few months a series of excavations has brought to light some most invaluable relics of the past civilisation of Etruria.

Corneto is a small town situated between Orbetello and Civita Vecchia. It is now easy of access, thanks to the railroad, and the interest of the visit at this season of the year, when the swallows are preparing to flit southwards, will well repay any fatigue. Opposite Corneto lies the site of Tarquinii, one of the largest and most important cities of Etruria, at a time when the Maremma, now a fever-stricken tract, was a habitable, well-cultivated district the Etruscans had skillfully reclaimed from the state to which their descendants have again, through their neglect, allowed it to degenerate. Corneto, which to the lover of mediæval and Renaissance art offers not a few elements of study,\* owes, however, its chief interest to its Etruscan antiquities, and this the municipality have with wisdom understood.

The Etruscan tombs which have been the scene of the recent excavations,—the result of which it is our intention to lay before our readers,—lie scattered over the very hill on which Corneto is built, it having been the necropolis of Tarquinii. It is beyond the limits at our disposal to enter into any lengthy description of these interesting Etruscan remains, which have been the subject of a very long and learned paper recently published in the pages of the *Revue des Deux Mondes* by the well-known archaeologist, M. Gaston Boissier. We shall simply endeavour to summarise as briefly as possible the contents of this article with a view to placing before our readers the chief results of the recent discoveries made in the tombs at Corneto respecting the mysterious art of the Etruscans. It is to the labours of the eminent scholar, Herr Helbig (whose connexion with the German Archaeological Institute of Rome has long rendered his name familiar to readers), that we are chiefly indebted for the fund of information now at our disposal, and his careful research among the tombs at Corneto has, we think it will be seen, enabled him to most satisfactorily solve many very involved and intricate points respecting what has so far appeared puzzling in the art and civilisation of the Etruscans.

What especially increases the interest of these tombs,—a description of the art represented in which would lead us beyond our limits,—is the fact that they form our chief and only trust-

worthy source of information respecting the Etruscans, their language having remained as yet an enigma to the archaeologists. Problems apparently far more difficult to solve have been satisfactorily dealt with; the inscriptions of Egypt and Assyria we now read with comparative facility; those of the Etruscans remain as yet a dead letter to us, yet their language was one spoken till the time of the Roman Empire; the inscriptions in our possession are numerous, and consisting mostly of epitaphs, might be, it would be supposed, easily understood; but each student interprets their meaning differently. After a century of study we are no further advanced than when Luzzi (1789) published his *Saggio di Lingua Etrusca*. The promising labours of Corssen\* were only very recently interrupted by his death; the archaeologists, in fact, have been so far fairly baffled in their researches respecting the Etruscans. Their language remaining for the present unreadable, we have no other means of judging of their life than through their tombs and the art they display. As yet, even a definite chronology has not been established. The monuments of Etruria being in almost every case imitations of foreign examples, it is alone by comparing them with those of Egypt, of Assyria, and of Greece that it is possible to assign them to any school or any date. Those who prosecute the inquiry must, therefore, be familiar with the whole known art of antiquity.

Among the tombs, the oldest, it is true, are easily distinguished. This year the excavations pursued at Corneto have brought to light a number of tombs of evident antiquity. These are mostly simply composed of a round hole some 5 ft. broad, and 6 ft. to 9 ft. deep, an urn containing the ashes of the dead being placed at the bottom of each. About the urn are arranged the different objects which the piety of the survivors desired to preserve, such as bracelets and fibule of bronze, in some cases hand-made vases of greyish black clay, decorated (when not entirely plain) with a purely geometrical incised pattern; such vases most of the European museums have long possessed, and their interest lies chiefly in their proving the early existence of that desire for decoration, for the superfluous, in fact, which marks the first stages of civilisation, the growth of the germs of a brilliant future art. In these antique tombs neither gold nor iron is to be found. In what are known as the *terremare* of Northern Italy have been discovered among the remains of villages built on piles and belonging to the bronze age, vases strikingly resembling those recently found at Corneto, and evidently belonging to a civilisation only one degree or so behind that of archaic Etruria. The archaeologists may, therefore, now be said to be in possession of the elements of the entire progres-

\* The new Etruscan Room in the British Museum has received in these pages a lengthy notice.—See *Builder*, vol. xli., p. 623.

\* The superb Palazzo Vitelleschi, and the interesting Church of Sta. Maria in Castello, untouched in its twelfth-century simplicity, are both remarkable works.

\* Corssen published in 1876 "Beitrage zur italischen Sprach kunde." His work, "Ueber die Sprache der Etrusker," illustrated, appeared in 1874-75.

sive civilisation of Italy, from its earliest productions down to what we all understand as classic times. One point is worthy of attention; archaeological research has brought to light in almost every portion of the Italian peninsula similar relics, a fact which would go far to show that there existed in those primitive days a greater and more widespread degree of civilisation than is generally believed; this civilisation, however, we find very unqually distributed. Italy, when it was conquered by the Romans, did not become entirely Roman. In the midst of the general culture there still remained some isolated spots of barbarism. History is unable to point to these, and here it is that archeology steps in to reveal their existence. As an instance, recent excavations made at Este have unearthed works of art which, though known (from the presence of a coin) to be of the Augustan age, might easily be mistaken for the work of two or three centuries earlier.

Etruria, however, rapidly developed an advanced civilisation. Tarquini especially, situated as it was near the sea-coast, received at an early date the visits of merchants and traders from the East. A curious tomb, discovered only last January, singularly proves this fact; in this tomb, that of a young girl hurried with all her jewelry about her, were brought to light, among a number of pieces of bronze and goldsmith's work, several pieces of amber. The presence of these evidences of refinement represents a first step on the road of luxury which we see later on leading to a high degree of elegance.

The period which follows presents a marked progress. For the first time we meet with those beautiful black vases termed by the Italians *vasi di bucchero nero*; in the early periods smooth, and then ornamented with reliefs. Later on these vases, then doubtless deemed the perfection of the potter's art, we see ridiculed by the Romans as "old black pottery," which it required Martial's satire to recall to his countrymen had, however, once served the great king Porosenna. The tombs containing these vases have yielded numerous other objects, scratched in *pictra dura*, delicate jewelry, and, above all, perfume-vases strangely decorated with chimerical figures of a markedly Assyrian type. Beyond question, these vases are of Oriental origin, and how they reached Italy modern research has come forward to explain by the commercial activity of the Phœnicians. Recent authorities lean to the supposition that these Phœnician objects came from the colony of Carthage, and hence a definite date can at length be arrived at. Herr Helbig traces back the Phœnician trade to about the seventh century before the Christian era. With the sixth century, while Rome was still unimportant, the trade between Carthage and Italy was most active, and to this period we may attribute the large importation of Oriental objects found in the tombs of Italy.\*

This point settled, a great advance is made in our acquaintance with Etruscan civilisation, the presence in which of elements, evidently Oriental, has long puzzled the archaeologists. But the influence of Asia on the art and industry of the Etruscans has in no way any connexion with their origin. We continue to remain in doubt on this point, but the problem is relieved of one difficulty, and is thus brought nearer a definite solution.

**Free Library at Twickenham.**—Twickenham has set a good example to other and more considerable places by the adoption of the Free Libraries Act. Its Free Library was opened to the public on Monday morning, without ceremony, at the Town-hall, the owner of which, Sir Charles Freahe, has generously placed a suite of rooms at the disposal of the committee until their funds will admit of the erection of a permanent free library building. This is only one of many ways in which Sir Charles Freahe has sought to benefit the town. We trust that means will soon be forthcoming for the erection of the permanent home of the library.

\* M. François Lenormant (whose position as an archaeologist is well known in this country) is inclined, while thoroughly accepting the theory of Herr Helbig, to urge a certain share of credit to the Greeks, who also imitated the products of Egypt and Assyria; and this view the eminent antiquary has been able to support by the evidence of several vases discovered by him at Vulci and Cervetri.

#### A GERMAN CRITIC ON ENGLISH ARCHITECTURE.

An observant German critic, whose account of the progress of the minor arts in England we reproduced in a recent number, has now given his impressions of the state of architecture in this country. In this art, which, according to the opinions of some of the greatest thinkers, is the root of all the other plastic arts, there is, according to Herr Zimmer, undoubtedly a very lively interest taken in England. At the present moment the art of house-building amongst us is in a transition stage. Like all the other arts subservient to the wants of ordinary life, this department of architecture has, of late, undergone a remarkable change. As in many other cases, the change has taken the form of a revival of older models. It has led to a good deal of national self-condemnation, to the disparagement of everything modern, and laudation of the distant past, whose best productions are still preserved while the less valuable have disappeared. How far the present state of things merits the disdain shown by one party or the praise passed upon it by another school, is a question open to debate. But all critics are agreed that the condition of affairs which immediately preceded the present was about as bad as possible. The worst of it was that men were blissfully in the dark as to their own ignorance. There was a time when Englishmen were quite content that row after row of stucco-covered houses should be built of undeviating similarity, all being alike unbecomingly, both as regards design and materials. The iron railings in front of these houses were all after the same pattern. Street after street arose upon the same monotonous model in all the towns of England. Nor were their architects and builders awakened either by their own feeling or by the voice of their neighbours to the consciousness that there was any imperfection in their work. On the contrary, while, for instance, Gover-street has now become proverbial for its stiff uniformity or monotony, there is a topographical history of London belonging to the days when Gover-street was built which speaks with delight of its majesty and beauty, and of the honour it reflected upon its noble proprietor. And from that period,—that is, the earliest years of the present century,—things have been constantly going downhill.

The small houses of the suburbs of London are almost without exception very ordinary and common as regards design. They are, as regards material, cheap almost to worthlessness, and dishonest in construction. Where there are ornaments they are faulty and insignificant.

Fortunately, however, the time has come when we are no longer content with this state of things. Englishmen have arrived at the perception that the new parts of a town have no need to be ugly as a matter of course. They have seen that ancient houses, even in towns, present forms that are not so wearisome to the eye. They have begun vehemently to condemn the men who covered the land with long rows of villas, shops, and residences, all destitute of variety. English architects looked round and glanced backwards. They observed that the ancestors of Englishmen had built solid red brick walls and pointed roofs, a style in which there are many country houses still existing,—and they commenced to design occasional houses after this model. Thus for some time past new country houses and suburban villas have mostly been built of brick without stucco. Gables, dormer windows, and turrets have been becoming by degrees more frequent. At various points there are small projecting balconies, and deep portals have taken the place of the simple house doors.

This favourite style of building, which is named after Queen Anne, was at first revived for detached houses, and then for groups of single and semidetached villas. It was a long time before the style gained ground in the uniform rows of houses in London streets or squares; but finally a well-known architect, instead of the ordinary dirty-brown rectangular boxes of Bloomsbury-square, had built for himself there a house in common mottocoated brick, with the deep portal, the pointed roof, and the broad windows of the above-mentioned style, for whose spread this master has done so much in other districts. The house is not, perhaps, one of his happiest efforts; yet it forms so pleasant a break in the monotony of the square in question that every one who has frequently

to pass there cannot but be sincerely grateful for it. In Kensington there soon arose one red-brick house after another, with numerous projecting corners, points, and gables. Such a house is noticeable in the Exhibition-road, South Kensington. It is distinguished by a niche in the external wall, in which stands a blue porcelain ewer, an unusual ornament, which produces a most pleasant effect in the way of colour. In Hampstead, a district which has always been a favourite one with lovers of art, the Queen Anne style has become the predominant one, and there some of the finest buildings of this description are to be found. A new street, called Fitz-John's-avenue, is inhabited mostly by artists, and the new houses, many of which are not yet completed, form typical examples of the modern English style of building. There we see clearly manifested how much the appearance of a street gains by variety. Hardly two houses are to be seen there alike, except in the case of the semidetached or double villas. They are all different in design and colour, but the materials employed are in almost every case brick, while the designs are mostly widely different from the square box-like forms that once satisfied us. Although these houses are still new, and have the naked and rather glaring appearance which is almost unavoidable in the case of new houses, they nevertheless present even now a perspective which charms and delights the eye. By this it is not intended to assert that every house in Fitz-John-avenue is satisfactory in architectural respects. But the effect upon the whole is refreshing, the colour of the roofs in particular has this effect. They are mostly covered with tiles, instead of slate, and these quite surprise the ordinary Londoner, who is accustomed to walk about the long grey streets without knowing why they produce such a gloomy effect. He has no experience of the fact that a row of houses may present agreeable colours.

A short distance from London, in Bedford Park, Turnham Green, the Queen Anne style has attained a remarkable degree of development. There, a gentleman, owner of some hundred acres in that district, conceived some years ago the idea of covering the entire estate with houses of this description. He believed that the dearthness of such buildings at that time was ascribable to their comparative rarity. He thought that the cost of erecting, so to speak, an entire village in this style could not prove excessive, while such dwellings were sure to be greatly in demand. He employed the services of Mr. Norman Shaw as architect, a gentleman who, perhaps more than any one else in England, has contributed to the revival of this old style. Plans were prepared by him, and afterwards by other architects, and monotony was most carefully avoided. The roads were made winding, and the houses either stand quite detached or are in pairs, semi-detached. In order to increase the charm presented by variety, the old trees that were on this estate have been carefully preserved, while young ones have been planted along the streets. This bold experiment of Mr. Carr's, for which at first a complete failure was prophesied, has proved most successful. Bedford Park has become quite a noticeable part. Everybody speaks of it. The newspapers publish articles about it, and the houses are eagerly sought after. Within a period of barely six years several hundred houses, a church, a club-house, and a supply store have risen up in the district. The general effect produced by the village is charming. The houses are all of convenient moderate dimensions, and are nowhere pretentious. Few are entirely alike, though all have a generally similar character. They do not stand shoulder to shoulder, but each has its bit of garden-ground, which is often, as we have said, adorned with old trees. The gardens are railed in with unpainted wooden fence of rural appearance. The wooden window-frames and balcony rails are painted white or green. The roofs are covered with tiles, and, in order to soften their glaring appearance, old tiles have been employed along with new ones. The lower window panes are frequently of painted glass. Sometimes the entire window consists of a number of small panes framed in lead, such as up to a few years ago were only seen in very old houses or cottages. There are no shops, as the wants of this colony of villas are supplied by the stores of the association. A school of art, erected in a picturesque style, exists in the village, and there is an inn of still more picturesque appear-

ance. It is named after the hostelry which has been rendered immortal by Chaucer as the starting point of his pilgrims. The whole is very pretty and pleasing, although it may have an appearance of imitation. The character of the community which has gathered here corresponds to the secular and idyllic character of the place. The inhabitants are not wealthy. The dwellings are not built for rich people, and yet among the denizens are artists of all kinds, painters, musicians, novelists, actors, and numerous artistic and art-loving personages. The prevailing tone of society there is pleasant, cheerful, companionable. The club-house possesses a library, billiard and conversation rooms, lawn-tennis grounds, grass plots for fine weather, and asphalted covered places for wet days; there is likewise a large dancing-hall and a theatre. The club is open to both sexes, and may be described as a kind of co-operative amusement association.

This is the favourable side of the picture; but, unfortunately, there is also an unfavourable side. On inspecting several of the new and still unoccupied houses, numerous faults have been disclosed, and they are such as considerably to diminish the desire to take up a residence in this paradise. In the brick walls, whose colour produces so pretty an effect, it is found that the bricks are more or less cracked, and there is no doubt that shortly they will be penetrated by dampness. The ornamental tile roofs, too, have failed to withstand the heavy rains which have fallen in the past summer. It is not that the tiles are a bad material for roofing; only they have not been laid so as sufficiently to cover one another. Again, some of the woodwork in the rooms has proved to have been badly done. As soon as the doors dry, the cracks show themselves in the panels. The door-locks are inferior, and the stoves of the new-fashioned chimneys are often bad. All these, however, are faults in carrying out the construction. They are not defects in the plan itself. It is not the architect, but the builder or operative, that is at fault. These facts are, according to the opinion of Herr Zimmern, a new proof of the demoralisation of operatives in general, and of the operative builder in particular; but we hold that he is clearly wrong in basing so sweeping a conclusion on such narrow data. We agree with him, however, in regretting that these defects should have shown themselves to such an extent at Bedford Park, as ignorant persons will be apt wrongly to ascribe them to the style of building instead of to the builders. There are some defects, however, arising from the style, defects which the tenants soon discover when they find that they have to pay more or less heavily for repairs. Woodwork has been employed in the Bedford Park houses after old models, without asking why they had gone out of use. Thus the outer frames of windows of wood can never be quite watertight, and hence wood had given way to other materials. The garden palings are not painted nor covered with metal. The unprotected woody fibres of the palings are, therefore, at once wet through at the joints, and the natural consequence is rapid decay. In many of the houses a platform covered with cement is used, which serves as a roof for part of the lower story and as a balcony for the upper. The chimneys rising from this platform are of a height that is not artistic. In spite of this they do not reach to the upper roof line, and it is well known that chimneys which are not carried beyond this line have the quality of smoking. The problem of providing chimneys at once elegant and practical has not been solved at Bedford Park. Some good chimneys are there, but only in the houses which were first built.

The church is also a work of Mr. Norman Shaw's; the style is also Queen Anne, and most observers will admit that, however well adapted to dwelling-houses for the middle classes, this style is not suited for ecclesiastical architecture. The church shows a want of beauty, dignity, and, we would also say, of soul. The internal woodwork is painted green. This is a departure from the healthy modern habit of allowing the grain of wood to be seen wherever practical. To coat the well protected wood of the interior of a church with paint appears just as absurd as it is not to paint the garden palings which are exposed to the weather. In both cases that rational adaptation which is the secret of all success in decorative art has been lost sight of. The architecture which is merely a fantastic revival or imitation can never be a living art. When the artist takes

care that his work should, above all, be adapted to its aim and end, then it will be capable of living and show real progress. It is to the effort to attain complete appropriateness that the art works of the Greeks owe that perfection which no other nation has yet attained. In English architecture as in English clothing and domestic arrangements, it is too often the case that custom or fashion or the example of others is the guide rather than propriety or suitability. At present the Queen Anne style has become the fashion; it is adopted by most architects, not because brick is a good material for building, or because it shows the construction and admits variety of form, but simply because others have built according to this style, and they wish to follow the example. There is a lack of feeling for the internal laws of architecture, and hence external forms are applied without understanding or purpose. Gables, dormer windows, and projecting corners have been introduced for their own sakes. Rational sense has almost everywhere been sacrificed to picturesque effect, and so the artistic spirit, which is based on reason, is lost. Nevertheless it is a great advance that the meaningless monotony that once ruled in England is broken through, and that the attention of Englishmen has been actively turned to the exterior of their dwelling-houses. There has hardly yet been sufficient time to reach the rational middle path, but it seems to us that the efforts of recent years, in spite of all defects and faults, have given us the germ of a style which is capable of living.

In another branch of English architecture remarkable things have been accomplished in recent years. Since the passing of the Act making education of the people obligatory, there has been a need for large elementary schools. Thus it is that in almost all the larger towns one or more such schools has been built. For their designs there were no traditional prescriptions. The requirements were clear: durability, avoidance of all unnecessary ornament, light, ventilation, and lofty rooms. To satisfy these requirements, schools have been built that exactly fulfil their purpose, and by this very fact of being adapted to their ends no small degree of architectural merit has been attained. They are large high buildings, constructed of brick, and frequently with a bell-tower serving as a ventilation shaft. The walls, which are not covered with anything in the interior, and show the bricklayer's work, are well put together. The visible roofing is of good timber, and the joinery work well done. As playgrounds in wet weather, there are rooney arcades or open colonnades, the arches being often of truly noble dimensions, as pillars and posts had to be avoided to the utmost possible extent. The men who designed these edifices saw what was necessary, and carried it out excellently and in the simplest manner. The spirit out of which these productions have sprung fills us with more hope for the future than we feel when we see the houses which it has become the fashion to build in Queen Anne's style. Meanwhile, the old Classical style of masonry for which London was remarkable, but which is exceedingly unsuitable to the climate, is decidedly dying out. This is a great advantage. That in England we are gradually approaching the right road cannot be doubted. Already the streets of London have a far less monotonous aspect than that which had so long distinguished them.

#### TIMBER IN RUSSIA.

It is Mr. Gallenga, we think, who remarks, in the course of more than one of his accounts of travel, that he believes that far more than half the forests which existed at the date of his childhood have now been cut down, without any means being employed to keep up the supply of timber, the loss of which will undoubtedly begin to be felt by the world at no remote date, as agricultural effects, depending on climate, water-supply, and other circumstances, in which the destruction of woods have been the chief cause, have already been felt, and at last recognised, in many parts of Europe. Russia, where wood constitutes almost universally the sole building material, as well as the sole fuel, is already beginning to recognise the necessity of providing for the future in this respect. The northern forests will not last for ever, and they are now disappearing far more rapidly than they are replaced by either natural or artificial means. The trees, too, in these northern lati-

tudes, are much longer in attaining a size suitable for timber than in warmer regions. Government domains especially suffer much depredation, for from them large quantities of timber are stolen during the winter, when the snow quickly obliterates all trace of the marauders, who are the peasants of the neighbouring districts. If this even were wholly put a stop to, however, the economical situation with regard to the wood supply, looked at as a whole, would be but little changed. The total consumption of wood would not presumably be very much greater, though it would be met with more advantage. The Institute of Forestry, attached to the Petrovsky Agricultural Academy, is an excellent institution, under the management of an able professor, who has his heart in his work. Here a number of young men are instructed in the principles of forest management as far as these are at present known. The most economical ways of obtaining timber supply, the best way of planting, and the knowledge of soils suited to various trees, are demonstrated theoretically and practically. For indoor study there is a capacious and well-stocked laboratory, where numbers of earnest students may be seen absorbed in their work. A good library, supplied with the chief European and American periodical publications bearing upon the subjects upon which instruction is given, and various museums of practical scope, are among the aids to study which the visitor will there note. The present writer has to thank M. Ivanukof, one of the professors who gives instruction at the Academy, for his most obliging guidance and explanation during a visit made to this admirable establishment. M. Ivanukof, besides his high reputation as professor, is well known as a writer on subjects connected with land, and has travelled much for purposes of observation in both the Old and the New World. The College of Lyessovodstvo, or Forestry, has its special museum, which contains a great deal that is, or should be, interesting to the architect and builder, as well as to those more nearly concerned with the production, supply, and preparation of timber.

Among the curiosities is a highly-finished set of miniature tools used in the cultivation or hewing of timber. But specimens of practical instruments of different sorts will there be found, from Birmingham and other seats of iron manufacture. We remember noting an Irish spade, the peculiar elongated form of which resembles a tool much used in certain districts of Russia. One of the most important features of this museum is the section devoted to the investigation of blights, and there is a most interesting collection of blight insects, and of specimens of wood injured by them as well as by fungus, showing the way in which injuries of this sort are inflicted upon timber. The attention of students is particularly drawn to the study of blights, the mode of their propagation, as well as of remedies and preventives against them. This institution is doing an excellent work, though how far it may be able to cope with the denudation of the forest tracts at present going on it is impossible to say.

The forests of the Baltic provinces, which but a quarter of a century ago seemed inexhaustible, are now disappearing at a too rapid rate. Twenty years ago the little port of Lihau, which the grain trade is now elevating to importance, was surrounded with forests, and was accounted one of the chief centres of merchant shipbuilding in those provinces. Shipbuilding is now, however, reported to have quite ceased, owing to the absence of timber, all the woods in the immediate vicinity having been cut down, and there being no water communication to float timber from a distance to the spot. The wood consumed as fuel or employed for other purposes is at present mostly brought to the town by coasting boats from the north of Kurland, chiefly from Dondanhen, a locality which at present abounds in wood.

The vicissitudes of climate in Russia seem to have a bad effect upon the timber of telegraph-posts and railway-sleepers. On the 7th of August last, near the Chassoff Yar Station, a whole passenger train completely left the rails. This accident, which might have had fearful consequences, is stated to be due entirely to the rotten condition of the sleepers, which, it is said, are much in the same state throughout the whole line on which this occurrence took place. An experiment is being tried on the St. Petersburg-Warsaw line of railway with the object of preserving the telegraph-poles from rotting,

of Damascus and Jerusalem to that of Touloun, there is none from that time onwards. Cairo alone furnishes nearly sufficient material for the purpose." With so respectable an antiquity it can be understood that the mosque of Touloun, like that of Amr, in spite of frequent restoration and repair, has now fallen, in the hands of the Turks, into that sad state of ruin which is only too characteristic of all the finer old cities of the East.

Cama el Azhar (A.D. 969-981) is one of the oldest mosques of Cairo, its foundation dating from that of the city proper. An inscription determines the date and name of its founder,—Djouhar, the general of the armies of the Caliph Moez-el-Din-Allah, the builder of the existing city of Cairo. In plan, El Azhar, the brilliant mosque, as it is termed, resembles that of Amr. It contains no fewer than 350 columns, disposed in nine ranks; they are mostly from buildings belonging to the Lower Empire, and, as may be imagined, are of the most varied materials,—marble, granite, and porphyry,—all coupled with the most heterogeneous selection of capitals and bases. In the course of centuries the mosque, an object of the utmost veneration with the Mussulmans, having been frequently repaired, forms, in itself, a monument illustrative of the development of Saracenic art; but its sacred character renders access to it by all but believers impossible, or beset with the utmost difficulty. A college was early established in connexion with the mosque, and here, from every portion of the Mahometan world, students have come for centuries to acquire an acquaintance with the Mussulman religion.

Of the mosque of El Hakem Bismillah (A.D. 1003), only a few pillars remain. The Gama el Daher is of A.D. 1266. Here the windows are all pointed, and filled with the stucco tracery so peculiar to the Saracenic style and character. The Mosque of El Daher is contemporary with the Alhanhra, with the wonders of which there are many of the ornaments executed in stucco and stucco in the Mosque of El Daher that might well vie; but, as will be remarked in the buildings of the best period, the decoration will be found to be broadly distributed; it possesses none of that confused intricacy which forms too conspicuous a feature of the Moorish work.

To the year 1356 belongs the great mosque of the Sultan Hassan, in some respects one of the most remarkable mosques ever erected. "Islamism," remarked the Arab historian Makrisy, "possesses no temple that can be compared to the mosque of the Sultan Hassan for the height and grandeur of the building and for the beauty of its architecture." The mosque is, indeed, for the boldness of its design, its graceful cupola, its delicate minarets, its imposing grandeur generally, and, in detail, its wealth of marble and coloured decoration, its brilliant and varied arabesques, one of the most beautiful monuments of Islamism. Not a small portion of its effect is due, in some measure, to the irregularity of the ground-plan forced on the architect by the circumstances of the site, so successfully dealt with that a thoroughly Oriental tradition relates how the Sultan Hassan caused the right hand of the unfortunate artist to be cut off that he might never trace a rival to the mosque he had erected. Any detailed description such as this work of art merits would be out of place when our space has already been so largely intruded upon.

To the year 1386 belongs the mosque, or rather mosques, of El Barkook (the first of the Circassian mameluke sultans, monuments which Ferguson strangely attributes to the twelfth century (A.D. 1149), not unreasonably remarking on the great change which had come over the style in the period that succeeded the mosque El Azhar, next to which he classes chronologically the mosques of El Barkook.

To 1414 belongs the Cama el Moyed, a "mixed mosque," largely built of older materials, set together in the most incongruous manner; the strongly-marked character of the purest Arab style is, however, plainly stamped on the building.

To 1466 belong the mosques of Qayt or Kait Bay, one *intra muros* the other *extra muros*, both masterpieces of the art of fifteenth-century Saracenic art.

With the early years of the sixteenth century (1517) Egypt became, through conquest, what it has since remained, a province of the Ottoman Empire; from this moment Cairo ceases to be the centre of an active

and creative original art. The mosques erected after this time are mere imitations of those at Constantinople, Santa-Sophia serving henceforth as the model. In the Gama Khair-kekyh (1520) the Arab art is still pure, the mosque ranking among the most beautiful in Cairo, but the Turkish influence was already traced. A visit to the mosques erected after this time shows painfully through all the wealth of heauty the decline of the once pure art of the Arabs. As affording the means of comparison, Prisse d'Avennes has given us in his work representation of the mosque El Simanieh of the date 1569. Through the succeeding centuries a few mosques continue to be erected, but their interest is alone derived from the still lingering traditions of their decoration. With the political revival in this century these few artistic traditions fled before the pretentious productions of the refugee Italian architects employed by the successive viceroys to adorn and Europeanise their capital. This period can scarcely be said to have yet passed away. The last fifteen years have seen terrible changes in Cairo. Broad glaring streets have been ruthlessly cut through a city whose chiefest charm lay in its narrow cool and picturesque thoroughfares; pseudo-Parisian houses have been erected in every direction, and, not least destructive element, restoration has been carried out too often by far from competent officials.

With the new era which now seems promised to Egypt there is, we are afraid, from an artistic point of view, ground for alarm; we may hope, however, that the interests of art will not be neglected. Cairo is a city which appeals peculiarly to the artist and the archaeologist; it offers in its too little known monuments a field of research which will well repay the enthusiastic student whose presence, be he English, American, French, Italian, or Russian, we may depend upon it, will soon follow the restoration of order on the banks of the Father of the Waters.

#### SIR EDMUND BECKETT ON SCIENCE AND ART.

BEFORE presenting the prizes awarded after the examinations in the St. Alban's School of Science and Art, Sir Edmund Beckett, who resides in the neighbourhood, delivered a lengthy address. Some of the more striking portions may be interesting to our readers:—

If I were only to do my duty,—all that is formally required of me,—I should simply present the pupils with the prizes; but I am afraid they would be disappointed if that was all I did, for there is a passion for talking which distinguishes Englishmen and English women, which has caused a number of my hearers to come here. I have seen an archbishop, in distributing prizes, try for an hour to vary the monotony of telling young gentlemen and young ladies of the pleasure he had in handing them their prizes, but he was not particularly successful, and therefore I will not attempt to do that. Perhaps the best thing will be that I should make some general remarks beforehand. I must confess, however, that I am in a state of extraordinary ignorance on the subject. Science is a very good thing, and art, in its way, is a very good thing too. But I am afraid that the meaning of both words is a good deal less understood than it should be. I am afraid that the two things are commonly put together nowadays owing to a misunderstanding. I heard the late Cardinal Wiseman give a lecture on the Connexion of Science and Art, and if any one could have made a good case as to the supposed connexion I am sure the Cardinal could. He set to work, gave a very ingenious and amusing lecture, full of eloquence, such as I wish I could give you. At the end of the lecture I amused myself by thinking "how much real connexion between the two subjects has this gentleman shown?" It resolved itself into this. Being a distinguished person in the Church of Rome, and having spent a great deal of time in Rome, he naturally talked about St. Peter's,—a triumph of art of a certain kind. What he said was something to this effect:—"St. Peter's is a very famous place; its dome is almost the largest in the world, and, taking the height and the width together, it is really the largest in the world. But the dome is cracked, and the people set about to mend it."

That was very shabby language to use about such a thing as St. Peter's; but I am in the habit of boiling things down, and seeing what

#### THE ARCHITECTURE OF CAIRO.\*

THE mosque built by order of Amr after his conquest of Egypt (A.D. 640) is now the oldest specimen existing of Arab or Saracenic architecture; the mosque erected by Omar at Jerusalem having been, it may be remembered, rebuilt on a new plan in the eighth century of the Hejira by Sultan Walid, who covered the edifice with a dome of copper gilt, looted from a church at Baalbek; this sultan, it may be mentioned, was the first to build a minaret, now so essential a feature of every mosque. At the time the mosque of Amr was built, the Arabs had only recently seized Egypt, the first of their long line of brilliant conquests. They possessed, as we have already shown, no art of their own, and especially no architecture. The mosque of Amr was built, so tradition tells us, by a newly-converted Christian, who, as was customary in those, and even in much later days, employed for his purpose the materials of previously-existing buildings. Egyptian, Greek, Roman, and Byzantine relics will be found worked up throughout the whole of the older portions of the mosque. The plan is a large square. The presence of arches that are undoubtedly pointed has more than once been drawn attention to as bearing on the much-disputed question of their first appearance. Certainly their existence is curious here, as also in the contemporary mosque of El Akaah at Jerusalem,—in buildings, that is, of the seventh century.

More than two centuries were to elapse after the erection of the mosque of Amr before any great architectural feature was added to Cairo. The general disposition of the mosque of Teyloun or Touloun, built in A.D. 876,† is similar to that of the mosque of Amr. It is built of red brick, covered with stucco, and, though of coarse execution, is not unjustly regarded as a model of elegance and grandeur; the taste for excessive ornament, which was to mark the Arab art of later times, had not yet made its appearance. But the chief interest of this mosque arises from the fact that it may be regarded as the definite point of departure of Arab or Saracenic architecture. "It is from the mosque of Touloun," remarks Ferguson, "that we must date the complete foundation of the new style. Although there is considerable difficulty in tracing the history of the style from the erection of the mosques

\* See p. 359, ante.

† M. Prisse d'Avennes, as we have already stated, is our chief authority.

the meaning of a thing is when reduced to its simplest elements. The best case the Cardinal could make out was that the dome of St. Peter's got cracked, and that scientific men set to work to mend it, and mended it by putting a chain round it. That is not the most beautiful style of mending a crack, and it does not seem to say much for science connected with art. It seems rather like a severance; it appears to show that the artistic people who designed the dome had not much science, and it certainly demonstrates that the scientific people had not much art.

I have been thinking about a good many things of the same kind with a view to finding connexion between science and art, and could never find any until the other day I read in one of the papers as to these classes that the students painted on china, and that the china was fired or burned afterwards to make the colours fast. This is a combination of science and art, no doubt. The art of painting would not do much in regard to china without the science or art of burning. Art means a good many things. There is the art of making bread, and the art of making clothes. The people who call themselves artists are very numerous indeed. I have had to do a good deal with architects, and always found that, for some reason or other, they wish to call themselves artists, though I have never been able to make out why. It seems to me that an architect is not an artist. An artist must do something with his fingers; he does not work with his mind only. An architect does not do anything with his fingers; he merely makes drawings, and tells other people how they are to do the work. A number of people claim the title of artists with much better reason than architects. Painters and sculptors are artists; there is no doubt about them. In modern times singers are called artists in the newspapers; I do not know much about singing, and never go to the opera. Actors are often called artists. Going a little further down, I think I have heard hairdressers called artists. Dressmakers are frequently called artists; and I know also that tailors are called artists. So they ought to be, because they produce very excellent results, and I am not sure but that when they have good subjects to work upon,—very unlike myself—they produce more successful results than architects generally.

I remember once giving tremendous offence at the Architectural Museum, or some such place, where I was making a speech, by venturing to say that the carvers who executed the ornamental work, such as is now going on at St. Alban's Abbey, were really people almost of as much importance as the architects themselves. Of course the architects glared at me, and some would not speak to me for a week after. Yet, surely, a carver is an artist. The man gets up on a scaffold, and with his few tools chisels out flowers and heads, such as may now be seen by going to the west front of the Abbey. An architect can do nothing of the kind, though he may do what is much greater if he does it well. Art, if it means anything, means the art to do something; it may be a good or a bad thing; by usage it may come to be associated with a beautiful thing, or what people call beautiful. But it is very difficult to say what is beautiful, for there is no canon of beauty that I know of,—no rule except following the example of Nature. There is no unquestionable standard of beauty except Nature. Nature never copies herself. There are millions of leaves on trees, but I defy you to find two alike. This is a lesson I have endeavoured to impress upon the workmen with whom I had had to do here and elsewhere. They imitate to too great an extent. I urge them not to be too exact, but to use a little freedom, as Nature does and as the old builders did. Have pointed out to workmen over and over again pieces of old work. I have asked them to look at a moulding; examining it, at first the moulding seems to be the same throughout, but close inspection shows that the work varies. The old workmen were really artists, and they did as Nature does. They made both sides of their buildings tolerably alike and symmetrical, just as both legs and arms and the two sides of a man's face are alike. But let any one hold up his two hands and look closely at them, and he will find that they are different. The two sides of a person's face are not exactly alike. The same thing applies to the colours of animals. Did you ever find two dogs or tigers coloured alike, or with both sides alike? That is the way with Nature: she works by general uni-

formity and not by exact uniformity. Nature never copies herself. What I have said is the result of observation of Nature, which is the source of all beauty.

What do you mean by Nature? There are philosophers nowadays who are always ready to state that Nature does everything, and that what they call natural selection does everything. Professor Huxley, who is a most advanced philosopher (a gentleman who believes in nothing but matter and himself, as a great man said once),—is too much of a philosopher not to know the true meaning of Nature. He said, "Nature is only the general result of all causes." He might have said, "Nature is the result of all causes and the cause of no result." Nature cannot be talked of as if she were the inventor and creator of all things. Look at what the thing called Nature has done in the way of beauty. Some of you have been reading, no doubt, that the colours of flowers are produced spontaneously, or by the action of bees. That may be true to a certain extent, but consider to what a small extent it goes. What are the bees fond of? According to my observation in this neighbourhood, they are fond of mignonette flowers and lime-trees. There is a fine tree of that kind in the rectory garden, and I never go there without being struck with the number of bees about that tree. How much colour have the bees managed to impart to those two favourites of theirs,—mignonette and the lime-tree? They are two of the dullest coloured things in nature. According to the philosophy to which I have referred, bees have been at work millions of years making colours, but they have had none on those two things. I say, therefore, that they have been a very small cause. If bees made the colours of the trees, have they also made them the shape they are? Have they made the beauty of hills and dales and mountains, and all the forms of water and clouds, and ice and snow, and everything of that kind? It is the object of art to imitate Nature in pictures; and in other ways, by having regard to results, and the observation of methods and laws. Take the rainbow, the most beautiful thing in Nature, and the northern lights, or aurora borealis,—what has produced them?—the regular laws of Nature. Nature is the result of natural causes,—the action of all causes, the action of the Creator, and nothing else. Art is the producing of beautiful results; or perhaps of simply useful results, or perhaps of results which are neither beautiful nor useful.

Next comes science. I began by pointing out that although this is a school of science and art, there is very little connexion between the two things. It does not follow, however, that things which ought to be learned need have any necessary connexion with each other. There is very little connexion between classics and mathematics, yet they ought both to be learned. The real distinction between art and science is that art is uncertain and science is certain,—or ought to be certain. A great many people talk about science, and pretend to arrive at certain results, although they are very untrue in their knowledge. That is not true science. Science is simply a fine word for knowledge, and knowledge is certainty, or such certainty as is to be achieved. You know, no doubt, that Napoleon Buonaparte was beaten at Waterloo, but most of you would find it very difficult to prove it. That may be called the science of history. Until fifty or sixty years ago electricity was hardly known for any practical purpose. There is a great deal of certain knowledge about it in these days, and a great deal of uncertain knowledge, if I may use the phrase,—that is, a great deal of positive statement, which is no knowledge at all. Some people think they know what electricity is; but a great philosopher,—the greatest philosopher almost of this century,—said, in my hearing, "I have not the least idea what it is." That was Faraday; he said he knew the results, but did not pretend to know what electricity is. But it is the fashion now-a-days for people to be in such a hurry to know everything,—they must be up in the latest theory. They pick up something in the newspapers, and at once talk of it as if it were an accepted truth. They say that there is no doubt that ultimately all force is alike,—gravity is heat, heat is electricity, and everything is everything else. Faraday tried to find it out, but he never got a step towards it. That is the difference between sham and real science. Faraday was really a scientific man, and was not afraid to utter that

dread phrase,—"I don't know." What science could do nobody could say, because science was necessarily progressive. Yet people write of what it is certain can be done and what cannot be done. Philosophers proved that steamboats could not go across the Atlantic, and a great many other things, which a few years afterwards were done every day. When people talk confidently about science they should not take things for granted; very often they think they know things which they do not know.

One science is absolutely certain, and only one,—mathematics. There is one infallible rule, and that is the multiplication table. The multiplication table, and the laws of triangles, and things that follow on them, are about the only complete certainties we have. As I have said somewhere else, if a man told me that with dice sixes had been thrown a thousand times running, I should stare at him, and say that the chances against such a thing were millions beyond all calculation; still it might happen. I might tell the person that I very much doubted whether he was not a liar for saying so,—tell him so civilly, of course; but the thing is possible, and therefore I could not positively say he was a liar. But if a man told me that the two sides of a triangle together measured no more than its third side, I should say to that man, "Sir, you are a lunatic. That is only fit for a lunatic asylum. Go there to be believed; don't come and teach it here." So it is with everything connected with mathematics. Linear perspective is mathematics,—there is certainty; and that reminds me that many artists have not the slightest idea about perspective. If a man tells me that his colours are right, I cannot tell him that they are not, not having the knowledge which the artist is supposed to have on that point; but if a person tells me that a drawing which is manifestly out of perspective is in perspective, I say, "Sir, I know you are wrong. You may just as well tell me that four fours are fifteen." Coming to another part of the list of prizes to be presented, I see that free-hand drawing is taught; that is hardly to be called a certain subject, though a near approach to it, and a valuable study. I cannot say much for the painting on china, which is very much talked about at present,—that is "an art." As to chemistry, that is approaching to a certainty, no doubt; but it is only an approximation, and a thing somewhat given to change.

I am sorry to say that I must after all end as I began. I am going to parody a saying of Sydney Smith. He was invited by a nobleman who was not celebrated for hospitality to go and see his house and pictures; he accepted the invitation, and on going to the house was treated with a shabby luncheon. He, however, was shown a lot of fine pictures in gilded frames. When he was about to leave, the host said to him, "Well, I hope you liked it." He replied, "Oh, yes, it is all very fine; but I would rather have seen more carving and less gilding." So I would rather have seen more science and less art. We must, however, take things as we find them. It is better to do art than nothing, though I have not a high opinion of it, from its uncertainty and other qualities which I will not recite again. In a letter to me your secretary stated that the art of building is taught in this school. I am very glad to hear it; it is an art that very much wants teaching. A great many errors have crept into it. There is one error with regard to the old builders which I should like to correct. It is said that the builders of old times knew a great deal of science and art. Of art they did know something, but of science little. Art, somehow or other, does not accompany and go along with civilisation, as one might expect. It seems somehow to get squashed by civilisation. People now-a-days are infinitely above savages in knowledge, yet they lack notions of art which some savages possess. Ever so long ago, when I was at college, some weapons made by South Sea Islanders out of stones and sticks used to be shown. When they were examined, the handles of the weapons were found to be decorated rather nicely. In Indian art the work in silver and brass is very beautiful,—beautiful in shape, beautiful in ornamentation, and following Nature in not being too uniform. Take the statuary of Greece, the most famous in the world; they had very little science in those days, nor indeed in the Roman days. At the time the best English buildings were done, down to the fourteenth century, when the work

manifestly began to deteriorate, there was hardly any science. People think there must have been a tremendous lot of science among the old builders, because they constructed those high towers, stone vaults, and other things of the kind. But I have been behind the scenes, and found that a great deal of that work was done very badly indeed. It is true that they had science enough to make their buildings stand for a number of years, but they were bad builders,—did not know how to make their mortar or how to select their stone. They designed contrary to all rules of mathematics and of mechanics; their buildings began to split and almost to fall down from time to time. St. Alban's Abbey has been a succession of ruins and repairs from the earliest times until now. The state of a great deal of it has been before your eyes in the last three or four years. Therefore you should not run away with the idea that the old builders, by some sort of inspiration or magic, possessed science and art. John de Cellā [Abbot of St. Alban's from 1195 to 1214] was a bad architect; he did not know how to build and make his work stand, or what sort of mortar he should use. He knew nothing of those things, though he was a good artist as far as mere beauty went. If you have classes for the art of building, I hope the students will be taught how to make mortar, how to make proper abutments for arches to stand against, not allowing large arches to rest against 9-inch walls, as was done in the case of the Abbey. Two or three architects wanted to do the same thing again, and more than two or three,—the whole Institute of Architects,—wanted to do it, and if they hadn't had such an obstinate customer as I was to deal with, they would have succeeded. I like walls like myself. Where John de Cellā had a wall 9 in. thick, over which he put a great arch and window, I put 9 ft. I do not wish to impose my figures on everybody, but what I have done was the result of mathematical teaching. If any of you are going to begin building again at the bottom, with a mathematical knowledge of mechanics. Mothers, with sons who can draw "pretty things," put them into architects' offices, there to develop their admirable tastes. A young man of this sort is set to work to copy his master's specifications and drawings; he does that over and over again; the parents pay the architect 300l. or 400l.; afterwards the young gentleman takes an office, and is an architect; and that I am not.

#### PARKS AND GARDENS IN LONDON.

It is profitable at times to compare the present of things with the past, and thus to find in detail some elements of that progress of which we hear so much. There are certainly, as there needs must be in so vast a city as London, not a few evidences of this, but none more so than in the year, we had almost said daily, increase in the size of it, from north to south, and from east to west. Of new house-building there would seem to be no end, and it would certainly tax the imaginative powers of the most hopeful and dreamy to speculate as to its ultimate future. We have before us a map of Old London, showing the Great Wall of it, and when Grayes Inn was out of town, and Spittle Feyldes a garden. This was in A.D. 1593, an almost forgotten date in London history. Our next map is but just half a century old, and it shows Hyde Park and Kensington Gardens, and even the Green Park, field-surrounded, and fairly out of town. The Regent's Park is field-surrounded, and Primrose Hill an isolated mount. Kensington Gardens, with its so quiet and dignified palace, quiet in its seclusion even yet, is now as much in town as is Buckingham Palace Garden itself, and even for a royal palace in these days of progress to be quite sure of a quiet garden, it must needs be at a railroad journey's distance from the busy brick-built city.

It may, indeed, seem strange that this great fact has not attracted somewhat more of public attention than it has done. We have more than once called attention to it as to a growing fact in London's history. Other cities have grown, it is true, and made, in the fact of doing so, no small noise in the world, but none of them quite in the same unnoticed way. A comparison of the London of to-day is sufficiently striking, and there is nothing in it more so than the fact of the changes which

have taken place in the position, as regards the town, of our great public parks, such as Hyde Park and Kensington Gardens, so noted for its palace and its great trees and the number of them. It would be indeed difficult to divine what the constant dweller in London town would do without the parks. That they are truly the "lungs" of it none will doubt, and that they do their part right well in adding to the healthiness of it is certain. And it thus becomes an anxious matter for inquiry as to what element this is more especially due, whether simply to the wide open spaces, thus affording space for the movement of the air, or to their being grass-covered, or to the number and size of the trees in them, or to the presence of large areas of water, as the Serpentine, in their midst. All these causes probably combine to make of the parks objects of beauty and utility, and sources of health.

But a word or two in re Hyde Park. It is a something wonderful that this famous park has existence even, when the rage for "building" is considered, and the opportunity the site of it offered for "building" is taken into account. The history, such as it has been, of this park is curious, though there would seem to be a somewhat good field for research for the antiquary in getting a little more together of its history and first beginnings. Kensington Gardens as they now are, Hyde Park, the Green Park, and St. James's Park would seem at one time to have formed one "manor," as it is termed, and to have been subject to the authority of the abbots of Westminster, and to have formed what was termed the Manor of Westminster. A right goodly domain! But time changes all things, and these three parks, or open spaces, or "woods," as they then were, are now happily public property, and it is for the purpose of reminding at least the artistic portion of the public that this is so, that we call attention to them, and to what is proposed to be done in at least one of them, in Hyde Park. We would, therefore, here state a fact or two not so generally known and kept in view as might be. All, indeed, are interested in the parks, on very many grounds, but our main purpose now is to urge the preservation of the noble trees that are yet left standing, but waiting only, we fear, to follow the fate of the many that have been already cut down within the last few months. Not to be too general, we would name more especially as worth preservation the row of noble trees, of some generations' growth, running east to west, near to the old barrack buildings and storehouse. A glance at a map of the park will show the exact position of them, though, better still, a visit to the spot on which many are yet standing. These trees, many of them, are "hollow," time having dealt in the usual way with them, and they needed, a few of them only, to be protected by a slight iron fencing, thus to protect those that are hollow from further offence and mischief. Much needs yet to be learned of tree growth and death, for it not infrequently happens that a huge branch or limb of a noble forest tree dies, and eventually falls, while the rest of the tree remains in the full vigour of its life and growth. It is surprising, indeed, to note, even in Hyde Park and Kensington Gardens, and Windsor Forest, and Hampton Court Park, and other places, how vigorous is the growth, and how luxuriant the leafage, of many of the very old trees, and of the quite hollow trees, and where the rising of the sap, or its circulation, must be, one would suppose, totally stopped by the decay of the inner and heart wood or timber of the tree. But it is not so, for the life of the tree and the luxuriance of its leafage are yet there.

There is one item connected with this subject of Hyde Park and its tree growth that may interest and even instruct the scientific. It has been proposed to lessen the number of the trees here and in Kensington Gardens, from the fact of there being too many of them on a given space of ground, and from their growing too closely together, and from their having been too thickly planted. To compare things so wide apart may, it is true, be somewhat venturesome, but we are told by the great traveller,—Humboldt,—that in the forest-tree growth, of which he saw so much in South America and other countries, and where nature does all the work, that the trees grow so thickly that but a very small space is to be found between the separated tree trunks. This, of course, could not be in Hyde Park, but it may well read a useful lesson, and evidence that healthy tree-growth is not injured by the fact of their noble

forms growing in thickly-set groups and clusters. Indeed, it would seem to be the very reverse, and that, judging from what nature does in all "neglected spots" of ground, there is advantage in this closeness of vegetable growth. It is a curious and not a little interesting subject, and might be well worth a few trials and a little careful experimenting. It is curious to note in any waste and neglected spot of ground, even in towns, and in their very midst, how close and luxuriant is the growth of the vegetable forms, and how close the tree-growth, should there happen to be clusters or groups of them.

We have ventured to thus call attention to these few facts, in the hope that this important subject of Hyde Park and its tree-growth will receive further consideration before more is done in the doing away with those noble forms of vegetable growth, which it must take generations to replace. We do not venture into details, though it be, indeed, hard to forbear, when so much is done year by year in this special park and Kensington Gardens, which, indeed, forms practically, as things now are, a part of it. That there is much to be done in Hyde Park we do not doubt, but it cannot well consist in cutting down week by week trees of old growth that yet remain in it, or in the further adding to the not a little dangerous and unsightly iron bar, a few inches in height, which line the formal footpaths across it. It is somewhat singular, this last "improvement," and is worth note, and the attention of the Chief Commissioner, for the British public will, in spite of it all, walk on the green grass. Hyde Park but a generation ago was fairly "out of town," and was but a part of the surrounding country; now, at this present date, it is fairly in the very midst of it, and as much surrounded by houses and house-building as the very City itself! Much, as we say, without doubt, remains yet to be thought over and done here, but with kindly nature, not only as worker, but as guide. It is subject of ever-growing interest, if there be one, to the brick-and-mortar-surrounded Londoner.

#### THE BIRTHPLACE OF VITRUVIUS.

WAR, which Pentham has well defined as mischief on the largest scale, busily as she has been of late at work, has, within a few short days past, been outstripped in her task of destruction by the action of nature. Since the war telegrams have ceased to detail the destruction of Alexandria and the horrors of the battlefield, perhaps no sadder news has reached England than that which relates the disaster that has overtaken the city of Verona. The rise of the river Adige, swelled by the mountain torrents which have also been wreaking dire mischief over the whole north of Italy and south of Austria, has swept away more than one stout bridge of the classic city, and laid its streets under water to a height that far exceeds any previous inundation. Those who know picturesque Verona will recall how, scattered about the town, the mark will be found on the walls of the height to which the Adige rose in the inundation of 1868. This year, on the 15th ult., the water rose 5 ft. higher than on that memorable occasion, and for days, as the flood retired, the city was three quarters under water.

The accounts that reach us of the destruction done and the misery suffered are indeed sad. To all familiar with the too general poverty of the modern inhabitants of the once wealthy Italian cities of Venetia, the position of the Veronese can be only too well understood. It is the poorer and the most severely that, of course, have suffered the most severely, but even the stouter work of the past has been injured. The solid Ponte Nuovo has been entirely swept away, and Fra Gioccondo's famous Ponte delle Navi, after three centuries of sturdy resistance to the swirling Adige, has been so severely shaken by the floods as to be in imminent danger of requiring demolition. Verona, writes a local paper, is in great part destroyed, and the damage done amounts to millions of francs. No words can express the awful disaster that has overtaken the city, writes the *Nuova Arena*. On the river itself, in addition to the entire destruction of the Ponte Nuovo and the wreck of the Ponte delle Navi, the new iron Ponte Alardi, which was commenced only two or three years since, has been almost destroyed; the Ponte Garibaldi, another iron bridge, has been seriously injured. The picturesque old sulphur-mills on the river were,

of course, among the first to be swept away, and dashed against the bridges, only served to add to the terrible force of the waters. In the midst of the sweeping destruction, the Medieval quaintly-crenellated bridge of the Castel Vecchio, still remains standing, as also the old Ponte Pietra, a Roman work, having thus resisted one more of many attacks during its venerable existence.

Divided as the city is in two by the river, it can be understood what damage has been done by the flood. There exists no quay, the houses being built on, in many cases actually overhanging, the river, which sweeps and swirls romantically under long lines of dark arcades and arches.

Every one knows how enthusiastically Mr. Ruskin has spoken of Verona, one of those almost flawless gifts which the Middle Ages have handed down to our prosaic present. As yet no descending tramway has invaded the narrow bustling streets of Verona, as is the case in almost every other Italian city of any importance. Overshadowed by innumerable balconies—for Verona is the true city of Romeo and Juliet, though Shakespeare can never have visited it,—the busy streets seem to have retained in their twilight the living spirit of the day which so many a quaint doorway and architectural detail recalls at almost every step. Classic remains meet one at every turn, to speak of the great citizens of Verona, of whom she is so justly proud, Cornelius Nepos and Pliny, and, above all, that early master of architectural learning, Vitruvius. As the birthplace of Vitruvius alone, apart from the memory of Paul Veronese and San Micheli, Verona holds a hallowed place in the history of art.

Pleasant, delightful city, now so sadly devastated, we can well understand how, two hundred years ago, John Evelyn, when he visited Verona, jotted down in his diary (1646), "Here of all places I have seen in Italy would I fix a residence." The home of the classic recollections which appealed to him, the home of the Medieval memories of Dante and his protectors the art-loving Scaligers, of all the interest of the Renaissance architects, painters, and sculptors which we attach to the story of Verona, the sad calamity which has overtaken the city may indeed appeal warmly for sympathy from the whole artistic world. We hear a great deal in the present day concerning the destruction caused by restoration, but the destruction worked by the hand of man is paltry compared with the work which Nature is able to perform where her action is left unchecked.

There will, we suppose, be some inquiry immediately made by competent engineers as to the causes of the recent floods in Northern Italy, and means will be devised to prevent the possibility of the recurrence of such disasters. That measures are capable of being taken, and that the danger of the mountain torrents has at all times been understood, may be shown by the great engineering works which, as far back as the sixteenth century, the Veronese architect, Fra Giocondo, planned and carried out in the neighbourhood of Treviso, with a view to protecting that city and the flat plain stretching down to Venice from the possibility of inundation, works which, it may be mentioned, remain to this day as serviceable as when they were first erected.

But the good old architect's bridge at Verona has, as we have said, now been severely shaken. Fra Giocondo's reputation as a bridge-builder was great in the sixteenth century. He was employed at Paris to build the Pont Notre Dame, which only succumbed to modern requirements. The modern requirements of the Veronese have, however, found their worthy citizen's bridge ample for their purpose for three centuries past, and Verona, if it loses the Ponte delle Navi, will have lost one of its most characteristic features. Otherwise there is ground for congratulation that the city of the Scaligers will not have suffered much artistic loss from the recent floods. The chief works which give it in architectural history so important a place, the Church of San Zeno, the Duomo, San Fermo, and St. Anastasio, the tombs of the Scaligers, the huge Arena, the picturesque Piazza delle Erbe and the Roman gateways, the picturesque fortifications, the innumerable Medieval and Renaissance palazzi scattered about the streets, will remain still to delight the traveller to smiling Italy.

But before all is again set to rights there must be much suffering in Verona. The poorer portions of the population will have been the most tried, and though perhaps, from a sanitary point of view, there may be small grounds for regret that many sections of the city will have to be rebuilt, yet the funds that will be required to carry out the work will be sadly wanting.

#### EDINBURGH.

UPON returning to the city after the summer holidays, we feel some curiosity and anticipate considerable pleasure in making a survey of the different building operations which were in progress when we left. The result, however, is generally somewhat disappointing, for we invariably expect more to have been done during the month or two of our absence than is actually achieved.

Our steps are, in the first instance, by a natural impulse, directed towards Princes-street, and nowhere else do we find a more picturesque and charming urban scene, one where nature and art combine more effectively. Proceeding westward, we observe that the Conservative Club is gradually asserting itself, and remark the careful attention to every detail given by Mr. Anderson, even to the size and joining of the masonry, a matter which is too often left to the discretion of the builder, but which, if judiciously controlled, gives a distinctive expression to the construction. The masonry of the new chancel and porch of St. John's is completed, and the detail we observe is almost a repetition of that in the original building. One departure, however, consists in the arching of the long windows, which embrace both aisle and clearstory, in which the use of the four-centred arch has not been adhered to; the tracery, too, is slightly varied. We cannot say that we admire the depressed battlemented gable of the porch; a little more freedom might have been used without the additions being out of keeping, and the original structure is not of much account as regards style.

We find that a new south front is being put up to St. Thomas's Chapel. The principal façade is towards the north, and abuts upon Rutland-place. It is a tame modern version of Norman style carried up in two false gables, against one of which is a semicircular projection containing stair to galleries. The south elevation towards Rutland-street was carried out in unison with the plan of that street, in a plain Domestic style, with square-headed windows, cornice, and balustrade. The opposite side of the street was removed several years ago to make way for the new Caledonian Railway Station, and an open place formed, which left the side of the chapel more exposed to observation than before. The new elevation shows two stories of semicircular-headed windows, divided into two lights by shafts, those in the upper tier having a circular pierced opening at the apex. There is a small doorway which has been brought into unison with the rest.

The centring for the new west door to St. Giles's Cathedral is in place, but, at the present rate of progress, it will be some time before it is completed. We find the chancel still in the hands of the workmen, but are given to understand that it will be opened for public worship in a few weeks hence. The scaffolding of the spire of new West St. Giles's Church has just been removed; it tapers up gracefully over the trees of the Meadow Park. The interior is in a state of chaos, but, so far as observation permits, it appears to be constructed in a thorough manner. The architects, Messrs. Hay & Hardy, have adopted a Scottish peculiarity in using the semicircular arch in the windows of aisle and nave, the general character of the design being of the Flamboyant style, this arch having been used in Scotland in conjunction with the pointed arch throughout all the different phases of Gothic architecture.

The stonework of the new Board School for this district, situated at the junction of Marchmont-crescent and Marchmont-road, is almost complete. The site consists of an acute irregular triangle, and irregularity of plan was a necessity which might have been taken greater advantage of than has been done in regard to grouping of parts; as it is, the building is tame and uninteresting, the new tenements built and in progress beside it having much more spirit in them. The variety and character of the elevations of these new tenements are cer-

tainly remarkable, comprising gables, oriels, dormers, and angle turrets, each builder emulating his neighbour in producing something different. The effect is striking, and would be more so if the buildings were not all of a uniform height; but this is most probably regulated by the conditions of the ten charter.

At Watson's College, to the north of the Meadows, an addition to the west of the existing building is being carried out under the supervision of Messrs. Macgibbon & Ross. The additions will partake of the same Classical character as the rest of the building, and will be about 30 ft. long with a depth of 55 ft. The ground-floor is to be utilised as a gymnasium, the second floor is to be appropriated to school-rooms, and the third or uppermost floor is to form one large class-room for drawing, &c. The two upper floors will communicate with the corridors of the existing building. These additions have been rendered necessary by the great success of the school, which is under the care of the Merchant Company, the number of applicants for admission to this and the other schools governed by the company being greatly in excess of the accommodation.

The new Chalmers Territorial Church, at the West Port, begins to show over the enclosing hoarding, and the Newforth United Presbyterian Church is in a similar stage of progress.

At the north-west margin of the grounds of Greenhill, recently acquired by the Messrs. Beattie at a cost of about 4,400l. per acre, building operations have commenced. The designs for these works have been prepared by Mr. Hippolyte J. Blanc, and comprise three blocks, each having a frontage of 100 ft. and a height of five stories. The main doors are expressed by projecting porches, having moulded architrave, frieze, and pediment; Venetian windows and oriels alternate, the former having a projection of 4 ft., with three lights in front, and narrow ones at the sides; these are carried up two stories, and the oriels, which are set on a projection of 2 ft. 6 in., rise to the main line of the eaves. The sky-line is diversified by Mansard roofs, double and single pedimented dormers, and large gables with ogee curves, in which are placed square-headed windows between fluted pilasters. From this description it will appear that there is a departure from the common-place builder's plan, and that the aim has been to secure a pleasing variety in outline and detail. Equal attention has been given to the internal arrangements, where the sanitary provisions are to be of the best description. Another departure from the usual plan is that the ground behind each block is to form one area instead of being divided into narrow plots by party-walls.

The new Established Church at St. John's-street, is now completed, and it is satisfactory to be able to report that the interior is more seemly than the exterior, which is positively ugly. Everything within, it is true, is plain, but the proportions are good, and the arrangements well suited for an auditorium; everything seems thorough, and there is none of the pretensions plaster work too often indulged in.

Pretentiousness of the most rampant description appears in the Colston-street United Presbyterian Church. You approach an imposing front with a large doorway and great traceried windows, and turning the corner observe a small oblong conventicle, hidden, or rather meant to be hidden, behind the grand frontage.

The Guthrie Memorial Church is not so pretentious, but it is an unsatisfactory specimen of the Nonconformist Gothic type, with cast-iron columns and wooden clearstory. It unfortunately is placed beside a beautiful little Episcopal church, which it swamps, but an addition is being made to the latter, which may counteract this.

By the will of the late Captain Hugh Reid, a sum of 1,000l. was placed in the bank at the credit of the Edinburgh Town Council, to accumulate for twenty-five years, as a fund to assist in the erection of a memorial to the Scottish heroes, Bruce and Wallace. It was suggested that the monument should be in the form of "an ornamental piece of water in the Nor Loch, with a fountain in the centre, and colossal statues in bronze of each hero in conference." The stipulated twenty-five years having expired, the Corporation invited an open competition, stipulating that the cost of the completed design should not exceed 2,000l., and offering premiums of 30l. and 15l. to the designers of the works which might be con-

sidered second and third in merit respectively. The models to be 3 ft. in height, and the treatment of the design and suggestion as to site to be at the discretion of the competitors. The completed figures to be not less than 12 ft. in height. Seven sets of models have been sent in, as we have already stated, and they mostly represent the warriors clad in mail, Bruce with his battle-axe and Wallace with his great two-handed sword. The designs have been inspected by a committee of the Town Council, but as yet no decision has been arrived at.

By a new arrangement the Corporation has undertaken the supervision of the sanitary arrangements in each house within their jurisdiction. Any citizen having a suspicion that his drains are not in good working order, may give notice to the burgh engineer, who will thereupon send a competent inspector to examine the house, and thereupon a report, containing a statement of the deficiencies and proper remedy, will be furnished.

A proposal was made at the Council Board that the vacant space at the east end of the School of Arts in Chambers-street should be filled with a semicircular recess, as intended by Mr. Cousins, the architect of the street; but this proposal was objected to, as it appeared that the ground might be required for an addition to the School of Arts. The ground in question is very shallow, and it was intended that a screen wall should be erected to shut off the view of a workshop, the recess towards the street being left for a fountain or monument of some sort.

The City Treasurer, in his report, states that there is a remarkable coincidence between the actual expenditure of last year, and the estimated expenditure of the current year. The actual expenditure of last year was 144,335*l.* 5*s.* 11*d.*, and the estimated expenditure of the current year was 144,335*l.* The respective items differed widely, but the fact that the totals were so very near was one of those curious things which happen now and then. The estimate for carrying out the Improvement Act for the current year is 20,000*l.*, which is equivalent to a rate of 3*d.* per pound on the rental.

#### CHENIES.

ONE of the consequences of the feverish life of the present day is the natural tendency of society to seek holiday pleasures in hurried travel, among great cities, in crowded centres, and in the grand scenery of the Alps. English landscapes are apt to be too tame and too wanting in the excitement which has become so necessary a part of modern life to have attractions for more than a few quiet and moderate people. Yet, in some of the least frequented and yet most accessible parts of England, within comparatively a few miles of London, is to be found scenery which is full of charms, and of a quiet and unique beauty which can be seen nowhere else. Among the hills and woods of Hertfordshire there are scenes of woodland beauty not to be surpassed in England. The western borders of this county, and that part of Buckinghamshire which lies to the east of the Great Western Railway, and is bounded by the little river Chess, have a beauty peculiarly their own. The heavier woods of the eastern part of Hertfordshire are lightened by the greater variety of trees,—oaks and beeches and firs grow side by side in the same wood. The streams winding through the "bottoms" give a brightness to the view, and the cornfields and brown-roofed farms bring a warmth and homeliness in character by the numerous cherry orchards. It is quite in this pleasant country that one walking northward from Rickmansworth finds the village of Chenies. No spot could better fulfil the idea of a typical English village, whose neat and comfortable cottages are surrounded by gardens bright in summer with phloxes and carnations. The wooded hills and valleys of Buckinghamshire disappear to the west, and on the other side the valley of the Chess sweeps in steep slopes and with a graceful curve, beautiful with woods and cornfields and hedges burdened with the traveller's joy. Past the great clump of elms which shades the end of the village, and the avenue which leads to Sarratt Bottom, and on the brow of the hill, is the old manor-house of the Cheneys. It carries us back for more than three centuries, dating, in its present form,

from the reign of Henry VIII., when the first Earl of Bedford, who had married the heiress of the Sapcotes, the owner of the manor, changed the old house which had been the home of the Cheneys, predecessors of his wife's family, into the Tudor mansion which we now see. It has been well preserved against the ravages of time, and though it now is inhabited both as a farm and cottages, yet its mellow red walls and chimneys rising from among the dark ivy, and forming two sides of a triangle, its sunny terrace and bright garden, and the dark shadows of the angled front, give it the beauty without the painfulness of age. Standing alone it would be architecturally interesting, but forming a part of a picturesque village itself, in harmony with the country round, it helps to make Chenies a singularly delightful place. But it is when we cross the road and enter the church that the perfect uniqueness of this Buckinghamshire hamlet is really understood. A quiet country church has always attractions which have never been so fully expressed as in Gray's incomparable Elegy, but the church of Chenies brings into focus a long period of English history. On the northern side of the church is the vault of the Russell family, and above is the chapel in which the monuments, the tablets, and the banners tell of three centuries of an historic family. Chenies possesses the only church in England which is so completely the tomb of one single race, and a race which has entwined itself so well with the best features of our history. We take no note of the Cheyne family, but we find Russell after Russell buried beneath our feet. They begin with that Sir John Russell who became the first Earl of Bedford, a Privy Councillor of Henry VIII., Lord High Admiral to Edward VI., and Lord Privy Seal to his sister Mary. Among them is a well-known historical figure, that Lord William Russell, one of the victims of the Rye House plot; among them also lies the great Whig statesman of our own century. But each generation has brought forth some man who has done good service to his country, though the political position which he has occupied has not been so high as to cause him to be an historical figure; but men and women, generation after generation, they were brought for burial to this Buckinghamshire churchyard. The mere fact that these men lie here is, perhaps, the most enduring and the most striking monument they could wish, and the small black marble slabs are more telling than the more elaborate monuments which are also to be seen in this chapel. In fact, the great structure which occupies the west side of the chapel in which William, the first duke, and his duchess are seated in full court dress, with medallions of their children round, in the florid and disorganisable taste which marks English monuments of the seventeenth and eighteenth centuries, seems wholly out of place. That which artistically is most attractive is the fine alabaster monument which represents the first earl and his wife laid recumbent side by side. The figures are of life-size, and the work is characteristic of the period and of the style of which Torrigiano was the chief master in this country. The most barren spot filled with these memories would be full of interest, but when to them is added the picturesqueness of a pretty English village, the charms of a singularly attractive county, and the mellow beauty of the old manor-house, the epithet which we have applied to Chenies that it is a "unique" village is obviously no more than the truth. It may, indeed, be almost called the most remarkable village in England. Fortunately it is not likely to lose its quiet charms, which agree so well with the last resting-place of a great political house. The railway is at a distance, and, amongst strangers, it is chiefly the trout fisher who has been fortunate enough to obtain a day on the Chess who most frequents Chenies.

**Liquidations in the West.**—Builders in the neighbourhood of Exeter seem rather "shaky" just now. Within the last few days the failures have been announced of Mr. Thomas Redway, builder, of Exmouth (Mr. Redway is the partner with Mr. Mous for building Sir Henry Peck's mansion at Rousdon, under Messrs. Ernest George & Peto, architects); of Robert Davis, of Newton Abbot and Exeter, builder (this bankrupt is stated to have also succeeded); and of Frederick W. Vanstone, builder, of Torquay.

#### HEALTHY HOUSES AND HOW TO SECURE THEM.

PROF. HENRY ROBINSON, C.E., in his address as president of the Engineering and Architectural Section of the Newcastle Health Congress, said:—Engineers and architects may agree on right principles, and may devise skilful means for carrying them out, but their field of labour will depend entirely on the appreciation by the masses of the requirements of health. There is less difficulty in getting people to see the necessity for new roads or railways, and to find the money for them, than to find the money to make their homes healthy. Referring to house sanitation, he said it is no exaggeration to state that not one quarter of the dwellings of all classes, high or low, rich or poor, are free from dangers to health due to defects with respect to drainage, water, or ventilation which were capable of being easily avoided at the outset. The public are now more alive than they were to the necessity for inquiry into these matters, and consequently sanitary authorities (who cannot go much ahead of public opinion) are better able to enforce regulations, and are more willing to bear the expense of doing so. To ensure healthy homes, local authorities should have by-laws requiring compliance with general rules, which are now well known and hardly require to be specified. It is obvious that the condition of the drains, soil-pipes, ventilation, &c., of the old houses should also be the subject of investigation. But it is not till the attention of the Medical Officer of Health is attracted by the occurrence of fever, or other form of illness, that their condition is inquired into at all, although they might have been in so unsanitary a state as to be unfit for habitation. The conversion of unhealthy old dwellings (which form so large a proportion of the houses in large towns in this country) into healthy ones is a task which, without reference to by-laws, presents no attractions from an architectural point of view, but has nevertheless to be undertaken by those who are best fitted, from their position and influence, to deal with the subject. These observations apply with the greatest force to the houses of the poorer classes, who have not the opportunities of exercising any critical supervision of their own. As regards the houses of the better classes, the same remarks apply to a greater extent than should be the case, considering the irretrievable mischief consequent on treating these matters apathetically. In order to direct attention to the condition of houses, and to expose their unhealthy state, the following plan is suggested: It should be compulsory on the part of medical men, or of the occupier, after notification by the medical man, to return to the Officer of Health for the district any case of illness of the classes agreed on as arising from sewer gas, infected water, and the like. This notice should be accompanied by particulars of the house in which the illness occurred, and whether it was an imported case or originated in the house. It should then be the duty of the Sanitary Authority to have affixed to a plan of the district a coloured wafer or dot corresponding with each disease. This plan should be open to public inspection, as well as any reports explanatory of each case. The effect of this would be that a house, or group of houses, in which fifth-diseases occurred would be revealed at once to the eye of an intending occupier by the array of wafers, warning the unwary against the danger they are running. This suggested registration of disease by maps appears to be in operation in Newcastle. In the *Lancet* of the 16th of September, it is stated that a map "records, by dots of different colours, all the cases of scarlet fever, enteric fever, typhus, small-pox, and whooping-cough, affording to the locality in which they are reported." It is further stated that all such cases are voluntarily notified to the officer of health. Dr. Armstrong deserves well of all sanitarians for having introduced this system. A means of compelling inquiry into fatal cases of typhoid and enteric fevers, and similar diseases arising from preventable causes, would be to require an inquest to be held, at which evidence would be elicited which would point to the cause of the disease, and the necessary steps to remedy the mischief would follow. On the efficient way in which the plumbing and sanitary work in a house is executed depends, to a large extent, whether a house is healthy or not. Experience proves continually that much of this work is done by incompetent or careless people, and

requires subsequent rectification, probably after illness has caused an investigation to be made. In America, legislation has aimed at correcting this evil by making it a penal offence for plumbing work to be badly carried out. He contended that an intending purchaser or occupier of a house should require a certificate that certain stipulated conditions have been fulfilled. This would render it necessary for the landlord or vendor to ascertain (what is only equitable that he should) that the house is fit for habitation before he derives any benefit from his property in it. Similar certificates should be required for all new houses, and no one should be allowed to let or sell a new house until the local authority had given a certificate. This would involve more inspection and a larger staff than now exists, but the cost of this might fairly be borne chiefly by the builders, who should pay according to a sliding scale.

#### "INDUSTRIAL DWELLINGS" FROM A SANITARY POINT OF VIEW.

This was the subject of a paper read by Mr. John Price in the section devoted to Engineering and Architecture at the Newcastle Sanitary Congress. Mr. Price, as resident agent of the Newcastle Industrial Dwellings Company, says,—"Twelve years' continuous residence in a block of industrial dwellings, and thirty years' intimate association with the working classes, enable me to speak practically as to their opinions and requirements, and that as great a diversity of views exist amongst them on sanitary matters as amongst any other section of the community. Some have great regard for their own health and that of their family; others treat this important subject with ignorant contempt. The low death-rate exhibited by blocks of industrial dwellings in contrast to the surrounding neighbourhood is a striking proof of their healthiness. The London Improved Industrial Dwellings Company, which now provide accommodation for about 20,000 persons, shows an average death-rate of 18·4 in the 1,000 for the year 1881, against 21·2 in the metropolis generally during the same period. The dwellings of the Peabody Trust exhibit an average death-rate of 17·23 during the same year. The Metropolitan Association record an average death-rate of 14·3 in the 1,000, whilst the block belonging to the Newcastle Improved Industrial Dwellings only show an average death-rate of 12 in the 1,000 for the year ending 30th June, 1882, which is more satisfactory when it is remembered that the majority of the tenants belong to the worst paid section of the labouring classes. This may be considered a striking testimony of their value from a sanitary point of view, apart from all other considerations. The evidence given before the recent Parliamentary Committee shows that the problem of how to provide the lowest class of the poor with healthy dwellings has not yet been satisfactorily settled. The poor in many cases have been driven from their homes, and excellent dwellings erected on the sites, but at rents much beyond the means of the poor. Companies having heavy charges on their revenue naturally make a satisfactory return one of their first considerations. The poor can only expect relief from philanthropic aid in the matter of better dwellings. Industrial dwellings, to be successful, must be placed in convenient situations, and possess essential sanitary requirements. The working man, both in London and in the country, strongly objects to travel far from his home to his work, and will sacrifice many advantages for this one great privilege. Industrial dwellings should not be too lofty for the tenants, should be spacious, well ventilated, and have a plentiful supply of pure water. The stairs and landings should be of fire-proof construction, the steps easy to ascend. Water-closets, which should be situated in an offshoot from the main building, should be of the simplest construction and well ventilated, a simple metal or earthenware pan, with feed-pipe flushing-rim and plug, the most serviceable for large buildings. These should be under the sole control of an attendant, who should inspect these places, as well as the sinks and drains, daily, to prevent the stopping up, which so often occurs when left to the tenants, especially when these conveniences are used by more than one family. The prejudice which existed against the first-built block of model dwellings is now dying away. Handsome buildings built to suit the requirements of the working-classes are

now to be found in London and elsewhere. The dwellings belonging to the Newcastle Improved Industrial Dwellings Company, though a comparatively small block, have shown excellent result,—the death-rate only averaging twelve in the 1,000 for the year ending 30th June, 1882. The buildings are now fully occupied, the majority of the tenants being labourers on the Quay-side and surrounding neighbourhood. The operations of the company have in many ways been productive of benefit to the neighbourhood, and limited capital alone prevents their doing still more. Much regret has been expressed that the Corporation of this city has hitherto done but little to assist this movement.

In the discussion that ensued, Captain Galton said that the question before them was becoming in our town populations one of absorbing interest. The price of land was, no doubt, one of the greatest difficulties. Of course it was possible to erect dwellings outside towns, but there was an early limit to that, because a very large number of the class of population for which they were intended must live close to their work. It was there where land was the most costly, and therefore he would commend to the attention of town authorities the importance of assisting private enterprisers willing to devote themselves to making improved industrial dwellings.

Mr. S. Alcock said that this was one of the most important questions that could come before them, and he thought after all they could only look upon industrial dwellings companies as pioneers of the way in which these dwellings ought to be provided. Unless it could be shown that these companies could provide dwellings which would give remuneration for the capital persons invested in them, what they would be able to do would be infinitesimal; they would not succeed really in providing for the wants of the working classes generally. So far as Sunderland was concerned, they had very advantageous dwellings for the working classes, consisting of cottages of one story, self-contained, and having three or four rooms, at a rent of 4s. or 5s. per week.

Alderman Gill said that in Newcastle and Gateshead there was a class of houses very valuable to the working classes. The buildings were two stories high, and each story was a self-contained house, with distinct outlets, yards, and conveniences. These houses were being built to an immense extent, and he thought they would meet the wants of the working classes in the best manner possible.

#### THE SCOPE AND INFLUENCE OF ART.

MR. GEORGE ATENISON, A.R.A., as president of the Art Department of the Social Science Congress at Nottingham, concluded his opening address with the following words:—"It is the true nobility of nature that pervades our race, that makes the very highest literature equally admired by the Queen on the throne by the poorest peasant. "One touch of nature makes the whole world kin." Horace's maxim that if you want your hearers to weep you must weep yourself is true of every art; it is the intense feeling of a passionate nature expressed by the subtlety of skill that makes all true and noble art:—

"'Twas partly love, and partly fear,  
And partly 'twas a bashful art,  
That I might rather feel than see  
The swelling of her heart."

In painting, this master chord of nature is sometimes touched, and then, though the beholder may be ignorant of the technical merits of painting, he is forcibly impressed. No one ever looked at Francia's Madonna mourning over the dead Christ, in the National Gallery, without tears coming into his eyes. Sir Edwin Landseer knew, loved, and honoured dogs, and his "Chief Mourner" is one of the most popular pictures of modern times, not in England alone, but amongst all civilised nations. You may see engravings of it in the shops of every capital in Europe; but, as a rule, both in painting and sculpture, we must look upon anything that is the mere petrifying of a momentary emotion or movement, as nothing but a feat of skill: beauty and calmness, dignity and composition, are much higher and more proper qualities, as the same action or the same expression is ever with us. The great Italian painters, when they painted a martyrdom, avoided the physical agony and dwelt on the seraphic calm and resig-

nation of the saint, who was already tasting the delights of Paradise. We look for gorgeousness and exquisiteness of colour in painting as its peculiar attribute, and we also look for perfection of form and grace, and subtlety of composition in sculpture and painting. If we want the expression of passion and violent action we look for it in the drama. When we deal with genius in one line of achievement we may perhaps make an approximate scale, but we have no means of comparing different classes of genius with one another. To discover a natural law or the application of one, to invent a machine, to solve a great engineering problem, may require as much genius as to paint a picture or carve a statue, to write a poem, or to compose an oratorio; so I shall not attempt to exalt the great architects above the great men in the other fine arts, but, at any rate, I know more about the difficulties of architecture than about those of any other fine art. A building has to be made convenient for its purpose, and to be securely built,—both difficult arts, though perhaps not fine arts. It must be imposing, dignified, or graceful, before we admit it to be architectural, and yet the difficulties may be almost insuperable; to take a high rank, it must plainly declare its object; it must, at all events, not be mistaken for a class to which it does not belong, and, moreover, it must be in accordance with the tastes of the age. But what if the age have no taste, and only asks for a brick wall with holes in it, what is to be done then? You may point to many a fine front as a contradiction, but be sure that, however fine that front may be, if there be a back that only the owner sees it is a plain brick wall with holes in it. If it were done for the owner's delight he would be more anxious for the part he sees to be beautiful than the part he rarely or never sees. I was once at a doctor's before his last patient was done with, and the doctor was impressing on him the advantages of cleanliness, and finished up by saying, "And be sure you wear a clean shirt." Thinking the patient's shirt was as clean as my own, I said, as soon as I was alone with the doctor, "You are rather emphatic about a spotless shirt"; but the doctor said that it was only a "front"—that the man must have worn his shirt for six months, it was as black as the hack of the chimney. So you see that though the patient was desirous of being thought clean, he did not care for cleanliness himself. A real love for anything is the beginning of culture, and is a stimulus to the creative artist; but a pretended love is merely a blighting curse; to love plainness is the honest confession of insensibility; to love dignified or elegant simplicity is to love the very highest form of art. I would fain see every man having his own house built to meet his own requirements, both of arrangement and beauty, and not living like a soldier-crah in the left-off shell of some one else. And that he should at least have something put on it that is interesting to him, and have this done by a good sculptor, or a good painter, an episode of his life, a family tradition, or something natural that he loves, he it had a dog, a cat, a sparrow, or a flower. There is one thing we may all desire, and which applies, not only to architecture, but to all the fine arts, viz.—to have art-schools in all the large towns,—not drawing-schools only, but the art itself, flavoured by the genius of the place. As the French sometimes say in praise of one of their wines, "It has a smack of its native soil." We do not want everything to have the London flavour. In Italy, we have the Tuscan, Umbrian, Venetian, Lombard, and Bolognese schools,—nay, even Florentine and Siennese schools,—and why should we not have the schools of Nottingham and Liverpool, York and Manchester? Separate schools would cause a generous rivalry, which would not be without its effect. There are two theories of government at each end of the scale, one in which government does everything and possesses everything, down to the penny steamboats and the apple-stalls; the other, which confines it to external and internal police and the enforcement of contracts; and I think, as a rule, our prayer should be that of the French merchants, "Let us alone." Still there are certain things to be done and certain contributions to be made by all for the good of all, and this the Government alone can enforce. Every Government should at least desire to have the people free, virtuous and healthy, courageous, industrious, and happy. Doubtless the way of obtaining these six desirable conditions is being shown in

the other sections, but we want more; we want every one of our people to be raised by the exercise and enjoyment of all his higher faculties, and for the sake of the nation we want all our human raw material to be worked up. When we use the word "free" as applied to costly things, we know that nothing is free but light and air, and few of us can get our duo allowance of these; what we mean is, that they must be bought by national co-operation, every man paying his quota, and every one getting his full enjoyment. So I say we want free parks and gardens, free lending and reference libraries, free picture-galleries and museums, and,—I suppose the musician will say,—free music. And that these may be used and enjoyed by the bulk of the nation they must be open on the one day in the week when the people are free from toil. You may open all our national churches from sunrise to sunset the six days they are now shut. I, for one, rather envy the Moslem and the Roman Catholic their freedom to enter their churches and mosques when they like, and to pray if they please, while we poor Protestants can only do so for a few hours on Sunday. I would add fine contemporary buildings and monuments enriched by the sculptor and painter. Such things stimulate emulation more than any number of triumphs of by-gone days, and can be seen Sundays and week-days alike. The Government does something for architecture when it picks out the best architect for a public building, and it did something once for painting and sculpture when it had the frescoes and statues at the Houses of Parliament executed; but, as far as I know, it has never done anything for poetry, for music, or for the drama. It must be a great incentive to excellence to have a poem declaimed, an oratorio played, or a drama acted before an assembled people, and with all the excellence and appropriate surroundings that a nation only can afford. We have colonies and dependencies in Asia, Africa, America, and Australia, and nothing is more wanted than a means by which all these branches of the English race may be knit together. Our one national holiday is the Derby Day, devoted to horses alone. Is it too much to suppose that we might have combined with it for one week, and with the betting-ring suppressed, a festival to celebrate the highest achievements of men? If the ancient Greeks could do it, why could not the England of today?

#### FILLING THE PORES OF WOOD.

STAINED or painted woodwork is finally submitted to the various treatments known as polishing, rubbing (with wax), or lacquering or japanning. Those processes are intended, on the one hand, to beautify the work or to give lustre to it, and, on the other, to protect its surface against exterior injurious influences, consequently to impart to it greater durability. By closing the pores of the wood it becomes smoother, and is capable of greater resistance. Very much depends upon an efficient closure of the pores, also upon the operation being effected with the proper substances. The latter should harden within a few hours, and should not undergo any changes from exterior influences during their transformation which might have injurious effects upon the layer of polish, lacquer, or wax. Although in recent times means have been placed at the disposal of the workman which meet all these evils, in nearly every one of our joinery and cabinet-making shops the old method of filling the pores,—smoothing or polishing with linseed oil and pumice-stone,—is still practised. Our joiners and cabinetmakers of the old school will have nothing to do with newer methods, because their shops are worked on the old system of smoothing with oil; it is said that the wood becomes brighter through the oil entering it, and the system permits them to dispense with the more chlorate treatment with plane, scraper, glass-paper, and Dutch rush, which is indispensable in the methods of filling the pores, as described below, and which we copy from an article on the subject in the *Deutsche Tischler-Zeitung*.

The writer of the paper, Herr L. E. Andés, of Vienna, admits that, as regards the polish of the obtained surface, smoothing with oil has the advantage. On the other hand, it is a well-known fact that work thus prepared loses in appearance in a very short time by the sweating of the oil. The outside smooth surface becomes rough and dead, loses its polish, the

percolating, not yet dried, and consequently still sticky oil absorbs dust, and the furniture, &c., loses in colour, and a repetition of the polishing process becomes necessary. As a matter of fact, the sweating of the oil cannot be prevented by this method, for the fine particles of pumice-stone which, mixed with the oil, fill up the pores of the wood, retain the fat substance. The wood itself has eagerly absorbed all the oil, its cells are deeply filled with it; and when the linseed oil, if exposed to the influence of the air, dries only after six to eight days, it is quite out of the question to speak of a solidification of the whole. Now, it is generally the custom to begin with polishing directly after smoothing. Thus we apply the polish upon a surface not yet dry, polish it, and only then, when this latter operation is completed, we give to the oil, which now is no longer in contact with the air, an opportunity for drying, by standing in a warm room, &c.; but in course of time, the oil below the layer of shellac begins to dry up without exposure to heat; the shellac layer is torn into numerous fine cracks and turns rough, while at the same time the fine particles of pumice-stone are beginning to come out. The still sticky oil absorbs all dust, the pumice-stone particles become more prominent, and we have, as the result, instead of the desired shining surface which should remain smooth, a rough, dirty crust, which disfigures our furniture.

The durability of the lustre and the smooth surface can be guaranteed only if the wood, after smoothing with oil, is left for six months before being polished. By that time the putty formed of the pumice-stone and linseed oil is perfectly dried up, and the polish then applied is lasting, and the sweating of the oil prevented. But as, under present conditions, it is almost impossible to let work stand so long, it is highly desirable that means should be found by which we might be able to dispense with oil altogether. Herr Louis Köhler, of Giessen, suggests the following method:—"Polishing is still the same operation that it was 100 years ago. The polish has also remained the same, without essential improvement. And yet the whole process is very faulty and imperfect, and as long as it is pursued, the exudation of the oil and the deadening of the best work cannot be avoided. If no oil is to sweat out of the wood, none must be put in; the latter, however, is done on a large scale with the old procedure, consequently the work is spoiled. Now, instead of smoothing the wood with oil and pumice-stone, it is only necessary, after the piece of work is completely finished, to put on the lacquer with a so-called badger brush. This is done quickly because the lacquer (a spirit lac) dries at once. Successive coats of lac are applied until a so-called ground is obtained. Porous woods, of course, require more lacquering than close-grained kinds. If the work is well performed, the whole is now smoothed with fine pumice stone, rotten stone, or hartshorn. The polishing is proceeded with, but without oil, only a little of the latter being used for finishing."

This procedure effects one thing. The pores are completely sealed up with shellac, and as no oil can enter, none can exude in course of time. Spirit lac, however, is expensive, and we must therefore try to employ other materials which close the pores of wood by a simple and cheap process. This may be attained by sizing with glue-water, by coating with starch-paste, or by filling the pores of the wood by the American method, with "wood-filler." By either of the three methods the pores of the wood are completely filled, and as no oil enters the wood, none can come out afterwards. Sizing with glue-water is almost exclusively employed for soft woods, the size being applied three or four times with a brush. After drying, raised fibres of the wood are rubbed off with fine glass-paper, and polishing or japanning is proceeded with in the usual manner. Coating with starch-paste is much more advantageous than sizing, starch once dried being perfectly impervious to exterior influences. A moderately thick paste is prepared by pouring and stirring in boiling water a dough made of powdered starch and cold water. The wood is coated as required with a brush, and then treated as usual.

The most perfect process of filling the pores of wood has come to us from America. At the Philadelphia Exhibition of 1876 articles of wood were shown for the first time the almost startling smoothness and high lustre of which astonished all experts, the latter properties being enhanced by the contrast supplied by

objects, japanned and polished in the usual manner, exhibited by the side of them. The procedure by which this extraordinary smoothness and, at the same time, extremely small consumption of polish or lacquer are attained is a very simple one, and is based upon a mechanical closing of the pores of the wood by a composition of certain ingredients, hitherto the property of the inventor. This composition, termed "wood-filler," is supplied in closed tins as a thick, sticky mass, and in applying it the quantity to be used is thinned to the consistency of ordinary varnish by adding good turpentine. The mass thus prepared is put on to the finished woodwork with a moderately stiff brush, and left to coagulate. When this coating, from a shiny appearance, becomes dull, the mass is rubbed across the grain of the wood and well into it with a handful of wood shavings or a suitable piece of wood, at the smooth bottom of which a piece of stout leather has been fastened. Care must be taken that everything on the wood is rubbed clean off, only the "filler" remaining in the pores. The wood thus prepared is left to dry for the space of eight hours, this being quite long enough to harden the filler. The latter is also said to act as a preservative of the wood, as it is not attacked by the influence of the atmosphere, nor by chemicals. After the hardening of the filler, the wood is once more well rubbed with glass paper, and the polishing or lacquering may be at once proceeded with. Less polish, time, and labour are said to be required than with the usual method; no sweating of oil takes place, as none has been absorbed by the wood. The lustre is, at the same time, most remarkable; there is a glassy surface; its durability is stated to be unlimited.

The American wood-filler is supplied in two colours,—white for light woods, brown for dark woods. Any shade may be produced by a corresponding blending of the two. The white wood-filler consists of one part by weight of pulverised starch, one part of barytes, and one-sixth part of dryer; the dark filler, of the same materials, with the addition of one-half part of brown. The finely-ground dry substances are well mixed with the dryer, rubbed down fine in a colour-braying machine, and are now, as thinned with turpentine,—ready for application as "wood-filler."

#### THE FLOORING OF COLOGNE CATHEDRAL.

This question has for a long time occupied the attention of the cathedral authorities, and, although public notice has not been taken of the fact, experiments have been carried on in a small portion of the northern nave, which has been enclosed for that purpose. Looking at the matter from a theoretical point of view, the *Cologne Gazette* remarks that the principle of Gothic architecture, which introduced pillars instead of wall-surfaces, tended to encourage plastic instead of pictorial ornamentation as an adjunct of ecclesiastical architecture. Polychromatic and mosaic effects were gradually banished, and the Chapter is reminded that, however appropriate a flooring in a carpet-pattern might be in a church built in the Roman style, such an arrangement would be out of place in such a representative monument of Gothic architecture as the Cathedral of Cologne. The importance of uniformity between the general ideas which pervade the architecture of the cathedral and its flooring is urged in the remarks made. It is maintained, however, that with proper limitations as to colouring and style of design, an ornamental flooring is not out of place. St. Bernard used to protest against the flooring of churches containing representations of a sacred character which would be subjected to the desecration of being trodden upon. The *Cologne Gazette* is of opinion that this argument is liable to be carried to excess, for there is never any scruple in exposing the images of saints to all the winds of heaven on the exterior of a church. It is urged that the stained-glass windows point to the necessity of the flooring not being entirely devoid of ornament, and as a limitation of the extent of pictorial decoration allowable in such a case, it is remarked that the figures should never become plastic, or apparently rise from the surface.

As to the material for the flooring (apart from the question of its ornamentation), none of the various plans suggested seem to have

met with universal approval. Marble, sandstone, and ceramic ware are the three principal substances between which a choice may be said to lie. Marble is practically excluded, from the fact that its costly nature would only render its employment excessive on the ground of the dignity of the purpose for which it is used. Thus there only remain stone or dull unglazed tiles, and a combination of the two is suggested as a possible means of solving the difficulty.

The plan which is now before the chapter is nominally an improvement upon one designed in June, 1881, the drawings of which do not appear to bear any signature. The improvements do not seem to have any practical value. A queered design of the commonest kind is (according to the *Cologne Gazette*) the foundation of this plan, and it is remarked that it is of a character which would be condemned if suggested for a railway station or a market. It is stated that this plan is designed to be carried out in marble. It is urged that a thorough examination by competent authorities of the entire question is absolutely necessary.

#### TECHNICAL SCHOOLS.

MR. WILLIAM WOODALL, M.P., in concluding his address as president of the Education Department of the Social Science Congress at Nottingham, said:—I must now ask leave to return to the pupils of the primary schools, for whom we have seen provision made up to the time when, by age or by compliance with the educational conditions, they leave to take their part in industrial occupations or the other duties of life. With a large proportion of these, as is well known, the leaving school is equivalent not merely to the discontinuance of a study, but to the loss of the major part of what has been there acquired. No view of our subject is more worthy of careful and earnest thought than that which prompts us to take steps which will make permanent the acquisitions and the good influence of the school, and to devise some way by which the zest for knowledge may be strengthened, and continuity of instruction be unbroken. In some Continental countries children are allowed to go into employment at twelve, on condition of their attending the *Fort Bildung Schule* until they reach sixteen. But whether compulsory attendance is enforced or not, throughout Germany the necessity for these Continuation Schools is universally felt by the authorities, and they are greatly appreciated by the people. There is much diversity in their character, and the titles by which they are known; sometimes the classes are held on two half-days a week, sometimes as Sunday schools, generally in the evenings, and in the Communal Primary School Buildings. They undoubtedly serve useful purposes in preventing the waste of the labour and expense incurred in primary instruction, they carry on pupils to the age when they are more likely to realise for themselves the practical value of knowledge, and apparently they prepare their pupils, by cultivating in them the habit and taste which find profitable exercise in the various technical schools which are now exciting so much interest. The experience of our English Mechanics' Institutions has been that an interval of some three years usually elapses between the time at which a boy leaves his day school and that at which he is prompted to join an evening class. The gap finds him without the controlling restraints which in former days were part of the discipline of apprenticeship. He is in the possession of new freedom and new appetites, and exposed to mischievous influences against which he is as yet unarm'd by the knowledge he is destined to acquire only by costly experience. The filling of this gap is the problem which has exercised, not without success, the minds of many earnest people, and nowhere more than in this good town of Nottingham. Hitherto the Government aid given to night schools was limited to payments for instruction in the "three Rs." In their time these evening classes have been of considerable utility to those who had to lament the neglect they had experienced in their early days. But, happily, this class is steadily disappearing, and under these circumstances the Government have wisely remodelled the provisions of the Code affecting night-classes, and grants are now to be paid in aid of teaching in the class and specific subjects, as well as in

the higher elementary standards. The concession is a most important one, and the changes are avowedly for the purpose of supplementing the work of the day schools. These new night schools ought now to be made to serve, in conjunction with other classes diversified according to the occupations and wants of different localities, the purpose of the *Fort Bildung Schulen* of Germany. Obviously, too, these classes ought to be able to earn grants from the Science and Art Department, and every such school should be the nucleus of a group of technical classes, such as those which, to their honour, the representatives of the local trade unions, in concert with the educationists of Nottingham, are endeavouring to establish here for training, as they express it, "both the mind and hand of all persons engaged in handicraft trades, so as to make them intelligent and skilful workmen." In company with my colleagues the members of the Royal Commission appointed to inquire into the subject of technical instruction, and in discharge of the duty confided to us, it has been my privilege to visit many foreign countries and to see much of what is being done on the Continent. You will not expect me to anticipate in any statement here the report which will be made to Parliament when our investigations have been completed. But there are facts which are open to the view of every intelligent observer. It is impossible to over-estimate the zeal and activity which is everywhere apparent, or the vigorous and costly efforts which are being made to satisfy the eager demand, or to stimulate the desire for instruction. The preliminary Report of the Commission presented last February will have testified to the progress which France has made in recent years, and to the fact that from the commencement of the present year education in all the elementary schools is gratuitous, as is also the case in all the superior primary schools in which technical instruction is given or trades are taught. The action taken by the State is well seconded by the municipalities, by other local bodies, and by trade syndicates, while the religious orders engage in vigorous emulation. The expenditure, though large, is fully sanctioned by the public sentiment, and the evening classes which we visited in Paris, Lyons, Toulouse, and other prominent centres, especially those in industrial art, were generally crowded to inconvenience. Apprenticeship schools, respecting which much valuable information has been published by Mr. Sylvanus Thompson, complete the necessary training for particular trades, while in the primary schools much attention is given to drawing and modelling, and in numerous schools in Paris the boys have manual teaching in wood and iron given in large school workshops furnished with lathes, benches, &c., for the purpose. In the German States, in Italy, in Switzerland, in Belgium there are equally earnest manifestations of the value which is set upon professional and technical training for all ranks. Besides the complete graduation of schools which lead up from the primary, on the one hand by the *Gymnasium* to the University, and on the other by the *Real Schule* to the Polytechnic, there exists an infinite variety of special schools for weaving, for dyeing, for building, for mining, for clock-making, for wood-carving, for metal work, for pottery, and for art in application to other local manufactures. In parts of Switzerland the Cantonal Budget applies to education nearly one-third of the whole revenue, while the towns sustain the primary schools with great liberality. We hear much of the enormous expenditure on the military system of Germany, and it is truly large. But in some of the German States the aggregate expenditure on education will bear comparison with their quota of the German war tax. Last year the City and Guilds of London Institute published a most valuable work which ought to have been read with great interest in Nottingham, because it describes with great force as well as minuteness the system of education in a Saxon town of 90,000 population, which appears to have successfully competed with this district in one of its long-established staple trades; and because, further, it is written by a gentleman who, although now engaged in business at Chemnitz, earnestly desires the welfare of his native town of Nottingham. Mr. Felkin describes the provision for general instruction as having been provided at a cost for buildings of 153,000*l.*, while the technical school buildings have cost 88,000*l.* The cost of maintenance may be imagined when it is seen that 363 teachers are employed,

and that the fees are so low that they are no impediment to the poorest pupils. The State technical institutions and the higher weaving school there, as well as the hosiery school at Limbach close by, have beyond doubt had an enormous influence in advancing the prosperity of Chemnitz, and the recommendations which Mr. Felkin makes may well be pondered by all who are concerned in the maintenance of the industrial supremacy of our own country. I cannot leave this subject without felicitating the inhabitants of Nottingham on the efforts which they have made in the right direction, and upon the valuable assistance which they have received of 500*l.* a year through the agency of the City and Guilds of London Institute from the Drapers' Company, which I am told now subscribes 4,500*l.* a year in aiding that valuable organisation to stimulate local efforts of the description which are now being made in connexion with Nottingham College. The estimate of what is being done in other countries would be very incomplete without some reference to the influence which is exerted by the museums in which, in addition to the examples of general, artistic, or antiquarian interest, there are generally good collections of machines and models of mechanical appliances. There are also often preserved specimens of the manufactures of all countries and periods which can be supposed to be of interest to the local producer, which are carefully classified and made easily accessible to all persons concerned. At Carlsruhe, and at Nuremberg too, at this moment there are exhibited illustrations of the extent to which the teaching in the schools of design is applied by manufacturers, and which afford very convincing evidence of the essentially-practical character of that teaching, and of the familiarity of the teachers with the requirements of the local trades. In bringing this paper to a conclusion, I feel a certain sensation of regret that so much of it has apparently been devoted to considerations which may seem to appeal to merely mercenary motives. I trust, however, I shall not be misunderstood. The commercial and manufacturing supremacy of England is as essential to the influence it exercises as a great governing and civilising power as it is to the continued welfare of its own population. The stranger who visits the professional school at Rouen will find a cabinet of objects, in the centre of which is a Prussian helmet; and he will be told that this relic of the invasion of ten years ago is preserved as a reminder of the humiliation which was brought upon France by its neglect of the education which gave the Germans their superiority in war. The rapid and triumphant march of events in Egypt during the last few weeks has shown how accurately to-day we may speak of the art of war. And so in arms, in arts, in commerce, as in all the important engagements of life, hearing our part, as we are called upon to do, in a world which is ever moving at an accelerated pace, the very condition of existence is that we should adapt our institutions to the progressive condition of things, and this will we do, conscious that the effort it involves will only strengthen our sinews for any strain they may be called upon to bear in the future that is before us.

#### BYRNORŪ CHURCH.

A MEMORIAL church to the late Mr. Wynne, F.S.A., of Penrith, has just been completed at Brynŵr, near Towyn, Merionethshire, from the designs of Mr. B. Edmund Ferris, carried out by Mr. Richard Morgan, builder, of Brynŵr. The plan, it consists of a nave, 36 ft. by 29 ft. 3 in. broad, with south porch, and a chancel, 19 ft. by 15 ft. 9 in. An archway on the north side of the latter opens out into a small vestry screened off. At the west end is a massive bell-gable. The walls are built of a beautiful grey-coloured syenite, with Ruabon stone for the dressings. The roofs are covered with local blue-grey slate, with red ridge tiles. The nave has an open pitch-pine roof, with ornamental moulded trusses at intervals; and the chancel a panelled ceiling of the same wood, with carved cresting to the cornice. The nave is supplied with plain open pitch-pine benches, and English oak seats and prayer-desks to the chancel of a more ornamental character. The pulpit is of English oak, with perforated panels, standing on a base of Shropshire red sandstone. The paving is of Gwynedd tiles, arranged in patterns by the architect. The font is of Ruabon stone. The windows are glazed with quarry cathedral and clear white glass, in various ornamental devices. The heating apparatus is on the system of Porritt, of Bolton.

## SALES OF BUILDING LAND.

LAST week Messrs. Baker & Sons submitted for sale, at the Stag Inn, South Acton, the third portion of the Beaumont Park Estate, at South Acton, belonging to the National Liberal Land Company. The plots offered were seventy-five in number, some of them containing frontages of 16 ft., and others of 18 ft., with depths ranging from 64 ft. to 133 ft. There was a numerous attendance at the sale, and sixty out of the seventy-five plots offered were sold. The plots having 16 ft. frontages and 64 ft. in depth realised prices averaging 52*l.* each; those having frontages of 18 ft., with a depth of 120 ft., were sold for from 66*l.* to 70*l.* each; whilst the plots having a depth of 133 ft. realised 90*l.* each. The total proceeds of the sale amounted to about 3,200*l.*

Mr. Richard J. Collier also last week offered for sale a freehold building estate at Hendon. The property is situated close to the Hendon Station on the Midland Railway, and within a few minutes' walk of the Welsh Harp. The plots were described as having frontages to Edgware-road and the several new roads leading therefrom, and the estate was described as offering attractive sites for the erection of small residences, for which there is a great demand in the locality. The number of plots submitted was sixty-one. The number of plots submitted was thirty-four of which forty-two were sold, and a depth of from 80 ft. to 90 ft., realising prices ranging from 5*l.* to 66*l.* each. Four shop plots, with frontages of 19 ft. and a depth of 86 ft., were sold for 100*l.* each, and four other shop plots, containing a similar area, realised 90*l.* each. The entire proceeds of the sale amounted to 3,406*l.*

## ST. JOHN'S CHURCH, DÜSSELDORF.

THE new Church of St. John, Düsseldorf, of which we give an exterior view in our present issue, has been the outcome of long-continued efforts on the part of the Evangelical community of the town. So long ago as 1855 the nucleus of the building fund was formed, and twenty years later, in 1875, the building site was acquired. But the foundation-stone was laid the same year, and the church, of which Herren Kyllmann & Heyden, of Berlin, are the architects, was recently opened for public service. The style chosen by them is a blending of Gothic features with Italian Renaissance, the most striking characteristic of the building being the very elegant steeple. The exterior of the church needs no description, being well represented in our engraving. On entering the building by the vestibule under the tower, the view is a very fine one, a most striking impression being produced by the ample flow of light coming in through the broad windows. The high arches are semicircular; the ceilings, pillars, and walls are decorated by dull colouring. In the centre of the apse, which is somewhat higher than the floor of the nave, the altar, of black marble, and surrounded by a gallery in white marble, is placed. The pulpit has been placed in the nave, to the right of the altar, at the principal pillar of the intersection. The organ, flanked by the choirs, fills the whole width of the nave. Its builder is Herr E. F. Walter, of Ludwigsburg. Generous donors have provided the altar, pulpit, painted windows, a set of bells, the tower clock, &c.

## NEW BRANCH BANK AT LEEK FOR THE MANCHESTER AND LIVERPOOL DISTRICT BANKING CO., LIMITED.

THESE buildings are now approaching completion. They occupy an important site in Derby-street, the main thoroughfare of the town, and closely adjoin the old Roebuck Hotel, an interesting bit of "black and white." The frontage of the new premises, which include a commodious house for the manager, is about 80 ft. The materials used in construction are thin dark-fired red Ladder-edge bricks, with pink Roche stone dressings; the exposed timber framing and cornices, and doors and windows to the street, are of teak; the decorations in the gables are modelled in Portland cement; Broseley tiling is used for the roofs; and the windows in the main are glazed with patent plate in lead quarries. The portico has a high dado of Burmantofts thin glazed russet bricks, Roche stone dressings, and a frieze of Mr. de Morgan's tiles.

The length of the banking-room, each end of which is segmental in plan, is 48 ft.; its width, 24 ft.; and its height 15 ft. In view of the cost and great inconvenience to business of periodical renovation, this room is finished throughout in durable material which will not require it. The walls, arched, have bands of St. Sylvester marble and white marble concrete, with the moulded parts in scagliola to match the St. Sylvester. The fireplaces are furnished with dog-grates in tiled recesses, with Dove marble chimneypieces in harmony with the rest of the interior. American walnut is used for the wainscoting of the walls, the doors, and the counters and desks, which are made to the architects' designs. The panelled ceiling is of American whitewood and walnut and old-seasoned pitch-pine: it is fixed under a fire-proof concrete and iron flat, which carries the leads.

A short corridor from this room gives access to the consulting-room and the large cast-iron strong-room. In the basement there is ample accommodation for storage.

The works are being carried out in a substantial and satisfactory manner under the direction of the architects, Messrs. William Sugden & Son, Leek. The builders are Messrs. Isaac Massey & Son, of Alderley Edge; the sub-contractor for the brickwork is Mr. Broadhurst; for the stone-masonry, Mr. Leadbetter; and for the plumbing, &c., Mr. Edwin Phillips, of Leek. The heating (by warmed air) has been entrusted to Messrs. Haden, of Manchester, and in conjunction with them a scheme of general ventilation has been arranged. Mr. Roddis, of Birmingham, and Mr. Millson, of Manchester, are carving the wood and stone; and Messrs. Collinson & Lock are modelling the decorative plaster-work,—all to full detail drawings by the architects.

## EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY COMPETITION.

WE illustrate this week the design submitted in this competition by Mr. H. H. Bridgman, architect, of 42, Poultry.

It consists of a block of buildings extending nearly the whole length of the site (which fronts the sea, immediately opposite the pier), a length of 198 ft., and on an average 28 ft. deep, with the exception of two projected portions, which take up the limited building line, and is five stories in height, the lower story being sunk about 4 ft. only below the Parade level. The 24 ft. wards, with cross-ventilation, have been adopted for all wards of more than three patients, without exception. The general arrangement of the building is: administrative department and children in the centre, men left, and women right. There are two staircases, with an ambulance lift within each. The kitchen, stores, and servants' rooms are in the rear, and nurses' dormitories on the top. Two airing-yards, 40 ft. by 30 ft. each, clear space, are arranged for in the rear, giving a compact whole, airy and well lighted, and ensuring perfect classification and facility of administration.

The basement or sub-ground floor is approached by a short flight of six steps, and contains in the front centre the out-patients' waiting-hall, 48 ft. by 28 ft. 6 in., entered from the open areas, and seated to accommodate eighty patients, with physicians' and surgeons' rooms, &c., on either side, the dispensary being in the middle, adjoining the waiting-hall. The medicines are sent up to the various wards by light lifts. The two ends of this story contain wards for male and female contagious cases, four of each sex, with day-room, nurse's room, bath, water-closets, &c., attached. These wards have no communication whatever with the interior of the building, but are quite isolated, and entered from the outside. 6 ft. in height of this story being above the street level, perfect through-ventilation is secured. In the rear extreme corner at one end, and detached, are provided the mortuary, *post-mortem*, and ambulance rooms, whilst in the opposite back corner, also detached, are the workshop, coffin-store, and disinfecting house. From each staircase there is an approach to the kitchen apartments, and the staircase lifts are used at meal-times for speedily supplying the various wards with food. The kitchen is 32 ft. by 20 ft., and 19 ft. high, lighted on two sides, and having two skylights for carrying off the heat and steam. On one side of the kitchen are placed the larder, pantry, and wash-up room, and on the other side

the general scullery, bread-room, and china-stores; the coal-stores, water-closets, &c., and ovens, projecting from the kitchen, being placed under the footpath of the back road. The large open spaces above referred to ensure ample air space all round. In a mezzanine story over the side rooms are the general store-rooms of the infirmary.

The ground-floor is 6 ft. above the Parade level, and approached by a flight of steps and through the principal entrance and hall. Immediately opposite the entrance, the operating-room, 22 ft. by 18 ft., is entered; the casualty-rooms, surgeon's appliances room, &c., adjoin. In the front, on one side of the entrance, are the committee-room, &c., and on the other side the office and surgeon's house, whilst the ends of this floor are occupied by accident wards, ten and eight of each sex, with nurses' rooms, baths, water-closets, &c., the latter projecting at the ends. From the staircases on this floor is approached the nurses' general dining-room, immediately over the kitchen, and which is supplied by small lifts direct. On this level also are all the male and female servants' bedrooms.

The centre portion of the first floor contains twelve children, six of each sex, with a nurses' room; bath and water-closets (built out) adjoin for each. The ends of this floor are occupied by two general wards, ten and eight of each sex, with nurses' rooms, baths, and water-closets, as below; whilst two convalescent wards, 24 ft. by 16 ft., for each sex, occupy the projections.

The second floor contains, in the centre, special wards for six men and six women, with nurses' rooms, baths, and water-closets, as before. The ends are used as general wards, eight of each sex, and the arrangement below is repeated, excepting that on the men's side there is also a separate ward for two, whilst on the women's side are the matron's rooms.

The third floor is a repetition of the second floor, excepting that the eye wards are on this floor, and the centre portion is taken up with nurses' dormitories.

It will thus be seen that every section overlooks the sea, balconies being provided on all floors to enable the patients, when convalescent, to enjoy the full benefit of the sea air. Each section, without exception, has its own nurses' room, baths, and water-closets. The latter are in all cases built out and cut off by an intervening lobby, and are adjacent to their respective wards. The staircases pass up close to the ward doors, and the lifts within them extend to every story. The contagious cases are quite isolated. The out-door patients have no communication with the indoor, and the kitchen departments are apart, though easily controlled,—all being important points for consideration.

The principal elevation, which is a simple and free adaptation of Renaissance in red brick and stone, is broken up by two projections dividing the building into three bays, the roof being rather high-pitched, and at the intersections are two open turrets utilised as ventilators for the staircases, whilst there is a slight break in the centre, having an elliptic and rusticated arched entrance, supporting a balcony which runs the entire length between the projections. The centre is crowned with a pierced pediment resting on small fluted piers, with side scrolls and carved work. Balconies occur in all instances, except at the projections. The building itself is designed to accommodate 108 patients, at an estimated cost, including the allowed 10 per cent. margin, of 12,110*l.*, or about 112*l.* per patient.

## NEW ROMAN CATHOLIC ORPHANAGE, HOMERTON.

THIS orphanage, of which view and plans are given, is for the reception of 120 Catholic girls from the workhouses, and is being erected at the expense of the "Sister Servants of the Sacred Heart of Jesus," a community whose services are devoted exclusively to the poor and sick, visiting and nursing them night and day at their own homes gratuitously without distinction of religion.

As shown by the plans, the new buildings for the children are attached to an old house which is used by the community for their convent, and which stands in about an acre of garden very advantageously situated, with frontages to Hasset and Balance roads,—the general orphanage facing the latter, and the infirmary separated by the convent, facing the former.

ST. JOHN'S CHURCH, DÜSSELDORF.—HERREN KYLLMANN AND HEYDEN, BERLIN, ARCHITECTS.

*New BRANCH BANK Buildings at LEEK for the  
MANCHESTER and LIVERPOOL DISTRICT BANKING COMPANY  
Limited*

LEEK, JUNE 1882.

THE BUILDER, OCTOBER 7, 1882.

Wynne and Sons, Printers, 27, Queen St.

EAST SUSSEX, HASTINGS, AND ST. LEONARD'S INFIRMARY.—MR. H. H. BRIDGMAN'S DESIGN.

111

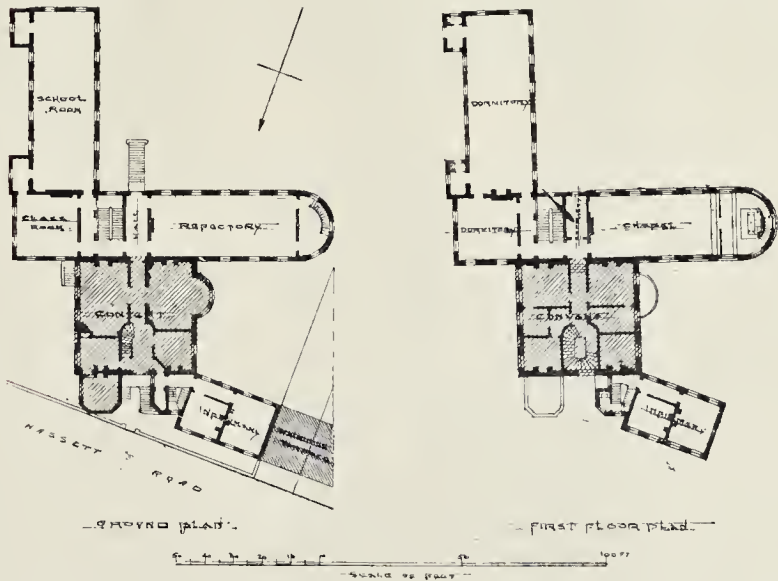

NEW ROMAN CATHOLIC ORPHANAGE, HOMERTON.—MR. C. G. WRAY, ARCHITECT.

On the basement floor, the children are provided with a play-room, 62 ft. by 21 ft., opening out into a play-ground, out of which is an inclosed water-closet yard, containing a range of sixteen of Bowes, Scott, & Read's patent self-clearing trough-closets. The lavatory and bath-room are also on this floor, the rest of which is taken up by the laundry, kitchen, larder, store-room and other usual offices. On the ground-floor is a school-room, 62 ft. by 21 ft., class-room 21 ft. square, and refectory also 62 ft. by 21 ft., with sewing-room in the apse at the end, and two rooms for the infirmary.

On the first floor are two dormitories of the size of the school and class rooms respectively, and a chapel of the size of the refectory, plus the apse at end, with a sacristy attached, and two rooms for the infirmary.

On the second floor are two dormitories and two rooms for the infirmary similar to those on the first floor; and the chapel, which extends to the height of two floors, is provided with an organ-gallery over the sacristy, and a gallery for the sick opening out of one of the rooms of the convent.

On the roof-floor are arranged convenient clothes, linen, and box rooms.

The school and class rooms are each provided with hook-rooms, and the dormitories with night water-closets in an adjoining building, having external openings on three sides for free ventilation. The infirmary is also provided with water-closets on each floor similarly ventilated, and with bath-room and surgery, &c. The rest of the accommodation is devoted to the convent use.

The height of the rooms throughout is 12 ft.,

and besides the windows they are ventilated by Sherringham's ventilators placed between the windows in each wall. The interior of the chapel is 26 ft. in height to the wall-plate, and has a quasi hammer-beam roof with moulded brackets springing from stone corbels, the ceiling being lined with V-jointed matchboarding, and formed into panels with moulded ribs. The windows are glazed with cathedral glass in tints.

The elevation has been made of plain design to accord with the purpose for which the building is intended, the materials used being picked stock bricks with red brick bands for the facings, York stone sills, and slate roofs.

Messrs. Perry & Co., of Tredgar Works, Bow, are the contractors, Messrs. Fraser & Fraser, of Bromley-by-Bow, supplying the laundry, baths, and lavatory fittings. Mr. C. G. Wray, of London, is the architect.

RECENT SANITARY WORK AT  
NEWCASTLE-ON-TYNE.

From a paper read to the congress of the Sanitary Institute by Dr. H. E. Armstrong, Medical Officer of Health, on the sanitary history of the town, we take the following:—

By the Newcastle Improvement Act, 1865, the Corporation obtained various sanitary powers, which, since that time, have not been allowed to lie dormant. Two years after the passing of the Act, several important sanitary reports were presented to the Town Council. From one of these,—the work of a committee under the presidency of Ald. Wilson, the chairman of the present Sanitary Committee,—it is evident that energetic action was then taken to put in force the different provisions of the Act for the protection of the public health. Thus,—under the powers enabling the Corporation to raise in advance the moneys required for paving, sewerage, &c., a large number of previously defective streets were put in good order; the sanitary staff was permanently increased; active steps were taken to prevent overcrowding; upwards of 500 unhealthy dwellings were closed in less than two years, and to meet the difficulty of the persons removed from their homes, rooms were provided elsewhere by the committee: about a tenth of the most unhealthy of the dwellings before mentioned were purchased and pulled down; a temporary hospital, in anticipation of cholera, was erected on the town-moor, and a disused chapel in Forster-street, fitted up with beds for the same purpose, was soon afterwards successfully employed for the reception of cases of scarlet fever. A large special staff was also organised and engaged for a considerable period under the extensive provisions of the Sanitary Act of 1866, the town being divided into districts for the purpose. The ashpits, previously cleansed at the expense of the owners, were now cleansed out of the rates; vigorous measures were taken to purify tenement and other property, &c. The report shows that, at that time, upwards of 23,000 rooms, representing the dwellings of 55,000 persons, or half the population, were inspected, of which one-eighth were found to be without the means of good ventilation; the same proportion were without water; one-fifth were without privacy accommodation; two-thirds only of the houses had good drainage, and one-eighth had none at all; nearly 8,000 persons lived in rooms yielding less than 300 cubic feet per person. The committee, among other conclusions, expressed their conviction that, for the cure of many of the sanitary evils of habitations of the lower classes, one remedy only would be effectual, the provision of other accommodation, the opening out of thoroughfares, and the demolition of habitations incapable of being put into proper sanitary condition. This opinion was given eight years before the passing of the Artisans and Labourers' Dwellings Act of 1875, of which it is the foreshadow. At the time of the report referred to, the annual death-rate of Newcastle was 32.3 per 1,000. It has since fallen gradually to 21.7 last year. Five years after this saw the birth of the Public Health Act of 1872, and in the following year, Newcastle, in common with other urban and rural districts throughout the country, had a medical officer of health. Of the doings of this functionary it becomes not me to speak. The proceedings, since his appointment, for the improvement of the dwellings of the poor, the prevention of disease and the sanitary benefit of the inhabitants in general,—are they not written in his nine annual reports? Among matters of importance in relation to the hygienic condition of Newcastle to-day, not the least is the amount of recreation-ground open to the public. Including the Town Moor and Leazes (lands in grass, but not laid out ornamentally), and the Armstrong, Brantling, Elswick, and Leazes ornamental parks,—the exercise-ground to which the inhabitants have right of free access comprises a total area of 1,268 acres, being almost one-fourth of the entire city, and at the rate of one acre to every 114 persons,—an amount probably unequalled in any other large city or town. An official representation under the Artisans and Labourers' Dwellings Improvement Act, 1875, was made to the Corporation as the Local Authority in 1876. The areas specified in the representation were those of the New and Old Pandon Groups, the former of which has already been referred to. In support of this representation, the sanitary committee recommended the purchase of the

property of the New Pandon Group, at a cost of 26,000*l.*, for demolition of the houses thereon, and the erection of new dwellings elsewhere. The buildings were ultimately acquired and demolished under the provisions of a local Act, and, as already stated, the hollow in which they stood is now filled up. A large proportion of the property in the Old Pandon Group has also been dealt with under the same power. Since the passing of the Newcastle-upon-Tyne Improvement Act, 1865, the cost of the different sanitary works executed by the borough engineer has amounted to upwards of half a million sterling, and included the following:—

Sewering .....	£74,583
Flagging and paving .....	172,370
Street watering .....	14,349
Scavenging .....	102,839
Asphalt cleansing .....	104,400
Other sanitary works.....	52,895
Total .....	£521,496

The powers with respect to the notification of infectious diseases and other sanitary matters,—acquired by the Corporation under the Improvement Act of the present year,—are fresh in the memory of this Association. The necessity for the provision of a new sanitary hospital to meet the requirements of this populous city, in place of our ancient fever house, has for years been strongly represented by the Sanitary Committee, and, in the abstract, is pretty generally admitted by all. But the mere indication of a site for such a purpose,—and many sites have, one after another, been proposed,—has invariably met with very great opposition. Dr. Armstrong concluded by remarking that the reduction of the yearly death-rate per 1,000 of the population by ten in as many years, and the diminution of typhus in the same time to one-fifth its prevalence in the corresponding period immediately before, are tangible results of their more than Herculean labours.

PLANS AND PLANNING.

THIS was the subject of the public introductory lecture (delivered on Wednesday evening last) to Professor Roger Smith's courses at University College (Session 1882-83) on Architecture, Construction, and Modern Practice. Planning, the lecturer observed, was one of the radical elements,—he might almost say the foundation-stone,—of all architecture. A plan was a map of a building as it would appear if everything above a certain level were removed. In other words, it represented the floor of the building, and, to a certain extent, the walls and the openings therein. The plan of the principal floor was the most important drawing made when the drawings for a building about to be erected were prepared, for upon it the success of the building mainly depended, not only as to matters of contrivance, but in regard to architectural effect. All buildings, reduced to their simplest elements, contained never more than six, sometimes only four parts. The floor, walls, roof, and openings were the four essentials of every building. If to these were added columns and ornaments, there were thus found to be six elementary groups of things, all or some of which went to make up every building. Although the plan was mainly intended to represent or map out the floor of a building, it also represented, as he had said, the walls and the openings, and at the same time indicated, to those who knew how to read it, the method of roofing. It was so seldom that opportunity offered for thinking out the nature of things that many young architects who were engaged on plans believed themselves to be occupied in arranging the walls of the buildings, whereas they were really arranging the floor,—a work which, although the least recognised, was perhaps the most important which the architect had to perform, inasmuch as it involved the disposition of the site to the best advantage. The first attempt to group or classify plans would show that they were comprised in two great main classes or divisions, which, for want of better terminology, he should distinguish as single and complex plans. What he called single plans were those of buildings which consisted in the main of one interior bounded on all sides by the external walls. On the other hand, what he designated as complex plans were those of buildings which consisted of a number of separate parts welded together into one whole. The single plan, then, was one with an undivided floor, while the

complex plan was one in which the floor was divided into several spaces. Buildings with single plans were, and always had been, those which possessed the highest merit as works of architecture: hence St. Paul's and Westminster Abbey claimed higher rank than the Bank of England or the Houses of Parliament. The greatest buildings of the world were those which were planned as single structures. The Egyptian and Assyrian temples were illustrations of complex planning, those buildings being made up of a number of parts; but when we came to the Greeks,—the greatest of all architects, and the foremost of all artists,—we found that their great buildings were almost all single in plan, and very simple. As a work of architectural art the Greek temple took the highest rank. The Romans erected buildings which were both single and complex in plan, but judging of their works from what remained, we justly regarded the Pantheon and the Coliseum,—both single plan buildings,—as the finest specimens of Roman architecture. The Parthenon at Athens might be taken as a typical example of the great series of temples erected by the Greeks and Greek colonists. Here we had a floor space of very moderate size, divided into two chambers, in the larger of which the figure of the goddess was placed. These chambers were enclosed by massive walls, and there were indications of internal columns. The peristyle, extended at each end so as to form a deep portico, and the stylobate, extending all round the building, were elements of grandeur in the plan. The exterior of the temple was most carefully studied and richly adorned. We were, for the most part, ignorant of what the appearance of the interior must have been, but however beautiful or highly decorated, there was little reason to suppose that it was at all so powerfully impressive as the exterior. A noteworthy feature in the plan of the temple was the absence of openings, which led to the inference that the temple was lighted from the top, an inference supported by the presence of the interior columns referred to. The absence of outward thrust by the roof was indicated by the disposition of the columns of the peristyle in relation to each other; these were among other points clearly indicated by the plan. The Pantheon at Rome afforded another notable instance of a single plan. Even were the vast dome of the building non-existent, the great thickness of the walls, and the absence of columns in the interior, would indicate the method of roofing, while the absence of openings in the walls would suggest that the interior was lighted from above. The ground-plan of Westminster Abbey, or of any other great Christian church, afforded another type of single plan, in striking contrast to that of the Pantheon. The clustered pier-shafts, with buttresses to the walls opposite them, would, in the absence of the roof, indicate to the architect, or to any one able to read a plan, that the roof was vaulted. The apsidal east end would show him how that part of the building had been influenced by French examples. The large amount of window-space in Henry VII.'s Chapel would indicate that the architect was desirous of obtaining as much space as possible for stained glass. Westminster Abbey was a single instance, but a very perfect one, of the planning of Gothic churches of large size. Another group of single plans comprised those which characterised the Christian churches of the Greek or Eastern communion, and of which St. Sophia at Constantinople and St. Mark's at Venice were well-known typical examples. In these plans the aim had been to get a large central space roofed in by a dome, surrounded by a number of smaller spaces roofed by smaller domes. Suggested by these plans were those of St. Peter's at Rome, our own St. Paul's as carried out by Wren, and Wren's first plan for St. Paul's. Wren appeared to have attached great importance to securing uninterupted vistas along the nave and choir aisles across the transepts, and in order to do this he had to plant his dome on eight piers. In St. Peter's at Rome the dome was carried on four very massive piers only, but these piers had necessarily to be so placed as to destroy the aisle vistas across the transepts. Although this was to some extent a disadvantage, it was, perhaps, preferable to the method adopted by Wren, who seemed to carry his idea too far. Had he followed the same course as that pursued in St. Peter's, the nave of our metropolitan cathedral would not have that appearance of narrowness and crampedness in propor-

tion to the rest of the building, which was noticeable. Passing to the consideration of specimens of complex planning, Professor Smith instanced the plan of the Egyptian temples, specially mentioning and describing that at Carnae, the Assyrian palaces explored by Layard and others, the Baths of Caracalla at Rome, and, as a typical Roman dwelling, the so-called house of Pansa at Pompeii. When civilisation was thrown back by the destruction of the Roman empire, the need for complexly-planned buildings did not assert itself for a long time, but gradually the wants of the great monastic houses, and the requirements of the occupants of castles and palaces, led to a development of complex planning which had been carried on through the seventeenth and eighteenth centuries down to the present time with continually increasing demands on the skill of the architect. For Vieux must be claimed merit of a high order for plans of domestic buildings, such as Chelsea and Greenwich Hospitals, and still more so for the Palace at Whitehall, of which the Banqueting Hall,—now the Chapel Royal,—was the only portion built. The planning of our ordinary dwelling-houses was necessarily complex, the problem being to provide for continually-varying requirements on sites which, especially in towns, were usually restricted in size and aspect, and very often irregular in shape. The disposition of an adequate staircase in the least possible space was one very important test of skill in house-planning, but this was a kind of skill in which modern French architects excelled. The skill in planning shown by Sir Charles Barry, Mr. E. M. Barry, Mr. Street, and Mr. Waterhouse having been remarked upon, and reference made to the plans of the great public and municipal buildings erected by those distinguished architects, the lecturer referred to the skill in domestic planning shown by the late Mr. George Somers Clarke. Modern requirements, he went on to point out, had created many occasions for the architect to distinguish himself by ingenuity and contrivance in planning the various institutions, schools, colleges, &c., which had been erected and were being erected on all hands. In some of these public and semi-public buildings, such as prisons, work-houses, &c., and in private buildings, such as factories, warehouses, &c., there would at first sight appear to be little scope for studying anything but utility, but, although in many such buildings ingenuity in planning had been divorced from artistic treatment, there were many others in which the two were combined. There was no royal road to planning. Success in it was only to be obtained by repeated efforts. No man was by nature a good hand at a plan. It was essentially an artificial accomplishment, which, like swimming or riding a bicycle, had to be acquired. In conclusion, the lecturer urged his hearers to endeavour to form a proper estimate of the value to an architect of the power to plan. There was, indeed, little danger of exaggerating the value of the plan as an element in architectural design, for it was impossible to arrive at a good design in any other way than by making a good plan. As he had said at the outset, the plan was the foundation of every architectural design, hence the necessity that the architect should take thought to make the plan a good one. The effect of the superstructure would depend upon his knowledge in acquiring architectural details, and upon his success in properly using them.

#### THE DRAINAGE AT FRANKFORT.

SIR,—The description of the drainage of Frankfort-on-the-Main, which appeared in your issue of September 23 [p. 388], would, I have no doubt, be interesting to many of your readers, but to some of them it would, I imagine, seem strange that no mention was made of my name in connexion with it. The facts used in the article are taken from the report of Mr. Lindley, of May, 1877, and if the author of the article had translated the introductory paragraph to the statistics he has used on page 2 of the report (copy of which I enclose herewith) it would not have been necessary for me to trouble you with any explanation. I have no wish to enter into any controversy, and would have preferred asking the writer of the article to correct the omission, of which, from a want of knowledge of the full history of the works in question, he has probably unintentionally been guilty. The Com-

mission alluded to in the article consisted of four engineers, namely, Messrs. Blonden, Eichberg, Lindley, and Wiehe, and the eminent sanitarian, Dr. Varrentrapp, their report being in favour of a system of sewerage, the leading features of which were entirely different to those of the scheme which had been prepared by the city engineer of that date, Mr. Eckhardt. Two years later, Mr. Lindley, sen., was asked to undertake the chief or consulting engineership of the work, which he did, on the condition that an acting engineer was appointed to work out the proposed scheme in detail. I was appointed to that position, and Mr. Lindley and myself entered into separate agreements with the Senate of Frankfort on January 5th, 1866, at equal salaries of 600*l.* each. Mr. Lindley undertaking to visit Frankfort two or three times a year, while my duties were to work out the scheme and correspond with him thereon, as occasion required. An office was established, and I entered upon the duties in the following April, supported by able German assistants, placed at my disposal by the authorities.

General plans, sections, and details were proceeded with as rapidly as possible, and contracts issued for materials, it having been determined to provide these for contractors undertaking the execution of the works. Details were published for all ironwork, stoneware, and other articles required, and subsequently drawings showing generally the character of the details of the works, all of which will be found to be signed by Mr. Lindley and myself, and are well known by many eminent engineers in this country, as well as on the Continent. Advertisements were issued from time to time in your valuable paper, inviting tenders, and a reference to them will bear out what I am now stating.

In 1868 I drafted regulations for the private drainage, which embraced some suggestions of Mr. Lindley's, and had, at the request of the magistrates, owing to the strong opposition met with on the part of local builders, eight sheets of drawings prepared to illustrate more precisely what was required. These regulations and details, which I was anxious to make as perfect as possible according to the ideas I then entertained (but which I had not been able to fully carry out in England), were approved by Mr. Lindley and published by the authorities, but not bearing his signature and mine, and had not been substituted by any other than I am aware of, up to the present time, except that the Town Council have modified their stringency on one or two points,—notably in reference to the original requirement of extra trapping of hono-drains outside the house, and utilising of the whole of the available fall.

One of the first things I thought desirable when the works were commenced was the continuous testing of the cement (alluded to by your contributor) as being most important and necessary where it had been determined to build all brickwork with that material. As Mr. Grant had done in London, so the testing under my directions (for which a man was specially appointed, and did nothing else) led the way to the general testing of this material, now so prevalent, well regulated, and scientifically carried on all over Germany.

In the beginning of 1869 I prepared a statement of the cost of the works executed and an estimate of the cost of those remaining to be carried out, showing a total expenditure amounting to 330,000*l.* for the whole scheme, and this was approved in February by Mr. Lindley, then, if I remember rightly, in Pesth, and submitted to and sanctioned by the Board of Works and the Town Council in the following June, and will be found signed by Mr. Lindley and myself in No. 16, volume ii., of the published Proceedings of the Town Council for 1869.

There was no such firm as Messrs. Lindley at that time, the sons now practising as a firm being then much too young, not having, in fact, I believe, left school when these works were commenced. I have not the remotest intimation that anything I may say should be construed to detract from the position which Mr. Lindley's sons have since so rapidly attained, but think that it is exceedingly unfair that a work on which I spent the best years of my life with a devotion and determination to make it what it is acknowledged to be by all who have had the opportunity of seeing and studying it, should be accredited entirely to those who are only entitled to a share of whatever credit is due to its authors.

I retired from the works in October, 1873,

after having devoted seven years and a half thereto, and the most difficult of them were completed under my immediate directions at a cost, up to that period, of 172,000*l.* Mr. Lindley retained the chief engineership, while Mr. Hallenstein, now carrying out the works I designed for, Munich, and who had been engaged on the Frankfort works from the commencement, remained as chief of the office-staff. Mr. Lindley's eldest son then entered the office, and subsequently, on the retirement of his father, about two years and a half ago, succeeded to the chief control, and continues to carry on the works on the old lines, and to extend them as the rapid increase of the city requires it.

This, I believe, is something like the true history of the engineership of those now well-known works, and I cannot but suppose that neither Mr. Lindley, senior, nor his sons, who are now also occupied with other works on the Continent, would wish to ignore the part I took in connexion with them.

I could have wished to say something about the works themselves, but must defer that to some future occasion or other opportunity; at the same time I quite expect that, if the description of them as given in the *Builder* is carefully looked into by English sanitarians, they will be inclined to criticise two points on which the works differ so widely from English works of the present day, viz., that of the direct connexion of the house-drains and admittance of all rain-water. These two points alone open up a wide field of discussion, and I am afraid there would be little hope of an agreement of opinion on the Frankfort works in reference to them. I feel sure of one thing, however, that no works will be found to be better ventilated, this essential feature of all good sewerage systems having been carried far beyond anything I am acquainted with elsewhere; and I should very much doubt whether the same amount of control over the works of private drainage as has been exercised in Frankfort has been accomplished in other towns, except some few on the Continent which have taken the Frankfort regulations as their basis, namely, Düsseldorf, Crefeld, Stuttgart, Munich, and Dortmund, with the two first of which Mr. Lindley was connected as consulting engineer, and the writer in that capacity with the three latter.

J. GORDON, Mem. Inst. C.E.

Dorough Surveyor, Leicester.

SIR,—After reading the admirable article in the *Builder* of September 25*th*, I was very much disappointed that the author of it did not mention Mr. Gordon's name. I feel sure, if Mr. Lindley had been aware that the paper was going to be published, he would have insisted that Mr. Gordon's name should be coupled with his own, as it always has been in the published plans and papers connected with the undertaking.

During the construction of the Frankfort sewerage works, professional matters called me five times to Germany; and on three of my visits I passed through Frankfort, viz., in September and November, 1870, and in March, 1872, and I then had the pleasure of thoroughly examining the sewerage works.

Knowing Mr. Gordon as I do from the time he commenced his professional career, I can speak confidently of the ability and untiring energy which he has always thrown into any work he may have had in hand; and in no work he has ever undertaken did he display more ability and greater energy than on the Frankfort sewerage works.

Robin Hood, so the tale goes, would not have a man who could not in some points beat him, and the credit given to Robin Hood's men does not detract from his own fame.

I believe Mr. Lindley, whose name is so deservedly well known, will be as proud to see honour done to those with whom he has worked in perfecting this sewerage scheme. H. U. McKIE, City Surveyor, Carlisle.

#### HASTINGS AND ST. LEONARD'S INFIRMARY COMPETITION.

SIR,—Will you allow me, through your columns, to request the competitors to favour me with their names preparatory to concerting an action in regard to the above matter. I would especially request it of "Fair Play" and your other correspondent. Letters should be addressed to Box 604, Office of "The Builder."

A CORRECTOR.

#### FERNERY.

SIR,—Having built a fernery composed of a quantity of painted "tubs," from Dorsetshire, and desirous of constructing some tanks of the same to hold fish. I have tried Portland cement, which cracks and gives way. Will any one suggest a means? Would slaying pulkling, and cement on top, do? D.

## BUILDING NOTES FROM THE WEST.

The Bristol General Hospital has just been closed for extensive alterations and repairs. The immediate cause of this step was the faulty arrangement of some of the drains connected with the institution, and a committee having been delegated to see what should be done, consulted Mr. Bassie, of London, who reported to them that, from a variety of causes, but chiefly from the direct communication of the drains with the public sewers without any ventilation, the house was full of sewer gas. He also pointed out that the water supply came from cisterns which were used for the purpose of flushing the closets, and expressed an opinion that from a sanitary point of view the building was in a dangerous condition. A thorough alteration of the drainage system was decided on, and an alteration in the mode of supplying the house with water. This necessitated closing the hospital, and it was determined at the same time to improve the ventilation of the wards, and to lay the floors with wood instead of cement, as at present. On the latter point there was some time ago a great difference of opinion, and the faculty of the institution, who then had not votes on the Board of Trustees, strongly opposed the use of cement for flooring. In part of the house, however, cement was laid down, and the committee, on which the medical staff have since been given votes, decided, though not unanimously, to lay the whole of the flooring of wood specially prepared with paraffin. Other smaller items are also to be attended to before the institution again opens its doors for the reception of patients. The estimated cost of the works is between 6,000*l.* and 7,000*l.* A member of the committee having called attention to the fact that the contract was to be given without tenders to a London contractor, the Bristol Master Builders' Association has entered a protest against this mode of procedure. The letter of the secretary to the Association said: "That a London contractor and his workmen should be appointed to do the work if he obtained it by fair competition would have provoked no feeling on the part of the tradesmen here, but what we do complain of is the fact that this appointment has been made without giving the tradesmen of Bristol the slightest chance of competing for the work, and this in the face of the knowledge the authorities must have that contributions and subscriptions, both from employers and workmen, form no mean part of the income of the institution."

At Bishopsworth parish church, in memory of the late Mr. Thos. Maynard a stained-glass window by Messrs. Wailes & Strang (Newcastle-on-Tyne), and a font by Mr. Frank Bell (College Green, Bristol), have just been erected. The subject of the window is the Crucifixion, and the treatment is that of elongated medallions on a rich mosaic ground, surmounted by a border of similar design. The font is of Norman design.

Messrs. Budgett's new business premises in Bridewell-street, Bristol, are lighted by electricity, supplied by the Great Western Electric Light and Power Company, Limited. This company has recently purchased premises in the centre of Bristol as the headquarters from which to supply electricity. Messrs. Budgett are their first customers, and when their order is carried out their premises will be illuminated by over a hundred Lane-Fox incandescent lamps and four 2,000-candle Brush lamps. At present, pending the fixing of the Lane-Fox apparatus, twenty or thirty of the arc lights are in use, and work very steadily.

The electric light at the new East Dock at Swansea is now in full work, and every evening when vessels can enter and leave the dock brightly illumines the entrance locks and basins. Five 2,000 candle-power Brush lamps are used, and are driven by a No. 5 Anglo-American dynamo machine fixed 400 yards off, the wires being taken underground. An eight horse-power engine supplies the driving-power.

The tender of Mr. W. Veales, 4,23*l.*, has been accepted by the Bristol Docks committee for the erection of sheds at Prince's wharf. The other tenders were Mr. A. J. Beavan, 4,262*l.*; Mr. Reesiter, 4,408*l.*; Messrs. R. & J. Davey, 4,549*l.*; Mr. Church, 4,561*l.*; Messrs. Lewis & Edbrooke, 4,568*l.*; Mr. G. Humphries, 4,574*l.*; Messrs. Stephens & Bastow, 4,593*l.*; Mr. Krauss, 4,719*l.*; Messrs. Howell, 4,722*l.*; Mr. Cowlin, 4,750*l.*; Messrs. Brock & Bruce, 4,766*l.*; Mr. Easterbrooke, 4,945*l.*; Mr. Walters, 4,965*l.*; and Mr. H. A. Forse, 5,040*l.*

It is stated that Mr. J. Lysaght, of the St. Vincent Ironworks, is about to erect speller works near Bristol, thus reviving a once important but long absent industry.

Combe Down Church is about to be improved and enlarged at an expense of 2,000*l.* The proposed enlargement will consist of two aisles, a chancel, and chancel aisles, and it is also intended to reseat the church.

The new Church of St. Peter, Clifton Wood, Bristol, was opened on the 26th of September. The building takes the place of an old and inconvenient one close by. The style is Early Gothic, of a substantial character. The nave is 83 ft. 2 in. long by 39 ft. 7 in. wide; and the chancel, which has a circular apse, is 30 ft. 6 in. long by 27 ft. wide, the total length of the building being upwards of 113 ft. One of the aisles is 65 ft. 8 in. by 13 ft. 8 in., and the other 81 ft. 2 in. by 13 ft. 8 in. The tower, 20 ft. square, is 65 ft. in height, and has a handsome freestone turret. The walls are of Pennant stone, in random-range work, with Bath stone dressings for the windows and doors, and Draycot stone arches. A spire will be erected when funds permit. The nave and aisles are roofed with Brosley tiles. There are three entrances; the principal one, at the south end, (the site necessitated the church being built north and south), is a hold arch of Bath stone, heavily moulded, and enriched with handsome cusplings. On the east side of the chancel, to utilise a corner of the site, a chapel has been erected, which gives increased accommodation. On the other side, a corresponding wing is used as an organ-chamber, and both the chapel and organ-chamber open into the chancel with boldly-constructed arches of freestone. The nave and aisles are divided by four freestone arches, with handsome moulded caps and bases, and sanded Mansfield octagon piers. The building will accommodate 1,000 persons, and has cost about 8,000*l.* Mr. R. J. Crocker, of Bedminster, was the general contractor; Messrs. Bell & Sons had charge of the stained-glass windows; Mr. Frank Bell executed the carvings; Mr. Wood erected the pulpit; Mr. Singer, of Frome, the brass lectern; Messrs. Gardner & Sons, Bristol, the heating apparatus; and Messrs. Priest & Son part of the ironwork. The architect was Mr. Vincent W. Voisey.

## RUSSIAN NEWS.

ABOUT half-way down the Novsky prospect, on the left hand as one turns one's back upon the Neva, is the fine Catherine-square, as those who have seen St. Petersburg will well remember. At the end opposite the Novsky stands the Alexander Theatre, and the two other sides are faced respectively by the long facade of the public library and by the Czarevitch Palace.

In the centre stands a fine bronze monument of Catherine II., and around and below the figure of the empress are grouped the celebrated persons whom she delighted to honour. At the corners of this square it has now been decided to erect statues of four prominent personages of this sovereign's reign, and models for these monuments are now being prepared in the St. Petersburg Academy of Arts.

Several of the Imperial palaces built by former sovereigns, but now never used by the Imperial family, are to be given up to public uses. One of these residences, built for Alexander I., at Taganrog, will be arranged to receive the town library and an interesting museum of local antiquities, which sadly needed housing.

Fires are unhappily at all times common enough in Russia; the magnitude of some of the recent ones, however, and the vast destruction of property which has resulted from them, seems to have awakened the attention both of inventors and of public bodies to the necessity of taking every measure possible to avert or diminish this evil, to which Russia is particularly subject. The local Council of the St. Petersburg Government have assigned a considerable sum for the establishment of model rural fire stations, upon the pattern of those founded by the Moscow Society of Rural Economy, and every effort is to be made to get the rural communes to adopt similar institutions.

The municipal authorities of St. Petersburg have issued an order which makes it compulsory upon the proprietors or lessees of all theatres, music-halls, and places of entertainment, to coat all side-scenes, curtains, properties,

costumes, and other scenic accessories with the incombustible paint of MM. Spychensky and Molgounof, or some similar composition. This is to be done within the period of six months from the publication of the order, and neglect of the precaution renders the delinquents liable to prosecution. It is added, in a mollificatory way, that now smoking in green-rooms and behind scenes will be free from danger, as burning cigar-ends, &c., cannot cause the ignition of materials covered with these preservative paints.

It is reported that a contract has been agreed to with an American firm to light all the theatres under Government management by electricity.

A recent number of the *Inzynierja i Budownictwo*,—a periodical devoted to engineering and construction, published in Warsaw,—contains a description and drawings of an automatic apparatus for extinguishing fire and signalling its outbreak, which has been invented by a mason, M. F. Balv. The apparatus begins to act automatically under the action of fire, and at the same time signals the fire at the fire-station with which it is in communication. The apparatus is comparatively simple in action, and does not require a very large quantity of water.

The cost of the new University about to be established at Tomsk is definitively estimated at 1,220,000 roubles. The requisite buildings will, it is considered, be completed by the year 1885.

It is anticipated that the whole of the scaffolding which has so long shrouded the Isaac Cathedral in St. Petersburg will, before long, be entirely cleared away, and the church exposed to view. The work of covering the walls with thick marble slabs is to be resumed next summer. The renovation of the large picture of the "Fall and Expulsion from Paradise" is already nearly completed. The mosaic decoration of the interior is said to be proceeding successfully. Eight pictures of saints are at present being treated in this way, and will probably be finished at no distant date.

With regard to the higher education of women, Russia has for many years been entitled to a high place among European nations. The higher courses for women in St. Petersburg, and those in Moscow initiated by the well-known Professor Gueric, justly enjoy a high reputation. A retrograde step has, indeed, been recently taken by the exclusion of female students from the higher medical courses in St. Petersburg. The organisation of a museum of the products of female labour is just now occupying attention in Moscow, and appears to have a fair chance of a successful issue. Many objects exposed in the national exhibition, which will close on October 13, will be devoted to this museum. Funds were left by the late M. Ponomaref for an analogous purpose; as, however, the testator committed suicide, the decision of a legal tribunal is awaited as to the disposition of the bequest.

Frequent attempts have been made to establish steam locomotion upon the ice which covers the Neva and a great part of the Gulf of Finland during winter. It cannot be said, however, that these efforts have hitherto been crowned with what may be regarded as anything like a secure and remunerative success. Last year indeed steam communication was established for a short period between Oranienbaum on the mainland on the southern side of the gulf and the island port of Kronstadt. Attempts, however, to employ the ordinary railway appliances upon the ice have proved more or less failures. Quite recently, M. Vradig has devised a kind of engine for use upon ice, by the employment of which metal rails may be dispensed with. M. Vradig has been negotiating with the St. Petersburg Town Council with a view to establishing his system of locomotion upon the Neva and its estuary during the ensuing winter. It is understood that the Prefect of Police has advised the Town Council that there is no objection to locomotion by steam upon the ice.

**Ventilation.**—Messrs. Robert Boyle & Son's system of ventilation has been selected by the Committee and Architect for the ventilation of "Lloyds," Royal Exchange, to which it is being at present applied. Messrs. Boyle's system is also being applied to Clarendon, the residence of H.R.H. the Duke of Albany, and has been adopted for the ventilation of Portland Prison.

## DAMAGE TO LEAD PIPES BY RATS.

In the cellar of a house in Berlin, a large number of rats had recently taken up their permanent abode. Notwithstanding traps and poison, the vermin could not be got rid of. The brickwork was carefully examined, and a good many holes were discovered, which probably served as nests for the rats or led to the outside soil. All the openings were filled with cement, and the walls of the cellar pointed. The floor, which had hitherto been loose, was laid with bricks in cement. The rats disappeared; but after a short time a wet spot was observed in the brickwork, near where the water supply pipe ascended. On examination, a number of dead rats were found in a space of the cutting made for the pipe which had not been filled up when the pipe had been moved, and, closed by, the lead pipe had been gnawed right through. The above may be very easily explained. A family of rats had settled in the cutting; exit had been cut off by the closing up of all the holes; the rats, trying to get out, had attacked the lead pipe as being the softest material in their prison. They gnawed until they had made an opening, when they were drowned by the outflowing water. It may be of use to mention here that lead pipes may be efficiently protected against attack by rats or oxidation by winding well-tarred canvas round them, and afterwards applying another coat of tar.

## WORKMEN'S VIEWS AS TO THE PATENT LAWS.

At the recent Manchester congress of trade unionists, Mr. W. J. Davis moved:—

"That this Congress again expresses its strong disapproval of the continuance of the unjust patent laws, which tax intellect unduly, and act to the disadvantage of the mechanic, who, generally unable to secure the benefits of his inventive capacity, is compelled to remit his right of originality; also regrets that the President of the Board of Trade has been unable to introduce his promised Patent Bill, and trusts that the Government measure will remove anomalies of which poor inventors so justly complain; and, further, this Congress instructs its Parliamentary Committee to watch both the Government and private measures, and to use every exertion to obtain equitable provision to all classes of the community."

He said if the patent laws of this country were compared with those of others, a great difference would be seen to exist. In England when a man brought out an invention he had to pay 25*l.* within the first six months, and 50*l.* seven years afterwards. Thus, whilst an invention cost 75*l.* in England, in France the fees were only 16*l.*, Germany 16*l.* 10*s.*, Austria 10*l.*, United States 7*l.*, and Belgium 4*l.*, which conclusively proved that English artisans laboured under a great disadvantage to those of other countries. It often happened that a struggling inventor in Great Britain, finding he could not pay the 50*l.* at the conclusion of the seven years, sold his invention for a mere song to a capitalist, who traded upon it, and probably made a fortune; and this state of things was highly undesirable.

Mr. Threlfall (Southport) seconded the resolution.

Mr. Evans (Manchester) said he thought the law was one of the most unequal that an ingenious labourer had to contend with, and the sooner it was done away with the better. He could not understand why the law should be allowed to remain such a drag upon the intelligence of a workman. He heartily endorsed the endeavour which was being made to get the matter rectified. He only regretted that the machinery required to be put in motion was of such a cumbersome character. It was not very creditable to our legislature that gentlemen like Mr. Broadhurst, and others, who represented them in the House of Commons, had such great difficulty in obtaining a bearing upon such practical questions as these, and it was the duty of working men especially to support them in their efforts to bring about a remedy.

Mr. Drummond said that in Glasgow they had given their support to Mr. Anderson's Bill, and he thought that Congress would unanimously approve the motion now before it.

Mr. Evans (London) said he had received communications from twenty-six working-men inventors who were unwilling to exhibit their inventions at the Railway Safety Appliances Exhibition at Darlington, as they had not the

means to obtain patents. Besides the great cost of taking out a patent, inventors had to contend with patent agents, whose charges were almost equivalent to a second patent-tax.

The resolution was carried unanimously.

## THE NEW PUBLIC HALL AT BATTERSEA.

The new public hall which is to be erected at the foot of Lavender-hill, immediately adjacent to Clapham Junction Railway Station, by the Battersea and New Wandsworth Public Halls Company, is to be commenced at once. The first meeting of the company was held last week, when it was stated that the plans and specifications were all ready, and that the directors had received eight tenders from different builders, ranging from 12,430*l.* down to 9,500*l.*, the lowest tender being that of Messrs. Holloway, of Lavender-hill, and this tender was accepted. The foundation-stone of the building is to be laid in the course of the ensuing month by Mr. Sydney Stern. The site of the intended building is at the corner of the Lavender Sweep Estate, on which a large number of new houses are now in course of erection. It will have two bold and prominent frontages, one facing Lavender-hill and the other St. John's-road, Battersea-rise.

## PROVINCIAL NEWS.

**Birmingham.**—Birmingham is about to receive an addition to its charitable institutions. In connexion with the Wesleyan "Thanksgiving Fund," which has now reached a total of nearly 304,000*l.*, Mr. Solomon Jevons made an offer to the committee that if from the fund they would make a grant of 10,000*l.* towards establishing an orphanage in the neighbourhood of Birmingham, he would supplement it by a donation of 10,000*l.* After due consideration the offer was accepted. Plans were prepared by Mr. J. L. Ball for as much of the building as it is proposed immediately to erect, and after tenders had been received from ten of the prominent building firms of the district, the contract has recently been let to Messrs. J. Wilson & Sons, Handsworth. The sanction of Her Majesty the Queen has been obtained to call the building the "Princess Alice" Orphanage, in memory of her lamented daughter, the late Princess of Hesse. A site has been selected on the Chester-road, about equally distant from Erdington and Sutton Coldfield, and close to the Beggar's Bush. The arrangement of the orphanage buildings will be such as to give the idea of a village rather than that of a public institution. Facing the Chester-road, at a distance of about 130 ft., will be an irregular line of buildings, altogether nearly 250 ft. in length, which may be regarded as the administrative block, consisting of the master's house, the offices and Board-room, the belfry and great hall, the kitchens, store-rooms, bakehouse, and kitchen offices. These buildings, though of varying heights and outlines, are connected. The most important is the great hall, 90 ft. by 33 ft. and about 29 ft. high, intended to be used not only as a dining-hall, but also for the daily morning prayers, for general gatherings, and until the chapel is built, for divine service. Behind the administrative buildings, on the right hand and on the left, the cottages or "bomes" will be placed irregularly and at varying intervals. When complete, there will be twelve cottages for boys, and twelve for girls, each providing accommodation for about twenty-five children, together with matron's rooms. These farm-cottages will stand detached in separate plots of ground, and will be of different designs. Schools, workshops with facilities for carrying on about a dozen industries, baths, farm buildings, and a farm bailiff's house will be built on various parts of the estate, and the little colony will be completed by a chapel.

**Nottingham.**—The Nottinghamshire Guardian says that lovers of the picturesque in the quaint Old English style of architecture prevalent in our oldest towns will soon lose a well-known specimen, recently dignified by the name of King John's Palace, situate in Bridlesmith-gate, Nottingham. The whole of the premises known as the "Palace," and the old oaken-built structure known as Rose-yard, are now being pulled down to make way for other buildings to meet modern requirements. The proposed new

buildings, which are to be erected from the designs of Messrs. S. Dutton Walker & Howitt, are, in style, to follow the semi-timbered framing of the ancient structures which formerly were so frequently seen in our streets, but which are now nearly all swept away. The building about to be removed is mainly constructed of oak framing, owing, no doubt, to the contiguity of Nottingham to Sherwood Forest. In the interior much of the quaint old work has been demolished, especially on the ground-floor, but the upper rooms are all whitewashed with oak panelling,—of course painted, as usual by the Goths and Vandals, with beautiful stone colour. On removing part of the whitewashing, Mr. Walker found in several rooms some very interesting stencilled decoration. Photographs have been taken to preserve some record of the old structure.

**Heaton Mersey.**—Mantheth Hall, Heaton Mersey, was on the 15th ult. opened by the Bishop of Manchester as a hospital for incurables. The building was formerly occupied as a mansion by Mr. W. Romaine Callendar, from whose executors it was bought for the sum of 15,000*l.* It stands in well-wooded grounds, with gardens and lawns, and may be described as palatial. It is of Classic architecture, with frontages of Yorkshire stone. A wing has been added, and the interior altered and improved, the total cost of the additions and alterations amounting to 8,000*l.*, making a grand total of about 24,000*l.* The architect is Mr. Charles Heathcote, Manchester; and the builders, Messrs. Wilson, Toft, & Huntley, City-road, Manchester. Bishop Fraser, in the course of the proceedings, said the building, in its original shape, once belonged to him. The last bishop selected it as a suitable house for the Bishop of Manchester. He (the bishop) did not think it was suitable, and he absolutely refused to live there. For two years the building was a considerable burden to him. The Ecclesiastical Commissioners would not allow him to part with it until he got a house in its place. By good fortune he did get another house, and in 1873 was relieved from his responsibility. Mr. W. Romaine Callendar bought the property from the Ecclesiastical Commissioners, and spent a considerable sum of money in ornamenting and enlarging the house, but, unhappily, was spared only a few years afterwards to live in it. The building had thirty acres of land belonging to it, including some admirable gardens, which were now let out and produced an income of 200*l.* a year. By the taste and skill of the architect, the building had been enlarged and adapted to its present purpose.

**Accrington.**—On the 16th ult. the new Conservative Club at Accrington was opened. The building is situate at the junction of Blackburn-road and Eagle-street, nearly opposite the Railway Hotel, and close to the railway station. The entrance is in the Blackburn-road façade. Ascending four stone steps in the outer vestibule, the inner hall, 8 ft. wide, is reached. On the left, towards Eagle-street, is the news-room, 24 ft. by 20 ft., lighted from Blackburn-road and Eagle-street, and fitted with newspaper desks, tables, and furniture. This room has an enriched ceiling, and is surrounded by a dado lining, 4 ft. high. Beyond this room, on the same side, is the billiard-room for first-class members, 25 ft. by 20 ft., lighted from two sides, and fitted with permanent seats on one side and one end. On the right of the hall is the smoke-room for first-class members, lighted from Blackburn-road. This room is furnished by Messrs. Kendal, Milne, & Co., of Manchester, who have supplied most of the movable furniture. At the extreme end of the hall are the lavatory and offices. The floors of the hall and vestibule are paved with encaustic tiles from the works of Messrs. Maw & Co., Broseley. The principal rooms on this floor are 14 ft. 6 in. high. On the right of the hall are also the servery and porters' kitchen. On the first floor to the right is the large billiard-room for second-class members, 48 ft. by 20 ft., lighted from the two main fronts and from the roof. This room will contain two billiard-tables, and is fitted with permanent seats. In connexion with this is a smoke-room, 20 ft. by 9 ft., lighted from Eagle-street. Over the front lobby is a dining-room, 15 ft. by 8 ft., lighted from Blackburn-road, and in communication with the balcony fixed over the entrance gateway. To the left of this is a large committee or lecture room, 22 ft. by 20 ft., calculated to seat about 130. The wrought-iron gates, gasfittings, and railings are

by Messrs. Dutton & Powers, of Manchester. The internal joinery is executed in Baltic timber, selected pitch-pine being used for panels, and all stained and varnished. Externally, the walls are built of Yorkshire stone, the ashlar being from the Ringley quarries. The style of the building is Domestic Gothic. The architect is Mr. Henry Ross, of Accrington.

**Lancaster.**—Extensive alterations and improvements will be made to the Palatine Hall early next year. The Committee of Trustees have adopted designs prepared by Mr. Geo. D. Oliver, of Carlisle and Workington.

#### ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

A Northern district meeting of the members of the above association was held in the Town-hall, North Shields, on the 27th ult., under the presidency of Mr. J. G. Lynde (Manchester). The advisability of reviving the adjourned discussion of the paper on "Private Improvement," read by Mr. Hall, of Stockton, in April last, was the subject of debate. It was resolved that the consideration of Mr. Hall's paper be deferred till the next district meeting. Mr. P. W. Thompson, hon. local district secretary, Willington Quay, read a paper on "The Operation of the Canal Boats Act," written by Mr. E. C. Buchanan Tudor, engineer and surveyor to the Goole Local Board, who was unable to be present. It stated that when the Act of 1877 came into operation there were upwards of 1,000 boats, commonly called keels, trading through the port of Goole, the whole of which were used as dwellings, and required legislation. The cabin space was almost in every instance too limited for the number of people inhabiting it; the means, if any, adopted for ventilation were insufficient, and the arrangements for the fittings were defective. The sleeping accommodation was rarely, indeed, what could be desired or deemed even decent, and frequent occurrences of overcrowding and immorality prevailed. He thought that a systematic periodical inspection of the boats would be a practical improvement. The effective and beneficial working of the Act must always to a certain extent depend on the industry, zeal, and knowledge of those appointed to carry it out, and his opinion was that if these officials were appointed by Government for combined districts, rather than by local authorities, constant supervision would be maintained. In the discussion which ensued, a unanimous opinion was expressed that the best suggestion was an important one worthy the consideration of engineers and surveyors. The meeting closed with votes of thanks to Mr. Tudor for his paper, and to the Mayor and Corporation of the borough of Tynemouth for their courtesy in placing the Town-hall at the disposal of the association. The members afterwards visited the Coble Dene Dock, the Piers Works, and the North-east Coast Exhibition.

#### THE MUNICH ELECTRICAL EXHIBITION.

Though perhaps not such a brilliant display as the Paris Electrical Exhibition, that of Munich is, from a scientific point of view, of exceptional value, more particularly from the fact that metric and other instruments of quite recent invention are shown, which facilitate the estimation of the power and consequent value of any dynamo-electrical machine. In this manner calculations are rendered much more simple as to the cost of the electric light, respecting which there has been hitherto a want of means of arriving at an exact idea of the expense it entails.

There are no less than twenty-two steam-engines at work for the purpose of furnishing the motive power required by the electric light in the exhibition; there are also several gas engines. A remarkable instance of the transmission of force is furnished by the over-ground copper-wire communication, which renders available for the working of several kinds of machinery the water-power at the Maffei machine-factory at Hirschau, three miles distant, and in a similar way there is a transmission of power effected from Miesbach, which is at a distance of thirty-one miles. The transmission of sound affords visitors the opportunity of hearing music which is being performed at a

distance. Special prominence is given to the discoveries of Edison, to which a special department in the exhibition is devoted.

Amongst the other specialities of the exhibition is a photographic gallery, in which electric illumination is utilised both for the taking and copying of photographs. A model on a large scale of a railway, with two termini and an intermediate station, exemplifies in a lucid manner the system of railway telegraphy. An instrument, entitled the Glossograph, registers in an automatic manner spoken words, and though not at present in a complete form, it is, nevertheless, an interesting exhibit.

The electric fire-alarm is shown in connexion with the protection of buildings from the ravages of fire, and lightning-conductors also form appropriate objects of exhibition. The financial results of the enterprise seem to have been so far of a satisfactory character.

#### NOTINGS FROM THE NEWCASTLE HEALTH CONGRESS.

In the section devoted to Chemistry, Meteorology, and Geology,

Mr. G. J. Symons read a paper, prepared by Mr. H. C. Bartlett, Ph. D., F.C.S., "On the Influence of Minute Suspended Matter on Health: its detection, collection, and examination." He said pollutions of the air were frequently diffused in a gaseous form, and required great delicacy of chemical investigation to estimate the proportions in which the gases might be taken up by the atmosphere, and in what proportions such gases must be deemed injurious to health and life. Men worked in breweries, soda-water factories, and gasworks without loss of health from breathing offensive gases, while people in crowded buildings often suffered from headache and depression. He had, therefore, been forced to the conclusion that the serious and even dangerous effects of bad ventilation were mainly due to matters carried in the air not in a gaseous form, but suspended as minute particles. It had been ascertained many years ago that solid particles of matter, either inorganic or organic, living or dead, were suspended in the air, and practically these same particles might be found in suspension in almost all drinking-water open to the air.

Mr. Symons also read a paper on "The Improvement of Climate with Slight Elevation," which had been prepared by the Hon. F. A. Rolle Russell. He showed that repeated observation had proved that at points artificially or naturally raised above the surrounding district the range of temperature was smaller. The practical conclusions seemed to be that invalids and delicate persons would generally be best placed in high-sheltered situations, in the highest rooms of a house, and by no means on a ground-floor; that a climate resembling that of the seaside, but less damp, could be obtained by living at the top of a high house; that every house ought to be built on arches, or thoroughly ventilated below and raised on piers above the ground level, and that no house or cottage which is not ventilated underneath, with damp-proof walls, should be considered habitable; and that in the country no house should be considered habitable of which the floor is on a level with or below the ground.

A paper by Mr. R. Carr-Ellison on "The Influence of the Purity or Impurity of the External Atmosphere on Public Health, Public Comfort, and on Domestic Habits of the People," was read in his absence by his son, Mr. Edmund Carr. He said that on Tyneside such was the cheapness of coal that it had always been used with a most lavish and wasteful profusion. The discharge of densely-opaque smoke from the chimneys of furnaces, factories, breweries, and the like, in vast volumes after every replenishment of fuel, was the rule and not the exception. There was, however, one honourable and distinguished exception,—that of Sir William Armstrong & Co., at Elswick,—where a vast business was conducted with as little production of smoke as possible, and with corresponding economy of fuel. The smoke plume which hung over Newcastle and Gateshead from Monday morning till noon on Saturday was fearful to behold, and had a decided effect upon the ventilation of even the best class of dwelling-houses in the two towns. He strongly advocated that the local authorities should take steps to stop the disgraceful cloud of smoke so often seen in the district.

The chairman (Dr. Arthur Mitchell, F.R.S.) said he did not suppose there could be a doubt that the smoke of a town had an unwholesome influence upon the health of the people, and it had been proved that by mechanical arrangements they could get quit of it, but the law to suppress it was not applied. He did not think that attention could be too often directed to a subject of this kind, which was of public interest; but, for the reasons which had prevented the discussion of other papers, he proposed that they should receive the paper without discussion, and that they should record a vote of thanks to Mr. Carr-Ellison for communicating it.

Mr. R. B. Grantham read a paper "On the Establishment of a Library for a special Branch of Sanitary Information at Newcastle." Having for some time taken a practical interest as an engineer in the execution of sanitary works, he had become impressed with the necessity which existed for a collection of the numerous reports and other authoritative publications on the subject, and he was desirous of suggesting that a special library of such works be formed at Newcastle for reference, and as a means of promoting the study and diffusion of sanitary science. He had made a small collection, which he was willing to place at the disposal of the Scientific and Philosophical Society as the nucleus of such a library, and he had added a list of works which he considered might be proper to include in the collection. These would, however, be inadequate to carry out his views, but he wished to intimate that many of the learned societies would, upon application, furnish copies of their publications, reports, &c., upon the understanding that a really representative collection would be formed and efficiently maintained for purposes of reference and as a means of information to those who were desirous of studying and practising sanitary science.

In the section devoted to Sanitary Science and Preventive Medicine, Dr. Ledlard read a paper on "Arsenic in Domestic Fabrics." He showed that large amounts of arsenic existed in wall-papers, materials used for dress, curtains for bed-hangings, carpets, &c., and that these things had a seriously injurious effect on the health of persons coming in contact with them, and were frequently fatal. He contended that a case had been made out for legislative interference. Some amongst those interested in this subject objected to the further interference with the liberty of the subject by the imposition of additional laws to prohibit the use of arsenic and other poisons in domestic fabrics, but he held strongly that laws were good if only to appeal to in cases of real necessity. Much work, he thought, still required to be done in systematically examining all and every kind of material of wearing apparel or fabrics used in house decoration; for it would be found that arsenic was present in many things apart from wall-papers, which had performed the task of calling attention to this important subject.

#### ECCLIASTICAL ART EXHIBITION AT DERBY.

In connexion with the Church Congress this week in Derby, there has been held an ecclesiastical art exhibition, the special feature of which was the loan collection, numbering upwards of 400 separate exhibits. Embroidery, both ancient and modern, was largely represented, and amongst the former may be mentioned a vestment of thirteenth-century date, exactly the same as the celebrated chasuble in Salisbury Cathedral. By some chance it came into the possession of the Dutch, and was stolen from one of the churches of Holland during the Wars of Independence, and latterly was in the possession of the Archbishop of Utrecht. It is the property of Mr. W. Baker. There were numerous specimens of modern work, including sets of vestments from Prestbury, contributed by the Rev. Bagehot de la Ber; a cope worked for St. Clement's, Bournemouth, by Messrs. Cox & Co., and an altar frontal, cope, and dalmatic, by Messrs. Jones & Willis; the two last having been shown at the Great Exhibition in 1851, when they received a prize medal. Mr. Douglas Horsfall exhibited an altar frontal, worked by Mrs. Robert Horsfall, intended for the new Church of St. Agnes, Liverpool, shortly to be erected as a memorial to her late husband. Modern embroidery was represented by specimens of the work of the East Grimstead Sisterhood.

Metal work and enamels formed an important branch of the collection. Mr. Russell showed a good example of *champlevé* work of the twelfth century, being a plate with a representation of the Presentation. Mr. Clark's exhibit included a selection of bronze plaques, ornamented with Scriptural subjects. Mr. Malin showed the chalice and paten used at St. Dunstan's Brotherhood at Plaistow. Mr. Llewellyn Jewitt sent a pair of Russian consecrated pendants, or images for personal wear, in gold, silver, and enamel; some Greco-Roman bronze crosses and crucifixes, together with a triptych and a pectoral plate in bronze and enamel.

One of the most striking items of the collection was the model of the Shrine of St. Ursula, the original of which is at the Hospital at Bruges, and is the work of Hans Memling. It consists of a cabinet in the form of the nave of a cathedral, covered with exquisite paintings, representing various incidents in the life of St. Ursula, from the landing at Cologne to her apotheosis.

Pictorial art was represented by various photographs and chromolithographs of ancient pictures, illuminations, drawings of churches and ecclesiastical furniture, engravings of chalices, and a large collection of rubbings of monumental brasses and incised slabs.

The Rev. J. Fuller Russell sent a very interesting and valuable collection of manuscripts and early printed books. Amongst the former were included a Sarum Missal of the fifteenth century, containing elaborately-executed borders of the "English flower type," together with the usual "Crucifixion" at the beginning of the Canon.

Amateurs of ivories and wood-carving found much to admire in Mr. Henry Clark's collection, which included about a hundred examples of plaques, statuettes, triptychs, caskets, &c., mostly belonging to the sixteenth century. Mr. Watkin Williams Wynn contributed a fine ivory diptych of fourteenth-century date, probably Nuremberg work, and the Rev. F. Jourdain showed part of an ancient triptych with figures of saints, belonging to a Derbyshire church.

#### HAMMERSMITH BRIDGE.

At the meeting of the Metropolitan Board of Works on the 29th ult., several deputations from local authorities and inhabitants attended to urge the provision of a temporary bridge during the reconstruction of the superstructure of Hammersmith Bridge. Mr. Richardson subsequently moved:—"That it be referred to the Bridges Committee to ascertain and report whether the Board has statutory power,—(1) Entirely to close Hammersmith Bridge during the progress of the works now under contract; (2) To incur expenditure in making temporary provision for the traffic during such time as the bridge may be closed. That the committee be authorised to obtain the opinion of counsel, if it should be considered necessary." The mover observed that the agitation that had been going on during the recess in regard to Hammersmith Bridge had at one rate been the means of informing him of one circumstance of which he was not previously aware. He most certainly was not aware that any provision was to be made for the conveyance of the traffic across the river while the bridge was closed. He had made inquiries on the subject, and the Engineer had told them that these clauses in the specification for the provision and maintenance of a ferry were submitted to and approved by the Bridges Committee. He had endeavoured to ascertain if this was the case, but neither the clerk nor the chairman of the committee knew anything about it, and he thought he might say that this particular point was never brought before the committee at all, except that the specification was submitted for approval in the usual formal manner. So far as Hammersmith Bridge was concerned, the Board was proceeding under the Act of 1877, and the only duty or power of the Board in respect of the bridge under that Act was contained in the words, "The bridge shall be maintained and repaired by the Board." The question, therefore, arose under what authority the Board had the power to expend a considerable sum of money for the purpose of providing means of communication across the river when the bridge was closed. There was no such power given to the Board in this Act or in any other Act. There appeared to be no authority whatever, except that of the

Engineer, for such clauses being inserted in the specification, and it was quite clear that the insertion of these clauses had given rise to all the excitement that had arisen. It had also given rise to the idea that the Board was responsible for the conveyance of the traffic across the river during the time that the bridge remained closed, whereas any such action would be outside the powers of the Board, and any expenditure incurred for such a purpose would be liable to be disallowed by the auditor when the accounts were examined. This was a matter in which the Board was entirely subject to the control of Parliament, and, although they were a body representing the whole metropolis, they were not allowed by Parliament any discretionary power whatever in dealing with these questions. He thought it very desirable that the Board should have a discretionary power to provide for the conveyance of traffic across the river during the time that a bridge was closed.

The motion having been seconded, Mr. Runtz said it appeared to him altogether unnecessary. The whole subject had been referred to the Works Committee, and, if the reference now suggested by Mr. Richardson was necessary at all, it ought to go to the Works Committee, and not to the Bridges Committee. Mr. Fell moved, as an amendment, that the Works Committee be substituted for the Bridges Committee.

Mr. Richardson accepted the amendment, and the motion, altered in accordance therewith, was agreed to.

#### WHAT IS PROPORTION?

SIR,—Both your correspondents of last week, —Mr. Aitken and Mr. Girard,—attribute opinions to me the very reverse of those I hold, and that I have repeatedly expressed. I have always contended that it is absolutely impossible to separate proportion, in the sense of quantitative relation, not merely from construction, but from existence. Everything in the universe exists either in proportion or in disproportion. But of those things which are proportioned to their purposes, only some are at the same time proportioned to taste. The satisfying of taste is an end in itself, and to formulate the science of the beautiful we have to discover those degrees of manifestation and those quantitative relations (proportions) which are apposite to taste. But the beautiful is neither the sole aim of nature nor of art. If the beautiful had been the sole aim of nature we should never have had to discuss the matter, for everything would then have been beautiful; but as things are constituted, we know that some, though perfectly proportioned to their special ends, are not beautiful, whilst others, equally fitted to their special ends, are coincidentally apposite to taste. The hippopotamus, the toad, and the floating derrick, for instance, though perfectly proportioned to their respective purposes, do not exist in proportions agreeable to taste, whilst, on the other hand, the human form and the egg-shape exist in proportions which, at the same time that they are proportioned to their ends in creation, are proportionate to taste.

In respect to Mr. Girard's letter, I beg to say that not a word about "habit" or "custom" will be found in my letter of the 16th ult., though I have endeavoured to show in my correspondence on former occasions that "habit" is a factor which complicates aesthetic questions, and increases the difficulty of determining those proportions that are purely apposite to taste. He also falls into the common and fatal error that taste is founded upon some arithmetical harmony, some occult harmony in numbers, or on geometrical relation. Now, the music of form, of colour, and of sound is not founded on anything of the kind, but on the laws of our own nature, on the nature of the senses of sight and of hearing. Numbers are but the symbols by which we write down, numerically express, those degrees and quantitative relations that are apposite to our sensuous nature. From this error proceeds the perennial insistence on the virtues of the regular geometrical figures. Now these are demonstrably not those figures which are most apposite to taste; these regular forms are approximated in nature only in its more elementary, material, and primordial forms; they are rarely to be found in the higher forms either of life or of art. Neither in the Grecian pediment, frieze, columination, nor general forms do we find the regular geo-

metrical figures, much less in that quintessence of the beautiful,—the human form.

Your correspondent forgets when he sneers at the word "aesthetic" that that word was in use when the Parthenon was built, and in the same scientific sense as at present. Its introduction is novel only to this un-aesthetic race. I believe that the Greeks had a science of proportion, and that I have re-discovered and re-formulated that science. But if they had a science of formative proportion, it must have been founded in reason. If "the depth and projection of the smallest member was regulated" in Grecian architecture, as your correspondent affirms, let us know the why and the wherefore, or it must be set down as mere assertion. And if it be known why, why then we are on a level with the Greeks, and we could go and do likewise. I maintain that no one is in a position to affirm whether the Greeks were aesthetically right or wrong, unless they themselves have topped the science of proportion. Until the science of proportion be mastered we must withhold our judgment, for it is possible to be the slaves of habit in matters of taste. Without such a science, clearly worked out, it is merely bold and bald reiteration to affirm the perfection of Grecian art. In conclusion, I must most emphatically deny that I "dabbled" all those who may differ from me as half-educated. What I did say, with respect to half-education, had reference to a special form of misconception, with the correction of which, in the very opening of his letter, your correspondent concurs. One word more, and I have done. In my letter of the 16th ult., "opposite to sense," ought to have been, as may be gathered from the context, *opposite to sense*.

W. CAVE THOMAS.

#### SANDOWN CASTLE.

I HAVE just returned from Deal, and quite echo the remarks of Professor Hayter Lewis a few weeks ago. The ruins of Sandown Castle should be preserved, and if they could be used for no other purpose they would form an admirable bathing-machine. For bathing, Deal is about the worst place on the coast,—the sands have all gone to Goodwin! Nothing but shingles left on the beach,—larger than walnuts, and very unpleasant to the feet. At Sandown Castle, on the contrary, bathing is very pleasant, and the old castle makes an excellent shelter. Could not the idea be improved upon? The above suggestion is not mine; it is the idea of many I saw there bathing,—old and young. The castle is a gentle walk from Deal, just beyond the bathing regulations. Might it not be included within them, so as to prevent the idea from being abused?

Deal boasts of being the oldest bathing town in England. The inhabitants tell you Julius Cæsar bathed here August 26th, B.C. 55, with his Roman followers, on their first introduction to the Britons! The Saxons and Danes subsequently frequently bathed here before having a plunge at each other! But, joking apart, Deal is a very interesting central point to spend a week's sojourn from London. Here are Deal and Walmer castles, of similar plan, date, and style to that at Sandown. Walmer Church is noticed in Parker's Glossary, and Dover is within easy reach. Inland are Upper Deal, Great Mongeham, and Northbourne, described by the late Mackenzie Walcott in his "Coast of Kent" (a little book published by Stanford, Charing-cross, which no one should go without). North of Deal is the famous Roman Richborough Castle, and the quaint old town of Sandwich with its Norman church of St. Clement.

W. F. POTTER.

**The Opera by Telephone.**—An interesting experiment took place at the opening of the present session of the London Hospital Medical College, on Monday evening, when a *conversazione* was given to a large company. By the kind permission of Mr. W. S. Gilbert and the United Telephone Company the Anatomical Theatre was placed in telephonic communication with the Savoy Theatre, and by this means many of the audience in the former building heard distinctly the aesthetic opera "Patience." The electric light used on the occasion is spoken of as being a great success, Professor Crookes's incandescent lamps being adopted (for the first time at a public exhibition), driven by a Gùlcher dynamo machine.

**BELLMAN'S PATENT GULLY.**

MESSRS. BELLMAN & IVEY, of Wigmore-street, have recently introduced a gully, as shown below and in our advertising columns, which appears to be making its way. In size it measures 16 in. by 8½ in. by 7 in. deep. It receives the main rain-water pipe of the house, and three waste-pipes, and disconnects the whole from the drain, as between it and the gully a P or S trap is fixed, which will necessarily always contain a water-seal. Over the outlet to the trap a grating is fitted, which prevents any solid matter

passing through, and the surface-grating being loose and of ample size, the trough of the gully can be kept clean with the greatest ease. Bellman's gully offers a great advantage over those made with the trap in one piece, as no matter where the drain may be, the gully may always be placed at right angles, as the trap can be turned in any direction to meet it. There is no splashing, and, at the same time, the gully acts to a certain extent as a ventilator to pipes and trap. Taken as a whole, it seems well adapted for the purpose for which it is intended, and is introduced at a price calculated to promote its extensive adoption.

From what we have seen of it in operation, we are disposed to recommend it for trial.

**REREDDOSES.**

THE parish church of Betsys-y-coed has lately received the addition of a reredos, as also a low stone wall, with moulded capping, under the chancel arch. The reredos, of simple design to suit the character of the church, is of Corsham Down Bath stone, the panels being of Forest of Dean stone. The central portion is emphasised by being slightly brought forward, and has a carved cresting. It consists of a wider central panel, with square shoulder cusp, having three panels on each side, containing, in carving, the lily, rose, wheat, grapes, passion-flower, and trefoil, and, over them, six square panels, quatre-foils cusped. The side wings each contain five arched and trefoil cusped panels, with circular carved bosses between the arches. Above is a delicately-carved frieze of flowing foliage. Below the arched panels is a species of enriched string-course, with square pateras, and, underneath, a diapered ground. The funds were raised by a member of the congregation.

A neighbouring church, Yspry, has likewise been furnished with a reredos, the gift of Lady Penrhyn. It is executed in Corsham Down Bath stone, the panels being of Dumfries stone. The height between the top of the table and the window being very limited, special means had to be taken to emphasise the centre. The hollow of the string-course or cornice is enriched by a pearl ornament. There is an elaborate Greek floriated cross in the centre, having on each side two square-headed cusped panels, separated by narrow projecting hands, containing various emblematical carvings. The panels to the wings of the reredos contain grotesqueness in the upper part, and, underneath, some reticulated work, formed by narrow projecting hands.

Both reredoses were executed from the designs of Mr. B. Edmund Ferrey, and carried out by Messrs. White & Sons, of Vauxhall Bridge-road.

**MASTERS AND MEN IN THE BUILDING TRADE.**

Sir,—I have just read the letter of "A Builder," in your impression of September 23, in which Mr. Potter's name is mentioned. Can it be possible that another strike is being worked up? I do hope that my brother working-men will not be influenced in that direction by any individuals any more. What about 1859, when many a man starved his wife and family, and himself too; sold his home; and what good has come of it? The secretaries of two or three trades have got into freehold houses; the victims are scratched, or in their grave, and the price of food, lodging, and clothing is

forced up to an unnatural height; in point of fact, the money has lost its purchasing value, so that, in reality, wages have not risen at all.

I have read the report of the Trade Unions Congress: they do well to speak against paying wages in the public-house, but they would do better if they took their lodges from the public-house, and they would do better if they abolished the striking rules. If a man is not satisfied with his pay, let him seek a job elsewhere, and let him aid his fellow workman too. It is what we all ought to do, but when a secretary tells him that he must sell his home at the bidding of a committee, then I say "Perish the committee."

The vote and the ballot, and the knowledge how to use them, are of more consequence, and will do more good for the working class of the country than all the strikes rolled in one; and let me beg my brother workmen to pause before they are led into one. If the young men who have got into the building trade were to study the history of the struggles of the working class, and notably strikes, they would find that organised strikes are only another name for the most odious tyranny under the sun.

There is much reform needed in many things; an English workman's life is not all honey, neither is an employer's, as the records of the Bankruptcy Court can tell; but when men come forward to lead us, those who are to be led have a right to inquire, Where are you going to lead us? What are you going to bring us to? Starving wives, broken homes, documents, blacks, whites, rows, riots, examinations before the magistrates! Look at the gas-stokers, the masons, the cabinet-makers, and others.

I am only a tailor myself, and I have fought in many a battle for progress, but there never has been, and there never will be, any permanent good come out of organised strikes; they are only palliatives.

For mercy sake, Mr. Editor, find a space for these few lines. ANTI-STRIKE.

P.S.—I have been ruined by the striking system, and if you were to be so kind as to insert my letter, I should feel obliged. Why should employers and employed act the part of madmen and destroy one another?

**DRYING BUILDINGS.**

WITH reference to the particulars we gave of the new Railway Hotel, Preston, Lancashire (p. 410, ante), Messrs. Dreyfus & Co. say:—

"We saw in your pages an article on this building. We beg to inform you that the whole of the building was dried by us with 'Ligny's Patent System.' This is the second hotel we have dried for the London and North-Western Railway Company,—Euston being the first one. We have also just completed drying the new Church of St. Mary, White-chapel, so that the plaster of the interior may be decorated at once."

**CHURCH-BUILDING NEWS.**

Revelstoke.—The new church which Mr. E. C. Baring, the well-known banker and princely owner of Membrand Hall, near the picturesque river Yealm, has just erected upon his estate at Revelstoke, was consecrated on the 6th ult. by the Bishop of Exeter. The church is perched upon the steep hill side, overlooking the sluggish Yealm. In the Perpendicular style of Gothic, it has a western tower, nave, aisles, chancel, and a large south-western porch. The fall of the ground is utilised for the introduction of vestries underneath the north aisle,—with which they communicate at their eastern end by a winding staircase, with turret. The main walls are of stone raised on the estate, and all the masonry dressings are of local granite. The roofs are of the local "wagon-head" shape,—stopped at the intersection of every rih and purlin by bosses. In the chancel the roof is made additionally rich by the introduction of sculptured angels representing the Church militant and triumphant, and by continuous running ornamentation. The walls of the chancel are lined with polished marble inlaid in various hues. This is the work of Mr. Gullett, of Yealmpton. The green Devonshire marble used is said to rival the best specimens from Galway. The pulpit stands upon the north side, and is of oak, upon a granite base. The seating throughout the church is entirely of massive oak. The

bench ends and their fronts and backs are all diversely carved, the rich type of work prevalent in this county in the fifteenth century being carefully kept to. In the corner of one of the sculptured bench-ends, representing apparently a great sea-fight between galleons belonging to the Barings with their ancient foes the Spanish aggressors, there is inscribed in modest characters the following legend:—"Hary Hems and his merrie men carved all these benches at Exeter, A.D. 1882." It has been the aim of Mr. Baring that the church should be, in all respects, an entirely West Country production,—that Devonshire workmen and materials should be employed in preference to all others. The church has been designed by Mr. James Piers St. Aubyn, architect; the windows and other decorations are by Messrs. Foutaere & Watson, of Stonehouse. The main part of the whole edifice has been entirely built by Mr. Baring's own estate workmen, under the general supervision of Mr. Samuel W. Adams, of Plympton, his agent, and the immediate direction of the resident clerk of works, Mr. George W. Crosbie.

Andelside.—The work now being carried out at Andelside Church comprises re-seating to nave in oak, new vestry and heating chamber, and windows to nave in freestone. The pulpit will be of old dark oak, with stone base and steps, having drapery panels in the lower part and open tracery work in the upper part. The floor of the church throughout will be laid with wood paving of an improved kind, recently introduced by the architect, and now very largely used in churches, schools, &c. A new chancel and organ-chamber with roof to nave will be built as funds permit. A special interest gathers round this church from the fact that Wordsworth, the poet, worshipped there, his residence being close by. The work is being carried out by local contractors, Mr. W. Stalker having the contract for woodwork, and Mr. T. Newton that for masonry. The whole of the alterations have been designed by Mr. R. Walker, architect, of Kendal and Windermere.

Small Heath, Birmingham.—On the 9th ult. the foundation-stone was laid of the Memorial Church which is about to be erected in Cooksey-road, Small Heath, to the memory of the late Rev. Dr. Oldknow. The style of the building will be Early English, simple in character, with very little attempt at ornamentation. When completed the church will consist of nave, with tower and spire at the north-west angle, north and south aisles and transepts, chancel, morning chapel on the north side of the chancel, and sacristies on the south side for the clergy and choir, with an organ-chamber over the latter. The exterior walls will be of red brick, with red Kenilworth stone mouldings and dressings; and the interior will be lined with white bricks, with red-moulded brick arches to nave, transepts, chancel, windows, &c., with Kenilworth stone mouldings and dressings and Wilderness stone columns. Provision is made for Devonshire marble shafts to carry the roof principals, which it is to be hoped may be given by generous donors during the execution or after the completion of the work. The extreme length from east to west will be 124 ft., and the width from north to south 56 ft. The height to the wall-plate will be 36 ft. The height of the spire will be 120 ft. Accommodation will be provided for about 700 sittings eventually, the first contract, consisting of the nave and north aisle, having accommodation for 510. The contract has been taken by Messrs. J. Barnsley & Sons, of Ryland-street North, and the plans have been prepared by Mr. A. E. Dempster, architect and surveyor, Temple-row, Birmingham.

Hebburn Colliery.—On the 2nd ult. the foundation-stone of the Church of St. Oswald, Hebburn Colliery, was laid by the Rev. H. B. Carr, vicar of Whickham. The church is being erected from drawings by Mr. C. H. Fowler, F.S.A., architect, Durham, and will, when complete, consist of nave, aisles, chancel, bell-turret, organ-chamber, and vestry. The present contract (amounting to 1,777l. 10s.) is for nave and aisles only, to seat about 350 adults. The chancel will be built at an early date. The builder is Mr. S. B. Burton, of Newcastle. The church will be built of brick, with stone window dressings and arches. The lighting will be by a large four-light window in the west end, and windows in the aisles, and eight windows in the clearstory. The floors will be formed of solid wood blocks, bedded on concrete, to prevent liability to dry rot. Special care has been also taken to prevent damp rising in the walls

by the use of asphalt and Taylor's patent vitrified damp-course.

**Oswaldtwistle.**—On the 16th ult. the foundation-stone of a church to be dedicated to St. Paul was laid by Mrs. Watson, of the Rhyddings. The new church will seat 800 adults, and its cost, exclusive of tower, spire, and houndary-wall, is estimated at 6,500l. The site was given some years ago by Mr. R. Watson. The design is in the Middle Pointed style of architecture, and the total length of the church, outside measurement, will be 146 ft. 10 in. The interior will consist of chancel, a large parish-room, vestry and organ-chamber, nave, north and south aisles. The arcade dividing nave from aisles will be supported by ten granite columns with bases and fluted capitals. The western front will have two entrances, with a spacious narthex, 6 ft. wide. There will also be three other entrances. The church is to be built of local stone, from the Starhill quarry of Mr. W. Metcalf, with Box-ground dressings. The architects are Messrs. W. G. Habershon & Co., 38, Bloomsbury-square, and the builder is Mr. Thomas Clegg, Oswaldtwistle.

#### ROMAN CATHOLIC CHURCH-BUILDING NEWS.

**Boyle.**—On the 17th of September the new Roman Catholic church, dedicated to St. Joseph, at Boyle, was consecrated. The church, which is within a short distance of the town, is erected on a picturesque site, close to the Convent of the Sisters of Mercy and to the new schools. It is separated merely by the river Boyle from the magnificent ruins of the Cistercian Abbey. It is late thirteenth-century Gothic in style, and is of the usual cruciform shape, consisting of nave, aisles, and transept. The length extends fully 120 ft., the breadth is nearly 60 ft., and to the ridge of the roof the height is about 70 ft. from the ground. At the western end is the tower, rising 60 ft., the roof being surmounted by an elaborately-wrought cross. The inside of the church has been thoroughly finished. The roof is supported by twelve massive pillars of limestone, and the aisles are subdivided from the nave by four bays of the same material, resting upon caps, shafts, and bases. The three altars, which have been executed by Mr. O'Neill, of Great Brunswick-street, Dublin, are the work of Irish industry. The canopy of the high altar reaches to a height of 13 ft., and is 12 ft. wide, while beneath the table is an elaborately-carved panel bearing a motto on either side, and containing a group of the Annunciation and an angel. The general material is of Caen stone, all the shafts being of emperors' red and Irish marbles. In the reredos, which is subdivided into four panels, there are four statues representing the four evangelists. This altar is the gift of the late Mr. Thomas M'Dermott, Belanagare. The side altar of the Blessed Virgin, and the altar of St. Joseph, consist chiefly of Irish marbles. The entire cost of the church is about 8,000l. Messrs. Goldie & Child are the architects of the building.

#### SCHOOL-BUILDING NEWS.

**Cheadle Hulme.**—On the 2nd ult. the Bishop of Manchester opened new school-buildings for the Manchester Warehousemen and Clerks' Orphan Asylum at Cheadle Hulme. The design of the new schools is Gothic in character, and in keeping with the architecture of the orphanage buildings. The elevations are of red stock brickwork, with stone dressings and terra-cotta strings and label moulds. The accommodation on the ground-floor consists of a large central schoolroom with a large classroom at each end, divided from the central school by movable partitions. These partitions, when raised, will form the three rooms into a large lecture-hall, 86 ft. long by 25 ft. wide, and capable of seating nearly 500 persons. There are separate entrances for the boys and girls at each end of the building, with stone staircases leading to the first floor. On the first floor is placed a large central schoolroom for the juniors, of the same size as the one below, and at each end are placed the chemical laboratory, with apparatus-room adjoining, for the boys on the one side; and a large sewing-room for the girls on the other. Ample cloak-room and lavatory accommodation is provided on both floors for the different schools, and

private cloak-rooms for the teachers. There is also a storeroom for the school materials. The schools will accommodate about 400 scholars. The buildings have been erected by Messrs. R. Neill & Sons, contractors, of Manchester, from designs by and under the superintendence of Messrs. W. & G. Higginbottom, architects, St. James-square, Manchester. The schools have been erected in commemoration of the twenty-fifth anniversary of the foundation of the institution, and to meet its increasing requirements.

#### VARIORUM.

"THE Practical Steam Engineer's Guide," by Emory Edwards (Sampson Low, Marston, & Co.), is addressed especially to the engineers, firemen, and steam-users of America, but will be found, we are inclined to think, a valuable guide and assistant to a similar class in this country. It includes a large number of illustrations, and is clearly printed.—The first article in the October number of the *Nineteenth Century* will interest many of our readers; it is on the "Financial Condition of Trade Unions," by Mr. George Howell, and should certainly invite criticism, it is so charmingly rose-coloured. He thinks the gross balances of all the Unions may be put down as being equal to one-third more than the gross annual income; this would give them, he says, a total available balance of cash in hand of about three millions sterling,—equivalent to eighteen months' contributions, fees, and fines.—The proprietors of the *Victorial World* are making strenuous efforts to raise the character of this periodical, and are obviously succeeding. The first number of the new series, containing among other illustrations a portrait in colours of Sir Garnet Wolseley, is being reprinted as a special edition.—"*Fish's Academy Skits*" (153, Fleet-street) is a good shilling's-worth, very funny, and not ill-adapted. Although the Exhibition is closed, the little book of skits is still worth buying.—The "Metal Turner's Handbook" by Paul N. Hasnek (Crosby Lockwood, 1882) should be useful to some of the younger candidates for the prizes offered by the Turners Company. It includes 100 illustrations, and costs but a shilling.

#### Miscellaneous.

**Presentation to a Builder.**—A few evenings ago a numerous company supped together at the Russell Arus, Bedford-street, Amptill-square, on the occasion of the making a presentation to Mr. Stephen Jakins, builder, of Fitzroy-court, Tottenham-court-road. Mr. C. Spence, Mr. Jakins's foreman-president, and amongst those present were most of the firm's employes, as well as several contractors and merchants. On the removal of the cloth, the chairman made a few remarks as to the character of the gathering, observing that they had met together to do honour to a very worthy man. Mr. Jakins was not one of those "jerry" builders who put up a building which was blown down soon afterwards. His structures would last for centuries. The tenants on the estate of the Marquis de Rothwell, in Camden Town, and for whom Mr. Jakins was the builder, had freely come forward with their contributions, and the Marquis and Marchioness, directly they heard of the proposal, had sent cheques. Mr. Jakins was a straightforward, honourable, and businesslike man, and he had the greatest pleasure in asking the company to drink his health. Mr. Jakins, in a few appropriate and earnest words, thanked the subscribers for their gift (a valuable musical box), and the company for their good wishes. The members of the committee, Messrs. Pilkington, Brown, Jackson, Heal, and Sherriff, each spoke and alluded to the merits of Mr. Jakins, both as a builder and as an employer of labour, and referred to the amicable spirit that had been maintained between him and his employes.

**Northern Architectural Association.**—The annual meeting of this Association was held on the 3rd inst. in the Castle, Newcastle. The affairs of the Association were shown by the report read to be in a satisfactory condition. Mr. J. Tilmam, F.R.I.B.A., of Sunderland, who presided, was re-elected president, and other officers were chosen for the next twelve months.

**The Turners Company.**—The prizes awarded by this company were presented at the Mansion House on Thursday morning last. The exhibition included a considerable number of articles. Among the exhibits in wood were thermometers, vases, epergnes, flower-stands, candelabra, paper-racks, picture-frames, fruit-stands, and egg-cups. The judges in this class were Colonel Sandeman, Mr. C. Ilutson Gregory, C.M.G., Mr. J. Holtzapffel, and Mr. Joselyne, and they awarded the first prize, consisting of a silver medal and the freedom of the company, to Thomas Macdonald, of Chapel-house-street, Millwall, and the second prize, comprising a bronze medal and four volumes of "Holtzapffel's Turning and Mechanical Manipulation," to W. A. Barber, of 92, Cleveland-street, Fitzroy-square. There were twenty other prize-winners, seven of whom were apprentices. The judges recognised a general improvement in the quality of the works sent in, both in design and execution. In stone, the judges considered the whole competition most satisfactory and useful. The first prize they awarded, for tazza and three plates, to William Banks, of 6, Henry-street, Battersea, and the second to John Thomas Stevens, of 21, Douglas-street, Vincent-square, for candelabra and candlesticks. In the precious stones class the principal prizes went to W. Gorsuch, Mr. Brown, Frederick Shambrook, and Edward Renton. We cannot quite endorse the appreciative expressions of the judges. There was a considerable amount of good honest work, but the art displayed in many of the specimens was execrable.

**Steven Brothers & Co.**—The Milton Iron Works in Glasgow, with annexes in Upper Thames-street, London, is a very large establishment, and the newly-revised Illustrated Catalogue, just now issued (21st edition), is a large and expensive book to match. It is devoted more particularly to open and close fire kitchen-ranges, and will enable those who wish to make choice of such wares to do so with ease. One of Messrs. Steven Brothers' ranges ("123 in the book") obtained the first award at the Melbourne International Exhibition.

**St. James's Church, Clerkenwell.**—This parish church, which has undergone restoration, is about to be re-opened. Two large painted windows have been placed in the east-end of the church, the gift of the "Crusaders" Lodge of Freemasons, to commemorate the restoration; the subjects are "The Building of the Temple," and "The Queen of Sheba visiting the Temple on its completion." The Freemasons' and Crusaders' arms, numerous Masonic emblems, &c., are introduced. The windows are from the studio of Mr. Charles Evans, of Warwick-street.

**Competition: Christmas Card Albums.**—Messrs. Hildesheimer & Faulkner, publishers, are offering money for the best eighty albums containing Christmas and New Year cards and a further sum for certain fancy articles. It is a mere business advertisement, and they should take the ordinary means to make it known.

**Herne Burial Board.**—This Board advertised in August for competitive designs for a fence of oak, iron, or stone, and of a lych-gate for Herne Churchyard. The premium was awarded on September 26 to Mr. Allan O'Collard, of the Metropolitan Board of Works Office.

**Angell's Airtight Covers.**—Mr. Angell, of 144, Fulham-road, has sent to the Exhibition of the Sanitary Congress in Newcastle specimen of his Airtight Manhole Covers, which are used at various points of the drainage in basements so as to admit of examination, and are found to answer the purpose thoroughly well.

**Stained Glass.**—Another Munich window has just been placed in St. Alphege's Church, Blackfriars-road, representing Christ blessing little children. It is in memory of the wife of the Major-General Taylor, and has been designed and executed by Messrs. Mayer & Co.

**Great International Fisheries Exhibition, 1883.**—The construction of building for the Great International Fisheries Exhibition 1883, has begun in the Royal Horticultural Society's Gardens, and considerable progress has already been made.

**Barnley Borough Surveyorship.**—At a meeting of the Barnley Town Council on Wednesday afternoon, Mr. Stafford, of Liverpool was appointed borough surveyor, at a salary of 250l. per annum.

**"Dixon's New Metallic Gas."**—The *Liverpool Daily Post* gives some particulars of a new illuminating gas, introduced by Mr. John Dixon, a gas engineer. Mr. Dixon claims for his invention the production of improved gas for illuminating purposes by the decomposition or dissolution of the component parts or constituents of metals, carbons, acids, carbon, and hydro-carbon substances, the salts of alkalis, the dissolution of the substance being caused by heat. Certain chemical substances, when strongly heated, produce flames of peculiar colours, which, when blended, produce a white light, and, acting on this knowledge, the inventor claims to have realised what he says has been the dream of his life, and to have produced an apparatus capable of manufacturing and storing a gas the result of the decomposition of the above-mentioned chemicals, so that now he is prepared to supply a gas which, he says, is not only superior to, but vastly cheaper than, any supplied by any other persons or companies in any part of the globe. The new gas can, it is stated, be made at about one-tenth of the cost of coal gas, and another merit claimed for it is that it can be burnt without vitiating the atmosphere of apartments to anything like the extent which results from the combustion of coal gas. Its luminosity, as tested with the photometer, is stated to compare very favourably with that of coal gas. A limited liability company has been formed to work the patent, and model works, capable of supplying gas for upwards of 1,000 ordinary burners, have been established in the Commercial-road, Liverpool.

**What Co-operation can do.**—A correspondent writes:—"In 1847 the four sold in London by the millers of the neighbourhood was dear and bad, and the principal sufferers by this were the operatives of the district. A few of the most intelligent of their number got together and projected and started a co-operative mill. This proved a success, and, as years went on they added other articles to flour,—groceries, provisions, upholstery, tailoring, dressmaking, boot and shoe making, coal, &c. All these have been successful. I shall not trouble you with details or rate of progress; I desire simply to say that on last Saturday this society had 20,453 members, a capital invested by these members in business of 190,039*l.*, and a freehold and fixed stock in addition of 127,111*l.* Their business done during the last twelve months amounted to no less than 440,057*l.*; while in bonus and interest they paid to their members no less than 45,523*l.* during the same twelve months. This is one society, and there are in the country about 1,200 of them, though this is numerically the largest. I may add, that since 1844, when the first co-operative store was opened, 24 millions sterling have been divided among these working men in bonus and interest. There are nine millions sterling invested in business, and at the present moment two millions sterling per annum are divided among the working men composing these associations."

**TENDERS**

For new shop, and alterations to the Royal Oak Inn, Fenton, for Messrs. Keeling & Wright, Messrs. Keates & Bradford, Miles Bank-chambers, Hanley, architects. Quantities by the architects:—  
Bradley & Co., Wolverhampton ..... £1,240 0 0  
J. Gallimore, Newcastle, Staffordshire ..... 1,333 0 0  
J. T. Clarke, Hanley ..... 1,276 0 0  
Hancock & Tipping, Fenton ..... 1,270 0 0  
W. Collis, Longton ..... 1,169 0 0

### The Months and Seasons in Early English Art.

It has been shown, in our recent article upon Tessellated Pavements, that the artists of ancient Rome have left to us, but little injured by the devastations of twenty centuries, several mosaic pictures of the deities who presided over the months or the seasons, and representations in squares of coloured stone and glass of the months personified in human guise surrounded with attributes of conventional detail. Whether these pictures, elegantly and chastely conceived as they are, and executed in a manner which speaks eloquently of the labour and feeling of the art-workman to whom their fabrication is due, were suggested by any race older in the application of pictorial devices to paved floors than the Romans, or not, it would be difficult to decide. It may be that they were originally suggested to æsthetic minds by the fortuitous arrangement of the multi-coloured pebbles of a Mediterranean beach. But it matters little to speculate how first the idea of perpetuating a picture in a pavement arose. There can, however, be no doubt that just in the same way as the ornamental borders and geometrical patterns of the Roman pavements, at that period fairly numerous in England, were studied and reproduced in the earliest ornamental moldings, ornaments, cornices, and other subordinate parts of native English ecclesiastical architecture, for example, in the guilloché and hillet moulding, so also it is clear that the representations in the circular panels and compartments of these pavements,—themselves not altogether unlike the pictures which are found on the walls of Roman villas, or in the vellum pages of the early Roman manuscripts in the Vatican Library,—suggested to the expanding mind of the draughtsman and illuminator many of the beautiful groups which are found in the calendars prefixed, from the tenth to the fifteenth century, by the scribes of the Psalters and miscellaneous Service Books, to the volumes which yet exist to testify to the elegant character of this class of early art. These groups, of which the manuscripts in the British Museum contain a considerable number, are introduced into the

portions set apart for the monthly calendar, and in many cases they are balanced by similar pictures, also set in round panels or niches, of the zodiacal symbols with which we are all familiar; some, however, of the earlier pictures are drawn along the lower margins of the pages without any bounding line. In one of these, the celebrated Cottonian MS., Julius A. vi., a work of the eleventh century, January is illustrated in outline drawing by a group representing the practice of the art of ploughing. Four oxen are drawing the double-handed and wheeled plough over the peculiar hummocky ground which is so thoroughly representative of Saxon landscapes. The construction of the plough shows considerable intricacy. The oxen, yoked in two pairs, are guided by a man standing before them, and holding a long goad. Close behind the ploughman walks the sower with a bag of grain in his grasp, handfuls of which he is scattering among the irregular heaps and clods thrown up by the ploughshare. The whole picture is as natural and intelligible to-day as it was when first drawn 800 years ago. It may be compared with similar scenes in the celebrated Utrecht Psalter. Another Cottonian manuscript, Tiberius B. vi., contains a picture very richly coloured, but not so firmly drawn, containing but few points of difference in its details from this one. Later MSS., such as Nero C. iv., of the twelfth century and of English style, represent the opening month of the year as Janus, the two-faced Classic deity, holding a key in his hand, thereby symbolising the unlocking of the new year. This design is clearly of ancient origin, and there can be little doubt that it was suggested by a similar treatment of the month in a mosaic pavement, similar to those of personified months and seasons found at Corinth or Cirencester to which reference has been formerly made. Still later art symbolises January by a pretty little vignette of a man seated on a stool or chair, drinking from a bowl, which he raises to his mouth with one hand, while in the other he holds a hoot, the naked foot from which he has taken it being held to get warmth in front of a blazing fire upon the hearth. Sometimes a variation is introduced by the addition of a crutch in the hands of the figure, so as to point more conspicuously to the effects of winter upon the feet. Occasionally, a wine barrel, with a spigot in it, is painted at the side or in the background, thereby pointing out the nature of the beverage which the principal figure is quaffing, for January was in the early Middle Ages quite as markedly a month of feasting and jollity as it is even in these later days. Sometimes, also, the dress of the man seems to indicate that he belonged to some religious order, monastic or ecclesiastical. This scene of warming the feet before a fire is occasionally enhanced with the addition of a caldron or pot hanging over the fire upon a serrated hook. At other times it is replaced by the scene of a table set out with

viands of somewhat uncertain kinds, at which a hungry host or guest is being regaled.

February is variously symbolised. The earliest manuscripts show scenes of pruning or lopping trees, the operator being armed with a curved bill, not unlike those used for chopping wood at the present day, the trees being, however, of a stiff and conventional form, with branches fantastically bent into unnatural positions. Sometimes the month is personified by a woman with freely-flowing hair and gaudily-decorated robes, holding up in each hand a long candle or taper, lighted and ornamented with spiral bands. This device appears to refer to the great church feast of Candlemas, *Festum Candelarum*, or the Purification of the Blessed Virgin Mary. One early manuscript departs from this conventional design, and places in its stead a figure of a man seated warming himself before a fire, a device more commonly attributed, as has been shown above, to the preceding month. Another MS. in the Harley collection in the British Museum, No. 4,940, has for its February illustration a nun, or female in quaint attire, wearing a pair of black stockings, and holding up one leg in the attitude of a ballerina.

March is represented in several ways. The oldest manuscripts show various agricultural operations proper to the month, such as sowing grain, digging, raking, or hoeing the earth, and breaking up the clods with an axe or chopper; some of the hoes have an axe-head of peculiar form, almost Eastern in its curve; the sower is provided with a basket or sieve; the digger has a spade with a single shoulder only, not unlike some of the ancient spades recently figured by the late Mr. James Drummond, and described by Mr. Joseph Anderson in the work entitled "Ancient Scottish Weapons." The rake is broad and armed with nine teeth; the pickaxe and hoe have forms with which we are not unfamiliar from their frequent occurrence in works of archaeological illustration. A man lopping trees is a favourite symbol of the month of March, and in illuminated calendars of the twelfth and thirteenth centuries the resplendent colouring of the scenes, the gorgeous hues of the dress of the woodman, the golden backgrounds, and the elegant curves of the branches enriched with leaves of trefoil or other conventional and regular patterns, combine to make up a very beautiful and typical picture of the spring-time occupations of our rustic forefathers. One of these pictures of woodland is enriched with a bird's curious conical nest on the branches of a tree, but horizon is wanting and perspective faulty or disproportioned.

April is a joyous month, for the spring has already come in, and therefore the greater number of pictures symbolical of this month contain a youth in light clothing advancing towards the front, and holding up in each hand a branch of hawthorn or other native tree loaded with flowers and foliage. This, there can be little doubt, points to the custom pre-

valent at the present time of gathering the may, or whitethorn, a custom dear to the lower classes who dwell in great cities, and only too often ruthlessly destructive of the suburban hedges. It may be that some reference to the going of Noah out of the ark, a festival celebrated on the penultimate day of the month, is involved in this ancient custom of gathering the green leaf as an earnest that the wet season of winter was passed and the by-ways of the earth once again become pleasant and habitable. One early manuscript in the Cottonian collection replaces this usual scene with that of a feast, where three personages are seated on a throne or couch, which is adorned with terminals having the form of animals' heads,—the lion and wolf,—with an attendant pouring out wine or other festive drink on the right hand, and a guardian warrior, armed with shield and spear, on the left hand. Another equally ancient manuscript, dating from the eleventh century, has a picture of similar import, with the addition of an attendant blowing a horn. The month of May, in the earliest calendars, is illustrated by a picture of shepherds tending their flocks of sheep, in which the ram with his curling horn, and the ewe with her lamb, the crook, and the lamb in the arms of the shepherd, are naturally depicted with that charm which the simple homely character of Saxon drawings always possess. In another equally early manuscript a group of shepherdesses or country girls is introduced. But this scene gives place in succeeding ages to the far more frequent vignette of a falconer, either riding upon a horse or standing full-length, and holding on his wrist a falcon, hooded and jessed. Dancing, love-making, and turning sheep out to grass are also met with occasionally.

June is a very varied month in its early symbolical representations, and there is some confusion in the early manuscripts between this month and July and August. One of the oldest illustrations (Julius A. vi.) consists of a man loading the felled stumps of trees into a primitive wain or car, which is furnished with two wheels, and drawn by a pair of oxen yoked together. This very scene is given in another Saxon manuscript (Tiberius, B. v.) as the emblematic picture of July, the June scene in this manuscript being derived from the August scene in the Cotton Julius. Later illuminations attributed to June show scenes of haymaking, sheep-shearing, field sports, or tournaments, but principally of mowing with scythes, in some examples serrated on the cutting edges, in other examples indistinguishable in point of shape from those at present in use,—a striking instance of the survival of the forms of implements in common use; of gathering trefoiled and quatrefoiled flowers in a gaily-coloured field; or of men carrying bundles of faggots or boards, carefully corded, upon the back. The early Cotton manuscript already mentioned indicates July by a party of five grass-cutters each carrying a scythe, one in the act of sharpening his blade with a whetstone, another preparing to do so, while the three others are cutting the grass before them. An assistant stands by, using a two-pronged fork. Reaping with a sickle having a toothed edge in some cases is found in the vignettes of early calendars, but by far the most frequent is that of mowing.

In July, also, the manuscripts of English origin represent not only haymaking, but hoeing wheat, and French and Flemish manuscripts indicate the art of reaping. August is indicated in Saxon MSS. by a walled wagon, men reaping with the sickle, and carrying the cut corn to the cart, a watchman being stationed at each side of the field, on guard with a spear, against any sudden irruption of the too frequent enemy. One labourer appears to be using a kind of hand-drill. But scythes and sickles are frequently given in illustrations for this month. Sometimes the reaper gives place to the sower, as in the Cotton MS. (Nero, C. iv.); and the foreign manuscripts show the thrashing of the new grain, or a scene of shearing sheep.

September marks an epoch of the year; the Saxon MSS. are illustrated in this month of their calendar with driving swine to the forests, while an attendant blows a horn to warn the wanderer, and as an indication of his peaceful presence in the neutral ground which at that time lay between village and village, the "mark" land where law and right had little power to assert their ascendancy over prehistoric custom of indiscriminate attack. Sow-

ing grain from a bin or pocket, pruning vines and fruit-trees, gathering and treading out the grapes, also not infrequently form the emblematic representation of the month of September. The wine-vat, the earnest manner of the vintager, naked or draped gorgeously, and often raising a bowl of the juice to his lips, and the accessories of the wine harvest, are vividly and truthfully portrayed.

October begins to indicate a flagging of the annual spirits. Early codices show a heron or other large feathered game feeding in a forest, a man on foot, with rugged alpenstock or staff, flying a falcon at the game, a horseman also letting loose his trained hawk at the quarry, but ploughing, sowing grain out of a basket, wine-treading and juice-tasting, gathering grapes with a knife of strange crescentic form into a hemispherical basket, and heating down acorns for the swine, are also found to be used as typical illustrations for the month.

But November appears to have been the really correct time for driving herds of swine to the woods and beating down the acorns and the beech-mast for them, the curious form of the club being well worthy of notice; but the earliest manuscripts show a party of persons warming their hands before a blazing fire, while others carry a handful of sticks or fuel to add to it, the tongs, the handles of faggots, and the wattled wall being in every case details of interest. Killing fattened oxen or pigs with the two-handed axe, and carrying the dead meat away on a man's back while another destined victim looks vacantly upwards at the butcher, are not infrequent representations of this month in our early art-pictures.

December ushers in, at length, the end of the year's round of typical employments and customary duties. The early art indicates the carrying of corn in heavy baskets, borne by two men, on a pole; thrashing the grain with the flail; sifting or winnowing the results of the harvest; feasting at a well-spread board; killing cattle or swine with a heavy axe, upraised while the slaughterman places one foot upon the creature whose life he is about to take; sometimes the butcher is draped in a blue apron, girded up, and armed with a large axe, of which he appears to use the back, and not the edge, upon the devoted animal. One class of manuscripts represents December by a baker standing before an open oven and holding a peel in his hand, in the act of attending to the baking of bread and cakes. In some cases scenes of hunting are substituted for, or added to, the above-mentioned autumnal scenes; and occasionally, but very rarely, the December amusements are skating and sleighing. Most of these illuminated pictures are represented in minute detail, and afford to the student of ancient and Mediæval arts excellent examples of manners and customs, dress and details of interiors. A copious list of the manuscripts in the British Museum, containing the subjects of these calendar emblems, will be found in a volume, published in 1879, entitled "Early Drawings and Illuminations in the British Museum," by W. De Gray Birch and H. Jenner, at p. 265. Every one of the manuscripts will bear the closest and most careful scrutiny, for they are the representations of an art which has perished along with the scenes they delineate. The pictorial art which finds a place in modern calendars, although often ingenious, does not appear to have been inspired or influenced by a due and proper examination of these, its ancient prototypes, and, in so far, it fails to carry out the sacred, if not divine, precept of handing down to posterity the gift of human observation, which should be taken in hand with reverence and passed on to future ages with undiminished lustre, and, if possible, increased admiration for the things that belong to past ages, although the spirit of their influence is even yet not altogether dead among us.

**Woolwich.**—A monument is being erected at the entrance to the Gun Park, Woolwich Common, in memory of the officers and men of the Royal Artillery who fell in the Zulu and last Afghan wars. The memorial is in the form of massive granite blocks, and is being erected by voluntary contributions from the officers and men of the Royal Artillery throughout the world, the subscription being limited to one day's pay. The monument was designed by Count Gleichen, the artist for the new Prince Imperial memorial at the Royal Military Academy.

## PROPORTION IN PRACTICE.

A QUESTION STATED.

THE subject of proportion as an essential agent and element in architectural design has been treated so frequently and so variously, and nevertheless so irrepressibly recurs, that it seems to be matter of importance, in the interest of all parties to the discussion, that the questions which bear upon it should be clearly stated; and before discussion goes further,—as go further it certainly will,—certain hearings should be established which will enable bystanders to distinguish confused or irrelevant arguments from those which go straight at the obstacles to a simple and satisfactory solution.

The importance of proportion in architectural design in a general sense no one denies. So far as architecture leans upon engineering,—so far as it works under the conditions of stability of construction and economy of materials,—the designer is occupied with a succession of problems that turn upon the adjustment of relative quantities; that is, of proportion between weights and supports, thrusts and counter-thrusts, strains and resistances, voids and solids. A general regard to proportion is concerned no less in the combination of apartments and communications, in section and in plan.

And so as regards elevations and decorative treatment of members and details,—all are agreed to give chief applause to the designer whose work commends itself as pervaded by a fine sense of proportion. It is to such a sense, in fact, that the largest share of honour is assigned, altho when clumsiness and when feebleness is craved,—when the mean between the too little and too much, the *poco più* and *poco meno* of the Italian master, is happily and harmoniously achieved.

So far there appears to be scarcely an opening for disagreement; but, as usual, it is when generalities are narrowed down to the requirements of specific application,—when abstract theory has to make good its importance and utility in the face of a novel and diversified complex of particular circumstances, that occasions spring up for conflict of opinion, or for hesitations and perplexities, that forbid the student to commit himself to a very positive expression of either differences or agreement.

Difficulties enough are likely to arise with respect to selection of occasions for the application of proportion; but even when these are settled, opportunity is opened for discussion over a principle which may or may not affect more or fewer of these applications.

The importance of general regard to proportion in design being conceded, the question arises as to the degree of strictness with which we are to hold ourselves bound to such concession. Is there, in fact, any value in the observance of minutely precise proportions, whether extensive or moderate dimensions are to be dealt with? Is there, to take one example, any advantage to compensate for expenditure of solicitous care in exacting that a dimension of 100 ft. shall be executed without an error in excess or defect equal to the tenth of an inch?

A question in this extreme form might never have arisen but for the precedents which remain to us in the works of the Greeks. It is avowed on authority, that the example given is an exaggeration of the scrupulousness of their best architects in their noblest works. And whatever differences and doubts may exist as to the extent and definiteness with which any theory of proportion was worked out and accepted by the Greeks, there are none whatever as to their sense of proportion as evidenced by the effects of their works; their practical success is at least beyond cavil. A controversy is thus prepared for between those who assume,—and even say that they are prepared to prove,—that the Greeks worked upon a system of refined numerical proportion, and those who ascribe their success to no theory, but to an instinctive appreciation of the relative dimensions and magnitudes that would produce a beautiful effect. Even so, they will observe, one gifted with a good ear will sing in tune though entirely destitute of musical culture, and may even originate expressive airs which surpass the inventions of many a scientific musician; but an explanation of this kind manifestly goes no way towards accounting for the execution of architectural proportions with the infinitesimal accuracy of the example.

Here at once the controversy opens, and upon a donkey issue; or, rather, as they are not writing as controversialists, here at once we have to

pause and clear our ground before all parties to the inquiry can move on easily and amicably abreast. What sufficient assurance have we, in the first place, that the Greeks did execute their works with such marvellously scrupulous accuracy, whatever might be the process by which they decided on relative dimensions? And in the next place, and, after all, supposing that they are to be, indeed, credited with such astonishing conscientiousness, is there reason to think that any real advantage would accrue therefrom? It may, indeed, be still further a question whether, if the practice of the Greeks was in their particular circumstances both possible and advisable, it may be advisable and good for us to attempt to follow their footsteps in this direction. But this consideration may stand over; it is due to their great and merited authority that we should do our best to verify what their system was, and what was their own appreciation of its importance and the importance of its minute application.

Certainly there is great preliminary difficulty in conceiving how minute accuracy, such as that of our example, can be of any real value under the conditions of the case,—even in the clearer Grecian atmosphere, the comparative smallness of even their largest structures, and the sharpness of the Pentelic marble which they employed in them throughout. Is there any reasonable ground for ascribing to the sense of sight, marvellous as the faculty is, a power of appreciating differences of dimensions by special pleasingness or the reverse, with a delicacy that would more than rival the discriminating power of the musical ear?

When two musical notes sounded together are produced by concurrent sequences of vibrations of the air, which are so related that the third vibration of one is constantly coincident with the second of the other, a pleasing effect is produced which we call consonance. No one supposes that our pleasure on such occasions is due to recognition of this agreement in proportion. The fact of such agreement is only to be made evident by careful experiment. The vibrations which are propagated from a pair of strings travel to the ear together, and their periodical coincidence produces satisfaction in the absence and independently of explanation, and a musical ear is offended by the fact, not by the scientific knowledge, of the minutest failure in preciseness of proportion. The baton and the glance of Costa give sign when a semitone is false amidst the stormy melody of a full orchestra; but it would seem that the case must be very different with impressions which are propagated by vibrations, not of air, but of the luminiferous ether, and affect the eye concurrently from proportionate visible quantities. The eye has difficulties in responding to proportions which the ear is not troubled with.

The height of the Parthenon, from the line of step to the apex of the pediment, is proportioned to the breadth of the step, or stylobate, as 7 to 12; 12 : 7 :: 101:341 : 59:115 ft. The measured height (59:127 ft.) differs from that which is so brought out proportionately by the utterly insignificant dimension 0.012. But let this façade be seen in oblique perspective, when the stylobate would be foreshortened visually, as indeed it would be as most frequently seen, and what is then to become of any precise visual proportion? And even if we suppose the spectator to take up position directly in front, the visual angles under which he would receive impressions of height and breadth would be entirely different from, and therefore would entirely confound, the proportions of the dimensions as measured.

Let us take a still simpler example in another form. The height of a spire is precisely equal to that of a tower which it surmounts; any value which there may be in such equality may be expected to tell when we inspect a geometrical elevation, or when we view the structure itself from a very considerable distance, or from a station which brings the eye to an exactly intermediate level. But when it is viewed from any of the nearer and lower points of view which are chiefly to be considered, the upper division will be seen under a smaller visual angle than the lower, and the proportions of these angles will vary constantly as the observer shifts his position. What then, we may again ask, becomes of any value of approximation to equality of dimensions even within a foot or two, to say nothing of scrupulosity as to the fraction of an inch? Why may not the designer reasonably set aside respect for definite proportions altogether, complete his design by "scowl of brow,"

and settle dimensions for working drawings by scale of feet and adherence to the accepted divisions of the foot-rule?

If hesitation is felt in giving in to this conclusion, it will probably be on the part of those who, rightly or wrongly, are convinced that it was not so that the great designers of antiquity and (in their degree) of the Middle Ages also, worked, and that, considering results, it is scarcely safe to put aside the process which attained these results because we are incompetent to evolve the innermost secret of its importance. The stand which may be made on this line of defence is not to be treated contemptuously. We come here to the discussion not of the value of a theory in the first instance, but as to the matter of fact whether a theory was employed at all. If it is but in rare instances that Gothic architecture emulates the precise finish of the Greek, there is no lack of evidence in favour of a progressive consideration for systematic proportions, as when a preference appears for a triforium to be made just half the height of the clearstory in a bay, and both together just half the height of the central aisle; an arrangement which brings out a proportional sequence of 1, 2, and 3, between triforium, clearstory, and opening to the side aisle.

In the *Builder* of 12th June, 1880, p. 737, the interior dimensions of Henry VII.'s Chapel are given as,—length, 103 ft.; breadth, 35 ft.; height, 60 ft. It can scarcely be by accident that these dimensions are in continued proportion,—that the breadth is to the height precisely in the same simple proportion as the height to the length, viz., 7 : 12,—a proportion which, curiously enough, has other applications in the Parthenon besides that which has been quoted,—

$$7 : 12 :: 35 : 60.$$

$$7 : 12 :: 60 : 102.875.$$

The full demonstration that a system of proportion was employed by the architect of the Parthenon, and, of his mode of applying it, would require the reduction to form of materials for a treatise which is now not likely to be written. The appendix to Mr. Cockerell's "*Bassae and Ægina*" gives the general lines of the argument. It is enough to say that candid controversy is not likely to extenuate the significance of such a fact as that, in a building so pre-eminent for dignity of proportion as the Parthenon, no systematic regulation of dimensions by the foot-rule can be established, while adjustments by direct proportion made us everywhere. To take one example—the normal eastern abacus of the column is exactly one-fifteenth part of the breadth of the stylobate, and in this manner has a covert relation to the sum of eight diameters of columns and seven intercolumns which complete the plan of the portico. The stylobate measures 100 Greek feet, and it might be thought that 6½ such feet would be a convenient dimension, and near enough for proportion; it was not so thought, however, by Letimius, and instead of the simple 6:50, he chose to take the trouble to adopt the accurate fifteenth, or G:C6. If any architectural member whatever might seem to invite adherence to one settled dimension, it is the abacus. Yet on the western front it is varied, and again by a recognisable proportionate adjustment.

It appears, therefore, that if these questions are to be made matter of controversy, the parties to it are likely to confront each other as advocates of these incompatible theses. On one part it will be maintained that the employment of a precise and systematic scheme of proportion would in no way assist,—in fact, would hamper,—the designer, and so far be detrimental to beauty of design, and therefore could not have been an instrument of such masters of design as the great Greek architects.

On the other part we should hear,—As it can be positively made out that the Greeks of the best time did employ a scheme of proportion in the final adjustment and scrupulously exact execution of their designs, the presumption from their success is decidedly in favour of the importance of such an instrument, if we moderns can only recover and master it.

This latter view is, in any case, consistent with what all will acknowledge,—that in architecture, science and art join hands; there is a scientific element in all arts, but in architecture especially is the mion conspicuous, inevitable, salutary. Architecture, however, in its noblest forms, is still, is ever, an art specifically; and science must be content to occupy an

ancillary position, with so much self-respect as not to endure being jostled aside into insignificance, if also with so much modesty as not to pretend to undertake the functions of imagination and to oust her from her chair. Architectural science has some cause for complaint in having been gratuitously called upon to disown any such presumptions and having to struggle against unauthorised imputations which are advanced in prejudice of her most legitimate claims. It is too often assumed, by doubtless unintentional injustice, that those who earnestly hold that there is an important place in architecture for a systematic theory of definite proportions, imagine and inculcate that a student, when equipped with such a formula, is prepared to decide the dimensions of a few leading lines of his proposed building, and then to expect the other proportions to follow as a matter of course. No theorist who is sufficiently sober-minded to be worth attention entertains a notion so preposterous: he would be quite as ready to assert that when Beethoven had decided that his key should be C sharp minor, and made progress with some half-dozen phrases, his sonata was so far a finished work that any accomplished contrapuntist could complete it as well as himself. He would be quite as ready, or rather quite as little ready, to propound that, when a painter had resolved on a certain key of colour, and set his palette, and put in a few leading tints, difficulties were at an end, that imagination might go to sleep and beauty be trusted to evolve itself mechanically, to come out like a conclusion worked by Professor Jevons's logical machine.

What inevitable guidance may be involved in the adoption of certain leading proportions would seem at most to be of the scope and nature of those which the painter submits to when, having deliberately committed himself to certain conspicuous tints, he has thereby bound himself to keep the rest of his colouring in harmony with them as best he may, and, in considering how he may best, has to arbitrate among the artistic advantages of a variety of competing stratagems and combinations. The very selection of these dominant tints in the first instance is not arbitrary in any loose sense. It is in virtue of capacity for a lively conception of a suitable and expressive treatment of his subject, that proportionate combinations are recognised as emergent from the very subject itself; a certain harmony, a generative ideal, is begotten, so to speak, in his mind, and his problem is to realise it by working out the more reconcilable relations which are ultimately involved, but do not spontaneously declare themselves. The problems involved in the adjustment of proportionate forms by the architect are in strict analogy to those of duly balanced, relieving, contrasted, and generally related tints and tones in painting, and even of schemes and stratagems of composition. In how many a fine Italian picture, in how many a group of a Holy Family, do we observe the affection of the master for a triangular grouping, "the principle of the pyramid"? We may number example after example in the National Gallery alone; and how little way does the adoption of the principle advance a mere imitator to the position of a rival? Even so we find that while an identical proportion governs the ground-plan of both Parthenon and Theseum on their largest lines, their subsequent proportions are divergent with a decided ultimate contrast of effect.
