A candidate for registration as a chemist and druggist in Great Britain must have attained the full age of twenty-one years, as attested by a Registrar's certificate of birth, and be registered as having passed a preliminary examination in Latin, Arithmetic, and English. That examination should have been passed before apprenticeship, and may be the First Examination of the Pharmaceutical Society, or one of those included in the list at page 260. Candidates are advised, in their own best interests, to pass the Matriculation or the Senior Local Examination of one of the universities, and preferably the Matriculation Examination of the University of London, the more especially as, after August, 1900, the Society's First Examination will be discontinued, and candidate will be required to produce certificates of having passed approved examinations in Latin, Arithmetic, English, Euclid, Algebra, and French, German, or some other foreign language.

A certified declaration that for three years he has been registered and employed as an apprentice or student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions, must also be produced by the candidate when giving notice of his intention to present himself for the Minor or qualifying examination, and he is expected to specify whether he desires to be examined in London or Edinburgh. That notice must be given, and the fee of five guineas paid, to the Registrar of the Pharmaceutical Society, 17, Bloomsbury Square, London, W.C., on or before the fifteenth day of March, June, September, or December, and it may be stated, by the way, that the candidate must have attained the full age of twenty-one years on or before that day. The necessary notice having been given, and the fee—which covers the cost of registration as well as examination—paid, the candidate in due course will receive an intimation of the date on which he will be required to present himself for examination.

On the morning of the specified day he must attend at 17, Bloomsbury Square, London, or 36, York Place, Edinburgh, and, at ten o'clock, he will be set to work at practical chemistry, or practical pharmacy and dispensing, as the case may be. At two o'clock in the afternoon of the same day he will be examined in the practical subject not taken in the morning, and by five o'clock the practical portion of the examination will be concluded. If the candidate has satisfied the examiners in the practical subjects, he will shortly receive another notice, instructing him on what day to present himself for the oral portion of the examination. That usually occupies less than half a day ; the subjects are botany, chemistry and physics, materia medica, pharmacy, and prescription reading. A complete syllabus of the examination is given at page 260 *et seq.*, and suggestions regarding suitable text-books are printed at page 240.

It should be noted that the Council of the Pharmaceutical Society recommends all who propose to present themselves for the qualifying examination to undergo previously a systematic course of instruction occupying a period of not less than six months. That course of instruction, it is suggested, should include at least sixty lectures in chemistry, eighteen hours' work in each week in practical chemistry, forty-five lectures and demonstrations in botany, and twenty-five lectures and demonstrations in materia medica. The course recommended is an extremely modest one, and, added to a three to five years' apprenticeship, should be considered the fixed minimum of what is requisite. During apprenticeship—which, as already urged, should not be entered upon until a recognised preliminary examination has been passed—the student should devote as much time as possible to practical work in chemistry, botany, materia medica, and pharmacy. Theories of any kind should not be allowed to trouble his mind, as he will do better to approach them without prejudice after entering upon his college course. Everything should be regarded in connection with the British Pharmacopœia, the drugs, chemicals, and galenicals in the pharmacy being composed with the official descriptions, and those descriptions in turn carefully studied until they are thoroughly understood. The doses of all official medicaments should be committed to memory, the reading and interpretation of prescriptions should receive no inconsiderable share of attention, the chemical tests described in the Pharmacopœia should be applied practically, and field work in botany ought to be supplemented by dissecting and studying the specimens collected. Work with the microscope will be found to present a useful variety, as will also the work of preparing galenicals and compounding prescriptions, which is usually entered upon during the latter part of the apprenticeship.

With such a practical substratum of knowledge as has been briefly outlined, the student will commence his college course in a state of active receptivity, and six months' systematic work should then enable him, without difficulty, to secure qualification as a chemist and druggist. He will then be eligible for election as a member of the Pharmaceutical Society, and should not neglect the opportunity thus afforded him of becoming associated with the body which has been chiefly instrumental in organising pharmacy as a craft in Great Britain, and through the medium of which alone that craft is likely to reap any tangible benefit in the future. He will also be entitled to present himself for the Major examination, on passing which he will be registered as a pharmaceutical chemist, and become exempt from service on all juries and inquests in England and Wales.

This higher examination attracts but a small number of candidates compared with the qualifying examination, but the question of entering for it is well worth the attention of everyone who passes the Minor. It is a more purely scientific examination than the latter, and the subjects are only four—botany, chemistry, physics, and materia medica. As in the previous examination, the practical work is taken first, a whole day being devoted to practical chemistry. Half a day is occupied with the practical work in botany and materia medica, and the remainder of the examination is usually in writing, four papers being set—in botany, chemistry, materia medica, and physics respectively. The detailed syllabus of this examination will be found at page 262 *et seq.*, and past examination papers are printed in the *Pharmaceutical Journal* for July 8 last, at page 39.

After passing the Major examination, an attempt should be made to secure the Pereira Medal or one of the Pharmaceutical Society's medals. All pharmaceutical chemists who were members of the Society at the time of passing the Major examination are entitled to enter for those prizes, at the competition next following the date on which they passed. The subjects of examination are botany, chemistry, and materia medica, and candidates may sit for the examination—a written one—at London or Edinburgh. Other post-graduate work can be carried out in the Research Laboratory of the Pharmaceutical Society, which is open, without payment of any fee, to properly qualified persons who wish to carry out scientific investigations. Pharmaceutical chemists, who are members of the Society, will find no difficulty in securing permission to work in the Research Laboratory, provided space is available. Full particulars concerning the regulations, etc., will be found in the Society's Calendar, a copy of which every registered chemist will find it advisable to possess.

REGULATIONS OF THE BOARDS OF EXAMINERS.

FIRST EXAMINATION.

N.B.—This Examination will be discontinued after August, 1900.

(For Registration as Apprentices or Students.)

Fee Two Guineas.

This Examination will be held, at the following centres, at Eleven o'clock, on the second Tuesdays in January, April, July, and October:—

Aberdeen	Carnarvon	Lancaster	Nottingham
Birmingham	Cheltenham	Leeds	Oxford
Brighton	Darlington	Lincoln	Penzance
Bristol	Dundee	Liverpool	Peterborough
Cambridge	Edinburgh	London	Plymouth
Canterbury	Exeter	Manchester	Sheffield
Cardiff	Glasgow	Newcastle	Shrewsbury
Carlisle	Hull	Northampton	Southampton
Carmarthen	Inverness	Norwich	York

Also at the following centres in July only:—

Jersey; Guernsey; Isle of Man (Douglas); Orkney (Kirkwall).

Candidates must give notice to the Registrar in London, on a printed form of application, which can only be obtained from him, and pay the fee not less than *fourteen* days prior to that on which the examination is to be held. Each candidate must at the time of entry state at which of the centres he desires to present himself.

The Examination is wholly in writing, and comprises the following

SUBJECTS.

Latin. Grammar; Translation of simple sentences from English into Latin. Translation into English from Cæsar, "*De Bello Gallico*," Book I., or Virgil, "*Æneid*," Book I.

In each examination paper passages from both of these authors will be given, but a candidate is required to translate from one author only.

Arithmetic. Numeration; the first four rules—Simple and Compound; Reduction; Vulgar and Decimal Fractions: Simple and Compound Proportion; a thorough knowledge of the British and Metrical Systems of Weights and Measures; Percentages and Stocks.

In each examination paper a question will be given involving a knowledge of the Metric System, which every candidate will be required to attempt.

English. Grammar and Composition.

In awarding marks, Spelling and the quality of the Handwriting are taken into account.

TIME ALLOWED.

Latin, 11 a.m. to 12.30 p.m.; Arithmetic, 12.30 p.m. to 2 p.m.; English, 3 p.m. to 4.30 p.m.

Certificates Accepted in Lieu.

The Boards of Examiners are empowered to accept in lieu of the First Examination of the Society a certificate of having passed at one examination, all the compulsory subjects of any one of the following examinations, provided Latin, Arithmetic, and English were included in the subjects of the examination for which the certificate was granted. Each certificate must be forwarded to the Registrar with the fee of two guineas for the approval of the Board of Examiners, and must have been so approved by the Board of Examiners before the candidate will be eligible to enter his name for the Minor Examination.

The Honours and First Grade Leaving Certificates are accepted, provided the Certificates in English, Latin, and Arithmetic are all obtained at any one Annual Examination.

MAJOR AND MINOR EXAMINATIONS.

The Boards of Examiners in London and in Edinburgh will meet during the year 1899, in January, April, and July, also at the end of September or the beginning of October. The dates of the commencement of the examinations are duly announced in the *Pharmaceutical Journal*. The written and practical portions of the Examinations precede the oral portions.

Instructions to Candidates.

Each Candidate must give notice and pay the fee to the Registrar, Mr. Richard Bremridge, 17, Bloomsbury Square, London, W.C., on or before the fifteenth day of March, June, September, or December, and he will receive due notice of the date on which he will be required to present himself for examination.

When giving notice (for the first time), a Candidate for the Minor Examination must have attained the full age of twenty-one years, and must have been registered as having passed the First Examination. He will at the same time be required to produce a Registrar's Certificate of Birth, and a certified declaration that for three years he has been registered and employed as an Apprentice or Student, or has otherwise for three years been practically engaged in the translation and dispensing of prescriptions. The printed form on which this declaration is to be made can only be obtained from the Registrar in London. Each candidate must state, at the time of giving notice, whether he desires to be examined in London or in Edinburgh.

Modified Examination.

Persons entitled to enter for the Modified Examination and desirous of so doing, should apply to the Registrar for particulars. No person is eligible for this Examination who did not register for the same on or before December 31, 1869.

MINOR EXAMINATION.

For Registration under the Pharmacy Act, 1868, as Chemists and Druggists, and entrance to the Pharmaceutical Society as Members.

The following are the Subjects of Examination:—

Botany.

The candidate is required to possess a practical knowledge of:—

(*a*) CLASSIFICATION. The main divisions of the vegetable kingdom and their most important characteristics:—Thallophyta, Bryophyta, Pteridophyta, Phanerogamia. The following Sub-

classes and Natural Orders of the Angiosperms:—Thalamifloræ, Calycifloræ, Corollifloræ, Monochlamydeæ, Petaloideæ, Spadicifloræ, and Glumifloræ; Ranunculaceæ, Cruciferæ, Rosaceæ, Leguminosæ, Umbelliferæ, Compositæ, Solanaceæ, Liliaceæ. The description of flowering plants in technical language.

The candidate is also required to recognise any of the plants in the following list:—

List of Plants for Recognition.

Aconitum napellus.	Datura stramonium	Papaver somniferum.
Althæa officinalis.	Digitalis purpurea.	Pinus sylvestris.
Anthemis nobilis.	Fœniculum capillaceum.	Prunus lauro-cerasus.
Aspidium Filix-mas.	Hordeum distichon.	Quercus robur.
Atropa belladonna.	Hyoscyamus niger.	Rosa canina.
Avena sativa.	Juniperus communis.	Rosmarinus officinalis.
Brassica alba.	,, sabina.	Ruta graveolens.
,, nigra.	Lavandula vera.	Salix alba.
Bryonia dioica.	Matricaria chamomilla.	Sambucus nigra.
Cochlearia armoracia.	Mentha piperita.	Solanum dulcamara.
Colchicum autumnale.	,, viridis.	Taraxacum officinale.
Conium maculatum.	,, pulegium.	Taxus baccata.
Cytisus scoparius.	Menyanthes trifoliata.	Triticum vulgare.
Daphne laureola.	Œnanthe crocata.	Ulmus campestris.
,, mezereum.	Papaver rhœas.	Valeriana officinalis.

(*b*) Morphology, including Anatomy. The external form of plants:—thallus, stem, root, leaves, inflorescence, flower, fruit. The distinguishing features and common modifications of these structures. Principles of branching and different kinds of branch systems. Phyllotaxis, including vernation. The different kinds of buds and their arrangement on the stem.

A general acquaintance with the elements of plant anatomy; the vegetable cell, tissues, *e.g.*, merismatic, epidermal, fundamental and vascular. The characteristic anatomical features of roots, stems, and leaves of flowering plants and ferns.

The candidate is expected to recognise by means of the microscope, and describe sections illustrating the above plant structures.

The method of increase in thickness of stems and roots, and the characters of primary and secondary tissues. The characters of the flowers. The methods of pollination; self and cross-fertilisation. The formation of the seed and germination.

(*c*) Physiology. The *elementary facts* in connection with the physiology of plants, including the nature and source of the food of plants, and the manner in which the raw materials are elaborated. Chlorophyll, its manner of occurrence in the plant; its functions and the conditions under which it discharges them. Reserve materials, their nature, mode of deposition, and the manner in which they are utilised by the plant. The manner in which plants grow, and the conditions necessary for the growth of a plant. The manner in which plants respond to external stimuli, *e.g.*, light, gravity, etc. Sexual and asexual reproduction.

Chemistry and Physics.

The candidate is expected to possess an *elementary* knowledge of the following subjects:—

(*a*) The law of the conservation of energy; the law of gravitation; the balance; specific gravity; atmospheric pressure; pressure of aqueous vapour; the barometer, air-pump, and siphon; the law of Boyle; temperature; thermometers; the law of Charles; the law of gaseous diffusion; V. Meyer's method for determining vapour densities.

(*b*) The chief characteristics of chemical action, the distinction of elements and compounds; the laws of chemical combination by weight and volume; the hypothesis of Avogadro; atomic weight and molecular weight; chemical formulæ and nomenclature; valency; the distinction between metals and non-metals.

(*c*) The general characters of the non-metals; the chief methods of preparation and the typical reactions of the following non-metallic elements and compounds:—hydrogen, oxygen, ozone, water, hydrogen peroxide; chlorine, bromine and iodine, and their compounds with hydrogen and oxygen; fluorine, hydrofluoric acid; nitrogen, ammonia, the oxides of nitrogen, nitrous acid, nitric acid; sulphur, hydrogen sulphide, sulphurous and sulphuric anhydrides and acids, thiosulphuric acid; phosphorus, phosphine, the oxides and oxy-acids of phosphorus, the chlorides of phosphorus; silicon, silica, fluoride of silicon, silicofluoric acid; boron, boric acid. The usual impurities in such of the above-named substances as are included in the British Pharmacopœia.

(*d*) The general characters and classification of the metals, and the general methods of forming oxides and salts; the sources, the usual methods of extracting, and the chief properties of, the undermentioned metals, also the modes of preparation, properties, adulterations and contaminations of their principal compounds—potassium, sodium, ammonium, lithium, barium, strontium, calcium, magnesium, zinc, aluminium, iron, chromium, manganese, nickel, cobalt, arsenium, antimony, tin, copper, bismuth, lead, silver, mercury, gold, and platinum.

(*e*) Carbon, its oxides, cyanogen, hydrocyanic acid, cyanides, ferrocyanides and ferricyanides, oxalic acid. The chief methods of preparing methane, ethane, ethylene, acetylene, methyl and ethyl alcohols, formic and acetic aldehydes and acids, ethyl acetate, acetamide, olein, glycerol, benzene, phenol, nitro-benzene, aniline, benzoic acid, salicylic acid, hydrate of chloral, chloroform, iodoform, ether; the principal properties, reactions, and mutual relations of these compounds. The candidate will also be expected to possess a general knowledge of the methods of estimating carbon, hydrogen, oxygen and nitrogen in organic compounds, and of obtaining molecular formulæ.

Note.—The candidate is expected to solve simple problems relating to the weight and volume, under different conditions of temperature and pressure, of elements and compounds concerned in chemical reaction.

Chemistry.—Practical Examination.

The candidate is required to determine the specific gravity of liquids and solids, and to be familiar with the general construction and use of the thermometer and barometer.

To recognise by chemical tests the more important non-metallic elements and compounds, as well as the metals and salts indicated in the foregoing list; to detect the chief impurities in those that are included in the British Pharmacopœia; to recognise by their physical properties those which possess well-defined characteristics. To analyse a mixture containing not more than two metals and two acid radicles.

To identify by chemical tests the following organic compounds: hydrocyanic acid, cyanides, ferrocyanides, ferricyanides, oxalates, acetates, tartrates, citrates, salicylates, starch, cane sugar, grape sugar, salicin, quinine, morphine, strychnine, and their salts; and to detect the impurities in such as are included in the British Pharmacopœia.

To perform those volumetric determinations which are described in the British Pharmacopœia. To understand the principles of volumetric analysis, and to prepare, standardise, and use volumetric solutions.

To be familiar with the construction and use of the balance, and to have a practical knowledge of the Imperial and Metric Systems of Weights and Measures.

To quantitatively determine the total alkaloids in cinchona bark, and its official preparations, in the liquid extract of belladonna and its preparations, and in the liquid extract of ipecacuanha; also the strychnine in the extract, liquid extract, and tincture of nux vomica; the morphine in opium and its extract, liquid extract and tincture; and the resin in tincture of jalap.

To have a practical acquaintance with the methods of preparing the more important inorganic substances including the non-metals and their compounds, and such metallic compounds as are included in the British Pharmacopœia, and also the following organic compounds:—ether, chloroform, amyl nitrate, ethyl acetate, and hydrocyanic acid, so that he may be able to explain to the examiner the operations involved in their preparation, and if called upon, to perform the operations or certain stages of them himself.

Materia Medica.

The candidate is required to recognise specimens of any crude drugs mentioned in the British Pharmacopœia or in the annexed list, as well as their principal commercial varieties; to be acquainted with their botanical (or zoological), geographical, and commercial sources, the natural orders to which they belong, as well as the modes of collection and preparation for the market; to indicate the morphological nature of such as are organised, and the mode of formation of such as are unorganised; to correctly describe them,

and to point out diagnostic characters either chemical or physical, the latter as far as they can be ascertained by the use of a lens. To name the chief active constituents of official drugs, to know the proportion present in good samples of the more important of them, and to possess a practical knowledge of any pharmacopœial tests or processes of assay applied to crude drugs or their official products.

Animal Substances.
Castoreum
Mylabris cichorii
Mylabris phalerata

Barks.
Berberis vulgaris
Canella alba
Cinchona calisaya
Cinchona lancifolia
Cinnamomum cassia
Coto
Erythrophlœum guineense
Nectandra rodiæi
Pinus larix
Quercus robur
Rhamnus frangula
Ulmus campestris
Ulmus fulva

Cryptogamic Substances.
Cetraria islandica
Chondrus crispus
Fucus vesiculosus
Lycopodium

Flowers.
Arnica montana
Calendula officinalis
Pyrethrum cinerariæfolium, etc.
Rosa centifolia

Fruits.
Ægle marmelos
Cuminum cyminum
Laurus nobilis
Piper longum
Punica granatum
Vanilla planifolia

Gum-Resins.
Euphorbium
Olibanum

Hairs or Glands.
Mallotus philippinensis
Mucuna pruriens

Herbs, etc.
Convallaria majalis
Euphorbia pilulifera
Grindelia squarrosa et robusta
Juniperus sabina
Lactuca virosa
Marrubium vulgare
Ruta graveolens
Solanum dulcamara

Juices, etc.
Black catechu
Cape aloes
Gutta percha
Lactucarium
Manna
Natal aloes

Leaves.
Aconitum napellus
Nicotiana tabacum
Piper angustifolium

Resins.
Dragon's Blood
Elemi
Mastiche
Sandarac
Shellac

Rhizomes, etc.
Acorus calamus
Agropyron (Triticum) repens
Helleborus niger
Iris florentina
Sanguinaria canadensis
Veratrum album
Veratrum viride

Roots.
Alkanna tinctoria
Althæa officinalis
Bryonia dioica
Inula helenium

Seeds.
Amomum melegueta
Areca catechu
Dipteryx odorata
Hordeum distichon
Hyoscyamus niger
Paullinia sorbilis (Guarana)
Pyrus cydonia
Strychnos amara
Theobroma Cacao
Trigonella fœnum-græcum

Pharmacy.

The candidate is required to possess a general knowledge of the following branches:—

(*a*) Operations requiring the use of heat. Evaporation, with particular reference to the preparation of extracts and inspissated juices; special characters and modes of preparing the various classes of extracts; influence of surface, temperature and pressure upon the rate of evaporation; water, steam and sand baths; distillation, ordinary, fractional and destructive, distinctive characters and objects of each; official preparations illustrating the various kinds of distillation, apparatus employed, the retort and receiver, still and worm, Liebig's condenser, principles on which they are constructed and used. Sublimation; its objects and applications in pharmacy; official products of sublimation, calcination and fusion. Desiccation; temperature best suited for drying particular drugs, loss in drying vegetable drugs, forms of drying ovens, principles on which they are constructed and used.

(*b*) Disintegration of solid substances: cutting, bruising, and pulverisation; apparatus employed, principles indicating which is to be adopted in particular instances; methods for controlling the degree of comminution, sieves and sifting, trituration, levigation, elutriation, granulation, including methods for producing certain chemicals as fine powders, small crystals, scales, etc. Solution: its nature, solvent power of various menstrua, influences of (*a*) temperature; (*b*) state of division of the substance to be dissolved; (*c*) time; (*d*) position of the substance in the menstruum; lixiviation, infusion, digestion and decoction; maceration, percolation and displacement, principles on which the successful performance of these processes depend; form and materials for percolators and other vessels employed. Filtration, objects and methods, filtering media, means of expediting filtration; dialysis, its application in pharmacy, construction and use of the dialyser. Expression; methods of obtaining the juices from plants; recovery of the residual liquids from tincture marcs, etc., screw, hydraulic and other presses. The principles involved in the dispensing of medicines, particularly with reference to the best excipients and methods for forming pill masses, the preparation and nature of emulsions, the most suitable emulsifying agents, and the best means of suspending insoluble substances in liquids.

The candidate is also required to show a general knowledge of the processes, and understand the principles of the processes by which the official preparations belonging to the following classes are made: collodions, confections, decoctions, dilute acids, extracts (solid and liquid), glycerins, infusions, juices, liniments, lotions, mixtures, ointments, pill masses, plasters, powders (simple and compound), solutions, spirits, suppositories, syrups, tinctures, vinegars, waters and wines. A knowledge of the proportion of active ingredient or crude material in official preparations containing aconite, antimony, arsenic, belladonna, Calabar bean, cantharides, chloral hydrate, chloroform, caustic potash and soda, colchicum, digitalis, elaterinum, ergot, iodine, iodoform, ipecacuanha, lead, mercury, nux vomica, opium, phosphorus, scammony, stramonium, squill, alkaloids and alkaloidal salts.

The candidate is required—

(*a*) To enumerate the poisons contained in Schedule A of the Pharmacy Act, 1868, and those since added thereto, in pursuance of the provision contained in Section II. of that Act, viz.:—

Poisons within Part I. of the Schedule.
Poisons within Part II. of the Schedule.

(*b*) To describe minutely the conditions required upon the sale *by Retail* of poisons, both in Part I. and Part II. of Schedule A; and to write the proper entry required, according to Schedule F of the Act, for the sale of a poison coming within Part I. of Schedule A.

(*c*) To state the conditions imposed on the sale of scheduled poisons *by Wholesale and for Export*, and upon the sale of a scheduled poison when forming an ingredient in a medicine dispensed.

The candidate is also expected to possess a knowledge of the conditions imposed on the sale of Arsenic by the Arsenic Act.

Practical Pharmacy and Dispensing.

The candidate is required—To conduct such operations of the British Pharmacopœia, or such parts of them as may be practicable, involved in the processes for preparing collodions, confections, decoctions, dilute acids, extracts (solid and liquid), glycerins, infusions, juices, liniments, lotions, mixtures, ointments, pill masses, plasters, powders (simple and compound), solutions, spirits, suppositories, syrups, tinctures, vinegars, waters and wines.

To weigh, measure, and compound medicines; to write the directions in concise language in a *neat and distinct* hand; to finish and properly direct each package. [*In awarding marks in this subject the time taken by the candidate in doing the work is taken into account.*]

Prescriptions.

The candidate is required to read without abbreviation autograph prescriptions, translate them into English, understand the grammatical construction of the Latin, and render a literal as well as an appropriate translation of the directions for use. To detect errors, discover unusual doses, and have a general knowledge of posology. To calculate percentages and other quantities occurring in prescriptions; also to render in good Latin ordinary prescriptions written in English.

Candidates must not take into the Examination Rooms or Laboratories any books or any notes or memoranda, whether written or in print.

MAJOR EXAMINATION.

For Registration as Pharmaceutical Chemists under the Pharmacy Act, 1852. *Pharmaceutical Chemists are exempt in England and Wales from service on all Juries and Inquests under Juries Act*, 1862.

Fee Three Guineas.

The examination in the respective subjects may be oral, practical or in writing.

Botany.

In addition to what is required for the Minor Examination, the candidate is expected to show a competent practical knowledge of the following subjects:—

CLASSIFICATION.—The general principles of classification the Natural system.

The characteristic features of the following groups :—

- CRYPTOGAMIA.
  - THALLOPHYTA.
    - ALGÆ.
    - FUNGI (INCLUDING LICHENS).
  - BRYOPHYTA.
    - HEPATICÆ.
    - MUSCI.
  - PTERIDOPHYTA.
    - FILICINÆ.
      - Filices.
    - EQUISETINÆ.
    - LYCOPODINÆ.
- PHANEROGAMIA.
  - GYMNOSPERMÆ.
    - Coniferæ.
  - ANGIOSPERMÆ.
    - Dicotyledones.
      - *Thalamifloræ.*
        - Papaveraceæ.
        - Caryophyllaceæ.
        - Violaceæ.
        - Malvaceæ.
      - *Discifloræ.*
        - Geraniaceæ.
        - Rutaceæ.
      - *Calycifloræ.*
        - Saxifragaceæ.
      - *Corollifloræ.*
        - Dipsaceæ.
        - Valerianaceæ.
        - Gentianaceæ.
        - Scrophulariaceæ.
        - Boraginaceæ.
        - Labiatæ.
        - Primulaceæ
      - *Monochlamydeæ.*
        - Polygonaceæ.
        - Euphorbiaceæ.
        - Ulmaceæ.
        - Urticaceæ.
        - Cupuliferæ.
        - Salicaceæ.
        - Betulaceæ.
        - Myricaceæ.
    - Monocotyledones.
      - *Petaloideæ.*
        - Orchidaceæ.
        - Amaryllidaceæ.
        - Iridaceæ.
      - *Glumifloræ.*
        - Cyperaceæ.
        - Graminaceæ.

MORPHOLOGY.—Alternation of generations as illustrated by the life-histories in the several classes of plants; relative magnitude and degree of development of the sporophyte and the gametophyte. The general anatomy of plants, treated more fully than in the Minor Examination.

PHYSIOLOGY.—The general physiology of nutrition and growth. The relationships and adaptations of plants to their surroundings.

PRACTICAL WORK:—The candidate is expected to make and mount microscopic preparations illustrating vegetable structure, and to be able to apply microchemical tests for cellulose and its modifications as they exist in the cell wall, and for the chief products which are formed in plant cells.

Chemistry and Physics.

In addition to the subjects indicated by the Schedule for the Minor Examination the candidate is expected to possess a knowledge of the most important facts connected with—

(*a*) The physical constitution of the three states of matter; liquefaction of gases, critical point; the diffusion of gases and liquids, dialysis; methods for determining vapour densities; solution.

(*b*) The dynamical theory of heat; heat and temperature; sources, development and propagation of heat; radiation, diathermancy and athermancy, separation of heat from light; latent heat; boiling point, distillation; freezing mixtures; specific heat; calorimeters; relation of specific heat to atomic weight; methods of determining exceedingly high and low temperatures.

(*c*) The undulatory theory of light; reflection; refraction; interference of light; propagation of light, the photometer; mirrors and lenses, the microscope; decomposition of white light by a prism; the spectroscope, spectrum analysis; double refraction; polarisation, the polariscope; influence of light in promoting chemical change, the principles of the ordinary photographic processes.

(*d*) The methods of producing magnetism; magnetic induction. Sources of electricity, frictional electricity; the electroscope; electric induction; electric machines; the Leyden jar; voltaic electricity; the principal forms of voltaic batteries; the galvanometer; chemical effects of current; electrolysis; measurement of current, Ohm's law; voltameter; secondary currents; secondary batteries; thermo-electricity, the thermopile; production of heat and light from electricity; electromotors; dynamo-machines.

(*e*) The history of the atomic theory; the hypothesis of Avogadro; the methods by which the standard atomic weights have been determined; dissociation; specific volume; the periodic law.

(*f*) Classification of carbon compounds; rational formulæ; isomerism. The characteristics and constitution of the chief typical organic compounds. The constitution, sources, methods of preparation, properties, reactions and mutual relations of the following organic compounds: *Cyanogen derivatives.*—Urea, cyanuric acid, uric acid. *Hydrocarbons.*—The principal members of the paraffin, olefine, acetylene and benzene series; their chief haloid and nitro-derivatives. Theory of isomerism in paraffin and benzene series. *Paraffin derivatives.*—Distinction of primary, secondary, and tertiary alcohols; the chief primary monohydric alcohols: glycol; glycerin (glycerol); mannite; acetaldehyde; chloral; choral hydrate; acetone; ether; the principal acids of the acetic series: oleic acid; glycollic and lactic acids; oxalic, succinic, malic, tartaric, racemic and citric acids; ethylamine; acetamide; glycocine; cane sugar; grape sugar; milk sugar; maltose; starch and cellulose. *Benzene derivatives.*—Phenol sulphonic acid; phenol; resorcin (resorcinol); aniline; benzaldehyde; salicylaldehyde; benzoic acid; salicylic acid. The principal properties of the terpenes and camphors, essential oils, resins. The characteristics of naphthalene and its derivatives. The processes of alcoholic, acetic, lactic, and ammonic fermentation. The properties and decomposition products of the principal glucosides, alkaloids, and other substances of definite chemical composition in the British Pharmacopœia.

Chemistry.—PRACTICAL EXAMINATION.

The candidate is expected to be able—

To analyse mixtures containing three metallic salts; to estimate the nitrogen in organic compounds by the soda-lime and Kjeldahl processes; to determine melting and boiling points. To perform processes of gas analysis which can be carried out in a nitrometer. To perform the operations (or certain stages of them) necessary for the preparation of cyanogen, artificial urea, ethyl chloride, iodoform, ethylene, ethylene dibromide, acetaldehyde, formic acid, oxalic acid, nitro-benzene, aniline, benzoic acid, the nitrophenols. To recognise by their chemical reactions, and to determine, where necessary, by the Pharmacopœial gravimetric or volumetric methods, the strength and purity of the most important of the inorganic and organic compounds (including crude drugs and galenical preparations) described in the British Pharmacopœia. To detect and separate the most important alkaloids, alkaloidal salts and glucosides, and to separate in the pure state morphine from opium and strychnine from nux vomica. To detect methyl alcohol in tinctures, liniments, and other preparations.

In the practical portion of the Major Examination standard works of reference are provided for the use of candidates, at the discretion of the examiner. No other books or memoranda are allowed.

Materia Medica.

In addition to what is required for the Minor, the candidate is expected to show a practical knowledge of the methods of estimating the value of important drugs, of distinguishing commercial varieties of the same, and of separating such of their active principles as are official in the British Pharmacopœia.

The candidate is also expected to have a general acquaintance with the active constituents of all important drugs, and to possess a general knowledge of the chemical properties of the official alkaloids, glucosides, resins, and essential and fixed oils.

The candidate is expected to make and describe microscopical preparations of any organised vegetable drug official in the British Pharmacopœia, and to point out distinctive histological features in the same. The candidate is also expected to discover obvious adulterations present in powdered drugs, from comparison with authentic material.

EXAMINATION FEES.

	£	s.	d.
First Examination	2	2	0
Minor Examination	5	5	0
Major Examination	3	3	0

All fees must be paid at the time of giving notice to attend an Examination; and no portion of a fee will, under any circumstances, be returned.

Reduced Fees.

Persons who have failed to pass an examination, or who have failed to attend an examination at the time appointed, may on payment of reduced fees, re-enter for Examination.

THE REDUCED FEES PAYABLE ARE AS FOLLOW:—

(*a*) In the case of a person who has attended an examination and failed to pass.

	£	s.	d.
First Examination	1	1	0
Minor Examination.....	3	3	0
Major Examination	2	2	0

(*b*) In the case of a person who has failed duly to attend an examination at the time appointed } ONE GUINEA.

or

(*c*) In the case of a person who shall have proved to the satisfaction of the Council or the Boards of Examiners (by production of Medical Certificate or otherwise) that failure to attend was occasioned by unavoidable or proper causes ..... } ONE SHILLING.

SUBSCRIPTIONS TO THE PHARMACEUTICAL SOCIETY.

	ANNUAL SUBSCRIPTION. £ s. d.
Persons who have passed the First Examination, or whose certificates have been accepted in lieu thereof, are eligible to be elected "*Student-Associates*" *of the Society*	0 10 6
Persons who are registered as Pharmaceutical Chemists, or as Chemists and Druggists, are eligible to be elected *Members of the Society* .	1 1 0

Life Composition fee for Members . . . . Ten Guineas.

All subscriptions are due on election, and on January 1st in each succeeding year.

PRIVILEGES OF SUBSCRIBERS TO THE SOCIETY.

Members and Student-Associates of the Society are supplied with the Journal of the Society regularly as published, free of charge. They have also the use of the Library and Museum. Members have a voice in the administration of the Benevolent Fund of the Society, and, in case of need, may receive assistance therefrom. Student-Associates of the Society are eligible, under certain conditions (*see* below), to compete for the Jacob Bell Scholarships, the Manchester Pharmaceutical Association Scholarship, and the Herbarium Prize.

PRIZES AND SCHOLARSHIPS.

Council Examination Prizes.

Pharmaceutical chemists who were Members of the Society at the time of passing the Major Examination will be entitled to enter for the following prizes at the competition next following the date on which they passed the Major Examination:—

First Prize.—Pereira Medal in silver, and a present of books value £5, or thereabouts, given by the late Thomas Hyde Hills in memory of Jacob Bell.

Second Prize.—The Pharmaceutical Society's Medal in silver.

Third Prize.—The Pharmaceutical Society's Medal in bronze.

Subjects of Examination.—Materia Medica; Botany; and Chemistry.

The competition for these prizes takes place in April of every year, after the ordinary meetings in that month of the Boards of Examiners.

The Registrar communicates with each person entitled to compete, requiring not less than three days' notice of his intention to present himself for examination, and no person will be admitted to compete unless he shall have given the required notice.

The examination is a written one, and competitors may be examined in London or in Edinburgh.

The Council selects and appoints special Examiners, who set the questions, examine the answers, and report the result direct to the Council.

The Jacob Bell Memorial Scholarships.*

TWO BELL SCHOLARSHIPS are offered annually, and come into operation at the commencement of the Session in October, and the scholars shall for that Session be pupils in the Pharmaceutical Society's School.

ANNUAL VALUE OF SCHOLARSHIPS.—Each Scholarship is of the annual value of thirty pounds, and is tenable for one year only; each Scholar may, however, at the termination of his year of tenure, apply for free admission to the next ensuing Advanced Course in the Society's School. The payment will be made in two moieties; the first to be paid when the scholar enters upon his studies in the school, and the second at the expiration of five months. In addition to the endowment, the Council provides for the Bell scholars free laboratory instruction and admission to the lectures, and books of the value of £5—given by the late Thomas Hyde Hills—are divided equally between them.

Subjects of Examination.

Latin:—Virgil: the first three books of the Æneid; Latin prescriptions; translations of Latin into English and English into Latin; translations from any Latin pharmacopœia, and parsing. *French or German. English*:—Composition and parsing. *Arithmetic*:—The first four simple and compound rules, fractions, and decimals; the British and metrical systems of weights and measures. An elementary knowledge of *Chemistry*, *Pharmacy*, *and Botany*.

Conditions of the Competition.—Each competitor must give notice to the Secretary on or before June 1.

The notice must be accompanied by

(*a*) A Registrar's certificate of birth.

(*b*) Testimonials from present or previous employers, or masters, as to capability, industry, and general conduct.

(*c*) A declaration that the competitor has passed not less, or has been engaged not less than three years in the pharmacy of a Registered Pharmaceutical Chemist, or Chemist and Druggist. (The form on which this declaration is to be made can only be obtained from the Secretary.)

At the time of giving notice the competitor must be a Student-Associate of the Society.

On the day on which the examination is held the competitor must be not less than 20 or more than 22 years of age.

No person to whom a Manchester Pharmaceutical Scholarship has been awarded is permitted to compete for a Bell Scholarship.

The examination for these scholarships takes place on the second Tuesday in July, at the same centres as for the First Examination. It will be wholly in writing, and will be conducted under the same conditions as the "First" Examination, and such safeguards as the Council may from time to time deem expedient. The written papers must be distinguished by a motto, and not by the name of the candidate.

The examination will be conducted by two or more persons appointed by the Council, and the award made (subject to the approval of the Council) by a Committee consisting of the President, the Vice-Presidents, and the said examiners.

MANCHESTER PHARMACEUTICAL ASSOCIATION SCHOLARSHIP.

One Scholarship is offered annually, and will be presented at the commencement of the Session of the Pharmaceutical Society's School in October. The Scholar shall for that session be a pupil in the Society's School, or in case he may elect, he shall be a pupil in any Provincial School of Pharmacy approved by the Council of the Society.

The Scholarship is of the value of about £26 (the income arising from a sum of £750), which is to be expended for instruction in the Society's School, or in the Provincial School selected by the Scholar and approved by the Council of the Society.

* A scholar is supposed to be commencing his studies, or at least to have made only that progress which may be reasonably looked for during an apprenticeship. The object of the examination is to ascertain that the candidate has such an amount of ability, and affords evidence of having made such use of it in the acquirement of elementary knowledge, as will justify the expectation of his proving a successful student, who may do credit to the appointment, and become a useful and accomplished member of the pharmaceutical body.

Subjects of Examination:

Latin:—Virgil: *Æneid*, first three books, or Cæsar, *De Bello Gallico*, first three books of Commentaries;* Latin prescriptions; translation of Latin into English and English into Latin; translations from any Latin pharmacopœia, and parsing. *French or German. English:*—Composition and Parsing. *Arithmetic:*—The first four simple and compound rules, fractions and decimals; the British and metrical systems of weights and measures. An elementary knowledge of *Chemistry, Pharmacy, and Botany.*

Conditions of the Competition.—Each competitor must give notice to the Secretary on or before June 1.

The notice must be accompanied by

(*a*) A Registrar's Certificate of Birth.

(*b*) Testimonials from present or previous employers or masters as to capability, industry, and general conduct.

(*c*) A declaration that the competitor has passed not less, or has been engaged not less than three years in the pharmacy of a Registered Pharmaceutical Chemist, or Chemist and Druggist, in Lancashire, Cheshire, or the High Peak Parliamentary Division of Derbyshire. (The form on which this declaration is to be made can only be obtained from the Secretary.)

At the time of giving notice the competitor must be a Student-Associate of the Society.

On the day on which the examination is held the competitor must be not less than 19 or more than 21 years of age. The Examinations are held at the same time and centres as for the Jacob Bell Scholarships, and the award made in the same manner and by the same persons as in the case of those Scholarships.

No person to whom a Bell Scholarship has been awarded is permitted to compete for the Manchester Pharmaceutical Association Scholarship.

HERBARIUM PRIZE.

A Silver Council Medal is annually offered for the best Herbarium, collected in any part of the United Kingdom, the Channel Islands, or the Isle of Man, between the first day of January in one year and the first day of July in the year following, and should there be more than one collection possessing such an amount of merit as to entitle the collector to reward, a second prize consisting of a Bronze Medal, and also Certificates of Honour, will be given at the discretion of the Council. In the event of none of the collections possessing sufficient merit to justify the Council in awarding Medals or Certificates, none will be given.

Competitors must be Student-Associates of the Society, and under twenty-one years of age.

The collections must consist of Phanerogamous Plants and Ferns, arranged according to the Natural System adopted in some work on British Botany (such as that of Babington or Hooker), and be accompanied by lists, arranged according to the same method.

No collection may contain more than 150 specimens, which must be carefully selected and mounted so as to display the characteristic features of the more prominent and *typical* genera of the chief British Natural Orders. The name of each plant, its habitat, and the date of collection, must be stated on the paper on which it is mounted.

Each collection must be accompanied by a note, containing a declaration signed by the collector, and certified by his employer, or a Pharmaceutical Chemist to whom the collector is known, to the following effect:—The specimens which accompany this note were collected by myself, between the 1st day of January, 19—, and the 1st day of July, 19—, and were named and arranged without any other assistance than that derived from books.

The merits of the collections will be estimated not so much by the number of plants as by the correctness with which they are named, and by their being typical specimens. The manner in which they are preserved and mounted will also be taken into account.

The collections must be forwarded to the Secretary of the Society, 17, Bloomsbury Square, so that they may be received by him not later than the first day of July, indorsed "Herbarium for Competition for the Prize." After the Prize Distribution in October, they will be retained one month, under the care of the Curator of the Museums, and then returned to the collectors, if required.

* Passages from both authors are given, but a candidate is only required to translate from one author.

SCHOOLS OF PHARMACY.

LONDON SCHOOLS.

School of Pharmacy, 17, Bloomsbury Square, London, W.C.—STAFF: *Botany.*—Professor J. Reynolds Green, Sc.D., F.R.S., F.L.S. *Chemistry.*—Professor J. Norman Collie, Ph.D., F.R.S., F.I.C. *Materia Medica and Pharmacy.*—Professor Henry G. Greenish, F.I.C., F.L.S. Each professor is assisted by demonstrators. Applications for admission should be addressed to the Secretary of the Pharmaceutical Society at the above address.

BOTANY.—The Elementary Course will extend from October 5, 1899, to the end of June, 1900, the lectures being delivered on Thursdays and Fridays at 12 o'clock. The laboratory work will be held on Friday mornings, commencing at half-past 9, and will be conducted by the demonstrator under the supervision of the professor. The Advanced Course will extend from October, 1899, to the end of March, 1900. From October to December lectures will be delivered on Thursdays and Fridays at 2 o'clock, and from January to March on Thursdays only, at the same hour. The laboratory work will be held on Thursday mornings from half-past 9 till 1, and will be conducted by the demonstrator under the direction of the professor. The gardens of the Royal Botanic Society, Regent's Park, will be open for purposes of study to all students of the School. FEES: Elementary course, £5 5s.; advanced course, £3 3s.

CHEMISTRY AND PHYSICS.—The lectures on elementary chemistry will be delivered by the professor on Wednesday and Saturday, commencing on October 4, and those on physics by the assistant lecturer on Thursday mornings at half-past 9 o'clock. The lectures on advanced chemistry will be on Monday and Tuesday at 12 o'clock, commencing on October 9, and those on physics by the assistant lecturer on Wednesday at 2.30 and Friday at 9.30. The Elementary Course terminates at the end of June. The Advanced Course, which is more particularly intended for advance students, terminates at the end of March, but students who have passed the Major examination at the end of this course are entitled to apply for admission to the Research Laboratory without payment of any further fee. Other students who have completed the Advance Course and are desirous of taking a supplementary course in practical chemistry may be admitted for the remainder of that session on payment of a special fee of three guineas. FEES: Elementary course, £5 5s.; advance course, £3 3s.

PRACTICAL CHEMISTRY.—The chemical laboratories are open from 7 a.m. until 5 p.m. daily. On Saturdays they are closed at 2 o'clock. These laboratories are fitted up with every convenience for the study of the principles of chemistry by personal experiment. They are specially designed for the students of pharmacy, but are equally well adapted for the acquirement of a knowledge of chemistry in its applications to medicine, manufacturers, or analysis. A complete elementary course of instruction occupies about nine months, students working not less than three hours daily; a complete advanced course, including the higher branches of quantitative analysis, occupies about six months. FEES: Elementary course (three hours daily), £12 12s.; advanced course (three hours daily), £9 9s.

THE RESEARCH LABORATORY.—Students who have passed the Major examination, and others desirous of obtaining information concerning the application of chemistry to the higher branches of pharmacy, or of undertaking scientific inquiries, are eligible for admission. In this laboratory advanced instruction is given, without fee, in chemistry in its relations to pharmacy and in the methods of chemical investigation, under the direction of the professor and his assistants. Applications for admission should be made, in the first instance, to Professor Collie, who will submit the names to the Research Committee for approval.

MATERIA MEDICA.—The Elementary Course of lectures in this subject will be delivered on Tuesdays at half-past 9 o'clock, commencing on October 3, 1899, and extending to the end of June, 1900. Each lecture will be followed by practical work in the histological laboratory, which will be conducted by the demonstrator under the supervision of the professor. The Advanced Course of lectures will be delivered on Wednesdays at 12 o'clock, commencing on October 4, 1899, and terminating at the end of March, 1900. The lectures will be preceded by practical laboratory work. FEES, £3 3s. for each course.

PHARMACY.—The lectures on this subject will be delivered on Mondays and Tuesdays at half-past 2 p.m., commencing on October 3, 1899, and extending to the end of June, 1900. Each lecture will be followed by practical work in the laboratories. The subject matter will be divided into pharmacy and dispensing. During the course of instruction in pharmacy and dispensing, modern appliances for the pharmaceutical laboratory and the dispensing counter will be described, and, if possible, practically used, special attention being directed to such apparatus as the retail pharmacist may advantageously employ in the daily routine of his calling.—FEE: £6 6s.

PRIZES.—At the end of June, bronze medals and certificates of honour are offered for competition by students who have attended the elementary course, and at the end of March silver medals and certificates of honour are open for competition by students who have attended the advanced course. The silver medallists are presented by Mr. Thomas Hanbury with a copy of 'Pharmacographia,' and of 'Science Papers,' in memory of his brother, the late Daniel Hanbury, F.R.S. For particulars of scholarships see p. 264.

Brixton School of Chemistry and Pharmacy, 12, Knowle Road, Brixton, London.—PRINCIPAL, Dr. A. B. Griffiths, F.R.S. (Edin.), F.C.S. At this school Day and Evening Classes are held for the Minor and Major examinations. Tuition is afforded in chemistry, botany, materia medica, pharmacy, physics, prescription reading, and biology for medical students. A medal is awarded at the end of each full course, to the best Minor and Major student respectively. Students may join at any time, and full information as to fees, etc., may be obtained by writing to Dr. Griffiths, at the above address.

City School of Chemistry and Pharmacy, 27, Chancery Lane, London, E.C.—STAFF: Mr. F. A. Hocking, B.Sc., Ph C.; Mr. Dallas, M.A. (Honours); Mr. Lee, B.A., B.Sc. (Lond. with honours); Mr. M. J. Cole, etc. Day Classes are held in all subjects for the Minor Examination beginning in January, April, June and October respectively. FEE for the six months' course, £12 12s. Evening Classes for the Minor are also held. Six months' FEE, £7 7s. The next term commences September 4, but students can join during September and October. Full details will be supplied by the Principal or Secretary.

Imperial College of Chemistry, 49 and 51, Imperial Buildings, Ludgate Circus, E.C.—PRINCIPAL, Mr. Frederick Davis. Classes (day, 10 to 5; evening, 5.30 to 8) are held in chemistry, biology, botany, materia medica, microscopy, pharmacy, physiology, prescriptions, sanitary science, and hygiene. FEES, Minor £10 10s. Especial private tuition may be arranged for any desired subject. Major course, £6 6s. The analysis of food and drugs is now taught at this College, and an especial course of instruction has been organised for Fellows and Associates of the Institute of Chemistry to meet the requirements of the Local Government Board in Therapeutics, Pharmacology and Microscopy, as recommended by the Council of the Institute.

The London College of Chemistry, Pharmacy, and Botany, 323, Clapham Road, S.W. Staff, Mr. Henry Wootton, B.Sc. Lond. (Principal); Mr. William Arthur Knight, Ph.C.; Mr. C. E. Franklin Vallet, Ph.C.; Mr. J. Griffith Edwards, M.P.S. This college has been established for the purpose of providing thorough and practical instruction in all branches of science, especially for students preparing for pharmaceutical, medical, and university examinations. The next complete course of lectures, classes, and practical work for Minor and Major students begins on October 11. Lectures will be delivered daily, at 10 a.m. and 3 p.m., on chemistry, physics, botany, materia medica, and pharmacy. Practical work in the chemical, pharmaceutical, and physical laboratories daily, 11 a.m. to 2 p.m. (except Saturday). Tutorial Classes daily at 4 p.m. (except Saturday). The Special Tutorial Classes in the various subjects are held daily (in addition to the regular lectures and practical work). Evening Classes are also held for Minor and Major students. Particulars as too fees, etc., on application to the Secretary.

London College of Pharmacy and Chemistry for Ladies, 5 & 7, Westbourne Park Road, Porchester Square, W.—Courses of instruction are given at this school for the Minor and Major examinations, the fees being £10 10s. for the Minor, and £8 8s. for the Major. Dispensing or separate subjects £2 2s. Students who cannot attend may correspond through the post. A special feature is an employment agency for lady dispensers. Particulars may be obtained from the Secretary.

Metropolitan College of Pharmacy, 162, Kennington Park Road, London, S.E.—PRINCIPAL, Mr. Watson Will. Demonstrators: Messrs. G. T. Branch, H. Lucas, and F. Filmer De Morgan. Secretary, Mr. W. S. Carver. There are three sessions, winter, from September 1 to December 31; spring, from January 1 to April 10; summer, April 12 to July 24. FEES: Minor course, £10 10s.; Major course, £8 8s.; Major evening course, from September 1 to following July, £12 12s. Minor evening course, £3 3s. Extra evenings may be taken for practical work.

School for Lady Pharmaceutical Students, 33, Store Street, Bedford Square, W.C.—This school has been established by Miss L. de Lassasie, M.P.S., for the coaching of lady pharmaceutical students. There is a fully equipped laboratory and a dispensary fitted with every appliance necessary for a complete course of studies. The new term commenced on September 4, but arrangements can be made by which single students may commence their studies at any time. For full particulars application should be made to Miss de Lassasie, at the address given above.

South London School of Pharmacy, Limited, 325 and 409, Kennington Road, London, S.E.—STAFF: Dr. Muter, F.R.S. (Edin.), F.I.C., etc.; Mr. D. Kingan, M.P.S., ; Mr. W. F. Mawer, F.C.S., M.P.S.; Mr. F. Armstrong; Mr. J. Thomas, B.Sc. (Lond.), First Class Honours in Chem. and Physics; and Mr. A. H. M. Muter, A.I.C., F.C.S. The school premises include a chemical laboratory; a very complete museum of drugs, chemicals, and plants, and a laboratory for the manufacture of pharmaceutical preparations. There is also a fully-furnished dispensary, and rooms specially furnished with microscopes and all appliances for practical biology; and also with full sets of electrical, optical, and thermal instruments. The lecture room is in a separate building from the laboratories, so as to be free from fumes. The session lasts from the beginning of October in each year until the middle of July in the following year. A fresh course of lectures (commencing at the foundation of each subject) is begun in October, January, and April. FEES:—Minor course, £5 5s. Major course, £3 3s. No ordinary student can attend the theoretical classes without also taking the practical work, the fees in the practical department for both Minor and Major divisions being £3 3s. per month. Compounding fees for every necessary subject either for Minor or Major (theoretical and practical): £12 12s. for the first term (about 3½ months), £8 8s. for a second, and £7 7s. for a third term. Students having once paid three terms' fees become perpetual students and can remain in the schools as long as they please on payment of a nominal fee of £2 2s. per month to cover expenses of practical work.

The Students' Laboratory, 40, Lamb's Conduit Street, W.C.—TEACHERS: Mr. T. A. Ellwood, F.I.C., F.C.S.; Mr. C. E. Sage, F.C.S., M.P.S. In connection with this laboratory classes are held to prepare students for the examinations of the Pharmaceutical Society, the system employed being devised to ensure individual teaching and personal attention to each student in both practical and theoretical work. The laboratory is open every evening except Saturdays, from 6.30 to 9.30. FEES for three months: One night weekly, £1 11s. 6d.; two nights weekly, £2 17s. 6d.; three nights weekly, £4 4s.; four nights weekly, £5 5s.; five nights weekly, £6 6s. During the winter months a class is held for teaching more advanced practical work, the analysis of foods, drugs, water, and commercial products.

Westminster College of Chemistry and Pharmacy, Trinity Square, Borough, London, S.E.—PRINCIPAL, Mr. G. S. V. Wills, F.L.S., Ph.C.; Secretary, Mr. E. Walden. Day Classes are are held in chemistry and physics, materia medica, botany, pharmacy, and dispensing. The college is open from 9 to 5 daily, and the time not devoted to lectures and tutorial classes is occupied in practical work in the various subjects. FEES: Minor complete course, £10 10s.; two courses, £15 15s.; until qualified, £15 15s. if the ticket be purchased before December 31, 1899; Major course, three months, £6 6s.; until qualified, £10 10s.; Evening Classes, for the Minor and Major examinations, and practical work are held every Tuesday, Wednesday, and Thursday from 7 till 9. FEE, three months, £1 1s.

PROVINCIAL SCHOOLS.

BARROW-IN-FURNESS.

Barrow-in-Furness Higher Grade School. — At the Barrow Higher Grade School technical classes are held on Monday, Tuesday, Thursday, and Friday evenings, commencing September 11, in theoretical and practical chemistry, physiology, and hygiene. Further particulars may be obtained from the Secretary, Mr. C. F. Preston, town clerk.

BIRMINGHAM.

Birmingham Municipal Technical School, Suffolk Street, Birmingham.—Day Classes are held in theoretical and practical chemistry for pharmaceutical students. Teachers, Mr. C. J. Woodward, B.Sc., and Mr. A. W. T. Hyde. Fee, 5s. per session. Evening Classes are held in botany. Teacher, Mr. J. W. Oliver. Fee, 3s. 6d. per session; and also in physics. Teachers, Dr. Sumpner, and Mr. P. C. Coultas, A.R.C.Sc., etc. Fee, 5s. per session.

Central School of Pharmacy, 90, New Street, Birmingham.—Mr. F. Stokes Dewson holds classes for the pharmaceutical examinations—Major, Minor, and Preliminary. The classes are held day and evening. Practical pharmacy and dispensing receive special attention.

Mason University College, Birmingham.—Teachers: Professors Percy F. Frankland and Hillhouse, and Mr. Dencer Whittles. Day classes are held in chemistry, botany, materia medica, pharmacy, etc. Fees: Chemistry (from October to March and a weekly tutorial class) £5 5s.; organic chemistry suitable for Major students (April to June), £1 11s. 6d.; botany (spring and summer terms), £2 2s.; systematic botany (summer term), £1 1s.; materia medica and pharmacy, £1 1s.; incidental fee for practical pharmacy, £1 1s.

Temple Chambers Tutorial Classes.—Mr. F. H. Alcock holds classes at Temple Chambers, Broad Street Corner, Birmingham. Special facilities are offered to students who desire to improve themselves in practical work. The classes are tutorial and personally conducted. A time table will be forwarded to intending students on application. The fees are dependent upon time and subjects, a full time student in all subjects paying seven guineas per quarter.

BRADFORD.

Bradford Technical College.—Head of Chemistry Department and Lecturer in Chemistry, Mr. Walter M. Gardner; Assistant Lecturer and Demonstrator, Mr. W. F. Sutherst, Ph.D.; Lecturer in Botany, Biology, and Materia Medica, Mr. W. West. Day and Evening Classes are held in chemistry, etc., and a special pharmaceutical course has been arranged, extending over two (evening) sessions, adapted for students who are preparing for the Minor examination, and an inclusive fee, at a reduced rate, is charged to students who enter for the full course.

BRIGHTON.

Brighton Municipal Technical Schools.—Classes are held in connection with this school for pharmaceutical students, particulars of which may be obtained from the Secretary.

BRISTOL.

University College.—Professors: Sydney Young, D.Sc. (Lond.), F.R.S.; A. P. Chattock, M.I.E.E.; C. Lloyd Morgan, F.R.S.; S. H. Reynolds, M.A. Lecturers: Messrs. F. E. Francis, B.Sc., Ph.D.; E. Jackson, M.A., B.Sc., Ph.D.; L. N. Tyack; G. Brebner; A. B. Prowse, M.A.; and F. W. Stoddart, F.I.C. Day and Evening Classes are held at the University College in chemistry (organic and inorganic), experimental physics, and botany. There are also chemical and physical laboratories.

CAMBRIDGE.

Cambridge Pharmaceutical Association.—Classes in botany and chemistry are held at the Technical Institute, from October to May, in conjunction with the Science and Art Department of Kensington. Further information may be obtained from Mr. E. Saville Peck, 30, Trumpington Street, Cambridge.

EXETER.

Exeter School of Pharmacy.—Full instruction is given at the Exeter Technical and University Extension College in all subjects required for the Minor examination. The session begins about the first week of October, and terminates at the end of June. Evening Classes are also held. For prospectus and particulars apply to the Secretary of the College.

LANCASTER.

Lancaster Municipal Technical School. The Storey Institute.—Instruction in physics, inorganic and organic chemistry by means of lectures, fully illustrated by experiments, classes, and of practical work in the laborotory, is given in connection with this school.—Lecturer, Dr. A. Schloesser, assisted by Mr. Ayrton. Lectures on botany, fully illustrated, are also given by Mr. W. Wyatt, Ph.C. Further particulars may be obtained from the principal, Dr. Schloesser.

LEEDS.

Leeds College of Pharmacy, 19, Spring Field Place, Leeds.—Principal: Mr. F. Pilkington Sargeant, Ph.C. Full time, evening and weekly classes for Minor and Major students are conducted at this college, the two latter classes being specially adapted for assistants who wish to prepare for the Minor examination whilst retaining their situations, or apprentices desirous of obtaining a good foundation for future work. The Major classes also include an evening class working on Tuesday, Wednesday, and Thursday from 8 a.m. to 10 p.m. Fees: Three months' course, £8 8s.; six months' course, £14; August to January course, £10 10s. Evening and weekly classes, six months' course, £4 4s. Separate courses on individual subjects may be taken by arrangement.

Leeds Technical School (in connection with the Leeds Institute of Science, Art, and Literature), Cookridge Street.—Evening classes are held for students in pharmacy, in theoretical and practical chemistry, physics, and botany. Practical work in chemistry, physics, and botany is offered in addition to the lecture courses. The lecture fees are from 2s. 6d. per session, and the laboratory fees from 7s. 6d. Prospectuses of the classes with other information may be obtained from Mr. Arthur Tait, Secretary.

LIVERPOOL.

Liverpool School of Pharmacy, 6, Sandon Terrace, Upper Duke Street, Liverpool.—Principal, Mr. R. C. Cowley, Ph. C., assisted by demonstrators. Day classes are held in all the subjects of the Minor and Major examinations. Fees: Minor course, £10 10s.; September to April or January to July, £16 16s.; Major course, £9 9s. Once a week classes are held, one evening for juniors and one for advanced students. The fee for this class for a course is £3, or for the whole session £7 10s. The course of study in this school is controlled by the Council of the Liverpool Chemists' Association.

University College, Liverpool. School of Pharmacy—A complete course of instruction for the examinations of the Pharmaceutical Society may now be taken in University College. The Professors of chemistry, physics, botany, and materia medica afford instruction in their particular subjects, and a lecturer in pharmacy has been appointed. There are very complete museums of chemistry and botany, and a materia medica museum. The Session comprises a first course suited to the requirements of students preparing for the Minor examination, commencing on October 2, 1899, and a second course, embracing the higher branches of study required for candidates for the Major qualification, beginning in May, 1900. A scholarship of the annual value of about £26 is tenable in this school. Applications for admission and all inquiries must be addressed to the Registrar, University College, Liverpool.

MANCHESTER.

Manchester College of Chemistry and Pharmacy, 225a and 227a, Oxford Street, Manchester. Principal: Mr. Charles Turner, Ph.C., F.C.S. The year's work for the Minor and Major examinations is divided into the following Courses:—January to July, fee £14 14s.; second Monday in August to January, fee £11 11s.; October to April, fee £14 14s. In addition to these Main Courses there are Short Courses for Advanced Students for all examinations, also a Special Evening Class for Lady Students. All Students have the privilege of free admittance to the Royal Botanical Gardens at Old Trafford.

Northern College of Pharmacy, 100, Burlington Street, Manchester. TEACHERS: Messrs. George Clayton and Frederick Lawson. The fees for the Full Time and Afternoon Classes are: Minor course, (day), January to April, £9 9s.; April to July, £9 9s.; September to January, £10 10s.; (afternoon), January to July, £4 4s.; September to December, £2 10s. Major course, January to April, £5 5s.; April to July, £5 5s.; September to January, £6 6s. The fees for the Evening Classes are: Minor course, January to July, £4 4s.; September to December, £2 10s. Major course, January to July, £3 12s. 6d.; September to January, £2 5s.

Owen's College, Manchester.—PRINCIPAL, A. Hopkinson, LL.D. Pharmaceutical department. TEACHERS, Professor A. Schuster, H. B. Dixon, W. H. Perkin, D. J. Leech, and F. E. Weiss, Mr. W. Kirkby, and Mr. J. Grier. Day Classes are held for Minor and Major students. The first year (October, 1899, to July, 1900) is devoted to the subjects for the Minor examination, and the second year (October, 1899, to March, 1900) to courses suitable for Major students. FEES: A composition fee of £17 17s. admits to the College courses for the first year, and of £15 15s. for the second year. Students may pay for the classes separately. An entrance exhibition of £10 is awarded on the results of a competitive examination in elementary botany and chemistry. It is opened to students entering for the full pharmaceutical course. Intending candidates must give notice to the Registrar on or before September 20. A prize of £5 will be offered at the end of the first year, for competition among students proceeding to the course for the Major examination. The Manchester Pharmaceutical Scholarship, value about £26, is also tenable at this College.

MIDDLESBROUGH.

Middlesbrough High School.—Evening Classes are held at this school for students preparing for the Minor and the first Professional examination of the Royal College of Surgeons. Classes in materia medica and pharmacy are conducted by Mr. E. C. Bennison, Ph.C., M.P.S. FEES for the session beginning September 11: Materia medica, £1; pharmacy, theoretical and practical, £1 10s. Classes for students of chemistry and botany are conducted by Mr. J. A. Jones, B.Sc., F.C.S., and Miss C. M. Young. Application to join the Classes must be made to Mr. C. Hood, at the School, from 7 to 9 p.m., September 11 to 15.

NEWCASTLE-ON-TYNE.

North of England School of Chemistry and Pharmacy, 55, Northumberland Street, Newcastle-on-Tyne.—PRINCIPAL, Mr. Frank R. Dudderidge, M.P.S. Day and Evening Classes are held in all subjects of the Minor and Major examinations. FEES: Full time classes, £8 8s.; evening classes, £3 3s.; Wednesday afternoon class, £3 3s. The fees are in each case per term of three months. A special weekly class for junior assistants and apprentices is held by Mr. Dudderidge. The fees for this class are £1 1s. for each subject, or £3 3s. for all. Classes for Medical and Veterinary Students: Chemistry, botany, materia medica, pharmacy, etc., are also held. PRIZES (competitive examination at the end of each winter course), offered, of books, to apprentice students.

NOTTINGHAM.

University College, Nottingham.—By arrangement with the Nottingham and Notts Chemists' Association, a course of twenty experimentally illustrated lectures on pharmaceutical chemistry, extending over two terms and embracing the requirements of the Minor examination, will be delivered on Monday evenings at eight o'clock, by Dr. F. S. Kipping, F.R.S., assisted by Mr. R. M. Cavan, B.Sc., F.S.C. Each student will be entitled to three hours per week laboratory practice (or more by arrangement). FEE, 15s. per term. A class in botany will be held on Tuesday at 8 p.m., in the first and second term, by Professor Carr, M.A., assisted by Mr. E. A. Smith, B.Sc. FEE for the course 15s. Practical dispensing to be arranged for the second term. A course of lectures on organic chemistry will be arranged for the third term. Further particulars can be obtained from Mr. A. Eberlin, Hon. Sec., 2, Chapel Bar, Nottingham. A prize fund to the value of £5 per annum, the gift of Messrs. Newball and Mason, Nottingham, is available, and will be distributed by the Council on the result of the session's work. All students joining these classes must be associates of the N.N.C.A.

PLYMOUTH.

Plymouth, Devonport, Stonehouse, and District Chemists' Association, 7, Whimple Street, Plymouth. Summer Classes in botany are conducted by Mr. Hooper from May to September, inclusive, with fortnightly field excursions. During the winter months materia medica classes are held weekly by the same teacher. Lectures and demonstrations are given every week during the winter by Mr. Morgan on pharmacy and pharmaceutical chemistry. Prizes are distributed annually to the students in both sections. There is a well-fitted class-room, fairly supplied with apparatus, including microscope and lanterns, and a good collection of specimens of drugs, chemicals, and microscopical mountings, also a small but useful library of text books and works of reference. The attendance of the pupils is good, and the results very satisfactory. At last year's Herbarium Competition one of the students obtained the Silver Medal, and another one the Certicate of Honour from the Pharmaceutical Society. Occasional lectures and papers are given by members and friends of the Association.

READING.

Reading College.—PRINCIPAL, Mr. H. J. Mackinder, M.A.; *Chemistry*, Mr. C. M. Luxmoore, D.Sc., F.I.C., Mr. A. M. Ryley; *Physics*, Mr. G. J. Burch, M.A.; *Botany*, Mr. Percy Groom, M.A., F.L.S., Mr. B. J. Austin, F.L.S.; *Latin*, Mr. W. G. de Burgh, M.A. Day and Evening Classes are held in mathematics, physics, chemistry, botany, zoology, Latin, French, etc. The chemical laboratory, which has accommodation for forty-five students, is open daily and on the first four evenings of the week, and special attention is paid to the needs of pharmaceutical students. Dr. Luxmoore will give a special course of lectures on pharmaceutical chemistry during the session 1899-1900, at an hour to be arranged. For full particulars, see calendar of Reading College, to be obtained from the Registrar.

SHEFFIELD.

Sheffield College of Pharmacy, 118, Princess Buildings, The Moor, Sheffield.—PRINCIPAL, Mr. J. W. J. Turner, Day Classes are held for Minor and Major students. FEES, Minor (full course), £8 8s.; (short course), £4 10s,; Major (full course). £7; (short course), £4. Evening Classes are held in botany, chemistry, and practical chemistry. The fee per term is £1 10s. inclusive. Winter session commences September 15, for evening students, and for ordinary day classes October 3.

Sheffield School of Pharmacy.—TEACHERS: *Chemistry.*—Professor, W. Carleton Williams, B.Sc., F.I.C.; Demonstrator, George Young, Ph.D., F.R.S.E. *Botany.*—Professor, A. Denny, F.L.S.; Demonstrator, B. H. Bentley, M.A., F.L.S. *Materia medica.*—Mr. J. Austen. HON. SCHOOL SECRETARY, Samuel T. Rhoden, 33, Church Street, Sheffield. Under the auspices of the Sheffield Pharmaceutical and Chemical Association a three years course of instruction for Minor students will be given at the University College, Sheffield, on Wednesday, Thursday, and Friday evenings during the winter session. The course beginning on October 11 and ending about the last week in March. The first year the students attend a course of 20 lectures on elementary physics and inorganic chemistry (illustrated by experiments), and also work in the chemical laboratory, at practical chemistry, on Wednesday evenings, 6 to 9. FEE, £1 10s. The second year's course consists of 20 lectures on inorganic and organic chemistry. Practical chemistry as above. FEE, £1 10s. Botany (first course), 20 lectures, each followed by a practical class, on Thursday evenings; lecture at 6.30, laboratory, 7.30 to 9.30. FEE £1 10s. The third year's course consists of practical chemistry on Wednesday evenings, 6 to 9. FEE, £1 10s. Botany (second course), 20 lectures, each followed by a practical class. Time and fee as in the second year. A class will also be held for students in materia medica, who have already passed the first and second years, provided a sufficient number present themselves. FEE, 10s. 6d.

NOTE.—The first and second years' lectures on chemistry are given in alternate years. The second course will be given in the session 1899-1900.

SOUTHAMPTON.

The Hartley College.—LECTURERS: *Physics*,, Dr. Wallace Stewart (Principal); *Chemistry*, Dr. D. R. Boyd, B.Sc.; *Botany*, Mr. E. T. Mellor, B.Sc. (Lond.) The courses for pharmaceutical students at this college in physics, chemistry and botany are adapted for both the Minor and Major examinations. The FEE for the course in each subject is £3 3s. per session, which commences on September 28 and closes on July 14. Prospectuses may be obtained on application to Mr. D. Kiddle, Clerk.

SOUTHSEA.

The Queensborough College of Pharmacy, 179, Albert Road, Southsea.—PRINCIPAL, Mr. F. B. Elwell, Ph.C., M.P.S. Day Classes (full time), for Minor and Major examinations. FEES (inclusive of books, apparatus, and all petty extras): Three months' course, £3 8s.; every subsequent three months, £4 4s. Afternoon and Evening Classes are held for students by special arrangement. Prospectus of lectures, etc., on application.

WOLVERHAMPTON.

Free Library Science and Technical School.—Courses suitable for medical and pharmaceutical students in inorganic and organic chemistry (practical and theory), physics, and botany are held during the winter months, commencing September 11. For particulars and programme apply, Mr. J. Elliot, Secretary.

SCOTTISH SCHOOLS.

ABERDEEN.

Robert Gordon's College.—Day and Evening Classes for the Minor Course are held in connection with the local pharmaceutical association, lectures on botany, materia medica, pharmacy, chemistry, prescription-reading and the poison laws being delivered daily during the term. Special subjects can be selected by students, for which proportional charges are made.

DUNDEE.

Technical Institute.—Classes are held in chemistry (theoretical and practical) and in materia medica. TEACHERS: *Chemistry.* Dr. Lumsden, Mr. J. K. Wood, B.Sc., Mr. J. Foggie, F.C.S. Special arrangements are made for pharmaceutical students.

EDINBURGH.

Central School of Chemistry and Pharmacy, 26, Clyde Street, Edinburgh. PRINCIPAL: Mr. W. B. Cowie, Ph.C., assisted by Mr. William McEwan, and Mr. A. C. Cameron. Pharmaceutical students are prepared for the Minor and Major examinations, the courses for the day classes commencing in October, January, and April, and in September for the evening classes. FEE PER QUARTER: Minor or Major course, £8 8s. (day); £3 3s. (evening); and £1 1s. for "First" course.

Edinburgh Royal Dispensary and School of Pharmacy, West Richmond Street.—TEACHERS: Messrs. Duncan, W. G. Mackenzie, C. M. German, and G. Simpson, pharmaceutical chemists. The full-time session lasts from October to July, being divided into three terms, commencing October, January, and April. FEES: £8 8s. a term. Evening classes are also held on Mondays, Tuesdays, and Thursdays. FEES: £3 3s. a term.

GLASGOW.

Glasgow School of Pharmacy, 180, West Regent Street Glasgow.—PRINCIPAL, Mr. John Lothian, Ph.C., assisted by Messrs. Bertram Cockburn, Ph.C., Martin Meldrum, M.P.S., Henry Rodwell, M.P.S., Walter Blythe, M.A., and A. Campbell Low. For the Minor and Major examinations full courses of instruction by Day Classes commence October 2, and continue to the end of March. Short advanced classes are held from April to July and from the middle of August to the end of September in preparation for the July and October examinations. Evening Classes for the Minor examination are conducted in three stages—junior, intermediate, and senior, so that students can enter at any time, the whole of the work in each of these sections being systematically covered. Evening classes for the First examination are held twice weekly, on Tuesday and Thursday evenings. FEES: Minor or Major day classes, £8 8s. per quarter; evening classes (4 evenings per week), £3 3s. per quarter; preliminary class, 10s. 6d. The Kinninmont Gold Medal has been awarded three years in succession to students of this school.

West of Scotland College of Pharmacy, 157, St. Vincent Street, Glasgow.—PRINCIPALS, Messrs. T. S. Barrie, Ph.C., and T. Maben, Ph.C., F.C.S., assisted by demonstrators. Day Classes are held in theoretical and practical chemistry, physics, botany, theoretical and practical pharmacy and dispensing. FEES: Major and Minor, £8 8s. per term; two terms, £15 15s. Evening classes are held in which are taught all the subjects taken in the day course. FEES: Three nights a week, £3 3s.; two nights a week, £2 2s. per term. Preliminary classes are also conducted. FEE, 10s. 6d. per term. "Post-Graduate Courses" are conducted during the session on "Urine Analysis," and "The Chemistry of Photography." Students attending the college are admitted to these courses without extra fee; for others the fee is £1 1s. per course, or £1 11s. 6d. when both courses are taken. The winter session begins on October 3.

PHARMACEUTICAL QUALIFICATION IN IRELAND.

So far as the regulation of the practice of pharmacy is concerned, Ireland enjoys home rule, since Great Britain and Ireland have distinct Pharmacy Acts, and the regulations imposed by them differ to some extent. Moreover, there is no reciprocity, pharmaceutical certificates granted in either of the British Isles not being recognised in the other.

Preliminary Examination.

The Preliminary examination of the Pharmaceutical Society of Ireland is held on the first Tuesday of January, April, July, and October. The following are the compulsory subjects:—

LATIN.—To translate into English and parse sentences from a Latin author:—Cæsar's 'Commentaries,' First Book; or Virgil's 'Æneid,' First Book. To translate an easy English sentence into Latin.

ENGLISH.—English grammar, including orthography and parsing. To write on a subject selected by the Examiner, and to write from dictation.

ARITHMETIC.—The first four rules, simple proportion, vulgar fractions, and decimals. To describe the British weights and measures, and the metric system.

ALGEBRA.—As far as simple equations, inclusive.

GEOMETRY.—Including the first book of Euclid.

ELEMENTARY THEORETICAL CHEMISTRY.—Chemical Action: Illustrations and examples; simple and compound substances; atoms and molecules; chemical symbols and nomenclature; formulæ and equations; general nature of acids, bases, and salts. Combustion: Structure and properties of flame. Water: Proofs of composition; methods of purification. The Air; Its constitution; reasons for considering it a mixture and not a compound. The chief physical and chemical characters, with methods of preparation of the following elements and compounds: Hydrogen, oxygen (and ozone), nitrogen, carbon, chlorine, sulphur, nitrous oxide, nitric oxide, nitric acid, ammonia, carbon dioxide, carbon monoxide, marsh gas, olefiant gas, hydrochloric acid, sulphur dioxide, sulphurous acid, sulphuric acid, sulphuretted hydrogen.

In addition, candidates must pass in one of the following optional subjects:—

ELEMENTARY PHYSICS AND MECHANICS.—Sound, light and heat, as given in Ganot's 'Elementary Course of Natural Philosophy'; mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics.

THE RUDIMENTS OF BOTANY.—Oliver's 'Lessons in Elementary Botany.' Part I.

FRENCH, GERMAN, or any other modern language.

As in the case of the British Preliminary, certificates of certain other examining bodies are accepted in lieu of this examination.

The fee for this examination is £2 2s., which should be lodged in the Bank of Ireland to the credit of the Pharmaceutical Society of Ireland, and the receipt sent with the candidate's application to the Registrar, at the Society's office, 67, Lower Mount Street, Dublin, not later than the Tuesday fortnight preceding the day of examination. The optional subject selected should be stated, and the application be accompanied by a certificate of birth. A candidate who has failed to pass is at liberty to present himself for re-examination six months later on payment of 10s. 6d.

Assistants' Certificates.

These certificates are granted on passing the Preliminary or its equivalent and a special examination in the following subjects:—

PRESCRIPTIONS.—Candidates will be required to read autograph prescriptions, translate them into English, render a correct translation of the directions for use, and detect unusual doses.

PRACTICAL DISPENSING.—To weigh, measure, and compound medicines, write the directions in suitable language, finish, and properly direct each package.

MATERIA MEDICA AND QUALITY OF SPECIMENS.—To recognise the Pharmacopœia chemicals in frequent demand, and specimens

of roots, barks, leaves, fruits, resins, and gums in ordinary use; also to estimate the quality of each specimen submitted, and its freedom from adulteration.

PHARMACY.—To recognise the preparations of the Pharmacopœia which are not of a definite chemical nature, such as extracts, tinctures, and powders, and give the proportions of the more active ingredients. The candidates will also be examined in the Sale of Poisons (Ireland) Act.

Rejected candidates may present themselves again after a lapse of six months, on payment of 10s. 6d. A necessary condition in the case of all candidates is that they must have been engaged for four years in an open pharmacy kept (*a*) by a pharmaceutical chemist or an apothecary in Ireland, or (*b*) by a pharmaceutical chemist or chemist and druggist in Great Britain, or (*c*) he may have served two years in a registered druggist's or chemist and druggist's shop in Ireland, and two years subsequently in an open pharmacy.

Registered Druggists.

Registered druggists may sell poisons, but are not entitled to compound medical prescriptions. The qualification of "registered druggist" is acquired by passing an examination testing the candidate's knowledge of English orthography and composition, arithmetic, the weights and measures of the British Pharmacopœia, the appearance and properties of the various drugs and chemicals in general use, and the Irish Poisons Act. The candidate must previously have served a four years' apprenticeship with a pharmaceutical chemist, licentiate apothecary, registered chemist and druggist, or registered druggist; and be twenty-one years of age. The examination fee is £2 2s., and there is a registration fee of the same amount.

The Pharmaceutical License.

The candidate for the pharmaceutical licenses must have attained the age of twenty-one years, passed the Preliminary not less than twelve months previously, served four years, as for the assistants' certificate, and attended a course in practical chemistry of not less than three months' duration, including 100 hours' practical work at the bench, and a course in botany and materia medica, he will have fulfilled all the conditions imposed on those who seek to pass the final examination and acquire the right to term themselves "pharmaceutical chemists." This qualification is superior to the British "chemist and druggist," as it gives the holder the extra advantage of enjoying a monopoly in compounding medical prescriptions.

The following are the examination subjects:—

BOTANY.—To recognise the principal indigenous plants used in medicine, to refer them to their natural orders, and to give the definitions and the distinctive characters of their several parts.

MATERIA MEDICA.—To recognise specimens of the drugs of the Pharmacopœia, to describe their characters and active principles, name the sources from which they are obtained, and the official preparations into which they enter; and to detect adulterations.

GENERAL AND PHARMACEUTICAL CHEMISTRY.—The elementary laws of chemistry and physics, including chemical equations. To recognise the chemical substances of the Pharmacopœia; to describe the processes by which they are obtained; qualitative analysis (including the tests of the Pharmacopœia) and volumetric analysis; and to submit to a practical examination in those subjects.

PRACTICAL PHARMACY.—To translate Latin prescriptions; to detect dangerous doses; to compound and dispense correctly; to explain the processes of making the non-chemical preparations of the Pharmacopœia, and to recognise them; and to have an intimate knowledge of the Sale of Poisons (Ireland) Act, 33 and 34 Vict., chap. 26, 1870.

A clear fortnight's notice must be given to the Registrar, the fee of £5 5s. being also paid, and proofs submitted that the candidate has fulfilled the different requirements of the Society. He will then be summoned in due course to attend the examinations, which are held at Dublin on the second Wednesday and following days of January, April, July, and October. If unsuccessful, the candidate can try again after the lapse of six months on payment of £1 11s. 6d.

Further particulars respecting the Irish examinations, etc., are published in the Society's Calendar (1s. 8½d., post free), which can be obtained from the Registrar, 67, Lower Mount Street, Dublin.

IRISH SCHOOLS.

BELFAST.

Belfast School of Applied Chemistry, Dublin Road, Belfast.—STAFF: *Chemistry*, Mr. S. Templeton, Assoc. R.C.Sc., F.I.C., Principal; *Botany*, Mr. W. A. Rice, B.A.; *materia medica* and *Pharmacy*, Mr. T. Harper, L.P.S.I., M.P.S. (Great Britain); preliminary subjects, Mr. J. D. Wylie, B.A. Full course of instruction for the Minor and Irish License examinations begin in the last week of September and the first week of January. Day and Evening Classes. FEES: Chemistry (lectures and tutorial work), £2 2s.; practical chemistry (100 hours), £4 4s.; botany and materia medica, £2 2s.; pharmacy, £2 2s.; compounded fee for all subjects, £8 8s. Evening students, £2 2s. per quarter for two evenings weekly. Classes are also held for the Preliminary and Druggists' License.

DUBLIN.

School of Botany and Materia medica, 67, Lower Mount Street, Dublin.—DIRECTOR, Professor Ninian Falkiner, M.B., assisted by Mr. J. N. Laird and Mr. Henry O'Connor, M.P.S.I. The lectures are given twice a week in the evenings, but besides there are demonstrations in Trinity College Botanic Gardens. These classes are so highly prized that, although only four years in operation, over one hundred and seventy students have taken advantage of them. FEE: £2 2s.

School of Chemistry and Practical Pharmacy, 67, Lower Mount Street, Dublin.—DIRECTOR, Professor Tichborne, LL.D., F.I.C., assisted by Mr. P. Kelly, M.P.S.I. The Irish Pharmaceutical Council established this school about ten years ago in order to obviate the serious inconvenience caused to pharmaceutical students through the discontinuance of evening lectures by the medical schools. FEE: £6 6s.

MEDICAL QUALIFICATION.

An intending candidate for the medical profession has the choice of a variety of universities and colleges in England, Ireland, and Scotland, but in every case he will find that he has to conform to the regulations of the General Medical Council. The curriculum of the hospital or school where he is taught must agree with the Council's regulations, and when at length he has obtained his qualification, be it degree or diploma, he must have it duly registered by the General Medical Council before he can practise his profession.

Five years is the minimum period of study for a medical student, after registration. This applies equally to all schools in Great Britain, whether the student seeks a university degree or a college diploma. The universities and colleges only vary from each other in the severity of the examination tests which they impose.

For those who aspire to an authoritative position in the profession, or intend seeking the higher official positions, a University degree is necessary, but for the general practitioner, the less ornamental but equally useful double diploma of the Conjoint Boards of England, Scotland, or Ireland will be found to answer every purpose. The diploma of the Apothecaries' Society of London or of the Apothecaries' Hall, Dublin, also qualifies for practice.

The cost of a University degree is a serious matter to many, as well as the extra year which is so often required to complete the studies. The possible cost of living, fees, etc., at the English universities may be roughly put down at about £1,000, while that of the colleges in London, with attendance at the best hospitals is not likely to exceed £650, and in provincial towns it is considerably less. In Scotland and Ireland the fees and expenses of living are much lower both for universities and colleges; in fact, the M.D. degree of Ireland or of Scotland need not cost more than the diploma of the Conjoint Board of England. There is always the possibility in any case of rejections at the intermediate examinations, and that may prolong the time of study, or coaching may be necessary, and so add to the expense. Every school offers scholarships to brilliant students; obtaining those greatly lessens the expenses.

When an intending student has decided upon the degree or diploma that he intends to study for he should write to the

warden or dean of the school most suitable for his purpose, and he will furnish him with every information as to fees, scholarships, etc., etc.

Before a student can commence his professional studies either in medicine or dental surgery, he must pass one of the recognised preliminary examinations of Arts or that specified by the General Medical Council, particulars of which will be found further on, or they may be obtained from the Registrar, 299, Oxford Street, W.; or from the Registrars of the Branch Council in Scotland, 48, George Street, Edinburgh; or, Ireland, 35, Dawsou Street, Dubliu. In the case of a student seeking a University degree, he must pass the particular preliminary examination laid down by that University for the necessary examinations of Oxford or Cambridge will not admit the student to the examinations for the degrec of the University of London, for which the only recognised preliminary is the Matriculation Examination of that University. Full particulars of which are given elsewhere. No time spent in study or attending lectures will be allowed to count previous to registration by the General Medical Council as part of the five years required by the regulations of the Council to be spent in medical study, but students may prepare for the different intermediate examinations at different periods if they attend the necessary lectures, etc.

The following are the regulations of the Medical Council relating to the Preliminary Examination:—

Preliminary Examination.—Subject to such exceptions as the Council may from time to time allow, every medical and dental student shall, at the commencement of his studentship, be registered in the manuer and under the conditions prescribed by the standing Resolutions of the Council.

No person shall be allowed to be registered as a medical or dental student unless he shall have previously passed (at one or more examinations) a preliminary examination in the following subjects of general education:—

(*a*) English language, including Grammar and Composition.

*** Marks not exceeding 5 per cent. of the total marks obtainable in this section of the examination may be assigned to candidates who show a competent knowledge of Shorthand.

(*b*) Latin, including Grammar, Translation from Specified Authors, aud translatious of easy passages not taken from such authors.

(*c*) Mathematics, comprising (*a*) Arithmetic; (*b*) Algebra, as far as Simple Equations, inclusive; (*c*) Geometry, the subject matter of Euelid, Books I., II., and III., with easy deductions.

(*d*) One of the following optional subjects:—(*a*) Greek; (*β*) French; (*γ*) German; (*δ*) Italian; (*ε*) any other modern language.

*** The Council will not in future (except in final examinations for a degrec in arts or science of the Universities of the United Kingdom) accept any certificate of having passed a preliminary examination in General Education unless the whole subjects included in the preliminary examination required by the Council for registration of students of medicine or dentistry have been passed in at the same time.

The following educational bodies' (other than Universities) certificates are recognised by the Medical Council.

College of Preceptors.—Examination for a first class certificate or a second class certificate of First or Second Division (to include all the required subjects at one time). Preliminary examination for medical students (certificate to include all the required subjects at at one time).

Scotch Education Department.—Examination for Lower Grade Leaving Certificate (to include all the required subjects at one time). Examination for Higher Grade or Honours Leaving Certificate to include the required subjects.

Educational Institute of Scotland.—Preliminary Medical Examination (certificate to include all the required subjects at one time).

Intermediate Education Board of Ireland.—Junior or Middle Grade Examination (certificate to include all the required subjects at one time).

Senior Grade Examination (certificate to include the required subjects).

A list of the pass certificates of the various Indian, colonial, and foreign Universities and colleges that are accepted by the General Medical Council can be obtained on application to the Registrar, but no certificate from these bodies will be accepted unless it shows that the examination has been conducted by or under the authority of the body granting it, and includes all the subjects required by the General Medical Council, and states that all subjects of examination have been passed in at one time. Copies of the form of the required certificate arc supplied by the Registrar of the Council for the purpose.

In the case of natives of India or other Oriental countries whose vernacular is other than English, an examination in a classic Oriental language may be accepted instead of an examination in Latin.

It is anticipated that the standard of the Preliminary Examinatiou will be raised in 1900, so iutending students, either for medicine or dental surgery, will do well to pass the Preliminary Examination before the change is made.

The period of professional study, from the date of registration to the final examination for any qualification which entitles the holder to be registered under the Medical Acts, must be for a period of *bonâ-fide* study of not less than five years, and the course of professional study and examination must include the following subjects:—

(i.) Physics, including the elementary mechanics of solids and fluids, and the rudiments of heat, light, and electricity; (ii.) Chemistry, including the principles of the science, and the details which bear on the study of medicine; (iii.) Elementary Biology; (iv.) Anatomy; (v.) Physiology; (vi.) Materia Medica and Pharmacy; (vii.) Pathology; (viii.) Therapeutics; (ix.) Medicine, including medical anatomy and clinical medicine; (x.) Surgery, including surgical anatomy and clinical surgery; (xi.) Midwifery, including diseases peculiar to women and to newborn children; (xii.) Theory and Practice of Vaccination; (xiii.) Forensic Medicine; (xiv.) Hygiene; (xv.) Mental Disease.

The first four of the five years must be passed at a school or schools of medicine recognised by any of the licensing bodies, but (*a*) the first year may be passed at a University or teaching institution recognised by any of the licensing bodies where the subjects of Physics, Chemistry, and, Biology are taught; and (*b*) a graduate in Arts or Science of any University recognised by the General Medical Council who has spent a year in the study of physics, chemistry, and biology, and has passed an examination in three subjects for the degrees in question is held to have completed the first of the five years of medical study, provided that he has registered as a medical student with the General Medical Council. Any student who, previous to registration, has attended a course or courses of study in one or all of the subjects of physics, chemistry, or biology in any University, school of medicine, or teaching institution recognised by any of the licensing bodies, may, without further attendance, be admitted to examination in these subjects, provided always that such course or courses shall not be held to constitute any part of the five years' course of professional study.

The General Medical Council recommends the licensing bodies to require that the fifth year should be devoted to clinical work at one or more public hospital or dispensaries, British or foreign, recognised by any of the medical authorities mentioned in Schedule A of the Medical Act (1858), provided that of this year six months may be passed as a pupil to a registered practitioner possessing such opportunities of imparting medical knowledge as shall be satisfactory to the medical authorities.

DENTAL QUALIFICATION.

To practise as a dental surgeon in the United Kingdom it is necessary to be registered by the General Medical Council. Registration can only be secured (1) By those who were engaged in practice before July 22, 1878, or (2) By obtaining the Diploma of a Licentiate of Dental Surgery (L.D.S.) from one of the four examining bodies in Great Britain, viz., (1) The Royal College of Surgeons, England; (2) The Royal College of Surgeons, Edinburgh; (3) The Faculty of Physicians and Surgeons, Glasgow; (4) The Royal College of Surgeons, Ireland.

Candidates, before they can present themselves for examination, must produce (1) a certificate of registration as a student by the General Medical Council; (2) Of having received a professional education from recognised medical and dental schools; (3) Of being twenty-one years of age.

Dental students who commenced their professional education by apprenticeship to dentists eutitled to be registered, or by attendance upon professional lectures before July 22, 1878 (when dental education became compulsory), are required to produce evidence of having passed a preliminary examination.

The registration of dental students is carried on at the General Medical Council's Office, 299, Oxford Street, London, W., in the same manner as the existing registration of medical students—as previously stated, and subject to the same regulations as regards preliminary examinations—but in the case of dental students professional study may commence by pupilage with a registered dental practitioner.

Candidates for a diploma in dental surgery shall produce certificates of having been engaged during four years in professional studies, and of having received three years' instruction in mechanical dentistry from a registered practitioner.

One year's *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study.

The three years of instruction in mechanical dentistry, or any part of them, may be taken by a dental student either before or after his registration as a student; but no year of such mechanical instruction shall be counted as one of the four years of professional study unless taken after registration.

The curriculum includes instruction in general surgery and medicine, dental surgery, and mechanics, and should be commenced by an apprenticeship to a registered dentist. The mechanical training must extend over three years. A student should register his name at the offices of the General Medical Council as soon as he commences his medical training, form for which can be had on application. After three years' apprenticeship the hospital career should be taken up, both at the general and dental hospitals, and students will do well at this stage to register as a medical student as well, so that if at a future time he wishes to continue his studies for a surgical and medical qualification he will be able to go on with his studies; the work done at the general hospital being much the same as for the general qualification, will count as part of the medical curriculum. The dental hospitals offer every facility for students to acquire a thorough training in the various branches of dental surgery, and the two years spent in them should be made full use of.

The fees for the two years' course in the general and dental hospitals of London may be roughly stated to average about £135, including the necessary outfit of dental instruments, etc., but in this, as in the medical profession, fees vary in different parts; those charged in London may be regarded as the maximum. Several of the schools both in England, Ireland, and Scotland charge much less. A list is given of the various recognised dental schools, and all information as to their fees, etc., can be obtained on application.

The Royal College of Surgeons of England demands three examinations, while those of Edinburgh, Glasgow, and Ireland demand two. In all other matters as to subjects of examination, etc., they differ only in minor details. All particulars as to subjects, examination fees, etc., can be obtained from the secretaries of the four examining bodies mentioned.

Many of the dental schools now give instructions in mechanical dentistry.

The following are the dental schools recognised by the examining bodies in *Great Britain*:—Dental Hospital of London and London School of Dental Surgery, Leicester Square (Morton Smale, Dean); National Dental Hospital and College, Great Portland Street, London, W. (Sydney Spokes, Dean); Guy's Hospital Dental School, S.E. (Dr. Lauriston Shaw, Dean); The Victoria Dental Hospital of Manchester, Devonshire Street, All Saints (George G. Campion, Dean); The Owens College, Manchester (Sydney Chaffers, Registrar); Liverpool Dental Hospital, Mount Pleasant (Dr. A. M. Paterson, Dean); Mason College, Birmingham, Dental Department (apply to Registrar); Birmingham Dental Hospital, 71, Newhall Street (Fred W. Richards, Dean); Devon and Exeter Dental Hospital, Exeter (Henry Yeo, Hon. Secretary); Plymouth Dental Hospital, Bank Street Chambers, Bank Street, Plymouth (E. A. Bennett, Hon. Sec.). *Scotland*: Edinburgh Dental Hospital and Schools (apply to the Dean, 31, Chambers Street, Edinburgh); Glasgow Dental Hospital and School, 5, St. Vincent Street (apply to D. M. Alexander, Solicitor, 97, West Regent Street, Glasgow). *Ireland*: Dental Hospital of Ireland, Lincoln Place, Dublin (Wm. A. Shea, Registrar).

DANGERS OF HYDROGEN PEROXIDE AS A SURGICAL ANTISEPTIC.—G. U. Spencer sounds a note of warning against the use of hydrogen peroxide as a disinfectant for wounds in certain localities. He cites numerous cases, both in his own experience, and in that of others, in which the employment of the solution appears to cause the spread of pus-producing bacteria to other parts. This is due to the passage of bubbles of the gas evolved from the agent, which possess the power of travelling through relaxed tissue, along nerves, in the tendon sheath, and in the planes of the muscles, and thus carry infection with them. For this reason it is unsafe to use it for abscess cavities, or in the washing out of infectious wounds, also in the tissues surrounding the larynx and trachea, especially in young children.—*Therap. Gaz.*, **15**, 438.

THE SALE OF FOOD AND DRUGS ACT.

PROCEEDINGS AGAINST CHEMISTS.

On Friday, September 1, Mr. Blanco White, solicitor to the Fulham Vestry, attended at the West London Court, Vernon Street, West Kensington, to support summonses against the following chemists: Charles William Andrew, 781, Fulham Road; William Fletcher Barrett, 123, Wandsworth Bridge Road; Keith Longstaff, 811, Fulham Road; and William Arthur Shepherd, 4, Greyhound Road, Fulham, for selling a compounded drug not composed of ingredients in accordance with the demand of the purchaser.

Mr. Blanco White explained that the proceedings have been taken under the seventh section of the Food and Drugs Act. In order, he said, to test the accuracy of preparations made up by chemists, Dr. Jackson, the medical officer of health for Fulham, wrote out prescriptions and had them made up by the defendants. He pointed out the necessity that doctors' prescriptions should be accurately dispensed, for the reason that the lives of patients might be imperilled if the doctors' requirements were not perfectly performed.

The summons against Mr. Andrew was taken first, and Mr. H. T. Waddy appeared on his behalf. The sample of medicine prepared by him contained, according to the analysis of the vestry's analyst, Mr. Cecil H. Cribb, 258 grains of potassium iodide in six ounces of mixture, whereas the prescription required 240 grains, showing an excess of eighteen grains. The prescription was as follows:—"G. Clarke, Esq.—℞, Potassii Iodid., ʒiv.; Syr. Aurant., ʒi.; Aq. ad ʒvi. M. ft. Mist. Sig. Two teaspoonfuls in a wineglassful of water to be taken three times a day.—(Signed) C. J."

Dr. Jackson, the medical officer, was questioned concerning the nature of his prescription. He said the mixture contained twenty-four doses, and in each there would be an excess of three-quarters of a grain of potassium iodide. Twenty grains would be an exceptional dose, but he would not anticipate serious consequences from it.

Mr. Cribb, questioned by Mr. Waddy, said that the gravimetric as well as the volumetric silver process furnished his figures.

Dr. John Attfield, F.R.S., was called in the interests of the defendant, and gave the result of his analysis of a portion of the same mixture which was submitted to him. It was duly sealed, and was labelled "187 M." By the silver process, under which any small and officially allowable quantity of potassium chloride would be reckoned as more than double that quantity of potassium iodide, he could only find an excess of two grains above the 240 ordered by the prescription. Even this insignificant excess was to be credited to the analytical process, not to the dispenser. In his opinion the prescribed medicine had been compounded with perfect accuracy. Witness was unable to give any decided opinion as to what rule of procedure guided Mr. Cribb in arriving at his decision. Pressed by the magistrate, Dr. Attfield said that if the public analyst had so multiplied the small quantity of potassium iodide in the small volume of the medicine used in the experiments as to show the quantity present in an old 480-grain ounce, instead of in the official 437½-grain ounce, the high figures would be explained; but he did not suggest that Mr. Cribb would make such a mistake. In answer to a further question to the witness, as editor of the Pharmacopœia, he stated that the dose of potassium iodide mentioned in the Pharmacopœia, namely, five to twenty grains, represented the average range of dose in ordinary cases for adults.

Mr. Andrew, the defendant, was allowed to enter the witness-box to state that he knew the prescription was that of Dr. Jackson, and he used, as he always did, the greatest care and accuracy in its preparation; but, impressed at the time by the probable motive of the purchaser, he was absolutely certain that he had put neither more nor less than 240 grains of potassium iodide into the compounded medicine.

Mr. Rose, in dismissing the summons on the facts, observed that he had the greatest doubt whether the Food and Drugs Act was meant to be applied to a case of this nature. The Act, he thought, was intended to deal with frauds, and had no relation to a trifling excess of an ingredient in a bottle of medicine. The seventh section should be read in the light of the preceding and succeeding lines of the Act. Moreover, it would not be supposed that the Act intended to enforce absolute exactness of a prescription.

Mr. Blanco White argued that the Act contemplated such a contingency, and asked for an analysis by the Somerset House authorities, but his worship refused, remarking that if the analysis did take place, it would not debar him from considering the opinion of Dr. Attfield.

Replying to the other contention, Mr. Rose pointed out that it could not have been the intention of the Legislature to deal with a

man's own loss in putting in a little more than he need to of an ingredient.

The summons against Mr. Shepherd was withdrawn, Mr. Rose allowing him £3 3s. costs.

Mr. Oswald Hanson defended Mr. Longstaff, and subjected Dr. Jackson to severe cross-examination as to his opinion of what constituted an excessive dose of potassium iodide. He was asked whether he agreed or disagreed with the Pharmacopœia that the maximum dose was twenty grains, and he replied that as a dose to an individual it depended very much on circumstances.

Mr. Hanson: Is it an excessive dose?

Dr. Jackson: I say it is to start with.

Mr. Hanson: I don't want any quibbling or qualification. Is it an excessive dose?

Dr. Jackson: It is a full one.

Mr. Hanson: Is not potassium iodide a somewhat expensive article?

Dr. Jackson: Yes.

Ultimately this summons and the one against Mr. Barrett were adjourned.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

At a meetiug of the committee of this Association, held at Blackburn on Tuesday night, the secretary was requested to communicate with various members of the Pharmaceutical Council to arrange for the discussion at its October meeting of the following resolution:—

That the Council be petitioned to prepare (1) An amendment to Clause 2 of the Companies Fill, embodying its views in reference to company pharmacy; (2) A Pharmacy Bill; and that steps be taken to secure consideration of such amendment and Bill before the Companies Bill is again laid before Parliament.

It was arranged to hold a general meeting of the members on September 19, to receive the reports of the delegates to the Federation Conference at Plymouth.

ANALYTICAL NOTES.

Detection and Rapid Determination of SO_2 in Beverages.—Sulphurous acid may be quickly detected in wines, beer, or cider, according to G. Guerin, as follows:—A few C.c. of the liquid are placed in a test tube fitted with a cork pierced with a short pointed tube. The liquid is warmed, and a piece of filter paper, moistened with a solution of potassium iodate, 0·1 Gm. in two or three C.c. of starch solution, acidulated with 10 drops of sulphuric acid, is applied to the point of the tube. If 0·1 Gm. SO_2 per litre or less, be present, the test paper will turn blue. To rapidly and approximately determine the amount of SO_2 present 14 C.c. of hydrogen peroxide (standardised to 12 volumes) is diluted with water acidulated with H_2SO_4 to 1 litre. In each of a series of test glasses 10 C.c. of the suspected liquid is placed. To the first, 1 C.c. of the standard peroxide is added; to the second, 2 C.c., and so on. Each glass is tested with the starch test paper, as described above. The one in the series where the reaction disappears indicates roughly the limit of the SO_2. Thus if no reaction is obtained at No. 3 the liquid must contain less than 0·1 Gm. × 3 SO_2 per litre. The operation is then repeated with greater delicacy, adding the standard peroxide to the series of glasses in increasing quantities of 0·1 C.c. Then if the starch reaction ceases between the glasses containing 2·1 and 2·2 C.c. of the solution, the liquid will contain from 0·1 Gm. SO_2 × 2·1 or × 2·2 per litre.—*Union Pharm*, **40**, 291.

Separation of Citral, Citronellal and Methyl-Heptenone.—The following method is recommended by Tiemann for the separation of these bodies. The mixture obtaining them is shaken out, first with a ten per cent. solution of sodium sulphite, containing sodium bicarbonate. This only removes the citral as the unstable citraldihydrosulphonate, from which it is easily regenerated by soda. Citronellal is then removed from the residual liquid by adding to it a much stronger solution of sodium sulphite and bicarbonate, containing 350 Gm. of the former and 62·5 Gm. of the latter in each litre. Normal citronellal bisulphite then separates. The methylheptenone is then extracted with ether, the ethereal mixture cooled with ice, and shaken with solution of commercial sodium bisulphite, which removes the ketone from its accompanying impurities.—*Berichte*, **32**, 812.

LETTERS TO THE EDITOR.

Of Pharmacy as a Profession.

Sir,—The task of the educational reformer is ever hampered and often totally nullified by the operation of a greedy commercialism of such a protean character as to deceive if possible the very best disposed, and to cause them to work obscurely against the very objects they have most at heart. This sort of evil has been actively at work against the student of pharmacy ever since the passing of the "wretched Poisons Act," 1868. A brood of bird-catchers then at once sprang into existence because it was found that by merely getting through the "Minor," trade in everything also might be carried on coterminous with legalised and protected poison-vending. The School of Pharmacy was doomed to extinction by men who had just managed to get through their own examinations, and, ignorant of the fact that a wide margin always exists between what one himself knows and what he can successfully teach to others, undertook the task of training youth and coaching men by short cuts for the qualifying examinations. Need we add that many were thus disabled, dishonoured, and ruined. Of the so-called schools of chemistry and pharmacy that sprang up then in competition with one another all over the country, many being of a mere bogus character, did quickly their little bit of mischief and subsided in disgrace; others still survive, having got their households into some sort of order which has been forced upon them by the outward march of events; whilst a few of them have been a help and a credit to us from the first in consequence of the high character and wide attainments of the men engaged on their teaching staffs. But, notwithstanding that the word "pharmacy" has at length become a popular one, and the title "pharmacist" one of general acceptance and respect, we have the like evil to fight with still. The spirit that would entrap the unsuspecting youth of both sexes who are casting about in search of a genteel and largely lucrative occupation for their future lives at the smallest possible cost is active in all directions, caring not for the miseries that in the long run are entailed upon others by loss of time—that priceless treasure—or upon ourselves by the inclusion within our ranks of the discontented, the muddle-headed and the half-hearted. Otherwise, what means the following from the *Chemist and Druggist* of the 2nd instant? "Pharmacy, the handmaid of medicine, is an appropriate introduction to any scientific pursuit other than mechanical." Not very lively composition, but the drift becomes clear upon reading further on; which is, that the chemist is simply the doctor's scullion, but that his pharmacy knowledge may be made a good stepping-stone to various nobler pursuits. Again: "Although pharmacy is professional in character, its practice is mostly that of a trade, and many who enter it in the hope that they are being introduced to a profession become dissatisfied with the work they have to do," etc., etc. Surely, sir, an enemy hath done this, and members of the Pharmaceutical Society should take note. Finally, there comes a beauty of a specimen of journalistic tergiversation; for after all the complaints we have up to now been nauseated with about the trade being all neglected by the wicked and slothful Council of the Society, and the consequent ruin of the craft, there follows this strange statement: "Notwithstanding certain disadvantages pertaining to the practice of pharmacy, it still stands (splendid alliteration) one of the most prosperous shop-trades in this country." That is, I suppose, that "pharmacy, one of the most prosperous shop-trades in this country," offers exceptional advantages to parents and guardians who would devote their darlings to the pursuit of a good money-making trade, and when those darlings, having grown to man's estate, think it not good enough for them, it will but have been an appropriate step to some professional trade to which the rising man may take a better fancy. Then there follow "seven portraits of M.D.'s who have risen from the ranks of pharmacy." I may be wrong, but I cannot help myself, in the light of a long and varied experience, and a vivid recollection of pharmaceutical developments from very nearly the first establishment of the Society—I cannot help viewing all this I have quoted in the light of a double insult; an insult to the members of the Pharmaceutical Society, a society whose great aim has been all along to get the whole of the chemists and druggists of Great Britain incorporated into "one ostensible, recognised, and independent body," and an insult to the seven distinguished members of the medical body whose portraits are appended, who it is quietly assumed became discontented with the vileness of pharmacy, and determined to change for something higher. If it were any business of mine to touch upon such a

topic, I should, I think, more safely assume that the gentlemen named chose beforehand the goal before them, and finding that the School of Pharmacy at Bloomsbury Square was the one most suited for obtaining that knowledge of chemistry, botany, and materia medica necessary for a successful medical examination, entered as students in due form and passed the examinations as a matter of duty; but this seems no more my business than it is the business of an editor of a trade journal. It is of the greatest importance that the young candidate for a pharmacy career should be warned of the onerous nature of the work in which he is likely to be engaged after his studies and examinations are over; and of the risks that usually attend any change of front after having once chosen for himself. Pretty certain it is that the pharmacist of the future will be loaded with duties of a most honourable kind, which he will not with safety be able to entrust to the performance of a deputy, that he will cease to be a mere agent for the distribution of packages, and that pharmacy being no shop-trade at all, but rather a unique and happy blend of several arts and sciences, "*quae prosunt omnibus*," he will have to make for himself special siftings of what is staple and what mere flimsy accessory, and form for himself his own environment in a calling which is essentially as noble a one as any on the face of the earth; which rigidly demands of its votaries a diligent preparation for its proper exercise and a life's devotion.

Marylebone, N.W., September 5, 1899. J. C. HYSLOP.

Food and Drugs Act Prosecutions.

Sir,—With reference to the proceedings against me, as reported in all the leading dailies on Monday, there is a point which affects ch m'sts generally, Although the case was dismissed, I was obliged to incur heavy expenses in defending my reputation (to say nothing about the worry and loss of time), and I have no redress, as I cannot recover because the prosecutor was a public body. If this be law, it seems to me that however careful a chemist may be he is constantly liable to vexatious interference at the hands of public officials, who might be more profitably engaged in matters affecting the general welfare, and at the mercy of analysts' blunders, without being able to recover for damages.

CHARLES W. ANDREW.

Fulham Road, S.W., September 5, 1899.

The Bell Scholarship Examination.

Sir,—Since, after August, 1900, we enter on a new *régime* as regards the Preliminary examination, it seems to me that as a necessary and natural corollary the Jacob Bell Scholarship Examination must be altered in some way. A mere superficial examination of the new conditions will at once show that it will be somewhat absurd that candidates should be examined by a paper in Arts subjects, when by the certificate of preliminary knowledge, which must be submitted, they will show themselves to have almost reached in their work at school that amount of knowledge required in the present Arts Paper. I would suggest that in future the Arts Paper should be abolished, and at least a two-days' examination substituted for the present one. Part of the time should, of course, be spent in practical work. I would suggest the papers following:—(1) Inorganic Chemistry (six questions); (2) Botany (four questions) and Materia Medica (two questions); (3) Pharmacy (four questions) and Elementary Physics (two questions); (4) Practical Chemistry (two simple salts); (5) Practical Botany and Materia Medica; (6) Practical Pharmacy; and (7) French and German.

September 5, 1899. PAST SCHOLAR (200/35).

"Income-Tax Overcharges."

Sir,—The publicity afforded by the Press to the grievances suffered by Income-Taxpayers has resulted in an enormous increase in the amount of repayments of overcharges; but complaints are daily more frequent and bitter of the action of local Commissioners of Income-Tax in ignoring the returns of their profits made by traders and others on the too familiar buff form, which comes with such unfailing regularity. The blue notices of charge are now being delivered, and we would ask you to allow us to inform your readers who have made returns which have been ignored, or who have been assessed for the current year at a sum greater than the average of their profits for the three years ending April 5, 1899, that they must at once give notice of appeal in accordance with the instructions on the notice of charge. Their best course is to appeal to the "Special Commissioners," as these gentlemen are Government officials, and, not being rival tradesmen, nor influenced by personal, political, or other local feeling, may be relied upon to act with the greatest fairness. Moreover, if they find that the profits of the three years named show an average profit less than the amount upon which they paid tax for 1898-99, they should give notice of appeal in respect of that year also, and claim repayment of the amount overpaid. There is no time to lose in business appeals, while a claim to set-off a loss in farming or business against income from other sources must be lodged before October 6 next. Many people are now entitled to make a claim for three years to April 5 last, where the income arises from investments, even when dividends are paid "free of Income-Tax," and the tax recoverable might amount to £38. We shall be pleased to advise our readers gratuitously whether they are entitled to any repayment, on their sending us full particulars of their incomes from all sources and a stamped directed envelope for reply.

THE INCOME-TAX ADJUSTMENT AGENCY.

12 *and* 13, *Poultry, London, E.C., September* 6, 1899.

ANSWERS TO QUERIES.

Ammonium Sulphocyanide (H. C. S.—33/27).—It is not a scheduled poison.

Preliminary (J. C.—33/28).—Full particulars are given in this week's issue, at page 260.

Botanical (T. H. B.—33/26).—The names of your specimens are *Inula dysenterica* and *Viola sylvatica*.

Grasses (T. J.—33/22).—(1) *Festuca gigantea*; (2) *Aira uliginosa*; (3) *Molinia cærulea*; (4) In bad condition, but apparently *Festuca myurus*.

Dispensing (W. B. W.—33/23).— (1) Presumably, Allen and Hanburys' preparation is meant; (2) As the prescription is written, the B.P. preparation would appear to be intended.

Essence of Barley for Whiskey (W. R. C.—33/18).—We do not know of any preparation that can be added to new whiskey to give it the aroma of malted barley. Possibly by distilling well torrified malt you would obtain volatile empyreumatic bodies which might answer your purpose. The chief flavouring bodies of whiskey are probably traces of ethylic and amylic esters. Hydrogen peroxide is said to have the property of rapidly "maturing" new whiskey.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Attfield, Bevay, Beach, Bostock, Clark, Clarke, Crombie, Deed, Dewhirst, Downes, Ferrall, Holmes, Hulme, Jones, Kirkby, Lloyd, Maben, Moore, Poole, Reynolds. Robb, Ruoff, Skerry, Smith, Taylor Timson, Tinker, Turner, Wamsley, Wills.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

ALBUMIN OF LOCUST BEAN. E. Bourquelot and H. Hérissey confirm the statement of A. von Ekenstein that mannose results from the hydrolysis of the albumin (the earoubin of Effront) of the seeds of locust bean. They state that earoubin gives upon hydrolysis a mixture of mannose and galactose.—*Journ. de Pharm.*, [6] **10**, 153.

GALENA IN SCAMMONY. A specimen of scammony has recently been reported on by F. Baucher, which was found to be adulterated with galena and starch. It contained but 51·3 per cent. of ether-soluble resin. The appearance of the specimen was abnormal, since it showed small cavities which were sprinkled with well-formed bluish-grey crystals.—*Journ. de Pharm.* [6], **10**, 172, after *Ann. de Chim. Analyt.*

CUPRIC PHOSPHIDES. E. Rubénovitch finds that the cuprie phosphide Cu_5P_2 is formed by the action of PH_3. on cupric oxide on cupric hydrate, and on basic cuprie carbonate. In each case the action is very energetic, much heat being generated, and with the two last-named, even incandescence taking place, unless the copper compound be suspended in water; phosphoric acid is formed at the same time. The cupric phosphide obtained, when washed and dried without contact with the air, is a greyish-black amorphous body very soluble in nitric acid and in bromine water; hot concentrated sulphuric acid attacks it with the liberation of sulphur and SO_2. The cuprous phosphide Cu_3P_2 is obtained by passing a current of PH_3 and CO_2 over Cu_2O.—*Comp., rend.*, **129**, 336.

PHYSIOLOGY OF ROOTS. Herr A. Rimpach proposes the following classification of roots according to their physiological properties:—(1) Nutrient Roots, whose sole function is the conveyance of food material to the rest of the plant. The central vascular bundle, which consists chiefly or exclusively of conducting elements, is surrounded by a comparatively insignificant cortical parenchyme, which may entirely disappear. (2) Attachment Roots: These do not store up food materials, are not contractile, and the conveyance by them of food material is so unimportant that their sole or chief function may be regarded as the fixing of the plant in the soil or other substratum. They are characterised by the large development of stereome, and are especially characteristic of the epiphytic Bromeliaceæ, Araceæ, and Cyclantheæ, and of the terrestrial Bromeliaceæ, Gramineæ, and Palmæ. (3) Contractile Roots: These contain no or but little stereome, while the thin-walled parenchyme is relatively well developed, and is permanent. Contractile roots may or may not be also storing organs. (4) Storage Roots: The structure of this class of root agrees with that of other organs used for the same purpose. They consist chiefly of a permanent parenchyme filled with food material, and are often swollen into the form of a tuber.—*Ber. Deutsch. Bot. Gesell.*, 1899, 18.

ALDEHYDE IN GREEN LEAVES. J. Reinke and E. Braunmüller have carried out a series of observations on different plants, in order to determine the effect of light on the amount of formic aldehyde contained in green leaves. The results were not uniform; but the general conclusion was that in most cases, deprivation of light caused a distinct diminution in the amount of aldehyde. The test employed was precipitation by metanitrobenzhydrazid. The authors conclude that the aldehyde is probably not the first product of assimilation; but that, whatever this may be, it is, in the majority of cases, first condensed into sugar, in other cases into "leaf-aldehyde."—*Ber. Deutsch. Bot. Gesell.*, 1899, 7.

SOLID HYDROGEN. According to the *Comptes rendus* (**129**, 434), H. Moissan has read before the Académie des Sciences a short note on solidified hydrogen, by Professor Dewar, giving further particulars of his remarkable experiment. The appearance of the solidified element is likened to white foam (*écume*), or to a mass of transparent glass. It melts at about 1.6° on the absolute scale, which is equivalent to −257° Centigrade. Pure helium undergoes a change of state when it is cooled by means of solid hydrogen and subjected to a pressure of eight atmospheres. Seeds, after they are frozen in liquid hydrogen, retain the power of germinating. This communication is of great scientific interest, inasmuch as hydrogen is now known to be non-metallic in the solid state, contrary to the conjectures which have been largely entertained hitherto. Further, the approach to the zero of absolute temperature, slow though it is, is steadily going on. Two months ago Dewar arrived within twenty-one degrees of it, and now only sixteen degrees separate him from his goal. Will he attain it?

FORMATION AND DECOMPOSITION OF ALBUMIN IN PLANTS. M. N. Prianischnikow derives the following conclusions from a series of experiments on *Pisum sativum*, *Vicia faba*, and *Lupinus luteus*. The process of decomposition of albumin has a "great period," and is characterised by a "great curve" of its own. The process of accumulation of asparagin has also a great curve, and the maxima of the two curves nearly or entirely coincide. These two curves attain their maxima some days earlier than those which represent the elimination of carbon dioxide. At the close of the period of germination, the energy of the accumulation of asparagin, or rather that of the accumulation of the asparagin-nitrogen, exceeds the rapidity of the passage of albumin-nitrogen into the form of other combinations.—*Ber. Deutsch. Bot. Gasell.*, 1899, 151.

DETERMINATION OF MANNOSE. E. Bourquelot and H. Hérissey find that mannose may be determined quantitatively by means of its crystalline compound with phenylhydrazine, in the presence of other sugars, in consequence of the fact that the mannose compound crystallises readily and entirely from solutions at a low temperature (10° C.). The phenylhydrazine reagent employed consisted of phenylhydrazine, 2·4 C.c.; glacial acetic acid, 2·4 C.c.; distilled water to produce 12 C.c. The mixture was allowed to stand to from eight to twelve hours, at 10° C., the crystalline mass drained on the filter pump, washed successively with iced water, alcohol, and ether, was dried first *in vacuo* over sulphuric acid, then at 100° C., and weighed. When solutions containing less than 3 per cent. of mannose are operated on, a correction of 0·04 Gm. for every 100 C.c. of solution should be made. Experiments show that mannose may be separated quantitatively by this method from mixtures containing galactose, arabinose, maltose, and dextrin.—*Comp. rend.*, **129**, 339.

FUNGI WHICH DESTROY TIMBER. Herr F. Czapek confirms the observations of Miyoshi and Marshall Ward, that the hyphæ of certain fungi have the power, not only of perforating wood, but also of consuming the stores of starch and other food-materials in the tissues of the host-plant. In the cases of *Pleurotus pulmonarius* and *Merulius lachrymans*, he succeeded in extracting the enzyme by means of which the lignified walls of the cells are destroyed, and proposes for it the term *hadromase*, in contradistinction to the cytase which consumes the cellulose.—*Ber. Deutsch. Bot. Gesell.*, 1899, 166.

COD-LIVER OIL EMULSIONS.*

BY PROF. H. V. ARNY.

At the meeting of this Association last June, I had the pleasure of reporting an investigation of a powder from which an emulsion could be prepared by the easy method of adding thirty grains of the powder to one fluid ounce of cod-liver oil contained in a four-ounce bottle, agitating, adding one fluid ounce of water, and finally shaking for one minute; wherewith a beautiful, creamy emulsion was produced. The powder on analysis showed the presence of saccharin, saponin (or else extract of quillaja), and a gum that was either tragacanth or Irish moss gelatin. From this analysis I devised a modified formula, which possesses the advantage of requiring only fifteen grains of powder to emulsify an ounce of oil, instead of the thirty grains which is required of the commercial article.

The formula of the modified powder is:—

Saccharin	15 milligrammes.
Saponin	65 milligrammes.
Powdered tragacanth	1 gramme.

This formula was given without recommendation, since the cautious pharmacist will look askance at any emulsifier containing the two questionable ingredients, saccharin and saponin.

Experimenting to Produce a "Flask" Emulsifier.

In the paper of last year the promise was given of further investigation on these lines, the aim being to prepare a flask emulsifier of absolutely harmless character. Before the writer had gotten well under way, a southern friend called his attention to an original flask emulsifier, consisting of ten grains each of powdered acacia, tragacanth, and sugar. Like the commercial emulsifier first mentioned, thirty grains of this powder would prepare two fluid ounces of a 50 per cent. emulsion. The product, however, is not perfectly satisfactory. Ten grains of sugar is not sufficient to sweeten two fluid ounces of emulsion, but this can be easily remedied by increasing the quantity of sugar to twenty or even to thirty grains, using a proportionally larger amount of the powder. The chief objection is that tragacanth makes an emulsion which is inclined to a buff tint, and that the acacia is not sufficient to counteract this colour defect.

The writer then tried gelatin, and was surprised to find what a dazzling white product resulted. Gelatin preparations of cod-liver oil were suggested long since (see *Proc. A. Ph. A.*, vii., 62; xi., 70; xii., 85; xxv., 92; xxx., 98), but each of the formulæ given produces a jelly, while the writer's aim was a preparation perfectly liquid, yet not so susceptible to separation. In the earlier efforts of the writer, thirty grains of shredded gelatin (Coxe's) was mixed with one fluid ounce of oil, and an ounce of water added. On agitation this finally resulted in an emulsion of dazzling whiteness. The process was not practical, however, as that proportion of gelatin dissolved in the liquid only after actual agitation for twenty-five to thirty minutes, covering a period of one hour, and so efforts were made to secure powdered gelatin. Finally two samples were obtained—one a No. 60 powder, the other a No. 80 powder. The sixty powder proved unsatisfactory, while the eighty powder served admirably.

Thereupon extensive experiments were made with quantities of gelatin, varying from ten to thirty grains to the ounce of oil and ounce of water, and it was found that gelatin in an eighty powder yielded on agitation an emulsion as readily as did any of the emulsifiers mentioned above. The finished products were submitted to variations of temperature, ranging from 3° to 40° C.—a range far beyond the ordinary variation in a house or store. The conclusions deduced from this test were that gelatin alone did not yield an ideal emulsion; for a preparation which would not solidify at the ordinary temperatures (one made, say, by adding fifteen grains of gelatin to an ounce of oil and one of water) invariably separated at higher temperatures—say 30° C. Likewise, combinations of gelatin and acacia failed to yield a satisfactory product, but happy results were obtained from mixtures of gelatin and tragacanth; the gelatin counteracted the yellowish tint of the tragacanth emulsion, and yielded a produet which was fluid at low temperatures, and yet which scarcely separated at high temperatures.

*Read before the Ohio Pharmaceutical Association, and reprinted from the *Bulletin of Pharmacy*.

Results.

Then various combinations were tried, such as:—

Gelatin, 20 grains; tragacanth, 5 grains; sugar, 20 grains.	To one ounce each of oil and water.
Gelatin, 10 grains; tragacanth, 5 grains; sugar, 20 grains.	
Gelatin, 10 grains; tragacanth, 10 grains; sugar, 20 grains.	
Gelatin, 15 grains; tragacanth, 5 grains; sugar, 20 grains.	

All these yielded emulsions, and these were submitted to all the variations of temperature from 30° to 40° C. The results showed that the combination of gelatin ten grains, tragacanth ten grains, and sugar twenty grains, yielded the finest product.

Are Flask Emulsions Advisable?

But, after all, are these flask emulsions the ones that the conscientious pharmacist should make? Is a pharmacist who objects to making an emulsion, because, forsooth, it is an unpleasant task to clean a dirty mortar, a pharmacist worthy of success? A man who will be deterred by such considerations is the man who prefers buying his preparations from some manufacturer.

A successful emulsion is the best advertisement of a pharmacist's skill, and that pharmacist whose efforts are directed toward the dispensing of palatable and elegant preparations of this class makes little complaint of hard times. The regulation emulsion of cod-liver oil is, as a rule, carelessly put together by the retailer, hence I feel permitted to suggest special forms of this emulsion which are above the ordinary.

The first is

A Chondrus Emulsion.

The Irish moss emulsion of the National Formulary has never given satisfactory results in the writer's hands. Perhaps the fault lay with the operator, who desires to avoid snap judgment; but the fact still remains that to him the recipe is not all that seemed desired. Quite different, however, is a chondrus emulsion worked up from an acacia base, a process suggested by Bedford (*Proc. A. Ph. A.*, xl., 432). A formula on this plan, given by a Cleveland friend, begins with a continental emulsion of acacia 1½ ounce, oil 6 fluid ounces, and water 3 fluid ounces. To this is added 18 fluid ounces of a decoction of chondrus, prepared from 248 grains of chondrus and a quart of water, and to this oil and water are gradually added, under constant trituration, until one-half gallon of a 50 per cent emulsion results. The product is beautifully white and remarkably limpid, while its keeping properties are excellent, especially when fortified with alcohol, as suggested by the National Formulary.

Formula for Glyconin Emulsion.

A splendid emulsion can be prepared from yolk of egg; the formula of the National Formulary making an emulsion both beautiful and palatable. Glyconin, U.S.P., gives better results than the yolk, which is recommended in many works, and it is a splendid demonstration of the preservative value of glycerin. A sample prepared by the writer in November last is to-day perfectly sweet.

In answer to a demand for an "egg-nog" emulsion, the following modification of the N.F. preparation was devised:—

Glyconin	2½ fluid drachms.
Cod-liver oil	1 fluid ounce.
Syrup	1½ fluid drachm.
Brandy	2½ fluid drachms.
Water	*q. s.* ad 2 fluid ounces.

Emulsionise the oil by gradual addition of the glyconin, with constant trituration; then add the other ingredients in the order given. Flavour with vanilla.

The product is delicious and beautiful, and it should keep as well as, if not better than, the glyconin from which it was prepared.

Extract of Malt as an Emulsifier.

Extract of malt is more successful in covering the taste of cod-liver oil than any other substance yet tried. The following formula was devised by the writer in 1891, and has been used by him almost every winter since. The product is a perfect emulsion, save an aqueous layer of about a thirty-second of the entire bulk, and its stability was proven by subjecting a sample to the action of New Orleans sunshine from October of one year to April of the next. A sample prepared last November is as sweet and palatable to-day as when made. The preparation consists of:—

	Parts.
Cod-liver oil	4
Syrup of wild cherry	2
Extract of malt	1
Sherry wine	1

Emulsify the oil by gradual addition to the extract, alternating with the syrup. Lastly, add the wine.

If any trouble is experienced in emulsification test the malt with litmus paper, for it is likely to become a trifle acid on standing; as is well known, acids interfere with emulsification. If the malt be found acid, add a trace of sodium bicarbonate and the trouble will be removed. For this suggestion I have to thank Mr. M. G. Tielke, of Cleveland.

SELECTED PRACTICAL FORMULÆ.

Diuretic Medicaments.

Martz gives a number of formulæ for diuretic compounds. Pills composed as follow:—Extract of convallaria, 1 grain; powdered convallaria, 1 grain; or a syrup made of extract of convallaria, 4 drachms; syrup of bitter orange, 6 drachms. A teaspoonful night and morning. In other cases he uses, Tincture of squill, 75 minims; syrup of bitter orange, 1 ounce; distilled water, 3 ounces. One teaspoonful every few hours. Or: Extract of squill, 1 grain; powdered squill, 1 grain. Make into one pill and give one night and morning. Or: Theobromine, 7 grains. Place in one cachet, and give four a day. Or: Caffeine, 15 grains; benzoate of sodium, 30 grains; syrup of bitter orange, 1 ounce; water, 4 ounces. This may allbe taken in 24 hours. Or, again: Powdered digitalis, powdered squill, powdered scammony, of each, one grain. Make into one pill, and give one such night and morning. Or: Carbonate of lithium, 7 grains; lemonade, with carbonated water, 1 pint. This to be drunk each day. Or, by the bowel: Nitrate of potassium, 30 grains; oxymel of squill, 6 drachms; milk, 3 ounces. This is to be given by the bowel.—*Therap. Gaz.*, **15,** 468, *after La France Medicale.*

Ointment for Hæmorrhoids.

Nehigan (*Der Frauenartz*) prescribes the following ointment for hæmorrhoids:—Compound tincture of camphor, 1 drachm; camphor, 1 drachm; belladonna ointment, 15 drachms. To be applied directly to the painful part.—*Therap. Gaz.*, **15,** 468.

Elixir of Boldo.

Crushed boldo leaves, 30; alcohol (60 per cent.), 120; Madeira wine, 500; simple syrup, 350; distilled water, *q.s.* to produce 1,000 fl. pts. Macerate the boldo in the alcohol for 48 hours, then add the wine and macerate for 8 days; strain and press, then add the syrup. The residue is treated with sufficient water to bring up the volume of the expressed liquid to 1,000; allowed to stand for some days, then filtered. It is given in atonic dyspepsia, as a stomachic, in doses of a tablespoonful daily after meals.—*Rev. Med. Pharm.*, **6,** 183.

To Remove Wrinkles.

Oil of sweet almonds, 2 drachms; cacao butter, 4 drachms; lanolin, 2 ounces; glycerin, 2 drachms; otto of rose, 2 drops. Melt the three first ingredients, then add the other two. It is applied at night. Another useful application is:—Glycerole of tannin, rosewater, of each 1 drachm. Mix. To be applied to the wrinkled surface with a camel's hair brush.—*Practitioner*, **63,** 117.

THE PROGRESS OF SCIENCE AND ITS RESULTS.*

BY PROFESSOR SIR MICHAEL FOSTER, K.C.B., Sec.R.S.

He who until a few minutes ago was your President said somewhere at the meeting at Bristol, and said with truth, that among the qualifications needed for the high honour of Presidency of the British Association for the Advancement of Science, that of being old was becoming more and more dominant. He who is now attempting to speak to you feels that he is rapidly earning that distinction. But the Association itself is older than its President; it has seen pass away the men who, wise in their generation, met at York on September 27, 1831, to found it; it has seen other great men who in bygone years served it as Presidents, or otherwise helped it on, sink one after another into the grave. Each year, indeed, when it plants its flag as a signal of its yearly meeting, that flag floats half-mast high in token of the great losses which the passing year has brought. This year is no exception; the losses, indeed, are perhaps unwontedly heavy. I will not attempt to call over the sad roll-call; but I must say a word about one who was above most others a faithful and zealous friend of the Association. Sir Douglas Galton joined the Association in 1860. From 1871 to 1895, as one of the General Secretaries, he bore, and bore to the great good of the Association, a large share of the burden of the Association's work. How great that share was is perhaps especially known to the many men, among whom I am proud to count myself, who during his long term of office served in succession with him as brother General Secretary. In 1895, at Ipswich, he left the post of General Secretary, but only to become President. So long and so constantly did he labour for the good of the Association that he seemed to be an integral part of it, and meeting as we do to-day, and as we henceforward must do, without Douglas Galton, we feel something greatly missing. This year, perhaps even more than in other years, we could have wished him to be among us; for to-day the Association may look with joy, not unmixed with pride, on the realisation of a project in forwarding which it has had a conspicuous share, on the commencement of an undertaking which is not only a great thing in itself, but which, we trust, is the beginning of still greater things to come. And the share which the Association has had in this was largely Sir Douglas Galton's doings.

In his address as President of Section A, at the meeting of the Association at Cardiff in 1891, Professor Oliver Lodge expounded with pregnant words how urgently, not pure science only, but industry and the constructive arts—for the interests of these are ever at bottom the same—needed the aid of some national establishment for the prosecution of prolonged and costly physical researches, which private enterprise could carry out in a lame fashion only, if at all. Lodge's words found an echo in many men's minds; but the response was for a long while in men's minds only. In 1895, Sir Douglas Galton, having previously made a personal study of an institution analogous to the one desired—namely, the Reichsanstalt at Berlin—seized the opportunity offered to him as President of the Association at Ipswich to insist, with the authority not only of the head for the time being of a great scientific body, but also of one who himself knew the ways and wants at once of science and of practical life, that the thing which Lodge and others had hoped for was a thing which could be done, and ought to be done at once. And now to-day we can say it has been done. The National Physical Laboratory has been founded. The address at Ipswich marked the beginning of an organised effort, which has at last been crowned with success. A feeling of sadness cannot but come over us when we think that Sir Douglas Galton was not spared to

* Presidential Address to British Association for the Advancement of Science, delivered at Dover Wednesday, September 13, 1899.

see the formal completion of the scheme whose birth he did so much to help, and which, to his last days, he aided in more ways than one. It is the old story—the good which men do lives after them.

Still older than the Association is this nineteenth century, now swiftly drawing to its close. Though the century itself has yet some sixteen months to run, this is the last meeting of the British Association which will use the numbers eighteen hundred to mark its date.

THE POSITION A HUNDRED YEARS AGO.

The eyes of the young look ever forward; they take little heed of the short though ever-lengthening fragment of life which lies behind them; they are wholly bent on that which is to come. The eyes of the aged turn wistfully again and again to the past; as the old glide down the inevitable slope their present becomes a living over again the life which has gone before, and the future takes on the shape of a brief lengthening of the past. May I this evening venture to give rein to the impulses of advancing years? May I, at this last meeting of the Association in the eighteen hundreds, dare to dwell for a while upon the past, and to call to mind a few of the changes which have taken place in the world since those autumn days in which men were saying to each other that the last of the seventeen hundreds was drawing towards its end?

Dover in the year of our Lord seventeen hundred and ninety-nine was in may ways unlike the Dover of to-day. On moonless nights men groped their way in its narrow streets by the help of swinging lanterns and smoky torches, for no lamps lit the ways. By day the light of the sun struggled into the houses through narrow panes of blurred glass. Though the town then, as now, was one of the chief portals to and from the countries beyond the seas, the means of travel were scanty and dear, available for the most part to the rich alone, and, for all, beset with discomfort and risk. Slow and uncertain was the carriage of goods, and the news of the world outside came to the town—though it from its position learnt more than most towns—tardily, fitfully, and often falsely. The people of Dover sat then much in dimness, if not in darkness, and lived in large measure on themselves. They who study the phenomena of living beings tell us that light is the great stimulus of life, and that the fulness of the life of a being or of any of its members may be measured by the variety, the swiftness, and the certainty of the means by which it is in touch with its surroundings. Judged from this standpoint life at Dover then, as indeed elsewhere, must have fallen far short of the life of to-day.

The same study of living beings, however, teaches us that while from one point of view the environment seems to mould the organism, from another point the organism seems to be master of its environent. Going behind the change of circumstances, we may raise the question, the old question, Was life in its essence worth more then than now? Has there been a real advance?

Let me at once relieve your minds by saying that I propose to leave this question in the main unanswered. It may be, or it may not be, that man's grasp of the beautiful and of the good, if not looser, is not firmer than it was a hundred years ago. It may be, or it may not be, that man is no nearer to absolute truth, to seeing things as they really are, than he was then. I will merely ask you to consider with me for a few minutes how far, and in what ways, man's laying hold of that aspect of or part of truth which we call natural knowledge, or sometimes science, differed in 1799 from what it is to-day, and whether that change must not be accounted a real advance, a real improvement in man.

I do not propose to weary you by what in my hands would be the rash effort of attempting a survey of all the scientific results of the nineteenth century. It will be enough if for a little while I dwell on some few of the salient features distinguishing the way in which we nowadays look upon, and during the coming week shall speak of, the works of Nature around us—though those works themselves, save for the slight shifting involved in a secular change, remain exactly the same—from the way in which they were looked upon and might have been spoken of at a gathering of philosophers at Dover in 1799. And I ask your leave to do so.

THE KNOWLEDGE OF THE ELEMENTS.

In the philosophy of the ancients, earth, fire, air, and water were called "the elements." It was thought, and rightly thought, that a knowledge of them and of their attributes was a necessary basis of a knowledge of the ways of Nature. Translated into modern language, a knowledge of these "elements" of old means a knowledge of the composition of the atmosphere, of water, and of all the other things which we call matter, as well as a knowledge of the general properties of gases, liquids, and solids, and of the nature and effects of combustion. Of all these things our knowledge to-day is large and exact; and, though ever enlarging, in some respects complete. When did that knowledge begin to become exact?

To-day the children in our schools know that the air which wraps round the globe is not a single thing, but is made up of two things, oxygen and nitrogen,* mingled together. They know, again, that water is not a single thing, but the product of two things, oxygen and hydrogen, joined together. They know that when the air makes the fire burn and gives the animal life, it is the oxygen in it which does the work. They know that all round them things are undergoing that union with oxygen which we call oxidation, and that oxidation is the ordinary source of heat and light. Let me ask you to picture to yourselves what confusion there would be to-morrow, not only in the discussions at the sectional meetings of our Association, but in the world at large, if it should happen that in the coming night some destroying touch should wither up certain tender structures in all our brains, and wipe out from our memories all traces of the ideas which cluster in our minds around the verbal tokens, oxygen and oxidation. How could any of us, not the so-called man of science alone, but even the man of business and the man of pleasure, go about his ways lacking those ideas? Yet those ideas were in 1799 lacking to all but a few.

Although in the third quarter of the seventeenth century the light of truth about oxidation and combustion had flashed out in the writings of John Mayow, it came as a flash only, and died away as soon as it had come. For the rest of that century, and for the greater part of the next, philosophers stumbled about in darkness, misled for the most of the time by the phantom conception which they called phlogiston. It was not until the end of the third quarter of the eighteenth century that the new light, which has burned steadily ever since, lit up the minds of the men of science. The light came at nearly the same time from England and from France. Rounding off the sharp corners of controversy, and joining, as we may fitly do to-day, the two countries as twin bearers of a common crown, we may say that we owe the truth to Cavendish, to Lavoisier, and Priestley. If it was Priestley who was the first to demonstrate the existence of what we now call oxygen, it is to Lavoisier we owe the true conception of the nature of oxidation and the clear exposition of the full meaning of Priestley's discovery, while the knowledge of the composition of water, the necessary complement of the knowledge of oxygen, came to us through Cavendish and, we may perhaps add, through Watt.

The date of Priestley's discovery of oxygen is 1774, Lavoisier's classic memoir "on the nature of the principle which enters into combination with metals during calcination" appeared in 1775, and Cavendish's paper on the composition of water did not see the light until 1784.

During the last quarter of the eighteenth century this new idea of oxygen and oxidation was struggling into existence. How new was the idea is illustrated by the fact that Lavoisier himself at first spoke of that which he was afterwards, namely in 1778, led to call oxygen, the name by which it has since been known, as "the principle which enters into combination." What difficulties its acceptance met with is illustrated by the fact that Priestley himself refused to the end of his life to grasp the true bearings of the discovery which he had made. In the year 1799 the knowledge of oxygen, of the nature of water and of air, and indeed the true conception of chemical composition and chemical change, was hardly more than beginning to be, and the century had to pass wholly away before the next great chemical idea, which we know by the name of the Atomic Theory of John Dalton, was made known. We have only to read the scientific literature of the time to recognise that a truth which is now not only woven as a master-thread into all our scientific conceptions, but even enters largely into the every-day talk and thoughts of educated people, was a hundred years ago struggling into existence among the philosophers themselves. It was all but absolutely unknown to the large world outside those select few.

THE WORD "ELECTRICITY."

If there be one word of science which is writ large on the life of the present time, it is the word "electricity"; it is, I take it, writ larger than any other word. The knowldege which it denotes has carried its practical results far and wide into our daily life, while the theoretical conceptions which it signifies pierce deep into the nature of things. We are to-day proud, and justly proud,

* Some may already know that there is at least a third thing, argon.

both of the material triumphs and of the intellectual gains which it has brought us, and we are full of even larger hopes of it in the future.

At what time did this bright child of the nineteenth century have its birth?

He who listened to the small group of philosophers of Dover, who in 1799 might have discoursed of natural knowledge, would perhaps have heard much of electric machines, of electric sparks, of the electric fluid, and even of positive and negative electricity; for frictional electricity had long been known and even carefully studied. Probably one or more of the group, dwelling on the observations which Galvani, an Italian, had made known some twenty years before, developed views on the connection of electricity with the phenomena of living bodies. Possibly one of them was exciting the rest by telling how he had just heard that a professor at Pavia, one Volta, had discovered that electricity could be produced not only by rubbing together particular bodies, but by the simple contact of two metals, and had thereby explained Galvani's remarkable results. For, indeed, as we shall hear from Professor Fleming, it was in that very year, 1799, that electricity as we now know it took its birth. It was then that Volta brought to light the apparently simple truths out of which so much has sprung. The world, it is true, had to wait for yet some twenty years before both the practical and the theoretic worth of Volta's discovery became truly pregnant, under the fertilising influence of another discovery. The loadstone and magnetic virtues had, like the electrifying power of rubbed amber, long been an old story. But, save for the compass, not much had come from it. And even Volta's discovery might have long remained relatively barren had it been left to itself. When, however, in 1819, Oersted made known his remarkable observations on the relations of electricity to magnetism, he made the contact needed for the flow of a new current of ideas. And it is perhaps not too much to say that those ideas, developing during the years of the rest of the century with an ever-accelerating swiftness, have wholly changed man's material relations to the circumstances of life, and at the same time carried him far in his knowledge of the nature of things.

The Evolution of Geology.

Of all the various branches of science, none perhaps is to-day, none for these many years past has been, so well known to, even if not understanded by, most people as that of geology. Its practical lessons have brought wealth to many; its fairy tales have brought delight to more; and round it hovers the charm of danger, for the conclusions to which it leads touch on the nature of man's beginning.

In 1799 the science of geology, as we now know it, was struggling into birth. There had been from of old cosmogonies, theories as to how the world had taken shape out of primæval chaos. In that fresh spirit which marked the zealous search after natural knowledge pursued in the middle and latter part of the seventeenth century, the brilliant Stenson, in Italy, and Hooke, in our own country, had laid hold of some of the problems presented by fossil remains, and Woodward, with others, had laboured in the same field. In the eighteenth century, especially in its latter half, men's minds were busy about the physical agencies determining or modifying the features of the earth's crust; water and fire, subsidence from a primæval ocean, and transformation by outbursts of the central heat, Neptune and Pluto, were being appealed to, by Werner on the one hand, and by Desmarest on the other, in explanation of the earth's phenomena. The way was being prepared, theories and views were abundant, and many sound observations had been made; and yet the science of geology, properly so called, the exact and proved knowledge of the successive phases of the world's life, may be said to date from the closing years of the eighteenth century.

In 1783, James Hutton put forward in a brief memoir his "Theory of the Earth," which in 1795, two years before his death, he expanded into a book; but his ideas failed to lay hold of men's minds until the century had passed away, when, in 1802, they found an able expositor in John Playfair. The very same year that Hutton published his theory Cuvier came to Paris, and almost forthwith began, with Brongniart, his immortal researches into the fossils of Paris and its neighbourhood. And, four years later, in the year 1799 itself, William Smith's tabular list of strata and fossils saw the light. It is, I believe, not too much to say that out of these geology, as we now know it, sprang. It was thus in the closing years of the eighteenth century that was begun the work which the nineteenth century has carried forward to such great results. But at that time only the select few had grasped the truth, and even they only the beginning of it. Outside a narrow circle the thoughts, even of the educated, about the history of the globe were bounded by the story of the Deluge—though the story was often told in a strange fashion—or were guided by fantastic views of the plastic forces of a sportive Nature.

Problems of the Living Body.

In another branch of science, in that which deals with the problems presented by living beings, the thoughts of men in 1799 were also very different from the thoughts of men to-day. It is a very old quest, the quest after the knowledge of the nature of living beings, one of the earliest on which man set out; for it promised to lead him to a knowledge of himself, a promise which perhaps is still before us, but the fulfilment of which is as yet far off. As time has gone on, the pursuit of natural knowledge has seemed to lead man away from himself into the furthermost parts of the universe, and into secret workings of Nature in which he appears to be of little or no account; and his knowledge of the nature of living things, and so of his own nature, has advanced slowly, waiting till the progress of other branches of natural knowledge can bring it aid. Yet in the past hundred years the biologic sciences, as we now call them, have marched rapidly onward.

We may look upon a living body as a machine doing work in accordance with certain laws, and may seek to trace out the working of the inner wheels, how these raise up the lifeless dust into living matter, and let the living matter fall away again into dust, giving out movement and heat. Or we may look upon the individual life as a link in a long chain, joining something which went before to something about to come, a chain whose beginning lies hid in the farthest past, and may seek to know the ties which bind one life to another. As we call up to view the long series of living forms, living now or flitting like shadows on the screen of the past, we may strive to lay hold of the influences which fashion the garment of life. Whether the problems of life are looked upon from the one point of view or the other, we to-day, not biologists only, but all of us, have gained a knowledge hidden even from the philosophers a hundred years ago.

Of the problems presented by the living body viewed as a machine, some may be spoken of as mechanical, others as physical, and yet others as chemical, while some are, apparently at least, none of these. In the seventeenth century William Harvey, laying hold of the central mechanism of the blood stream, opened up a path of inquiry which his own age and the century which followed trod with marked success. The knowledge of the mechanics of the animal and of the plant advanced apace; but the physical and chemical problems had yet to wait. The eighteenth century, it is true, had its physics and its chemistry; but, in relation at least to the problems of the living being, a chemistry which knew not oxygen, and a physics which knew not the electricity of chemical action, were of little avail. The philosopher of 1799, when he discussed the functions of the animal or of the plant involving chemical changes, was fain for the most part, as were his predecessors in the century before, to have recourse to such vague terms as "fermentation" and the like; to-day our treatises on physiology are largely made up of precise and exact expositions of the play of physical agencies and chemical bodies in the living organism. He made use of the words "vital force" or "vital principle" not as an occasional, but as a common, explanation of the phenomena of the living body. During the present century, especially during its latter half, the idea embodied in those words has been driven away from one seat after another; if we use it now when we are dealing with the chemical and physical events of life we use it with reluctance, as a *deus ex machina* to be appealed to only when everything else has failed.

Some of the problems—and those, perhaps, the chief problems—of the living body have to be solved neither by physical nor by chemical methods, but by methods of their own. Such are the problems of the nervous system. In respect to these the men of 1799 were on the threshold of a pregnant discovery. During the latter part of the present century, and especially during its last quarter, the analysis of the mysterious processes in the nervous system, and especially in the brain, which issue as feeling, thought, and the power to move, has been pushed forward with a success conspicuous in its practical, and full of promise in its theoretical, gains. That analysis may be briefly described as a following up of threads. We now know that what takes place along a tiny thread which we call a nerve-fibre differs from that which takes place along its fellow-threads, that differing nervous impulses travel along different nerve-fibres, and that nervous and psychical events are the outcome of the clashing of nervous impulses as they sweep along the closely-woven web of living threads of which the

brain is made. We have learnt by experiment and by observation that the pattern of the web determines the play of the impulses, and we can already explain many of the obscure problems not only of nervous disease, but of nervous life, by an analysis which is a tracking out the devious and linked paths of nervous threads. The very beginning of this analysis was unknown in 1799. Men knew that nerves were the agents of feeling and of the movements of muscles; they had learnt much about what this part or that part of the brain could do; but they did not know that one nerve-fibre differed from another in the very essence of its work. It was just about the end of the past century, or the beginning of the present one, that an English surgeon began to ponder over a conception which, however, he did not make known until some years later, and which did not gain complete demonstration and full acceptance until still more years had passed away. It was in 1811, in a tiny pamphlet published privately, that Charles Bell put forward his "New Idea" that the nervous system was constructed on the principle that "the nerves are not single nerves possessing various powers, but bundles of different nerves, whose filaments are united for the convenience of distribution, but which are distinct in office as they are in origin from the brain."

Our present knowledge of the nervous system is to a large extent only an exemplification and expansion of Charles Bell's "New Idea," and has its origin in that.

If we pass from the problems of the living organism viewed as a machine to those presented by the varied features of the different creatures who have lived, or who still live on the earth, we at once call to mind that the middle years of the present century mark an epoch in biologic thought such as never came before, for it was then that Charles Darwin gave to the world the 'Origin of Species.'

That work, however, with all the far-reaching effects which it has had, could have had little or no effect, or, rather, could not have come into existence, had not the earlier half of the century been in travail preparing for its coming. For the germinal idea of Darwin appeals, as to witnesses, to the results of two lines of biologic investigation which were almost unknown to the men of the eighteenth century.

To one of these lines I have already referred. Darwin, as we know, appealed to the geological record; and we also know how that record, imperfect as it was then, and imperfect as it must always remain, has since his time yielded the most striking proofs of at least one part of his general conception. In 1799 there was, as we have seen, no geological record at all.

Of the other line I must say a few words.

To-day the merest beginner in biologic study, or even that exemplar of acquaintance without knowledge, the general reader, is aware that every living being, even man himself, begins its independent existence as a tiny ball, of which we can, even acknowledging to the full the limits of the optical analysis at our command, assert with confidence that in structure, using that word in its ordinary sense, it is in all cases absolutely simple. It is equally well known that the features of form which supply the characters of a grown-up living being, all the many and varied features of even the most complex organism, are reached as the goal of a road, at times a long road, of successive changes; that the life of every being, from the ovum to its full estate, is a series of shifting scenes, which come and go, sometimes changing abruptly, sometimes melting the one into the other, like dissolving views, all so ordained that often the final shape with which the creature seems to begin, or is said to begin, its life in the world is the outcome of many shapes, clothed with which it in turn has lived many lives before its seeming birth.

All, or nearly all, the exact knowledge of the laboured way in which each living creature puts on its proper shape and structure is the heritage of the present century. Although the way in which the chick is moulded in the egg was not wholly unknown even to the ancients, and in later years had been told, first in the sixteenth century by Fabricius, then in the seventeenth century in a more clear and striking manner by the great Italian naturalist Malpighi, the teaching thus offered had been neglected or misinterpreted. At the close of the eighteenth century the dominant view was that in the making of a creature out of the egg there was no putting on of wholly new parts, no epigenesis. It was taught that the entire creature lay hidden in the egg, hidden by reason of the very transparency of its substance, lay ready-made but folded up, as it were, and that the process of development within the egg or within the womb was a mere unfolding, a simple evolution. Nor did men shrink from accepting the logical outcome of such a view—namely, that within the unborn creature itself lay in like manner, hidden and folded up, its offspring also, and within that again its offspring in turn, after the fashion of a cluster of ivory balls carved by Chinese hands, one within the other. This was no fantastic view put forward by an imaginative dreamer; it was seriously held by sober men, even by men like the illustrious Haller, in spite of their recognising that as the chick grew in the egg some changes of form took place. Though so early as the middle of the eighteenth century Friedrich Caspar Wolff, and, later on, others had strenuously opposed such a view, it held its own not only to the close of the century, but far on into the next. It was not until a quarter of the present century had been added to the past that Von Baer made known the results of researches which once and for all swept away the old view. He, and others working after him, made it clear that each individual puts on its final form and structure not by an unfolding of pre-existing hidden features, but by the formation of new parts through the continued differentiation of a primitively simple material. It was also made clear that the successive changes which the embryo undergoes in its progress from the ovum to maturity are the expression of morphologic laws, that the progress is one from the general to the special, and that the shifting scenes of embryonic life are hints and tokens of lives lived by ancestors in times long past.

If we wish to measure how far off in biologic thought the end of the last century stands, not only from the end, but even from the middle of this one, we may imagine Darwin striving to write the 'Origin of Species' in 1799. We may fancy him being told by philosophers, explaining how one group of living beings differed from another group because all its members and all their ancestors came into existence at one stroke when the first-born progenitor of the race, within which all the rest were folded up, stood forth as the result of a creative act. We may fancy him listening to a debate between the philosopher who maintained that all the fossils strewn in the earth were the remains of animals or plants churned up in the turmoil of a violent universal flood, and dropped in their places as the waters went away, and him who argued that such were not really the "spoils of living creatures," but the products of some playful plastic power which, out of the superabundance of its energy fashioned here and there the lifeless earth into forms which imitated, but only imitated, those of living things. Could he, amid such surroundings, by any flight of genius have beat his way to the conception for which is name will ever be known?

A Difference Which Means Progress.

Here I may well turn away from the past. It is not my purpose, nor, as I have said, am I fitted, nor is this perhaps the place, to tell even in outline the tale of the work of science in the nineteenth century. I am content to have pointed out that the two great sciences of chemistry and geology took their birth, or at least began to stand alone, at the close of the last century, and have grown to be what we know them now within about a hundred years, and that the study of living beings has within the same time been so transformed as to be to-day something wholly different from what it was in 1799. And, indeed, to say more would be to repeat almost the same story about other things. If our present knowledge of electricity is essentially the child of the nineteenth century, so also is our present knowledge of many other branches of physics. And those most ancient forms of exact knowledge, the knowledge of numbers and of the heavens, whose beginning is lost in the remote past, have, with all other kinds of natural knowledge, moved onward during the whole of the hundred years with a speed which is ever increasing. I have said, I trust, enough to justify the statement that in respect to natural knowledge a great gulf lies between 1799 and 1899. That gulf, moreover, is a twofold one; not only has natural knowledge been increased, but men have run to and fro spreading it as they go. Not only have the few driven far back round the full circle of natural knowledge the dark clouds of the unknown which wrap us all about, but also the many walk in the zone of light thus increasingly gained. If it be true that the few to-day are, in respect to natural knowledge, far removed from the few of those days, it is also true that nearly all which the few alone knew then, and much which they did not know, has now become the common knowledge of the many.

What, however, I may venture to insist upon here is that the difference in respect to natural knowledge, whatever be the case with other differences between then and now, is undoubtedly a difference which means progress. The span between the science of that time and the science of to-day is beyond all question a great stride onwards.

We may say this, but we must say it without boasting. For the very story of the past which tells of the triumphs of science bids the man of science put away from him all thoughts of vainglory. And that by many tokens.

Whoever, working at any scientific problem, has occasion to study the inquiries into the same problem made by some fellow-worker in the years long gone by, comes away from that study humbled by one or other of two different thoughts. On the one hand he may find, when he has translated the language of the past into the phraseology of to-day, how near was his forerunner of old to the conception which he thought, with pride, was all his own, not only so true but so new. On the other hand, if the ideas of the investigator of old, viewed in the light of modern knowledge, are found to be so wide of the mark as to seem absurd, the smile which begins to play upon the lips of the modern is checked by the thought: Will the ideas which I am now putting forth, and which I think explain so clearly, so fully, the problem in hand, seem to some worker in the far future as wrong and as fantastic as do these of my forerunner to me? In either case his personal pride is checked. Further, there is written clearly on each page of the history of science, in characters which cannot be overlooked, the lesson that no scientific truth is born anew, coming by itself and of itself. Each new truth is always the offspring of something which has gone before, becoming in turn the parent of something coming after. In this aspect the man of science is unlike, or seems to be unlike, the poet and the artist. The poet is born, not made; he rises up, no man knowing his beginnings; when he goes away, though men after him may sing his songs for centuries, he himself goes away wholly, having taken with him his mantle, for this he can give to none other. The man of science is not thus creative; he is created. His work, however great it be, is not wholly his own; it is in part the outcome of the work of men who have gone before. Again and again a conception which has made a name great has come not so much by the man's own effort as out of the fulness of time. Again and again we may read in the words of some man of old the outlines of an idea which in later days has shone forth as a great acknowledged truth. From the mouth of the man of old the idea dropped barren, fruitless; the world was not ready for it, and heeded it not; the concomitant and abutting truths which could give it power to work were wanting. Coming back again in later days, the same idea found the world awaiting it; things were in travail preparing for it; and someone, seizing the right moment to put it forth again, leapt into fame. It is not so much the men of science who make science, as some spirit which, born of the truths already won, drives the man of science onward and uses him to win new truths in turn.

It is because each man of science is not his own master, but one of many obedient servants of an impulse which was at work long before him, and will work long after him, that in science there is no falling back. In respect to other things there may be times of darkness and times of light, there may be risings, decadences, and revivals. In science there is only progress. The path may not be always a straight line, there may be swerving to this side and to that, ideas may seem to return again and again to the same point of the intellectual compass; but it will always be found that they have reached a higher level—they have moved, not in a circle, but in a spiral. Moreover, science is not fashioned as is a house, by putting brick to brick, that which is once put remaining as it was put to the end. The growth of science is that of a living being. As in the embryo phase follows phase, and each member of the body puts on in succession different appearances, though all the while the same member, so a scientific conception of one age seems to differ from that of a following age, though it is the same one in the process of being made; and as the dim outlines of the early embryo become, as the being grows more distinct and sharp, like a picture on a screen brought more and more into focus, so the dim gropings and searchings of the men of science of old are by repeated approximations wrought into the clear and exact conclusions of later times.

The Effect of Increasing Knowledge on Man.

The story of natural knowledge, of science, in the nineteenth century, as, indeed, in preceding centuries, is, I repeat, a story of continued progress. There is in it not so much as a hint of falling back, not even of standing still. What is gained by scientific inquiry is gained for ever; it may be added to, it may seem to be covered up, but it can never be taken away. Confident that the progress will go on, we cannot help peering into the years to come and straining our eyes to forcsee what science will become and what it will do as they roll on. While we do so, the thought must come to us, Will all the increasing knowledge of Nature avail only to change the ways of man—will it have no effect on man himself?

The material good which mankind has gained and is gaining through the advance of science is so imposing as to be obvious to everyone, and the praises of this aspect of science are to be found in the mouths of all. Beyond all doubt science has greatly lessened and has markedly narrowed hardship and suffering; beyond all doubt science has largely increased and has widely diffused ease and comfort. The appliances of science have, as it were, covered with a soft cushion the rough places of life, and that not for the rich only, but also for the poor. So abundant and so prominent are the material benefits of science that in the eyes of many these seem to be the only benefits which she brings. She is often spoken of as if she were useful and nothing more, as if her work were only to administer to the material wants of man.

Is this so?

We may begin to doubt it when we reflect that the triumphs of science which bring these material advantages are in their very nature intellectual triumphs. The increasing benefits brought by science are the results of man's increasing mastery over Nature, and that mastery is increasingly a mastery of mind; it is an increasing power to use the forces of what we call inanimate nature in place of the force of his own or other creatures' bodies; it is an increasing use of mind in place of muscle.

Is it to be thought that that which has brought the mind so greatly into play has had no effect on the mind itself? Is that part of the mind which works out scientific truths a mere slavish machine producing results it knows not how, having no part in the good which in its working it brings forth?

What are the qualities, the features of that scientific mind which has wrought, and is working, such great changes in man's relation to Nature? In seeking an answer to this question we have not to inquire into the attributes of genius. Though much of the progress of science seems to take on the form of a series of great steps, each made by some great man, the distinction in science between the great discoverer and the humble worker is one of degree only, not of kind. As I was urging just now, the greatness of many great names in science is often, in large part, the greatness of occasion, not of absolute power. The qualities which guide one man to a small truth silently taking its place among its fellows, as these go to make up progress, are at bottom the same as those by which another man is led to something of which the whole world rings.

The features of the fruitful scientific mind are in the main three.

In the first place, above all other things, his nature must be one which vibrates in unison with that of which he is in search; the seeker after truth must himself be truthful, truthful with the truthfulness of Nature. For the truthfulness of Nature is not wholly the same as that which man sometimes calls truthfulness. It is far more imperious, far more exacting. Man, unscientific man, is often content with "the nearly" and "the almost." Nature never is. It is not her way to call the same two things which differ, though the difference may be measured by less than the thousandth of a milligramme or of a millimetre, or by any other like standard of minuteness. And the man who, carrying the ways of the world into the domain of science, thinks that he may treat Nature's differences in any other way than she treats them herself, will find that she resents his conduct; if he in carelessness or in disdain overlooks the minute difference which she holds out to him as a signal to guide him in his search, the projecting tip, as it were, of some buried treasure, he is bound to go astray, and the more strenuously he struggles on, the farther will be find himself from his true goal.

In the second place, he must be alert of mind. Nature is ever making signs to us, she is ever whispering to us the beginnings of her secrets; the scientific man must be ever on the watch, ready at once to lay hold of Nature's hint however small, to listen to her whisper however low.

In the third place, scientific inquiry, though it be pre-eminently an intellectual effort, has need of the moral quality of courage—not so much the courage which helps a man to face a sudden difficulty as the courage of steadfast endurance. Almost every inquiry, certainly every prolonged inquiry, sooner or later goes wrong. The path, at first so straight and clear, grows crooked and gets blocked; the hope and enthusiasm, or even the jaunty ease, with which the inquirer set out leave him, and he falls into a slough of despond. That is the critical moment calling for courage. Struggling through the slough, he will find on the other side the wicket-gate opening up the real path; losing heart, he will turn back and add one more stone to the great cairn of the unaccomplished.

But, I hear someone say, these qualities are not the peculiar attributes of the man of science; they may be recognised as belong-

ing to almost everyone who has commanded or deserved success, whatever may have been his walk of life. That is so. That is exactly what I would desire to insist, that the men of science have no peculiar virtues, no special powers. They are ordinary men, their characters are common, even commonplace. Science, as Huxley said, is organised common sense, and men of science are common men, drilled in the ways of common sense.

For their life has this feature. Though in themselves they are no stronger, no better than other men, they possess a strength which, as I just now urged, is not their own, but is that of the science whose servants they are. Even in his apprenticeship, the scientific inquirer, while learning what has been done before his time, if he learns it aright, so learns it that what is known may serve him not only as a vantage ground whence to push off into the unknown, but also as a compass to guide him in his course. And when fitted for his work he enters on inquiry itself, what a zealous, anxious guide, what a strict and, because strict, helpful schoolmistress does Nature make herself to him! Under her care every inquiry, whether it bring the inquirer to a happy issue or seem to end in nought, trains him for the next effort. She so orders her ways that each act of obedience to her makes the next act easier for him, and step by step she leads him on towards that perfect obedience which is complete mastery.

Indeed, when we reflect on the potency of the discipline of scientific inquiry we cease to wonder at the progress of scientific knowledge. The results actually gained seem to fall so far short of what under such guidance might have been expected to have been gathered in that we are fain to conclude that science has called to follow her, for the most part, the poor in intellect and the wayward in spirit. Had she called to her service the many acute minds who have wasted their strength struggling in vain to solve hopeless problems, or who have turned their energies to things other than the increase of knowledge; had she called to her service the many just men who have walked straight without the need of a rod to guide them, how much greater than it has been would have been the progress of science, and how many false teachings would the world have been spared! To men of science themselves, when they consider their favoured lot, the achievements of the past should serve not as a boast, but as a reproach.

If there be any truth in what I have been urging, that the pursuit of scientific inquiry is itself a training of special potency, giving strength to the feeble and keeping in the path those who are inclined to stray, it is obvious that the material gains of science, great as they may be, do not make up all the good which science brings or may bring to man. We especially, perhaps, in these later days through the rapid development of the physical sciences, are too apt to dwell on the material gains alone. As a child in its infancy looks upon its mother only as a giver of good things, and does not learn till in after days how she was also showing her love by carefully training it in the way it should go, so we, too, have thought too much of the gifts of science, overlooking her power to guide.

Man does not live by bread alone, and science brings him more than bread. It is a great thing to make two blades of grass grow where before one alone grew; but it is no less great a thing to help a man to come to a just conclusion on the questions with which he has to deal. We may claim for science that while she is doing the one she may be so used as to do the other also. The dictum just quoted, that science is organised common sense, may be read as meaning that the common problems of life which common people have to solve are to be solved by the same methods by which the man of science solves his special problems. It follows that the training which does so much for him may be looked to as promising to do much for them. Such aid can come from science on two conditions only. In the first place, this her influence must be acknowledged; she must be duly recognised as a teacher no less than as a hewer of wood and a drawer of water. And the pursuit of science must be followed not by the professional few only, but, at least in such measure as will ensure the influence of example, by the many. But this latter point I need not urge before this great Association, whose chief object during more than half a century has been to bring within the fold of science all who would answer to the call. In the second place, it must be understood that the training to be looked for from science is the outcome not of the accumulation of scientific knowledge, but of the practice of scientific inquiry. Man may have at his fingers' ends all the accomplished results and all the current opinions of any one or of all the branches of science, and yet remain wholly unscientific in mind; but no one can have carried out even the humblest research without the spirit of science in some measure resting upon him. And that spirit may in part be caught even without entering upon an actual investigation in search of a new truth. The learner may be led to old truths, even the oldest, in more ways than one. He may be brought abruptly to a truth in its finished form, coming straight to it like a thief climbing over the wall; and the hurry and press of modern life tempt many to adopt this quicker way. Or he may be more slowly guided along the path by which the truth was reached by him who first laid hold of it. It is by this latter way of learning the truth, and by this alone, that the learner may hope to catch something at least of the spirit of the scientific inquirer.

This is not the place, nor have I the wish, to plunge into the turmoil of controversy; but, if there be any truth in what I have been urging, then they are wrong who think that in the schooling of the young science can be used with profit only to train those for whom science will be the means of earning their bread. It may be that from the point of view of the pedagogic art the experience of generations has fashioned out of the older studies of literature an instrument of discipline of unusual power, and that the teaching of science is as yet but a rough tool in unpractised hands. That, however, is not an adequate reason why scope should not be given for science to show the value which we claim for it as an intellectual training fitted for all sorts and conditions of men. Nor need the studies of humanity and literature fear her presence in the schools, for if her friends maintain that that teaching is one-sided, and, therefore, misleading, which deals with the doings of man only, and is silent about the works of Nature, in the sight of which he and his doings shrink almost to nothing, she herself would be the first to admit that that teaching is equally wrong which deals only with the works of Nature and says nothing about the doings of man, who is, to us at least, Nature's centre.

SCIENCE WORKS FOR GOOD.

There is yet another general aspect of science on which I crave leave to say a word. In that broad field of human life which we call politics, in the struggle not of man with man, but of race with race, science works for good. If we look only on the surface it may at first sight seem otherwise. In no branch of science has there during these later years been greater activity and more rapid progress than in that which furnishes the means by which man brings death, suffering, and disaster on his fellow-men. If the healer can look with pride on the increased power which science has given him to alleviate human suffering and ward off the miseries of disease, the destroyer can look with still greater pride on the power which science has given him to sweep away lives and to work desolation and ruin; while the one has slowly been learning to save units, the other has quickly learnt to slay thousands. But, happily, the very greatness of the modern power of destruction is already becoming a bar to its use, and bids fair—may we hope before long?—wholly to put an end to it. In the words of Tacitus, though in another sense, the very preparations for war, through the character which science gives them, make for peace.

Moreover, not in one branch of science only, but in all, there is a deep undercurrent of influence sapping the very foundations of all war. As I have already urged, no feature of scientific inquiry is more marked than the dependence of each step forward on other steps which have been made before. The man of science cannot sit by himself in his own cave weaving out results by his own efforts, unaided by others, heedless of what others have done and are doing. He is but a bit of a great system, a joint in a great machine, and he can only work aright when he is in due touch with his fellow-workers. If his labour is to be what it ought to be, and is to have the weight which it ought to have, he must know what is being done, not by himself, but by others, and by others not of his own land, and speaking his tongue only, but also of other lands and of other speech. Hence it comes about that to the man of science the barriers of manners and of speech which pen men into nations become more and more unreal and indistinct. He recognises his fellow-worker, wherever he may live and whatever tongue he may speak, as one who is pushing forward shoulder to shoulder with him towards a common goal, as one whom he is helping and who is helping him. The touch of science makes the whole world kin.

The history of the past gives us many examples of this brotherhood of science. In the revival of learning throughout the sixteenth and seventeenth centuries, and some way on into the eighteenth century, the common use of the Latin tongue made intercourse easy. In some respects in those earlier days science was more cosmopolitan than it afterwards became. In spite of the difficulties and hardships of travel, the men of science of different lands again and again met each other face to face, heard with their ears, and saw with their eyes what their brethren had to say or show. The Englishman took the long journey to Italy to study there; the Italian,

the Frenchman, and the German wandered from one seat of learning to another, and many a man held a chair in a country not his own. There was help, too, as well as intercourse. The Royal Society of London took upon itself the task of publishing nearly all the works of the great Italian Malpighi, and the brilliant Lavoisier, two years before his own countrymen in their blind fury slew him, received from the same body the highest token which it could give of its esteem.

In these closing years of the nineteenth century this great need of mutual knowledge and of common action felt by men of science of different lands is being manifested in a special way. Though nowadays what is done anywhere is soon known everywhere, the news of a discovery being often flashed over the globe by telegraph, there is an increasing activity in the direction of organisation to promote international meetings and international co-operation. In almost every science inquirers from many lands now gather together at stated intervals in international congresses to discuss matters which they have in common at heart, and go away each one feeling strengthened by having met his brother. The desire that in the struggle to lay bare the secrets of Nature the least waste of human energy should be incurred is leading more and more to the concerted action of nations combining to attack problems the solution of which is difficult and costly. The determination of standards of measurement, magnetic surveys, the solution of great geodetic problems, the mapping of the heavens and of the earth—all these are being carried on by international organisations.

In this and in other countries men's minds have this long while past been greatly moved by the desire to make fresh efforts to pierce the dark secrets of the forbidding Antarctic regions. Belgium has just made a brave single-handed attempt; a private enterprise sailing from these shores is struggling there now, lost for the present to our view; and this year we in England and our brethren in Germany are, thanks to the promised aid of the respective Governments, and no less to private liberality, in which this Association takes its share, able to begin the preparation of carefully organised expeditions. That international amity of which I am speaking is illustrated by the fact that in this country and in that there is not only a great desire, but a firm purpose, to secure the fullest co-operation between the expeditions which will leave the two shores. If in this momentous attempt any rivalry be shown between the two nations, it will be for each a rivalry, not in forestalling, but in assisting the other. May I add that if the story of the past may seem to give our nation some claim to the seas as more peculiarly our own, that claim bespeaks a duty likewise peculiarly our own to leave no effort untried by which we may plumb the seas' yet unknown depths and trace their yet unknown shores? That claim, if it means anything, means that when nations are joining hands in the dangerous work of exploring the unknown South, the larger burden of the task should fall to Britain's share; it means that we in this country should see to it, and see to it at once, that the concerted Antartic expedition which in some two years or so will leave the shores of Germany, of England, and, perhaps, of other lands, should, so far as we are concerned, be so equipped and so sustained that the risk of failure and disaster may be made as small, and the hope of being able not merely to snatch a hurried glimpse of lands not yet seen, but to gather in with full hands a rich harvest of the facts which men not of one science only, but of many, long to know, as great as possible.

Another international scientific effort demands a word of notice. The need which every inquirer in science feels to know, and to know quickly, what his fellow-worker, wherever on the globe he may be carrying on his work or making known his results, has done or is doing, led some four years back to a proposal for carrying out by international co-operation a complete current index, issued promptly, of the scientific literature of the world. Though much labour in many hands has been spent upon the undertaking, the project is not yet an accomplished fact. Nor can this, perhaps, be wondered at, when the difficulties of the task are weighed. Difficulties of language, difficulties of driving in one team all the several sciences which, like young horses, wish each to have its head free with leave to go its own way, difficulties mechanical and financial of press and post, difficulties raised by existing interests—these and yet other difficulties are obstacles not easy to be overcome. The most striking and the most encouraging features of the deliberations which have now been going on for three years have been the repeated expressions, coming not from this or that quarter only, but from almost all quarters, of an earnest desire that the effort should succeed, of a sincere belief in the good of international co-operation, and of a willingness to sink as far as possible individual interests for the sake of the common cause. In the face of such a spirit we may surely hope that the many difficulties will ultimately pass out of sight.

Perhaps, however, not the least notable fact of international co-operation in science is the proposal which has been made within the last two years that the leading academies of the world should, by representatives, meet at intervals to discuss questions in which the learned of all lands are interested. A month hence a preliminary meeting of this kind will be held at Wiesbaden; and it is at least probable that the closing year of that nineteenth century in which science has played so great a part may at Paris during the great World's Fair—which every friend, not of science only, but of humanity, trusts may not be put aside or even injured through any untoward event, and which promises to be an occasion not of pleasurable sight-seeing only, but also, by its many international congresses, of international communing in the search for truth—witness the first select Witenagemote of the science of the world.

I make no apology for having thus touched on international co-operation. I should have been wanting, had I not done so, to the memorable occasion of this meeting. A hundred years ago two great nations were grappling with each other in a fierce struggle, which had lasted, with pauses, for many years, and was to last for many years to come; war was on every lip and in almost every heart. To-day this meeting has, by a common wish, been so arranged that those two nations should, in the persons of their men of science, draw as near together as they can, with nothing but the narrow streak of the Channel between them, in order that they may take counsel together on matters in which they have one interest and a common hope. May we not look upon this brotherly meeting as one of many signs that science, though she works in a silent manner and in ways unseen by many, is steadily making for peace?

Much to Give Hope.

Looking back, then, in this last year of the eighteen hundreds, on the century which is drawing to its close, while we may see in the history of scientific inquiry much which, telling the man of science of his short-comings and his weakness, bids him be humble, we also see much, perhaps more, which gives him hope. Hope is indeed one of the watchwords of science. In the latter-day writings of some who know not science, much may be read which shows that the writer is losing or has lost hope in the future of mankind. There are not a few of these; their repeated utterances make a sign of the times. Seeing in matters lying outside science few marks of progress and many tokens of decline or of decay, recognising in science its material benefits only, such men have thoughts of despair when they look forward to the time to come. But if there be any truth in what I have attempted to urge to-night, if the intellectual, if the moral influences of science are no less marked than her material benefits, if, moreover, that which she has done is but the earnest of that which she shall do, such men may pluck up courage and gather strength by laying hold of her garment. We men of science at least need not share their views or their fears. Our feet are set, not on the shifting sands of the opinions and of the fancies of the day, but on a solid foundation of verified truth, which by the labours of each succeeding age is made broader and more firm. To us the past is a thing to look back upon, not with regret, not as something which has been lost never to be regained, but with content, as something whose influence is with us still, helping us on our further way. With us, indeed, the past points not to itself, but to the future; the golden age is in front of us, not behind us; that which we do know is a lamp whose brightest beams are shed into the unknown before us, showing us how much there is in front, and lighting up the way to reach it. We are confident in the advance because, as each one of us feels that any step forward which he may make is not ordered by himself alone and is not the result of his own sole efforts in the present, but is, and that in large measure, the outcome of the labours of others in the past, so each one of us has the sure and certain hope that as the past has helped him, so his efforts, be they great or be they small, will be a help to those to come.

Distinction Between Human Milk and Cow's Milk.—If 2·5 C.c. of human milk be heated on a water bath for 15 to 20 minutes' with an equal volume of 10 per cent. solution of ammonia, a violet rose coloration is produced. N. Umikoff attributes this reaction to the presence of a peculiar albuminoid. Cow's milk does not give the reaction.—*Pharm. Zeit.*, **44**, 253.

THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.*

Potassii Tartras.—The constitutional formula given in the Pharmacopœia is intended to show that tartaric acid is di-oxy-succinic acid.

CH_2—CO·OH	CH·OH—CO·OH
CH_2—CO·OH	CH·OH—CO·OH.
Succinic Acid.	Tartaric Acid.

It will be seen that the acid contains four hydroxyl groups, but only two are readily replaceable by bases, *i.e.*, the acid is dibasic. This serves to show how the properties and behaviour of an element are influenced by its environment. For the two replaceable hydrogen atoms are still those of the hydroxyl groups associated with the —CO— or carbonyl-groups, which are strongly electro-negative. The close proximity of these negative groups causes the hydrogen to be readily interchangeable with metals which are more electro-positive than hydrogen. The other hydroxyl groups are connected with the basic residues HC—CH and behave therefore like the hydroxyl groups in the alcohols.

In the official test for purity the salt is ignited and converted thereby into alkali carbonate like the alkali salts of all organic acids—

$$K_2C_4H_4O_6 = K_2CO_3.$$

The excess of carbon is partly burnt off as carbon monoxide and dioxide and partly left behind as charcoal. The charred mass when lixiviated with water and filtered should yield a *colourless* solution of potassium carbonate. Any trace of yellow or brown colour indicates insufficient incineration, and consequently incomplete conversion of the tartrate into carbonate. The results yielded by the titration of a coloured solution will be, therefore, always too low.

Since one molecule of tartrate ($K_2C_4H_4O_6$, H_2O = 242·46) yields one molecule of carbonate, which is capable of neutralising one molecule of sulphuric acid (H_2SO_4 = 97·34), it follows that 242·46 grammes of tartrate having the formula given in the Pharmacopœia, after incineration, will yield an alkaline solution equivalent to 2,000 C.c. normal sol. of sulphuric acid (N/1 H_2SO_4 contains $\frac{1}{2}H_2SO_4$ = 48·67 grammes per litre). From this it follows that one gramme—the quantity given in the official test—will be equivalent to

$$\frac{2000}{242{\cdot}46} \text{ C.c.} \times \frac{N}{1} H_2SO_4 = 8{\cdot}25 \text{ C.c. of } \frac{N}{1} \text{ sulphuric acid solution.}$$

Unless the salt contains some free potassium carbonate before incineration, it cannot therefore yield more alkali than is sufficient to neutralise 8 25 C.c. N/1 H_2SO_4.

The discrepancy between this figure 8·25 and the number of C.c. given in the Pharmacopœia, viz., 8·4, is due to the employment of an incorrect formula. Neutral potassium tartrate crystallises with only half the water stated in the Pharmacopœia, *i.e.*, the formula should be $(K_2C_4H_4O_6)_2H_2O$, or more simply, $K_2C_4H_4O_6\ \frac{1}{2}H_2O$. The molecular equivalent then becomes 233·52, and one gramme of this salt, if absolutely pure, will, after incineration, neutralise

$$\frac{2000}{233{\cdot}52} \text{ C.c.} \times \frac{N}{1} H_2SO_4 = 8{\cdot}56 \text{ C.c.}$$

Potassii Tartras Acidus.—When pure 1 gramme of the salt neutralises 5·35 C.c. N/1 NaOH. The official requirements are that not less than 5·2 C.c. of soda solution are required. This corresponds very closely with the presence of not more than 2½ per cent. of impurities which may be moisture and neutral salts—chiefly calcium tartrate and sulphate—and do not, therefore, consume any of the soda during the titration.

Pulveres.—The only important change in the preparations belonging to this group is the omission of saffron from aromatic chalk powder. This does not affect the medicinal value of the powder, but produces a great alteration in the appearance and odour of the product, particularly when it is administered—as is usually the case - suspended in water.

Pyroxylin.—To the notes on this substance in the previous series (*P. J.*, Dec. 25, 1897), the following may be added. Although the products of the nitration of cellulose are commonly called nitro-celluloses, it would be more correct to describe them as cellulose nitrates. The prefix nitro is used to indicate compounds (of which nitro-benzene is a familiar example) containing the NO_2 group, the nitrogen being linked directly to the carbon of the nucleus R—NO_2. Such nitro-bodies are not easily hydrolysed, and when reduced they yield amines, *e.g.*, nitro-benzene yields aniline—

$$C_6H_5NO_2 + 6H = C_6H_5NH_2 + 2H_2O.$$

Both these reactions indicate that nitrogen connected directly with the carbon is not easily removed. The nitrated celluloses, on the other hand, behave like esters of nitric acid, *i.e.*, they contain NO_2 groups linked, not directly, but through an oxygen atom to the carbon of the nucleus: thus R—O—NO_2. As a consequence of this method of linkage both hydrolysis and reduction easily effect the separation of the NO_2 group, thus—

$$R—O—NO_2 + H—O—H = R—O—H + HO—NO_2,$$

nitric acid being regenerated. The products of reduction are not so simple. The original alcoholic body R—O—H is, however, obtained, and various products resulting from the reduction of the NO_2 group. In order to avoid confusion in nomenclature, it should also be noted that the empirical formula for cellulose is sometimes written $C_{12}H_{20}O_{10}$, that is, double the formula we have employed. viz., $C_6H_{10}O_5$. The formulæ for the cellulose mono-, di-, and tri-nitrates (commonly called nitro-celluloses), then become $C_{12}H_{18}(O{\cdot}NO_2)_2O_8$, $C_{12}H_{16}(O{\cdot}NO_2)_4O_6$, and $C_{12}H_{14}(O{\cdot}NO_2)_6O_4$, and they would be called cellulose di-, tetra-, and hexa-nitrate respectively. The reason for this doubling of the formula is based chiefly upon the alleged production of penta-derivatives such as cellulose penta-nitrate $C_{12}H_{15}(O{\cdot}NO_2)_5O_5$, for which the half formula is clearly inadmissible. The correctness of this view is, however, not definitely settled.

ANALYTICAL NOTES FOR STUDENTS.

(From a Correspondent.)

Soluble Sulphides.—In Attfield's 'Manual' ammonio-sulphate of copper is given as a test for soluble sulphides, with which it would produce a black ppt., but this reagent will do the same thing in the absence of soluble sulphides with such a solution as of a mixed ferrous and ferric salt, the ppt. being $Fe_3(HO)_8$. As this is a pitfall into which students of the kind sometimes to be met with in chemical laboratories may fall, it seems advisable to make reference to it.

Insoluble Phosphates.—Such salts as the insoluble phosphates of Ca, Ba, Sr, and Mg may very easily be detected, so far as their acidulous radical is concerned, by boiling them with an aqueous solution of silver nitrate—a yellow ppt. is produced which, when separated by filtration, can be identified in the usual way, and the liquid will contain the bases as nitrates. The phosphate of iron does not respond to this test unfortunately. Why?

* NOTE.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J.* during 1897-8.

THE SCIENCE OF THE CENTURY AND ITS OUTCOME.

THE subject chosen by Sir MICHAEL FOSTER for his presidential address to the British Association was an ample one, being neither more nor less than the development of science during this fast-expiring nineteenth century, and the results of that development. Not that he attempted the impossible—a survey of all the scientific results of the century; for, as he well said, it was enough to dwell on some few salient features distinguishing the way in which we nowadays look upon the works of Nature around us. In 1799, he points out, the ideas which now cluster around the words oxygen and oxidation were lacking to all but a few, the light of truth about oxidation and combustion, which had flashed out in the writings of JOHN MAYOW, in the third quarter of the seventeenth century, having died away as soon as it had come. The phantom suggestion called phlogiston misled philosophers for the next hundred years, and it was not until the end of the third quarter of the eighteenth century that the new light which still persists lit up the minds of men of science. During the last quarter of the eighteenth century, then, this new idea of oxygen and oxidation, which is now woven as a master-thread into all our scientific conceptions, was struggling into existence, and a hundred years ago it was all but absolutely unknown to the world outside a select few among the philosophers. Again, electricity, as we now know it, took its birth in 1799. It was then that VOLTA brought to light the apparently simple truths out of which so much has sprung, and the ideas suggested by him and stimulated by OERSTED have since wholly changed man's material relations to the circumstances of life, while carrying him far in his knowledge of the nature of things. Turning to the science of geology as we now know it, we find it was struggling into birth in 1799. "Outside a narrow circle the thoughts, even of the educated, about the history of the globe were bounded by the story of the Deluge—though the story was often told in a strange fashion—or were guided by fantastic views of the plastic forces of a sportive Nature." Finally, in biology—that branch of science which deals with the problems presented by living beings—the thoughts of men in 1799 were also very different from the thoughts of men to-day. The quest after the knowledge of the nature of living beings was one of the earliest on which man set out, but, as time has gone on, the pursuit of natural knowledge has seemed to lead him away from himself, and his knowledge of the nature of living things, including that of his own nature, has advanced slowly, waiting till the progress of other branches of natural knowledge could bring it aid. But the biologic sciences have marched rapidly onward during the past hundred years. Most of the exact knowledge of the laboured way in which each living creature puts on its proper shape and structure is the heritage of the present century, and if we wish to measure how far off in biologic thought the end of the last century stands, it is only necessary to try to imagine DARWIN striving to write the 'Origin of Species' in 1799.

The sciences of chemistry, electricity, and geology, then, have grown to be what we know them now within about a hundred years, and the study of living beings has been so transformed within the same time as to be to-day something wholly different from what it was in 1799. Our knowledge of mathematics and astronomy, too, has moved onward during the past hundred years with a speed which is ever increasing. "Not only has natural knowledge been increased, but men have run to and fro spreading it as they go. Not only have the few driven far back round the full circle of natural knowledge the dark clouds of the unknown which wrap us all about, but also the many walk in the zone of light thus increasingly gained. If it be true that the few to-day are, in respect to natural knowledge, far removed from the few of those days, it is also true that nearly all which the few alone knew then, and much which they did not know, has now become the common knowledge of the many." The great point insisted upon, however, by Sir MICHAEL FOSTER, is that the difference between then and now is a difference which means progress. "The path may not be always a straight line, there may be swerving to this side and to that, ideas may seem to return again and again to the same point of the intellectual compass; but it will always be found that they have reached a higher level—they have moved, not in a circle, but in a spiral." The growth of science is likened to that of a living body, phase following phase as in the embryo, and each member of the body putting on different appearances in succession, though all the while the same member. A scientific conception of one age may seem to differ from that of a following age, though it is the same one in the process of being made, and as the dim outlines of the early embryo become more distinct and sharp as growth proceeds, so the dim gropings and searchings of the old philosophers are by repeated approximations wrought into the clear and exact conclusions of later times.

But while the story of natural knowledge in the nineteenth century is one of continued progress, the question suggests itself, will all the increasing knowledge of Nature avail only to change the ways of man, and have no effect on man himself? The material good accruing to mankind through the advances of science is so imposing as to be obvious to everyone, but is science useful and nothing more, asks Sir MICHAEL FOSTER. "Beyond all doubt science has greatly lessened and has markedly narrowed hardship and suffering; beyond all doubt science has largely increased and has widely diffused ease and comfort. The appliances of science have, as it were,

covered with a soft cushion the rough places of life, and that not for the rich only, but also for the poor." But, whilst the material benefits of science are so abundant and so prominent that in the eyes of many they seem to be the only benefits which she brings, is her work only to administer to the material wants of man? In reply, it is urged that the pursuit of science may be regarded as itself a training of special potency, giving strength to the feeble and keeping in the path those who are inclined to stray. That being so, it is obvious that the material gains of science, great as they may be, do not make up all the good which science can bring. Science has been defined by HUXLEY as organised common sense, and that dictum may be read as meaning that the common problems of life, which common people have to solve, are to be solved by the same methods by which the man of science solves his special problems. But that will necessitate the pursuit of science by the many; the influence of science must be acknowledged, and it must be understood that the training to be looked for from science is the outcome of the practice of scientific inquiry. A man may have a wide knowledge of accomplished results and current opinions of one or more branches of science and yet remain wholly unscientific in mind; but if he has carried out even the humblest research the spirit of science must in some measure rest upon him. Those are wrong who think that, in the schooling of the young, science can only be used with profit to train those for whom science will be the means of earning their bread, and scope should be given to show the value claimed for it as an intellectual training fitted for all sorts and conditions of men. The studies of humanity and literature need not fear the presence of science in the schools, for she herself would be the first to admit that teaching to be wrong which deals only with the work of Nature and says nothing about the doings of man.

In conclusion, looking back on the century which is drawing to its close, Sir MICHAEL FOSTER sees much to give the man of science hope. There are not a few writers, who know not science, who are losing or have lost hope in the future of mankind. But if the intellectual and moral influences of science are no less marked than her material benefits, such men may pluck up courage and gather strength by laying hold of her garment. To men of science the past is a thing to look back upon, not with regret, but with content, as something whose influence is still with them, helping them on the further way. The past, indeed, points to the future, the golden age is in front, and that which we know is a lamp whose brightest beams are shed into the unknown before us, showing how much there is in front, and lighting up the way to reach it.

MEDICAL MEN AND SECRET COMMISSIONS.

IT was not to be expected that Sir EDWARD FRY'S letter on the subject of secret commissions, alleged to be accepted by the medical profession, would be allowed to go unanswered, and several replies by leading medical men have since appeared in the *Times*. Dr. SAUNDBY has explained that he had no intention of palliating the acceptance—whether before or after the event—by a medical practitioner of any payment or consideration from a tradesman for recommending his wares. What he endeavoured to show at the annual meeting was that no evidence was forthcoming in support of the charge that medical men received commissions in order to induce them to do certain things, and he quite agrees that it would be better for the profession if the General Medical Council would take more notice of the conduct of members than it does. Dr. J. ROBERTS THOMSON, the new President of the Council of the British Medical Association, thinks Sir EDWARD FRY'S description of the action of that body is the reverse of the actual position, and a gross travesty of the facts. But a much more important contribution to the controversy is a letter signed "F.R.S.," the writer of which is apparently one of the heads of the medical profession. In his opinion the strictures of Sir EDWARD FRY'S letters derive their importance entirely from the eminence and uprightness of their author—a former Lord Justice of Appeal, and now a Privy Councillor, and "to reply to them may have been a duty of courtesy, but was scarcely a duty of defence." Nothing has ever occurred in this writer's long experience of thirty-two years as a consultant, which suggested a corrupt practice, and he retorts upon Sir EDWARD FRY by suggesting that barristers and solicitors are not absolutely impeccable.

In reply to his numerous critics, Sir EDWARD FRY deals in detail with their objections to his remarks, and practically leaves the matter where it was before. He does not consider that the allegations against the medical profession have yet been disproved, and he insists that, while there are apparently black sheep in the medical profession, the Council of the British Medical Association has shown no zeal against those black sheep, but abundant zeal against those who point them out. At the same time he repeats that he was anxious not to be understood as making a charge against the medical profession as a whole, and refers some of his critics to an explicit statement to that effect in his first letter, wherein he stated that he was "sure that many of its members are as incapable of taking a secret commission as her Majesty's judges are of accepting a bribe." Unfortunately, he does not yet define what is a secret commission. So far as chemists are concerned, it may be remarked that there is nothing more criminal in a medical man realising a profit from the dispensing of medicines for his patients than there is in one of her Majesty's judges receiving dividends as a shareholder in a joint stock company of unqualified persons who, by registration under the Companies Acts, are enabled to evade the Pharmacy Act and carry on a business which, as individuals, they are legally incompetent to conduct. Of the two, the medical man has the cleaner hands; and on the whole it must be concluded that Sir EDWARD FRY is hardly justified in writing about "evidence which shows that a noble profession is not untainted in its lower walks by the vice of secret commissions." Nevertheless, the Council of the British Medical Association has undoubtedly been remiss in not dealing with the allegations of the London Chamber of Commerce in a firmer manner. It is always difficult to prove a negative, but that fact should not have deterred the leaders of the medical profession from doing their utmost either to show that the charges brought against certain members of the profession did not apply generally, or to agitate for the enforcement of suitable disciplinary measures in the event of such charges being borne out by satisfactory evidence.

ANNOTATIONS.

Though Exemption from Jury Service is secured by Statute to all registered pharmaceutical chemists actually in practice in England and Wales, it is essential that those who wish to avoid serving upon any juries or inquests should ascertain whether, by any chance, their names have been inserted in the jury lists. It is specifically provided by the Legislature that no person whose name appears in the jury book as a juror shall be entitled to be excused from attendance when summoned, on the ground of any disqualification or exemption other than illness, unless the disqualification or exemption has been claimed by him at or before the revision of the list by the Justices of the Peace. The list of "all men qualified and liable to serve on juries" should be found at the door of "every church, chapel, or other public place of religious worship," on the first three Sundays of September, with a notice subjoined to the effect that all objections to the list will be heard by the Justices in Petty Sessions on a given day in September.

The Jury List, it should be noted, is expressly provided for by Statute, the Clerk of the Peace in every county in England and Wales being bound, on or before July 20 in every year, to issue a precept to the churchwardens and overseers, requiring them to make out a list of all men qualified and liable to serve on juries. Complaints are sometimes received that jury lists have not been prepared or publicly exhibited in certain districts. But, in the event of the Clerk of the Peace, churchwardens, or overseers neglecting their duties with regard to the preparation and public exhibition of the lists, pharmaceutical chemists should bring the facts at once to the notice of the Justices. Sunday next, September 17, is the last day upon which the lists are required to be affixed to the church and chapel doors this year, and readers who have not already searched the lists are advised to do so at once. It should be noted that the lists are not, as a rule, actually affixed to the doors, but to notice boards which may be some distance apart. If any person finds that his name has been included in error, he should promptly notify the overseers, stating his claim for exemption, and follow up the matter, if necessary, by appearing before the Justices of the Peace upon the day named in the notice subjoined to the list. If after appeal to the Justices the error is allowed to remain unremedied the pharmaceutical victim would be justified in standing upon his statutory right and refusing to serve if summoned.

The Arrangements for the October Examinations in London, unless the number of candidates should be abnormally large or unexpectedly small, will be as follow: The Minor practical work will commence on Friday, September 22, and is expected to continue each day until the following Friday, September 29. On Saturday, September 30, the Major practical chemistry will be taken. In Edinburgh, the practical portion of the Minor examination will not commence so early as it does in London. The Major written work in chemistry and physics, and in botany and materia medica, will proceed simultaneously at the two centres on Tuesday, October 3, and Wednesday, October 4.

Persons Desirous of Entering for the October "First" examination are requested to note that the last day for sending in entries to the Registrar is Tuesday, September 26—that is to say, fourteen days prior to the date of examination. This timely intimation, it is hoped, may save some intending candidates the unpleasant experience of having their entry refused, and should thus deliver them from the temptation of anathematising the Society, its bye-laws, and all its works, for faults which are personal to the anathematiser.

The Medicines Stamps sold in Great Britain during the twelve months ending March 31 last brought in a revenue of £266,404—a record sum. The revenue from this source amounted to £240,062 in 1892, but dropped to £213,210 two years later; since that time, however, it has steadily risen, year by year, the increase for the year ending March 31 being £5,552 over the preceding twelve months. The receipts for the past ten years have been as follow; 1890, £217,264; 1891, £225,701; 1892, £240,062; 1893, £220,325; 1894, £213,210; 1895, £234,881; 1896, £238,946; 1897, 254,726; 1898, £260,852; 1899, £266,404. The total for the ten years is £2,372,371, a not inconsiderable sum to be derived by the State from the sale of quack medicines, and indicative of an almost fabulous amount actually spent on those nostrums by a gullible public.

The Death of Rai Bahadur Kanny Lall Dey, C.I.E., at the age of sixty-eight years, is reported as having occurred at Calcutta on August 16 last. The deceased was an honorary member of the Pharmaceutical Society of thirty-six years' standing. He had devoted much attention to the investigation of the indigenous drugs of India, and his book on that subject is a useful work of reference. At an early age he entered the service of the Government of India as an assistant surgeon, and he was subsequently appointed Assistant to the Professor of Chemistry in the Calcutta Medical College. Later, he was appointed Professor of Chemistry in the Residency College, Calcutta, and he also occupied many other important positions as a teacher and examiner.

The Appointment of Pharmacists as Analysts is not likely to become common unless evidence is forthcoming of a much more thorough training in analytical work than can be compassed in a pharmaceutical course of the usual kind and length. The question was discussed by the Council of the Pharmaceutical Society of Ireland last week, but though pharmaceutical chemists might possibly, many years ago, have secured recognition as public analysts, they must not expect to attain to that position now without further effort, such as is required by candidates for the Fellowship of the Institute of Chemistry. Professor Tichborne was entirely wrong in describing that as an English institution, for its full title is the Institute of Chemistry of Great Britain and Ireland, and as such it has been incorporated by Royal Charter. The headquarters of the body are in London, it is true, but they must be somewhere, and can hardly be in two places at once, even if one of those places should happen to be Dublin. And, after all, London is the larger and more important city of the two. With regard to the statement that there are very few "F.I.C.'s" in Ireland, the only remedy we can suggest is to import more or to educate more Irishmen up to the necessary standard, and let them qualify for the Fellowship. So long as the supply of "F.I.C.'s" falls short of the demand, the Irish Local Government Board—which is not altogether an unreasonable body—will doubtless continue to sanction the appointment of trained analysts possessed of an inferior qualification—inferior, that is to say, when considered from the point of view of the work required to be done.

The Fulham Cases under the Sale of Food and Drugs Act, reported in last week's Journal, have attracted much attention locally, and we understand that general dissatisfaction is expressed in the district at the action taken by the local medical officer in initiating the prosecutions. It is curious, by the way, to notice how differently the magistrate's decision appears to have affected some persons. Mr. A. J. Giles, Secretary of the Federation of Grocers' Associations, writing to the *Grocer*, expresses the opinion that the Fulham Vestry authorities received a well-merited snub from Mr. Rose, and he thinks it is no wonder that the magistrate dismissed the summons and gave three guineas costs against the

Vestry. On the other hand, the Editor of *Food and Sanitation* writes absurdly about a London magistate encouraging drug adulteration. Where could the adulteration come in when, as the magistrate apparently found, there was merely an excess of one-third of a grain of potassium iodide in each fluid ounce of the mixture? There should have been only forty grains in each fluid ounce, and the excess of one-third of a grain hardly seems sufficient upon which to base a prosecution. It is, of course, a fact that the Vestry analyst alleged that he had found an excess of potassium iodide equivalent to three grains in each fluid ounce, *i.e.*, nine times more than the magistrate was persuaded the excess really was, but too great accuracy must not be looked for in the average public analyst's certificate. As a case in point, reference may be made to a recent prosecution at Manchester, for selling flour which was alleged by the county analyst to contain one hundred and seventy grains of alum to the pound. The defendant said she had put no alum in the flour, and the analyst engaged by her could detect none. The Somerset House chemists also failed to find any trace of alum in the sample of flour purchased, and the obvious explanation was that the county analyst had made a mistake. That explanation commended itself to the magistrate who tried the case, and he dismissed the summons. But even the editor of *Food and Sanitation* fails to take umbrage at that decision, possibly because the defendant was not a registered chemist.

INACCURATE DISPENSING should undoubtedly be regarded and dealt with as an offence against the public health, but the evidence of such inaccuracy should be clear and irrefutable. The use of adulterated or otherwise unsatisfactory drugs and chemicals should also be a punishable offence. But it is neither adulteration nor substitution to dispense the one-hundred-and-twentieth part more of a medicament such as potassium iodide, and we question whether many public analysts could dispense such a mixture with much greater accuracy than was proved to exist. They might, of course, weigh the required quantity of medicament exactly to within the third decimal place, but a much greater discrepancy than that is inevitable in ordinary dispensing work. Moreover, if public aualysts perform their especial work as crudely as appears to have been the case in the instances commented upon any efforts of theirs to dispense medicines would probably land them in a coroner's court. Seriously, however, there seems to be nothing but prejudice against registered chemists to justify the editor of *Food and Sanitation* iu writing about "surprising decisions," the "vagaries of magistrates," or the "amazing incapacity" of Mr. Rose. Fortunately that worthy magistrate realised that defendants have rights as well as the public, and that even local authorities may be misled at times into doing what is unjust.

THE PHARMACEUTICAL SOCIETY OF IRELAND has been favoured by its president with a succinct and vigorous statement regarding the present position of the company-pharmacy problem. In his speech, a full report of which appears at page 290, he claims credit for his Couucil where credit is due; defines the Lord Chancellor's real or supposed position; pleads for the co-operation of the British Society; and corrects the misstatements of the official organ of his own Society. It will be noted that Mr. Downes is decidedly averse to any further tinkering of the Pharmacy Acts, and regards it as essential that the attention of pharmacists should be limited to the Companies Acts. He asks, in brief, that the principle of the Pharmacy Acts should be recognised by Parliament in considering any other legislatiou, and that it should not be possible to evade the Pharmacy Acts by registration under the Companies Acts. Not the least important point in the speech was the warning to pharmacists, that they must be prepared to do something iu defence of their own interests. As Mr. Downes wisely said, they must bear in mind that the question is theirs, and that according as they enlighten and instruct their representatives in Parliament will the fight be made easy or difficult, successful or unsuccessful. In other words, though the Councils of the two Pharmaceutical Societies may foresee events and take action, it depends upon the Societies themselves—*i.e.*, upon their individual members—to make that action effective.

WIRELESS TELEPHONY follows close upon the heels of wireless telegraphy, some remarkable experiments by Sir William Preece being recorded by the *Daily News*. It appears that for some weeks experiments of great interest in wireless telephony, as distinguished from Signor Marconi's wireless telegraphy, have been carried on near Carnarvon. Four high poles have been erected near Llanfaglan Church, at the South end of Menai Straits. On a sandbank across Gwyrfal River, half-a-mile off, four similar poles were erected. Half-a-mile still further, at Belan Fort, is a high pole supporting a coil of wire, one end being anchored in deep water between these points. Sir William Preece has succeeded without other intermediary than the ether in transmitting the sound of a succession of taps. Those taps were made with a view of sending messages by the Morse code. They were distinctly heard at the receiving station by placing the newly invented ethereal telephone to the ear. Messages have been sent without interruption for several days. Further experiments from Belan Fort to Llanddwyn Lighthouse and to Carnarvon Castle are contemplated. So far the system is reported to yield much more rapid results than Marconi's, although the sounds are not quite so distinct as could be desired.

THE RECONSTITUTION OF LONDON UNIVERSITY, as should be well known, is now under consideration by a Statutory Commission, of which Lord Davey is Chairman, and a "draft statute" is understood to have been issued to various parties concerned, for consideration prior to the reassembling of the Commission after the recess. What purports to be part of that draft statute was published by the *British Medical Journal* a fortnight ago and is reprinted iu this week's Journal, but we have reason for believing that the publication is entirely unauthorised, and that the matter published must not be regarded as representing the intentions of the Statutory Commission. It is only fair to add that the *British Medical Journal* refers to the document from which it quotes as beiug "strictly confidential," but points out at the same time that the Convocation of the University was summoned to consider it iu public meeting. In view of the fact that "pharmacy" is included iu the list of Boards of Studies, an impression prevails that this may be an indication of the possibility of a degree iu pharmacy being instituted by the University of Loudon. Such an event, however, is in the highest degree improbable. A degree "for" pharmacists is not unlikely to be a feature of the reconstituted University, but it will not necessarily be a degree "in" pharmacy. Indeed, the probability is that it most certainly will not, though training in pharmacy may iu some way be taken iuto consideration in the grauting of a degree in science.

THE LONDON UNIVERSITY COMMISSION ACT provides that the members of each Board of Studies are to be appointed by the Senate of the University from (*a*) members of a faculty who teach or examine in the Board's subjects; (*b*) other teachers of the University, who teach the Board's subjects; or (*c*) such other persons, not exceeding one-fourth of the total number of the Board, as it may think fit; adequate representation on each Board being secured for teachers of the University not belonging to any school of the University. Whether or not the Pharmaceutical Society's School of Pharmacy may be expected to be recognised as a school of the University it would be premature to state, but in auy case members of the teaching staff of that institution will be eligible to become teachers of the reconstituted University, and as such may be appointed as members of a Board of Studies.

THE RECONSTITUTION OF THE UNIVERSITY OF LONDON.

When the Statutory Commission reassembles after the recess it will have before it the various representations made by the University of London, the Technical Education Board, the medical schools, and various colleges respecting the "Draft Statute No. 1," which together with certain draft regulations having reference to the B.Sc. Examination, were issued to the parties concerned in June last. According to the *British Medical Journal* the "draft statute" contains 93 clauses which deal with the whole question of the reconstitution of the University, and amplify while they follow the main provisions of the Act of last year and the schedule attached thereto, which contained the so-called "com promise" arranged between the rival parties in university politics.

The Senate.

The new Senate will consist of the Chancellor, the Chairman of Convocation, and 54 other persons. The schedule to the Act requires 16 senators to be elected by Convocation and 16 by the faculties. Clause 11 deals with the appropriation of the 16 senators to be elected by Convocation among the graduates in the various faculties.

At first the 16 representatives are to be elected as follows: 6 by the graduates in arts, 1 by the graduates in laws, 1 by the graduates in music, 2 by the graduates in medicine and surgery, 6 by the graduates in science; but as soon as the registered graduates in theology number 30, 1 member shall be elected by the graduates in theology, and 5 by the graduates in arts; in the meanwhile the graduates in theology are to vote with the graduates in arts. The same clause appropriates the 16 members of the Senate elected by the faculties among the several faculties as follows: 1 by the faculty of theology, 4 by the faculty of arts, 1 by the faculty of laws, 1 by the faculty of music, 3 by the faculty of medicine and surgery, 4 by the faculty of science, 1 by the faculty of engineering, 1 by the faculty of economics and political science.

The Academic Council.

The Academic Council is dealt with in Clauses 28 and 29; the constitution of the Council is defined by the Act, and of the 20 members 16 are the persons appointed to the Senate by the faculties. The Act, Schedule, Part 2, provides for the due representation on the Senate and the Academic Council of all sections of teachers of the University. The draft statute provides in Clause 66, in accordance with the Act, Schedule 1, Section 11, that the Senate shall take care that teachers of the University, not belonging to any school of the University, shall be adequately represented on each Board of Studies, but there is no such corresponding provision with respect to the representation of teachers not belonging to a school of the University on the faculties, and therefore there is no guarantee that such teachers will be found among the representatives of the faculties on the Senate, and as the representatives of the faculties on the Senate constitute the great majority of the Academic Council, there is no guarantee that the external teachers will be adequately represented on the Academic Council.

External Students and University Extension.

The next following clauses in the draft statute relate to the Board for External Students and that for the promotion of University Extension.

The Faculties.

Clause 54 provides that there shall be eight faculties, namely :—

Theology.
Art.
Law.
Music.
Medicine and surgery.
Science.
Engineering
Economics and political science (including commerce and industry).

The faculties will consist of (1) those teachers who are nominated as members of the respective faculties by the Commissioners, (2) professors, (3) assistant professors, (4) readers and lecturers appointed by the Senate, and (5) such other teachers of the University as may from time to time be admitted by the Senate.

The Boards of Studies.

Clause 64 provides for the appointment of 35 boards of studies. These boards are the following :—

(1) Theology.
(2) Greek and Latin.
(3) Oriental (including Semitic) languages.
(4) Mediæval and modern languages.
(5) Ancient mediæval and modern history and geography (see also 29).
(6) Greek, Roman, and Syriac, Egyptian, and general archæology with palæography and diplomatique.
(7) Philosophy, including logic, psychology, and metaphysics, moral, political, and social philosophy and the history of philosophy.
(8) Pedagogy.
(9) Fine art, including architecture.
(10) Law.
(11) Economics and political science (including commerce and industry).
(12) Music.
(13) Preliminary medical studies, such as physics, chemistry and biology.
(14) Early medical studies, such as anatomy, physiology, general pathology, and pharmacology.
(15) Advanced medical studies.
(16) Dentistry.
(17) Pharmacy.
(18) Hygiene and public health.
(19) Mathematics.
(20) Astronomy and navigation.
(21) Physics.
(22) Chemistry.
(23) Chemical industries.
(24) Geology, including petrology, palæontology, and mineralogy.
(25) Ethnology.
(26) Zoology and comparative anatomy.
(27) Physiology and experimental psychology.
(28) Ethnology (?)
(29) Physical, political, and commercial geography.
(30) Mechanical and marine engineering.
(31) Electrical engineering.
(32) Naval architecture.
(33) Civil engineering.
(34) Mining and metallurgy.
(35) Agriculture.

Matriculation.

Clause 80 provides that every candidate for admission as internal or external student shall pass such entrance or matriculation examination or fulfil such other test of fitness as may be from time to time prescribed. The Senate may make provisions for separate examinations by way of matriculation for different classes of students according to the course of study they propose to follow, and there is to be a special board to advise the Senate on questions relating to the matriculation both of internal and external students, the Board to consist of the Vice-Chancellor, the Chairman of Convocation, and such teachers of the University and other persons as the Senate may annually appoint, provided that the number of such other persons shall not exceed one-fourth of the total number.

Internal Students.

The last six Clauses, 88 to 93, relate to internal students. The course of study for an internal student must be approved by the Senate and extend over not less than three academic years. The Senate is to provide for the guidance of the courses of study for internal students, with however a wide option in the choice of study and with power to vary the course. It appears that a matriculation may be dispensed with in some cases, but certificates of courses f study must be produced by candidates before admission to examination for the first degree. Such course of study, if approved by the Senate, may be carried on in any school of the University. A graduate who has taken a degree as an external student may proceed on approved conditions to the next higher degree as an internal student.

PHARMACEUTICAL SOCIETY OF IRELAND.

The monthly meeting of the Council of the Pharmaceutical Society of Ireland was held on Wednesday, the 6th instant, at 67, Lower Mount Street, Dublin.

The President, Mr. R. J. Downes, was in the chair, and there were also present the Vice-President (Mr. Beggs), and Messrs. O'Sullivan, Porter, Michie, Simpson, Professor Tichborne, J. J. Bernard, Wells, and Grindley.

The Lord Chancellor's Speech.

The PRESIDENT said: Gentlemen, I am very pleased to meet you again after two month's absence, and allow me to express my acknowledgments for the sympathy I received from every member of the Council, as well as from other members of the Society. Since we last met we have had a pronouncement by the Lord Chancellor in moving the third reading of the Companies Acts Amendment Bill in the House of Lords. You will remember that in July I reported that the clauses to control company pharmacy had been inserted in the Bill, and I claimed credit to this Society for that. I consider we may now claim to have won the whole of our case in the House of Lords, for on the 2nd of August the President of the Pharmaceutical Society of Great Britain said: "He might say that they had probably pursued a wise course in lying low, and not taking the course they were much pressed to do on some sides, of opposing the Bill in the House of Lords." I am much obliged to him for that admission, for I confess I am jealous for the honour of this Council that we should get credit for what we have done. When we turn to the address of the Lord Chancellor, and consider it paragraph by paragraph, you find that he admits all our contention. He says:—"I am still very strongly convinced that a company ought not to be permitted to do what a private person is prohibited from doing, and that the public must be protected against practising of that sort." After expressing his agreement with the decision of the House of Lords, he proceeds:—"and that decision left the law that a company could be formed to do the very thing which an individual is not permitted to do without examination as to qualifications"; and having defined the law as it is, he says: "I think I may say that the Committee to whom this matter was referred was unanimously of opinion that the formation of companies to practise any profession, and also intended really to take advantage of the company machinery to do that which an individual without qualification may not do, should be stopped." This pronouncement is, to my mind, definite and clear, and quite in harmony with our desires; but we have another statement which is equally satisfactory, and that is his reply to those who are opposing us. They have been in correspondence also, suggesting "that this is an effort to prevent enterprise, and so forth," so he has had both sides of the question before him, and his reply is: "As a matter of fact I think the writers were not familiar with the state of the law. It is true to say that although at present a company cannot be prosecuted for doing it, and a company cannot undergo an examination to enable them to do it, yet if an individual dispenses without qualification you can catch him and prosecute. And it was in view of that state of the law on the subject that the Committee to which this matter was referred came to their conclusion." That is, the entity of a company should be treated as an individual, and, being unqualified, should not be allowed to practise. I would again draw attention to the stress that is laid throughout on what I would call the pharmaceutical side of the question. His statement that "we should guard very carefully the language used" indicated that we are not to regard the phrasing of the clauses as definite; but I rather think that the clauses have been given a place in the Bill in order to secure their discussion, and no doubt the fight will be in the Commons. I think that altogether we may be satisfied with our position to-day as compared with that of this time last year. It remains now for the two societies to unite, and, if they can, to agree as to the phrasing of the amendment we require. Our modes of action may not be identical, but I do deem it essential that we should be at one as to what we want; and I believe that this Council will be pleased to receive the overtures of the British Society, and through our committees to discuss matters in confidence. I think it essential that we should bear in mind that it is an amendment of the Companies Acts that we are dealing with, and that we cannot hope for—nay, it would be damnation to our cause to try for—any amendment of our Acts. We want them and their principle to be recognised under any other legislation that may be passed by Parliament. Our questions are:—(1) How can we provide that no unqualified person may be proprietor in an establishment kept open for the purposes for which our Acts require that the person keeping open shop shall be qualified; and (2) what are "proper vested interests." I fear the Lord Chancellor takes a broader view of this question than we may be expected to take, and I think this will be our hardest nut to crack. In an editorial of the *Chemist and Druggist* on August 26 it was asserted that "the representatives of the Society appear to be endeavouring to drive the trade to secure the exclusion of pharmacy from the privileges of the Companies Acts, seeing that they advocate complete negation of the company principle as far as pharmacy is concerned." It may be that this was written of the British Society. I do not think it is true of it; it can hardly be, seeing that several of the Council are company men; and it certainly is not true of this Council, which has always contended for the proviso "unless each member of the company is qualified." On the contrary—and I throw it out as a suggestion—I believe we would be glad if the number 7 in the Act was reduced to 3 so that the advantages of the Act might be more conveniently availed of, and I see no reason why a partnership of three should not have equal law with a partnership of seven. Our licentiates must bear in mind that the question is theirs, and according as they enlighten and instruct their representatives in Parliament will our fight be made easy or difficult, successful or unsuccessful. Our own conferences are of little value, except in so far as they reach and influence public opinion. I do not dwell on what course we ought to adopt, for that will properly be for our Law Committee to consider, or for a joint committee if there should be *rapprochement*. I don't know whether anyone wishes to make a remark on the speech of the Lord Chancellor, which has been printed and sent to the licentiates. If not, we shall proceed to the next business.

Licentiates as Analytical Chemists.

The VICE-PRESIDENT reported that a deputation, consisting of Messrs. Wells, Grindley, Bernard, Kelly, Dr. Walsh, and himself had an interview with the Local Government Board at their office. They did not gather much from Dr. Stafford, the Medical Inspector of the Board, but from what they did gather his mind seemed made up that pharmaceutical chemists could not be accepted as analytical chemists. He suggested that if the Society could establish a higher grade the members of it might possibly in future be deemed eligible.

Mr. WELLS said they certainly received a very patient hearing from Dr. Stafford. He was very courteous, but they could see that his mind was definitely made up that their men were not competent to be public analysts. They contended that they were. He asked, did they say that every one of their licentiates was competent to get into the box and give evidence as an analyst in court? They said they did not go so far as that, no more than it could be said that every medical man was competent to take patients; but they maintained that their licentiates, from their training and the examinations that they passed, were perfectly competent to do the work that was required from an analyst of drugs. They pointed out that the training received by those who were Fellows of the Institute of Chemistry afforded no guarantee that they knew anything whatever about drugs. He relied on the curriculum of the Institute of Chemistry, which recommended students intending to qualify for appointments as public analysts to take out courses in therapeutics, pharmacology, and microscopy; but he (Mr. Wells) found that what they were examined in was "the recognition of poisonous chemicals and crude drugs ordinarily found in commerce, and having well-marked physical characters." They pointed out that that afforded no guarantee of competence to analyse drugs, and that what was wanted for the position was a competent pharmacist, who could walk into a dispensary, examine the drugs, and take home and analyse any that he thought were wrong. Until something of that sort was done the system would never succeed. He (Mr. Wells) felt, however, that the Society had done its duty to their licentiates in approaching the Local Government Board, but at present he did not think it could do anything more for them. But it was a great blot on the Society that the Government should act in this way. It was perfectly clear that only a few of the members of the Institute of Chemistry were qualified in some of the technical matters that were required for the office. It was further pointed out by the deputation that any of the men taking out the qualifications required by the Board, who were connected with wholesale houses, would not be fit persons for the office.

Mr. Bernard said Dr. Stafford explained that the course taken by the Irish Local Government Board was not really their own action, because they felt bound to follow on the lines of what was done in England. They gathered that he fully recognised that pharmaceutical chemists could render valuable service in the way of detection, but that the difficulty the Board felt was that prosecutions could not be sustained without the technical evidence of men who held the degree of "F.I.C." It was not fair, therefore, to lay the blame altogether on the Irish Local Government Board. He (Mr. Bernard) thought that Dr. Stafford met them very reasonably. On the one hand they could not contend that all their men were eligible; and, he said, on the other, how could the men that were eligible be selected? Therefore, until some degree was established for the benefit of the licentiates they would have to let the F.I.C.'s have a monopoly of those offices. According to the newspapers, it was not a very valuable monopoly.

Mr. Wells: I think Mr. Bernard is in error in saying that they were bound to follow the course taken by the English Local Government Board. The Irish Act is a distinct one.

Mr. Bernard: I don't say he said that they were bound, but that they felt compelled to follow the course taken in England.

Professor Tichborne said that, although he had the honour of holding a professorship in connection with the Society, he felt that on this question he was a perfectly free lance, for he was too old to take any extra work, and was, therefore, out of the running. He could not see why the Council should not meet the objections that were made by instituting a course that would meet the requirements of the Local Government Board. It should be a course supplementary to the existing courses. The medical candidate for the position of officer of health had to take out an extra six months in chemistry, and an extra six months in bacteriology. The Institute of Chemistry was an English institution. He was himself one of its Fellows, but he did not see why Irishmen should not be provided with facilities for obtaining an equivalent degree. He was quite sure that if they got up a good degree the Local Government Board would accept it. It was not merely a matter of chemistry; they would have to teach microscopy and several other things bearing on the matter. And when they should have done that they would have instituted a course that would probably pay, for his experience was that voluntary courses in Ireland did not pay. Students would not come to them. But if something tangible was offered they would join the course. When the Society's school was first proposed there was considerable opposition to it on the ground that their funds could not be legitimately spent on it, but the establishment of the school was sanctioned by the Privy Council. In the present case it was necessary to educate men in order to supply a public want—to educate them so that they would be able to make the required analyses. That was perfectly germane to the function of the Society, and he thought that in instituting a course such as he suggested they would receive every encouragement both from the Privy Council and the Local Government Board.

Mr. Wells: You would have to get a charter or a new Act of Parliament.

Professor Tichborne: I don't think so.

Mr. Kelly said nothing could have been nicer or kinder than Dr. Stafford's reception of the deputation. He listened to everything they had to say, and said he had a high opinion of the Society's qualifications and examinations. He (Mr. Kelly) asked could the Board themselves appoint two examiners like Professor Hartley or Dr. Reynolds by whom the Society's licentiates could be qualified, but his answer was that the Board could not do that because they were not an examining body. He asked why the Society's licentiates could not go in for the degree of "F.I.C.," but their reply was that they could not—that it would take three years to get. They added that there were very few "F.I.C.'s" in Ireland, that the present supply would not last for ever, that they would afterwards have to be imported, and that that would be creating a new Irish grievance.

Mr. Bernard: He warmly impressed on us the advisability of establishing this examination, saying that the Board would do anything in their power to assist us to create such a body. I think he felt that being a pharmaceutical chemist first, and a qualified analyst afterwards, would form a man who would be far more suited to their purpose than the present men.

The President said that when the last examinations were going on he was so impressed with the appropriateness of the examination that he thought if a representative of the Local Government Board had been present at the Society's last July examination he would have been convinced that it was exactly what was wanted to qualify men for the detection of impurities in drugs, and having consulted with Mr. Baxter, who was present, he drove over and sought an interview with the head of the Local Government Board, to invite him or his representative to attend and inspect the examination. This was before the deputation waited on Dr. Stafford. He (the President) was most courteously received, but he ridiculed the idea of licentiates of the Society being fitted as witnesses in court against large wholesale houses possessed of an immense amount of capital. He said the former would not have a leg to stand on. He also said that the Board had referred the question as to whether they should accept the Society's licentiates for the posts in question to the English Local Government Board, and the language of the latter in reply was so strongly negative that he (President) did not like repeating it. Dr. Stafford admitted that some men who were not "F.I.C.'s" were recognised, but they had been appointed public analysts previously, and that the Board had felt bound to recognise them still; but he said that he would be delighted to see an Irish qualification established, and that he would give the Society all the support he could for that purpose.

Mr. Wells: The question is shall we go further in this matter? The present system is a new one, and may not be adhered to. It may be better to hold our hand.

Professor Tichborne remarked that although the fees paid to the public analysts might be very small, the appointments brought other business to those who held them.

Further discussion on the subject was reserved till later on.

The Conference at Plymouth.

The Vice-President reported that he and Messrs. Wells and Kelly attended the Pharmaceutical Conference, which took place at Plymouth, and were very warmly and graciously received.

Mr. Wells: It may be well to add that we gave an informal invitation to the Conference to meet in Dublin in 1901. It was very warmly received. They meet in London next year, and I am sure that if you send someone to London next year to renew our invitation it will be cordially accepted. I know that they are anxious to come here again.

A letter from Mr. Robert Spence, of Castleblaney, who had been co-opted a member of the Council, intimated that he would not seek re-election, as he found that he would be unable to attend the Council meetings.

Irish Pharmacists in the Colonies.

A letter from the Colonial Office having reference to the proposed Gibraltar Pharmacy Ordinance intimated that Irish pharmacists would be placed on an equal footing there with British pharmacists, and that as regarded other Colonies the attention of the Governors had been called to the claims of Irish pharmacists as being equally entitled to recognition with British pharmacists.

Mr. Wells: It is well that some Government department is prepared to recognise us.

A letter from Mr. J. B. Dougherty, Under-Secretary, Dublin Castle, intimated that in a case of R. H. Anderson, chemist and druggist, who had been fined £5 for using the title "Pharmaceutical Chemist," the Lords Justices had decided that the law should take its course.

A letter from the Under Secretary, Dublin Castle, requested the observations of the Council on a memorial of William Carlin, praying for a refunding of a fine of £5 which had been imposed on him for unlawfully selling phosphorus paste.

Mr. Wells: Has the Lord Lieutenant any power to make us disgorge the money?

A letter from Mr. J. A. Woodside, licentiate of Ballymena, complained that the Local Government Board had declined to sanction his appointment as public analyst by the Guardians of Ballymena, Larne, and Antrim Unions, and that the Guardians had passed a resolution disagreeing with the Board.

The President: Let him get the Guardians to forego the refusal and then they can hold on to him.

Donations.

Donations were received from the Ontario College of Pharmacy of a copy of their "Announcement"; from the Missouri Botanical Garden of a copy of their Tenth Report, 1899; and from the Smithsonian Institute of a copy of a pamphlet entitled "The Rarer Metals and their Alloys."

On the motion of Mr. Kelly, seconded by Mr. O'Sullivan, thanks were voted to the donors.

THE LICENSE.

From reports of the Examiners it appeared that at the last examination for the License twenty-three candidates presented themselves, of whom eight passed.

SCHOOL SESSION—ANNUAL DINNER.

Committees were appointed to make arrangements for the opening of the School Session and for the Annual Dinner.

ELECTION.

On the motion of the VICE-PRESIDENT, seconded by Mr. MICHIE, Dr. M. R. Whitla was re-elected Examiner for the Practical Pharmacy Division of the License Examination.

HONORARY MEMBERSHIP AND FELLOWSHIP.

The following notice of motion stood in the name of the President:—(*a*) Honorary Members.—The Council may elect to honorary membership persons of eminence in pharmacology and its kindred subjects. Such honorary members shall have the privileges of members, but shall not be licentiates of the Society, nor shall they exceed the number of twenty at any time, nor shall more than three be elected in any one year.

(*b*) Fellows.—That members of five years' standing may be elected Fellows of the Society for approved original scientific work done and laid before the Evening Meetings of the Society. For the purpose of judging of the merits of such work it shall be referred to a committee, consisting of three of the Fellows, assisted by an expert nominated by the Council. The subject may be either chemico-pharmacological or botanico-pharmacological.

The PRESIDENT moved the adoption of the first part of the notice relating to honorary membership. It had been objected that as the wording stood it would exclude licentiates of the Society from honorary membership, and, therefore, he proposed to make the latter clause of the motion read "such an election shall not confer the privileges of a licentiate."

VICE-PRESIDENT: There would be a large number.

The PRESIDENT: It would not follow that you should have twenty at any time.

Mr. GRINDLEY: The question is: Have you power to institute this Fellowship?

The PRESIDENT: I would be inclined to send it on to the Privy Council.

Mr. GRINDLEY said he thought there was only one means of becoming a member of the Society under the Act, namely by becoming a licentiate, being elected a member in the ordinary way, and paying a guinea.

Mr. SIMPSON; I do not see what advantage it would be to the Society to have honorary members.

Mr. WELLS said he failed to see that there was power under the Society's Acts to elect such members. The Pharmaceutical Society of Great Britain had power under their charter to elect honorary and corresponding members. Their Society had no such power. He failed to see what advantage they could give to such honorary members. According to the Bye-laws, only paying members could vote.

The PRESIDENT: Well, the resolution drops. As to the proposal of Fellowships, I would be inclined to refer it to the Law Committee in order to see whether a scheme could be framed on a basis which would meet the requirements of the Local Government Board in the matter of the qualification for public analysts.

Professor TICHBORNE said he would like to see Fellowships established, and moved by way of amendment to the President's motion:—"That the following subjects be considered and reported on to the Council: (1) The institution of a degree to meet the requirements of the Local Government Board as regards public analysts. (2) The creation of Fellows of this Society. (3) The best mode of carrying out a course of Theoretical Chemistry in connection with the Society."

The PRESIDENT: I agree to that.

THEORETICAL CHEMISTRY.

Mr. MICHIE moved: "That lectures on Theoretical Chemistry in addition to the present practical instruction be given in the School of Chemistry. That a special committee be appointed to draw up a syllabus with a view to improving the education in the Society's School of Chemistry, and report to the Council." There was an impression general amongst students that the School was not up to the standard that was needed for preparing them for the examinations. He did not want to condemn the School, but he thought something might be done to modernise it, especially as regarded the teaching of chemical theory, for without a knowledge of the theory he did not see how the student could understand the practical work. The students spent the hundred hours at the bench, and were pretty nearly as well educated when those hundred hours were done as when they went into it. They went there as a matter of course. If lectures on chemical theory were delivered contemporaneously with the bench work, it would give them an interest in the latter. There were one or two subjects which were not taught, namely, the estimation of alkaloids and the use of the microscope. A syllabus was necessary because a student joining the School would naturally desire to know what he would be taught.

The PRESIDENT: Theoretical chemistry is in the Preliminary Examination. The student is supposed to know it.

Mr. MICHIE: That is merely elementary. I mean that the theoretical teaching should be carried much further. I understand that there is no teaching of theory in the School.

Mr. O'SULLIVAN: There is.

Mr. WELLS seconded Mr. Michie's motion. There had better be a report from a committee on the subject, and then they would see what was being done in the School, and whether there were any faults.

Professor TICHBORNE said he had intended to second Mr. Michie's proposals. He had always thought, and had often said there, that a recognised course of theoretical chemistry was necessary for the students. Their work at the bench should be intelligent.

Mr. WELLS: The Council agreed long ago that we should have a theoretical class of some sort.

Mr. KELLY said he could not allow to pass without contradiction Mr. Michie's statement that the students came out of the School as they went into it. He could name men who had been trained in the School and who afterwards took the highest places in examinations for the Army and other services.

Mr. WELLS said he had known men who had attended the School and had afterwards boasted that they humbugged the professors. At the same time, he would not have seconded Mr. Michie's motion if he thought it was intended to cast a slur on the School.

Mr. MICHIE said he meant no reflection on the school. What he had said only applied to some of those who attended it. Nor did he intend any reflection upon Mr. Kelly and Professor Tichborne as teachers.

Mr. Michie's motion was then put and carried unanimously; and the following committee were named by Mr. Michie:—Messrs. Wells, Bernard, Grindley, Kelly, Dr. Walsh, Professor Tichborne, Michie, and the President and Vice-President.

Professor Tichborne's proposal, which he had read as an amendment to the President's motion, was then put and carried.

Mr. MICHIE said he did not agree to the proposal to have Fellowships.

OTHER BUSINESS.

Mr. BERNARD called attention to the fact that the Council had on a former occasion passed a resolution that circulars should be issued for the purpose of obtaining the names and addresses of all pharmaceutical chemists and apothecaries keeping open shop for the compounding of prescriptions and the sale of poisons, and of all chemists and druggists keeping open shop. The object of this was to enable a directory of such persons to be compiled. The resolution had not been acted upon.

The PRESIDENT said the circular would be issued.

On the motion of Mr. GRINDLEY, seconded by Mr. WELLS, Mr. A. J. Paterson, of Dublin, and Mr. R. J. Savage, of Dublin, were elected members of the Society.

On the motion of Mr. KELLY, Mr. A. Forbes Watson, B.Sc., was re-elected Examiner to conduct the Pharmaceutical and General Chemistry Division of the License Examination.

On the motion of Mr. O'SULLIVAN, seconded by Mr. KELLY, Mr. J. Hartley, of Phipsborough, Dublin, was nominated for membership, and on the motion of the PRESIDENT, seconded by Mr. GRINDLEY, Mr. D. A. Stewart, of Londonderry, was nominated for membership.

Law and other business having been transacted,

The Council adjourned.

SAPONIN IN AËRATED BEVERAGES.—Saponin added to aërated beverages to increase the froth is detected by Frehse as follows:—The liquid is evaporated to the consistence of a pasty mass, then extracted with acetic ether. On evaporating off the solvent the residue, in the presence of saponin, will give a permanent froth on shaking with water; when treated with strong H_2SO_4 it develops a reddish violet colour. On boiling with HCl a precipitate of sapogenin is formed, generally accompanied by the evolution of an odour resembling that of cedar wood.—*Journ. de Pharm.* [6], **10**, 13.

EXTRACTS FROM CONSULAR REPORTS.

Gut Industry in Procida.—Consul Neville-Rolfe, in an interesting report on the trade of the consular district of Naples for the year 1898 states that some of the inhabitants of the island of Procida manufacture very fine gut from silkworms. They call the product "fili di seta," or "silk threads," their special properties consisting in their strength and flexibility. They are made from the stomachs of silkworms, just before they begin to spin their silk and form their cocoons. The following is the process of manufacture:—The worm is selected when fully matured, that is to say, at the moment when his nourishment ceases, and just before his metamorphosis. He is then cut open, great care being taken not to injure the membrane of the stomach. This is then removed, and usually reaches the length of 13 or 20 millims., with a diameter of 1½ to 2 millims. The stomachs are then put into a pickle, which is the keynote of the whole process and the secret of which is carefully kept. When the pickling process is over, the workpeople, who are mostly women, take one end of the stomach in their teeth, and draw the other end with their hands. This part of the work requires great dexterity, for the threads are drawn out to the length of thirty to fifty centimetres the whole value of the product depending upon its length in relation to its thickness, and the strain it will carry. There are two seasons for the production, namely, in spring, when the best gut is produced, and in autumn when the quality is inferior. The cost of production is considerable, as the worms must be bought just as they are coming into profit for making silk, when they are at their dearest, and again, many worms, on dissection, are found not to be suitable, and have to be discarded. The various operations require a good many hands, and though labour is cheap it runs away with a good deal of money, as skilled hands are alone satisfactory.

The Question of Stamping Out Tuberculosis has, according to Consul Neville-Rolfe, occupied the serious attention of the Italian medical faculty during the past year, and a very interesting pamphlet has been published by the Sanitary Commission of the Naples Hospital for Incurables, recommending that a separate hospital be opened in a selected situation for the treatment of consumptive patients. Various sites have been inspected and are reported upon by the Commission, the members of which are fully persuaded of the benefit to be derived from open-air treatment at a fairly lofty elevation, where pine trees and eucalyptus flourish in profusion. The salubrity of the Neapolitan district in cases of phthisis the Consul thinks is not sufficiently known to the British public, or to the doctors who attend them, and send them elsewhere on the Continent. The extraordinary dryness of the soil, and the refreshing air of the slopes of Vesuvius, it is stated, have proved of marvellous efficacy in many severe cases, and have arrested the disease altogether in numerous cases.

Intending Purchasers of Olive Oil in large quantities are urged by Consul Neville-Rolfe to be early in the field if they wish to secure the completion of their orders, as this year's olive crop in Italy may on the whole be considered considerably below the average. Hence stocks may prove inferior to the large requirements they may probably have to face, especially as it is expected that the Spanish crop will yield little, if any, surplus for exportation over local wants. An active trade is looked forward to in Italy during the coming season, the more so as the oil produced from the first crushings proved to be of excellent quality.

The Quantity of Tartars Exported to Austria from Barletta (Italy) in 1898 amounted to 268½ tons (241,700 lire), and tartaric acid to the United Kingdom amounted to 447½ tons (427,800 lire). The Società l'Appula, which produces tartaric acid, sent in the year 1898 330 tons to the United Kingdom, 150 tons to several countries, viz., France, Spain, Germany, Austria, Egypt, etc., and about 270 tons to Southern Italy. This is one of the most important industries in the district.

A Sharp Rise in the price of copper sulphate was witnessed in the Italian markets at the close of last year. From 63 lire per quintal, it rose to 68 lire, and even at the latter price, Vice-Consul Drinkwater reports, manufacturers would not deliver less than 53 quintals, nor engage themselves even to that for more than 24 hours at a time. A very brisk rise was anticipated, and advertisers cancelled the prices from their advertisements. The rise is a serious matter in Italy where such vast quantities are used as a remedy for vine disease.

The Camphor Monopoly.—The Formosa camphor trade, that is, the manufacture of camphor, for some time past in the hands of German merchants only, according to a recent report, has ceased to be of interest to any but Chinese and Japanese, the latter having in every way more facilities for handling this article in the interior. Since it has been decided by the Formosa Government to institute a camphor monopoly, production has materially increased, owing to the high prices ruling in Hong Kong during the last few months. The lines upon which the Government intends to work the monopoly are as follows:—The monopoly came into force on July 1 of this year, and after that date the Government alone will be allowed to purchase camphor from the producers, and as they will only buy a certain quantity per annum, they will have absolute control of the working of camphor, together with all matters respecting the cutting down of trees, etc.

Permits will be Issued to producers, and anyone having the proper concession-papers, and who has taken out a licence in due form, will be allowed to produce camphor. The Government will undertake the sale of the raw camphor after production in its unrefined state, and will dispose of it to purchasers at certain points. These places will probably be Daitotei (Twatutia), Shinchiku (Tekcham), Tokoham, and the towns on the West Coast where camphor has usually hitherto been deposited awaiting transport.

The Price of Camphor for the period from July 1 last to the end of the financial year has been fixed by the Government at 30 yen (say £3) per 100 catties (say 133⅓ lbs). This price, however, in the opinion of Consul Layard, seems to be too low, and will very probably be raised a few months after the monopoly came in force, for the following reasons:—If the Government buys at 30 yen at the places of production, *i.e.*, as it comes out of the stills, this would give the manufacturer only two or three yen profit, not taking account of possible and probable losses occasioned by typhoons or other causes, whilst if the Government proposes to make its purchases at Daitotei (Twatutia), Shinchiku (Tekcham), and the other places mentioned, thirty yen would be quite insufficient to give a profit after deducting expenses for cost of transport from the stills and loss in weight. The latter item alone would amount to at least 10 per cent.

The Profit on Purchased Camphor during the nine months of the financial year to run after July 1 last is estimated at 369,168 yen (say £36,917), but as the organisation and management of the monoply involves an outlay of over 277,000 yen (say £27,700), the net profits will scarcely exceed £20,000 per annum.

It is Very Doubtful, Consul Layard thinks, whether foreign firms will ever again engage in the manufacture of camphor in Formosa, after the reverses they have experienced since the arrival of the Japanese. The monthly export to Hong Kong is calculated at from 2,000 to 2,500 boxes from Tamsui, and from 100 to 200 boxes from Kelung to Japan. Owing to the enhanced prices ruling in Hong Kong, in anticipation of the monopoly, and prior to its coming into force the total export from Formosa increased by about 600 boxes a month. The Government will use every endeavour to put the camphor-producing business on a firm basis, but it will for some time be very uphill work, although the country is gradually becoming pacified. There has, it is stated, been some talk of a private arrangement between the Government of Formosa and a foreign firm for a grant of the monopoly, but authoritative information is wanting and, as a fact, it is doubtful.

The Government Opium Refinery at Taihoku (Taipeh), is reported to be in full working order, but it is stated that the drug is sold at cost price, and with no idea of making any profit. If it is to be assumed that the restrictions put upon the use of opium by the Formosa Government have been efficiently carried out, it would appear from the increased import figures that the authorities have been successful in checking illicit smoking to a considerable extent, for nearly a quarter of the increase of £305,171 in the total import trade is due to the large arrivals in 1898 of opium.

LETTERS TO THE EDITOR.

Pharmacy as a Profession.

Sir,—There has been handed to me a letter which is of so startling a nature that I have thought your readers may take interest in perusing it. It is from a first-rate tip-top Edinburgh pharmacist, wishful to engage a young man as assistant, and is as follows :—

Edinburgh, September 6, 1899.

Dear Sir,—I have received a satisfactory reference from Mr. —— and shall be pleased to hear from you by return that you can begin your duties on Monday, 11th, at 8.30 a.m. The hours are from then to 9 p.m. Saturdays, 10 p.m. Every second Sunday, 10 to 11 a.m., 12.30 to 2 p.m., 5.30 to 9 p.m. Salary, 18s. per week. Dinner-hour, 12 to 1 p.m. Tea half-hour, 4.30 to 5 p.m.

I am, yours, etc., ——.

From the letter one gathers that the hours of labour are sixty-seven for one, and seventy-three for the second week, or an average of seventy hours per week. And the remuneration is 18s. per week. And the prospective employee was an educated, intelligent, well trained young man. "O tempora! O mores!" This state of things I am quite aware is not typical of the drug trade generally, nor of Edinburgh; but it indicates sufficiently the callousness and utter want of consideration for others which characterises some at least of our members. Why, Mr. Editor, I ask you in all solemnity whether the life of a day labourer with his £1 a week and forty-five hours of toil is not preferable to the life of an assistant in a pharmacy such as this?

Dunfermline, September 9, 1899. JOHN H. FISHER.

The Ethics of Advertisement.

Sir,—Doubtless, like a large number of your readers, I have received a cutting from the *Police News* about a deceased chemist, a traveller, and a "frog in your throat." I understand the last refers to some bronchial lozenges. My object in writing you is to point out that it is not the travellers and retail chemists only who do the poaching, but the capitalists who pirate the formulæ for iron pills, liniments, etc., and by their flagrant advertisements rob the chemists of their legitimate business. If medical men are prohibited advertising, how is it that we have Dr. Scott's Pills, Dr. Williams' Pills, Dr. Collis Browne's Chlorodyne, etc.? It may be they are dead, but the public does not know the fact, and it makes it none the less illegal. If ever the chemists become sufficiently professional to adopt pharmaceutical ethics, I should suggest including "That it is vulgar to advertise."

Newark, September 12, 1899. L. PRIESTLEY.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Cultures of Bacteria (S. E. D.—33/31).—Living cultures of bacteria, moulds, etc., can be procured from C. Baker, 244, High Holborn, London, W.C.

Depilatory (S. H.—33/30).—The most recent form of depilatory is the soap, which is said to give good results. Details for preparing and using it are given in the *P.J.* for June 10 last, p. 536, which see.

Siccative Amber Varnish (R. R.—34/3).—If you will send a sample of the varnish you wish to imitate, with full particulars of the purpose for which it is used, we may be able to assist you in the matter.

Sale of Laudanum (E. A. M.—33/32).—You exercised a wise discretion. The sale of large quantities of scheduled poisons to entire strangers, though perfectly legal, is a distinctly reprehensible practice.

Botanical (E. J. I.—201/20).—If you had looked carefully in the Journal of the same week (see page 198), instead of looking every week since, you might have avoided making the suggestion of neglect.

Subscriptions (C. P. A.—34/2).—Subscribers to the Society must be either student-associates or members, but anyone can subscribe to the Journal. The annual subscription of one pound must be sent to the publishers, 5, Serle Street, Lincoln's Inn, London, W.C.

Tobacco Flavour (J. R. S.—32/25).—Oil of amber, rectified, 10; oil of pimento, 10; oil of cinnamon bark, 5; vanillin, 1; coumarin, 3; oil of peppermint, 1. Mix. A trace of oil of spearmint or oil of cedar wood is sometimes used as well. For perfumed cigarettes oil of rose geranium may be employed.

Destroying Flies (T. C. B.—200/61).—It is gratifying to find that our suggestions have been the source of such favourable results. Doubtless the stable manure was greatly responsible for your plague. As others will probably find your recipe for fly poison useful we print it here :—Inf. quassiæ conc., 1 ounce; beer, 7 ounces; moist brown sugar, 1 tablespoonful.

Ferro-Prussiate Paper (F. B.—33/21).—First size raw paper, free from bleach, with a solution of arrowroot, 5 grains to the fl. oz. of water. Then treat with the following solution :—Ammonio-citrate of iron, 96 grains; distilled water, 1 oz.; potassium ferridcyanide, 72 grains; water, 1 oz.; potassium bichromate, 5 grains; water, *q.s.* to dissolve. Dissolve each salt separately, mix the three solutions, filter, and at once apply to the surface of the paper with a brush. Then dry quickly in the dark. For fuller and more minute details of the *modus operandi*, see *P. J.* [4] **6**, 402.

To Destroy Moles (J. H. C.—33/29).—Pour an ounce or so of carbon disulphide down the hole underneath the mole hill; plug it up at once with a good thick turf. Branches of elder placed in the runs are said to drive away the moles; so, too, are a few bulbs of garlic steeped in paraffin oil. Possibly pouring paraffin itself down the runs would have the same effect. Of all these expedients carbon disulphide is the most effectual, as it kills the animals. It is equally useful against rabbits and wasps applied in the same way. Care must be taken that the liquid is kept away from all lights and fire.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Appleyard, Baker, Bennett, Butcher, Cullurck, Dixon, Dowdy, Downes, Ferrall, Gartside, Glew, Goodman, Griffith, Hill, Hogg, Holoran, Hubbard, Ireland, Jennings, Mair, Morgan, Ramsey, Reynolds, Robinson, Roe, Sargeant, Shepherd, Smith, Walker, Waterhouse, White, Wills.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

CHEMISTRY OF CASCARA. In addition to the constituents already recorded, Leprince has isolated chrysarobin, chrysophanic acid and emodin from the bark of *Rhamnus purshiana*. It is evident that those constituents play an important part in the therapeutic action of the bark.—*Comp. rend.*, **129**, 60.

POISONING BY FORMALDEHYDE. The toxic effects of formaldehyde are apt to be disregarded now that the compound is so extensively used for antiseptic and germicidal purposes, but, as the *Medical Press* points out, the preparations of formaldehyde usually employed are quite strong enough to cause harmful, if not fatal, effects. Thus, a case is recorded of a young man who drank about two ounces of a four per cent. formaldehyde solution which was used for treating seed potatoes. The immediate effect was to cause vomiting of matter containing traces of blood, and death occurred about twenty-nine hours afterwards, as the result of heart failure. A post-mortem examination showed that the œsophagus was slightly inflamed, and escharotic changes were visible in the stomach.

WOOD-TAR CREOSOTE. L. F. Kebler is of opinion that the pharmacopœial requirements, in the case of wood-tar creosote, should be based on the following points:—Physical appearance, reaction, solubility, specific gravity (not below 1·08° at 15° C.), boiling point (200° to 220° C.), reaction with a 20 per cent. solution of potassium hydroxide in absolute alcohol, and a test for neutral oils, apart from the boiling point. To differentiate between creosote and phenols he thoroughly agitates the liquid with diluted glycerin (3 of glycerin to 1 of water), and the diminution in volume on standing roughly indicates the amount of soluble impurities. The collodion, ferric chloride, and bromine tests did not yield results on which any reliance could be placed.—*Am. Journ. Pharm.*, **71**, 409.

HISTOLOGY OF GELSEMIUM. C. B. Thompson has made a histologieal study of *Gelsemium sempervirens*, and finds that the internal phloem arises primarily as four longitudinal strands, which are an integral part of the leaf trace bundles. Its origin is simultaneous with, or slightly later than, the protoxylem and external phloem, so that the leaf trace bundles are bicollateral from the first. The patches formed by the internal phloem—two of which arise just below the cotyledonary node and the other two just below the node bearing the first pair of leaves—are bounded internally by a two-celled phloem sheath, and they grow centrifugally by means of a medullary cambium, the inner and older layers in time becoming crushed and obliterated. The pith dies early in the first year of the plant's growth, and the cavity is subsequently filled up with internal phloem. Where that phloem runs into the petiole it constitutes at first a bicollateral bundle system, but at the base of the petiole it descends through the xylem as two strands, and from that point upwards the primitive collateral bundle system prevails. No internal phloem occurs in the root, in the lower portion of the hypocotyl, nor in the cotyledons. In the root cortex a copious fungoid growth is found, and absorption of starch usually results in cells being occupied by the fungus. In conclusion, it is stated that internal phloem is an acquired characteristic of the plant, and has probably been developed in the long and sometimes twisted stems, to supplement the external phloem. The material used in the investigation consisted of specimens of varying age, preserved in alcohol, and of fresh seedlings grown in hothouses.—*Am. Journ. Pharm.*, **71**, 422.

IODINE IN SEA-WATER. Continuing his researches on the occurrence of iodine in its various combinations in sea-water, A. Gautier has found that, although the total iodine present in water collected at different depths in the Mediterranean does not show much variation in quantity, the condition in which it is present varies greatly. In the lowest depths the amount of mineral iodides is considerable, while that of insoluble organic iodine is relatively small; surface water collected at the same spot contained no mineral iodine, but a relatively large amount of insoluble organic iodine. Thus surface water gave: Insoluble organic iodine, 0·286; soluble organic iodine, 1·960; and inorganic iodine, *nil*; total iodine, 2·246 parts per million. At a depth of 880 metres the figures obtained were: Insoluble organic iodine, 0·100; soluble organic iodine, 2·130; and inorganic iodine, 0·150; total iodine, 2·380 parts per million. At 980 metres below the surface the following proportions were present: Insoluble organic iodine, 0·065; soluble organic iodine, 1·890; inorganic iodine, 0·305; total iodine, 2·260 parts per million. Thus, as organised life becomes more plentiful towards the surface, so the amount of insoluble organic iodine increases and the inorganic salts of the haloid decrease in quantity.—*Comp. rend.*, **129**, 9.

ACIDIMETRY OF ALKALOIDS. For the volumetric determination of alkaloids, E. Faliéres advocates the use of an ammoniacal solution of cupric oxide for the titration of free acid, since as soon as the last trace of uncombined acid is used up, an evident turbidity is produced in the solution. The copper solution is prepared by dissolving cupric sulphate, 10 Gm., in about 500 C.c. of water, adding ammonia until the precipitate at first formed is nearly dissolved, making up to 1 litre and filtering. The solution is then standardised with $H_2SO_4/10$. To conduct a titration about 0·10 Gm. of the alkaloidal substance is dissolved in 20 C.c. of $H_2SO_4/10$ solution, the containing glass vessel is stood upon a black background; the standard copper solution is then run in until a permanent turbidity results, indicating the moment when the free acid is neutralised; from the amount thus found the quantity used up by the alkaloid may be deduced. The author has obtained excellent results by this process with sparteine, morphine, codeine, cinchonine, cinchonidine, quinidine, strychnine, conine, atropine, veratrine, and brucine. In the case of cinchona, the total alkaloids may be determined in the first extraction since the accompanying impurities do not affect the appearance of copper oxide precipitate.—*Compt. rend*, **129**, 110.

PIRALAHY RUBBER. Piralahy or vahaelahy rubber is the product of a new species of *Landolphia*, named *L. perieri* by H. Jumelle. It is a native of the forests of Madagascar. The caoutchouc is described as being of excellent quality, containing but 5·5 per cent. of resin. The latex is obtained by the natives by cutting the climbing stems and allowing them to drain into suitable vessels, then coagulating it with lemon juice or crushed tamarind fruit. During the dry season but little sap is obtained, but this coagulates spontaneously; during the rainy season it is much clearer, but gives but little caoutchouc, only about 6 per cent. of the juice. The latex has a sp. g. of 0·996, which is lower than that of most rubber-producing plants. The density of the dry caoutchouc is 0·910 whereas that of Para rubber is 0·920. The latex contains but little solid matter besides caoutchouc, neither starch nor sugar being present. The whole of the caoutchouc is not coagulated on boiling, nor is it readily precipitated by alcohol. Acids, and most salts, such as sodium chloride and magnesium sulphate, which do not coagulate ordinary rubber, at once precipitate the caoutchouc of *Landolphia*.—*Comp. rend.*, **129**, 349.

ETHER-SOAP.

BY EDMUND WHITE, B.SC., F.I.C.
Pharmaceutist to St. Thomas's Hospital.

Among the many details of surgical technique which have received attention during the last few years the cleansing of the skin of the patient around the area of operation, as well as the hands of the surgeon, have taken a prominent position. With regard to the patient, one method which has been employed to secure the sterility of the skin has been to apply soft soap, and allow it to remain in contact with the skin several hours. After scraping off the soap, a brush is freely used to detach the upper layers of epidermis which have been loosened by the soap. As adjuncts to this treatment the skin may be treated also by various antiseptic fluids, preceded by ether, with a view to removing superficial grease, and so make the skin more readily penetrable by the antiseptics applied. The use of soft soap in this manner makes the skin and adjacent tissues rather tender, and requires more time for its accomplishment than can be given by the surgeon for the cleansing of his hands either before an operation or between several cases operated upon in succession. In order to facilitate the detergent action of the soap it has been proposed to use a solution of soap in some volatile solvent capable of penetrating the skin and carrying the soap with it. After the evaporation of the solvent the soap is thus left in the skin beneath the superficial layers of epidermis which it is desired to remove, since these will naturally be more infected than the skin below. If the skin be now moistened with warm water and scrubbed, the lather which is formed beneath the superficial cells will, so to speak, lift them off and considerably facilitate their removal.

I propose to publish here a formula for such a solution, which has been used in St. Thomas's Hospital for some time past, and which represents the result of numerous experiments made to prepare a solution which will best realise the conditions described above. The solution is made as follows:—

Oleic Acid	36 C.c.
Solution of Potassium Hydroxide, 1 in 1	7 C.c. or a sufficiency.
Alcohol, 90 per cent.	16 C.c.
Methylated Ether, 0·720	Sufficient to produce 100 C.c.

Mix the oleic acid with the alcohol in a flask, and drop in the potash solution until a neutral solution of soap is obtained, using phenol-phthalein as indicator. Then add 0·1 C.c. of potash solution in addition, so that the reaction is just alkaline. Set aside to cool, and finally add the ether. The composition of the finished product will be, in round numbers:—

Potassium oleate	40
Water	4
Alcohol, 90 per cent.	16
Ether	40
	100

When finished the solution may be set aside and decanted from a slight deposit which usually forms. The commercial oleic acid has been employed, and is sufficiently good for the purpose. To make the potash solution take 100 grammes of potassium hydroxide in sticks, add 55 C.c. of water, and dilute the resulting solution to the volume of 100 C.c. It will be found that this solution will neutralise about five times its bulk of oleic acid, but since commercial oleic acid and caustic potash are not absolutely constant in composition, it is necessary to determine the point of neutrality each time a batch of soap solution is made. I have also employed an alcoholic solution of potash, in order to obtain a product containing as little water as possible, but the alcoholic solution darkens rapidly on keeping, and yields a finished article whose colour varies with the age of the potash solution employed. For this reason I now use a strong aqueous solution, as described above, and do not think the presence of the small quantity of water so introduced diminishes the penetrative properties of the ether-soap solution. I also think a very slight alkalinity is advantageous, equal to about one per cent. of the total potassium hydroxide used. It improves the subsequent lathering, and, except in the case of very delicate skins, will not be found too strong. Considerable heat is developed by the neutralisation of the acid; hence it is advisable to set aside the alcoholic solution of soap till cold before adding the ether.

The method of using is as follows:—Pour over the surface to be cleansed sufficient of the solution to well moisten it—for the hands 5-10 C.c. is sufficient. Immediately rub it in vigorously, and continue until the solvent has evaporated. Next moisten with just sufficient water to produce a thick lather when the surface is well rubbed and kneaded with the hands or a brush, finally rinsing with a copious supply of water. Although it cannot be claimed that by this or any other method absolute sterility of the skin can be attained, there is no doubt that the detergent action of this soap solution is very great. Perfuming agents in the form of essential oils, terebene, etc., may be added if desired to mask the slight odour left upon the skin. 0·2 to 0·5 per cent. of an essential oil like lavender or about 1 per cent. of terebene is sufficient. If used in larger proportion than this they retard the production of the lather.

In addition to its use for strictly surgical purposes, the ether-alcohol solution of soap will be found very effectual in removing deep stains or offensive odours from the hands.

The direct solution of soft soap in solvents like ether has not yielded satisfactory results in my hands. It must be remembered that soft soap, as met with in trade, is a somewhat variable article, containing about half its weight of water. The removal of this water—a necessary preliminary operation for the end in view—is very tedious, and during the drying the soap suffers considerable alteration, and becomes more insoluble in alcohol and ether. Moreover, even the best samples of soft soap are not entirely soluble in alcohol, and the filtration of an ethereal fluid is to be avoided if possible.

I have obtained a presentable solution by warming 40 grammes of good olive oil soft soap with 20 C.c. of 90 per cent. alcohol and then adding ether to 100 C.c. Such a solution will, however, only contain half the proportion of soap and at least five times as much water as the solution made by the neutralisation of oleic acid as described above. My object has been to prepare a solution containing a very small proportion of water so that the penetrating property of the ether shall not be reduced by admixture with other fluids which are not solvents of fat.

ODOUR AS AN AID TO THE RECOGNITION OF DRUGS.*

BY PROFESSOR CLEMENT B. LOWE.

There is some little art in treating a drug so that its odour will be brought out most distinctly. If the drug is such that it can be readily powdered, then by rubbing a small portion briskly between the palms of the hands, so as to rupture the oil glands or resin cells, etc., and partly volatilise their contents, then by bringing the closed hands to the nose, the odour will be most distinctly perceived. In the case of a hard drug, a little powder can be scraped off with a knife and treated in this manner.

Thinking that it might be of some value in the recognition of drugs, or at least give us truer ideas of their odours (as even the Pharmacopœia contains some incorrect statements concerning them), I have endeavoured to work out a classification of drugs based on their odours. There are difficulties in making such a classification, as on account of the personal element involved, no two investigators will probably agree to all of the conclusions reached; besides, it is exceedingly difficult to describe odours in words. In quite a number of cases a drug will be found to have almost equal affinities for two or more classes.

* From the *American Druggist*.

CLASSIFICATION OF DRUGS BASED ON THEIR ODOURS.

Division I.

DRUGS HAVING AN AGREEABLE ODOUR.

CLASS A.—Drugs with an aromatic odour (odours which are spicy or strong, and generably agreeable):

(1) With a simple aromatic odour:

(a) Odour strong and characteristic—Asarum, anthemis, cascarilla (stronger when burned), gelsemium, hops, lupulin (strong on keeping), inula, marrubium, matricaria, rhubarb (peculiar), sage, tanacetum, sandal wood (somewhat musklike) wormwood.

(b) Odour less strong, and not characteristic—Arnica flowers, arnica rhizome, angustura (musty), columbo, eupatorium, juniper, melissa (fragrant, lemon-like when fresh), pilocarpus.

(2) With an aromatic, mint-like odour (the mint odour predominating)—Buchu, peppermint, spearmint, horsemint, pennyroyal.

(3) With an aromatic, camphoraceous odour (the aroma has a suggestion of camphor in it): Calamus, eucalyptus, rosemary, santonica, serpentaria.

(4) With au aromatic, spicy odour (the spicy odour predominates): Cloves ginger, cubebs, matico, pepper, pimenta.

(5) With an aromatic and fragrant odour (odours which are strong, spicy and agreeable):

Anise, Fennel, Illicium — Anise Group. Nutmeg, Mace, Cola — Nutmeg Group.

Coriander, Caraway, Cardamon.

(6) With a bitter-almond odour (odour developed by moistening or bruising) Bitter almond, cherry-laurel leaves, wild cherry bark.

(7) With a honeylike odour—Manna, mel.

(8) With a fenugreek odour—Elm bark, fenugreek, marshmallow.

CLASS B.—With a fragrant odour (odours which are sweet smelling and fragrant):

(1) With a simple fragrant odour:

Cinnamon, Canella, Cinnamodendron — Cinnamon Group. Bitter orange peel, Sweet orange peel, Lemon peel — Citrus Family Group.

Gaultheria, Sweet Birch — Wintergreen Group. Sassafras, Vanilla (peculiar).

(2) With an odour of flowers—Orange flower, pale and red rose, orris root (violet odour).

(3) Having an odour of tea—Cusso (fragrant), coca (slight), digitalis (slight), senna indica, thea.

(4) Having an odour of chocolate—Guarana, cacao butter.

(5) Having a fruity odour—Fig, persimmon, raspberry, raisin, prune (feeble), purging cassica (prune-like).

CLASS C.—With a balsamic odour (odours which are aromatic and resinous).

(1) With a simple balsamic odour—Eriodictyon, grindelia, myrrh, guaiacum wood (when heated).

2) With a balsamic and fragrant odour (odours which are balsamic and agreeable): Benzoin, storax, sweet gum, bals. tolu (vanilla-like), bals. Peru (also empyreumatic).

(3) With a balsamic and terebinthinate odour (odour increased by heating), Burgundy pitch, Canada pitch, Canada turpentine, gum olibanum, mastiche, sandarac, tar (empyreumatic), resin (faint), turpentine, thuja.

CLASS D.—Drugs with peculiar odours:

Camphor (penetrating), cochineal, convallaria, coffee (faint in green state), capsicum, gentian (sweet), jalap (smoky, sweetish), quercus (tan-like), pulsatilla (aromatic and hay-like).

CLASS E.—Drugs with a slight odour:

(1) Those having a characteristic odour—Logwood (faint, agreeable), rumex, red saunders.

(2) Those not having characteristic odours—Aspidium, aspidosperma, castanea, cypripedium, dulcamara, euonymus, catechu, caulophyllum, cetraria (odour when wet), frangula (little odour when dry), nutgall, when bruised), juglans, chimaphila, cimicifuga, chinchona (somewhat aromatic), menispernium, sarsaparilla (earthy), scattelaria.

Division II.

DRUGS WITH DISAGREEABLE ODOURS.

CLASS A.—Drugs with narcotic odours (odour heavy and somewhat stupefying)—Belladonna leaves and root (slight), calendula (somewhat heavy), canabis Indica (heavy), chelidonium (strong when fresh), hyoscyamus (heavy), lactucarium (somewhat heavy), lobelia (slight), tobacco (heavy, peculiar), stramonium leaves (slight).

CLASS B.—Drugs with alliaceous odours (sulphuretted odours resembling garlic)—Asafetida, garlic, sinapis alba and nigra (when moistened).

CLASS C.—Drugs with valerianaceous odours (odour produced on keeping, by oxidisation of the volatile oil)—Lupulin (when old), valerian, viburnum prunifolium.

CLASS D.—Drugs with animal-like odours—Ambergris, cantharides, civet, conium (mouse-like when triturated with potassa), pepsin (should be slight), sumbul.

CLASS E.—Drugs having disagreeable, characteristic odours.

(1) Odours which are strong—Ammoniac, aloes, chenopedium, copaiba, ergot, galbanum, podophyllum, senega (strong in fresh root), stillingia sabina.

(2) Odours not strong—Apocynum, chondrus (sea-weed like), hydrastis, ipecac (nauseous when powdered), iris, lappa, scammony (cheese-like), strophanthus, scoparius (when bruised).

DRUGS WHICH ARE DESTITUTE OF ODOURS.

Acacia (odour sometimes sour), aconite, asclepias, bryony, chirata, castor oil beans, croton oil beans, chrysarobinum, cocculus Indicus, colchicum root, colchicum seed, colocynth, gamboge, geranium, tamarind, taraxacum, tragacanth, cottou root bark, granatum, hamamelis, kamala, kino, krameria, leptandra, linum, lycopodium, mezereum, nux vomica, pareira, pepo, triticum, veratrum viride, viburnum opulus, physostigma, phytolacca root and fruit, pyrethrum, quassia, quillaja, rhamnus purshiana, rhus glabra, rhus toxicodendron, rubus, sassafras pith, squill, sweet almond, sinapis alba and nigra (when dry), xanthoxylum, tea.

THE PHYSIOLOGICAL TESTING OF DRUGS.*

BY F. P. TUTHILL, B.S., PH.G., PHR.D.

The physiological testing of drugs is one of the most important problems for the pharmacist of to-day. Many drugs have been gradually discarded owing to the unreliability of resultant products as made from apparently select material. The variance in strength of some crude material is remarkable, and hence, unfortunately, owing to the unreliability of chemical tests, several valuable drugs have been dropped by many physicians. In some cases no effect would be obtained, while in other cases alarming symptoms would be produced, causing suspicion on the part of the patient and much annoyance to the physician. The latter may be ever so well versed in therapeutics, but if his prescriptions are filled with inert drugs or drugs varying in strength, his efforts are apt to be useless or even harmful.

The therapeutic effect of all powerful drugs is almost wholly due to certain constituents, called active principles, which impart to a drug the particular effect derived from that principle which predominates in that drug. These principles may be alkaloids, glucosides, resins, or other specific substances. Thus, for instance, belladonna is used for the effect of its atropine; digitalis and strophanthus for the digitalin and strophanthine; mandrake for its podophyllin, and so on.

For years the only method of determining the strength of galenical preparations of these most important drugs has been by chemicals, based on the fact that alkaloids, like alkalies, have the power of combining with acids and neutralising them. Thus, by following the regular method of titration, the strength of the active principle was supposedly found. The all-important fact was overlooked, however, that many times the chemicals used in titration destroyed the active principle to some extent; therefore, the final result was uncertain. "Is it not then an advance step in pharmacy, when we can have reliable products of these important drugs, which have been physiologically tested, and can be used with safety and certitude?"

Only those drugs and active principles should be tested physiologically which cannot be assayed by chemical means. Dr. E. M. Houghton has found thus far that cannabis indica, ergot, digitalis, strophanthus, convallaria, and squill cannot be tested satisfactorily by the chemical method, and he, therefore, is using the physiological method for these drugs.

Ergot is one of the most important drugs that physicians prescribe. This drug loses much of its activity shortly after being harvested, and often becomes entirely inert. The menstruum used in extracting ergot often leaves the more important constituents in the improperly exhausted drug, all of which make the finished product very uncertain for the physician. There is annually placed on the market thousands of pounds of ergot which has little therapeutic value. A physiologically tested ergot will always be reliable. The

* Read before the Kings County Pharmaceutical Society and reprinted from the *Western Druggist*.

oxytocic power is determined upon pregnant animals, the related hemostatic action by feeding the drug or extract to cocks, the result being shown in the comb and wattles of the fowl.

In cannabis indica we have a valuable but much-abused drug, and through preparations inert or giving rise to alarming symptoms, many physicians have entirely discarded its use. Of twenty-seven samples of crude Indian cannabis of excellent physical appearance recently physiologically tested by Dr. E. M. Houghton, only thirteen proved to be active when administered to animals.

An amusing, yet serious, incident came to my notice some time ago, which proves the necessity of a reliable cannabis indica. A certain pharmacist had always made his tincture of cannabis from solid extract. He used a large quantity of this tincture on one particular doctor's prescription, who was also his family physician. The doctor prescribed tincture of cannabis indica in the usual dose for this gentleman's wife. It seems that a new lot of tincture had been made from a solid extract the pharmacist had never used before, but had used the same quantity of extract in making his tincture. After taking the medicine as ordered, his wife had symptoms most alarming, but to an outsider most amusing—a typical "hasheesh drunk," which is rarely serious, but said by those who have experienced it to be a most delightful sensation. Moral: Use only such preparations of cannabis as have been physiologically tested, which is usually done by administering the extract to dogs, the action being manifest in staggering gait, loss of muscular control, reduction of temperature and often insensibility.

In strophanthus and digitalis we have two drugs whose active principles are known but which cannot be assayed chemically because the glucosides, to which they owe their activity, are of such delicate structure that they decompose more or less by the chemical manipulations. The unreliability of these products has caused the discontinuance of strophanthus by many physicians, and others look upon digitalis with suspicion. These drugs are physiologically tested by administering them in fluid form to frogs and other animals, the demonstration of their action being rendered more vivid through the use of graphic tracings on the kimograph and similar instruments.

The physiological standardisation of pharmaceutical products is based upon the rational idea of administering to animals doses proportionate to body-weight, thereby producing manifestations of therapeutic activity such as we desire to produce in the human subject, but rendered relatively more intense in animals by the administration of larger proportionate doses. From the effects produced we are enabled to institute comparisons with standard samples.

WHAT IS PHARMACOGNOSY.*

BY HENRY KRAEMER.

It is rather difficult in these days of specialisation of knowledge and differentiation of the sciences to determine whether the various departments are becoming more and more distinct, or whether they are becoming more and more dependent upon one another. This apparent difficulty is due ofttimes to the fact of the objective importance of the study rather than its subjective dependence. For instance, bacteriology has received more attention at the hands of medical students than from any other class of investigators. This is due to the fact, however, that the results of bacteriological study more deeply concern the physician than the botanist, whereas, according to the nature of bacteria their study more properly belongs with that of cryptogamic botany, and is, to a limited extent, considered in all thorough courses in botany. The scope and influence of the different sub-departments of science cannot be determined once and for all, but must be evolved as experience and progress add to our knowledge of the various branches.

It may be said that some terms indicating the various sub-departments have been employed rather as a convenience, whereas others have been coined by reason of necessity. Materia medica is one of those convenient terms which may be utilised to mean anything or everything relating to the materials used in medicine. For a great many years it has been associated in colleges of pharmacy with botany and in schools of medicine with therapeutics. Years ago there were evidently some reasons for the use of an elastic term like materia medica, and it does not seem so long ago when a teacher of materia medica might be versed in botany, chemistry, pharmacy, and even medicine. Gradually, some of these subjects have been eliminated from the meaning of the term.

As early as 1821 the returns from the science of chemistry were so great as to cause the two distinct chairs to be made—viz., of chemistry and materia medica in the Philadelphia College of Pharmacy. In 1846, in the same institution, pharmacy, which up to this time had been considered in connection with materia medica, was given distinct rank. Nearly twenty years later (in 1864) the special training of the physician was not considered necessary in the teaching of materia medica, and in 1897 the department of botany and pharmacognosy was established as a separate course of instruction, thus more clearly differentiating the province of materia medica. It ought to be said, however, that this differentiation of these branches of study has not been carried to the same degree in all schools of pharmacy. As to what is meant by materia medica it is not my province to say.

It is recognised in Europe that the knowledge of botany and chemistry which the pharmaceutical student receives at the University is not of a character in itself to make him a pure botanist or chemist. For some time in some of the leading universities the lectures on chemistry have been given to the pharmaceutical students not by the professor in chemistry in the Chemical Institute, but by the professor of pharmaceutical chemistry at the Pharmaceutical Institute. The pharmacy students still go to the botanical institute for their botanical work, but they receive a distinct course of instruction in the science of botany as applied to them in their work. As in chemistry, so in botany, the need of a term to indicate the kind of work that the pharmacist is instructed in is manifest. Very wisely has the chemical work been denominated "pharmaceutical chemistry." It would be well if the botanical work were termed "pharmaceutical botany." Instead of this, however, we find that the word "pharmakognosy" (coming from two Greek words meaning drug knowledge) has been invented, or at least applied.

In 1867 Flückiger published the first edition of his book, entitled 'Pharmakognosie des Pflanzenreiches.' The last (or third edition) was published in 1891. It is practically a collection of brief scientific monographs on the various commercial products of the plant kingdom, treating of their origin, formation, gathering, physical properties, chemical composition, and history. The title of Flückiger's work indicates that we might have at least also an animal pharmacognosy, if not a mineral pharmacognosy. Marmé has published a work on the 'Pharmakognosie des Pflanzen- und Thierreiches.'

Quite a number of works on pharmacognosy of the vegetable kingdom have appeared within the past ten or twenty years. There has been little or no desire upon the part of anyone to define what shall constitute the study of pharmacognosy, but it is fair to say that each author has endeavoured to give in his treatise those facts that he considered essential for a work treating of the knowledge of vegetable drugs. A. Wigand, in his 'Lehrbuch der Pharmakognosie' (the second edition of which appeared in 1874), gives us to understand from his treatment of the subject that a knowledge of drugs consists, primarily, in knowing their macroscopic and microscopic structure. He also mentions the origin, natural order, adulterants and prominent chemical constituents. The work reminds one very much of Maisch's 'Materia Medica,' only there is no treatment whatsoever of medical properties.

In 1892 August Vogl published his 'Pharmakognosie.'

* From the *Alumni Report*.

One hardly observes that there is an undue prominence given in it to any of the features of the works of either Flückiger or Wigand. In fact, there is an apparent assimilation of all of the features contained in these and other works which will tend to promote a knowledge of the vegetable drugs of which he treats. He begins the consideration of each drug with a definition as to what it is, what plant yields it, the natural order to which the latter belongs, its habitat, and whether wild or cultivated. He then proceeds with careful macroscopic and microscopic descriptions of the commercial drug, following this with the study of related drugs, the chemical constituents, an enumeration of the preparations into which the drug enters and a few historical words on the drug. The more we study this work of Vogl, the more likely are we to arrive at a better significance of the term pharmacognosy and the more apparent does it become that pharmacognosy is an end and not a means. The end is drug knowledge, and everything that is likely to bring this condition to pass is to be utilised.

The test-tube, the microscope, or the senses, unaided by any apparatus, are all to be employed wherever necessary.

And yet the study of pharmacognosy has a subjective as well as objective side. The latter is dependent upon the former. Arthur Meyer, in the monographs which he has collected in his 'Wissenschaftliche Drogenkunde' (1889), as well as Tschirch and Oesterle, in their 'Anatomischer Atlas der Pharmakognosie und Nahrungsmittelkunde' (1893), clearly indicate to us that pharmacognosy or drug knowledge must be based on careful scientific work.

In later years we find that all of the valuable work in differentiating genuine from spurious drugs is based on prominent scientific facts. The whole study of powdered drugs is based on this same kind of information, and it is not too much to say that the more accurate knowledge of drugs in the future must be based on the results of scientific work on drugs in both a crude and a natural condition.

We may, therefore, say that while the end of pharmacognosy is drug knowledge and that the object is practical, nevertheless the treatment of the subject must be scientific. This is the part of the work that is so little understood, and that will require some time for comprehension by educators and investigators. We may say for convenience that we have a pure scientific pharmacognosy and a practical pharmacognosy.

Only they can labour in the former field who are trained scientists and possessed of the spirit of scientific research, whereas in the latter it is necessary that this knowledge be turned to some practical account. Indeed, a practical pharmacognosy is the art of making money out of drug knowledge. It plays the same *rôle* with drugs as the study of metallurgy does with ores.

The problems of the two kinds of pharmacognosy may be the same, and the results, to some extent, may be the same, but the objects had in view are very different. The one investigates that our knowledge of drugs may be made perfect. It considers neither the cost nor the time. The other only dares to proceed so far in the search for this knowledge as the object permits for the occasion in question. The results of the former will be published, whereas the results of the latter may be concealed. It is not the object of this paper to argue for a scientific pharmacognosy at this time, but rather to enable you to comprehend what is meant by a practical pharmacognosy and of what use it is to practical pharmacists. I can best do this by indicating to you some of the problems with which practical pharmacognosy is dealing to-day. I need hardly refer to the work in the identification of crude and powdered drugs as at present taught the students in this college (the Philadelphia College of Pharmacy), and which has been referred to on a number of occasions in various papers by the author.

(1) Practical pharmacognosy is concerned in developing that work which will enable the pharmacist to stick to his drugs. The necessity for the pharmacist grinding his own drugs and making his own preparations is very well known, but the economics of the question or the practical pharmacognostical consideration of it has not received the attention it should receive.

I am well aware that this subject is dependent upon certain commercial conditions. Pure powdered drugs may be easily obtained and our students are able to test the powders they purchase. It is questionable, however, as to whether this information has received more than a rather limited commercial value as yet. Most pharmacists, I understand, purchase most of their vegetable drugs in a powdered condition. Where time is an important consideration, business heavy, and room expensive, this may be a more economical procedure. But there are many pharmacists who are doing other work than that upon drugs. Their clerks, as well as they themselves, are putting their energies in outside fields. Their place of business, as well as time, is being devoted to these outside ends. When we consider that powdered drugs cost about 30 per cent. on an average more than that of crude drugs, and that the cost of pharmaceutical preparations purchased is also at least this much more (probably on an average 50 per cent. more) than if the pharmacist made them himself, we can readily enough appreciate that if the pharmacist's bills amount to 1,000dols. per year for these drugs and their preparations, that 300dols. or more is being paid to someone else for the work that could be performed in his store just as well. This means that he could devote 1,000dols. worthless energy in a certain direction and save 300dols. in his purchases by having the drugs ground, and the preparations made therefrom, in his store. This would alone pay for a junior clerk to carry on this work, and give him the kind of experience that he needs. Some pharmacists sell hundreds of pounds of spices alone per annum. Let us, for the purpose of comparison, see what are the prices per pound of some of these products in a whole and in a powdered condition:—

	Crude.	Powdered.
Allspice	$0 12	$0 18
Black Pepper	12	17
White ,,	21	25
Black Mustard	8	15
White ,,	8	20
	61	95

The question might be properly asked, Can the pharmacist practically grind his own drugs? I show you here samples of powdered nux vomica, mustard, flaxseed, pepper, mace, strophanthus, etc., all considered to be drugs that are with some difficulty powdered, which have been ground in this small Excelsior mill, which has cost but a few dollars. Finally, in view of these facts, the question may be asked as to whether the time of the pharmacist can be more profitably employed in the direction indicated than in some other way. I leave the question to the pharmacists themselves, as it is not one for me to answer.

(2) Practical pharmacognosy is furthermore concerned in the selection of drugs. It is very apparent in consulting the various price lists that the same drug may be purchased at various prices, according as it is considered to be "pure," "A," "garbled," etc., or whether it has come from a certain locality or through a certain firm, etc. An "A" of one firm may be like a "B" in another firm's warehouse, and this explains to some extent differences in prices quoted. One is apt to think that, in purchasing an "A" drug from one firm at an apparently less price than a similar drug from another firm, an economical transaction has been made. This is not necessarily the case, and is best exemplified in the purchase of drugs like asafœtida, ammoniac, etc. Fortunately, to-day some of our drugs are sold according to assay (as cinchona, ipecac., etc.), and yet assay is no criterion of price. Short buchu, for instance, sells at a price that is 35 per cent. less than long buchu, and yet it contains probably 50 per cent. more oil. Curaçoa aloes sells at 80 per cent. less than Socotrine aloes, and yet it contains 50 per cent. more aloin. Selection of drugs must be based on a knowledge

of their intrinsic value and not on price. Practical pharmacognosy is concerned in imparting such information as will enable its students to purchase the most valuable drugs with the least amount of money. It matters not what the terms or signs "pure," "garbled," "A," source, etc., may mean to some, to him it must mean actual value in quality of drug. If he chooses to pay a higher price for a drug because of appearance or brand, he must see to it that he receives a corresponding profit on its sale over one that is superior in point of activity and which he may purchase at a less figure. The practical pharmacognosist is conscious of the value of the drug that he is purchasing or selling, and he does not expend any more energy or money than is consistent with the object of utilisation for which he has purchased the drug.

(3) One of the most promising fields of experiment and study is in the collection of medicinal plants and their cultivation. It is true that in this country large quantities of certain drugs, as podophyllum, sanguinaria, caulophyllum, wild cherry, cataria, hamamelis, etc., are annually gathered. These are collected chiefly, probably by the poorer people, in the Blue Ridge Mountain districts of North and South Carolina and Tennessee. There are many regions where large quantities of our indigenous official drugs can still be gathered, as is manifest in all of our botanical excursions. These drug-yielding plants are by no means so abundant as formerly, and this extermination without replacement must be met some day by the products of drug farms. The pharmacists in our large cities may not practically be able to consider this field of operation, but he who is located in smaller towns can consider the collection of wild medicinal plants and their cultivation to at least some extent in supplying his own demand of trade. A few tramps in the neighbouring woods will reveal how many drugs may be profitably collected, and a glance at the catalogues of any of our seedsmen will show how many of our medicinal plants may be grown, and at very little cost. Of course there will be a limit found in every locality to the plants that may be successfully grown. This phase of the subject means the consideration of the principles of general gardening, agriculture, etc., from a practical and theoretical standpoint; various economic problems, as the getting the most out of the soil, the number and kind of plants that may be planted, the sacrifice of one part of a plant for another, as the leaves of hyoscyamus or stramonium for the seeds or the leaves of belladonna for the root, etc.—all of these problems must be solved on a limited scale before larger farms can be made. There is probably no part of practical pharmacognosy in which more profitable work can be done than in the prosecution of preliminary studies in both the collection of wild medicinal plants and their cultivation.

(4) Practical pharmacognosy has been always concerned with the origin and habitat of drugs. It makes a great amount of difference as to what is the origin of the plant which yields us our strophanthus, ipecac., etc., and what is the habitat of the plant which furnishes us coca, belladonna, etc. It is not always possible to decide whether differences are due to origin or habitat and to discern what further study is likely to reveal. Who can say as yet that Carthagena ipecac. is of different origin from that of Rio ipecac., or that the cocas of Peru and Bolivia are necessarily of the same origin. We must not forget that practical pharmacognosy is not concerned in publishing all of the information. Whatever is known and written about drugs may be of some commercial value, but the real and valuable information commercial of many of our drugs is a secret often only to those who profit by commercial transactions. This particular kind of information is to be ascertained most readily in our drug markets. Now and then some traveller or observer tells us something of value, but everyone who has tried to secure commercial information of our drugs finds that this is the information that is coveted, and that it is not printed. The books are rich in a certain kind of knowledge, but, after all, it is not the kind that the practical pharmacognosist desires. Mr. Heap (in a paper read at the Chemists' Assistants' Association, London, March 16) has given some pertinent facts relative to the necessity for commercial study of drugs. He says:—"The wholesale druggist buys one description of aloes always as Curaçoa, but he always sells it as Barbados."

"Sarsaparilla on the London market is divided into six or seven kinds, yet how many of these do you see described or even noted in text-books? Cardamoms are classed under two chief varieties, but who that does not follow the article on the market knows this? In the text-book there will be found at the most three descriptions of benzoin. In the primary market people are accustomed to four. "This commercial observation is not only necessary for commercial ends, but also for scientific ends—for the purposes of the botany and chemistry of drugs. To see this it is only necessary to reflect how, for instance, a pharmaceutical botanist, being desirous of investigating the botanical sources of an Indian gum, might be led by this common statement that it really came from African trees to waste a good deal of time and labour to no purpose. There is no doubt but that the botanical origin of many drugs has been long observed through imperfect commercial information as to their source. Much of this is due to the difficulty of obtaining the right sort of information, but some is also due to defective study of what information is available."

Sufficient has been said to indicate that a practical knowledge of the origin and habitat of drugs can only be gleaned satisfactorily from the drug markets of the world and by expeditions to the source of supply.

In summing up the foregoing observations, it may be said that pharmarcognosy is primarily concerned in the development of a knowledge of drugs. This knowledge may come through the common people as well as through the investigations of botany and chemistry, or the labours of the geographer and explorer. There is a scientific and a practical pharmacognosy. The results of the former are likely to be published and may be turned to account for practical purposes. The information pertaining to practical pharmacognosy is, in addition to the knowledge from literary sources, to be found chiefly in the commercial world among the collectors and dealers of drugs. The information from the latter source is less likely to be published than the former, for when once widely known it generally ceases to possess financial value. The problems of pharmacognosy are many, and some of the problems of practical pharmacognosy are indicated in this paper. Some of the problems of scientific pharmacognosy will be referred to later.

ANALYTICAL NOTE.

SATURATED SODIUM SALICYLATE SOLUTION FOR THE EXAMINATION OF ESSENTIAL OILS.—M. Duyk finds that a saturated (1:1) solution of sodium salicylate, sp. g. 1·14, is a useful solvent for separating many of the constituents of essential oils. It readily dissolves a number of alcohols, aldehydes, ketones, and phenols. The solution is perfectly clear, but again liberates the dissolved substances on dilution with water. In this way eugenol, geraniol, linalool, borneol, benzaldehyde, carvol, citral, carvone, cinnamic aldehyde, and citronellone may be separated from the oils containing them; esters and terpenes are insoluble in this reagent. Santalol, anethol, safrol, apiol, cineol, and camphor are only partially dissolved. This solution is applicable for the extraction of the soluble bodies from oils on the manufacturing scale as well as for the quantitative determination of them in the analytical examination of essential oils. For the latter purpose a known volume (1 C.c.) of the oil is introduced into a burette, graduated with 1/20 C.c., with three times its volume of the sodium salicylate solution, the whole is thoroughly shaken up, and allowed to separate; the clear lower liquid is drawn off, a fresh portion of the salicylate added, and the operation repeated. The volume of the insoluble oil is then read off. The details of the examination of various essential oils by this method are being published.—*Bull. de la Soc. Roy. de Pharm. de Brux.*, **43**, 225.

EGG ALBUMIN.*

BY THOMAS B. OSBORNE.

Hopkins has recently shown† that the crystallisation of egg albumin is greatly facilitated by the addition of acetic acid to the half-saturated ammonium sulphate solution. I have found that crystallisation is thus promoted, because the crystallised egg albumin is a compound of the protein substance with acid.

When egg white is first mixed with half-saturated ammonium sulphate solution an alkaline reaction towards litmus can be detected, and a decided odour of free ammonia develops. After this solution has stood for some hours, all evidence of free ammonia disappears, and the solution is then perfectly neutral to litmus and continues neutral during the gradual separation of the albumin. The deposited substance, whether in the form of spheroids or of crystals, when filtered out and dissolved in water, reacts distinctly acid with litmus, as well as with phenolphthalein.

In order to obtain the albumin in crystals, it has heretofore been necessary to precipitate it several times, evidently because, during the earlier evaporations, an insufficient amount of acid is formed to produce the crystalline compound. It is also for this reason that, if acetic acid be added as Hopkins directs, the albumin is obtained completely crystallised by a single precipitation, and that, too, without any concentration by evaporation.

I have found that if, instead of acetic acid, a molecularly equivalent quantity of hydrochloric acid be added, the separation takes place even more quickly, and, so far as my experience has as yet gone, within a short time is more complete than with acetic acid during the same time. Thus, I prepared from two portions of 1500 C.c. each of perfectly fresh egg white a quantity of crystallised egg albumin by aid of each of these acids, with the following results:—

After adding to one-half of the egg white acetic acid in the proportion and manner directed by Hopkins, and a molecularly equivalent quantity of hydrochloric acid mixed with 300 C.c. of half-saturated ammonium sulphate solution to the other half, the two solutions were set aside to deposit albumin. After three hours a very large crystalline precipitate had separated in the portion with hydrochloric acid. This precipitate was then filtered out, but the portion with acetic acid was allowed to stand for twenty-four hours, because the separation appeared to be much less than that in the hydrochloric solution.

These two precipitates were each twice recrystallised, freed as completely as possible from mother-liquor by pressing out with filter-paper, dissolved in water, and the solutions dialysed for ten days, until wholly freed from sulphate, when they were filtered clear and evaporated at about 50°. The residue left by the acetic acid solution, A.1, weighed twenty-nine grammes; that from the hydrochloric acid, H.1, fifty-nine grammes.

The filtrates from the several crystallisations of these two preparations yielded a second crop of completely crystallised albumin; that from the acetic acid solution, A.2, weighing forty-three grammes; that from the hydrochloric acid solution, H.2, seven and nine-tenths grammes. Similarly, from the mother-liquors from these preparations, two other entirely crystalline products were obtained, weighing respectively, A.3, eight grammes, and H.3, four and nine-tenths grammes. From the finally remaining acetic acid solutions another preparation separated, consisting wholly of spheroids, A.4, which weighed nine and one-tenth grammes.

There were thus secured from 1500 C.c. of egg white, by adding acetic acid, 80 grammes of wholly crystallised albumin, and from 1500 C.c., with hydrochloric acid, 73·2 grammes, or 5·30 and 4·90 grammes respectively per cubic centimetre of egg white.

The crystallised albumin, like all the other protein preparations which I have as yet examined, is a compound of a protein substance with an acid. In order to neutralise to litmus and to phenolphthalein the solutions of one gramme of each of these preparations of albumin, it was necessary to add the following quantities of decinormal potassium hydroxide solution:—

	A.1.	A.2.	A.3.	A.4.	H.1.	H.2.	H.3.
To phenolphthalein	2·05	2·30	2·30	2·35	2·05	2·25	2·20
To litmus	1·30	1·60	1·65	1·55	1·30	1·60	1·50
Difference	0·75	0·70	0·65	0·80	0·75	0·65	0·70

If, as pointed out in another paper, the molecular weight of the protein substance is about 15,000,* one gramme would react with 0·67 C.c. of a decinormal solution, a quantity nearly equal to the difference in acidity shown by these two indicators. Three molecules of acid reacting with one of albumin would be equal to two C.c. of decinormal solution per gramme of albumin, a quantity in very close agreement with that found for the two fractions constituting the greater part of the albumin, A.1, and H.1, and which also differs but little from that required to neutralise one gramme of all the other fractions.

When the albumin, dissolved in water, was neutralised with decinormal potassium hydroxide, the solution evaporated to dryness and the proteid matter burned off, an ash was left containing potassium carbonate almost molecularly equivalent to the acid of the albumin originally neutralised. From this it appears that the acid is mostly, if not wholly, organic.

It has been, thus far, impossible to discover what acid or acids were united to the albumin. Neutralisation of the albumin suspended in fifty per cent. alcohol resulted in the formation of a gummy mass difficult to filter and wash, and from which none of the products of neutralisation could be separated. Neutralisation of a solution of ten grammes of the albumin and dialysis in distilled water failed to give enough salts in the diffusate to shed light on the nature of the acid. Neutralisation with baryta of a solution of two grammes of the albumin gave a very slight precipitate which, after standing some days, was filtered out, washed, and ignited, but only four milligrammes of mineral matter were obtained.

The preparations showed no excess of sulphur over that usually found in coagulated and thoroughly washed albumin prepared without the use of sulphuric acid or sulphates. Determination of total phosphorus showed A.1 and H.1 to contain 0·38 and 0·40 per cent. phosphorus pentoxide respectively. These preparations contained 0·87 and 0·69 per cent. of ash, which was almost wholly insoluble in water, and appeared to consist chiefly of calcium phosphate. The total phosphorus in these preparations was equal to 0·59 and 0·64 per cent. of tricalcium phosphate respectively.

Towards lacmoid these preparations reacted alkaline, about one C.c. of decinormal acid being required to neutralise the solution of one gramme, and three C.c. to give an acid reaction. When one gramme was treated with decinormal hydrochloric acid no evidence of free acid was shown with tropæolin until eight or nine C.c. were added.

When pure water solutions containing two and five-tenths per cent. of my albumin preparations were heated they all became turbid at 58°—59°, and separated a minute quantity of flocks at 59°—60°. On gradually raising the temperature the coagulum slowly increased until at 70° much of the dissolved albumin had coagulated. The solutions, heated for some time at 74° and filtered, still contained a little proteid, which even on heating at 99° did not separate until some salt was added. No break in this gradual coagulation of the albumin was detected, the solutions when filtered after partial coagulation yielding a coagulum on again heating up to the temperature to which they had been previously heated.

When solutions of pure ten per cent. sodium chloride brine, containing two and one-half per cent. of each of these preparations except A.3, H.3, and A.4 were slowly heated, turbidity developed at 56°—59°, and flocks at 56°—60°.

* From the *Journal of the American Chemical Society*.
† *Jour. Physiology*, **23**, 131.

* Sabanejeff: *Chem. Centrbl.* (1891), 10, found the molecular weight of purified egg albumin by determining the lowering of the freezing-point to be 15,000.

Only a trace of coagulum was obtained, however, below 64°, and the solutions filtered from this remained perfectly clear until heated to nearly or quite 70°, when the alumin began to coagulate. It was, however, found necessary to heat the solution to nearly 84° before most of it was separated.

The three preparations, A.3, H.3, and A.4, behaved as just described, except that below 64° each yielded a relatively considerable coagulum. These preparations, it is to be noted, are final fractions obtained in small quantity, and it seems probable that this coagulum obtained at 60°—64° is due to the presence of a different substance from that constituting the chief part of the other fractions. This is the more probable as A.3 and A.4 also showed a difference in specific rotation, as well as in composition.

The degree of acidity was found to have much influence on the coagulation of the albumin. Exact neutralisation to phenolphthalein, as might be expected, entirely prevented coagulation, even on boiling. When the acid of the albumin was neutralised so that the acidity was equal to one and two-tenths C.c. of decinormal solution per gramme of albumin, a solution containing two and five-tenths per cent. of the proteid became slightly opalescent on heating to 72°, and remained otherwise unchanged, even after heating for a long time in a boiling water-bath. If, however, the acidity was but one-tenth C.c. greater—that is, equal to one and three-tenths C.c. per gramme of albumin—the solution became turbid at 70°, and very opaque after heating in the water-bath at 99°. The difference between the two solutions was marked, and it is evident that the additional one-tenth C.c. had caused a change in the condition of the albumin. An acidity of 1·33 C.c. per gramme is almost exactly equal to two molecules of acid per molecule of albumin, assuming the latter to have a molecular weight of 15,000. From this it would seem to be necessary to add three molecules of acid to one of albumin in order to form the coagulable substance.

The specific rotation of these preparations was approximately determined by means of a Schmidt and Haensch polarimeter using a 200 Mm. tube. The readings on the sugar scale were converted into degrees of circular polarisation by multiplying by 0·346. The formula used in calculating the results was:—

$$(a)_D = \frac{a \times 100}{p \times d \times l}$$ where

a = observed rotation,
p = per cent. of albumin in the solution,
d = density of the solution,
l = length of tube in decimetres.

The results obtained were as follows:—

Preparation.	Per cent. of dissolved albumin.	Solvent.	Rotation.	Average.
A.1.....	5·861	Water	—29° 48′	—29°
	6·670	,,	—28° 46′	
A.2.....	3·422	,,		—29°
A.3.....	3.273	,,		—33°
A.4.....	3·404	,,		—41°
H.1.....	3·425	10 per cent. NaCl	—29° 0′	
	3·237	Water	—28° 33′	—28° 35′
	6·478	,,	—28° 1′	
H.2.....	1·699	,,		—28° 14′
H.3.....	3·205	,,		—39° 31′

As the results obtained on A.1, A.2, H.1, and H.2 agree closely, and as these preparations represent very different proportions of the total albumin of the egg white, it seems probable that we have in these fractions but one substance.

Bondzynski and Zoja, working with solutions containing ammonium sulphate, obtained similar but somewhat lower figures for the specific rotation of their least soluble fractions—namely, 25° 8′ and 26° 2′, duplicate determinations on the same fraction. Two other fractions gave them 34° 18′ and 42° 54′, figures agreeing fairly with those obtained by me for my more soluble fractions. They determined the albumin in the polarised solution by coagulation, a process which does not admit of so exact a determination of the dissolved albumin as that employed by me, which consisted simply in evaporating the pure water solution to dryness, drying to constant weight at 110°, and deducting ash. A slight error in determining the dissolved albumin causes a considerable error in the specific rotation.

The effect of acid and alkali on the rotation of the albumin solutions is shown by the following results, obtained by dissolving one gramme of A.2 in twenty-five C.c. of water, and treating with the given quantities of acid or of alkali:—

1 gramme A. 2	+ nothing		—29° 17′
	+ 0·8 C.c.	N/10 HCl	—29° 5′
	+ 8·0 C.c.	,,	—33° 46′
	+ 1·4 C.c.	N/10 KOH	—28° 45′
	+ 2·7 C.c.	,,	—30° 20′
	+ 4·2 C.c.	,,	—32° 30′

It is to be noted that by eight C.c. of the acid and by four and two-tenths C.c. of the alkali a rotation was produced about ten per cent. higher than with the smaller quantities of acid or alkali. This increase may well be due to a local over-reaction taking place on mixing the acid and alkali with the proteid solution, it having been demonstrated that large proportions of acids and alkalies yield products of high specific rotation.

Panormoff* has studied the specific rotation of fractionally precipitated crystallised egg albumin, and concludes that there are two albumins present in egg white, one with a specific rotation of —23·6°, and the other —46·2°. The albumin with the lower rotation he obtains from the so-called egg globulin precipitated by adding an equal volume of saturated ammonium sulphate solution to the egg white. This he succeeded in crystallising, and, so prepared, finds it to have the properties and composition of albumin. He considers, therefore, the egg globulin to be a compound of egg albumin with some unknown substance.

As the egg white is alkaline to litmus and ammonia is set free on adding to it a saturated solution of ammonium sulphate, it is not surprising that a product should be produced of different solubility from that of the albumins which we have been considering.

Panormoff converted his crystallised albumin into a chloride by dialysis against two-tenths per cent. hydrochloric acid. He analysed the product obtained, and it is interesting to note that, if calculated free from hydrochloric acid, the figures for the albumin are in exceedingly close agreement with the average of the best analyses of albumin. Furthermore, the proportion of hydrochloric acid in the compound is exactly the same as that which I found with tropæolin to be fixed by the albumin—that is, I found that one gramme of albumin united with eight C.c. of decinormal acid or 0·0292 hydrochloric acid to form a compound showing no free acid with tropæolin, while Panormoff's chloride contained 2·92 per cent., or exactly the same quantity.

In regard to the composition of egg albumin, confusion has recently been caused by Hofmeister, who states† that he has found in repeatedly crystallised egg albumin 1·01 and 1·18 per cent. of sulphur, and that Dr. F. N. Schulz, in his laboratory, has obtained 1·24 and 1·27 per cent. He consequently calls in question the purity of the samples of crystallised albumin, analysed with great care by Bondzynski and Zoja. As Hofmeister's figures for carbon are higher, and for nitrogen lower, than those of Bondzynski and Zoja, as well as of other investigators who have analysed *amorphous* egg albumin, the whole question of the composition of this substance is again thrown into confusion.

Having at hand a sample of egg albumin, which had been three times recrystallised in the manner described by Hofmeister as necessary for its purification, and obtained in the same proportion from the egg white as stated by him to be the usual yield after thorough purification, and which had been coagulated with alcohol and thoroughly washed until all the ammonium sulphate

* Ref. in *Chem. Centrbl.* (1898), II., 358 and 487.
† *Ztschr. physiol. Chem.*, **24**, 166.

had been removed, I analysed it, dried at 110°, with the result given under No. 1.

Analyses of the seven fractionally crystallised preparations, A.1—4 and H.1—3, were made after drying them to constant weight at 110°.

	No. 1.	H.1.	H.2.	H.3.
Carbon	52·18	52·85	52·33	51·72

There can no longer be question about the amount of sulphur in albumin being greater than that stated by Hofmeister. My sulphur determinations were made with extreme care, fusing more than a gramme of the substance over an alcohol lamp with pure sodium hydrate and peroxide in a nickel crucible,* dissolving the fusion in excess of hydrochloric acid, neutralising most of the excess of acid, and precipitating with barium chloride from a boiling solution of at least 800 C.c. volume. Blank determinations showed no trace of sulphur in the reagents, and also that none was absorbed during the fusion over the alcohol lamp. These results agree with those obtained by Bondzynski and Zoja, though the difference in composition between their extreme fractions was not quite so great as found for my preparations.

The composition, rotation, heat-coagulation points and reactions of the crystallised egg albumin obtained by aid of hydrochloric or acetic acids show this to be the same substance as that which has in the past been regarded as egg albumin.

My results, those of Bondzynski and Zoja, and of Panormoff, make it plain that there are two protein substances in the egg white, which are commonly obtained admixed when preparing egg albumin by the usual processes. Whether the extremes of my fractional precipitations of these two albumins consist wholly or even largely of each one of these bodies requires further investigation of large quantities of egg white. This work we now have well under way.

Moerner† has described ovomucoid as identical with Neumeister's **pseudopeptone**‡, and states that it constitutes about one-eighth of the organic substance of the egg white. As this substance is described as largely, though not wholly, precipitated by two-thirds saturation of its solution with ammonium sulphate, it ought, if present as such in the egg white, to be found among the more soluble fractions thrown down by successive additions of ammonium sulphate. It is intended to direct especial attention to the isolation of this substance, and to determine if possible in how far it may be admixed with the albumins.

LABORATORY OF THE CONNECTICUT AGRICULTURAL EXPERIMENT STATION, NEW HAVEN, CONN.

* I have found many times when using a nickel crucible that, on dissolving the fusion, there was a black substance present (this looks and behaves like nickel sulphide, but it seems hardly possible that nickel sulphide could escape oxidation), which, when filtered out and oxidised, was found to contain sulphur. This black substance should be dissolved by the chlorine liberated from the hydrochloric acid by the peroxide of hydrogen, otherwise too low results will be obtained.

THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.*

Salicin.—The reactions of salicin have been already described [*P.J.*, Jan. 29, 1898, p. 100]. In this connection it is interesting to compare the remarks made under saccharum purificatum [*P.J.*, Sept. 1, 1899] with regard to the behaviour of cane sugar towards Fehling's solution. The absence of reducing properties in cane sugar and glucosides is probably to be referred to the same cause, viz., the atomic arrangement in the condensed molecule of cane sugar or glucoside, by which the carbonyl group (to which the reducing properties are due in glucose) is in some way altered. Several formulæ have been proposed by which it may be shown how the carbonyl group may be supposed to be altered in the cane sugar, and to reappear as ketone and aldehyde in the products of hydrolysis—lævulose and dextrose. The explanation is, however, somewhat hypothetical, and cannot be further pursued here. The formula given for salicin in the 1898 B.P. may be used to show how this substance splits up on hydrolysis into glucose and salicylic alcohol, the so-called saligenin—

$$\left.\begin{matrix} C_6H_{11}O_5\cdot O\cdot C_6H_4\cdot CH_2OH \\ + \\ HO\,H \end{matrix}\right\} = \left\{\begin{matrix} C_6H_{12}O_6 \\ C_6H_4\langle \begin{matrix} CH_2OH \\ OH. \end{matrix} \end{matrix}\right.$$

Salol.—This is the phenyl ester of salicylic acid. The esters derived from the phenols present certain differences in their formation and reactions as compared to the esters of aliphatic alcohols. For example, ethyl acetate and phenyl salicylate may be regarded as derived in an analogous manner, viz., by the condensation of a molecule of alcohol or phenol and acid with elimination of a molecule of water as shown below—

$$\left.\begin{matrix} CH_3COO\,H \\ + \\ C_2H_5\,OH \end{matrix}\right\} = \left\{\begin{matrix} CH_3COOC_2H_5 \\ + \\ H_2O \end{matrix}\right.$$

$$\left.\begin{matrix} C_6H_4\langle \begin{matrix} OH \\ CO\cdot O\,H \end{matrix} \\ + \\ C_6H_5\cdot OH \end{matrix}\right\} = \left\{\begin{matrix} C_6H_4\langle \begin{matrix} OH \\ COOC_6H_5 \end{matrix} \\ + \\ H_2O \end{matrix}\right.$$

The practical realisation of these two equations, requires however very different conditions, owing chiefly to certain differences between the behaviour of the aliphatic alcohols and the aromatic alcohols or phenols. Compare the properties of alcohols and phenols in your text-book of organic chemistry. These differences are chiefly due to the fact that the characteristic hydroxyl group is in one case connected with an aliphatic or open chain nucleus, and in the other with an aromatic or closed chain nucleus, which is comparatively rich in carbon and poor in hydrogen. This accumulation of carbon atoms causes the phenols to behave somewhat like acids, *e.g.*, ordinary phenol reacts with potash and soda solutions to form potassium and sodium phenates, C_6H_5OK and C_6H_5ONa, because the phenyl-radicle C_6H_5 is negative and influences the hydroxyl group, so that its hydrogen may be easily exchanged for the more strongly electro-positive metals potassium and sodium.

For the production of ethyl acetate, it is only necessary to disti the alcohol and acetic acid in presence of a dehydrating agent like sulphuric acid. Compare in your text-book the section on general methods of formation of esters. For the reason given above, however, the phenols do not so readily exchange the hydrogen of their hydroxyl for acid radicles, and hence this method does not yield good practical results in the case of salol. Some analogy may,

* NOTE.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J.* during 1897-8.

however, be found between the behaviour of phenols and tertiary alcohols of the aliphatic series. The tertiary alcohols contain the group $\equiv C{\cdot}OH$, *i.e.*, the hydroxyl is linked to a carbon atom, which is connected by its three remaining valencies with carbon. The phenols also contain their hydroxyl group linked to a carbon atom which is also connected with two, or perhaps three, other carbon atoms. As a matter of fact it is found that the formation of esters of tertiary alcohols by the direct action of acids only proceeds to the extent of about 6 per cent. of the alcohol. The subject of esters has been already treated very fully in the Student Columns *P.J.* [4], **7**, 552. In the case of esters of phenol the reaction must be assisted by using a high temperature in presence of some agent like phosphoryl chloride (phosphorus oxychloride) $POCl_3$ which reacts energetically with the water produced, and so prevents saponification of the ester. The reaction between phosphoryl chloride and water results in the formation of phosphoric and hydrochloric acids.

$$PO\begin{matrix}Cl\\Cl\\Cl\end{matrix} + \begin{matrix}H\,OH\\H\,OH\\H\,OH\end{matrix} = PO\begin{matrix}OH\\OH\\OH\end{matrix} + 3HCl$$

It is found in practice that a better yield is obtained when the sodium salts of salicylic acid and phenol are employed. In this case sodium phosphate and chloride are produced as by-products, and this prevents a secondary reaction between the phenol and phosphoric acid which results in the production of phenyl esters of phosphoric acid.

Carbonyl chloride behaves very similarly to phosphoryl chloride, thus—

$$CO\begin{matrix}Cl\\Cl\end{matrix} + \begin{matrix}H\,OH\\H\,OH\end{matrix} = CO\begin{matrix}OH\\OH\end{matrix} + 2HCl.$$

The carbonic acid so formed decomposes immediately into carbonic anhydride and water—

$$CO\begin{matrix}OH\\OH\end{matrix} = CO_2 + H_2O.$$

Among the official characters and tests the insolubility of salol in water should be carefully noted as a point to be remembered in dispensing this substance. The action of bromine in alcoholic solution results in the formation of an insoluble bromo-derivative by replacement of a hydrogen atom in the phenol residue by bromine. Compare action of bromine upon phenol itself. The violet colour with ferric chloride is characteristic of salicylates. Salol, like other esters, is saponified by boiling with solutions of caustic alkalies and more quickly by fusion as described in the Pharmacopœia.

$$\left.\begin{matrix}C_6H_4\begin{matrix}OH\\COO\end{matrix}C_6H_5\\+\\Na\,OH\end{matrix}\right\} = \begin{matrix}C_6H_4\begin{matrix}OH\\COONa\end{matrix}\\+\\C_6H_5OH\end{matrix}$$

In presence of excess of caustic soda the phenol yields sodium phenate

$$C_6H_5O\,H + HO\,Na = C_6H_5ONa + H_2O.$$

The fused mass dissolves in water but on acidulating with hydrochloric acid the sparingly soluble free salicylic acid is precipitated and phenol regenerated. Salol is not decomposed by contact with water, and is practically insoluble ; hence if water be shaken with salol and then filtered the filtrate should give no colour with ferric chloride unless the salol contains uncombined salicylic acid. The medicinal use of salol is based upon the combination of two powerfully antiseptic and caustic substances—salicylic acid and phenol—into a neutral, almost tasteless substance, which passes through the stomach unchanged, but is slowly hydrolysed by the alkaline intestinal juice into its constituents. Hence it is employed as an antiseptic in certain disease associated with putrefactive or fermentative changes in the intestine. Owing to its stability in the gastric acid juice and to its insolubility salol passes on unabsorbed until it reaches the intestine, whose secretion is alkaline and capable of hydrolysing it into its soluble and active constituents.

Sapo Animalis, Sapo Durus, and Sapo Mollis.—The official characters and tests for these soaps have been considerably amplified in the present Pharmacopœia. Even now they are very incomplete ; for example, the characters and tests for curd and hard soaps are practically identical, and no test is given to show that one is chiefly sodium stearate and the other sodium oleate. The identification by analysis of the exact kind of oil or fat used in making a given sample of soap is a matter of great difficulty, and in the case of a mixture of oils or fats it becomes almost impossible. In the case of two soaps like the official curd soap and hard soap the difference may be shown very simply in the following manner, which depends upon the separation and determination of the melting points of their fatty acids. Dissolve 5 grammes of the soap (in shavings) in 100 C.c. of hot water. To the solution contained in a beaker add a little solution of methyl orange and then standard sulphuric acid until a permanent acid reaction is obtained. The mineral acid decomposes the soap forming sodium sulphate and liberating the fatty acids. These, being insoluble in and lighter than water, rise to the surface of the hot liquid, and form a clear oily layer. Now set the beaker aside to cool : the oily layer will solidify and form a circular cake which may be removed and dried on blotting paper. In the case of curd soap the cake will be hard at ordinary temperatures and melt at about 45° to 50° C. With a soap made from olive oil the cake of fatty acids will be soft at ordinary temperatures, and melt at about 25° C. The method of testing for free alkali in soap given under Sapo Animalis should be carefully noted by the student. If perfectly neutral sodium stearate or oleate be dissolved *in water* an alkaline solution is obtained, and this alkalinity increases with increasing dilution. This is owing to the dissociating effect of water, which hydrolyses the neutral soap into an insoluble acid soap and free alkali. Hence alkalinity must be determined in strong alcohol which does not have this dissociating action. The Pharmacopœia does not admit the presence of any free alkaline hydroxide in curd, hard or soft soap, because the alcoholic filtrate from 5 Gm. exhausted by 90 per cent. alcohol should not give any colour with phenol-phthalein. Usually, however, even in the best made soaps, a trace of free alkali is found as carbonate, but since sodium carbonate is insoluble in strong alcohol it must be sought for in the residue (if any) on the filter paper. This is therefore washed with water, and the filtrate titrated with sulphuric acid, of which not more than 3 C.c. of N/10 solution should be required. This amount corresponds to rather more than 0·3 per cent. of anhydrous sodium carbonate because

$$1{,}000\text{ C.c.} \frac{N}{10} H_2SO_4 = \frac{Na_2CO_3}{20}$$

$$= 5{\cdot}2655\text{ Gm. } Na_2CO_3$$

$$\therefore 1\text{ C.c. } ,, = 0{\cdot}0052655\ ,,\ ,,$$

$$\text{and } 3\text{ C.c. } ,, = 0{\cdot}0157965\ ,,\ ,,$$

and 0·0158 Gm. Na_2CO_3 in 5 Gm. of soap is 0·316 per cent. Sodium soaps when incinerated yield a non-deliquescent ash of sodium carbonate, while soft soaps made with potassium hydroxide yield a deliquescent ash of potassium carbonate. The limit of moisture allowed in curd and hard soaps is rather high, for there is no difficulty in getting good soaps containing about 20 per cent. of water. In determining moisture the soap should be cut in the thinnest possible shavings ; even then many hours' heating will be necessary to remove all the moisture. Under Sapo Mollis a residue of 3 per cent. insoluble in 90 per cent. alcohol is allowed. This allowance is made because soft soap cannot be "salted out" like hard soap. Hence the impurities found in commercial caustic potash—potassium chloride and sulphate and silica for example—remain in soft soap, while in the case of soda soaps they remain in the aqueous liquor from which the hard soap has been "salted out." These impurities are for the most part insoluble in strong alcohol—hence the allowance of 3 per cent. insoluble residue. The copper test in the ash of soft soap is to exclude the use of that metal for communicating the conventional green colour to the soap.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, SEPTEMBER 23, 1899.

THE PHARMACEUTICAL SOCIETY AND THE COMPANIES BILL.

DURING the past few years the idea has been sedulously fostered by critics—apparently unacquainted with the facts of the case—that the Council of the Pharmaceutical Society has been backward in attempting to secure such amendment of the law as would prevent companies of unqualified persons from carrying on the business of a chemist and druggist. At the present time that idea is being brought to the front once more, as a means of instituting an invidious comparison between the Pharmaceutical Society of Ireland and the older body on this side of the Channel. Whilst disclaiming any desire to begrudge the President of the Irish Society the credit to which he is entitled for what he has done in the matter, it must yet be pointed out that his remarks published last week (see p. 290) betray a somewhat imperfect acquaintance with the earlier history of the matters referred to. Judging only from what has recently been published, it might be imagined by anyone not conversant with all the facts that, whilst the Executive of the Irish Society has long been labouring at the subject without intermission and with conspicuous success, the Council of the British Society has done absolutely nothing. But the real truth of the matter is that the Pharmaceutical Society of Great Britain has, for several years past, been actively engaged in attempting to obtain a remedy for the invasion of chemists' privileges by companies, while the Irish Society—like the medical and dental corporations—has taken up the agitation quite late in the day. The satisfaction expressed by the President of the Irish Society might therefore be regarded in the light of seeking to reap where others have sown. The whole credit of getting pharmaceutical affairs referred to in the Companies Acts Amendment Bill is being claimed for the Council of the Irish Society, and the Council of the British Society is blamed—not only by inference—for not having devoted its energies to the same end. So far as concerns the clause relating to pharmacy in the Companies Bill, no one need be particularly anxious to claim credit for it, as its chief effect would be—in direct opposition to the principle and obvious intention of the Pharmacy Acts—to recognise that unqualified persons have acquired a right to practise pharmacy and style themselves accordingly, if they only take the trouble to secure registration under the Companies Acts. But it is the principle of the Pharmacy Acts that is in question, and the point now to be considered is that there is not a particle of evidence to prove that any public body anticipated the Pharmaceutical Society of Great Britain in seeking to prevent companies of unqualified persons from carrying on a business which is prohibited to individuals until they have been duly examined and registered. Moreover, from the very outset of the agitation, the view of the Council of the British Society has been that the existing anomalous state of affairs should be remedied by an amendment of the Companies Acts rather than of the Pharmacy Acts.

As early as January, 1895, Mr. MICHAEL CARTEIGHE, who was then President of the Pharmaceutical Society, was authorised by his colleagues to communicate with the Departmental Committee appointed by the Board of Trade to inquire what amendments appeared necessary in the Companies Acts, and to direct the attention of that Committee to certain companies which had been registered under the Acts. He pointed out that, though it is obviously of paramount importance from a public point of view that the administration of the salutary provisions of the Pharmacy Act of 1868 should be subject to no serious hindrance, the decision of the House of Lords—that a "company" registered under the Companies Act is not a "person" within the meaning of the Pharmacy Act—prevented a joint-stock company from being made liable to penalties imposed on individuals convicted of offences. To that extent, therefore, the Pharmacy Act was rendered inoperative and incapable of being the safeguard which the Legislature intended it to be, since it was open to any person, without training, skill, or knowledge, associating himself with six others, equally ignorant and unqualified, to obtain sanction under the Companies Acts to sell, dispense, or compound indiscriminately any potent poison or dangerous drug by payment of the necessary registration fee. The Council of the Pharmaceutical Society, therefore, deemed it to be its duty to urge the Departmental Committee seriously to consider the desirability of so amending the Companies Acts that means might no longer be offered by those Acts for evading the provisions of the Pharmacy Act of 1868. Subsequently, in accordance with a suggestion made by the Secretary of the Committee, Mr. CARTEIGHE submitted a draft clause for the Companies Acts Amendment Bill. The effect of that clause would have been to prevent a company from practising any profession or calling in connection with which the law requires a personal qualification, except under the same conditions as individuals, and therein any rational person will recognise the origin of the clauses inserted in the Companies Bill. That is to say, a company would have been prohibited from practising pharmacy, medicine, etc., unless the individuals constituting it were all legally qualified to do so. The Departmental Committee, however, did not think the specific amendment of the law asked for fell within the scope of its reference, and in the report of the Committee the opinion was expressed that any real grievance should be met by an amendment of the Pharmacy and Medical Acts. The utmost, therefore, that the Committee did was to suggest the insertion in the draft Bill of a clause providing for winding up a company if it could be proved that the company had been formed for any illegal purpose.

After communications addressed to the Departmental Committee by leading medical bodies, supporting the action taken by the Pharmaceutical Society, had also proved abortive, a conference was held at the Society's London house for the purpose of discussing the position. As related in the Journal of April 9, 1898, the delegates attending that conference represented the British Medical Association, the Medical Defence Union, the Apothecaries' Society, the Pharmaceutical Society, the Royal College of Veterinary Surgeons, and the British Dental Association. After prolonged discussion, a deputation was appointed, which waited upon the President of the Board of Trade, and submitted the following clause for insertion in the Companies Acts Amendment Bill:—

If any company shall take, use, or exhibit any name, title, sign, description, or addition which cannot by law be taken, used, or exhibited, unless the person taking, using, or exhibiting the same has a personal qualification, such company shall (1) be deemed to be carrying on business for an illegal purpose within the meaning of this Act, and shall (2) be subject to the same consequences in all respects as though the company were a natural person taking, using, or exhibiting such name, title, sign, description, or addition, without having such qualification.

That clause was drafted and submitted in 1895, but it was not inserted in the Bill, although the late Lord HERSCHELL attempted to secure amendment of the Bill in the direction indicated. Subsequent attempts to influence the Board of Trade as well as the Privy Council also met with failure. The only response made by the Privy Council officials was, as explained in the article previously referred to (see *P.J.* [4], **6**, 356), the hint that, if the Companies Bill were left alone, a joint Bill promoted by the bodies interested might be supported by the Government. That vague half-promise was to some extent fulfilled when the LORD CHANCELLOR introduced his two Bills last year. By the subsequent incorporation of the substance of those Bills in the Companies Bill the Government has apparently endorsed the LORD CHANCELLOR'S action, and relinquished the position previously taken up—that a Companies Bill was not the proper measure in which to deal with the matter. How the clause in question came to be inserted in the Companies Bill is not evident, and though it is probable that the LORD CHANCELLOR was responsible for inserting the clause, it is more than likely that, in so doing, he was influenced by the representations made to him by Mr. WALTER HILLS, as President of the Pharmaceutical Society of Great Britain. But what is distinctively obvious is that the Council of the Pharmaceutical Society has missed no opportunity during recent years of bringing before the responsible authorities the necessity of amending the law relating to companies, so as to prevent unqualified persons from evading the provisions of the Pharmacy Acts. The Pharmaceutical Society of Great Britain was also the first important body to suggest to the Government that the chief defect proved to exist in the Pharmacy Acts could best be remedied by amendment of the Companies Acts. Though that view was not accepted by the Government at the time, nor for several years subsequently, the credit of first mooting the idea, and of pressing it whenever an opportunity offered, must rest with the Council of the British Society. The suggested clause, printed above, must also be regarded as the first definite declaration of the policy that unqualified persons should not be allowed—by registration under the Companies Acts—to secure immunity from the consequences of acts which would constitute offences against the law if committed by individuals.

ANNOTATIONS.

THE INAUGURAL MEETING of the fifty-eighth Session of the School of Pharmacy will take place on Monday, October 2, at 3 p.m., when the prizes for the past session will be distributed by the President, and an address by Dr. D. J. Leech—an honorary member of the Society and a member of the General Medical Council—will be given to the students. The meeting will possess additional interest on account of the presentation of the Hanbury Gold Medal, which has been awarded to Professor Ladenburg, of Breslau. It is hoped that the distinguished recipient of the award may be able to personally attend on the occasion of the presentation. Members and Student-Associates of the Society are cordiall invited to attend, and a crowded lecture theatre is expected. It may be of interest to point out that this classic home of inaugural addresses has undergone complete renovation, and an electric light installation, with electric fans, precludes the possibility of any future complaints on the ground of bad light or stuffy atmosphere.

MEDICAL DISPENSING is strongly advocated by a correspondent of the *British Medical Journal*, who infinitely prefers dispensing to non-dispensing practices. He states that double the income with half the work is the result of dispensing. If the practice exceeds £700 he recommends that a dispenser be kept, and, he continues, "this can be done with little expense, even in smaller practices by the aid of a pupil or lady dispenser, who will also act as governess." He has never found dispensing affect his social position, though he certainly thinks it is *infra dig.* to be seen mixing medicines (*sic*). As an example, says this exceedingly commercial-minded practitioner, "take a case of anæmia, say five shillings for a prescription; the patient takes the medicine six weeks and is cured, and prescribes for all her friends, whereas by supplying medicine, with an occa ional consultation, such case pays, say, fifty shillings." Comment on this effusion is unnecessary here, but it is noteworthy that the editor of the *British Medical Journal* publishes the letter without comment. In the editorial columns of the same paper, by the way, Sir Edward Fry's reply to his medical critics is commented upon, and it is stated that "if a medical man wishes to give up dispensing he is at liberty to send his patients to a chemist, but he must pay the chemist himself, and recover the cost of the medicines from his patients, or retain no interest whatever in the profit derived from their sale." To let the chemist charge what he pleases and take a share of the profit is condemned as unprofessional.

"A MEDICAL UTOPIA" is the heading of a letter by another correspondent, who remarks that in no country in Europe is the practice of medicine placed upon such a commercial basis as in England, and consequently in no country has the doctor such an inferior social position. "Such purely commercial transactions as buying and selling practices, entering into partnerships, keeping assistants, selling drugs, are not calculated to make the public look upon the practice of medicine as one of the learned professions." It is pointed out that anyone who has come into contact with the poor must be familiar with the expression "the doctor's shop," and that the poor are generally under the impression that it is chiefly for their medicines that they pay their doctor, and are often indignant if they be charged the same price for a 2-oz. as for a 6-oz. bottle. At the same time, it is urged that in a country so thickly populated as England, where, moreover, unlike some other countries, there is no Government monopoly, and hence no limit to the number of chemists' shops, there is no necessity for medical men dispensing their own medicines. The conviction is also expressed that all economic grievances and jealousies in the medical profession that are constantly being aired in the medical journals are due to nothing else but this commercial spirit, and the writer

of the letter continues: "If medical men did not enter into competition with chemists by dispensing their own medicines, the latter would not pay us back by prescribing and spreading the sale of quack medicines. The practice of keeping assistants, and thereby appropriating the profit of another's work, is far more unprofessional and injurious to the interest of one's fellow practitioners than the comparatively harmless practice of advertising."

The Capsicum Habit is discussed by Mr. J. H. Hart in the *Mirror*, a Trinidad paper. He points out that but few people who habitually use capsicum in any form as a condiment, are aware, or will admit, that they are indulging in a habit which is highly pernicious and specially hurtful to the constitution. So fixed does the habit of using "pepper" become that many persons, accustomed to its use, cannot enjoy a meal without their beloved pepper, in some one of its many forms. One individual who advanced special arguments as to capsicum being good for digestion, being an appetiser, good for the liver, etc., is now a confirmed dyspeptic, and a needle-woman who used to consume with her breakfast two or three large capsicums became a chronic dyspeptic, and only obtained relief by abandoning the vegetable. A high official in Trinidad once entered upon a discussion of the virtues of hot pepper, and, like many another converted one, told the story of his conversion. He said that one day he observed a pet monkey very sick, and refusing all offers of food. Thinking to trick him, a "hot pepper," or capsicum, was offered, and, contrary to expectation, was greedily eaten. The monkey got better, and the official was convinced of the virtues of hot peppers. That official, however, become a martyr to dyspepsia. A man or woman may certainly have dyspepsia without being a capsicum eater, and a man may have his food flavoured with capsicum for years without becoming a confirmed dyspeptic, but when capsicum is taken largely and regularly the result is as certain as in the case of the opium or ganjah smoker. "The evil result of capsicum eating is only recently becoming recognised, and investigations have already shown the pernicious character of the habit. Further investigation will probably prove that many of the ailments of the tropics are actually caused by indulgence in 'hot peppers.'" In moderation, of course, capsicum is useful as a condiment, but the habitual or excessive use of it is stated to be sure to result in impaired health and shortening of life.

The Licking of Gummed Labels is strongly condemned in the report of the Departmental Committee appointed to inquire into and report upon certain miscellaneous dangerous trades. Referring to the practice, as prevailing in various trades, the opinion is expressed that since the work is usually done by young persons and children at an age when growth is active and the system requires all its digestive secretions, the daily loss of saliva to the system cannot but be prejudicial to health. Analysis of certain labels has shown that they contain copper and lead, the presence of which constitutes a danger, but nothing but gum has been found in the adhesive matter. It is believed, however, that animal substances are occasionally substituted for gum, and it is pointed out that serious risk to health might be incurred by licking such materials, as the mouth might become the seat of irritable ulcers, and, from the surface of those sores, infective material might be carried to the glands underneath the jaw, and thus a constitutional illness might follow. Evidence was forthcoming showing that serious gastric disturbances had resulted from the long-continued licking of gummed labels, and it is noted that a kindred practice—that of licking postage stamps—has given rise to what is known as the "stamp-licker's tongue"; also that the application of stamp paper to an open wound has been credited with causing blood poisoning. There is, of course, no reason why the saliva should be put to such a use as the moistening of labels and stamps, and it is decidedly more cleanly to damp them by mechanical methods.

The Tendency of Tablet Medication appears to be slow in manifesting itself to the members of the medical profession, but a very clear exposition of it is given in a letter communicated to last week's *British Medical Journal*. The writer thinks it is high time that medical practitioners aroused themselves to the fact that, in prescribing drugs in tablet form, they are acting not only contrary to their own interests, but also encouraging the public in the ever-increasing tendency to self-medication. The evil is intensified, he points out, by the growing practice—fostered by chemists, who are blind to their own interests—of supplying the tablets to the public in original bottles, labelled with the name and dose of the remedy. "The chemist in many cases is too diffident or too lazy to remove the label, and they (the tablets) are dispensed in the original bottle, and even when—in order to check this evil—a broken number of tablets have been prescribed, the chemist has induced the patient to take the original 'conveniently-sized' bottle, on the plea that it will be so much cheaper." Now that he has been awakened to the abuse that exists, the writer of the letter intends to cease prescribing tablets, unless the manufacturers alter their methods of doing business. They should, he thinks, cater less for the convenience of the public and more for the interests of the medical profession, by supplying their preparations in bulk only.

A New Illuminating Gas has been introduced at Hunmanby, a village between Scarborough and Bridlington, which will in future be lighted with "electroid" gas, an illuminant which the Scarborough District Lighting Company (Limited) claims will revolutionise the lighting of villages, urban districts, and country mansions. Electroid gas, according to the *Times*, consists of acetylene, with the admixture of inert matter and a proportion of oxygen *(sic)*. Its manufacture is said to be simple, and the gas can be delivered through any ordinary gas main pipes at the ordinary pressure. It can be measured by means of gas meters, and charged for in the same way as is the custom where ordinary coal gas is used. It is said to give a light of great purity and brilliancy. The Scarborough District Lighting Company proposes to light a considerable number of villages throughout Yorkshire with the new gas.

A Distinguished Chemist, who had taken a most laudable and prominent part in the Dreyfus affair, has died just as the pardon of Dreyfus had been decided upon and officially announced. The allusion is, of course, to Mr. Scheurer-Kestner, an Alsatian, who as the *Times* correspondent points out, has given proof of his fidelity to his country, notably when he resigned his seat in the National Assembly in order to protest against the inevitable annexation to Germany of Alsace-Lorraine. He was re-elected, however, in the elections of July 2, and afterwards became Senator. He was a Vice-President of the Senate when he became convinced of the monstrous character of the condemnation of Captain Dreyfus in 1894. With indomitable will and inflexible uprightness he sought to inspire a similar conviction in others, but he was thwarted by the action of General Billot. He also had to contend with M. Méline and M. Cavaignac. Not being at that moment in a position to produce all the forged documents accumulated for the condemnation of Dreyfus, he found himself disarmed before the storm let loose against him. But he did not for a moment flinch, he accepted stoically the loss of the Vice-Presidency, and he went steadily on defending the cause which he had taken up.

Wireless Telegraphy continues to be the subject of successful experiments, excellent results having been obtained last week in the transmission of wireless telegrams between Dover and Boulogne. The current was considerably intensified by the placing at the masthead on Dover Town Hall a very large

cage of close wire netting, cone-shaped at both ends, the metal netting having the effect of collecting the electrical force. Messages were interchanged between Wimereux, near Boulogne, the South Foreland Lighthouse, and the East Goodwin lightship, which is twelve miles out in the Channel, with another four miles of high hills intervening between sea and the point where the transmitter is deposited at Dover. All the messages were transmitted with remarkable clearness. A very curious effect noticed in Dover was that the aerial messages could be heard very distinctly over the telephone wires at night. Numerous congratulatory messages were exchanged by wireless telegraphy between members of the British and French Associations on either side of the Channel.

THE CENTENARY OF THE ELECTRIC CURRENT has been celebrated at Dover by the delivery of a lecture by Professor Fleming, who directed the attention of his audience to the main conclusions arrived at since Volta's famous discovery in 1799. Having referred to Volta's researches in contact electrification, the lecturer proceeded to explain the phenomena of electro-static energy, magnetic flux, continuous and alternating currents, induction, and transformation. It was, he pointed out, the brilliant researches of Hertz which proved that where alternating currents of very high frequency are set up in an open circuit the energy may be conveyed entirely away from the circuit into the surrounding space in the form of electric waves. At a certain intensity of strain the air insulation breaks down, and the air becomes a conductor. This quality of passing quite suddenly from a non-conductive to a conductive state under the action of a critical electric pressure is a very peculiar and important characteristic of gaseous substances. Referring next to Marconi's results, Professor Fleming said it had been known for some years that tubes full of powdered metals are very curiously sensitive to electric sparks. The non-conducting mass at every spark becomes a conductor, but can be brought back to its original condition by a tap. Signor Marconi discovered that a long vertical wire attached to the sensitive powder tube has the property of increasing enormously the distance at which it can feel the effect of the electric spark, and it is as the outcome of that discovery that electro-magnetic wave telegraphy has been developed on such a large scale within the last few years. The chief principle which underlies this industrial application of the research is that the sensitive powder tube, when passing into the conductive condition, can be made to complete another voltaic circuit, and so operate any ordinary form of telegraphic instrument.

THE TRANSFERENCE OF ELECTRICAL ENERGY by wave motion was also referred to by Professor Fleming, who said that Hertz had proved that electrical energy could pass from a rod in which a very rapid oscillatory current was set up, and could travel with the speed of light outwards in all directions. After it had left the radiator and before it had arrived at the receiver it existed as free radiant or wave energy in the ether. Both optical and electrical phenomena had compelled the assumption of that imponderable material as the vehicle for energy in certain forms. After referring to Clerk Maxwell's researches, Professor Fleming concluded his lecture by observing that from the starting point of Volta's discoveries a century's development had brought us to this point—that the actions we call an electric current, if alternated rapidly enough in direction, would end by producing a ray of light. We are, however, as yet in the region of conjecture, when an attempt is made to formulate a specification of the exact nature of the motional and configuration changes which must be at the root of observed effects. It may be said to be the aim of physical inquiry at the present time to devise a theory of the ether, such that from the simplest possible assumptions can be deduced the facts of electricity, magnetism, and optics.

EXTRACTS FROM CONSULAR REPORTS.

THE ENORMOUS COMPETITION in the chemical and pharmaceutical trade, German manufacturers complain, has reduced the profits of this branch, which requires so great an expenditure of labour and capital, to an unprofitable minimum. Exceptions to this rule are the new patent medicines, which being protected by patent, can command a higher price than the cost of the chemical substances of which they are composed. That branch of the industry which employs itself in spirit preparations has not been able, in spite of various legislative privileges, to mitigate the injury to their trade caused by the rigorous "Brantweinsteuer" Law. In the matter of exports Consul-General Schwabach is of the opinion the lost ground will never be regained. Great Britain obtains the greatest benefit from this law, for since 1888 the whole of the tax on spirit exports has been reimbursed. In the United Kingdom, the Consul states, the business in tinctures and such preparations has rapidly developed, principally at the cost of the German industry, which has been paralysed by the tax regulations.

THE TRADE IN BORAX AND BORIC ACID in Germany has experienced many changes during the past year. The Union of German Borax Manufacturers in May of last year lowered their price from 50 to 47 marks per 100 kilos. On January 1 this year the price was raised to 50 marks, and it is possible that a further rise in price may take place, as, according to a recent report, negotiations are on foot to form a ring. The new syndicate will include British, French, and South American firms. South America is expected to supply the raw material, but the refining is to be done exclusively in Europe. The various groups forming the "ring" are each bound over not to disturb the market for the other, so that there may be nothing to hinder the formation of the monopoly. Such a large international union, Consul-General Schwabach thinks, will doubtless dictate the price, and keep the market in its own hands, at any rate until new fields of production arise, which may not be inclined to join the "ring."

WITH REGARD TO OXALIC ACID, the Anglo-German firms, which were acting together in the trade, were ceaselessly employed during the whole of last year to supply the demand. Prices, however, could not be kept up, as so many new firms started which did not belong to the syndicate. The demand still continues, according to a recent report, but the prospects of the trade are not brilliant; over-production will, it is thought, undoubtedly be the result of the establishment of new factories, and the price will sink still lower. The export of oxalic acid from Germany was more than in the previous year, 52,726 cwts. being exported, compared with 47,591 cwts. Of this the United Kingdom took 8,333 cwts.

THE TRADE IN AMMONIUM SULPHATE, in Germany, was more flourishing in 1898 than the previous year. With the exception of March, April, and May (when the trade suffered from the Spanish-American war), the prices steadily rose until, at the end of the year, they attained a height which they had not reached since 1895. It is remarkable (the British Consul observes) when one considers the near relationship of Chile saltpetre to this substance, that the price constantly rose, while that of Chile saltpetre went steadily down. There can be no doubt that the consumption of ammonium sulphate greatly increased during the past year, and it seems probable that it will be still more freely used for agricultural purposes. The production in Germany last year amounted approximately to 100,000 tons, of which 46,000 tons tons were produced in the Bochum district, Eschweiler, and the Saar, 40,000 in Upper and Lower Silesia, and 14,000 tons in the gasworks. The import of ammonium sulphate into Germany amounted to 30,253 tons, compared with 33,113 tons in the previous year. Of this 20,000 tons came from Great Britain and 7,000 tons from Austria-Hungary.

THE UNREMUNERATIVE PRICES OF SULPHATE are reported to have caused the coke works in Germany to employ themselves less than formerly in the winning of bye-products. It is to be expected, however, that steps will be taken for a better regulation of the prices of this article. The English trade in sulphate is watched with great attention by the German manufacturers, the more so as it has been reported that large coke works are projected in England for the purpose of the winning of bye-products.

THE BRITISH ASSOCIATION.

THE SECTIONAL ADDRESSES.

The Chemical Section.

In this Section the President—Mr. Horace T. Brown, LL.D., F.R.S.—took as his subject the fixation of carbon by plants. He began by pointing out that we have become so accustomed to the idea that the higher plants derive the whole of their carbon from atmospheric sources that we are apt to forget how very indirect is the nature of much of the experimental evidence on which this belief is founded. There can, of course, be no doubt that the primary source of the organic carbon of the soil, and of the plants growing on it, is the atmosphere; but of late years there has been such an accumulation of evidence tending to show that the higher plants are capable of being nourished by the direct application of a great variety of ready-formed organic compounds, that we are justified in demanding further proof that the stores of organic substances in the soil must necessarily be oxidised down to the lowest possible point before their carbon is once more in a fit state to be assimilated. Various new facts brought out by Acton, J. Laurent, and Mazé, justify the demand for more direct evidence than is at present available before we accept the view that the majority of chlorophyllous plants take in the whole of their carbon from the atmosphere. In the cycle of change which the organic matter of the soil is constantly undergoing under the influence of micro-organisms, it seems by no means improbable that intermediate substances may be formed which in some measure directly contribute to the nutrition of the higher plants, and sight must not be lost of the possible effect, in the same direction, of the symbiotic union of certain fungi with the root extremities of many plants, the Mycorhizæ, whose functions are still so imperfectly understood. Then, again, it must be remembered that we have another possible extra-atmospheric source of carbon dioxide in the transpiration water of the plant, which is derived from a soil whose gases may contain 5 per cent. or more of carbon dioxide. From the amount of water transpired in a given time, and an application of the law of partial pressures, it may be readily shown that the supply of carbon dioxide to the aërial organs of a plant from this source is by no means negligible.

Before these problems can be attacked for a particular plant with any hope of success it is clear that we must have some means of establishing

AN ACCURATE DEBTOR AND CREDITOR ACCOUNT

as between the plant and the surrounding atmosphere, and this account must extend over a sufficiently long period, and allow of an accurate balance being struck, with the amount of carbon found in the plant at the end of the experiment. Up to within a few years ago there were no means of even approximately determining the actual rate at which the assimilatory process goes on in a plant other than that afforded by its increase in weight in a given time. Such experiments, necessarily extending over weeks or months, can, at the best, only give certain average results, and consequently afford no measure of the activity of assimilation under fixed conditions of insolation. In the year 1884 Sachs, who had for some time been at work on the formation of starch in leaves under the action of sunlight, found that the accumulation of freshly-assimilated material in a leaf may, under favourable conditions, go on so rapidly as to give rise to a very appreciable increase of weight in the leaf lamina within the short space of a few hours. By observing at different times of the day the varying dry weight of equal areas of large leaves, Sachs obtained an approximate measure of the rate of the assimilatory process which he could express in terms of actual number of grammes of substance assimilated by a unit area of leaf in unit of time. In this manner he was able to show, for instance, that a sunflower leaf, whilst still attached to the plant, increases in weight when exposed to bright sunshine at the hourly rate of about one gramme per square mètre of leaf area. In the case of similar leaves detached from the plant, and of course under conditions in which the products of assimilation were entirely accumulated in the leaf, he found an increase in weight of rather more than 1½ gramme per square metre per hour.

When a leaf from *Catalpa bignonioides* is subjected to a modified form of Sachs' method, it may, under favourable conditions, show an increase in dry weight equal to about one gramme per square metre per hour. Since this increase in weight is due almost entirely to the formation of carbohydrates, we can calculate with a close approximation to accuracy the corresponding amount of carbon dioxide. This will, of course, depend, within certain narrow limits, on

THE NATURE OF THE CARBOHYDRATE

formed. The formation of a gramme of starch requires 1·628 grammes of carbon dioxide, whilst an equal amount of a $C_6H_{12}O_6$ or a $C_{12}H_{22}O_{11}$ sugar require 1·466 and 1·543 grammes respectively. From the knowledge we possess of the nature of the carbohydrates of the leaf, we are quite sure that the mean of these values—that is, 1·545 grammes—must be very near the truth. This amount corresponds to 784 C.c. of carbon dioxide at normal temperature and pressure, which must represent the volume extracted by the square metre of leaf surface in one hour from air containing only three parts of carbon dioxide in 10,000, supposing the method of leaf weighing to give correct results. This intake is equivalent to the total amount of carbon dioxide in a column of air of a cross section equal to that of the leaf, and of a height of 26 decimetres.

The extraordinary power which an assimilating leaf possesses of abstracting carbon dioxide from the air is best shown by comparing it with an equal area of freely-exposed solution of caustic alkali. In a moderately still air a square metre of surface of a freely-exposed solution of caustic soda will absorb about 1,200 C.c. of carbon dioxide per hour, and this can only be increased to about 1,500 C.c. even if the dish is exposed to the full influence of a strong wind out in the open. When the surface of the liquid is constantly renewed during the experiment by means of a mechanical stirrer, the rate of absorption is not sensibly affected, providing the agitation does not appreciably increase the surface area, and considerable variations in the strength of the alkaline solution are also without any effect. On the other hand, slight variations in the tension of the carbon dioxide of the air have a marked influence on the rate of absorption, and in order to study this point an apparatus has been constructed which allows a current of air to be passed over an absorptive surface of liquid in a stratum of known thickness, and with a known average velocity.

The method of using this apparatus was described, and the results of comparative experiments performed with it were given, with the view of bringing out the fact that a leaf surface which is assimilating at the rate of 1 gramme of carbohydrate per square metre per hour is absorbing atmospheric carbon dioxide more than half as fast as the same surface would do if wetted with a constantly renewed film of a strong solution of caustic alkali. The accumulation of air determinations, effected by means of the apparatus referred to, clearly shows that the ordinary statements in text-books as to the amount of carbon dioxide, and its limits of variation, are altogether misleading.

The actual intake of carbon dioxide is determined by enclosing the entire leaf in specially constructed, air-tight, glazed cases, through which a sufficiently rapid air stream is passed. These cases are so arranged that the leaf can be enclosed whilst still attached to a plant which is growing out in the open under perfectly natural conditions, and some of them are sufficiently large to take the entire leaf of a sunflower. If it is desired to estimate

THE ASSIMILATIVE POWER OF A LEAF

in an atmosphere artificially enriched with carbon dioxide, the air stream before entering the leaf case is passed through a small tower containing fragments of marble, over which there drops a very slow stream of dilute acid, whose rate of flow is so proportioned to the air stream as to give about the desired enrichment with carbon dioxide. The stream of air is then divided, one part going on directly to the leaf case, whilst the other passes through a separate absorption apparatus and meter for the accurate determination of its carbon dioxide content.

With a constant illumination, either in direct sunlight or diffuse light, it is found that the assimilatory process responds to the least variation in the carbon dioxide, and, within certain limits, not yet clearly defined, the intake of that gas into the leaf follows the same rule as the one which holds good with regard to the absorption of carbon dioxide by a freely-exposed surface of a solution of caustic alkali; that is to say, from air containing small but variable quantities of carbon dioxide the intake is directly proportional to the tension of that gas.

Since an increase of carbon dioxide in the atmosphere surrounding a leaf is followed by increased assimilation even in diffuse daylight, it is clear that, under all ordinary conditions of illumination, the rays of the right degree of refrangibility for producing decomposition of carbon dioxide are largely in excess of the power

of the leaf to utilise them. Under natural conditions this excess of radiant energy of the right wave-length must, from the point of view of the assimilatory process, be wasted, owing to the limitation imposed by the high degree of dilution of atmospheric carbon dioxide. But although the actual manufacture of new material within the leaf lamina is so largely influenced by small variations in the carbon dioxide of the air, we are not justified in concluding that the plant as a whole will necessarily respond to such changes in atmospheric environment, since the complex physiological changes involved in metabolism and growth may have become so intimately correlated that the perfect working of the mechanism of the entire plant may now only be possible in an atmosphere containing about three parts of carbon dioxide in 10,000. A series of experiments is being conducted which will, it is hoped, throw considerable light on this point, but the work is not at present in a sufficiently advanced state to make more than a passing allusion to it.

The penetration of the highly-diluted carbon dioxide of the atmosphere into the interior air-spaces of the leaf on its way to the active centres of assimilation must, in the first instance, be a purely physical process, and no explanation of this can be accepted which does not conform to the physical properties of the gases involved. Since there is no mechanism in the leaf capable of producing an ebb and flow of gases within the air-spaces of the mesophyll in any way comparable with the movements of the tidal air in the lungs of animals; and since also the arrangement of the stomatic openings is such as to effect a rapid equilisation of pressure within and without the leaf, search must be made for the cause of the gaseous exchange, not in any mass movement, but in

SOME FORM OF DIFFUSION.

This may take place in the form of open diffusion through the minute stomatic apertures, which are in communication both with the outer air and the intercellular spaces, or the gaseous exchange may take place through the cuticule and epidermis by a process of gaseous osmosis, similar to that which Graham investigated in connection with certain colloid septa.

The side of a leaf which is devoid of stomatic openings certainly neither allows any carbon dioxide to escape during respiration, nor does it permit the ingress of that gas when the conditions are favourable for assimilation. On the other hand, when stomata exist on both the upper and under sides of a leaf, gaseous exchanges take place through both surfaces, and, as a rule, in some sort of rough proportion to the distribution of the openings. There is, however, under strong illumination, a greater intake of carbon dioxide through the upper surface than would be expected from a mere consideration of the ratio of distribution of the stomata. Nevertheless, the general connection between gaseous exchange and distribution of stomata is so well brought out that it must be regarded as highly probable that these minute openings are the true paths by which the carbon dioxide enters and leaves the leaf.

One of the most interesting problems connected with plant assimilation relates to the efficiency of a green leaf as an absorber and transformer of

THE RADIANT ENERGY

incident upon it. It is already well known that the actual amount of energy stored up in the products of assimilation bears a very small proportion to the total amount reaching the leaf—in other words, the leaf, regarded from a thermo-dynamic point of view, is a machine with a very low "economic coefficient." We require, however, to know much more than this, and to ascertain, amongst other things, how the efficiency of the machine varies under different conditions of insolation, and in atmospheres containing varying amounts of carbon dioxide. For the actual measurement of the total energy incident on the leaf under various conditions, Professor Callendar's recording radiometer gives promise of excellent results, but up to the present time the work done with it is not sufficiently advanced to be described.

In the case of a sunflower leaf exposed to the strong sunlight of a brilliant day in August, the average amount of radiant energy falling on the leaf during the five hours occupied by the experiment was estimated at 600,000 calories per square metre per hour. The average hourly transpiration of water during that time was at the rate of 275 C.c. per square metre, and the assimilated carbohydrate, estimated by the intake of carbon dioxide, was at the rate of 0·8 gramme per square metre per hour. The vaporisation of 275 C.c. of water must have required the expenditure of 166,800 calories, and the endothermic production of 0·8 grammes of carbohydrate (taking the heat of combustion at 4,000 gramme calories) corresponds to the absorption of 3,200 calories. Thus, as the final result under these particular conditions of experiment, it is found that the leaf has absorbed and converted into external work about 28 per cent. of the total radiant energy incident on it, 27·5 per cent. being used up in the vaporisation of water, and only one-half per cent. in the actual work of assimilation.

In strong diffuse light, such as that from a northern sky on a clear summer's day, the leaf has a higher "economic coefficient," using that term in relation to the permanent storage of energy in the assimilatory products. In one instance of this kind, in which the total energy received by the leaf was approximately 60,000 calories per square metre per hour, it was found that 96 C.c. of water was evaporated, and that 0·41 gramme of carbohydrate was formed for the same area and time. This indicates an absorption and utilisation by the leaf of something like 95 per cent. of the incident energy, of which 2·7 per cent. has been made use of for actual work of assimilation, as against 0·5 per cent. in brilliant sunshine.

The brilliant discoveries of recent years on the constitution and

SYNTHESIS OF THE CARBOHYDRATES

have not brought us sensibly nearer to an explanation of the first processes of the reduction of carbon dioxide in the living plant. The hypothesis of Baeyer still occupies the position it did when it was first put forward nearly thirty years ago, although it has, it is true, received a certain amount of support from the observations of Bokorny, who found that formaldehyde can, under certain conditions, contribute to the building up of carbohydrates in the chloroplasts. The changes which go on in the living cell are so rapid, and are of such a complex kind, that there seems little or no hope of ascertaining the nature of the first steps in the process unless we can artificially induce them under much simpler conditions. The analogy which exists between the action of chlorophyll in the living plant and that of a chromatic sensitiser in a photographic plate, was first pointed out by Captain Abney, and more fully elaborated by Timiriazeff, who was inclined to regard chlorophyll as the sensitiser par excellence, since it absorbs and utilises for the assimilatory process the radiations corresponding approximately to the point of maximum energy in the normal spectrum. The view which Timiriazeff has put forward, that there is a mere physical transference of vibrations of the right period from the absorbing chlorophyll to the reacting carbon dioxide and water, is far too simple an explanation of the facts. Chromatic sensitisers have been shown to act by reason of their antecedent decomposition, and not by direct transference of energy, and the same probably holds good with regard to chlorophyll, which is also decomposed by the rays which it absorbs. The first and simplest stages of the assimilatory process must probably be sought in the interaction of the reduced constituents of the chlorophyll and the elements of carbon dioxide and water, the combinations so formed being again split up in another direction by access of energy from without. The failure of all attempts to produce such a reaction under artificial conditions is to be accounted for by the neglect of one very important factor. We are dealing with a reaction of a highly endothermic nature, which is probably also highly reversible, and on this account we cannot expect any sensible accumulation of the products of change unless we employ some means for removing them from the sphere of action as fast as they are found. In the plant this removal is provided for by the living elements of the cell, by the chloroplast, assisted, no doubt, by the whole of the cytoplasm. We have here, in fact, the analogue of the chemical sensitisers of a photographic plate, which act as halogen absorbers, and so permit a sensible accumulation of effect on the silver salts. When some simple chemical means of fixing the initial products of the reduction of carbon dioxide has been found, then, and then only, may investigators look forward hopefully to reproducing in the laboratory the first stages of the great synthetic process of Nature on which the continuance of all life depends.

The Botanical Section.

The presidential address by Sir George King, K.C.I.E., LL.D., M.B., F.R.S., was a sketch of the history of Indian botany. In the course of this he described the machinery by which systematic botany is carried on within the Indian Empire. About ten years ago, he stated, it occurred to the Supreme Government of India that it might be to the interest of science if the four botanical establishments at Calcutta, Seharunpore, Madras, and Poona were

to be formed into a kind of hierarchy under the designation of The Botanical Survey of India, without removing either the officers or the four institutions to which they were attached from the financial or general control of the local administrations within which they are respectively situated, the Supreme Government making a small contribution of money for the purpose of exploring little-known districts, and making itself responsible for the cost of a publication called 'The Records of the Botanical Survey.' The four institutions just mentioned continue, therefore, to be paid for and controlled by the Governments of Bengal, the North-West Provinces, Madras, and Bombay, but their superintendents are placed on the cadre of the Botanical Survey. The published Records of this Survey now extend to twelve numbers, each of which is devoted to an account of the botany of some part of the enormous and continually-expanding area to be explored.

But the work done in India itself by no means represents all the work that is being carried on in connection with the elucidation of the

Flora of the Empire of India.

On the contrary, the bulk of elaborating the materials sent from India in the shape of dried specimens has always been, and must always be, done in a large Herbarium; and until lately no Herbarium in Asia has been sufficiently extensive. The last word on every difficult taxonomic question must still lie in Europe. A very large number of the Herbarium specimens collected in India have found their way to the various centres of botanical activity in Europe, and have been described by botanists of many nationalities. The lion's share of these specimens has naturally come to the two great national Herbaria in the British Museum and at Kew, but especially to the latter. It was in the Kew Herbarium that Sir Joseph Hooker and his collaborateurs prepared the Flora of British India. And it is in the Kew Herbarium that are to be found the types of an overwhelming proportion of the new species described for the first time in that monumental work. The Kew Herbarium is, therefore, to the Indian botanist the most important that exists.

Economic botany has by no means been neglected. It was chiefly on economic grounds that the establishment of a Botanical Garden at Calcutta was pressed upon the Court of Directors of the East India Company. The botanists of the Seharunpore Garden, during the middle of the century, were especially prominent in this branch of botanical activity. Those botanists introduced into the Himalayas more than fifty years ago the best European fruits, and excellent apples grown in Gharwal and Kamaon are to-day purchasable in Calcutta. Peaches, nectarines, grapes, strawberries, of European origin, are plentiful and cheap all over the North-West Himalaya, and are obtainable also in the submontane districts. Potatoes, and all the best European vegetables, were introduced long ago; and at Seharunpore there is still kept up a large vegetable garden from which seeds of most European vegetables are issued for cultivation during the cold season in the gardens of the various regiments of the Queen's troops quartered in Upper India. More or less attention has been given in the past by Government botanists in India generally to the improvement of the cultivation of flax, hemp, rheea, tobacco, henbane, dandelion, vanilla, sarsaparilla, coffee (Arabian and Liberian), cocoa, ipecacuanha, aloes, jalap, indiarubber, Japanese paper-mulberry, cardamoms, tapioca, coca, tea, and cinchona.

Tea cultivation is one of the enterprises in the introduction and development of which botanists took a very leading part. The advisability of introducing the industry was first pressed on the attention of the East India Company by Dr. Govan (of Seharunpore), and in this he was seconded by Sir Joseph Banks as President of the Royal Society. Royle, in 1827, and Falconer slightly later, again urged it as regards the North-West Himalaya. In 1826 David Scott demonstrated to rather unwilling eyes in Calcutta the fact that real tea grows wild in Assam. In 1835 Wallich, Griffith, and McClelland were deputed by Government to visit Assam to report on the indigenous tea. In the year 1838 the first consignment of Indian-grown tea was offered for sale in London. The consignment consisted of twelve chests, containing 20 lbs. each. This first sample of 240 lbs. was favourably reported upon. Last year the exports of tea from India to all countries reached 157 millions of pounds, besides 120 millions of pounds exported from Ceylon!

The introduction of cinchona into India

originated purely with the Government botanists. As everybody knows, quinine, and to a less extent the other alkaloids present in cinchona bark, are practically the only remedies for the commonest, and, in some of its forms, one of the most fatal, of all Indian diseases—viz., malarious fever. The sources of supply of the cinchona barks in their native countries in South America were known to be gradually failing, and the price of quinine had for long been increasing. The advisability of growing cinchona in the mountains of British India was therefore pressed upon Government by Dr. Royle in 1835, and he repeated his suggestions in 1847, 1853, and 1856. Dr. Falconer, in his capacity of Superintendent of the Botanic Garden, Calcutta, made a similar suggestion in 1852; and his successors at Calcutta, Dr. T. Thomson and Dr. T. Anderson, in turn advocated the proposal. In 1858 Government at last took action, and, as the result of the labours of Sir Clements Markham and Sir W. J. Hooker, of Kew, the medicinal cinchonas were finally, in the period between 1861 and 1865, successfully introduced into British India—on the Nilgiris under Mr. McIvor, and on the Sikkim-Himalaya under Dr. T. Anderson. Various experiments on the best mode of utilising the alkaloids contained in red cinchona bark resulted in the production in 1870 by Mr. Broughton, Quinologist on the Nilgiri plantation, of an amorphous preparation containing all the alkaloids of that bark. This preparation was named Amorphous Quinine. Somewhat later (1875) a similar preparation, under the name of Cinchona Febrifuge, was produced at the Sikkim plantation by Mr. C. H. Wood, the Quinologist there; and of these drugs about fifty-one tons had been distributed from the Sikkim plantation up to the end of last year. The preparation of pure quinine from the yellow cinchona barks, so successfully grown in the Sikkim plantation, long remained a serious problem. The manufacture of quinine had hitherto been practically a trade secret. And when the Indian Government had succeeded in providing the raw material from which a cheap quinine might be made for distribution amongst its fever-stricken subjects, the knowledge of the means of extracting this quinine was wanting. Philanthropic platitudes were freely bandied about as to the immensity of the boon which cheap quinine would be to a fever-stricken population numbering so many millions. But there was a singular absence of any practical help in the shape of proposals, or even hints, as to how quinine was to be extracted from the rapidly-increasing stock of crown and yellow bark. The officers in charge of the cinchona plantations in India had, therefore, to do their best to solve the problem for themselves. It was ultimately solved by Mr. C. H. Wood, at one time Government Quinologist in Sikkim, who suggested, and Mr. J. A. Gammie, Deputy-Superintendent of the plantation there, who carried into practice a method of extraction by the use, as solvents of the cinchona alkaloids, of a mixture of fusel-oil and petroleum. The details of this process were published in the *Calcutta Official Gazette*, for the benefit of all whom it might concern. Very soon after the introduction of this method of manufacture the Government factories in Sikkim and the Nilgiris were able to supply the whole of the Government hospitals and dispensaries in India with all the quinine required in them (some 5,000 or 6,000 pounds annually), besides providing an almost equal quantity for the supply of Government officers for charitable purposes. The latest development of the quinine enterprise in India has been the organisation of a scheme for the sale at all the post-offices in the province of Bengal, and in some of those of Madras, of packets each containing five grains of pure quinine, that being a sufficient dose for an ordinary case of fever in a native of India. Those packets are sold at one pice each, the pice being a coin which is equal, at the current rate of exchange, to one farthing sterling!

Splash Preventers.—When water is taken direct from the main, it very frequently issues from the tap with such force as to be extremely inconvenient, not to say risky, to a negative showing an incipient tendency to frill. We have recently seen a description of a simple little filter attachment for a tap, which is intended to obviate this difficulty, and which is stated to permit the effluent water to issue in an unbroken gentle stream, but with its actual volume undiminished. We have not seen the apparatus in action, but it will very probably be efficient Our present purpose in writing is to draw attention to the fact that there is a very simple means readily available for subserving the same purpose. No matter how violently water may issue from a tap through pressure at the main, the violence will be quite destroyed if a short piece of indiarubber tubing be slipped over the end of tap. The bore of the tubing will be necessarily larger than that of the tap, and, the issuing column of water having its sectional area increased, the pressure is necessarily, *pro ratâ*, redueed.—*Brit. Journ. Phot.*

FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

The following communication has been sent to every Local Secretary of the Pharmaceutical Society by the Hon. Secretary of the Federation of Local Pharmaceutical Associations:—

Dear Sir,—I am instructed by the Executive Committee to send you a copy of a resolution adopted, and the rules as amended, at the last annual meeting of the Federation.

It is almost certain that the coming year will witness a vital struggle between registered chemists and unregistered persons who shamelessly usurp the titles and claim the position and functions of those who have obtained registration after examination. In view of the urgent necessity for more perfect organisation in every Parliamentary constituency, the Federation desires to give all the assistance in its power, in conjunction with the officers of the Pharmaceutical Society—that is, the Local Secretaries—in forming new local associations. In districts where chemists are not numerous enough to justify expectation of sustained interest in monthly meetings, it is advisable to form some kind of committee or other organisation of local chemists. These small associations could meet, say, twice a year, to consider, amongst other things, the local secretaryship and the business of the Federation. They would add materially to our fighting strength in protecting the interests of registered chemists, and would be available for immediate action if occasion should require it.

It is very desirable that the Federation should have the advantage of the experience of a representative of every local association, and that every part of Great Britain should be represented.

Will you favour us with replies to the following questions herewith enclosed?—I am, dear Sir, yours truly,

JAMES COCKS, *Hon. Sec.*

Stonehouse, Plymouth, September 15, 1899.

AMENDED RULES OF THE FEDERATION.

1. That this Association shall be called "The Federation of Local Pharmaceutical Associations of Great Britain."

2. That it shall consist of representatives from each subscribing local pharmaceutical or chemists' association, or other organisation, of chemists in England, Scotland, and Wales. That each association consisting of twenty-five members and under shall appoint one delegate, from twenty-five to fifty members two delegates, from fifty to seventy-five members three delegates, above that number four delegates.

3. That the objects of the Federation are:—

(i.) To assist the Council of the Pharmaceutical Society to establish more intimate communication and co-operation between local associations and between the Pharmaceutical Society's Local Secretaries.

(ii.) To advise and assist in the formation of local associations and other organisations of chemists.

(iii.) To assist the Council of the Pharmaceutical Society to secure a sufficient number of efficient Local Secretaries.

(iv.) To promote the interests of the Pharmaceutical Society and of local associations in every possible way.

4. That a chairman, secretary, and executive committee, consisting of the chairman, secretary and three other members, shall be appointed annually.

5. That every association or other organisation consisting of ten members and under shall pay an annual subscription of 5s.; ten members to fifty, 10s. 6d.; above that number, £1 1s.

6. That the annual meeting, subject to the approval of the Executive Committee, be held in the same town, and during the same week, as the annual meetings of the British Pharmaceutical Conference; representatives of five associations shall form a quorum.

7. That all Local Secretaries to the Pharmaceutical Society be admitted to the annual meetings, but that only those representing subscribing associations and committees be empowered to vote in the appointment of officers and Executive Committee.

8. These rules shall not be altered except at the annual meeting, and then only after fourteen days' notice has been given.

It was resolved that:—

"It is desirable that nominations of Local Secretaries of the Pharmaceutical Society should proceed from local associations and local organisations. That the objects of the Federation would be more effectually served if Local Secretaries were appointed by the associations to represent them on the Federation, and that the rules of the Federation be altered wherever it may be necessary to effect a closer co-operation between local associations and the Pharmaceutical Society's Local Secretaries in promoting the interests of these associations and of the Pharmaceutical Society."

QUESTIONS ADDRESSED TO LOCAL SECRETARIES.

1. Is there a local pharmaceutical or chemists' association in your immediate district?
2. If not, would you be willing to accept such assistance as the Federation can offer to endeavour to establish some kind of association or committee in your town or district? (See rules 2 and 5.)
3. Can you give the names of any towns containing five or more chemists where the Pharmaceutical Society has no Local Secretary?
4. Can the Federation rely on your co-operation in an earnest effort to improve the organisation of registered chemists?
5. Have you any suggestions to offer? If so, they will receive the careful consideration of the Executive.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

A special meeting of the members of the North-East Lancashire Chemists' Association was held at the White Bull Hotel, Blackburn, on Tuesday last, to receive the report of the delegates to the recent meeting of the Federation of Local Pharmaceutical Associations. Councillor T. CRITCHLEY presided, and there was a good attendance considering the inclemency of the weather.

Mr. R. LORD GIFFORD, the Hon. Sec., read the following report:—"They say the first inclination of an animal is to protect itself—therefore, the chemist is not an animal. This is the feeling most prominent in my mind reminiscent of Plymouth. Having accepted the responsibility of representing this Association at the annual meeting of the Federation of Local Associations, it is due to you to give some idea of what we did or did not accomplish in the direction of your Committee's desires. I may say at once that we accomplished nothing, or very nearly nothing, so that it will not take very long to describe what we did. On the other hand, to enter into a dissertation on the lessons and information derived from our visit would require greater insight, better judgment, and larger capacity than I am conscious of possessing. At the same time, it is my duty to you, and to pharmacy, to give you the best account I can, depending upon Councillor Shorrock's more eloquent tongue to expand and supplement my endeavours.

"Your Committee specially instructed us to 'endeavour to bring about an active agitation to be organised by the Pharmaceutical Council and persisted in,' and we were definitely instructed to bring this about 'by any measures whatever.' We found, however, that we had an impossible task, and could not do more than make the most of circumstances. In the first place, there was a meeting of local secretaries called for 9 a.m. It got to 'work' at something like 9.30, and we had to be at the Guildhall at 9.45. Is it wonderful we cannot report any historical result from that meeting? We, therefore, turn to our special work at the meeting of the Federation. You will naturally expect us to have brought the collective wisdom of the drug trade for your edification; but the whole of the time was occupied in making and altering rules, so that you may imagine there would not be much in the proccedings to interest or instruct you. We did, however, insist on a moment's consideration being given to what I venture to think was the point your Committee had most in mind, and a resolution was accepted and carried unanimously: 'That it is the urgent business of the Federation to bring about the earliest possible settlement of the question of chemists' titles.' There was now nothing left but to make our best efforts to impress individual members of the Council with the Committee's sense of the urgency of some action being taken and the folly of lying quiet. The members of the Council received us with every courtesy and consideration, as was to be expected, and we only seemed to express their own individual views, so that our condition is one of amazement that they can stand still, accepting a waiting policy, when every fact and circumstance seems to say: 'Fight and fight again!' How to give you information so acquired is a poser. Perhaps it may best be conveyed by discussing in a small way the various ideas which seem to occupy the minds of pharmaceutical chemists, though it does seem to wander from Plymouth. 'Profits have decreased,' says the oracle. 'So have failures. Some men who are jealous for the good of pharmacy as an art are known to have suffered severely in these latter days.' And to the already breaking back of the poor pharmaceutical aspirant must be added 'the teaching of book-keeping or of the

intricacies of ordinary buying and selling.' What does this sort of double talk amount to? It means that the best aspirations in pharmacy must be stifled, that the conscientious man cannot live under present conditions; but it is also an illustration of the sort of plucky stuff chemists are made of, and the fact that we have to repress our better selves, and of necessity cultivate our sordid and animal instincts. That we can go through training and education actually unfitting us for the battle of trade life, and then fight pure traders and capital on open (even unfair) ground is an unconscious tribute to the 'grit' present-day chemists are made of. But is it not a pity and a shame and unjust that we should have to prove our worth under such conditions? The *Pharmaceutical Journal* (see *ante*, p. 285) says:—'The sciences of chemistry electricity, and geology then have grown to be what we know them within about a hundred years, and the study of living beings has been so transformed within the same time as to be wholly different from what it was.' Let me ask the Pharmaceutical Council, in whose charge pharmacy has been for the most progressive third of that period, how much our calling has evolved? Whilst medicine, dentistry, and the whole world besides have been steadily marching on, we have actually gone back. No one can find a parallel to the Pharmaceutical Council of the last thirty years, and the only explanation it can make is to have, now, the courage of its convictions, and set about educating the drug trade and fighting its battle. It must be remembered that we have recognised always that the Council has attended to its educational duty to the State and to pharmacy. Indeed, it is this fact which makes it possible to fight for a reasonable practice of pharmacy to-day. You will ask what is the position your Committee take up? I think it can be given without any 'ifs' or 'buts.' We are quite satisfied that the right course, the statesmanlike course, is for the Council to formulate a Bill embodying all that it claims to be necessary for establishing the practice of pharmacy upon a sound foundation. This ought to be done at once; indeed, it ought to have been done already. This action on the Council's part would be merely formal, but it is essential in the first place to give direction to pharmaceutical thought, and in the second to make it impossible for anything we may gain or accept to be understood as in any way in satisfaction of our legitimate claims. This work is quite imperative, and its necessity cannot be affected by any circumstance whatever. It is right and essential that the Council shows its hand. Then, in your Committee's opinion, the question of title should be fought—in the first place, at once, by a test case, which, at the very least, would demonstrate the law's absurdity; secondly, on the Companies Bill; and, thirdly, wherever and whenever a fight can be had. Finally, what is the goal we are aiming at? The goal of Jacob Bell and the founders of the Pharmaceutical Society was emphatically a profession of pharmacy. Dr. Attfield cried aloud twenty years ago for the same ideal, and warned us of the consequences of the neglect. That is the goal your Commitee aim at. It believes there is nothing between, and it is prepared to stand or fall on our rights to legally-acquired titles and the reasonable consequence of qualifying. It holds strongly the opinion that on this simple and fundamental issue we have the best chance of winning. At the same time we recognise what the Pharmaceutical Society ever seems to forget, that the necessary momentum is essential to the accomplishment of any purpose. The last months of this wonderful century are swiftly gliding by, and in inaction the last hopes of Jacob Bell are dying too. But there is a chance, a distinctly reasonable prospect, of instituting a profession of pharmacy, which is urgently needed in the interests of the public. It only requires that our leaders in these dying months shall prove worthy successors of the never dead Jacob Bell."

Councillor SHORROCK (Darwen), the second delegate, also presented a report. He remarked of the meeting of local secretaries, called by Plymouth on the Wednesday morning, that it seemed to cause amusement and some suspicion, from the fact that it brought several members of the Council to the meeting. He believed they thought the secretaries were about to steal a march upon them, and the meeting certainly gave them to understand that it was not satisfied with the way things were going on; that it had many complaints to make; and that meetings ought to be held from time to time to exchange ideas and suggestions. After some plain talk they had the assurance from members of the Council that they would draw up a resolution to lay before the Council, and give it their greatest support. The Federation, in his opinion, was in a far better condition than it was the year before, when he and Mr. Holt attended the Belfast meeting. The North-East Lancashire Association had roused the country, and local associations were becoming alive to the fact that the Federation would exercise a power in the country before many years were past. They must keep the Secretary of the Federation warm, and supply him with ammunition, and they must also look after the Pharmaceutical Council. The labour of the past year had not been all lost.

Mr. WELLS said he did not feel satisfied with the amount of work done at the Federation meeting. Nothing seemed to have been done except what was brought forward by the North-East Lancashire Association. He was surprised that no member of the Executive had been elected from that district, and he held a decided opinion that the Federation would do no good if it held its meetings at the same time and place as the Pharmaceutical Conference. The most hopeful thing about it was an apparent increase of life about the Federation.

Mr. HOLT said he must express his disappointment with the miserably meagre result they had heard from their two delegates, although he should be sorry to blame those gentlemen for that result. The meeting of local secretaries, from which great things were expected, simply amounted to a farce. It appeared to him that the Pharmaceutical Society took it under its wing and addled the egg. The meeting was strangled at its birth, and never even got a name. With reference to the Federation meetings and results, he could not think of them without disgust. It was plainly to be seen that a number of the delegates had determined to stifle any discussion as to the future policy of the Pharmaceutical Council, for they saw a deliberate plan carried out to occupy all the time of the meeting in altering certain rules, crushing out the more important matter of their future action in the crisis pharmacy was now going through. He found from various sources that the Federation was disliked by the Pharmaceutical Society, and he came to the conclusion that the Society employed some of its usual methods through some of the delegates. It, therefore, behoved them to reconsider their position as one of the federated associations. If chemists cannot have personal qualification, and the privilege such qualification ought to confer, there was an end to the matter. Either they qualified for something or nothing, and the sooner they knew which the better. He thought the Pharmaceutical Society was not justified in accepting candidates and their fees without being able to carry out the other side of the bargain and secure to the men that were accepted, and to them alone, the privilege of that qualification. The Society was ever ready and willing to increase the stringency of the examination, and to increase the fees, but the past twenty years showed how unready it was to act for increasing privileges or keeping intact those they already had. The proposal to register unqualified limited companies was not worth taking off their coats for. When registered they would be recognised, and that the Association was not inclined to do. They heard continually cries for more support for the Pharmaceutical Society, but it was not altogether the men on the Council they supported, but the measures they adopted for the betterment of the position. If, however, they were not told what those measures were, what could they as intelligent men support? They hoped it would not be taken for granted that they would in future be satisfied with the mere assertion of one of the Council that it "had a policy." The attitude of the trade Press towards their Association and similar associations was not at all helpful or encouraging. They had their Journal, which very rarely inserted their reports and letters as they were written, leaving out and mutilating sentences until the meaning they wished to give them was entirely altered.* There was another journal which fairly accurately reported them, but had a habit of inserting nasty little bits of its own between brackets, and criticising them in a clownish sort of way in leaderettes and verses. They did not mind such criticism, but in face of their undoubted difficulties it was their duty to combine and act energetically together.

Messrs. LOMAX (Darwen) and HINDLE (Blackburn) also spoke, the meeting concluding with a vote of thanks to the delegates, proposed by Mr. HOWARTH and seconded by Mr. PICKWORTH.

*[If there be any foundation for the statement made by Mr. Holt he would undoubtedly have reasonable ground for complaint; we therefore invite him to produce any evidence by which he may consider that the serious charge he has made could be substantiated.—ED. *Ph.J.*]

SAINT LUC'S DISINFECTANT.—Commercial zinc chloride, 530; commercial zinc sulphate, 350; water to produce 1,000 fl. pts.; Filter.—*Rev. Med. Pharm.*, **6**, 183.

LETTERS TO THE EDITOR.

Re Soluble Sulphides.

Sir,—Last week, at page 284, under the heading "Analytical Notes for Students," a correspondent stated that Attfield's 'Manual' gave copper ammonio-sulphate as a test for soluble sulphides, affording a black precipitate; and he proceeded to show that a mixed ferrous and ferric salt would also give a black precipitate, hence, that the test might prove a pitfall. But in every edition of Attfield's 'Manual' for the past thirty years the copper ammonio-sulphate has only been alluded to, not in the unqualified manner just stated, but, as "the most convenient reagent for detecting a sulphide in solution of ammonia," a solution which obviously cannot contain a mixed ferrous and ferric salt. The correspondent should not have left out the qualifying words "in solution of ammonia." If any pitfall exists, is not it one fashioned by himself, and into which only he himself has been precipitated?

September 17, 1899. ANOTHER CORRESPONDENT (202/8).

The Government Laboratory Report.

Sir,—Our attention having been drawn to the paragraph in your issue of August 19, page 188, with reference to the Government Analyst's report on drugs supplied to the Army Medical Department, we—as contractors to the Army—wrote to the War Office asking for an explanation. In reply, the Director of Army Contracts states—"I am directed by the Secretary of State for War to acquaint you that the Government Analyst tests samples of drugs and pharmaceutical preparations for the Army Medical Department which are not necessarily supplied by your firm." He also wishes to add that it was not alleged that the ether referred to in the report was supplied by us.

London, September 18, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Licences (E. P. D.—34/5).—You must have a separate licence for each shop, both for the sale of stamped medicines and methylated spirit.

Glove Cleaner (S. H.—34/6).—Castile soap in fine powder is used as a glove cleaner, or a mixture of fuller's earth and alum may be employed. Apply with a stiff brush.

Trommer's Test (J. H. S.—33/13).—On adding to urine 1 or 2 drops of copper sulphate solution, followed by 4 or 5 C.c. of sodium carbonate solution, reduction takes place if glucose be present.

Use of Title (G. E. H.—34/4).—It is not legal for an unqualified person to style himself "manufacturing chemist," but unless he carries on a retail business as a chemist and druggist the offence would be regarded as a purely technical one.

Marking Ink for Use without Heat (H. J. H.—33/34).—Dieterich's formula for this is aniline, 26; potassium chlorate, 13; distilled water, 8. Heat on the water bath until the chlorate has dissolved, then add hydrochloric acid, 12. Continue heating until action ceases, then add copper chloride, 2, dissolved in distilled water, 6; again add hydrochloric acid, 10; and heat until the solution becomes of a bright reddish purple colour. Set aside for a few days to settle, decant, and add enough powdered acacia to make it flow easily from the pen. Use a quill pen, and avoid heating the writing. Allow it to dry for a couple of days before washing.

Egg Julep for the Hair (W. J. D.—34/8).—Dissolve soft soap, 1 oz., in rose water, 10 oz., then gradually rub down the whites of two eggs with rose water, 10 oz., and glycerin, 4 oz. Mix the two solutions, add essence of opoponax or other perfume, 4 oz., and make up to 2 pints with rose water.

Antiseptic Gauzes (W. J. D.—34/7).—You do not specify what kinds of gauze you wish to prepare. Numerous formulæ were published in the *Pharmaceutical Journal* for November 27, 1897; April 23, 1898; and July 30, 1898. Also see Braithwaite's 'Pharmaceutical Formulary,' pp. 219-220, where the formulæ of the French 'Codex' are given.

Essence of Wallflower (C. G.—34/1).—Alcoholic solution of hyacinthin, 10 per cent., 1 fluid drachm; essence of tuberose, 2½ fl. oz.; essence of orange, 2 fl. oz.; essence of jasmin, 10 fl. oz.; essential oil of almonds, 7 minims; heliotropin, 10 grains; vanillin, 10 grains; oil of neroli, 4 minims; coumarin, 10 grains; concrete oil of orris, 16 grains; caryophyllin, 5 minims. Rectified spirit to produce 20 fluid ounces.

Oil of Worms (J. H. S.—33/33).—Oil of earthworms, *oleum lumbricorum*, was official in the Edinburgh Pharmacopœia of 1744, and was made from earthworms (washed), 6 oz.; olive oil, 30 fl. oz.; white wine, 10 fl. oz. Boil gently together until the wine has evaporated, then strain. Previous to this, the oil was made by submitting earthworms to distillation in a retort. Nowadays, the more cleanly, and probably equally efficacious, oleum viride is substituted. This is generally prepared by boiling fresh elder leaves in rape oil until all moisture is evaporated, and then straining.

Cover to Unqualified Person (D. R. M.—34/9).—You ask on behalf of "a friend" what is "really necessary" to enable an unqualified person who buys a chemist's business, and engages a duly qualified person "as a cover," to protect himself against the operation of the Pharmacy Act. Your friend has probably not realised the sublime impertinence of his question, and you are apparently unconscious of the fact that you are asking us to explain how unqualified persons can deprive you of your present means of livelihood. The answer is that, whether or not the unqualified owner of the business employs a duly qualified person, he is equally liable under the Pharmacy Act.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Barrie, Botham, Brawn, Cocks, Crossley, Davies, Doe, Ferrall, Fletcher, Gorton, Hare, Hill, Hogg, Hope, Lindley, Lunan, McGonigal, Maries, Matthews, Mitchell, Morris, Pater, Reynolds, Walden, White.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

COCAINE HYDROCHLORIDE. It has on several occasions been pointed out in the Journal that Maclagan's test gives the best indication as to the purity of cocaine hydrochloride. This view is confirmed by Messrs. Zimmer and Co. (*Pharm. Zeit.*, **66**, 1899), who also contradict the assertion of Günther that pure cocaine hydrochloride should give no precipitate with ammonia in the dilution required in Maclagan's reaction. In fact, a pure salt should yield a crystalline precipitate in half a minute, showing the absence of poisonous isatropyl cocaine. Therefore, a salt that does not give a crystalline precipitate within five minutes should be rejected as being too impure, since the time required to obtain a precipitate serves as an index of impurity. Moreover, Messrs. Zimmer state that they have never met with Günther's isomeric ethyl benzoyl ecgonine, m.p. 111° C., in cocaine products, and they consider that its existence in the alkaloids of the coca leaf must be regarded as doubtful. In proof of its non-existence in cocaine hydrochloride, which answers Maclagan's test and, according to Günther, should contain the alkaloid with a higher melting point and less solubility than cocaine, 100 grammes were recrystallised from absolute alcohol, and the base, separated from the insoluble and soluble portion, fractionated several times from petroleum spirit. In all fractions, the alkaloid obtained had a melting point approximating to that of pure cocaine, thus showing the absence of Günther's base, which is stated to melt at 111° C. Experiments made with mixtures of isatropyl cocaine and cocaine hydrochlorides show that the presence of the former has an important influence in preventing the separation of crystalline cocaine in Maclagan's test. In the presence of 0·25 per cent. of isatropyl cocaine hydrochloride, for example, stirring for five minutes was required to obtain a flocculent precipitate, and thirty minutes with 5 per cent., whilst with an admixture of 1 per cent. of isatropyl cocaine there was no separation. In all cases the liquid was not clear, but opalescent. In conclusion, the opinion of other investigators—Paul and Cownley, Böhringer, Merck—is endorsed that cocaine hydrochloride which does not answer Maclagan's test, is impure, and should not be employed for medicinal purposes.

EUDESMOL. H. G. Smith has read a paper before the Royal Society of New South Wales, in which he deals with the chemistry of eudesmol, a crystalline stearoptene previously discovered by himself and R. T. Baker in eucalyptus oil. It is found in the oil of many species of *Eucalyptus*, and should, it is stated, be present at certain times of the year in all eucalyptus oils which are eventually rich in eucalyptol. The formula assigned to eudesmol—$C_{10}H_{16}O$—shows that the compound is isomeric with ordinary camphor, but it has the oxygen atom combined in a different manner. It does not appear to be ketonic, and it cannot be reduced by sodium in alcohol or by other methods. It is optically inactive, forms a dinitro-compound and a dibromide, but does not form a nitrosochloride. Eudesmol melts at 79°-80° when perwhen perfectly pure, but has a tendency to form products having a lower melting point. On oxidation with dilute nitric acid, camphoronic acid is formed, but no camphoric acid. A large amount of evidence was brought forward to show that eudesmol is intermediate in the formation of eucalyptol, and that eucalyptol is derived directly from the fraction containing eudesmol if the oil be kept in the crude condition for some time under ascertained conditions. Oxygen is necessary to this alteration. It is suggested that the oxygen atom enters the eucalyptol molecule during the formation of eudesmol, and that by the natural alteration of the high boiling fraction of oils containing eudesmol (*E. macrorhyncha*, for instance) eucalyptol is formed. The oil of *Eucalyptus camphora* was found to be rich in eudesmol at the time of year when distilled. It was shown that the oils from certain groups of eucalypts are dextrorotatory when their maximum eucalyptol content is reached, and that they do not at that time contain phellandrene, although at certain times of the year phellandrene may be present. Since camphoronic acid is probably trimethyl tricarballylic acid, and as eucalyptol is derived from eudesmol which in turn forms camphoronic acid, the question is raised whether Brühl's formula for eucalyptol is correct. It is suggested that the oxygen atom in eudesmol is quadrivalent, and that the peculiarity of eucalyptol may be thus accounted for. From the formula suggested for eudesmol camphoronic acid, as trimethyl tricarballylic acid, can be constructed.

EUCALYPTUS OILS. R. T. Baker and H. G. Smith have continued their researches on the essential oils of the "stringy bark" eucalypti, which include *E. baileyana*, F. v. M.; *E. eugenioides*, Lieb.; *E. fastigiata*, Deane and Maiden; *E. macrorhyncha*, F. v. M.; and *E. obliqua*, L'Her. E. EUGENIOIDES, or White Stringy Bark.—The crude oil contains 28·4 per cent. of eucalyptol, and the second fraction 34·8 per cent., but no phellandrene; no eudesmol or other constituent of special interest was noted. The percentage of oil was 0·6–0·7 per cent. E. CAPITELLATA, or Brown Stringy Bark.—The second portion of oil yielded 38·4 per cent. of eucalyptol, a mere trace of phellandrene, and very little, if any, eudesmol. E. MACRORHYNCHA, or Red Stringy Bark.—The authors consider this to be the most important commercial tree of the whole genus. The percentage yield of oil is about 0·28–0·31, and of eucalyptol in the oil, 50 per cent.; it contains only a trace of phellandrene. It contains also, in large quantity, a stearoptene, especially when the oil has been distilled in November; a crystalline body called eudesmol, which represents the fraction boiling between 269° and 289° C., and forms about 27 per cent. of the original oil. This appears to interfere with the estimation of eucalyptol by the phosphoric acid process in the crude oils. The oil of *Eucalyptus macrorhyncha* answers all the tests of the B.P., except sp. gr., which is 0·905 at 18° C. The authors point out that if the sp. gr. is enforced it will exclude the use of this oil, which is an excellent and agreeable oil, containing half its weight of eucalyptol. Eudesmol is left as a crystalline substance when the oil evaporates, but it will not crystallise out when the oil is subjected to a temperature of 10° below zero. The crystals are acicular, and polarise light extinguishing parallel to the principal axis, and so are probably rhombic. They have a melting point of 74°–75° C. The boiling point is 270°–272° C., so that it usually remains with the residue in the retort. Its therapeutic properties are being investigated. E. PIPERITA.—It was in this oil that eudesmol was first observed, forming a crystalline deposit on the cork of the bottle containing it. The yield of oil is 0·78 per cent. The oil rectified below 190° C. is free from eudesmol; the fraction between 170° and 190° C. contains phellandrene and only 25 per cent. of eucalyptol. E. PUNCTATA.—This tree yields an average of 0·79 per cent. of oil, which contains from 50 to 60 per cent. of eucalyptol in the crude oil. It does not contain phellandrene but traces of cuminic aldehyde. It appears to contain both dextro- and lævo-rotatory terpenes, which vary in proportion, apparently according to the age of the leaves. The onstituents of the eucalyptus oils do not appear to vary much in the same species, but the proportions vary according to the time of year at which the leaves are collected.

STANDARDISED PREPARATIONS— WITH SOME NOTES UPON EXTRACTUM CINCHONA LIQUIDUM.

BY EDMUND WHITE, B.SC.

Among the numerous changes introduced into the assay processes of the official standardised preparations by the 1898 Pharmacopœia is the purification of the alkaloidal material extracted for the standardisation of liquid extract of cinchona. Comparing the appearance of the residues upon whose weight the 1885 and 1898 standards are based, one finds that the former is dark and amorphous, while the latter is nearly colourless and distinctly crystalline.

Some experiments carried out by Mr. E. Gaul in my laboratory show also that, owing to the extra purification now enjoined, one may get less than half the weight of residue. The evaporated percolates for three different batches of liquid extract were examined in the following manner :—10 C.c. of percolate were treated with benzolated amylic alcohol and potassium hydroxide, as described in the Pharmacopœia. The washed alcoholic layers were united and divided into two equal parts. One part was evaporated to dryness on a water-bath, as required by the 1885 B.P. assay process. The other part was subjected to the further purification required by the 1898 B.P., viz.: (1) removal of the alkaloids as hydrochlorides from the benzolated amylic alcohol by agitation with dilute hydrochloric acid ; (2) transference of the alkaloids, liberated by addition of ammonia, to chloroform ; (3) evaporation of the chloroformic solution and drying the residue at 110° C. The benzolated amylic alcohol after agitation with the dilute hydrochloric acid was also evaporated, dried, and weighed. The following results were obtained :—

WEIGHT OF RESIDUE IN GRAMMES FROM 5 C.C. EVAPORATED PERCOLATE.

		Expt. 1.	Expt. 2.	Expt. 3.
A	Wt. of residue according to assay process B.P., 1885	0·440	0·451	0·191
B	Wt. of residue according to assay process, B.P., 1898	0·202	0·200	0·086
C	Wt. of residue from benz. amylic alcohol, after removal of alkaloids by HCl.	0·248	—	0·100

The sum of the weights of residues B and C should, according to the process described above, nearly equal the weight of A, for B represents the purified alkaloid and C the non-alkaloidal impurities, both of which are weighed together in A. In order to see if the residues C contained any appreciable quantity of alkaloid they were dissolved in water and 5 C.c. of N/1 H_2SO_4 added. In each case 49·9 to 50 C.c. N/10 NaHO were required to bring the mixture back to neutrality. From these experiments it follows that the extract standardised according to the 1885 Pharmacopœia would contain actually less than $2\frac{1}{2}$ per cent. of pure alkaloids. The ratio of alkaloid and non-alkaloidal matter extracted and weighed in the residue which formed the basis of standardisation would undoubtedly vary in the case of different samples of bark, but the objection to the process becomes really stronger because we should have to admit the possibility of variation as well as deficiency in strength. The assay process now employed is undoubtedly a great advance upon its predecessor ; at the same time there is no doubt that for thirteen years we had been supplying an extract credited with a potency which it could not have possessed. This aspect of the question induces me to make a few observations upon the subject of standardised preparations generally. What is the advantage of giving liquid extract of cinchona rather than an equivalent quantity of quinine ? Our process of standardisation implies that the alkaloids are the only constituents to be determined quantitatively, and quinine is admitted to be the most valuable of all the cinchona alkaloids. We take a deal of trouble to determine as nearly as possible the proportion of alkaloids in the cinchona percolate, and then we offer to the patient, under the name of liquid extract, this dirty quinine solution containing colouring and other matters which happen to be extracted along with the quinine. On economical grounds the employment of cinchona alkaloids in the form of liquid extract should apparently be regarded as a most extravagant method. The trade price for quinine sulphate at the present time is 24s. per lb., and in the wholesale price lists we find the liquid extract quoted at 5s. 6d. per lb. Since the extract contains but 5 per cent. of total alkaloids it follows that we are paying 110s. for every pound of mixed alkaloids consumed in this form. That is to say, for the privilege of taking quinine and the other less valuable cinchona alkaloids associated with various inert impurities which serve to make the remedy more nauseous than it need be, one pays more than four times the price of quinine sulphate itself. The prolonged evaporation to which the percolate is subjected in making the liquid extract effectually disposes of any claim for consideration on behalf of the aromatic properties of cinchona bark. The aroma of the finer qualities of cinchona bark may be a distinctly useful adjunct to its other properties when the bark is used for preparing tinctures or wines which are used as mild appetising bitters. The liquid extract is, however, quite unsuitable for this purpose, and when a moderate or considerable dose of cinchona alkaloids is required I can only describe the administration of the liquid extract as a messy and expensive method of obtaining that end.

With regard to standardised galenical preparations generally, it seems to me that the period of time during which most of the potent vegetable drugs should be employed in this form is distinctly limited. For if any process of standardisation is to provide us with preparations of constant and known potency, it follows that we must be in possession of information which enables us to state (1) what proximate principles are contained in a drug, and (2) their relative value as remedial agents. If our knowledge is not sufficiently advanced to do this, the value of the standardised preparation as a real standard may easily be overrated. Standardised galenicals can only be regarded in many cases as temporary expedients suitable for the transitional period when we are passing from an incomplete to a definite knowledge of the constituents of a given drug. The logical consequence of their employment ought to be their substitution by the pure substances which have formed the basis of standardisation. We may for the purpose of this argument divide drugs into three classes :—

(1) Drugs for which we cannot yet devise standardised preparations.

(2) Drugs from which may be prepared standardised preparations until they pass into Class (3).

(3) Those drugs about which our knowledge is sufficiently definite to enable their pure proximate principles to be employed to the partial or complete exclusion of crude galenicals.

In Class (1) I should place, for example, squill, digitalis and senna. Our inability to deal with drugs of this class is due to absence of the necessary chemical and pharmacological knowledge concerning them. As a rule, progress must first be made from the chemical side in order to furnish pure materials for pharmacological investigations. Before the latter are complete, the drug may be regarded as belonging to the second class, where it may remain until information is sufficiently advanced for the drug to pass entirely into the third class, or partially, as in the case of cinchona discussed above. In my opinion most, if not all, the drugs whose preparations are standardised in the 1898 British Pharmacopœia, should be regarded as properly belonging to Class (3). Why, for instance, in neuralgia should we smear our heads with liniment of belladonna, which leaves a sticky brown layer of resin on the skin? The action of belladonna upon the terminations of the sensory nerves is attributed

to atropine, and pure atropine has been used in most of the pharmacological investigations, upon which the medicinal use of belladonna is founded. Yet the effects obtainable with atropine have been bodily translated to belladonna, and partly owing to long use and partly to tradition, this alcoholic solution of the inert extractives of belladonna containing 0·375 per cent. of belladonna alkaloids is widely used under the name of belladonna liniment. It does not seem to occur to one that an alcoholic solution of atropine would give the same results without the mess.

I am quite aware that in following this line of argument I am touching an old controversy with regard to the relative medicinal action of crude vegetable drugs and the active principles contained in them. What I wish particularly to point out is the fallacy of regarding standardised preparations as the limit of pharmaceutical perfection. I maintain that when, as in the case of extracts of cinchona and nux vomica, our knowledge of the active principles is so clear and definite the excuse for using such galenical preparations ceases. There may be other cases, notably opium, where our knowledge is more obscure, and it may be held with some show of reason that the morphine, or morphine and codeine, do not represent the whole action of opium. But we can only regard standardised preparations of opium as temporary expedients. For if they are administered for their morphine effect and because they are known to contain a certain percentage of that body, then I contend that the use of the clean and pure alkaloid woul be more rational. On the other hand if the galenical preparations of opium are given in order to get an effect not obtainable from morphine, then the standardisation is only of use in so far that it has fixed the percentage of the preponderating poisonous principle and enables us to form an idea of the toxic dose. But if the desired medicinal effect is to be referred to some other constituent—not morphine—then our standardisation, which refers to morphine only, will yield us no guidance as to what effect we may expect to get beyond that referable to the known morphine content. Therefore I maintain that standardised preparations are only temporary expedients—useful in their day—but whose period of usefulness depends upon the progress made in our knowledge of the composition and action of drugs and their active principles. So soon as this knowledge becomes sufficiently definite to enable us to create processes of assay to yield standard preparations, using the term in its extended sense, then the time has arrived for the employment of the active principles to the exclusion of galenical preparations except in the certain exceptional cases such as the aromatic bitter preparations of cinchona for example. The administration of the remedy would become easier, more exact and cleanly, and I believe in nearly all cases less costly. As pharmacists we can do much to encourage this change, which I maintain ought to be carried out in many existing cases, some of which I have mentioned. In another communication I hope to propose at length a list of standardised preparations which might either partially or entirely be replaced by preparations of the active principles upon which the standardisation of the galenical preparations is based.

Pills for Toothache.—(1) Spermaceti, 1; chloral hydrate, 2; carbolic acid, 1; cotton wool, *q.s.* Melt the spermaceti and dissolve therein the chloral and carbolic acid, saturate small pellets of wool with this and allow to cool. (2) Hard paraffin, 98; carbolic acid, 2. (3) Hard paraffin, 12; Burgundy pitch, 14; parsley oil, 4; creosote, 4. Divide these masses into small pieces and place in the tooth. (4) Clove oil, 1; cassia oil, 1; black pepper, 4; sodium chloride, 4; gum acacia, 4. Mass into pills. (5) Salol, 10; liquid paraffin, 10; terebene, 10; beeswax, 65; alkannin, *q.s.* Divide into pills.—*Oest. Zeits. für Pharm.*, **53**, 378.

PERCENTAGE SOLUTIONS OF THE PHARMACOPŒIA.

BY F. A. UPSHER SMITH,

Demonstrator of Pharmacy, Pharmaceutical Society's School.

The different interpretations that are put on the term "percentage solution" frequently mislead the student, and, as will be seen, may possibly set a trap for the pharmacist.

It may be well to allude first, though this has often been done before, to the various interpretations referred to. (1) A percentage solution, strictly speaking, contains x parts by weight in 100 parts by weight, or x parts by volume in 100 parts by volume. In practice weight is generally used, because it is necessary to weigh in the case of solids, while definite small quantities of liquids are more accurately obtained by weight than by volume. It is obvious that where a percentage solution is desirable the utmost exactitude is required. (2) A so-called percentage solution is made by dissolving x parts by weight and making up to 100 parts by volume—*e.g.*, 1 gramme in 100 cubic centimetres. This method of expressing strengths is adopted largely for solutions in the Pharmacopœia, and though that work does not call such as these "percentage solutions," it is by no means rare for that construction to be put on the expression. (3) Another example of a so-called percentage solution is obtained by dissolving x grains by weight, and making up to 110 minims.* In the Pharmacopœia this is a favourite method of expressing strengths, and is frequently mistaken for a form of 1 per cent. solution. As pointed out in the *Pharmaceutical Journal*, [4] **8**, 84, this is neither strictly a percentage solution, containing x parts by weight in 100 parts by weight, nor is it a solution containing an integral part by weight in 100 parts by volume. Perhaps a simile will make this point clear. If a sixpence were contained in a bag together with 99 pennies the bag would not contain 1 per cent. by weight or volume of silver coin, though 1 per cent. of the coins were made of silver.

It would be well if, for the present, the phrase "percentage solution" could be laid aside in speaking of strengths, because its precise meaning is seldom adhered to, and when that *is* done the product contains an unsuitable dosage of the ingredient. A strictly one per cent. solution, when dispensed in a minim measure, cannot, as a rule, be administered in precise fractions of a grain. For example, the dose of sodium arsenate is 1/40th to 1/10th grain; the B.P. solution contains 1 grain of the anhydrous salt in 110 minims, the dose being 2 to 8 minims. It would be expected that the doses of the salt and solution would correspond. But they do not; a simple calculation shows that 2 minims of the solution contain 1/55th grain, and 8 minims 4/55th grain of the anhydrous salt. The trend towards uniformity of dosage that is evident in the new Pharmacopœia seems therefore to be capable of development. If, for instance, this Liquor Sodii Arseniatis were made to contain 1 grain of the anhydrous salt in 100 minims (=24 grains in 5 fluid ounces), a dose of 2½ to 10 minims would correspond to 1/40th to 1/10th grain of the anhydrous salt. Examples might be multiplied—*e.g.*, Liquor Potassii Permanganatis contains in 4 fluid drachms (the maximum dose) 24/11 or 22/11 grains of the salt, whilst the maximum dose of the salt is 3 grains. Measurable quantities of the solution should correspond to consistent and simple doses of the salt.

The Liquor Hydrargyri Perchloridi of the B.P. is a model of what is wanted in potent solutions, and shows what is here advocated to be neither unnecessary nor new. It contains 10 grains of the salt in 1 pint; the maximum dose of the solution is 1 fluid drachm, equivalent to 1/16th grain, which is the maximum dose, of the salt.

---

* This curious volume is taken to represent the volume at 62° F. of 100 grains of water. As the B.P. indicates, this is more correctly 109·7143 minims. The student will observe that—

437·5 grains = 480 minims

Therefore 100 ,, = $\frac{480 \times 100}{437{\cdot}5}$ = 109·714 minims.

It is hard to find a substantial reason to recommend the present strength of 1 grain in 110 minims. Grain measures are not popular, and they might well be dispensed with in this connection. If the adoption of the metric system in England be followed by a revolution in present dispensing methods, whereby liquids, as well as solids, are weighed, then the true percentage solutions will come to the front and replace other strengths, but at present, and so long as liquids are dispensed with measure, they are not convenient.

Uniformity in strengths and doses tends not only to simplify the learner's task, but also, and this is of far-reaching importance, to prevent mistakes. Experience of medical men and pharmacists in their daily work, as well as of students preparing for examination, shows plainly that in mental calculations these 1 grain in 110 minim solutions are often erroneously reckoned as 1 per cent. An example only recently emphasised this point. It was required to prepare 100 powders, each containing 1/100th grain of nitroglycerin. According to the usual custom an equivalent quantity of the Liquor Trinitrini B.P. was sought, and calculated as follows:—"Nitroglycerin required = $1/100 \times 100 = 1$ grain. Hence 100 grains of the 1 per cent. solution, when mixed in the ordinary way with milk sugar, will yield 100 powders, each containing 1/100th grain of nitroglycerin."

The fallacy of this method of reckoning will be apparent on inspecting the correct method of calculation. One grain of nitroglycerin is contained in 110 minims of solution. Now, 110 minims = 110/480 fluid ounce

$$= \frac{110 \times 0{\cdot}840}{480} \text{ ounce (Avoir.)} = \frac{110 \times 0{\cdot}840 \times 437{\cdot}5}{480}$$

= 84·219 grains. Hence, 84·219 grains of the solution contain 1 grain of nitroglycerin. Knowing the exact strength of the B.P. solution it would be best, of course, to take 110 minims straight away.

Consequently the powders, if made according to the original calculation, would be too strong by one-fifth, every five doses being equivalent to six doses containing 1/100th grain each.

In this connection it may be well to point out to the student one of the commonest pitfalls in pharmaceutical calculations. Except when dealing with pure water it is always necessary to consider the specific gravity of a liquid. Consequently it is necessary to thoroughly understand what is meant by specific gravity, and the methods of determining the same practically. It will be advisable to remember the formula

$$\frac{\text{Weight of liquid}}{\text{Specific gravity}} = \text{volume of liquid.}$$

This formula, when transposed by the ordinary algebraical method, will enable any expression to be found, the other two being given. For those who are unfamiliar with algebra, happily a diminishing number, these altered formulæ are given:—

$$\frac{\text{wt.}}{\text{vol.}} = \text{sp. gr., and sp. gr.} \times \text{vol.} = \text{wt.}$$

SUMMARY.

(1) True percentage solutions, containing x parts by weight in 100 parts by weight are not desirable so long as liquids are measured. (2) Solutions containing x grains in 110 minims are unnecessary and clumsy, because they serve no useful purpose, and do not admit of consistent and simple dosage of potent drugs. (3) Solutions containing x grains in 100 minims, or the official dose of the drug in the official dose of the liquid, are the simplest, and enable the prescriber to give doses of solutions with little or no calculation, consistent with the doses of the crude drugs. (4) A proper understanding is necessary as to what truly is a percentage solution, considering the confusion that exists, especially among students. In true percentage solutions we must speak of x grains in 100 grains, x minims in 100 minims, etc., where both terms are of the same kind. (5) To show the differences between the various methods enumerated, consider how much solution of nitroglycerin is required to make 100 powders, each containing 1/100th grain of nitroglycerin. (*a*) Of a solution containing 1 grain in 110 minims take 110 minims or 84·219 grains; (*b*) of a true 1 per cent. solution take 100 grains; (*c*) of a solution containing 1 grain in 100 minims take 100 minims.

THE PHARMACEUTICAL SERVICE IN THE GERMAN ARMY AND NAVY.

In the German army the military hospitals are supplied with the necessary medicines by special dispensaries connected with every garrison hospital ("Garnisonlazareth"). There are two kinds of such dispensaries, the "Lazarethapotheke" and the "Arznei-anstalt." Only simple remedies are furnished by the latter, while in the former every medicine prescribed by the doctors is dispensed and simple preparations are made. All dispensaries are provided with the necessary drugs by the medicinal division of the sanitary magazine ("Sanitaetsdepot").

The regular service in the "Lazarethapotheken" is carried out by pharmacists, who, having passed the higher examination before reaching the age at which they would be compelled to serve in the army, obtain a reduction of the term of service by entering the army as volunteers. They are then employed in the pharmaceutical service ("einjaehrig-freiwillige Militaerpotheker") in lieu of serving in the ranks. Having served their time (one year) and passed a special military examination, they are passed into the body of reserve as "Unterapotheker," and after two years, are advanced to the position of "Oberapotheker." Beyond the fully-qualified pharmacists, hospital assistants ("Lazarethgehülfen") and male nurses ("Krankenwaerter" are employed in the dispensaries, for their own instruction and to carry out manual work.

Generally, the "Lazarethapotheke" is under the direction of a military medical officer, and the service is controlled by the chief medical officer of the hospital. At the headquarters of the commander-in-chief of each army corps the hospital dispensary is directed by a garrison pharmacist ("Garnisonapotheker"), the number of which will amount to twenty-four next year.

The "Oberapotheker" of the reserve, as well as the "Garnisonapotheker," has an undetermined rank of officer ("allgemeiner Offiziersrang") as "obere Militaerbeamte." Applicants for appointment as "Garnisonapotheker" must have served their year as voluntary pharmacists or in the ranks. They must have a higher scientific qualification in chemistry than the ordinary qualified apotheker, especially in regard to the chemistry of foods, and they must hold the certificate of "Nahrungsmittel-Chemiker," obtainable only after higher education and prolonged study of three years at least. It is also the duty of the "Garnisonapotheker" to make water tests, and to do other analytical work, to instruct the volunteers, and to assist the "Sanitaetsdepot" in all matters connected with the buying and examining of drugs and preparations wanted by those magazines.

The special food chemists of the army and chiefs of the special laboratories at the headquarters of the "Generalkommandos" are the twenty-three staff pharmacists of the army corps ("Korps-Stabsapotheker"). These staff pharmacists, like the "Oberapotheker" and "Garnisonapotheker," are "obere Militaerbeamte," and they have also the general undetermined rank of officer. The "Korps-Stabsapotheker" must have served as a volunteer and possess the same higher scientific qualifications as the garrison pharmacists. Many of the present acting staff pharmacists have graduated as Ph.D. They are associated as branch assistants with the chief medical officers of the army corps ("Korps-generalarzt") and are not permitted to do any independent professional work. They have charge of the muster rolls of the army pharmacists, revise the hospital dispensaries, and are the directors of the chemical divisions of the research laboratories established at the

headquarters of the "Generalkommandos." They do all the analytical work for hygienic, forensic, and economical purposes connected with the military service.

In the ministry of war an "Oberstabsapotheker" is attached to the department to assist in mere administrative service.

The volunteer and garrison pharmacists are bound to wear their military uniform during the hours of service, the staff pharmacists only in the outdoor service. The "Garnisonapotheker" have an annual pay of 2,080 up to 3,280 marks, the "Korps-Stabsapotheker" of 2,780 up to 4,980 marks.

In active service, pharmacists of the body of reserve are appointed as "Feldapotheker" and attached to the hospitals ("Feldlazarethe, Sanitaetsdetachements, Kriegslazarethe"). Pharmacists also are employed in the depots, the reserve hospitals, and the hospitals of the fortresses.

In the German navy but two pharmacists ("Marine-Stationsapotheker" are appointed at Kiel and Wilhelmshaven. In general, their duty and rank corresponds with that of the army garrison and staff pharmacists. They are bound to manage the hospital dispensary, to fit out the dispensaries of the men-of-war, to instruct the navy surgeons in food analysis, and to do all analytical work required by the navy and dockyard authorities. There are no volunteer pharmacists admitted to the navy service. The ship dispensaries are conducted by the surgeons. In the "Stationsapotheken" there is one assistant pharmacist and several other assistants, "Lazarethgehülfen." The annual salary of the naval "Stations-apotheker" is just the same as that of the military staff pharmacist.

The German pharmaceutical body is not very well satisfied with this state of things, and many efforts have been made to have it improved. Only a few months ago the German Apotheker-Verein addressed a petition to the Government, asking that the volunteer pharmacist should be required to pass a six months' service with the troops under arms before entering the hospital dispensary, that the rank and pay of the "Korps-Stabsapotheker and the "Garnisonapotheker" should be advanced, and that all military pharmacists should have the right of being saluted by the rank and file.

SOLID HYDROGEN.*

BY PROFESSOR JAMES DEWAR, F.R.S.

In the autumn of 1898, after the production of liquid hydrogen was possible on a scale of one or two hundred C.c., its solidification was attempted under reduced pressure. At this time, to make the isolation of the hydrogen as effective as possible, the hydrogen was placed in a small vacuum test-tube, placed in a larger vessel of the same kind. Excess of the hydrogen partly filled the circular space between the two vacuum vessels. In this way the evaporation was mainly thrown on the liquid hydrogen in the annular space between the tubes. In this arrangement the outside surface of the smaller tube was kept at the same temperature as the inside, so that the liquid hydrogen for the time was effectually guarded from influx of heat. With such a combination the liquid hydrogen was evaporated under some 10 mm. pressure, yet no solidification took place. Seeing experiments of this kind required a large supply of the liquid, other problems were attacked, and any attempts in the direction of producing the solid for the time abandoned. During the course of the present year many varieties of electric resistance thermometers have been under observation, and with some of these the reduction of temperature brought about by exhaustion was investigated. Thermometers constructed of platinum and platinum-rhodium (alloy) were only lowered 1½°C. by exhaustion of the liquid hydrogen, and they all gave a boiling point of —245°C., whereas the reduction in temperature by evaporation *in vacuo* ought to be 5°C., and the true boiling point from —252° to 253°C. In the course of these experiments it was noted that almost invariably there was a slight leak of air, which became apparent by its being frozen into an air snow in the interior of the vessel, where it met the cold vapour of hydrogen coming off. When conducting wires covered with silk have to pass through india-rubber corks it is very difficult at these excessively low temperatures to prevent leaks, when corks get as hard as a stone, and cements crack in all directions. The effect of this slight air leak on the liquid hydrogen when the pressure got reduced below 60 mm. was very remarkable, as it suddenly solidified into a white froth-like mass like frozen foam. My first impressions were that this body was a sponge of solid air containing the liquid hydrogen, just like ordinary air, which is a magma of solid nitrogen containing liquid oxygen. The fact, however, that this white solid froth evaporated completely at the low pressure without leaving any substantial amount of solid air led to the conclusion that the body after all must be solid hydrogen. This surmise was confirmed by observing that if the pressure, and therefore the temperature, of the hydrogen was allowed to rise, the solid melted when the pressure reached about 55 mm. The failure of the early experiment must then have been due to supercooling of the liquid, which is prevented in this case by contact with metallic wires and traces of solid air. To settle the matter definitely, the following experiment was arranged. A flask, C, of about a litre capacity, to which a long glass tube bent twice at right angles was sealed, and to which a small mercury manometer can be sealed, was filled with pure dry hydrogen and sealed off. The lower portion, A B, of this tube was calibrated. It was surrounded with liquid hydrogen placed in a vacuum vessel arranged for exhaustion. As soon as the pressure got well reduced below that of the atmosphere, perfectly clear liquid hydrogen began to collect in the tube A B, and could be observed accumulating until, about 30 to 40 mm. pressure, the liquid hydrogen surrounding the outside of the tube suddenly passed into a solid white foam-like mass, almost filling the whole space. As it was not possible to see the condition of the hydrogen in the interior of the tube A B when it was covered with a large quantity of this solid, the whole apparatus was turned upside down in order to see whether any liquid would run down A B into the flask C. Liquid did not flow down the tube, so the liquid hydrogen with which the tube was partly filled must have solidified. By placing a strong light on the side of the vacuum test-tube opposite the eye, and maintaining the exhaustion to about 25 mm., gradually the solid became less opaque, and the material in A B was seen to be a transparent ice in the lower part, but the surface looked frothy. This fact prevented the solid density from being determined, but the maximum fluid density has been approximately ascertained. This was found to be 0·086, the liquid at its boiling point having the density 0·07. The solid hydrogen melts when the pressure of the saturated vapour reaches about 55 mm. In order to determine the temperature, two constant volume hydrogen thermometers were used. One at 0° C. contained hydrogen under a pressure of 269·8 mm., and the other under a pressure of 127 mm. The mean temperature of the solid was found to be 16° absolute under a pressure of 35 mm. All the attempts made to get an accurate electric resistance thermometer for such low temperature observations have been so far unsatisfactory. Now that pure helium is definitely proved to be more volatile than hydrogen, this body, after passing through a spiral glass tube immersed in liquid hydrogen to separate all other gases, must be compared with the hydrogen thermometer. For the present the boiling point, which is 21° absolute at 760 mm., compared with the boiling point at 35 mm., or 16° absolute, enables the following approximate formula for the vapour tension of liquid hydrogen below one atmosphere pressure to be derived:—

$$\log p - 6{\cdot}7341 - 83{\cdot}28/T \text{ mm.},$$

where T = absolute temperature, and the pressure is in mm. This formula gives us for 55 mm. a temperature of 16·7° absolute. The melting point of hydrogen must therefore be about 16° or 17° absolute. It has to be noted that the pressure in the constant volume hydrogen thermometer, used to determine the temperature

* Read before the British Association at Dover.

of solid hydrogen boiling under 35 mm., had been so far reduced that the measurements were made under from one-half to one-fourth the saturation pressure for the temperature. When the same thermometers were used to determine the boiling point of hydrogen at atmospheric pressure, the internal gas pressure was only reduced to one-thirteenth the saturation pressure for the temperatures. The absolute accuracy of the boiling points under diminished pressure must be examined in some future paper. The practical limit of temperature we can command by the evaporation of solid hydrogen is from 14° to 15° absolute. In passing it may be noted that the critical temperature of hydrogen being 30° to 32° absolute, the melting point is about half the critical temperature. The melting point of nitrogen is also about half its critical temperature. The foam-like appearance of the solid when produced in an ordinary vacuum is due to the small density of the liquid, and the fact that rapid ebullition is substantially taking place in the whole mass of liquid. The last doubt as to the possibility of solid hydrogen having a metallic character has been removed, and for the future hydrogen must be classed among the non-metallic elements.

SOME NOTES ON CHONDRUS.*

BY HENRY KRAEMER.

In this paper I desire to treat of some of the morphological characters of this plant, its collection, as carried out on the Massachusetts coast, and some reasons for the modification of the definition of the U.S.P. concerning the drug. *Chondrus* belongs to w' at we ordinarily consider to be a low order of plants—viz., one of the algæ, a subdivision of the cryptogams. The number of algæ, like that of fungi, is continually increasing, either because more forms are being observed or more forms are being made with the progress of time.

The algæ are divided according to whether they live in fresh water or salt water, and according to the colour they possess. By the latter division we have blue-green algæ, brown algæ, and red algæ. In only one of these divisions do we have algæ in which the green colour is manifest, in all the others it is hidden by means of other colouring substances, to which are given various names. The blue-greens are generally found in moist soil near fresh water, and seldom do they occur in salt water. The green algæ represent a rather ubiquitous group that may be said to be found anywhere where the conditions for CO_2 assimilation exist. The brown algæ represented by *Fucus, Laminaria, Sargassum*, etc., reach their greatest perfection in the colder waters, as north of Cape Cod and the English Channel. The red algæ attain their greatest perfection in the deeper waters. The outer morphology of the algæ appears to be rather simple. They may consist of a single row of cells placed end to end and forming thread-like masses, as *Lyngbya* (called mermaid hair), or cord-like masses, as in *Chorda*. In some cases the thread-like filaments may branch as in *Griffithsia*. The same may be said of some of the algæ which are made up of a large number of cells placed side by side, as *Weramium, Dasya*. In some cases the thallus is flattened, as in *Chondrus, Laminaria, Rhodymenia*. In some cases the parts of the plant are differentiated to such an extent that there is developed what looks like root ("hold-fast"), stem ("stipe"), and leaf ("blade"), as in *Laminaria*. In some cases there are incrustations of calcium carbonate produced, as in *Melobesia, Corallina*.

In regard to manner of reproduction in the algæ we have a number of distinct kinds of sexual and non-sexual reproduction. It is not fitting that I take up these different forms at this time. In the sexual mode of reproduction we have essentially three kinds: (1) The conjugation of two cells that look essentially alike, (2) the conjugation of two cells that may be distinguished one from the other, and to which the terms male and female are applied, and (3) the remarkable condition such as we find in the red algæ, as in *Chondrus, Gigartina*, and some others in particular, and which will be briefly described presently.

In its general outer morphology *Chondrus crispus* (L.) Stackh., consists of more or less purplish coloured fronds, which are from two to four inches long, dichotomous, flat, the segments being linear-cimeate. It is attached to the rocks by a slender hold-fast, and has not infrequently been found growing upon various forms of marine life. On making a transverse section, we observe a more or less differentiated epidermis, which may be distinguished from the remaining thick-walled cells. The fruit is known as a cystocarp, a term applied to the zygote or zygospore of the Florideæ. The development of the zygospores in *Chondrus* is a rather interesting one as described by Schmitz.* Briefly stated, it is as follows:—From one of the cells in the tissues of the thallus there is produced a three-celled branch which bends and almost touches the "Tragzelle." The end cell of the three becomes what is known as the carpogone cell, and developes a trichogyne, which protrudes from the thallus tissue. The Tragzelle becomes the "Auxillarzelle."

The nucleus of the spermatia unites with the nucleus of the carposporic or egg cell, and subsequently a division wall is formed between the trichogyne and egg cell. The egg cell then unites with the auxiliary cell, and from the latter there arise numerous thread-like processes which unite with some of the cells of the thallus. It is from this latter union that there is then developed a complex of four cells, which gives rise to the naked carpospores. In other words, we have here what may be termed, in view of this condition, a triple conjugation, and may we not ask what is fertilisation? Is a certain quantity of matter required before an egg may develop its progeny, or does it mean that a certain amount of stimulation is necessary?

This brings me to say a word on the industrial side of the seaweeds.

In the Old World the collecting and working up of seaweeds yields financial returns upon which a large number of people of a great many of the smaller towns are wholly dependent.

In this country all along the coast one observes that seaweeds are to some extent collected and utilised as a fertiliser, but besides this use of seaweeds there is an industry of great importance to the inhabitants of a number of smaller towns between Plymouth and Cohasset on the Massachusetts coast. It is the collection of Irish moss.

The situation at Scituate is particularly good for this industry. You find here an inlet with a fine beach, on either side of which extend rocky promontories, on the submerged rocks of which the Irish moss is found.

The beach extends probably 20ft. above high tide, at the top of which the frame houses are placed; back of this there is a gradual decline to the brackish salt marshes.

The moss is collected during the time from the latter part of May to September. June and July are the months when the greatest amount of collecting is done. They frequently work during these two months from four in the morning till eight at night.

The women used to be the great helping hands in gathering moss, but fortunately for them the moss is only found on the rocks that are from 15ft. to 20ft. below the tide, and the only way that moss can be collected to-day is by the use of long spruce poles to which is attached a heavy iron rake.

The men go out in their sail boats or dories (row boats) at half-tide, and come in at half-flood. With their long rakes they scrape the moss off the rocks. The amount collected varies with the season, but the quantity usually gathered is about 50lb.

The men return with boats and cast anchor until the tide is high, when they row out and bring their dories to the highest point on the beach, thus saving considerable energy.

They then carry the moss from the boats to points higher on the

* Presented at the annual meeting of the Pennsylvania Pharmaceutical Association, held at the Philadelphia College of Pharmacy, June, 1899.

* "Untersuchung über die Befruchtung der Florideen," in *Sitzungsberichten ned Königl. Akad, der Wissenschaft zu Berlin*, 1883.

beach in boxes about 2ft. square, and made of lathes. These are practically suitable trays, so that two men can handle them.

The moss is spread out on the beach and exposed to the weather for a week or so. The action of the sun and dew is to bleach the moss. The product is turned over every few days, and at the end of a week is like No. 1.

It is then put into half hogsheads and covered with canvas. On clear days they roll the half hogsheads containing the moss to the brackish marshes and fill the hogsheads containing the moss with salt water. The canvas is again put on and the half hogsheads rolled up on the beach and the moss uniformly spread out on the beach to dry and be further bleached. The salt water seems to preserve the moss, as well as assist in the bleaching action of the sun.

This is then raked over, the women assisting, until dry, and the treatment repeated four or five times until the moss is of a yellowish or white colour. The more favourable the weather has been and the more successful the treatment the whiter is the product.

When fully prepared, the moss is put into barns, and in the fall is packed in barrels, each of which holds about 100lb. It is estimated that about 10,000lb. are gathered at Scituate, and that they realise about five cents per lb.

When making some studies on *Chondrus* I was at the Marine Biological Station at Wood's Holl, and was told that *Gigartina mamillosa* grew only further north. A little later I journeyed north to the fields where *Chondrus* was gathered, and I was much impressed with the fact that all of the Irish moss that I saw collected was really *Chondrus crispus* (L.), Stackh. chiefly, if not entirely. I subsequently obtained specimens of *Gigartina* from Nahant, Mass. On turning to Dr. Farlow's 'The Marine Algæ of New England,' I find that he says that *Gigartina mamillosa Ag.* resembles and grows usually with *Chondrus crispus* (L.), Stackh., but that it is common from Boston northward. I have examined the collections of those who gather Irish moss on the Massachusetts coast, as well as that in the shops, and am inclined to believe that the *Chondrus* sold is chiefly, is not entirely, *Chondrus crispus* (L.) Stackh.

EFFECTS OF PRESERVATIVES ON SOLUTION OF HYDROGEN DIOXIDE.*

Probably no one article in the Pharmacopœia has been the subject of more investigation than hydrogen dioxide, but in none of the analyses published, and there have been many, have any definite data been given as to just what effect preservatives have upon the solution.

From the researches of Thenard, Schoenbein, Kingzett, and others, we know that hydrogen dioxide keeps best in a slightly acid solution, the amount prescribed by the United States Pharmacopœia being no more in 100 C.c. of the hydrogen dioxide than will be neutralised by 10 C.c. of a N/10 caustic alkali solution equivalent to about 0·049 per cent. sulphuric acid, or 0·0465 per cent. hydrochloric acid. This is a very small amount, but from actual experience has been found sufficient to prevent appreciable decomposition of a properly prepared 3 per cent. solution for from five to six months.

Experiments have indicated that certain preservatives could be used to apparently increase the stability of the solutions, and, with a view of ascertaining definite results a series of tests, extending over a year, were undertaken. At regular intervals each sample was carefully examined and notes taken, a summary of which is appended.

A standard 3 per cent. solution of hydrogen dioxide was used. The strength was determined by titrating 2 C.c. with a decinormal solution of potassium permanganate, while the acidity was found by titrating 50 C.c. with a decinormal solution of sodium hydroxide. The samples were allowed to stand in the laboratory, exposed to light and heat, in amber-coloured bottles, during the period named for each sample.

The results observed when alcohol and ether were used as preservatives are shown in Table I. The odd numbered bottles were left open one month after beginning the experiments to note whether any effect was produced by exposure and to allow the preservative agent to evaporate. The slight evaporation of water which occurred in these samples was allowed for.

It will be seen by referring to Table I. that sample No. 1 after one year lost 67·84 per cent. of its strength in the open bottle, and 59·08 per cent. in the closed bottle, while the acidity remained the same during the entire period.

TABLE I.

Standard Solution.	During 1st month bottle remained	Loss in 1 year. Per cent.	C.c. N/10 NaOH required to neutralise 50. C.c.	
No.			Nov. 30, 1897.	Nov. 30, 1898.

7 1 per cent Ether..	Open.	64·05	,,	5·6
8 1 ,, ,,	Closed.	58·11	,,	44·0
9 2 ,, ,,	Open.	77·90	,,	5·8
10 2 ,, ,,	Closed.	51·16	,,	50·4

Samples 3 and 4, containing 1 per cent. alcohol, lost in the open bottle 56·35 per cent. and in the closed bottle 57·27 per cent., but the quantity of decinormal caustic soda solution required increased from 5·2 to 64·2 C.c., indicating an increase of over 1,200 per cent. in acidity.

In all the other samples in this table an enormous increase in acidity appears except in Nos. 7 and 9, in which ether was the preservative used and the bottle left uncorked for the first month. The ether, being very volatile, much more so than the other preservatives, evaporated rapidly, and was practically gone before the bottle was corked, leaving the solution free from a preservative and nearly the same as standard.

Table II. shows the results with boro-glyceride and nitrous ether for a period of five months. It will be observed that decrease in strength is correspondingly less than for one year, but as in the other table the increase in acidity is very great, ranging from 300 to 600 per cent.

21 1 ,, Acetic Acid	24·33	43·9	39·5

Table III. A, B and C were solutions bought in the market and known to contain preservatives.

D and E were standard solutions known not to contain preservatives.

B, C and E were a year old when tested, while A and D were fresh solutions.

It is to be noted how much B and C have gained in acidity over A, and that they are still increasing is shown by the increase in the four months they have been standing since their first test.

C

* From *The American Druggist.*

E has been kept an equal length of time, but no increase in acidity was found.

TABLE III.

All in closed bottles.	Loss in 4 months per cent.	C.c. N/10 NaOH required to neutralise 50 C.c.	
		Jan. 14, 1899.	May 17, 1899.
A Fresh solution, containing preservative	2·74	4·8	5·5
B Sol. over a year old „ „	7·17	48·6	59·3
C „ „ „ „	6·13	71·0	72·0
D Fresh solution, free from preservative	— 6·97	3·8	3·8
E Old „ „ „	—10·0	4·9	4·9

It was evident that the oxygen of the preserved solution was used in transforming the preservative into acid.

These results indicate the necessity for forbidding the use of preservatives in the solution of hydrogen dioxide.

FROM A BOOK OF FORMULAS TO A BOOK OF STANDARDS.*

BY S. W. WILLIAMS.

In the perfection of official pharmaceutical products, manufacturers are setting such a swift pace, at the end of the century, as to make the task of bringing the Pharmacopœia up to date a very difficult one. From a chemists and druggists' formulary, coupled with a condensed catalogue of materia medica, the volume has been gradually changing toward a book of tests and standards, and conditions are such as to require continued and rapid advance in the same direction.

The chapter on reagents, totally absent in the revision of 1870, numbered thirteen pages in the Pharmacopœia of 1880, and fifty-one in the revision of 1890. Formulas for numerous chemical products which constituted an important feature of the book of 1870, were largely dropped in 1880, the descriptive materia medica much extended, and assay processes introduced for cinchona and opium. Belladonna leaves, for example, for which no description had been given in 1870, were accorded a four-line description in 1880. Directions for preparing atropine, which required a full page in the former, were dropped in the latter book, the description and tests being enlarged and improved. The same progressive metamorphosis obtained in 1890; for example, a full page which had been devoted to the preparation of phosphoric acid, was saved for more important matter, and an assay process for nux vomica was introduced.

The same process of evolution has been apparent in the British Pharmacopœia. Take citric acid, for instance; in 1885 twenty-four lines were devoted to its preparation and seventeen lines to its characters and tests. In the B.P., 1899, no method of preparation is given, while thirty-two lines are devoted to characters and tests. Most of the preparations of belladonna, cinchona, ipecac, opium and nux vomica are now standardised. The chapter on articles employed in chemical testing, which occupied twenty-one pages in 1885, has been doubled in the B.P., 1898. Thus, in both pharmacopœias formulas have been giving place to "characters and tests." Processes for standardisation and assay have been adopted as fast as was deemed consistent with a wise conservatism. There is the best of reason for all this, and a great advance is naturally expected along the same lines in the coming revision of the U.S.P. From 1870 to 1880 pharmacists decided that it did not pay them to make most of the chemical products for which formulas were given, and the revision of 1880 reflected this decision. The Pharmacopœia of 1890 accommodated itself as best it could to the further advance in ready-made pharmaceuticals.

For some time it has been a mooted question whether or not it pays the pharmacist to prepare his own fluid extracts, and, now that so many are being standardised, it is pretty safe to say that, all things considered, it does not. Even when we come to tinctures, the physician would doubtless feel safer in prescribing a diluted fluid extract of, say, cannabis indica or digitalis, which had been fairly well standardised physiologically, than a tincture officially prepared direct from the drug, the activity of which had not been determined. It would seem preferable to buy tincture of strophanthus, standardised by the most approved method, than to run the risk of disappointing the physician and endangering the patient by dispensing an article of uncertain strength.

Physicians naturally expect the best and most uniform preparations obtainable, and that they should have them admits of no argument. But can the Pharmacopœia possibly provide the retail pharmacist with either a practical method of production or valuation in the case of potent galenical preparations which can only be standardised physiologically? In many instances when the pharmacist finds it best to buy ready-made preparations, he can turn to the Pharmacopœia and find methods for determining the quality of his purchase. In other words, he is largely in control of and can assume direct responsibility for the quality of the pharmacopœial products he dispenses.

To multiply the facilities and extend the field of the pharmacist as an expert in determining the strength and purity of remedial agents is probably the greatest work of the Pharmacopœia; but the relation of the book to manufacturing pharmacy is of very great importance. It would seem desirable that the Pharmacopœia should, in so far as possible, establish standards for the guidance of manufacturers, even should the required methods not be adapted to the retail pharmacy. Uniformity can in no other way be better secured, if, indeed, it can be arrived at at all. And until there are such authoritative standards there is the best of reason why the physician should specify the particular make of medicines with which he is most familiar. That, for one reason or another, he will always do this to some extent, is quite probable; but that it should be necessary, in order to secure uniformity in essentials, is most unfortunate. It seems, therefore, that the best methods of standardisation and valuation, which are found to be practically attainable by the manufacturer, with the superior facilities at his command, should be adopted as official, whether or not they are beyond the scope of the retail pharmacy.

It is not to be expected that the dispensing pharmacist can have conveniently at hand a fine assortment of roosters, frogs, Guinea pigs, dogs, etc., and, even were it possible, it is only right that the number of living beings employed for physiological tests should afford the largest possible results. With the manufacturer, comparatively few will answer for hundreds of gallons of standardised products, whereas if we contemplate the pharmacist taking up any work of the kind, the prospect is bewildering. Even in chemical standardisation necessarily difficult or complicated processes should not be discarded because the pharmacist has not the time or facilities to apply them. It is distinctly to the advantage of the dispenser that the Pharmacopœia should go to any reasonable length to adopt practical standards to which manufacturers must adhere for their official products. Standards practically attainable by the manufacturer and admitting of verification by professional analysts are very desirable, all reasonable latitude being given for meeting them on the one hand and confirming them on the other—the one aim being correct and uniform results.

In so far as such standardisation can be accomplished, just in so far will the word "official" mean enough to do away with the necessity for specification on prescriptions calling for pharmacopœial preparations. Everything possible should be done to make it unnecessary for the retail druggist to stock more than one or two lines of regular official preparations.

While the dropping of aconitine in the 1880 U.S.P. was, indeed, a tribute to the relative superiority of the galenical preparations of aconite as then produced, in considering most galenical preparations of potent drugs which can be standardised, we must admit that standardisation is their salvation. Without it physicians will naturally go over to active principles to insure uniformity, and

* From the American *Druggists' Circular*.

when they do so the temptation is often strong to dispense them themselves. It is clearly not in the interests of the dispenser that methods of standardisation and valuation be limited to the scope of his time or facilities. When he can convince the prescriber that the galenical preparations he carries are as uniform as possible and U.S.P. standard, he can with considerable force argue for a discontinuance of the custom of specification, and not before.

It may be said that the Pharmacopœia will no sooner catch up with the manufacturers than they will speed away again for another ten years' handicap; but this is no argument against the best possible adjustment in 1900.

In considering the importance of the Pharmacopœia getting even once in ten years, the question quite naturally arises as to whether it would not be possible for a research laboratory, operating under the direction of the committee of revision, to keep abreast of the times and issue at stated intervals such "official" information as the committee deemed of too great importance to wait their sanction until the next revision.

As it is now, one manufacturer adopts what he considers a proper standard for his preparations of some potent drug; even if he publishes his methods in detail his competitors may honestly disagree with him or object to the apparent lack of independence involved in copying. They are quite likely to introduce standards of their own. They must be different to be original, and other reasons for the differences can readily be presented. The doctor who becomes accustomed to A's preparations is afraid to use B's, and the prescriber who has obtained satisfactory results from C's is naturally loth to change to D's, and so on through the alphabet. The druggist is compelled to carry numerous makes of the same preparations, involving a sacrifice of money, space and convenience.

The hardware man tells us, when we attempt to replace a lost nut or screw: "Here's one just like it in size and appearance, but it hasn't got the standard thread; we will have to send to the one who made the machine." And it is much the same in the case in question; the doctor wants the same "thread" he has had before, to fit the experience he has gained with a certain make. The comparison, however, is unjust to the pharmaceutical manufacturer, because, except in a few instances, he has no standard to go by, whereas the maker of machinery has, and wilfully and for a purpose deviates from it. Manufacturers cannot be expected to agree upon unofficial standards. Pharmacopœial standardisation must lead the way to reasonable uniformity.

THE CULTIVATION OF VANILLA IN MEXICO.*

BY M. SAINTE-CROIX DE LA RONCIERE.

Six varieties of vanilla are found in Mexico, known colloquially as "le mansa" (*Vanilla planifolia*), "le cimarrona" (*V. sylvestris*), "le mestiza" (*V. sativa*), "le pompona" (*V. rotundifolia*), "le puerco" and "le mono." The first two of these are alone cultivated. Le pompona, or the "banana vanilla," as it is called, possesses a fine odour, and is used by tobacco growers in Havana for perfuming cigars. Le puerco and le mono, which grow wild, have not yet been much used in commerce. Vanilla is best cultivated in a rich soil, such as is found in tangled forests, in hot regions, and particularly on the banks of rivers. In places such as these moisture is retained in the soil, a very necessary point where but little rain falls from February to June. Gravel and clay soils are respectively too dry in the dry season, and too damp during the heavy rains. The vanilla tree thrives best at a temperature between 25° and 28° C., neither too hot nor too damp, and far removed from sea breezes. A shady place is indispensable, at a height of 300 to 400 metres. The fact that the tree does not wither when cut at a certain distance above ground, has given rise to the erroneous notion that it derives its nourishment from the tree up which it climbs. That this is not so is seen in the case of vanilla plants that are trained along a wall.

The plant begins to flower the second year, but three or four years elapse before a good harvest is gathered. The parts of the flower are so arranged that self-pollination is impossible; consequently this is brought about by the agency of humming-birds, bees, or other insects. It is a good plan to keep bees in the neighbourhood of the plantation. These agencies being somewhat uncertain, the planter must make himself familiar with the structure of the flower, so that he himself can bring about pollination, in order to ensure a crop.

The flowers appear in March, April, or May, in clusters of 20 to 50; if one-half of these are fertilised, an ample crop is obtained. The fruit develops in about a month, but it takes another eight months to ripen. In the districts of Tuxpan, Misantla, and Papantla the harvest is gathered in January, February, and March.

The pods are gathered when the extremities begin to turn yellow, and when they produce a crackling noise on being lightly pressed between the fingers. It is important to gather the pods at the right moment; if too ripe they do not dry readily, possess little or no aroma, acquire a reddish colour, and do not keep, as they should do, for years. After the process of curing the pods are sorted by Mexican planters into five qualities:—(1) "Fina" or "legal," with pods at least 6½ inches long, thin at the end, sound, black, and not split. This class is again subdivided according to the length, into "tiercada," "primera," "chica," "primera grande," "marca menor," and "marca mayor"; (2) "Chica," like the "fina," but less than 6½ inches in length, and only half as valuable; (3) "Zacate," with recurved pods; according to the condition this variety is sorted into: "pescozada," "vana," "crueruda," and "apocoyonada"; (4) "Cimarrona," or wild vanilla, in more or less good condition. Three "cimarronas" are worth one "fina"; (5) "Rezate," consisting of the smallest pods, split lengthwise and badly prepared. Six of these are worth one "fina."

A plantation in working order, three years old, costs from 45 to 60 dollars per 100 plants (pieds). The cost of preparation is 4 to 5 dollars per 1,000. A hundred vanilla trees, three years old, together produce, on the average, in the wild state, and without artificial pollination, from 50 to 65 pods; in the fourth year from 165 to 225 pods; in the fifth year 325 to 500. After that the number produced diminishes annually until the tenth year, when the plants must be replaced. The plantation, therefore, gives the best harvests from the fourth to the sixth year. In good years each plant under cultivation yields 14 or 16 pods. Vanilla is ordinarily sold on the Mexican market by the thousand. Ripe, unprepared vanilla fetches 5 or 6 dollars a thousand, but when prepared the price ranges from 40 or 50 dollars at Michoancan to 50 or 75 dollars at Mislantla, Papantla, and Tuxpan. Statistics show that the port of Tuxpan exports more vanilla than all other ports in the world. Hence, it may be looked upon as the natural home of this valuable orchid. As the market price of vanilla in New York is 8 to 10 dollars per pound, it bears a considerable profit. Indeed, in good years, planters have owned to making a profit at the rate of 300 per cent.

* Abstracted from the *Revue des Cultures Coloniales*, **5**, 3.

Formalina.—Whilst everybody was busy at the Tuberculosis Congress at Berlin, endeavouring to find a way and means of curing consumption, the most destructive of known diseases, Cervallo, of Palermo, had already discovered a remedy which healed 65 out of 100 cases, and partly cured the other 35. The remedy is called formalina, and is used as a hypodermic injection. The happy discoverer will surely agree that serious science has still reason to doubt the efficacy of his discovery.—*Oest. Zeits. fur Pharm.*, **53.**

THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.*

Saccharum Lactis.—The Pharmacopœia now fixes the limit of ash at 0·25 per cent. This is to guard against the possible presence of magnesium and calcium salts which have sometimes been found to the extent of 1 or 2 per cent. in commercial samples of milk sugar. The objection to these mineral salts is that they produce or aid coagulation of milk to which milk sugar containing them may be added for the purpose of preparing infants' food. The occasional presence of calcium or magnesium compounds in sugar of milk is probably due to the use of magnesia or lime added to the milk whey during crystallisation to neutralise the acid previously used to curdle the milk.

Soda Tartarata.—The official test for purity is carried out in a manner similar to that described under Potassii Tartras.

$KNaC_4H_4O_6$, $4H_2O$, M. Wt. 280·15 yields by incineration $KNaCO_3$, *i.e.*, sufficient alkaline carbonate to neutralise one molecular weight of sulphuric acid.

∴ 280·05 grammes of pure soda tartarata ≡ 2,000 C.c. N/1 vol. sol. H_2SO_4.

$$\therefore \text{1 gramme of pure soda tartarata} \equiv \frac{2{,}000}{280{\cdot}15} \text{ C.c. N/1 vol. sol. } H_2SO_4.$$

$$= 7{\cdot}14 \text{ C.c.}$$

The Pharmacopœia states that at least 7 C.c. of the vol. sol. of sulphuric acid should be required, and this corresponds to a purity of a little over 98 per cent., for

$$7{\cdot}14 : 7 :: 100 : 98{\cdot}04.$$

Sodii Arsenas.—This salt is directed to be kept in the anhydrous state because the crystallised salt is not constant in composition. When freshly crystallised it has the composition $Na_2HAsO_4,12H_2O$, but by keeping under ordinary conditions it effloresces and loses water, until the composition $Na_2HAsO_4,7H_2O$ is attained. The actual percentage of arsenic therefore depends upon the extent to which efflorescence has occurred, but by drying at a little under 150° C. the whole of the water of crystallisation is expelled, and the anhydrous salt Na_2HAsO_4, which is constant in composition, is obtained. The quantitative determination of purity is based upon the precipitation of lead arsenate in presence of acetic acid. The addition of free acetic acid is made in order to prevent the precipitation of basic lead salt which would of course alter the quantitative relation of lead acetate and sodium arsenate as expressed in the following equation upon which the determination is founded. The necessity for adding acetic acid is really due to the fact that although the official sodium arsenate is acid in constitution, *i.e.*, it still contains one of the three replaceable hydrogen atoms of the arsenic acid it yields an alkaline solution (*vide* B.P. tests). It is supposed that a partial hydrolysis of the salt occurs in aqueous solution with formation of the sodium di-hydrogen arsenate and sodium hydroxide.

$$Na_2HAsO_4 + H_2O = NaH_2AsO_4 + NaOH.$$

The reaction between lead acetate and di-sodium hydrogen arsenate results in the liberation of some free acetic acid, because the lead arsenate precipitated is the normal salt, but at the commencement of the reaction the proportion of the acetic acid so formed is not sufficient to prevent the formation of basic lead salt—hence the addition of glacial acetic acid.

In order to carry out the official test, the sodium arsenate solution should be made as described. Now dissolve the 2·03 grammes of lead acetate in 50 C.c. of recently boiled distilled water. Add 49 C.c. of this solution to the sodium arsenate, warm slightly, agitate and set aside for a few minutes. Then filter a little of the mixture and to the clear filtrate add the remaining C.c. of lead solution. A distinct precipitate should form, showing that some sodium arsenate is still left in solution, and the filtrate from this will, if the salt be quite pure, again give a slight precipitate on the addition of more lead solution. The calculation is based upon the following equation :—

$$\left.\begin{array}{l} 2[Na_2HAsO_4] \\ + \\ 3[Pb(C_2H_3O_2)_2 3H_2O] \end{array}\right\} = \left\{\begin{array}{l} 2[Pb_3(AsO_4)_2] \\ + \\ 4NaC_2H_3O_2 \\ + \\ 2HC_2H_3O_2 \\ + \\ 9H_2O \end{array}\right.$$

M. Wt. sodium arsenate 184·78.

M. Wt. crystallised lead acetate 376·15.

∴ (184·78 × 2) grammes pure sodium arsenate will precipitate (376·15 × 3) grammes of lead acetate.

$$\therefore \text{1 gramme sodium arsenate will require } \frac{376{\cdot}15 \times 3}{184{\cdot}78 \times 2} \text{ grammes of lead acetate}$$

$$= 3{\cdot}05 \text{ grammes.}$$

The figure given in the official text is 2·03. This must, however, be an error, since it would only require the salt to be 66 per cent. pure. Probably 3·03 was intended.

Sodii Benzoas.—The precipitate given by ferric chloride with a solution of this salt is ferric benzoate. Its colour is very distinctive, and this test forms the chief qualitative reaction for the detection of benzoates. The volumetric test is based upon the incineration of benzoate to carbonate and titration of the residue.

$$C_6H_5COONa \equiv \tfrac{1}{2}Na_2CO_3 \equiv \tfrac{1}{2}H_2SO_4$$

M. Wt. 143·01

∴ the ash of 143·01 grammes pure sodium benzoate neutralises

$$\frac{1{,}000}{143{\cdot}01} \text{ C.c. N/1 vol. sol. } H_2SO_4$$

$$= 6{\cdot}99 \text{ C.c.}$$

Sodii Bicarbonas.—According to the equation

$$2NaHCO_3 + H_2SO_4 = Na_2SO_4 + 2CO_2 + 2H_2O$$

83·43 grammes of pure sodium bicarbonate will neutralise 1,000 C.c. N/1 vol. sol. of sulphuric acid.

$$\therefore \text{1 gramme } NaHCO_3 \text{ is} \equiv \frac{1{,}000}{83{\cdot}43} \text{ C.c. N/1 } H_2SO_4$$

$$= 11{\cdot}986 \text{ C.c.}$$

Allowing for the small quantity of adherent moisture the official requirements indicate a practically pure salt. The only official test which calls for remark is the ferric chloride test for thiocyanates. It is necessary first to convert the bicarbonate into chloride by the addition of a slight excess of hydrochloric acid, otherwise a red precipitate of ferric oxyhydrate, is obtained which would obscure the red coloration. Note that ferric carbonate, which one might expect to be formed, is so unstable that it decomposes with formation of oxyhydrate and liberation of carbon dioxide. The thiocyanate, if present, would be derived from impure ammonium bicarbonate used in the manufacture of the sodium salt. The commercial ammonium salts are obtained from the products of the destructive distillation of coal in the manufacture of illuminating gas. A certain proportion of the sulphur and nitrogen of the coal always comes over as sulphocyanic compounds, and through insufficient purification may be found in the ammonium salts prepared from the gas liquors.

* NOTE.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J* during 1897-8.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.
Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, SEPTEMBER 30, 1899.

SOME STILL UNDETERMINED QUESTIONS.

ARGUMENT is scarcely requisite to establish the fact that the intention of the Pharmacy Act, 1868, was to limit the business of chemists and druggists; to confine its exercise to persons ascertained by examination to possess a competent practical knowledge of that business. The principle of the Act was that in future the right to carry on a chemist's business and, in that connection, to make use of the title chemist and druggist, was to be acquired only by legal qualification. That prospective statutory limitation was adopted by Parliament solely out of regard for the public interest, and probably without showing as much consideration for the interests of the persons who were to become qualified under the operation of the Act as might have been beneficial in every sense. For ensuring the efficacy of the Act as a measure of public protection it followed, of necessity, that persons who did not pass the required examination could not lawfully carry on the business. Logically, and for the same reason, the inference might have been drawn that a like disability should attach to persons who could not pass the examination. That common-sense view of the matter appears to be equally applicable to a rejected candidate for qualification under the Act and to a person otherwise incapable of passing the qualifying examination, such as a composite person consisting of several individuals. Moreover, since the function for which qualification is required is an individual one, the qualification of the individuals forming a company appears to be a condition indispensable for lawfully carrying on the business of a chemist and druggist in that way. But the decision of the question raised as to the significance of the word "person" in the Pharmacy Act having led to the directly opposite result of affording opportunity for the exercise of the chemist and druggist's business by persons who are not legally qualified, the circumstances which led to that decision merit careful reconsideration at the present time, when the consequences of the decision are likely to receive attention from the Legislature, and the action that may be taken will in any case be of vital importance to registered chemists and druggists.

The assumption frequently made that the House of Lords' decision on the company question went so far as to declare that companies can lawfully carry on the business of chemists and druggists is not by any means justified by the terms of the judgment delivered by any one of the three judges. All three of them agreed that the whole question was as to the meaning to be put upon the word "person." The conclusion they arrived at was based upon construction of the language of the Act and its general provisions rather than upon consideration of what would be proper for securing the object of the Act or for giving effect to its principle. But the conclusion that it was impossible to infer that the object of the Act required a larger construction to be put on the word "person" was not based only upon consideration of the fact that the word "person" was generally used in the Act in undeniable reference to an individual—*i.e.*, a person who could undergo examination and perform other individual acts; but it was arrived at rather as a necessary consequence of the fact that the Act itself contained a special provision that the business of a chemist and druggist might be carried on by unqualified persons, a provision that further defined the means by which the interests of the public were to be provided for, in such a case, by the employment of a legally qualified assistant to conduct the business. Even the evident necessity of individual qualification for the performance of certain functions helped to confirm the conclusion that the exercise of the business by unqualified proprietors was not necessarily inconsistent with the object and policy of the Act. Thus the main argument in support of the principle of the Act—viz., that its object would be defeated unless a corporation as well as an individual were included under the word "person"—was held not to be maintainable in face of the consideration that the "person" actually selling could be struck at if unqualified.

But the decision on those grounds that a company should be regarded as outside the scope of the Pharmacy Act was based entirely upon construction of the language of the Act and the general purport of its provisions so far as that was evident from the language used. It left undecided the more important questions—Whether the consequences of the decision would be consistent with that protection of the public which was intended by the Pharmacy Act? Whether it was consistent with the object of the Companies Acts that their provisions should be made use of for the purpose of evading another Act? and Whether the reasonable claims of registered and legally qualified persons were not unjustly prejudiced by associations of unqualified persons carrying on business as chemists and druggists? as well as the question Whether, from either point of view, an individual, legally unqualified to carry on the business of a chemist and druggist, should be able to do so—and thus evade the Pharmacy Act—by nominal association with six other unqualified persons and by registration under the Companies Acts? These questions did not come before the House of Lords; but they are the questions which will now have to be considered, when the Companies Bill comes before Parliament, and in reference to them the recent observations of the LORD CHANCELLOR appear to be of considerable significance. From the opinion expressed by his Lordship, that a company ought not to be permitted to do what an unqualified individual is prohibited from doing, together with the unanimous conclusion of the Committee to which this matter was referred, viz., that a stop should be put to companies doing that which an individual may not do without legal qualification, much encouragement may be gathered as to the future prospect of an equitable settlement of the question which has been so long in abeyance. Registered chemists must, however, bear in mind that this question will now have to be dealt with under the head of company law amendment, and that it must not be complicated by the association of other questions that would come more appropriately within the wider scope of pharmacy law amendment.

ANNOTATIONS.

THE SCHOOL OF PHARMACY reopens on Monday next, October 2, and readers are reminded—for the last time—that the prizes for the past session will be distributed by the President of the Pharmaceutical Society at three p.m. on that day. Subsequently, an address to the students will be delivered by Profes or D. J. Leech, of Owens College, Manchester. The Hanbury Medal will be presented to Professor Ladenburg, of Breslau, the same afternoon. It is hoped that a large number of members of the Society and students will make it convenient to be present at the meeting.

AUSTRALIAN SASSAFRAS BARK appears to be the subject of some confusion in regard to its botanical source, and Mr. R. T. Baker, the Curator of the Technological Museum, Sydney, refers to the matter in a letter recently received from him (see p. 330). He also forwards a paper containing a description of *Cinnamomum oliveri*, Bailey (see 'Proc. Linnean Society, N. S. W.,' 1897, Part II., July 28, pp. 275–284, and pl. xii.), which he considers to be the botanical source of the bark hitherto known in a few museums in this country as that of *Beilschmiedia obtusifolia*. He points out that the bark of *Cinnamomum oliveri* is often sold under that name. Mr. Baker further states that he has sent to the Museums of the Pharmaceutical Society of London, specimens of the barks of *Doryphora sassafras*, *Atherosperma moschata* (Victorian sassafras), *Cinnamomum oliveri* (black sassafras), and *Beilschmiedia obtusifolia* (non-aromatic). On making enquiry of the Curator, we learn that these barks have not yet arrived, but he offers the following remarks on the subject: "The 'sassafras' bark offered in Mincing Lane in June last, 14 bags of which were shipped from Sydney, was, I believe, identified at Kew as that of *Beilschmiedia obtusifolia*, by comparison with a specimen existing in the Museum there. I had the opportunity (through the courtesy of the Curator, Mr. J. R. Jackson) of seeing both the Museum and the commercial specimen, and so far as it was possible to judge, by means of taste, smell, and a lens, the determination seemed to me to be a correct one. This is apparently the same bark on which the description in the 'Proposed Indian and Colonial Addendum' is founded. *Ph. Journ.* [4], **7**, p. 612. Moreover, it is the bark exhibited under that name in the Queensland Court in the Colonial and Indian Exhibition in London, in 1886. In the 'Catalogue of the Exhibits of the Queensland Court,' p. 66, it is thus described: *Beilschmiedia obtusifolia*, Benth. and Hook., Sassafras tree. A tall tree with fragrant bark and foliage. . . . . This contains a tannin similar or identical with cinchona tannin; the amount 7½ per cent. One ton of the dry bark yields 770 oz. of oil, K. T. Staiger." It is therefore evident that the Queensland botanist is responsible for the error—if, as Mr. Baker states, the bark of *Beilschmiedia obtusifolia* is non-aromatic. Mr. Baker's opinions on the subject are given in the 'Proceedings of the Linnean Society of New South Wales,' for July, 1897. Mr. F. M. Bailey, the Queensland botanist, at first considered the plant, now called by him *Cinnamomum oliveri*, to be the *Beilschmiedia obtusifolia* of Bentham and Hooker, but Professor D. Oliver, of Kew, suggested that it was a *Cinnamomum*, and Mr. Bailey subsequently described it as a new species, and named it after Professor Oliver. Whether the bark recently offered in the London market be that of *Cinnamomum oliveri* or *Doryphora sassafras* must be left undecided until Mr. Baker's authentic specimens arrive; it certainly is not that of *Atherosperma moschatum*, nor of *Beilschmiedia obtusifolia*, if that is non-aromatic.

A CERTIFICATE OF ANALYSIS, signed by Dr. Stevenson, has been rejected by a London police magistrate because the analysis had not been done by Dr. Stevenson himself. The prosecution was for selling ice-cream containing injurious organisms, and Dr. Stevenson, in cross-examination, admitted that the analysis had been performed by his bacteriological assistant. The solicitor for the defence then contended that the summons must fail, since the Sale of Food and Drugs Act distinctly states that the analysis shall be made by the public analyst for the district. That view commended itself to the magistrate, who said that, unless the question had been asked, he should have assumed that the analysis was made by Dr. Stevenson, and he would have accepted the certificate without suspicion. As it was, he dismissed the summons. The decision in this case, it may be pointed out, differs from that of the Manchester stipendiary magistrate, who ruled in a recent case (see *ante* p. 284*d*) that samples sent for analysis to a county analyst were not bound to be analysed by the analyst, but might be examined by his assistants. The point is an important one, and more will doubtless be heard about the matter.

THE BRITISH PHARMACOPŒIA should, in the opinion of the Secretary of the Grocers' Federation, be studied by all shopkeepers who sell drugs by retail. Writing on the subject of adulteration, Mr. Giles pointed out that in several places recently inspectors have been prosecuting shopkeepers for selling sweet nitre which was alleged to be deficient in nitrous ether, and that a co-operative society in Yorkshire had to pay a fine for that offence. For the defence, in many cases, it was stated that the evaporation of the ether is considerable, owing to the frequent opening of the bottle in which the article is contained. That, he grants, may be the case, "but if it is so, surely those who handle the article ought to take care that that which they sell is up to the proper standard." In connection with this matter also, he remarks, the question is raised of the sale of drugs by retail by persons other than duly qualified chemists. "If a shopkeeper handles drugs he ought to make himself familiar with the requirements of the British Pharmacopœia, a new edition of which was published last year. It is the recognised authority on the composition of drugs, and everyone who sells these goods should be acquainted with the latest requirements of this authority. A good many grocers sell such goods as cream of tartar, etc., which come under the Pharmacopœia, and they should take care that they stock only those which are guaranteed to be up to the required standard."

THE IDENTIFICATION OF POWDERED DRUGS is a subject which is occupying much attention in America at the present time, and, at the recent meeting of the American Pharmaceutical Association, several important papers on that subject were communicated. According to the *American Druggist*, Professor Henry Kraemer proposed to establish colour standards of powdered drugs. He has found that, with a type plate of twenty characteristic colours, it is possible to do much in the direction of securing uniformity of description. He acknowledged, however, that there is a great inherent difficulty in judging the actual colour of any particular powdered drug, since the character of the light employed, the colour of surrounding objects, the time occupied by the examination, and the fixity of attention with which the specimen is regarded, may all materially influence the observer's opinion. Professor Kraemer also disclaimed any quantitative value for the colour standards he suggests, since it would be much easier for an adulterator to prepare a mixture approximating to the colour of a particular standard, than it would be for a retailer to obtain in the market a drug of undoubted purity, which would exactly reproduce the colours of the standard. But apart from that, it is thought that the establishment of colour standards would do much to simplify the description of powdered drugs. Professor Albert Schneider also contributed a paper on the identification of powdered drugs, in which he insisted that histological structure must be the main, if not the sole, thing depended upon if accuracy of results is desired. That view, however, was dissented from by W. C. Alpers, in a paper on odour standards. A second paper by Professor Schneider embodied suggestions on the examination of drugs.

The Late Lord Watson, who was spoken of in the *Times* obituary notice as having been in the estimate of his brethren and of the Bar "the profoundest lawyer on the Bench," was one of the Lords of Appeal in Ordinary who assisted in the decision of the company question, in 1880, and it is interesting at the present moment to recall the fact that he then expressed himself as "almost inclined to hold that considerations of policy rather preponderate in favour of the appellant's argument," *i.e.*, that the word "person" should include a company or corporation. His ultimate concurrence with the opposite construction of the statute by the other two Law Lords who heard the appeal was a consequence of the impossibility of ascertaining from the ambiguous and confused language of the Pharmacy Act, whether it was the intention of the Legislature, or of the framer of Sections 1 and 15, "to give individuals registered under the Act the exclusive privilege of selling poisonous drugs by retail, and so impose penalties upon a corporation keeping open shop for that purpose."

The Adoption of Uniform Systems of Graduation, definite limits of accuracy, and standard methods for using all forms of measuring instruments, employed in chemical laboratories have been under consideration by a committee appointed by the American Chemical Society, with the result that the following recommendations have been published:—(1) That the American Chemical Society, in a manner consistent with its constitution and bye-laws, ask the U.S. Office of Weights and Measures to adopt regulations for the verification of volumetric apparatus which shall be similar in purpose and scope to the regulations of the Kaiserliche Normal-Aichungs-Commission, after due consideration of the criticisms to which the latter have been subjected. (2) That the U.S. Office of Weights and Measures be asked to give special consideration to the question of a standard temperature or temperatures to be adopted for the graduation of volumetric apparatus, and to obtain as far as practicable an expression of opinion from American chemists on this point. (3) That the U.S. Office of Weights and Measures be asked to submit its regulations to the American Chemical Society, or a duly appointed committee thereof, for suggestions before final adoption by that office. (4) That the international kilogram be adopted as the standard mass. (5) That the litre as defined by the International Committee on Weights and Measures be adopted; viz., the volume of the mass of a kilogram of pure water at the temperature of maximum density and under a pressure of 760 Mm. of mercury. (6) That all density determinations be referred to water at its maximum density and under a pressure of 760 Mm. of mercury. (7) That all temperatures be expressed in terms of the hydrogen thermometer of the International Bureau of Weights and Measures. (8) That if any question arise as to the interpretation of the above definitions the decision and standards of the U.S. Office of Standard Weights and Measures shall be accepted by the Society as final.

Aqua Vitæ, in its especially French form, is commonly supposed to be the alcoholic distillate obtained from the wine of the Cognac district; but according to the *Daily Telegraph* the grape appears to be played out as a factor in the production of French cognac, and can, in fact, be dispensed with altogether. Quoting from a lecture delivered on the subject at the Health Congress by Sir Charles Cameron and Professor William Smith, the statement is made that while the fertility of the vineyards is decreasing, the manufacture of eau de vie steadily grows. Corn and potatoes, with an admixture of chemicals, take the place of grapes. But this new kind of brandy does not fulfil the hopes based on the old-fashioned liquor ordered for patients by medical men. Professor Smith quoted statistics which showed that previous to the outbreak of phylloxera among French vines, in 1876, more than twelve million hectolitres of wine—a hectolitre is a little over twenty-two gallons—were annually produced, but that last year the production dropped to below one million. Yet, while at the earlier period less than two millions and a half hectolitres of cognac were produced, of which under two millions found their way to England, at the later period—from one-thirteenth of the output of wine—over two and one-third millions of French brandy were exported to this country. It seems that the Spaniards, being an old-fashioned and rather slow-going people, have not adopted these new methods of manufacturing brandy, and Sir Charles Cameron therefore thinks that medical men should prescribe Spanish brandy for their patients when they can get it.

A Grave Dispensing Mistake at Eastbourne, involving the death of a medical practitioner, revives the question of dispensing in doctors' surgeries on which Major Rasch, M.P., so pertinently interrogated Ministers last session. The facts of the case as presented to the public in the daily press are somewhat meagre as to detail, but, broadly speaking, they are as follow:—Mr. J. Dick, who had recently commenced practice in Eastbourne, prescribed for one of his patients a mixture intended to contain iron, and to be flavoured with chloroform water. The patient on taking a small, and, fortunately, much diluted, dose became very ill, and declared that she had been poisoned by the medicine. Mr. Dick, on being told this at his next visit, very naturally repelled the suggestion with some warmth, and to restore the confidence of the patient he impulsively took two generous doses of the mixture in her presence. This childlike faith in a suspected mixture had a very sad *dénouement*, for the poor fellow on reaching home presented all the distressing symptoms of strychnine poisoning, and died shortly afterwards, in spite of the prompt application of the stomach-pump and the continuous services of two medical attendants. At the inquest a Dr. Colgate is reported to have testified that the mixture after analysis revealed the presence of a considerable quantity of strychnine and demonstrated the absence of aqua chloroformi. Furthermore, it transpired that the bottles in the doctor's surgery were identical in shape and size and colour, so that the strychnine solution bottle differed in no respect from the neighbouring receptacles of less harmful substances. Yet the verdict was a plain riderless conclusion of "death by misadventure."

Without Inquiring into the question "Who dispensed the fatal mixture?" (and it might have been an unqualified servant of the victim) the public is surely entitled at least to ask why the regulations for the keeping, dispensing, and selling of poisons which are imposed by law upon registered chemists should not equally apply to the surgeries of medical practitioners? If it be a necessary measure of protection in the case of qualified chemists, it can scarcely be considered unimportant and unnecessary in the case of medical dispensaries where medicine is often dispensed hastily, and under other conditions likely to lead to mistake. It is evident from cases such as this, which we are given to understand are not so rare as one might expect, that the public incur considerable risk owing to the absence of any statutory guarantee that the medicines made up in private surgeries or dispensaries are compounded by duly qualified persons, or that the more potent remedies of the Pharmacopœia are kept in a proper manner. Accidents will happen, as the saying runs, under the best of regulations, but it is not logical to urge that it is, therefore, futile to trouble about rules and restrictions. At any rate, such argument is not convincing. Rather, should it be the duty of the Government to see that dispensing accidents should be reduced to a minimum by the exclusive employment of legally qualified persons, and the enforcement all round of the poison regulations already referred to.

THE BRITISH ASSOCIATION.

Mathematical and Physical Science Section.

Professor J. H. Poynting, D.Sc., F.R.S., presided over this section, and at the commencement of his address expressed the satisfaction felt by all physicists at the establishment of a National Physical Laboratory. He then went on to deal with

The Investigation of Nature,

and expressed the belief that in some directions there has been real progress in the range of investigation and the nature of the knowledge gained thereby, and that physicists are tending towards a general agreement as to the nature of the laws in which they embody their discoveries, of the explanations which they seek to give, and of the hypotheses they make in their researches for explanations. He next dealt with the range of the physicist's study and his methods of investigation, contrasting the old conception of laws as self-sufficing governors of Nature with present ideas. He pointed out that even now the early stages in the history of thought can be traced by survivals in our language due to the ascription of moral qualities to matter. Thus, gases are still sometimes said to obey or to disobey Boyle's Law as if it were an enactment for their guidance, and as if it set forth an ideal, the perfect gas, for their imitation. Language was still used which seemed to imply that real gases are wanting in perfection, in that they fail to observe the exact letter of the law. If that view were accepted it would have to be said that hydrogen came nearest to perfection, but then it would have to be regarded as righteous over-much, a sort of Pharisee among gases which overshoots the mark in its endeavour to obey the law. Oxygen and nitrogen might be regarded as good enough in the affairs of every-day life, but carbon dioxide and chlorine and the like would be looked upon as poor sinners which yield to temptation and liquefy whenever circumstances press at all hardly upon them. There was a similar ascription of moral qualities when bodies were judged according to their fulfilment of the purpose for which they are used; when they are described as good or bad radiators, good or bad insulators, as if it were a duty on their part to radiate well, or insulate well, and as if there were failures on the part of Nature to come up to the proper standard. The reaction of language on thought was so subtle and far-reaching that he was inclined to urge the abolition of all such picturesque terms. Let physicists remember that there is no such thing as a failure to obey a physical law. A broken law was merely a false description. He then proceeded to show that concurrently with the change in physicists' conception of physical law has come a change in their conception of physical explanation. The aim of explanation now is to reduce the number of laws as far as possible by showing that laws, at first separated, may be merged into one; to reduce the number of chapters in the book of science by showing that some are truly mere sub-sections of chapters already written. Professor Poynting then went on to trace the origin of the mechanical theories of physical phenomena to the dislike manifested by the human mind to the inexplicable discontinuities occurring during changes of form of energy.

Among the numerous subjects considered by this section was the desirability of establishing a standard for

Platinum Thermometry,

the discussion being opened by Prof. H. L. Callendar, F.R.S., who submitted the following proposals in consideration of the importance of adopting a practical thermometric standard for the accurate verification and comparison of scientific measurements of temperature:—(1) That a particular sample of platinum wire be selected, and platinum resistance thermometers constructed to serve as standards of the platinum scale of temperature. (2) That the scale of temperature deduced from the standard platinum scale by means of a parabolic formula, which has been proved to give a very close approximation to the true or thermo-dynamic scale, be recommended for adoption as a practical standard of reference, and be called the British Association scale of temperature. The gas thermometer would still remain the ultimate or theoretical standard, and the exact relation of the British Association scale to the absolute scale would be the subject of future investigation. (3) That the value of the difference-co-efficient in the parabolic formula be determined by reference to the boiling point of sulphur. (4) That the temperature of the normal boiling point of sulphur under a pressure of 760 millimetres of mercury reduced to 0° C., and latitude 45°, be taken for purposes of the British Association scale as 444·53 C., as determined by Callendar and Griffiths with a constant pressure air thermometer. (5) That a sub-committee be appointed to direct and supervise such measures as may be thought desirable for carrying out these proposals into effect.

In the course of the discussion on Prof. Callendar's proposals an opinion seemed to prevail that while the platinum instrument might be good, it had its faults, and was apt to play tricks; therefore it was a question whether the time was ripe for the adoption of his suggestions. He, however, pointed out, in reply, that he did not propose to establish any absolute standard of thermometry, but merely to establish a standard of reference for platinum thermometry.

Freezing Points of Solutions.

On Friday, September 15, Mr. W. C. D. Whetham presented the report of the Committee on Electrolysis and Electro-Chemistry. The report stated that the conductivity of a number of salts in very dilute aqueous solution at the freezing point of water had been determined by Mr. Whetham, while Mr. Griffiths had concurrently made observations of the freezing point for corresponding solutions. The observations of conductivity extended to solutions of sulphuric acid, potassium chloride, sodium chloride, barium chloride, copper sulphate, potassium permanganate, potassium bicarbonate, and potassium ferricyanide. The range of dilution was from below the hundred-thousandth to about the twentieth part of a gramme equivalent per thousand grammes of solution. The water used was specially distilled three times, the last time from a platinum still, and collected in platinum vessels. Its specific resistence was rather smaller than that of the water obtained by Kohlrausch by distillation *in vacuo*. The results obtained showed that the water used was good enough to enable trustworthy values to be obtained even at the lowest limits of dilution.

The next day, Saturday, the 16th inst., an interesting account was given by Professer J. J. Thomson, F.R.S., of recent researches on the

Existence of Masses Smaller than Atoms.

He showed that several lines of investigation lead to a determination of the ratio of the mass of an atom to the elcctric charge conveyed by it—namely, ordinary electrolysis; experiments on the velocity of charged particles; and experiments on the velocity of cathode discharges. These experiments indicated that the charge carried by an atom in cathode discharges and similar phenomena is apparently 1,000 times greater than in ordinary electrolysis, consequently either the atoms become dissociated and only a portion of their mass carries the negative charges of cathode rays, or else the atom can receive a greater charge than is assigned to it in explaining electrolytic phenomena. To discriminate between these two assumptions a method was employed to determine separately the charge carried by a known number of atoms in a case for which the charge per unit mass had the greater value. The method used was described as follows:—A flat metal plate, negatively electrified, is brought near to a very large perforated metal plate through which ultra-violet radiation can pass, the whole apparatus being enclosed in gas at a pressure of about 1-100 millimètre of mercury. The radiation causes a discharge of electrified particles from the negative plate, which move in parallel straight lines to the perforated plate which receives their charge. If now a magnetic field be set up between the plates, its direction being parallel to the plane of the plates, the paths of the particles become curved; in fact, cycloids, and the particles may not reach the perforated plate if the latter is far enough away from the negative plate. There will, therefore, be a diminution in the rate of discharge, which is the phenomenon actually observed; its amount corresponds with theory if the large value of the charge per unit mass is assumed. The charge conveyed per second is the product of three quantities—the number of "atoms," the charge on each, and the average velocity of the atoms. The charge conveyed per second may be observed and the average velocity determined by a method devised by Professor Rutherford. If the number of atoms is determined, the charge on each may be immediately found. These electrified atoms behave as nuclei on which water drops will condense when a cloud forms in the air; it is only necessary, therefore, to know the total amount of vapour condensed and the size of each drop in order to determine the number of drops, which is the same as the number of atoms. The amount of vapour condensed is obtained by suddenly and definitely expanding air of known humidity from a

given higher to a given lower pressure, and the size of the nuclei is obtained from the rate of their fall, since, like rain-drops, they can only attain a definite velocity. To ascertain whether the mass is collected at a point or diffused through space, the mass is allowed to impinge against a surface which is transparent to the energy carried—such as Röngten radiation or cathode rays—but which does not allow material of infinite size to pass through it. In all the experiments the atoms possessed negative charges; when positive charges are carried the results of experiments agree with those on electrolysis. The amount of charge carried by an atom depends on the gas and on the nature of the electrodes. From this it would appear that electrification seems to consist in the removal from an atom of a small corpuscle, the latter consisting of a very small portion of the mass with a negative charge, while the remainder of the atom possesses a positive charge.

Botanical Section.

On Tuesday, the 19th inst., a paper was read in this section by Mr. A. C. Seward, F.R.S., of Cambridge, at one time examiner in botany to the Pharmaceutical Society, on

A New Genus of Palæozoic Plants.

He commenced his paper by stating that the description of this genus, which represents a new type of Cycadofilices, is founded on a single specimen in the Binney collection of coal-measure plants. The specimen consists of a small piece of stem, unfortunately without the cortical tissues, with the structure of the primary and secondary wood very clearly preserved. Occupying the axial region is a strand of primary xylem, 1·9 Cm. in diameter and consisting of large isodiametric or slightly elongated tracheids with multiseriate bordered pits on their walls, associated with parenchymatous tissue; the primary stele is of exarch structure, the narrow and spirally thickened protoxylem elements occurring at its margin. Surrounding the primary stele there is a broad cylinder of secondary wood exhibiting anatomical features characteristic of cyadean stems. From the periphery of the primary strand leaf-traces are given off consisting of long tracheids intermixed with parenchyma. The most interesting features in the anatomy of this stem are:—(1) The manner of origin and behaviour of the leaf-traces; (2) the exarch structure of the primary system; and (3) the structure of the large primary tracheids.

Mr. Seward also read a paper by himself and Miss J. Gowan on "The Maiden-Hair Tree (*Ginkgo biloba*, L.)," in which *Ginkgo* was compared with various fossil types from Palæozoic, Mesozoic, and Tertiary horizons; and the geographical distribution of *Ginkgo* during the Mesozoic and Tertiary epochs.

The Germinative Power of Seeds.

Some interesting experiments made by Sir W. Thiselton-Dyer and Professor Dewar to ascertain the influence of the temperature of liquid hydrogen on the germinative power of seeds were described. The experiments showed that life goes on at a temperature so low that ordinary chemical action practically ceases. Commercial samples of the seeds of the vegetable marrow, mustard, barley, and the pea were immersed in liquid hydrogen for more than six hours, the lowest temperature attained being 453° F. below the temperature of melting ice. Subsequent examination revealed no visible change in the appearance of the seeds, they being as fresh and bright as they were before immersion, and on being planted all germinated.

Chemical Section.

In this section a number of interesting papers were read, amongst which was one by Colonel J. Waterhouse, honorary secretary of the Royal Photographic Society, on the

Action of Light upon Metallic Silver.

He showed that when cut masks are laid on the surface of silver leaf or foil, or on a Daguerreotype plate, and exposed to the sun's rays, a visible image ultimately appears on the metallic surface. The effect is produced more rapidly if the metallic surface has been exposed to mercury vapour or immersed in an acid solution of a ferrous salt mixed with silver nitrate. Copper is sensitive in the same way, and it is probable that other metals are also sensitive to the action of light.

Dr. A. Fernbach contributed a paper on the

Influence of Acids and of some Salts on the Saccharification of Starch by Malt Diastase,

in which he states that the slightest trace of free acid distinctly retards the action of diastase on gelatinised as well as on soluble starch, but the starch employed and the solution of diastase must be absolutely free from salts on which acids may act. In the presence of secondary phosphates which are unfavourable to diastatic action, the addition of acid is favourable so long as the stage of primary phosphate is not passed.

Dr. G. Harris Morris also contributed a note on the combined action of diastase and yeast on starch granules. He found that when starch granules are attacked in the ungelatinised form by diastase alone they are more vigorously attacked when yeast is present, alcohol accompanying the maltose that is the only product of the diastatic action.

Anthropological Section.

Our readers across the border will perhaps be interested to know that Mr. J. Gray, in a paper on

Recent Ethnographical Work in Scotland,

paid a high tribute to a Scottish pharmacist, Mr. Tocher, the secretary of the Buchan Field Club, to whose organising ability, assisted by the generous and gratuitous co-operation of the school teachers, he attributed the completion of a pigmentation survey of the whole of the school children of East Aberdeenshire, returns being received between October, 1895, and November, 1897, from over ninety schools, comprising nearly 14,000 children. The pigmentation of the school children (with that of adults added for comparison) was shown in a table of average results, and a comparison with the Continental districts whence, according to tradition and history, the United Kingdom has derived a large element in its population—viz., Schleswig-Holstein, Lüneberg, and Mecklenburg-Schwerin, the reputed original seats of the Angles and Saxons—was shown in another table. These tables showed that the three North German districts were clearly much more blonde than East Aberdeenshire; Germany as Virchow's survey had shown, got more brunette and less blonde from north to south, but on its extreme southern frontier—Upper Bavaria—a district is found approximating in pigmentation to East Aberdeenshire.

PROCEEDINGS UNDER THE PHARMACY ACTS.

Case under Section 17.

Pharmaceutical Society *v.* Ashburton Drug Company, Ltd.

At the Ashburton Petty Sessions, on September 26, before Mr. F. H. Firth, Chairman, Hon. R. Dawson, Rev. W. M. Burch, Mr. J. Bickford, and Mr. S. Berry, county magistrates, the Ashburton Drug Co., Limited, was charged with selling poison, to wit, oxalic acid, which poison was not labelled with the name and address of the seller, as provided by Section 17 of the Pharmacy Act, 1868.

Mr. T. W. Windeatt, solicitor, of Totnes, appeared for the prosecution, and Mr. Jenkins Richards, managing director of the company, appeared to answer the charge.

Mr. Windeatt, having read the Section, stated that the proceedings were taken at the instance of the Pharmaceutical Society in the interest of the public, and pointed out how necessary it was that poisons should be properly labelled, so that in case of accidental or criminal administration the police authorities could trace from whence the poison was procured.

It having been reported to the Society that poisons were being improperly sold by the company, a Mr. Vanstone was instructed to go to the shop in East Street, Ashburton, and he there purchased twopennyworth of oxalic acid, which bore the following label:—"Oxalic Acid—Poison. Coleberd and Co., Limited, the Cash Chemists, London and South-Western Drug Stores, Fore Street, Sidmouth." The packet was subsequently handed by Vanstone to Mr. Moon, one of the clerks to the Registrar of the Society, who would produce it to the Court.

As soon as the summons was served, and with a view to save expense, a communication was addressed to the company, and an admission was received to the effect that if anything was sold to Vanstone from the shop of the company, labelled oxalic acid, that was the article supplied. It was, therefore, unnecessary to produce any evidence as to analysis.

After quoting a portion of the judgment of Lord Selborne in the case of the London and Provincial Supply Association, Limited, showing that the 17th Section applied to companies as well as to individuals, Mr. Windeatt hoped the Bench would inflict such a

fine as would deter other Companies from selling poisons in such a flagrantly improper manner as had been done in this case.

J. Vanstone, examined by Mr. Windeatt, stated that acting under instructions he went on July 8 to the shop of the Defendant Company, and purchased twopennyworth of oxalic acid. He was served by an assistant who did not ask him any questions as to what it was required for. He identified the packet produced as the one he purchased.

Harry Moon stated that he gave the last witness instructions to make the purchase of the oxalic acid, and that it had not been out of his possession since it was handed to him by Vanstone.

In reply to questions from the Bench, Mr. Moon stated that there had been no undue delay in taking proceedings. The purchase being made on July 8, no action could be taken until the Council met in August. The summons was issued on August 17. He was quite sure that Coleberd and Co., Limited, and the Ashburton Drug Co., Limited, were not identical, as he had searched the registers at Somerset House. The latter was practically a one-man company.

Mr. Jenkins Richards said he could not dispute that the poison was purchased at the shop of the company. He did not sell it. It must have been sold by the assistant, who had put on an old label which had probably been sent from the Sidmouth branch of his predecessors, Coleberd and Co., Ltd. He submitted that there had only been a technical breach of the law.

The magistrates were unanimously of opinion that a gross infringement of the Act of Parliament had been committed, and inflicted a fine of three pounds ten shillings, three pounds of which was to be handed to the Pharmaceutical Society for costs.

ANALYTICAL NOTES.

DETERMINATION OF CANTHARIDIN.—Twenty-five Gm. of cantharides in fine powder are macerated with 2 C.c. of HCl and 100 C.c. of chloroform for twenty-four hours, with occasional agitation, then filtered on a covered filter, and 62 C.c. of the filtrate evaporated. The residue obtained, washed with 5 C.c. of petrolcum ether, is transferred to a small tared filter, washed twice with 10 C.c. of the same solvent, dried at 60° C. and weighed. Good cantharides should yield, according to Gehe, 0·12 Gm. equivalent to 0·8 per cent. of cantharidin by this method.—*Pharm. Cent.*, **40**, 230.

THE TESTING OF ROSEMARY AND TURPENTINE OILS. — For testing turpentine the author uses bromine water saturated at 15° C., or, for more exact work, a solution of potassium bromide, 37·234 Gm.; potassium bromate, 10·449 Gm., and concentrated sulphuric acid, 25 C.c., in one litre. The results are arrived at by shaking well one C.c. of turpentine in a 100 C.c. cylindrical measure graduated to 1 C.c., with the bromine solution in the cold, till the bromine colour is permanent. 1 C.c. fresh American or French turpentine requires 62·64 C.c., German, 56·58 C.c. of the 3 per cent. bromine solution. The author distinguishes between the rectified and raw turpentine oils by the rise of temperature of the two oils when mixed with hydrochloric acid (1·19 sp. g.), and the different colours of the acid solution. The results are arrived at by shaking the oil with an equal volume of fuming hydrochloric acid, or with an equal volume of hydrochloric acid (1·12 sp. g.), mixed with two-thirds its volume of concentrated sulphuric acid for 15 seconds, and taking the temperature before and after. The rise in temperature with the rectified oil should not be more than 88°, and the acid portion, when separated, should be of a pale yellow colour, while the separated oil must be colourless. Rosemary oil gives with bromine and with hydrochloric acid the same reactions as turpentine; perfectly fresh French rosemary (1 C.c.) requires 49 C.c. of 3 per cent. bromine water, new Italian oil, 44 C.c. Rosemary oil, adulterated with 20 per cent. turpentine, requires 55 C.c. bromine solution. Mixed with hydrochloric acid, the temperature rises 11° C. to 17° C. If the oil is old, the separated acid is reddish brown, while the separated oil is pale yellow. Rosemary oil which has been rectified over lime, gives, when shaken with hydrochloric acid, a rise of temperature of not more than 6° C., and both acid solution and oil should remain colourless. Older oils absorb less bromine, give higher temperatures with acid, and deeper colours than fresh oils. —*Pharm. Zeit.*, **43**, 578.

LETTERS TO THE EDITOR.

The Source of Sassafras Bark.

Sir,—Under separate cover I am posting you a copy of a paper of mine "On the Cinnamomums of N. S. Wales," read some time back before our Linnean Society. My object in sending it is that I notice that there appears to be some confusion in the botanical nomenclature of the barks that are sold in London under the name of "Sassafras," and this paper may be of use to you for future reference in this matter. I am posting also by this mail, for the Pharmaceutical Society's Museums, samples of the following barks: 1, "Sassafras," *Doryphora sassafras*; 2, "Victorian Sassafras," *Atherosperma moschata;* 3, "Black Sassafras," *Cinnamomum oliveri;* 4, *Beilshmiedia obtusifoba* (non-aromatic). These barks are very characteristic of the respective species and are not easily confounded.

Sydney, August 7, 1899. RICH. T. BAKER.

Federation of Local Pharmaceutical Associations.

Sir,—As late secretary of the Federation, I feel that I cannot let the opportunity slide of remarking on the report of the meeting of the North-East Lancashire Association in your last week's issue. I was unfortunately unable to attend the Plymouth meeting, and although personally I regret that a programme for the coming session was not drawn up, I have every confidence that the meeting, consisting as it did of responsible gentlemen, has come to a sound conclusion, and one that should not be questioned by an individual who was not present to learn their reasons for so doing. I sincerely believe that the Plymouth meeting was the most important one ever held by the Federation, as the change of rules, which Blackburn so much complains of, has fixed its position; and if conducted on progressive lines, which we are led to hope it will be from the recent communication it has sent out, it will be a force to be considered in future pharmaceutical politics. I think it fortunate that you are in a position to publish the report of the Blackburn meeting in the same issue you do the recent communication sent out by the Secretary of the Federation, as side by side they make interesting reading. But, may I ask about the part played by the North-East Lancashire Chemists' Association at the recent meeting? Everyone interested is aware that the recommendations regarding the change of rules, etc., issued by that Association filled the greater part of the agenda, and that the Blackburn programme is still before the country for consideration; also, I understand, the time of the meeting was occupied by one of the Blackburn delegates over a paltry matter that was not considered worthy of publication; and yet Blackburn complains! Now you will see, sir, and so will everyone who may read this letter, that if the alteration of rules was a deliberate plan for crushing out the more important discussion on the present pharmaceutical crisis (as Mr. Holt is reported to have said) Blackburn was at the bottom of it. I take this opportunity of saying that I entirely approve of the change of rules and the appointment of an Executive Committee for action in cases of emergency and for general purposes; also that I fail to see why a secretary living in Devonshire will not be as useful as one residing in Lancashire, or, in fact, in any other county.

Liverpool, September 25, 1899. R. C. COWLEY.

The Necessity of the Present Situation.

Sir,—When we, as a craft, are face to face with a grave crisis—surrounded by difficulties and smarting under an injustice which affects the entire body politic and places us in a false position before the public—is it not "passing strange" that there should be found amongst us those, who, instead of working shoulder to shoulder in the cause of equity and justice, are raising false issues and hankering after the impracticable?—at a time, too, when the Government of the day appears inclined to consider our grievances, to listen to feasible suggestions and to provide a remedy for the anomalous position in which we are at present placed, involving work which would require all our energies, prudence and strength to be united for its accomplishment. Now, sir, I am not animated by any personal motives, neither have I any private interests to serve; but, as an old member of an honourable and self-sacrificing craft, I should like—for the sake of the future of pharmacy—to see that spirit of unanimity and toleration (so essential in every good and just cause) exhibited, by upholding the dignity of our calling, and by placing it upon a broad and liberal basis, untainted by the

narrowness of mere self-interest. Minor differences must be set aside, and the whole influence of a united craft should be brought to bear upon those in power, to prove to them that we are well able to manage our own affairs, are keenly alive to our own requirements, and not forgetful of the claims of the public but have their interests at heart. Nothing can be done without compromise in some form or another in all the walks of life, but it can be accomplished without any sacrifice of principle. With us it is a moral question and it lies within ourselves. Shall we, or shall we not, give up some of our fads and crochets and work together for the common weal? We must decide for ourselves one way or another, or others will decide against us, Pharmacy is, and has long been, in troubled waters, and unless we pull together as men in earnest and insist upon maintaining our rights we shall be tossed about, and eventually stranded, without hope or sympathy; and if we allow ourselves to come to this—well, it will serve us right for our selfish folly. Here arises the question, What are our rights? Not protection against cutting; that is the moral side, and has nothing to do with Acts of Parliament. On the professional side we have been educated and trained to do certain things, well defined by Acts of Parliament, in the interests and well-being of the public. Those Acts have given us exclusively certain titles by which we are known to the public, such as pharmaceutical chemist, chemist and druggist, pharmacist, and so forth, and we must maintain that no unqualified individual—or combination of unqualified individuals—has the least right or claim to use these titles, or, in other words, to filch them from us. We have long held, and must still hold with the greatest tenacity, that no corporation or company of unqualified individuals has, or ever had, any right to hold itself out to the public as competent to do work which the members of that company were never trained or legally qualified to do. It is simple nonsense to talk about "vested interests" in this case. If there are any interests involved through outsiders having put money into such concerns, they have been fraudulently acquired, in so far as the practice of pharmacy is concerned and, as a matter of course, outsiders should pay the penalty in which their greed has involved them. Much has been said—I think injudiciously on both sides—about doctors dispensing and chemists prescribing. These are questions which should not distract us now. They may be left to work out their own remedy, which they undoubtedly will do in process of time, without Acts of Parliament or legal interference of any kind. There appears to be no reason why doctors, chemists, dentists, and midwives, too, if they will, should not join in one common aim and desire, and work together harmoniously to protect and hold fast in possession the hard-earned titles which belong to them, not by courtesy, but by right.

Rotherfield, September 26, 1899. G. G. Hornsby.

The Eastbourne Poisoning Case.

Sir,—The lamentable case of the engineer hoist with his own petard is again exemplified in the case of poor Dr. Dicks at Eastbourne. I cannot just now lay my hand on a table of the frequency with which certain drugs are prescribed, but nux vomica and its preparations stand high on the list. One is tempted to think that it is often employed as being the only tonic bitter ever heard of, especially by medical men who dispense their own medicine. Within quite a short time I have noted two deaths from strychnine supplied by doctors who were unable to account for its presence in the medicine. It is also too freely used in many of the wholesale formulæ supplied *ad lib.* to the public, and no questions asked, "But that is another story."

London, September 27, 1899. E. Warrell.

Ether-Soap.

Sir,—Having had occasion during the last few months to make several batches of an ethereal solution of soap according to a surgeon's formula, I was interested in reading Mr. White's note in last week's Journal; and as our method and formula differ somewhat from those given on page 296, an account thereof may be of interest. The formula is:—Oleic acid, 30 C.c.; KOH *q.s.* to neutralise; alcohol, 10 C.c.; ether, 30 C.c. It is made as follows:—The acid is placed in an ordinary mortar, an aqueous solution (3 in 2) of potassium hydroxide gradually added, until a mass, slightly stiffer than soft soap is produced, mixture of alkali and acid being promoted by stirring. Further addition of KOH solution is proceeded with cautiously until neutralisation is effected, small portions of the mass being withdrawn from time to time, dissolved in spirit; and phenol-phthalein used as indicator. In this method there is no necessity to use the indicator until the consistence mentioned is attained, as it serves as an indication that the point of neutralisation is not far off. The alcohol is added to the soap, the resulting mixture transferred to a bottle containing the ether, set aside, with occasional agitation, for a few hours when a clear solution is obtained. Having made a batch as Mr. White suggests, I prefer the above, as the product is equally good, and there is a smaller expenditure of time and trouble. My observations do not altogether coincide in some minor points with those of Mr. White. There is practically no deposit in the solution, even on standing. Although there is an appreciable rise in temperature during neutralisation, I am not disposed to speak of it as considerable; further, neither I nor my colleague (Mr. Kelf, Ph.C.) consider there is any discernible improvement of the lathering produced by a slightly alkaline solution as compared with that produced when a neutral solution is used. I believe this 'Ether-soap" is in use in a third hospital, if so, it may be interesting to have its experience. F. A. Hocking, B.Sc. (Lond.).

Evelina Hospital, Southwark, September 27, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Chemical Society (H. H.—34/19).—The address is Burlington House, Piccadilly, London, W.

Minor Examination (R. R.—34/14).—You will find all the particulars in the *Pharmaceutical Journal* for September 9 last.

Sale of Morphine (G. W. B.—34/12).—The most satisfactory way of answering your question would appear to be to try the experiment.

Cocaine Solution (G. W. B.—202/34).—If a solution of cocaine salicylate had been required the fact would, presumably, have been specified.

Qualitative Analysis (R. L. M.—34/11).—The latest edition of Fresenius's book is what you require. Bloxam's 'Chemistry' (Churchill, 18s. 6d.) is a standard work on theoretical chemistry.

Pharmaceutical Football League (A. G. G.—202/32).—We are not aware that there is one. Write to the Secretary of the School of Pharmacy Football Club, 17, Bloomsbury Square, London.

Use of "Bromide" in Developers (H. B. R.—34/13).—The precise action of bromides in the developer is not yet understood. The primary purpose for which it is used is to prevent the reduction of the silver haloid of the plate except where it has been acted upon by light—that is to say, to keep the plate clean and free from fog. Used in a considerable quantity it has a powerful action in slowing the action of the developer and in modifying the gradation of the resulting negatives, hence its employment in cases of over-exposure. The quantity of silver in the plate is in no relation whatever to the necessity or otherwise for using bromide in the developer. Indeed it may be said that slow plates which, as a rule, contain less silver than rapid ones are also less in need of bromide in the developer, but that arises from the fact that in a rapid plate the silver haloid is naturally in a more unstable condition than in a slow one. Another point to notice, and it is an obvious one, is that the more energetic the developer the more likely it is to reduce the silver of the plate independently of the action of light. Hence in a developer containing a large proportion of the accelerating alkali the presence of bromide is more likely to be necessary to keep the plate clean and prevent fog. Bromide is always necessary with caustic alkalies, but most plates will develop quite cleanly without it when the carbonates are employed.

DISPENSING PROBLEMS AND NOTES.

PHENAZONE WITH SODIUM SALICYLATE.

The day after the following mixture was dispensed crystals began to form:—

℞	Sodii Salicyl.	ʒiij
	Phenazoni	ʒi
	Tr. Aconiti	mxv
	Mag. Sulph.	ʒi
	Aq. Chlorof. ad	ʒviij
M.	Ft. mist.	

The sodium salicylate was physiologically pure and the phenazone answered the B.P. tests—J. H. S. (33/13).

It appeared probable, in this case, that the crystalline precipitate would be found to consist of phenazone salicylate or salipyrine, the phenazone and salicylic acid combining in the presence of the magnesium sulphate, which acts probably as a condensing agent. To clear up the point, the following experiments were carried out:—

(1) The mixture was dispensed as written. The reaction was slightly acid, and crystals began to fall after six or eight hours, continuing until an amount of deposit equal to the whole of the phenazone resulted.

(2) To see if the same phenomenon would be produced in an alkaline mixture, the prescription was made again and rendered distinctly alkaline to litmus by adding enough solution of caustic soda, and then filtered clear of traces of magnesium hydrate by running through cotton wool; on standing, crystals fell as plentifully as at first.

(3) A solution of sodium salicylate, 45 grs., and phenazone, 15 grs., with water to 2 ozs., was tried. This was slightly acid to litmus. No precipitate came down on standing twenty-four hours.

(4) A solution as last was made and kept at the heat of a water bath for half-an-hour, after which time the solution was alkaline, but no precipitate fell in twenty-four hours.

(5) A solution of magnesium sulphate, ʒ2, and sodium salicylate, 45 grs., with water to 2 oz., gave no precipitate, and was slightly acid to litmus.

(6) A solution of magnesium sulphate, ʒ2, and phenazone, 15 grs., with water to 2 ozs., was alkaline, and a faint precipitate similar in appearance to magnesium hydrate fell, but no crystals came down in twenty-four hours.

From these experiments it was clear that magnesium sulphate, phenazone and sodium salicylate, were all necessary to the production of the crystals.

The crystals from the first experiment were collected, washed with water, dried and crystallised from alcohol. When heated they melted, gave off the odour of phenol, turned black, and when further heated to redness left practically no residue other than a trace of magnesium oxide. To prove the presence of phenazone some of the crystals were boiled with water and potassium hydroxide to convert the salicylic radical to the potassium salt and liberate phenazone. The solution was shaken with chloroform three separate times, the chloroformic solution drawn off and again shaken with a trace of dilute hydrochloric acid and a little water. This acid solution, on addition of ferric chloride, gave the characteristic colour given with phenazone almost discharged with excess of dilute sulphuric acid. To the original acid solution of phenazone dilute sulphuric acid was added, and a few crystals of sodium nitrite, when a sea-green colour again proved the presence of phenazone.

The salicylic radical was proved in the alkaline solution by acidifying with hydrochloric acid and adding Fe_2Cl_6, which gave a violet colour, and confirmed by boiling a little of the alkaline potassium salicylate with methyl alcohol and excess of sulphuric acid, which gave an odour of oil of wintergreen (methyl salicylate).

The crystals from the first experiment could not, in appearance, taste, and general reactions, be distinguished from salipyrine.

LIBERATION OF IODINE.

The following mixture was distinctly alkaline when dispensed, et iodine was liberated:—

R	Pot. Iodid.	ʒj
	Spirit. Ammon. Ar.	ʒvj
	Æther. Sulph.	ʒij
	Aq. ad	℥vj
M.	Ft. mist.	

The mixture was made up in various ways, but without getting a satisfactory result. The addition of potassium bicarbonate or of ammonia solution did not prevent the liberation of iodine, unless a fairly large quantity was used.—D. G. (33/19).

In this case the mixture must have been dispensed with a bad ether, or one which had been exposed to light and a high temperature on the shop-shelves. Three mixtures were dispensed.

(*a*) With pure ether; (*b*) with anæsthetic ether (methylated); (*c*) with an equivalent of spirits of ether. In each cast the iodide was first dissolved in the water, and the ether (or spirit) added after being mixed with the aromatic spirit of ammonia.

In no case was there the slightest liberation of iodine, and the ethers on testing with the bichromate test gave not the faintest tint of blue. With an ether slightly changed and with only small traces of hydrogen peroxide or ozone present, mixing it with the aromatic spirit of ammonia would prevent the coloration, and the excess of ammonia, to say nothing of the terpenes in the spirit, would take up a relatively large amount of free iodine as it was liberated from the potassium iodide.

Theoretically, the terpenes present in old sal volatile should contain hydrogen peroxide, but practically that could only take place in the absence of ammonia, for all essential oils which absorb hydrogen peroxide or generate it must become acid in the process.

The ether used by D. G. must have been in a bad state, and hydrogen peroxide formed as a decomposition product would appear to have been the cause of the liberation of iodine.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

Correction.

EGG ALBUMIN.—In the article on "Egg Albumin" published in last week's issue, p. 301, the third line from the bottom of the first column should read "per 100 cubic centimetres of egg white," and not "per cubic centimetre," as printed.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Abram, Blythe, Druce, Durrant, Ellinor, Ferrall, Fryer, Gilmour, Gray, Hannah, Hartness, Haslegrave, Key, Longstaff, Marchant, Marshall, Matthews, Moon, Morgan, Murray, Plumley, Prince, Reade, Rowlands, Rudd, Thorne.

THE EVOLUTION OF PHARMACY.*

BY D. J. LEECH, M.D., D.SC., F.R.C.P.

Professor of Pharmacology and Therapeutics, Owens College, Victoria University.

Let me in the first place express my sense of the compliment paid me by the President and the Council of the Pharmaceutical Society, in asking me to give the address at the opening of the Fifty-eighth Session of this important School of Pharmacy. The high value I attach to the work of the Society of which I have the pleasure of being an honorary member, and the respect in which I hold its President, would have made it difficult to refuse the invitation even had my connection with pharmacy been only that which all physicians have. But at the Owens College I have had for many years to direct the teaching of medical students in pharmacy and materia medica, as well as to lecture on pharmacology and therapeutics, and when, at my suggestion, the Council of the College determined to make provision for the education of pharmaceutical students, I had to organise and supervise the new department. Hence I take a special interest in pharmacy and pharmaceutical education, and in pharmaceutical students also. Then, too, as a member of the Pharmacopœia Committee of the General Medical Council, I have come much into relation with the work of the Pharmaceutical Society bearing on the production of the Pharmacopœia, work, let me say in passing, for which not only the Medical Council, but the country at large, is greatly indebted to the Society.

On all these grounds I felt I must overcome a certain amount of inertia which affects me at the end of the summer season, and accept the invitation I had received, and so I am here to-day to welcome, advise, and congratulate the students of this School, and to make some remarks on pharmacy and pharmaceutical education.

Nearly a century ago, when the well-known surgeon Abernethy went to give the lecture with which he commenced his course, he looked round on the large number of students assembled and said in a sorrowful tone, "God help you all! What will become of you?" He could not see how work could be found for so many; and there are some who have a similar feeling now with regard to pharmaceutical students, who have misgivings with regard to the future of pharmacy, and fear that the work of the pharmacist will disappoint those who enter upon it. Now if I believed this, I should find it difficult to stand here to-day and congratulate those who are commencing their instruction at this School, or those who have completed their work here even though they have obtained distinction. But I do not believe it, and I think I can give reasons for my disbelief.

The pessimistic views with regard to the future of the medical profession which Abernethy entertained, and which many others too have held both before and since, have not proved well founded. The number entering on medicine has increased largely, but notwithstanding that the medical profession has been constantly occupied in trying to decrease professional work by preventing disease, and has been pretty successful in doing this, there does not appear to have been any lack of work, and there is no reason for believing that the medical profession, as a whole, ever stood better than at present.

The reason for this is that there has been a gradual development in medicine. By a process of evolution it has parted with some old functions, but new avenues for work and usefulness have been opened out. Above all, the standard of education has been raised, and the profession is being better fitted for that work which it is most in the interests of the public it should perform.

Now when we look at the history of pharmacy, we see that here, too, evolution has taken place, and I am satisfied that, provided the educational advances which have been entered upon are continued, the work of the pharmacist will become in the future increasingly pleasant, increasingly useful to the public, and, I trust and believe, increasingly profitable.

*Address, delivered at the opening of the fifty-eighth session of the School of Pharmacy of the Pharmaceutical Society, on October 2, 1899.

The Evolution of Pharmacy.

I propose in the first place to point out a few of the main features of this evolution, for although you gentlemen are more interested in the present state and future prospects of pharmacy than in its past history, it is through this history that we are able to understand the present and to form some ideas of the probabilities of the future.

A relative of mine who travelled much in the Hinterland of our West African possessions, told me that he was several times treated for serious illnesses by the natives with whom he was living. The chief, or the wife of the chief, or some wise man or woman reputed to have a knowledge of medicine, gathered a herb or herbs, and having prepared an infusion or decoction, administered the medicine to him, and he says that on several occasions he found very definite effects and great benefit from the drugs thus given him.

Here we have medicine and pharmacy in the simplest stage, and there is reason to believe that a similar stage was passed through amongst the primitive peoples of olden times. As civilisation advanced amongst ancient communities, the number of substances reputed to possess a curative influence increased. With this increase pharmacy became more complex, and Egyptian Papyri give us a good idea of the medicine and pharmacy of an ancient civilised community.

The "Papyrus Ebers," written about 1500 B.C., contains several hundred prescriptions with directions for the use of the medicines. The ingredients of the prescriptions consist largely of some form of food or condiment, as, for example, honey, dates, figs, and coriander. But potent medicines of mineral and vegetable origin are also included, as copper salts, juniper berries, and aloes. In addition, many gruesome substances are included, as the blood, brain, and fat of many animals. The prescriptions contain from one to eighteen constituents; in some cases decoctions and infusions are described. Very commonly directions are given for the solid ingredients to be mixed and taken in beer, milk, or wine. Sometimes a kind of confection is prescribed with honey; at others the constituents are made into cakes. Plasters, ointments, and collyria are ordered, and inhalations also, which were made by pouring fluid on hot stones.

There is no definite evidence that pharmacy was separated from medicine in Egypt, though there must have been in these times dealers in drugs. There is reason to believe, too, that many people kept drugs, and prepared their own medicines.

In Greece, in the time of Hippocrates, there were special classes who collected and sold drugs—the Rhizotomists and Pharmacopolists. The former gathered roots and herbs, and expressed the juices of plants for medicinal purposes. The Pharmacopolists dealt in drugs; they were to be found in public places, vaunting their wares and their knowledge, dealing in cosmetics and curiosities as well as drugs. In addition there was another class, cultivators of medicinal plants, about whom little is known. The physicians seem to have prepared their own medicines. In the establishment of separate classes collecting and dealing in drugs, we have the first step to the separation of medicine from pharmacy, which was rendered necessary by the increased number of drugs and the altered conditions of social life.

In later times the Greek and Roman physicians continued to prepare their own compounds. Galen, who lived in the second century of the present era, certainly seems to have done so, but Pliny says that some of them were unable to compound their own prescriptions and bought ready-made medicines. Dealers in drugs and medicines, both in the East and West, in Alexandria and Rome, seem to have abounded, but they all appear to have conjoined other functions with the preparation and sale of medicinal compounds.

The Pharmacopolists dressed wounds and appear to have trespassed in other ways on the functions of medical men. They earned, however, a bad reputation. Then there were "Unguentarii" and "Pigmentarii," who sold salves and pigments, but also dealt in drugs and other things. The "Seplasiarii" were shopkeepers who kept drugs, toilet accessories, and cosmetics chiefly, and there were some apparently who conjoined the sale of a great variety of articles, including wine, with that of drugs. In later times still the dealers in spices, "Aromatarii" and the "Confectionarii," seem to have been more specially engaged in dealing in medicines.

As time went on there was no doubt an increasing tendency on the part of physicians to employ outside help in the preparation of medicines, but the change in this direction became more marked when the Eastern physicians took up the work which fell from the failing hands of those of the Western world. The Arabian physicians added largely to the list of medicines used, and devoted much attention to the preparation and combination of medicaments, and owing to this, pharmacy was constituted as a separate work. According to Haeser, the true apothecary appeared first amongst the Arabians.

It is difficult to trace the rise of the apothecary in the Western world. Medicine sank to a low ebb in Europe after the fall of Rome, and when a revival took place the influence of the Arabian physicians on both medicine and pharmacy was very plainly seen. The custom of committing pharmacy into special hands spread from the East into Europe. Saladin, of Ascalon, physician to the Prince of Tarento, wrote a book about the middle of the twelfth century, for the use of the "Aromatarii," one of the names by which the compounders of medicine seem to have been known at this time; and in the thirteenth century the Emperor Fredrick the Second made regulations insuring the competence of the "Confectionarii," who acted as pharmacists at Salerno. Certainly in the thirteenth century we find in many parts of Europe the apothecary preparing the medicines which the physicians ordered.

Mr. Thompson, in his interesting 'Mystery and Romance of Alchemy and Pharmacy,' says that the earliest record of the apothecary in England seems to be of one Richard Fitznigel, who acted in that capacity to Henry the Second.

In 1345 we find in Rymer's 'Fœdera' a grant of sixpence a day to one "Coursus de Gangeland, Apothecarius," Londoniæ, for his care of King Edward the Third.

In Chaucer's time, a century later, the apothecaries are represented as vying with one another in preparing the medicines of the physicians. The doctor of physic, who is sketched in the Canterbury Tales, has his apothecaries.

> Full ready had he his apothecaries,
> To send his drugges and his lectuaries.
> For each of them made other for to win,
> Their friendship n'as not newe to begin.

The apothecaries held an intermediate position between the simple traders in drugs and the physicians. It is probable that some of them were at first assistants to physicians, and even at an early period they seem to have taken part in the treatment of disease. The majority dealt not only in drugs, but in other commodities, like the Pharmacopolists of Greek and Roman times. Indeed, as late as the sixteenth century we find them at times alluded to as Pharmacopolists.

The practice of medicine was to some extent regulated during the sixteenth century by Acts of Parliament, but pharmacy was in a deplorable condition until the early part of the seventeenth century. The apothecaries were in a subservient position, and their proper work, that of selling drugs and medicinal compounds, was much interfered with, for there were other classes who dealt in drugs and medicines. The grocers also sold them, and in the sixteenth century we find distillers and sellers of waters and oils and dealers in simples known as druggists, who supplied many forms of medicine. Another class connected with pharmacy had also arisen—the chemists. The introduction of chemical processes by the Arabs and the activity in research, largely due to a belief in alchemy, led to the production of many chemical substances having medicinal properties. Those who prepared them were known as chemists, and they, too, provided certain kinds of medicines. George Baker, a London surgeon, writing in 1576, says:—"I do know some excellent chemists, as one Mayster Kemmech dwelling in Lothburie, another Mayster Geoffray in Crouched Friers, men of singular knowledge in that way; another named John Hester, the which is a paynfull traveyler in those matters as I by proofe have seen and used of their medicines to the furtherance of my pacient's healthes, and also of one Thomas Hill."

Not only was the preparation and sale of medicines in many hands, but some physicians still carried on galenical operations, and themselves prepared the special formulæ they most commonly used. Moreover, owing to the method of prescribing in these times, the apothecaries did not get all the work which should have fallen to them. Certain formulæ known as "public medicines" were commonly ordered by the physicians. These, however, it was customary for the careful housewife to keep in stock, so that unless something special was ordered, the physician's prescription could often be compounded in the patient's house. No wonder then that the apothecary is described by Shakespeare as a man

> In tatter'd weeds with overwhelming brows,
> Culling of simples; meagre were his looks,
> Sharp misery had worn him to the bones.

And whilst, owing to competition, his profits were small, his education did not distinguish him much from others. He had, indeed, a certain amount of repute because he knew something of the action of drugs, and had, or was supposed to have, some knowledge of natural history generally.

> And in his needy shop a tortoise hung,
> An alligator stuff'd, and other skins
> Of ill-shaped fishes.

The fact, too, that he was acquainted with the action of poisons, and kept them in store, gave him a certain position which, however, could hardly be regarded as satisfactory.

In 1617 a great change took place. There was a feeling of dissatisfaction amongst the physicians with the condition of pharmacy, and a petition was addressed to King James the First, praying him to incorporate the apothecaries separately. In compliance with this petition a separate charter was granted in 1617 to 114 apothecaries who had been selected by the College of Physicians as the best instructed of the grocer apothecaries. It was set forth that no one should compound medicines in London unless he had served seven years to an apothecary and been examined and approved by the master and wardens of the Company, and a year later the first Pharmacopœia was published by the College of Physicians, which the apothecaries were ordered afterwards to use as their standard and guide in the compounding of medicines.

The constitution of the Apothecaries' Society had in several ways an important influence both on the practice of medicine and pharmacy. By it the apothecaries were made at first, at least, more useful to the physicians, to whom they to a certain extent acted as assistants, for, besides supplying the medicines ordered, they often aided in carrying out treatment; but in consequence of the establishment of this increased connection with treatment, they became in time recognised medical attendants. At this time the only qualified practitioners in medicine were the physicians, and the apothecaries undoubtedly supplied a much-felt want. It commonly happens when a new function is developed an older one fails, and the more the apothecaries attended to treatment the more dealing in drugs and medicines fell, first into the hands of the grocers, druggists, and chemists, but subsequently into those of the chemists and druggists alone. And this devolution of function went still further in the eighteenth century, for, as stated at a meeting of apothecaries in

1794, the establishment of druggists engaged in the sale of medicines, but supporting themselves also with the sale of other articles, had spread throughout the land, and there could scarcely be found a village or hamlet without a village or hamlet druggist.

You can well understand that these changes did not come about without serious controversies between the physicians and apothecaries on the one hand, and the apothecaries and the druggists on the other. The physicians bitterly complained that the apothecaries undertook the treatment of cases for which by their education they were not fitted. The apothecaries retorted that they were fitted to undertake treatment, for their experience concerning medicine was worth more than the learning of physicians. They, furthermore, stated that many of the physicians still made up their own medicines, and thus deprived apothecaries of their due revenue. They complained, too, that the druggists not only dealt in drugs, but compounded medicines without having had any education fitting them for this work, and that they even gave medicines for ailments, and thus competed with them in the matter of treatment, which the apothecaries thought was a very wrong proceeding. Attempts were made to prevent the apothecaries practising, but they were defeated by a judgment in the House of Lords in 1704, and ninety years later a proposal made by a society of apothecaries to limit the compounding of prescriptions and vending of pharmaceutical preparations to the apothecaries by legislative means was found to be impracticable. Indeed, the process of the transfer of pharmacy to the chemists and druggists seems to have gone on rapidly about this time. After the first few years of the present century it passed almost entirely into their hands, and the apothecaries ceased to dispense for the physicians.

It was perhaps to some extent owing to the curious evolution of apothecaries into medical practitioners and dealers in drugs, and chemists into pharmacists, that this country was so long without any regulations relating to the practice of pharmacy, such as have existed in other countries, and that until 1868 the practice of pharmacy was open to all, no restrictions, educational or otherwise, being in force.

I do not propose to enter into the history of the movement which culminated in the passage of an Act in 1868 preventing the dispensing of poisons, and the assumption of the titles of chemist and druggist by unqualified people, and necessitating, therefore, the due education of those devoting themselves to pharmacy. But, as a member of the medical profession, I desire to congratulate the Pharmaceutical Society on the honourable part it took in initiating and urging forward legislation, which has been advantageous alike to pharmacists and the public. The Act of 1868 was rendered possible by that which the Pharmaceutical Society obtained in 1852, and by the establishment of a museum, laboratories, lectures, and examinations in Bloomsbury Square, and when the Society of Chemists and Druggists joined forces with the Pharmaceutical Society the dislike which so many of our legislators seem to feel to enactments compelling education was at length overcome. Let me point out here that the General Medical Council, by representing to her Majesty's Government in 1864 the necessity of regulating the practice of pharmacy, and by a report issued in the following year gave material help to those who were engaged in pressing forward a Pharmacy Act.

I should like next to say a few words on another aspect of the evolution of pharmacy, the changes which have occurred in the nature of the work itself in our own country.

The Pharmacopœias.

These changes are best illustrated by the pharmacopœias which have been published in Great Britain, commencing with that of the Royal College of Physicians of London in 1618. The first English Pharmacopœias show the position in pharmacy which had been attained by the Greeks and Arabians, for a large number of the formulæ were taken from the works of their leading physicians. The main features of the earliest pharmacopœias are the large number of official substances, and of certain forms of preparations, the extreme complexity of many of the compounds used (one of them contains seventy-two ingredients and many from twenty to fifty), the minuteness of the directions given for compounding them, and the strangeness of some of their ingredients.

The catalogue for the first Pharmacopœia contained 1,254 articles for which the apothecaries were liable to be called upon. In 1632 not less than 180 simple and 27 compound waters were official, whilst there were formulæ given for 80 syrups and preparations of honey, 46 plasters, and 55 ointments, exclusive of sundry oils. One of these deserves quotation.

OLEUM VULPINUM,
MES.

R. Vulpem (quâ fieri potest) pinguem, ætatis mediæ, venatu defatigatam, recenterque occisam, mox et exenteratam, detractâque pelle, nec non ossibus diligenter confractis, in partes plures conscissam. Decoque in

Vini albi et
Aquæ Fontanæ ana libris sex.

Ad medietatem usque, nec sine diligenti despumatione in cocturæ principio: tum demum admisce.

Olei antiqui dulcissimi libras quator.
Salis communis uncias tres,
Florum Salviæ,
Thymi ana libram unam.

Procedatque coctio ad totius aquæ fere consumptionem. mox affundantur Aquæ impregnatæ

(Anethi,
Thymi, an. manipulo uno pleno incocto) libræ octo.

Denuo invicem coquantur omnia lento igne ad consumptionem aquæ: Oleumque ab aquositate post colaturam, infundibulo separatum, usui reservetur.

The details about the fox are very curious. The apothecary must have been a hunting man to be sure of obtaining the proper fat fox, or perhaps the apprentices of those days were told off to secure the right article. And note that the exact amount is given of the materials used to prepare the oleum vulpinum. In the handful of dill and thyme, however, we see a relapse into more primitive pharmacy, but generally the directions are most precise. When, as in many cases, from one to six dozen constituents were mixed together in various way to form one compound, it is manifest that the pharmacists of these early days had heavy duties. But, then, they had no chemical incompatibilities to consider, and the question of purity or impurity of a drug was decided in a very simple fashion. Many other curious and nasty things besides the fox are included amongst the medicines in the pharmacopœias of the seventeenth century, as, for example, human fat and the skull bones of a man who had met with a violent death. The apothecaries must have at times been hard put to it to obtain some of the official drugs, and pharmacists of the present day will not envy them their task of compounding medicines with them.

The pharmacopœias of the eighteenth century show a marked advance in both pharmacology and pharmacy. Chemical products increase in number, and the account of their method of preparation keeps pace with the advancing knowledge of chemistry. Almost all the substances of animal origin disappear, and the electuaries, powders, and other preparations containing a large number of ingredients are replaced by the simpler infusions and extracts. Tinctures increase in number, whilst the waters and syrups are greatly abridged.

In the first pharmacopœias of the nineteenth century we note the indications of a coming change, which greatly added to and altered the duties of the pharmacists. Previously only the mode of preparation of the various substances had been given, but in the pharmacopœias of the London College of Physicians published in 1809 and 1824 a few details are added with regard to the specific gravity which some of the chemicals should have. Though in commentaries on the Pharmacopœia tests for impurities had for some years been described, it was not until 1836 that short descriptions of chemical substances were given in the Pharmacopœia, by which they might be recognised, and by which to a certain

extent their freedom from adulteration might be ascertained. It is worthy of note that in 1836 several alkaloids were made official. In 1851 a further step was taken, and the compounders of medicines were furnished with an official description of some of the vegetable as well as some of the chemical drugs. In the production of the British Pharmacopœia of 1864, issued by the General Medical Council, the aid of the Pharmaceutical Society was sought, and a very great advance was made in the value and completeness of the tests and descriptions given. It was now assumed that the pharmacists had been so far educated in chemistry as to be able to conduct volumetric analysis, and the metric system was allowed in analysis. The tests and descriptions were made still more stringent and exact in the edition of 1885, and in this Pharmacopœia an advance of the greatest importance to pharmacy as well as to medicine was initiated.

Notwithstanding that our legislators have shown but little interest in forwarding the progress of pharmacy, and that no incentive has been given to original research, the pharmacists in Great Britain and Ireland have shown by the work published in the journals an immense amount of energy, not only in devising improvements with regard to the compounding of drugs, but in advancing knowledge as to the nature and amount of the active ingredients contained in drugs and preparations, and in devising methods by which the strength of preparations can be rendered uniform.

The labours of pharmacists and chemists had showed that however great may be the care exercised, the strength in active principles of preparations made in the ordinary way from drugs will differ considerably; they showed, too, that it was possible in the case of some drugs, by modifying the method of making the preparation, to bring them up to a certain standard so far as regard the active principles, and in the Pharmacopœia of 1885 the preparations of opium, cinchona, and nux vomica were standardised, whilst in that of 1898 the list of standardised drugs was increased by the addition of belladonna and ipecacuanha. The introduction of standardisation is a considerable addition to the skilled work required from the pharmacist, and it marks an epoch in both pharmacy and therapeutics.

The Present State and the Future of Pharmacy.

Having dealt very imperfectly, though I fear some of you may think at tedious length, with the evolution of pharmacy, I propose now to allude to some points in its present state and future prospects.

I approach this subject with hesitation, for I speak in the presence of eminent pharmacists. I should hardly, indeed, have ventured upon it here were not that it interests medical men as well as pharmacists and students, and that I know that some of the conclusions to which I, as a medical man, have arrived are in accord with those which have been expressed by pharmacists of large experience. You will have noticed that in recent years, with the publication of each Pharmacopœia, there has been a further call for scientific knowledge on the part of the pharmacists. It is assumed that those who use the Pharmacopœia have had a real and practical training in science, and the tests in the Pharmacopœia have not reached the high water mark of perfection. I do not mean by this that they require to be increased in stringency. I think, indeed, it is quite possible that some of the criticisms which represent certain of the tests as too severe may be found to be correct; but as time goes on, some of the cruder tests will be replaced by others requiring more chemical knowledge and more expertness for their performance, histological examinations will be increasingly relied on in the detection of the sophistication of vegetable drugs, and hence a wider and deeper knowledge of physics, chemistry, and botany will be called for.

I have already alluded to the introduction of standardisation as a considerable addition to the skilled work required from pharmacists, but I am inclined to look upon it also as a sign of other coming changes, which will very markedly affect the future of pharmacy. There are doubtless many who still believe that the active principles, which can be separated from vegetable substances, do not represent the entire curative power of drugs, that the natural combination of minute quantities of other principles present with those on which their activity seems to depend, exerts a subtle influence which renders the preparations of a drug more useful than the chief active principles which can be extracted from it or any possible artificial combination of them. In forming an opinion on such points, however, there is much room for the exercise of the imagination, and some of the differences now supposed to exist between the effects of preparations of drugs and their active principles are, I suspect, due to this. Anyway, it is certain that as the active principles and their exact pharmacological actions have become better known reliance on them has increased, and there has been a greater tendency to think of the preparations of such drugs as belladonna and nux vomica in terms of atropine and strychnine, whilst even in a drug like opium, which contains other active alkaloids, it is generally recognised that the value as a sedative at least is determined by the morphine. There can be little doubt that an important feature in the next Pharmacopœia will be the increased number of drugs standardised. Now between standardisation and the use of active principles, instead of crude drugs, there is only a short step, and though for many a day the galenical preparations which have been in vogue for centuries will be used, still they will, I think, be to a large extent gradually edged out by the active principles. The process has indeed already begun; the large number of granules, tablets, pilules, etc., now employed, containing fractions of a grain of active principles, points to a coming change, and the Pharmacopœia of 1898 has recognised this to some extent by laying it down that the drugs contained in the new forms must answer to the ordinary tests for purity. As the belief in the utility of active principles increases, pharmacists will be required to know more concerning the amount contained in drugs, what possible changes they may undergo inside and outside the body, and the exact chemical relationship between the various principles; they may be possibly called upon, too, for information as to the toxic effects of these principles; for all this they must be well and widely trained in science.

Another feature of the pharmacy of the present day is the great increase in the number of chemical preparations; a few of proved utility have been incorporated in recent editions of the Pharmacopœia, but an immense number built up chiefly by the German chemists, and supplied with the necessary recommendations, are being sent over for use by English doctors, who, for the most part, administer them simply on the faith of these recommendations. A large proportion will, I believe, be found less useful than the older remedies, and some have already been abandoned. Yet there seems no relaxation in the zeal with which new chemical remedies are tried. But for the intelligent employment of these compounds an idea of their chemical structure and its relation to their value is most desirable, while for their combination it is imperative. The pharmacist is often called upon now to give explanations of chemical points, and unless the present system of medical education is altered, and a real knowledge of chemistry and pharmacology made compulsory, a time must shortly come when the functions of the pharmacist will be greatly widened, and in addition to being an intermediary between the manufacturing chemist and the doctor for the supply of the new compounds, he will be an intermediary also for explaining to medical men who use these compounds (which are constantly increasing in complexity) the chemical reasons for their introduction and value, the changes which they may undergo inside and outside the body, and the dangers which may arise from these chemical changes. To fill this *rôle* the pharmacist will be obliged to have not only an advanced knowledge of chemistry, but some idea of physiological action.

Furthermore, if the claims made for the usefulness of some of the extracts of animal organs are made good, the pharmacist will, in the future, have to enter on the wide and intricate field of animal chemistry, which will tax his scientific knowledge even more than does the chemistry pertaining to products of the mineral and vegetable kingdoms.

The older methods of administering medicines by infusions, tinctures, pills and powders, will, I think, be less used, and the newer forms will increase in favour. So far the production of the latter seems to have been largely in the hands of wholesale manufacturers. I sometimes wonder whether it would not be possible for what are sometimes called the elegant forms of administration to be more freely made on a small scale. At the present time a medical man who desires to order medicine in one of these forms is often in doubt whether the preparation he desires can be obtained in reasonable time, unless it corresponds exactly to one of those on the lists of wholesale producers, and sometimes on this account he is driven to order other combinations than he would wish, and by naming the special producer to give the pharmacist much trouble for little profit. I will not enter further into this subject, but only say that I believe there is room in the future for a further development in the art of the pharmacist.

The considerations which I have brought forward, and others which might be urged if time allowed, point to the large amount of scientific knowledge which the practice of pharmacy will require in the future. But it may well be said, what about the other side of the question—will higher scientific education lead to a betterment in a pecuniary and social sense? Now it must be confessed that pharmacy like medicine, can rarely lead directly to fortune making. In medicine, part payment is taken in the pleasures arising from the work itself, and the pharmacist, too, will have to receive part payment from the pleasures of his scientific work, and the position which a knowledge of science will give him among his fellows. I do not suppose that pharmacists, any more than medical men, will ever be free from causes of complaint that unfair inroads are made on their work and emoluments, and that they do not receive a just reward for the amount of work they do. We have seen that from the earliest times the pharmacist has been harassed both on a commercial and on the medical and scientific sides. The work of the Pharmacopolists of old was trespassed on by the way in which other classes took to dealing in drugs, whilst the physicians undertook the compounding of medicines. Later on we find the apothecaries bitterly complaining of the losses entailed on them by the action of the physicians on the one side and of the grocers and druggists on the other.

The Pharmacopolists who combined the sale of drugs with that of other articles, took up a certain kind of medical work as well, and sank low in the social scale. The apothecaries have practically ceased to exist as pharmacists because they took up medical work and were evolved into general practitioners; how will the evolution of pharmacy proceed?

We may note already a loss of some of its older functions and a waning of others. The collecting of herbs has passed into special hands; so, too, has the dealing with drugs in bulk. The production of many medicinal substances, formerly undertaken by pharmacists, is now for the most part accomplished by manufacturing chemists, who use special processes adapted to work on a large scale. I think I see another change impending. The profit arising from the sale of many of the articles unconnected with pharmacy, formerly a source of revenue to pharmacists, is likely to diminish, especially in the large towns; the pharmacist cannot compete with the huge firms which have in recent times become dealers in everything.

But there are other directions in which the work of the pharmacists will develop; the compounding of drugs ought to pass into their hands, and I believe will do so. The practice of pharmacy by doctors is not only an evil to the pharmacist, but a disadvantage to medical men themselves. It leads practitioners to limit themselves unduly to the use of certain drugs, and they lose time which might be devoted to other and more profitable matters. It is true there are many who like to have their medicine from a doctor, but I believe medical men would gain if, wherever possible, they gave up dispensing, and there are few places in which there are not pharmacists ready to take up the work.

Here let me say a word on a matter akin to the one before us. It has been recently stated that secret arrangements are at times made between medical men and chemists, by which the doctor receives a certain proportion of the amount which the chemist charges the patients for the medicines dispensed. If such arrangements are made they are iniquitous and a disgrace to those who make them. I have made enquiries, however, from many chemists in the North of England, and am assured that no such system exists there, and so far those who have made the accusation have failed to substantiate it. It is possible, of course, among the 34,000 members of the profession there may be one here and there so devoid of principle as to be willing to stoop to such conduct. All I can advise you is, that should you ever be approached by such an individual, with a suggestion that you should hand him over any part of your charges for medicine, you should render his exit from your place of business more rapid than his entrance.

I believe not only will the whole of the duties connected with the compounding of medicine devolve before long on the pharmaci ts, but other functions will be taken up by them which pertain to science training, though they are not strictly pharmaceutical, just as in the case of medical men other functions have been taken up which are not distinctly connected with therapeutics, although they follow from medical training.

The chemical investigations which are becoming more and more essential to medical practice might well, I believe, fall into the hands of the pharmacists, as they do into the hands of the chemists and apothecaries in many parts on the Continent, and not only so, but if I divine rightly the future, the pharmacists will in all places be the men of science, the men who *know*. They will be looked up to as such, and it will come to pass that much other work, more or less allied to pharmacy and chemistry, requiring scientific knowledge, will fall into their hands, and they will be remunerated for the lo s of some of the emoluments arising from the purely commercial side of their present work, which I think is likely to occur. I think that even the depressing effects of company pharmacy will be much lessened as the pharmacist becomes more relied on by medical men, not only for safe-guarding the purity of drugs, but for giving help when special information is required on scientific points not directly connected with the cure of disease.

There is one direction in which the temptation to conjoin other work with the compounding of drugs must be avoided. The history of the evolution of pharmacy shows us that there has ever been a tendency for those who deal in drugs to take up treatment, but it also shows us the work of the pharmacist is injured if he assumes the *rôle* of medical practitioner. I know that people will apply to pharmacists for advice as to the use of medicine, but those who give such advice do not obtain the respect of the public, and do harm to the position of pharmacists. If pharmacy is to take the position it is entitled to, all attempts in this direction must be abandoned.

Education.

I have watched with interest and admiration the efforts of the Pharmaceutical Society to improve pharmaceutical education. But if my forecast of the future of pharmacy is correct, further

further educational changes will be required, and I trust I shall not be regarded as wandering out of my proper domain if I venture to make a few remarks on the question of education and examination in pharmacy.

With regard to the Preliminary Examination, I am glad to see the Pharmaceutical Society is following the examples of the various medical corporations, which, with one exception, have ceased, or are ceasing, to hold examinations in Arts, and that the certificates of a satisfactory general education must in future be obtained from bodies which are connected with Arts education and examination; but I hope that in time it may be ordained that these certificates should be furnished before apprenticeship commences. I am not in favour of very rigid rules with regard to the time and manner in which information is to be obtained; but education should be graduated, and the first step should be education in Arts, which should be acquired, not in the middle of, but antecedent to, the commencement of the real work of a pharmaceutical student.

At the present time the final education in the purely science subjects, botany, chemistry, and physics, for the qualifying examination is usually received by pharmaceutical students at the same time as the more technical subjects of pharmacy, pharmaceutical chemistry, and materia medica, and an examination in all at one time follows. The fact that pharmaceutical students pass through an apprenticeship before commencing with formal instruction, renders this mixture of subjects possible, but all men do not come up equally prepared, and some must take harm from it. I think that for the more thorough training in science, which is becoming necessary, an educational division of the subjects will be desirable for all. At present there is no curriculum, and students are tempted to spend as short a period as possible over lectures and laboratory work. The shorter the time men take to acquire knowledge of the subjects of examination and the greater the number of these subjects the less will be the amount of knowledge retained subsequently. I am quite satisfied it would be greatly for the advantage of all if a curriculum were established and students were obliged to distribute their work over a definite period, receiving instruction in science first, and then in the more technical subjects. My belief is that a year at least should be devoted to the science subjects, and that even this will be found all too short for that thorough grounding in science which a pharmacist requires. The lengthening of the educational period would allow of some wider knowledge of physics, and perhaps of some biological training. Moreover, it would allow of all education being practical.

A second year might be devoted to technical training and to the acquirement of a fuller knowledge of organic chemistry, and I think it will become necessary that the technical training be widened, and that instruction should be received in urine analysis, bacteriological analysis of foods, toxicology, and some other subjects. But even if the scientific and technical training be not widened, a two years' educational course for pharmaceutical students is very desirable. I may add that at the Owens College we find little difficulty in inducing most of the students to distribute their work over two years, and that this distribution is a great advantage to them.

The commingling of many subjects has been found to produce unsatisfactory results in medical examinations, and I think it is equally injurious in those connected with pharmacy. I note that the rejections at the minor are extremely high, and though defective methods of education may be to a considerable extent the cause of this, I am inclined to think that it is to some extent the necessary result of combining so many subjects in one examination.

The examination should be divided into at least two parts; there are many objections to the inclusion of all subjects in one examination. It leads to a system of cramming, even though the examination be to a considerable extent practical, for there is a system of cramming for practical as well as for oral examinations. It is a premium on what may be called the examination mind, which is not the highest kind of mind. It is often a hardship on the student who works well and honestly, but, above all, it prevents men working well at any one subject, for excellence in one does not necessarily cover a slight but fatal failure in another at the examination, and, indeed, may lead to it.

The excellence of the Major Examination as at present carried out leads me to think that the work of preparation for it might be utilised for obtaining a science degree in pharmacy. My impression is, and in this I am supported by others better able to judge than myself, that the knowledge required in some of the science subjects is quite equal to that which is necessary for a degree in science, and I look forward to the time when the universities will give a science degree in pharmacy, as they do now in engineering and some other subjects.

I am afraid you gentlemen who are students will think I have forgotten that in the early part of this address I said that I came here to welcome, advise, and congratulate the students of this School, and I acknowledge that the remarks I said I should make on pharmacy and pharmaceutical education have grown to an inordinate length and somewhat crowded out the other part of the work I proposed to myself. But a welcome I am sure you hardly need from me. I know what an interest all your professors take in those who come to work here, and with what kindly feelings they receive you, whether you come as past students or for the first time.

As to advice, my whole address has been devoted to indicating the general course you should adopt in order that you may be successful in life, but there is one thing further I should like to impress upon you who have just finished your work here. Remember that your education is not ended, but beginning; that you must be always adding to your knowledge, otherwise you will surely fall behind in the race of life. And do not be content simply to absorb the knowledge acquired by the work of others, but try yourselves to add to the sum total of knowledge. It may not be possible for many of you to take up work in the admirable laboratories which have been provided for research by the Pharmaceutical Society, though if you have a chance of so doing let me strongly advise you to take it. But cultivate exact observation, for by so doing you will not only advance your own interests, but by adding to knowledge you may advance the interests of your fellow men.

It is customary on occasions like these to advise students who are entering for the first time to devote themselves to work, but my experience of pharmaceutical students is that they do not require this advice, at least at the Owens College we find them amongst the hardest and steadiest workers of those who attend the classes, and if there are any among you who require urging to work, I would give you a different piece of advice—don't be pharmacists. Hard work will be always necessary, and without it you will assuredly fail.

With regard to you who are joining the School, I can very heartily congratulate you on the advantages you will have. You will work under some of the ablest men of the day in their special department, and I know that so far as laboratories and the Museum are concerned, you could nowhere find a better place to work in.

To those who have gone through the course here I offer my congratulations, because I feel sure that they have received great advantages and an education which will stand them in good stead through life.

Finally, I wish to congratulate those who have taken prizes and honours. Prizes may not be a certain sign of future success, but they point in that direction, and I trust that you who have gained prizes may show in your future career that your success was not the outcome of chance, but due to industry and ability.

PHARMACEUTICAL SOCIETY.

RE-OPENING OF THE SCHOOL OF PHARMACY.

The opening proceedings of the School of Pharmacy took place on Monday, October 2, in the Lecture Hall of the Society, when a large gathering of past and present students, members and friends, amongst whom were many ladies, assembled. The chair was taken at 3 o'clock by Mr. W. Martindale, President of the Society, who commenced the proceedings by announcing, with great regret, that the Secretary was unable to be present, owing to severe family bereavement, and that Professor Greenish also was that day attending the funeral of his father, a former President and Treasurer of the Society, and for many years a member of the Council.

Presentation of the Hanbury Medal.

The President said the first business of the day was the presentation of the Hanbury Medal. He said: This medal was established in memory of our esteemed countryman Daniel Hanbury, and is awarded biennially for high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs. It has been awarded to such illustrious men as (1) Flückiger, (2) John Eliot Howard, (3) Dragendorff, (4) William Dymock, (5) Gustave Planchon, (6) Hesse, (7) Maisch, (8) Vogl, and (9) De Vrij. The award is made by the Presidents of the Linnean, Chemical, and Pharmaceutical Societies, and of the Pharmaceutical Conference, with a pharmaceutical chemist in addition. Our choice this year has fallen upon Herr Geheimrath Albert Ladenburg, Ph.D., Hon. M.B., and Professor of Chemistry at the University of Breslau. He is best known to English pharmacists by his synthetic work in the production of homatropine. On splitting up atropine, tropic acid and tropine can be formed as derivatives; the latter he combined with amygdalic acid to form a compound which is easily converted into oxy-toluyl-tropeine or homatropine, an artificial alkaloid which, with its salts, has proved of the greatest service to ophthalmic surgery. His mathematical method of treating synthetic formulæ, and his prismatic benzene ring, place him in the first rank of chemists as a theorist, while, as regards his practical work, on looking through his long list of communications to scientific societies and literature at home and abroad, we notice articles on "The Valency of Nitrogen," on "Synthetic Alkaloids," on "The Relationship between Hyoscyamine and Atropine, and the conversion of one alkaloid into the other," on "Hyoscine," on "The Mydriatic Alkaloids Occurring in Nature," on "The Synthesis of Coniine," and "On the History and Constitution of Atropine," in addition to the compilation, with other collaborateurs, of a dictionary consisting of more than a dozen volumes treating on inorganic and organic chemistry. As an indefatigable worker and investigator, we have, therefore, few who are his equal. Further, his investigations on atropine, hyoscyamine and hyoscine have been the subjects of spirited discussions by other chemists who have followed him. I had the pleasure of being introduced to him by Dr. Thorpe at the recent meeting of the British Association at Dover, and he expressed regret at his inability to be present on this occasion, his duties at Breslau necessitating his early return to Germany. The medal will, therefore, be forwarded to him through the German Embassy, and Baron von Mirbach, representing the Embassy, has been kind enough to come here to take charge of it. I had the pleasure of receiving a letter from Dr. Ladenburg this morning, in which he says: —

Dear Sir,—It is with great regret that I have not been able to appear personally at the annual meeting of your Society on Monday to be awarded the Hanbury Medal; but I want to express to you, Mr. President, and to the members of the Pharmaceutical Society, on this same day, my best thanks for the great honour you have conferred upon me, a distinction I am proud of.

I shall announce to you the receipt of the golden medal as soon as it will be delivered to me.

You will have a copy of my paper I read in Dover in a few weeks, as the definite print will not be ready before.

Allow me to express to you the pleasure of having made your acquaintance at Dover, and I hope it will not be the last I saw of you.

Yours truly,

Kaiser Wilhelmstrasse 108. Albert Ladenburg.
Breslau, Sept. 29, 1899.

The President having handed over the gold medal,

Baron von Mirbach said he was quite sure it would be highly appreciated by the recipient.

The Dean's Report.

Professor Norman Collie, Dean of the School, who was next called upon to read his report, said that during the fifty-seventh session of the School of Pharmacy sixty-eight students had attended the various lectures and practical classes. In the chemical department the work throughout the year had been carried on satisfactorily, both by the ordinary students and those engaged in research. At the beginning of the session, owing to the chemical laboratory being entirely full, additional room had to be found; this was done by Professor Greenish vacating the octagonal laboratory, which was then handed over to the chemical department. Since then a further enlargement had been made, a number of new benches having been added to the chemical laboratory, making it possible for more students to work there. During the past year the attendance at the lectures and practical classes had been excellent. Also during the past year several changes have been made in the demonstrators in the chemical department. The staff regret that it has lost the services of Mr. Dewhirst and Mr. Frye, owing to their promotion; their places have, however, been efficiently filled by Mr. Wallis, a former student and prize man, and Mr. Gompertz. In this department the Sessional Silver Medal for Theoretical Chemistry was taken by Mr. T. E. Wallis, and the Certificates of Honour were awarded to Mr. H. Payne, who has also gained the Pereira Medal, and to Mr. W. J. Spurway. The Sessional Silver Medal for Practical Chemistry was awarded to Mr. W. L. Nundy, and Certificates of Honour to Mr. T. E. Wallis and Mr. G. Pattison. At the end of the elementary course the Bronze Medal for Practical Chemistry was awarded to Mr. T. W. Maddison, and Certificates of Honour to Mr. C. H. Baker and Mr. W. T. Ransom. In Theoretical Chemistry Mr. T. W. Maddison was awarded the Bronze Medal, and Mr. J. F. Snook and Mr. G. A. Taylor received Certificates. In the Research Laboratory Mr. E. M. Chapman has been awarded the Salters Scholarship, and Mr. W. Garsed the Burroughs Scholarship.

Professor Green reports that the attendance and attention of the students during the session were satisfactory. The medals and certificates were awarded as follows:—Major Course—Silver Medal, Mr. Wallis; Certificates of Honour, Miss Magan and Mr. Garsed. Minor Course—Bronze Medal, Miss Annesley; Certificates of Honour, Mr. Finnemore and Mr. Gray.

Professor Greenish reports that in materia medica forty-five students had entered for the Elementary Course and fifteen for the Advanced. In both classes the work had been well sustained throughout the session, the attendance being better than any previous session. In the Elementary Course Mr. H. Finnemore had carried off the Bronze Medal, and Mr. P. Gray and Mr. N. E. Melbourn the two Certificates of Honour. In the Advanced Course the Silver Medal had been awarded to Mr. H. Payne, and Certificates of Honour to Mr. T. E. Wallis and Mr. W. Garsed. The pharmacy class had also been well attended, forty-five students having been entered. In this class the work had been diligently carried on, and the attendance was no less satisfactory than in the materia medica. At the termination of the course the Silver Medal was awarded to Mr. T. W. Maddison.

The President then presented the prizes and certificates, as mentioned in the above reports, adding a few words of approbation and encouragement to the various recipients.

The Herbarium Competition.

Professor Green being called upon to report of the Herbarium Competition, after briefly describing the conditions imposed, pointed out the value of field botany as an introduction to the science. The points to which the examiner looked chiefly were not simply the number or rarity of the specimens—indeed, rarity scored rather against the collector—the plants should be those of common occurrence, and should be selected to illustrate as many natural orders as possible; secondly, they must be typical plants of the orders, and must represent the plant at different times of its life—it should be submitted in fruit as well as in flower, so as to form a complete picture of the organism. These points he was sorry to say were not always attended to. On the present occasion Mr. Bennett, of Dover, had sent in a collection of very high merit from all these points of view, and he had advised the Council to award him a Silver Medal. The other competitors showed considerable assiduity, but in many cases overlooked some or other of the points he had mentioned, and he was not able to recommend them for recognition.

The President having presented the Silver Medal to Mr. Bennett, Professor Thomson was called on to report on the examination for

The Council Prizes.

He said: On behalf of the examiners in the competition for the Council Prizes I have the honour to report that eleven candidates entered for the examination. In materia medica the papers, as a whole, were well done, showing an intimate knowledge of the literature of the subject. The replies of most of the candidates gave evidence of careful training and steady work. The papers of the three prizewinners indicated a wide range of reading, together with such a grasp of the subject as can only come from accurate observation and direct experiment. This was especially seen in the case of the paper of the winner of the Pereira Medal. In botany the papers were, on the whole, satisfactory; the better ones being of distinct merit. In chemistry the papers of the candidates getting the highest marks were very good indeed. The majority of the papers were satisfactory, but a few disappointing, in one or two cases coming below the standard of the Major Examination. The result of the examination, however, was satisfactory.

The President, previous to presenting the Pereira Medal to Mr. Payne, explained the origin of the prize, and remarked that eminence in pharmacy could only be attained by patient and long continued hard work.

The Jacob Bell Scholarships.

Mr. Lucas was next called on to report on this examination. He said: It is a great pleasure to me to take part for the second time in the examinations for the Bell Scholarships. I am sorry that my colleague Mr. Pinches is not here to-day to report for himself, and I must therefore do the best I can to report for us both. Before proceeding to the statistics of this year's competition, it is desirable to point out that a change has been made in the examination so far as the scientific subjects are concerned. Not a radical change, but rather a modification in the direction of a better definition of the standard to which competitors are expected to attain. Hitherto, these subjects have been defined as "Elementary Chemistry, Botany and Pharmacy," but the Council deeming it inexpedient to leave the interpretation of "Elementary" an open question, recently substituted in the regulations the following paragraph:—

> Botany, chemistry, and pharmacy, based upon an elementary knowledge of the principal chemicals, drugs, and processes of the British Pharmacopœia, such as a student may be reasonably expected to have acquired during his apprenticeship.

With a view to keeping the examination within the limits contemplated by the new regulations, the Council further decided that the technical examination should no longer be divided into three parts, each having separate examiners and each being independently appraised, but that botany, chemistry, and pharmacy should be regarded as one subject and be conducted by one examiner. My only colleague, therefore, has been Mr. Pinches, of the College of Preceptors, who has again set and examined the papers in the school subjects. As the first technical examiner under the new arrangement, the work of the candidates has been invested with especial interest, and I am glad to say that, speaking generally, the papers submitted were of a satisfactory nature, in so far as they bore little evidence of that *special preparation* or *cram* which the Council desires to discourage. Many of the answers showed a considerable degree of merit, and indicated that the student must have worked intelligently and industriously during his term of pupilage. Turning now to statistics, there were twenty-seven competitors for the Bell Scholarships and four for the Manchester Scholarship. Last year I find there were twenty-five for the Bell and two for the Manchester. Of the twenty-seven competitors for the Bell scholarships, no less than ten obtained two-thirds of the maximum number of marks, and the two who came out first obtained 80 per cent. of the maximum. There is something particularly gratifying in the fact of the first of the two scholars this year being Mr. Harold Deane, a grandson of a former President of the Society. I would, however, remind him that his fellow scholar, Mr. Heslop, came close at his heels. With regard to the Manchester Scholarship I am sorry to have to report that none of the four competitors came anyway near the standard required for the award of the Scholarship. According to Mr. Pinches' return not one of them merited a single mark in arithmetic, and in the other subjects they exhibited lamentable weakness. The competitor who did best in the whole examination only obtained slightly over 30 per cent. of the maximum number of marks. This unfortunate condition of affairs will, it is hoped, be remedied by the students in the Manchester District before the next competition. Weakness in arithmetic was also a prominent feature in the Bell competition, and this appears to me to point to a serious defect in the educational equipment of young men who are entering a calling in which ability to perform accurate calculations is an absolute essential. I speak with the painful experience acquired in the examination of Minor candidates, and if I am going outside the strict limits of my duty as a reporter on the Scholarships in alluding to such a defect, it is simply because I feel strongly on the subject, and am persuaded that publicity may produce some improvement.

The President, having suitably exhorted the winners of the Bell Scholarships, and handed them the books which accompany these prizes, and announced the names of the Salters' Research Fellow and Burroughs' scholar for the coming session, called upon Dr. Leech to give the Inaugural Address, which is printed at page 333.

The President, in proposing a vote of thanks to Professor Leech, said the Address had touched upon many points of great interest, not only to students entering the School, but even to those who had borne some of the heat and burden of the day. The employment of some animal substances as materia medica, such as cockroaches and Spanish flies, seemed to be gone out, but others had come in, and parts of animals were now used which a few years ago would have been entirely discountenanced. Reference had been made to the mode in which the art of medicine was formally carried on in the East, and he believed it still prevailed to a certain extent; at any rate, when he was in Cairo, some few years ago, he saw very much what had been described. They would all welcome the advance of scientific medicine in the direction of greater exactness and further standardisation, but there was a limit even to that. In the case of food it would be hardly possible to insist on a certain proportion of albumin, gelatin, etc., in a beef steak, and certain simples were often of great service in medicine, and he believed would play their part in it to the end of time. He was pleased to hear what Professor Leech said with regard to degrees in science for pharmacists, but he was inclined to think it would be better for them to take a degree in pure science, if it were open to them, without having to take up a branch of applied science. If, for instance, zoology were omitted from the examination for B.Sc., he believed a great many pharmacists would go in for it. They were much indebted to Professor Leech for his valuable address, which would afford much food for reflection.

Mr. Carteighe, in seconding the proposal, said he should like all present to bear in mind that they were indebted to Professor Leech, not only for his admirable address, but also because he represented that high type of physician who, while keeping himself in touch with his own special department of science, had also taken a deep interest in materia medica and pharmacy. He had succeeded in establishing in Owens College such conditions that anyone in the neighbourhood could go through an entire curriculum in all the subjects required for the examinations of the Pharmaceutical Society. He hoped the time was not far distant when the enforcement of such a curriculum as he had described would be practicable, and when in every great city where there was a University College young men who had been apprenticed in the neighbourhood, who had attended the science lectures and practical demonstrations there, would be able to come up and pass the examinations as easily as those who attended the course of instruction in that building. It was obvious now that education was so much in the air that the mere smattering of knowledge which used to suffice for passing an examination would not do in future. Professor Leech had been telling them what he as an ex-President and Examiner had been saying for over thirty years. It was no good mincing matters; those who entered pharmacy must be properly trained and educated; if they could not fulfil the requisite condi-

tions they would be nowhere in the race. Pharmacy was always undergoing a process of development, and Professor Leech had done infinite service, both to the students and members, in pointing out some of the possibilities of the future. The Council were deeply indebted to him for his unwearied efforts, under great difficulties, to secure at Owens College a complete system of pharmaceutical education, and he was pleased to have that opportunity of tendering him their warmest thanks.

The vote of thanks having been carried by acclamation,

Professor Leech, in responding, said he had always taken great interest in pharmaceutical education, and was pleased to think that he had been the first to provide a complete course in connection with a University College. He was also gratified to find that the idea had taken root in other places—Liverpool, Birmingham, Sheffield, and Nottingham—and he believed that in a short time similar opportunities would be afforded in all the leading towns. It had been a great pleasure to him to come amongst them, and he hoped both the School and its students would have a prosperous career.

The proceedings terminated by an adjournment to the Examination Hall for light refreshments and conversation.

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, OCTOBER 4, 1899.

Present:—

Mr. W. Martindale, President.

Mr. G. T. W. Newsholme, Vice-President.

Messrs. Atkins, Bateson, Carteighe, Corder, Cross, Glyn-Jones, Harrington, Harrison, Hills, Johnston, Park, Savory, Southall, Storrar, Symes, Warren, and Young.

The minutes of the previous meeting in August were read and confirmed.

Dr. Symes asked if any further communication had been received from the Privy Council with regard to the question of placing carbolic acid on the Poison Schedule.

The President said nothing further had been heard as yet, but he believed the matter was receiving the consideration of the authorities.

The Late Mrs. Richard Bremridge.

The President said they had to excuse the absence that day of the Secretary and of Mr. Allen, who were attending the funeral of Mrs. Bremridge, and he would ask the Vice-President to move a resolution on the subject.

The Vice-President moved: "That the Council desires to express its sense of sincere sympathy with the Secretary and Registrar, and with Mr. C. B. Allen, on the death of Mrs. Bremridge." It was not necessary to say anything to commend this resolution to the Council, for every member must sympathise very deeply with the Secretary and Mr. Allen. The occasions on which Mr. Bremridge had been absent from the Council were very few, and they would all hope that his health, which had not been very vigorous lately, would soon be completely restored.

Mr. Cross seconded the motion, which was at once carried unanimously by the members rising in silence.

The Late Mr. Thomas Greenish.

The President announced the death of Mr. Thomas Greenish, at the age of eighty-two, which took place on September 28. Mr. Greenish was a student of the Society from the year 1846 to 1847, and took the Pharmacy Prize in 1847, and became a member of the Society in the same year. He was elected a member of the Council in 1871, acted as Treasurer for the years 1878, 1879, and 1880, and President for the years 1880 and 1881. His term of office as President was rendered memorable by a meeting of the International Congress of Pharmaceutists in London in 1881, and by the legal proceedings against the London and Provincial Supply Association, Limited. He retired from the Council in May, 1895, owing to failing health. The late Mr. Greenish was a typical pharmacist, and had shown the interest he took in pharmacy, particularly with regard to a few pharmaceutical preparations, one of which being syrup of phosphate of iron. In his early days he was an amateur photographer, being a skilful manipulator in the wet plate process, but was latterly better known as a microscopist, and had taken up the histology of drugs. Mr. T. Greenish, who was also a frequent traveller on the Continent of Europe, left a distinguished son, a professor of the Society, with whom and the family of the deceased the Council wished to express their sympathy in their bereavement. He concluded by moving the following resolution:—"That the Council learns with deep regret the death of Thomas Greenish, who had filled with dignity, energy, and ability the responsible offices of Treasurer and President of the Society. During a period of nearly a quarter of a century he conscientiously served the Society as a member of the Council, securing by his unremitting devotion to the duties the grateful recognition of the members of the Society and the high regard of his colleagues. His personal qualities endeared him to a large circle of friends, who feel his loss, but who will long hold his memory in affectionate remembrance. The Council desires to officially record its high appreciation of the work and character of Thomas Greenish, and to tender its sympathy with his family."

The Vice-President seconded the proposition. He said the whole of the long life of the late Mr. Greenish had been full of work for pharmacy and science. It had been his pleasure to make Mr. Greenish's acquaintance in the year 1886, when he came to Sheffield to deliver the inaugural address. Although Mr. Greenish had been away from the Council for some time, the members had had many opportunities of meeting him since he retired from their body. He thought Mr. Greenish was one of the first men who applied the use of the microscope to materia medica, and from his labours had grown up the great work now being done in the histology of drugs.

Mr. W. Hills said he was one of the few remaining members present on the occasion of Mr. Carteighe being elected President as the successor of Mr. Greenish, and he wished to express his personal regard for the late Mr. T. Greenish, as a thoroughly representative pharmacist, a liberal supporter of the Pharmaceutical Society, a kind, generous, and honourable man.

Mr. Atkins said the President had given a very interesting sketch of the pharmaceutical history of the late Mr. T. Greenish, who had passed away to his rest full of years and honour.

Dr. Symes said he should like to add a word, as he was a member of the Council during Mr. Greenish's presidency. He also accompanied him on his first visit to Paris, when, though they were simply taking a holiday, having obtained introductions, they were able to visit and inspect several of the larger pharmacies and factories, and he was much struck with the keen interest which Mr. Greenish took in all pharmaceutical matters, and his great powers of observation, which enabled him afterwards to discuss what they had seen. He had the greatest respect for Mr. Greenish, who devoted his whole life to pharmacy, and had left his footprints on the sands of time.

The President, in putting the resolution, which was carried in the same way as the previous one, reminded the members that a biographical notice of Mr. Greenish, giving more particulars than he had been able to enter into, appeared in the Journal for November 12, 1898.

Decease of Honorary Members.

The President said they had also to regret the death of three honorary members since the last meeting, of whom he spoke as follows:—

Anton von Waldheim, died August 9, aged sixty-nine. He was probably the best-known Continental pharmacist in British pharmaceutical circles, and was styled the "Father of Austrian Pharmacy" by his fellow countrymen. His connection with the work of the International Pharmaceutical Congress, and his interest in the compilation of an International Pharmacopœia, are matters of history which are in every pharmacist's knowledge. He attended most of the meetings of the Congress, and had sufficient faith in the possibility of an universal medicine book as to draft an embodiment of his ideas on the subject. The subsequent fate of the draft is unfortunately wrapped in mystery. Herr von Waldheim was present at the London meeting of the Congress in 1881, when he represented the Austrian Pharmaceutical Society, of which body he was then Vice-President. There is a melancholy interest in recalling that the President of that Congress meeting was our dear old friend Thomas Greenish, whose death I have already had the sorrowful duty of announcing to you to-day. Herr von Waldheim had been an honorary member since 1887, and was a typical apotheker, having been born in the profession, so to speak (for his father was an apotheker), and he passed nearly the whole of his life in the Viennese "apotheke," which he inherited. For some time in his early life he learned English pharmacy in the establishment of Messrs. J. Bell and Co., Oxford-street. Personally I met him and fraternised a good deal with him in 1881, during the meeting of the Pharmaceutical Congress, and again in 1884 in

Vienna, during the first International Pharmaceutical Exhibition. His genial and polished manners attracted everyone to him with whom he came in contact.

Sir Edward Frankland, F.R.S., died August 9, in Norway. His connection with the Society as an honorary member dates from 1862, at which time he had already won a prominent place in the scientific world as an original worker in pure chemistry. His chief work has been in the direction of organic analysis and synthesis, and in investigating the problems of physico-chemistry. He was Professor of Chemistry at Owens College nearly fifty years ago, and subsequently held professorial appointments at St. Bartholomew's Hospital, Royal Institution, Royal School of Mines, and the Royal College of Science. He showed considerable interest in our Society's educational work, and was a member of the Research Committee. Perhaps that interest may have arisen from the fact that in his youth he had been for some time associated with a Lancaster chemist and druggist. Sir Edward was seventy-four years of age. His work on sanitary sewage science and water supplies has made his name a household word wherever English is spoken.

Dr. Kanny Lall Dey, Rai Bahadoor, C.I.E., died at Calcutta on August 16, 1899. He was elected an honorary member of the Society in 1863, at which time he was Professor of Chemistry in the Calcutta Presidency College, and was prominently associated with chemical teaching in India. He filled in succession nearly every post of importance in connection with the scientific work promoted by the Indian Government. But his chief claim to distinction lies not so much in his educational work in chemistry as in the valuable investigations on the medicinal resources of India, which he commenced as far back as 1862, and continued almost to the close of his life. His great work was the collection of descriptive notices on Indian medicinal products, published under the title of "Indigenous Drugs of India," and as a recognition of this Society's encouragement to workers in the field of pharmacognosy, Dr. Dey prefaced his book with a dedication to the Pharmaceutical Society of Great Britain. He was a F.C.S. of London, and had received the diploma (*honoris causâ*) of a number of foreign scientific bodies.

The list of hon. members had thus been reduced by three, and the Council would next year have to consider how it should be filled up. He would suggest that he be authorised to write to the respective families of these distinguished men, condoling with them on their loss.

This was unanimously agreed to.

Election of Members.

The following persons having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Baker, George Bertram; Sheffield
Bones, Arthur Anderson; Coventry
Bray, William John; Romford
Bryan, Howard William; Marshfield
Carr, James Bonwell; Weston-s.-Mare
Chadwick, Milner Bright; Manchester
Coleman, Joseph; Stansted
Cowling, Ernest; Wallingford
Davis, John Butler; Blackheath
Dring, Henry; Wymondham
Hardern, A. E.; Barrow-in-Furness
Jones, David Jordan; Barking
Legge, H. G. B.; Nottingham
Maddison, T. W.; Hebburn-on-Tyne
Maugham, Thomas; Brisbane
Mays, Sydney Walter; Reading
Mushet, Robert; Kilmarnock
Owen, Thomas Pritchard; Pentre
Read, Thomas; Sandwich
Scott, Samuel; Barrow-in-Furness
Stokes, Charles Albert; Bristol
Venables, Samuel Henry; Gorleston
Weiss, Richard; Houndsditch
Wilson, William Smith; Moffat

Election of Student-Associates.

The following persons having passed the First examination, and tendered their subscriptions for the current year, were elected "Student-Associates" of the Society:—

Bateman, Arthur R.; Christchurch
Benson, Sydney; Wigan
Brown, Benjamin J.; Leamington
Bryson, Robert D.; Walker Burn
Campbell, Collin; Ardrishaig
Earl, Fred Greenwood; Eccles
Furber, John; Bowes Park
Hilton, Norman R.; Coventry
Hodgkiss, Thomas W.; Ilkeston
Hopkins, Sherriff B.; Birmingham
Isherwood, Joseph E.; Blackburn
Jones, John Ellis; Penycae
Kenway, Bertha Anne; Bristol
Knight, Alfred W. P.; Wincanton
Laws, Karl A.; Newcastle-on-Tyne
Lindley, James Albert; Prescot
Longstaff, William C.; Houghton
Lowndes, Ernest A.; Birmingham
McCrae, A. C.; Newton Stewart
McLaren, Donald L.; Dollar
Morris, Skone R.; Haverfordwest
Nicholson, George; Kirkby Stephen
O'Hara, Thomas; Nottingham
Proctor, Samuel Hugh; Halifax
Readley, Robert; Jarrow-on-Tyne
Robinson, Alfred E.; Norwich
Robinson, George K.; Barnsley
Sambrook, John Thomas; Monmouth
Shepherd, Ernest F. G.; Lancaster
Stables, John; Doncaster
Thornewell, Albert R.; Birmingham
Tout, William Henry; Plymouth
Walker, William Towler; Settle
Watson, William Reid; Shetland
West, Francis Paynter; Liskeard

Restoration to Register.

The name of the following person, who has made the required declaration and paid a fine of one guinea, was restored to the Register of Chemists and Druggists":—

George Frederick Tuck, 3, The Pavement, East Ham, E.

Several persons were restored to their former status in the Society upon payment of the current year's subscription.

Finance Committee.

The report of this Committee was read, including a recommendation that various accounts be paid.

The President moved that the report and recommendations of the Committee be received and adopted, which was carried unanimously.

Benevolent Fund Committee.

The report of this Committee recommended the grant of £85 in the following cases:—

A registered chemist and druggist (66), who has had five previous grants. (Goole.)

A registered chemist and druggist (72), suffering from chronic illness, has had an annual grant since 1892. (Portsmouth.)

A pharmaceutical chemist member and subscriber (74), who had been in business for nearly fifty years, but had to retire in June last. (Seacombe.)

A widow (46), of a registered chemist and druggist, who has had several previous grants. (Walthamstow.)

A registered chemist and druggist (68), who has had three previous grants. (Nunhead.)

A former member (71), who had a grant last year. (Anstruther.)

A registered chemist and druggist (68), who recently failed in business, and is trying to obtain a situation. (Wrexham.)

A chemist and druggist member, formerly in business in a small way, but has recently failed. (Plaistow.)

A widow (78) of a member and subscriber. (London.)

Three cases were deferred for further information, and three were not entertained.

The death, on September 8th, of Mrs. Jessie McIntyre, of Berwick-on-Tweed, at the age of 84, who had been an annuitant since 1887, was reported.

A statement was submitted showing the financial condition of the Fund, the balance on current account on September 30 being £1,201 10s. 10d., and on the donation account £703 3s. 5d. The number of annuitants on the list in October, 1898, was 43, and 4 were added in December, making 47; 5 had died during the year, leaving 42 on the list. The Committee recommended that four annuitants be elected on Tuesday, December 12.

The following were unsuccessful at the last election:—

Baxby, Emily, 64, Forest Gate.
Stangroom, Fredk., 64, Cley-Next-the-Sea.

The Committee recommended that the following be placed on the list of approved candidates:—

Partridge, Thomas S., 71, Liverpool.
Troke, Charles, 72, Penge.
Burrows, H. Charles, 82, Syston.
Holt, Richard W., 74, Seacombe.

The Vice-President, in moving the adoption of the report, said a great number of cases had been dealt with by the Committee, which was due to the fact that two months' work was rolled into one, owing to the vacation. Several of the cases were of considerable interest, some being more deserving than others. One man who had applied for a grant would have had a very good chance of obtaining it if it had not been for the zeal and energy of one of their local secretaries, who had seen the applicant and made a searching inquiry into the circumstances of the case, the result of which was that the application was refused. The applicant had said that he was 90 years of age, but on investigation it turned out that he was born in 1854. Their thanks were due to the energetic way in which their local secretaries did their work.

The resolution was carried unanimously.

Election of Annuitants.

The Vice-President moved that four annuitants be elected in December next, and that the election take place on Tuesday, December 12, at 10 a.m. In October, 1898, there were forty-three annuitants on the list, and in December of that year four more were added, making a total of forty-seven. Since then there had been five deaths, but although the Fund was in pretty much the same position as it was in the previous year, having regard to the number of casual grants which had to be made, it was felt desirable to fill only four of the vacancies.

The President, in putting the resolution, said the Fund was supported very liberally by their members, but he pointed out that it was not yet sufficient to meet all the applications.

The resolution was carried unanimously.

Meeting of Local Secretaries.

Mr. Cross, pursuant to notice, moved:

That it be referred to the General Purposes Committee to consider whether it would be advisable to summon a meeting of Local and Divisional Secretaries of the Society, to be held in London during the week in which the sessions of the British Pharmaceutical Conference are to be held next year, with a view to secure uniformity of action among those officers in carrying out the Society's work, and to discuss matters affecting the welfare of the Pharmaceutical Society.

This was not a new subject. Two years ago he raised the question of holding such a meeting, and it was referred to the General Purposes Committee, but circumstances then arose which made it inconvenient that such a course should then be adopted, and the matter fell through. This motion did not commit the Council to anything. It merely asked the Committee to consider the advisability of calling the secretaries together, and why it occurred to him that it would be advisable now was that, during the late Conference at Plymouth, he found there was a desire amongst local secretaries, or, at any rate, amongst the members, that some such conference should take place. There was, in fact, a meeting of local secretaries held at Plymouth, but it was not in any degree representative, and some local secretaries even attending the Conference knew nothing about it. He happened to be present, and finding there was such a feeling as he had mentioned, he thought it would be much better for such a meeting to be called from headquarters, and it seemed that the Conference next year would offer an unique opportunity for such a gathering. By comparing notes and taking counsel together, results might be attained, which would conduce to further the best interests of the Society. He was aware that the time was pretty fully occupied at the Conference, but there would probably be less difficulty in getting a good meeting in London than elsewhere. The matter did not require any lengthy explanation at present, but he had no doubt an agenda could be prepared, the discussion of which would conduce to the best interests of pharmacy.

Dr. Symes, in seconding the resolution, said he made a suggestion some years ago that local secretaries should be invited to attend the annual meeting of the Society, with a view to holding such a conference as was now referred to; but after the able paper read by Mr. Smith, of Liverpool, last October, on the duties of local secretaries, in which he emphasised the necessity for their meeting together, he had come to the conclusion that the meeting of the Conference would be a more suitable opportunity than the annual meeting of the Society. There were many things which could be discussed with advantage at such a meeting, one being the desirability of having a large number of assistant local secretaries in large towns. As a former local secretary for Liverpool, he could say that the work was very much better done now, when there were six assistant local secretaries, and he had been told by gentlemen from other towns that the local secretaries would be very glad of such assistance; for it was impossible for the work to be thoroughly done single-handed. The Council never refused to make such appointments when asked, but it would be well, he thought, for the subject to be discussed. The tendency appeared to be for the business of the Conference to extend over another day, and he thought time could easily be found for such a meeting. At any rate the experiment might be tried next year, even if it were not found desirable to continue it every year.

The President, in putting the resolution, said some of the local Societies did their work very well, but some of them would be none the worse for a little more zeal, which might be infused into them by such a meeting as was proposed, which might be all the more useful as it would be held a few months before the appointment of local secretaries for the ensuing year.

The resolution was carried unanimously.

Law and Parliamentary Committee.

This Committee had passed the following resolution, which it recommended for adoption by the Council: "That a clause be prepared dealing with company pharmacy, with the object of asking the Government to include such a clause when a company's bill is next introduced in Parliament."

The President said the matter was discussed at great length by the Committee, especially as to what should be the policy of the Council, and what clause would meet the requirements of the present position. He moved that the report be adopted.

Mr. Young said he could not refrain from expressing his satisfaction that the Committee had brought forward this resolution. Possibly it was an unimportant step, but at any rate it was a step which would lead them from the abstract and chaotic into the region of the concrete. Until yesterday morning he was under the impression that Mr. Carteighe was correct in saying that they had a fairly definite policy before the country with reference to pharmaceutical questions, but after the discussion of last evening he had come to the conclusion that they had either no policy at all, which was confusion, or that they had a dozen or more policies, which was confusion worse confounded. This resolution committed them to nothing in particular, but it did commit them to the necessity of focussing their views into something concrete and tangible, which all could understand. It would be unwise to make any suggestion which might result in a debate such as took place in committee, and which was absolutely fruitless, but he might be allowed to express the hope that the clause when drawn should be more or less in accordance with the resolution passed by the Council in June last, and that, at any rate, one main feature should be the defence of their titles. Whatever it might be wise to leave out or to include, surely there should be perfect unanimity for this, that it ought to be impossible for any body of men as a corporation to use titles which could only be obtained by individuals.

Mr. Atkins said he wished it to be understood that he did not vote in favour of the resolution which had been passed by the Law and Parliamentary Committee on the previous evening because he distinctly objected to it. He was not prepared personally to surrender those privileges which, he thought, they had fairly earned and ought to retain. He had yet to learn that the suggestions which they had sent to the Lord Chancellor had not been favourably received. On carefully reading the Lord Chancellor's speech, he had come to the conclusion that the noble lord viewed their position far more favourably than was generally imagined. He thought it would be unwise on their part to show any measure or degree of surrender on this point. It had been argued with great ability that it was policy on their part to accept the inevitable, but he felt that if disestablishment and disendowment came at all it should be from without. Although Mr. Young said the resolution committed them to nothing, it at least committed them to a stage further than they arrived at last June. No doubt the suggestions that the Council had made might not be accepted by Parliament, but he had every hope that they would. If they were not, at least he should have a clear conscience that he had done his very best to secure what they had all along striven for, and to defend the chemist's personal qualification, obtained by education, examination, and registration, and he looked, with a profound sense of fear, to disaster if this cardinal point of their existence were surrendered. He had formulated in his own mind a policy which might be rejected by the higher authorities, but still it was a clear policy, viz., that there should not be conferred upon company trading the position which personal qualification alone could confer. He had a profound dislike to their licensing or registering that state of things.

Mr. Symes rose to a point of order. He submitted that Mr. Atkins was anticipating what the Committee would do in its report.

The Vice-President wished to endorse what Dr. Symes had said, though he agreed very largely with Mr. Atkins' views. He thought their first business was to maintain the Pharmacy Act, and it was not their policy to make matters easier for company trading.

Mr. Glyn-Jones said there had been one statement made by Mr. Atkins which he should like the members to understand did not convey the feeling of the Committee. Mr. Atkins had said that he would be no party to surrendering any rights they possessed. He (Mr. Glyn-Jones) thought the members ought to understand that there was not as yet any question of surrendering anything. As had been pointed out, the result of the resolution which the Committee had come too, and which it asked the Council to support, would be that a decision would be arrived at. It might be the decision which Mr. Atkins had outlined, or it might not, but he thought they could assure their members that it was quite certain that there was no danger of the Council surrendering any one right which chemists had a chance of successfully claiming.

Mr. Harrison did not wish to prolong the debate, but one remark, made by Mr. Young, he did not like, when he said the resolution did not commit the Council to anything. If the resolution had been intended to commit them to nothing, he (Mr. Harrison) should not have recorded his vote in its favour. It was because he thought the resolution committed the Council to deal with the question of company trading that he gave his vote on the previous evening. He rejoiced to think the time had now come when the Council had

fully made up its mind to deal with this very thorny question; he believed if chemists addressed themselves to it manfully they would find a solution of the difficultics that surrounded them. He hoped they would deal with the question without surrendering anything that properly belonged to them, and he believed the question could be dealt with on grounds satisfactory not only to themselves but to the great majority of the thinking practical men who formed their body.

Mr. Hills thought there was not so much difference between his colleagues as might appear. He was always so pleased to hear Mr. Atkins that he did not like to suggest that he was out of order, but he really thought he had gone unnecessarily into detail, and that the conclusion come to by the Committee was the right one. Company pharmacy was in the air and had been for a long time, and legislation dealing with it was also in the air; the Lord Chancellor had said distinctly that he proposed to deal with the matter next year; and the Committee after a long discussion thought it would be advisable to take up the matter as a practical question and see if it was not possible to frame some clause which might be usefully introduced. The Committee did not commit itself at all as to the line to be adopted; the principal idea underlying the discussion was that it would not be wise to let this opportunity pass without making some effort to lay the views of the Council before the Legislature. It was not committed to any particular action, but simply to considering very carefully whether this was not the time to frame some clause which might be included in a Company Bill which would be advantageous to pharmacy, and make things more endurable than they were at present.

Mr. Carteighe thought the resolution was a very proper one to pass, and he hoped Mr. Atkins would vote for it; the question of what was to be done would come forward later. Mr. Young had done him the honour of referring to his policy, but he did not know that he ever had a policy at all. All he had said was that the Council adopted a distinct policy when the Bill was before Parliament, but that Bill was now dead, and therefore the question arose whether they should be prepared to deal with it if it were revived; some people were very sure that it would be, but he did not feel at all sure himself, the question simply was, whether if it were re introduced the Council should be prepared to deal with it. That was the purport of the resolution, and he would appeal to Mr. Atkins to support it.

Mr. Young said he referred to a recent utterance of Mr. Carteighe in which he repudiated the idea that the Council had no policy.

Mr. Carteighe said the Bill was then alive; it was now dead.

Mr. Glyn-Jones said he thought Mr. Carteighe's statement was made after the Bill was dead.

Mr. Carteighe said the Bill was not actually dead until Parliament was prorogued.

The President, in putting the motion, said it no doubt committed the Council to this extent, that if the Bill were again introduced next session the Council should be prepared to deal with it, and he trusted it would do so in a reasonable and logical way by framing a clause which would be consistent with the best interests of the Society. How that should be accomplished would have to be thrashed out in committee, and he trusted they would all approach the matter with unprejudiced minds.

The resolution was carried with one dissentient.

General Purposes Committee.

A portion of the report of this Committee was read which recommended certain alteration in the syllabus for the examinations, and also the appointment of a sub-committee to select suitable persons for an appointment as member of the Board of Examiners.

This portion of the report was adopted.

Correspondence.

A letter was read from Mr. Smith, Liverpool, Chairman of the Federation of Local Pharmaceutical Associations, enclosing a copy of the rules of the Federation and the following resolution which was passed at the annual meeting held on July 25 last. "It is desirable that nominations of local secretaries of the Pharmaceutical Society should proceed from local associations and committees. That the objects of the Federation would be more effectually served if local secretaries were appointed by the associations to represent them on the Federation, and that the rules of the Federation be altered wherever it may be necessary to effect a closer co-operation between local associations and the Pharmaceutical Society's local secretaries in promoting the interests of these associations and of the Pharmaceutical Society."

It was agreed that this communication should be referred to the General Purposes Committee.

A letter was read from the Clerk to the Salters' Company approving of the nomination of Mr. E. M. Chapman as the Salters' Research Fellow at the Society.

Letters were then read from the North-East Lancashire Chemists' Association and the Preston and District Association enclosing resolutions calling upon the Council to openly discuss the question with regard to company trading at the October Council meeting.

The letters were referred to the Law and Parliamentary Committee.

A letter was read from the Colonial Office thanking the Society for the information and advice which it had given in respect of the Gibraltar Pharmacy Ordinance.

A letter from the Dewsbury and District Chemists' Association contained a resolution urging upon the Council the necessity of appointing local secretaries in all the Parliamentary boroughs and divisions throughout the kingdom, and also a resolution dealing with proposed legislation.

The Halifax and District Chemists' Association sent a letter containing a resolution passed by that body, suggesting that steps should be taken to place doctors' dispensaries under the same poisons' regulations as chemists' shops.

A communication from the Coroner for East Ham was next read, drawing attention to the fact that he had recently held an inquest on the body of a Mrs. Hickman, who was proved to have died from an overdose of opium, or some of its alkaloids, taken from a bottle which had no poison label upon it.

The President said the Council could not take any action in the matter, as it was not known where the poison was purchased.

Dr. Symes suggested that the Coroner should be asked for information on the subject.

The letter was referred to the General Purposes Committee.

The President moved that the dates of the Council Meetings for next year be fixed for January 10 and June 12, instead of the first Wednesdays in those months.

The resolution was adopted.

It was reported that a letter had been received from the secretary of the Education Department for Scotland, enclosing a Report for the year 1899 by Sir H. Craik on the inspection of higher class schools, and the examination for leaving certificates.

Legal Business.

The Council then went into committee to hear and consider the part of the report of the General Purposes Committee which dealt with legal matters.

On resuming, the report and recommendations were unanimously adopted, and special resolutions passed, authorising the Registrar to take proceedings against the persons named therein.

Determination of Phosphorus in Phosphorised Oils.—E. Louise advocates the use of the following method for the determination of phosphorus in phosphorised oils; it consists in precipitating the phosphorus from the oil, previously dissolved in acetone, by means of silver nitrate solution. From 8 to 10 Gm. of the oil are weighed accurately into a graduated 200 C.c. measure, then made up to 200 C.c. with acetone, and well mixed. The acetone solution is then divided into 10 equal portions each of 20 C.c., in a series of test tubes. Two solutions of silver nitrate are now made, one containing exactly 10 per cent., the other 1 per cent. of the salt. To the first of the series of test tubes two drops of the 10 per cent. solution of silver nitrate are added, by means of a Duclaux's drop-counter, which discharges 100 drops of distilled water; the contents of the tube are then well mixed and filtered from the black precipitate which falls. If the filtrate shows no further blackening on the addition of another drop of the reagent, a more delicate test is made with the remaining nine tubes. To each of these one drop of the 10 per cent. silver solution is added; then, to the first, 1 drop of the 1 per cent. solution, to the second, 2 drops; three drops to the third, and so on. On filtering, the tube which gives a filtrate which does not further precipitate is noted; if, for example, this be at No. 5, containing the equivalent of 15 drops of 1 per cent. silver nitrate solution, the original oil will contain, in parts per mille of phosphorus,

$$\frac{15 \times 0{\cdot}05036 \times 10}{W}$$

where W = the original weight of the oil taken.—*Journ. de Pharm.* [6], **10**, 241.

LONDON: SATURDAY, OCTOBER 7, 1899.

THE COUNCIL MEETING.

On the minutes of the previous meeting being read and confirmed, the President stated, in answer to Dr. Symes, that no further reply has yet been received from the Privy Council Office as to the Council's recommendation that carbolic acid should be added to the poison schedule, but he believed the matter was receiving consideration by the authorities.

The President then mentioned that the Council had to excuse the non-attendance of the Secretary and Mr. Allen, and at his request the Vice-President moved a resolution of condolence in reference to the cause of their absence.

In referring to the recent death of Mr. Thomas Greenish, the President mentioned that he was a student at the Society's School in the early days of its existence, a pharmacy prizeman in 1847, and had been a member of the Society from that time; he was also a member of Council from 1871 until 1885, Treasurer from 1878 to 1880, and President from 1880 to 1882. The period of Mr. Greenish's presidency was made remarkable by the House of Lords' decision of the company question as affecting the business of the chemist and druggist, and also by the International Congress of Pharmacists held in London. After brief mention of some scientific subjects to which Mr. Greenish had specially directed his attention, the President moved a resolution, expressing the esteem of his colleagues and their appreciation of his services in connection with the Society, which was seconded by the Vice-President and carried, after being supported by Messrs. Hills, Atkins, and Symes.

The President then drew attention to the deaths of three honorary members of the Society—A. v. Waldheim, Sir E. Frankland, and Dr. Kanny Lall Dey—which have taken place since the last meeting, and after giving some details of their position and work, suggested that an expression of condolence should be addressed by him to the respective families of those distinguished persons.

The report and recommendations of the Finance Committee were then adopted, and on the recommendation of the Benevolent Fund Committee, nine grants, amounting to £85, were ordered to be paid. The death of Mrs. Jessie MacIntyre, an annuitant since 1887, was reported. A statement was submitted showing that on the 30th ult. the current account balance was £1,201 10s. 10d., and that the donation account amounted to £703 3s. 5d. In accordance with the recommendation of the Committee a resolution was passed that four annuitants should be elected next December. In moving the adoption of the report and recommendations of the Committee, the Vice-President mentioned that one of the applicants, representing himself to be ninety years of age, had been refused, though he would otherwise have had a good chance of obtaining a grant, because it was found on inquiry that he was born in 1854.

In moving, pursuant to notice that has appeared in the Journal, a resolution relating to the efficiency and uniformity of action among local secretaries of the Society, and the advisability of holding a meeting to consider the best means of securing those objects, Mr. Cross recalled the discussions that have taken place in reference to the subject, and pointed out the special opportunity that would be offered for holding such a meeting when the Pharmaceutical Conference is held next year in London. He also spoke of having become aware, from views expressed at the meeting recently held at Plymouth, that there is a decided feeling that such a meeting of local secretaries would be useful.

In seconding the motion, Dr. Symes referred to the suggestion he made some years ago as to local secretaries being invited to attend the Society's annual meeting for the same purposes, but he agreed that the plan recommended by Mr. Smith, of Liverpool, was preferable.

In putting the motion, the President said that, while some local secretaries do their work very well, others would be better for a little more zeal that might be excited by such a meeting as was proposed, and the resolution was then carried unanimously.

The report of the Law and Parliamentary Committee stated that a resolution had been passed for adoption by the Council that a clause dealing with company trading as it affects pharmacy should be drafted with the object of asking the Government to include it in any Company's Bill that may be introduced into Parliament.

The President said this matter had been discussed at great length in the General Purposes Committee, and he moved that the report should be adopted.

In seconding the motion, Mr. Rymer Young said he could not refrain from expressing satisfaction with the step taken by the Council, for, though it might be unimportant, it was an advance by which they might be led from the existing abstract and chaotic condition into the region of concrete reality. Until yesterday he had been under the impression that Mr. Carteighe was correct in saying the Council had a definite policy, but the discussion last night led him to the conclusion that they had either no policy at all, or—worse still—that they had a dozen or more different policies. The proposed resolution did not commit the Council to anything in particular, but he was glad that it did impose the necessity of focussing their opinions into something tangible and intelligible. Without venturing any suggestion that might result in such a debate as took place in Committee, he would at least express the hope that the clause, when drawn, would be

in accord with the resolution passed by the Council last June, and that at any rate one prominent feature would be defence of their titles. Whatever might wisely be left out, there should not be any uncertainty on that point. There should be perfect unanimity in the claim that no body of persons should be permitted to use a title that could only be obtained by individuals.

Mr. ATKINS explained that his reason for not voting in favour of the motion was that he objected to any surrender of privileges which had been fairly earned. He had yet to learn that the suggestions sent by the Council to the LORD CHANCELLOR had not been favourably received, but, on the contrary, the LORD CHANCELLOR'S speech led him to conclude that the noble lord viewed chemists' position much more favourably than was supposed by some. For that reason he thought any premature indication of surrender would be unwise. Though the policy of acquiescing in the inevitable had been urged with ability, he felt still more strongly that if disestablishment and disendowment were to come at all, they should come altogether from without. By acting on that conviction he felt that he would have a clear conscience, as having done his duty in seeking to defend the personality of the chemists' qualification which had been obtained by education, examination, and registration. He apprehended serious disaster if that cardinal point of their continued existence were surrendered. That was, in his opinion, a clear policy, and the position which personal qualification alone could confer should not be given to company trading even to the extent of recognising such a state of things or even registering companies.

Dr. SYMES objected that Mr. ATKINS was out of order in anticipating what the Committee might do in its report, and the VICE-PRESIDENT endorsed that view, though largely agreeing with Mr. ATKINS'S remarks. He thought the first business of the Council was to maintain the principle and intention of the Pharmacy Acts, and not to make company trading easier.

Mr. GLYN-JONES drew attention to Mr. ATKINS'S mention of surrendering chemists' rights as not, in his opinion, conveying the view of the Committee. He wished it to be understood that as yet there is no question of surrendering anything. Whatever might be the decision arrived at by the Committee, he thought members of the trade might be quite certain the Council would never surrender any single privilege which chemists were able to claim.

Mr. HARRISON objecting to the remark that the resolution did not commit the Council to anything, said he should not, in that case, have voted for it. He held that its merit was that it did commit the Council to dealing with company trading, and he rejoiced that the Council had at length resolved to deal with that thorny subject. If chemists would address themselves to it manfully he believed they would find a satisfactory solution of the difficulties which surrounded them, without surrender of anything belonging to them and without losing the approval of the great majority of thinking men.

Mr. HILLS thought the difference of opinion as to company trading was more apparent than real. The chief point was that this opportunity of impressing the views of the Council on the Legislature should not be lost.

Mr. CARTEIGHE, in expressing approval of the resolution, said he hoped Mr. ATKINS would vote for it, and, referring to Mr. YOUNG'S remarks as to policy, said that so long as the Company Bill was before Parliament the Council had adopted a distinct policy: now that the Bill might be revived, the question as to what should be the policy of the Council would have to be dealt with by the Committee, and on that ground he appealed to Mr. ATKINS to support the resolution.

The PRESIDENT, in putting the motion, said that it would commit the Council to deal with the question of company trading if the Bill were again introduced, and in that case he hoped the question would be dealt with in a reasonable and logical manner consistent with the best interests of the Society.

Part of the report of the General Purposes Committee relating to alterations in the syllabus for the examinations and to the selection of persons for appointment as examiners was adopted.

The correspondence comprised a letter from Mr. SMITH, the Chairman of the Federation, in reference to the nomination of local secretaries, and to closer co-operation between local associations and the Pharmaceutical Society's local secretaries; letters from the North-East Lancashire Association and from the Preston and District Association in reference to company trading—these were referred to the Law and Parliamentary Committee. Other letters were from the Dewsbury and District Association in reference to the appointment of local secretaries and to proposed legislation; from the Halifax and District Association suggesting that doctors' dispensaries should be placed under the same poison regulations as chemists' shops; from the East Ham Coroner drawing attention to a case of poisoning; from the Colonial Office in reference to the Gibraltar Pharmacy Ordinance; from the Clerk to the Salters' Company approving the nomination of Mr. E. M. CHAPMAN as Salters' Research fellow; and from the Secretary of the Education Department for Scotland, enclosing Sir H. CRAIK'S report on the inspection of schools and the examination for leaving certificates.

THOMAS GREENISH.

THE extremely scanty list of Past-Presidents of the Pharmaceutical Society of Great Britain has been still further diminished by the death of Mr. THOMAS GREENISH at the mature age of eighty-one years. Though born at Lamphey, near Pembroke, Mr. GREENISH was of Flemish extraction. He received his early education at a small country school, and was subsequently apprenticed for five years to a chemist and druggist named WILLIAMS, at Brecon. His first engagement as an assistant was with Messrs. DALMAHOY, of Ludgate Hill, London, but, becoming acquainted with the late WILLIAM INCE, he was soon transferred to the establishment of Messrs. GODFREY and COOKE, in Conduit Street. That event occurred in 1841, the year the Pharmaceutical Society was founded, and six years later Mr. GREENISH was elected a member of the Society under the Charter. In 1847, also, he won the first prize for pharmacy at the Society's School of Pharmacy. From the very outset he took a great interest in the work of the Society, as evidenced by the numerous

papers read by him at evening meetings or contributed to the *Pharmaceutical Journal* from time to time. One of his favourite subjects was work with the microscope, and he was an ardent advocate of the application of that instrument in pharmaceutical research. He was a great traveller, having visited most European countries, as well as the United States of America, and was a firm believer in the virtues of lengthy annual holidays, free from all business cares, as being conducive to the better conduct of business during the remainder of the year.

Mr. Greenish was first elected a member of Council in 1871, and he succeeded Sandford as President in 1880, after having previously acted for two years as Treasurer. During his term of office the fifth International Pharmaceutical Congress was held in London, and it is noteworthy that the following resolution was adopted by that Congress:—"It is the duty of all pharmacists to urge that, in the future revision of any national pharmacopœia, it is necessary that there should be a permanent committee or commission, comprising among its members the largest possible number of pharmacists." Mr. Greenish was always a warm advocate of thorough educational training of pharmacists as a means of improving the position of the craft. In the presidential address delivered at the fortieth annual meeting he spoke of the tendency to overcrowding as an indication that the conditions of entrance to the business of a chemist and druggist were not properly understood. The unpreparedness for the Preliminary Examination was spoken of as forcible evidence of the deficiency of middle-class education, and the frequently apparent ignorance of the fact that a youth desiring to enter the calling would be called upon to pass examinations before being able to conduct a business on his own account, as showing the great responsibility resting upon chemists who took apprentices. In the address delivered at the next annual meeting reference was made to the attention that had been given to the subject of pharmaceutical education and the establishment of a compulsory course of study, to be preceded by the passing of a preliminary examination, affording evidence of a sufficient liberal education. The prevailing low condition of the business of chemists and druggists throughout the country was held to be largely due to the unreasonable demand for cheap labour bringing into an overcrowded trade young men of deficient education, who should rather be discouraged, for their own sake, from entering it, because they were not the material from which pharmacists could be made, and because the instinct of self-preservation should lead pharmacists to guard with tenacity all that pertains to admission to their business.

A striking resemblance manifests itself between certain of Mr. Greenish's utterances and some passages in the address delivered by Professor Leech on Monday last. The necessity of a compulsory curriculum in pharmacy was ever a strong point with Mr. Greenish, and he was greatly impressed with the necessity imposed upon the modern pharmacist of preparing himself to cope with the changes that are taking place in the practice of medicine. Throughout his long life he consistently maintained a lofty ideal with regard to the pharmacist's professional status, and his death is greatly regretted by a wide circle of friends, who recognised in him a typical scientific pharmacist.

ANNOTATIONS.

The President of the Pharmaceutical Society of Ireland admits ignorance of anything that has been done by the British Society since 1895, in the direction of seeking to prevent companies of unqualified persons from carrying on the business of a chemist and druggist. That admission bears out our statement that his previous remarks (see *ante*, p. 290) betrayed a somewhat imperfect acquaintance with the earlier history of the affair. As a matter of fact, much has been done by the Executive of the British Society in relation to this difficult problem since 1895, and even up to the present time, but the negotiations have been conducted privately and the Society's representatives have not felt at liberty to disclose publicly what passed on the different occasions.

The Standardisation of Galenicals was the subject of an article by Mr. Edmund White, in last week's Journal, which must be regarded as very timely in view of Professor Leech's reference to a probable increase in the number of standardised preparations. Mr. White's view is that it is a fallacy to regard standardised preparations as the limit of pharmaceutical perfection, and he maintains that, when our knowledge of the active principle or principles of a drug is clear and definite, the need for galenical preparations of that drug vanishes. The pharmacist, of course, must be prepared to make and supply such preparations so long as the physician orders them, but that is the only reason why official formulæ for them should persist. It is also desirable that a given preparation of a drug containing a potent active principle should not vary greatly in strength; so long, therefore, as that preparation receives official recognition, it may be desirable to standardise it. But it is clear that this can only serve as a temporary expedient, for if the effects produced by galenical preparations can be traced to certain definite substances contained therein, it is obviously more rational to resort to the use of the pure active principles. Time, labour and money will then alike be saved, and patients need no longer continue to swallow inert colouring matters, etc. As forcibly pointed out by Mr. White, in the case of liquid extract of cinchona, for the privilege of taking quinine and other less valuable cinchona alkaloids, associated with various inert impurities which serve to make the remedy more nauseous than it need be, one pays more than four times the price of quinine sulphate itself. Moreover, the special advantages sometimes claimed for galenical preparations are quite lacking in this case, and the administration of the liquid extract is not inaptly described as "a messy and expensive method" of attaining the desired end.

Those who Advocate Standardisation contend, on the other hand, that our knowledge of the active principles of some drugs from which standardised preparations are made is not sufficiently advanced to justify us in resorting to the use of the pure alkaloids, etc. But in such cases, as is cogently remarked by Mr. White, the value of the standardised preparations may easily be overrated. Standardised preparations, therefore, "can only be regarded in many cases as temporary expedients, suitable for the transitional period when we are passing from an incomplete to a definite knowledge of the constituents of a given drug," and "the logical consequence of their employment ought to be their substitution by the pure substances which have formed the basis of standardisation." In effect, Dr. Leech says the same thing. He thinks there is only a short step between standardisation and the use of active principles instead of galenical preparations of crude drugs. There are doubtless many, he states, who still believe that the active principles do not represent the entire curative power of drugs, and that the natural combination with them of minute quantities of other substances present in the crude drugs results in a subtle influence being exerted by galenicals,

which is lacking in the case of pure alkaloids. But, in forming an opinion on such points, "there is much room for the exercise of the imagination," and some of the differences now supposed to exist between the effects of galenical preparations of drugs and their active principles are, Dr. Leech suspects, due to that. "Anyway, it is certain that as the active principles and their exact pharmacological actions become better known reliance on them has increased, and there has been a greater tendency to think of the preparations of such drugs as belladonna and nux vomica in terms of atropine and strychnine, whilst even in a drug like opium, which contains other active alkaloids, it is generally recognised that the value as a sedative at least, is determined by the morphine." Whilst, therefore, there can be little doubt that an important feature in the next Pharmacopœia will be the increased number of standardised drugs and galenical preparations, the more general use of active principles in place of crude drugs is only deferred.

SUGGESTIONS FOR LOCAL ORGANISATION are submitted by Mr. James Cocks, of Stonehouse, Devon, the Hon. Secretary of the Federation of Local Pharmaceutical Associations. In these, it is pointed out that the objects of a local association should be such as will meet the wants of those engaged in the practice of pharmacy, from social, trade, and educational standpoints. Where towns have a population below fifty thousand, it is suggested that several should be grouped together into a district, with nominal headquarters conveniently situated for educational purposes, and that meetings to deal with social and trade topics should be held throughout the district. Many associations favourably started have come to grief, it is asserted, through devoting too little attention to social matters, none to trade interests, a certain amount to the improvement of education, and much to discussions about professional status. In looking for members of associations, organisers are said to be confronted generally with the following three classes:—The good-natured loyal individual who readily joins for old acquaintance' sake and ultimately proves the backbone of the association; the hard business man who wants something in return for his subscription; and the man who is suspicious because he has belonged to some former association long since deceased, and prophesies similar failure in the case of the new venture. Unfortunately no special suggestion is offered regarding the manner in which the last-mentioned should be treated. In catering for the members, Mr. Cocks suggests that chief prominence should be given to the social side. He thinks there should be the usual annual dinner, a ball in the winter, and an outing in the summer, which ladies should be invited to attend. With regard to trade interests, he says: "Appoint an honorary solicitor, who services would be free to the executive, through whom any individual member could ask a question on trade matters; establish a co-operative buying and trade defence section; arrange a contract rate for the carriage of goods; establish an exchange or sale at reduced prices for unsaleable or damaged articles or goods; an executive alert for legislative matters, such as interviewing local members of Parliament when necessary, in the initial stage; avoid the introduction of early closing, or arrangement for prices mutually." On the educational side, it is suggested that classes should be organised in such subjects as are not dealt with at local Technical Schools, so that a complete curriculum of study may be arranged, and the requirements for the Minor Examination met. The town chosen for this purpose should be the nominal headquarters for the district, and the library and museum of the Association should be kept there. Finally, it is urged that the Executive should consist of men who will think, speak, and act only for the good of the Association. If sincerely carried out, the above suggestions, it is thought, would in time result in the enrolment as members of almost the whole of the chemists in the district, who would then constitute a perfectly organised force always ready to assist the craft at large in arriving at definite opinions on urgent matters, as they present themselves for discussion from time to time.

THE CRY OF THE CONSUMPTIVES is voiced by Mr. J. A. Gibson, of Edinburgh, in the *Nineteenth Century*, where he points out that, though the true knowledge with regard to the causes, prevention and cure of consumption, are gradually being disseminated, the efforts which are being put forth to grapple with the evil are pitifully inadequate. The author has formerly contended that consumption can be cured in any climate, the only essential being the judicious location of sanatoria—in protected places, at a fair altitude, lying well with regard to the sun, with pure, bracing air about, and trees near. He insists that it is a matter of some importance that a consumptive should be cured in the climate in which he will afterwards have to live, and that the one essential of climate is pure air. It is recommended that special attention should be devoted to the quantity, quality, and kind of food to be given to patients, as well as to the methods of cooking it. Much must also be learned regarding temperature, bathing, exercise, and rest—as to when the patient should be in bed, when lying, when walking, and how far; in addition, attention must be devoted to sanitation, disinfection, washing, and heating, whilst the fear of the open window is to be for ever banished. In fact, medical men must be specially trained if there is to be hope of any measure of success in the crusade against consumption, and when they have been so trained they must give up their lives to that work alone. It is suggested that consumption ought to be made a notifiable disease, that the Government should build sanatoria, that efforts should be made to stamp out tuberculosis in cattle and to prevent overcrowding, and that patients should not be allowed, when cured, to return to their former occupations, if those be of an unhealthy nature.

WHISKEY AS AN ANTIDOTE TO CARBOLIC ACID is the latest American sensation, and the *Bulletin of Pharmacy* publishes some most startling facts (?) in connection therewith. In the first place, it is stated that a woman bent on suicide swallowed a considerable quantity of carbolic acid, but that—some whiskey having been mixed with the poison to render it palatable—no escharotic effect whatever was produced in her mouth and throat. Presumably, also, the woman recovered, for it is recorded that the whiskey "had completely neutralised the poison." Experiment, we are told, demonstrated that this must have been the fact; for after pure and undiluted acid had been applied to the skin, and even allowed to remain until painful escharosis began, "the application of alcohol at once stopped the pain, and almost entirely obliterated the scar." Next, it is related how one medical man declared that it was no unusual occurrence to see another medical man catch pure carbolic acid in his open hands, and in a few moments remove all the effects by washing his hands in pure alcohol. And, "he is now almost daily flushing abscess cavities with pure carbolic acid, and afterwards washing them out with pure alcohol." But the palm must be awarded to the tale of a medical man who "deliberately placed the tip of his tongue in some acid contained in a shallow dish, which, of course, immediately resulted in escharosis of the soft and delicate tissues. The pain was intense; yet the immediate application of alcohol, which was made by holding a half-ounce of the fluid in the mouth for thirty seconds, brought entire relief, and completely effaced all evidence of escharosis." The remarkable instances quoted prove, according to the *Bulletin of Pharmacy*, that "alcohol is *par excellence* the antidote for carbolic acid poisoning." It may, however, be suggested that the published records of the cases prove something else. At the same time, whiskey may possibly be used with advantage in cases of carbolic acid poisoning; it is well known to be a useful application generally, especially when taken under medical advice.

METHYL ALCOHOL AS A MENSTRUUM.*

BY WILBUR L. SCOVILLE, PH.G.,

Professor of Applied Pharmacy and Director of the Pharmaceutical Laboratory in the Massachusetts College of Pharmacy.

That methyl alcohol is being used to a considerable extent as a solvent in pharmaceutical preparations intended for external use, is generally known among pharmacists. As a substitute for ethyl or grain alcohol in internal remedies the sentiment of pharmacists is undoubtedly against the use of methyl alcohol, though the comparative physiological action of the two forms when in a condition of comparative purity is still in question. That the ordinary commercial grades of wood alcohol are decidedly poisonous none will deny, but that they contain foreign bodies in considerable proportion, to which the toxic effects may be chiefly due, is also generally admitted. It is not so very long ago, however, that scientific literature was considerably occupied with the consideration of the impurities found in alcoholic spirits, and which were produced in the same process and by the same means as those which resulted in ethyl alcohol. These by-products of a higher series of alcohols were found to produce a very energetic action when taken internally, and comparatively small amounts were sufficient to cause toxic symptoms. Modern methods have, however, succeeded in eliminating from commercial alcohols and spirits all except the merest traces of these more powerful products of fermentation, and the effects of ethyl alcohol are becoming better known. Could it be once proven satisfactorily that methyl alcohol in itself is no more toxic or injurious than ethyl alcohol, when taken internally, an increased demand for it in a pure state would stimulate efforts to more cheaply eliminate the objectionable substances and supply it at a low price. At the present time wood alcohol can be obtained almost free from odour, and of a high degree of purity, at a considerably less price than that paid for grain alcohol. This purified alcohol is adapted to many uses for which the crude product cannot be employed. It is not only more agreeable and less easily detected, but there is evidence to show that its effects upon the system are also different.

Effects of Methyl Alcohol upon the Human System.

The experience of Professor Puckner, of Chicago, who compared the effects of methyl and ethyl alcohol upon his own person, with favour to the former, are well known, and have been corroborated by H. D. Abbott, of Salem, Mass. Mr. Abbott is not in the habit of using alcoholic beverages, even occasionally, and his observations are thus the more clear. On two different occasions he tried the effects of a purified methyl alcohol and of commercial grain alcohol of corresponding strength. Doses of one-half ounce each were taken, upon an empty stomach, and within an interval of twenty-four hours between. In both trials the effects of the methyl alcohol appeared the more quickly and were more transient, passing off in a very short time and leaving no depression. The exhilarant action of the ethyl alcohol appeared more gradually, were more persistent, and were succeeded by a slight depression.

Toxic Effects Due to Impurities.

Another evidence that the toxic effects of wood alcohol may be due to the impurities which it contains more than to the alcohol itself, is found in tincture of iodine. Several writers have recommended that this preparation be made with wood alcohol, and a number of pharmacists have tried it. The iodine dissolves more quickly in this medium, and all appears well. But when the ordinary cheap grades of wood alcohol are employed the tincture develops a very penetrating odour, and becomes so irritant as to make it unsaleable. This does not appear when the purified alcohol is used. Samples prepared from purified methyl and ethyl alcohols, which have stood a year and a half, show no marked change in either case, and cannot be distinguished except by the odour.

* From the *American Druggist.*

A further knowledge of the properties of true methyl alcohol is, therefore, desirable, and for the pharmacist a consideration of the solvent powers of this fluid is of primary importance. In a general way it is stated that it has about the same solvent powers as grain alcohol, but that some differences exist is naturally to be inferred. These may be so slight as to be unimportant, or they may in some instances be wide enough to be of some consequence.

Relative Value of the Two Alcohols as Menstrua.

In the absence of specific data on this point, with regard to vegetable drugs, H. D. Abbott and F. A. Merriam carried out a series of experiments at the Massachusetts College of Pharmacy to determine the relative value of the two alcohols when used as menstrua. The drugs tried were those whose preparations are used externally, in liniments, etc., or such as are represented in solid extracts, wherein the menstruum being driven out plays no direct part in the physiological action of the remedy. An attempt was made to have all the alcoholic (solid) extracts of the Pharmacopœia prepared from the two alcohols for comparison, but a third student failed to finish her portion of the work, leaving the present list incomplete.

Method of Determination.

The method followed was to make an official preparation of the drug, a tincture, extract or fluid extract, selecting that which demanded the highest percentage of alcohol, and using for one portion of drug official alcohol, and for another portion of the same drug the best commercial grade of methyl alcohol. The two preparations were made under as like conditions as possible, the two portions of drug being moistened and packed at the same time, and percolation being carried on at as near the same rate as possible and under the same conditions of temperature, and the percolates carefully watched to note any difference in colour, rate of exhaustion, or other characteristics which might be discernible. In all cases percolation was allowed to proceed at a rate of 10 to 20 drops per minute, and exhaustion was determined by the colour and taste of the percolate, or by an absence of cloud when allowed to drop into water. Cylindrical percolators of the Oldberg pattern were employed, these being fitted with drop tubes passing through perforate stoppers, and sealed at the upper end, but perforated at the side near the upper end of the tube, so that the percolation could be regulated independently of the packing of the drug. The processes of the Pharmacopœia were followed in detail, except that in making extracts the first portion of percolate was not reserved, but the entire amount was collected in one body, in order to note any physical differences and to compare the solvent powers of the two alcohols.

Determination of the Total Solvent Power.

The relative rapidity of action is shown in the volume of percolate required to exhaust the drug, as given in the table below. The total solvent power was ascertained by estimating the soluble matters extracted from the drug. For this purpose 5 C.c. of the measured percolate was evaporated in a porcelain evaporating dish just on a steam bath, and when apparently dry it was transferred to a hot air-oven kept at a temperature of 100° C. until dried to constant weight. The total quantity of soluble matter in the percolate was computed from this weight, and the percentage extracted from the drug then calculated. By basing the percentage of extraction on the drug the differences in quantity of percolate obtained were allowed for.

Method of Assay.

The nux vomica extracts were assayed by the official process, using the dry extract. The belladonna extracts were assayed by a similar method. Fifteen grains of extract were treated with 150 C.c. of a mixture of ether, alcohol, and ammonia water for six hours, 100 C.c. of the clear fluid then separated, and the alkaloids extracted by shaking with successive portions of two per cent. sulphuric acid. The mixed acid washings were then rendered alka-

line with ammonia, and extracted with successive portions of ether, the ether evaporated and the residue titrated with decinormal sulphuric acid, using Brazil wood as an indicator.

The methyl alcohol employed had a specific gravity of 0·796, and boiled at 65° C. The ethyl alcohol had a specific gravity of 0·820.

The results are shown in the table.

Table of Results.

Preparation Made.	Amount of Drug Used.	Menstruum. Alcohol.	Menstruum. Water.	Total Percolate Obtained. Ethyl.	Total Percolate Obtained. Methyl.	Per Cent. Extractive. Ethyl.	Per Cent. Extractive. Methyl.	Active Principle Per Cent. Ethyl.	Active Principle Per Cent. Methyl.	Character of Principle Estimated.

A summarising of the table will show that there are but slight differences in the action of the two alcohols upon the drugs tried. The small differences in extractives and in the quantities of menstrua used may mostly be accounted for in differences in manipulation and errors in weight. A slight error in estimating the extractive matter in the percolate would be multiplied many times in the final result.

Little Difference in the Finished Product.

In no instance was there any marked differences in the appearance of the products when compared. Slight variations were sometimes noticeable, such as a slightly darker shade in the tinctures of aconite and arnica, and the resin of podophyllum, made with methyl alcohol, but these were observed only when the two products were compared. The extract of belladonna leaves made with methyl alcohol appeared slightly granular, while that made from ethyl alcohol was smooth.

In the case of cannabis indica number one, iris and rhubarb, the extractive matter reported is very high, and may refer to a moist rather than a dry extract. In the other instances the results agree well with data previously obtained regarding the amount of extractive matter in these drugs, which data were not accessible to the two workers.

The tinctures and fluid extracts made with methyl alcohol betrayed its presence by their odour, but in the case of the solid extracts the difference could not be detected.

The Surreptitious Use of Wood Alcohol,

whether for solid extracts or for preparations intended for external use, is not to be countenanced. If wood alcohol is suitable in all respects for these preparations, the fact will ere long be recognised by the medical and pharmaceutical representatives, and its use openly sanctioned. Until, however, the majority of pharmacists and doctors shall have become satisfied as to its freedom from objectionable qualities, and its adaptability to medicinal uses, it should be held in abeyance, or, if used, its substitution should be openly proclaimed.

REVIEWS AND NOTICES OF BOOKS.

Die Ætherischen Oele. Von E. Gildemeister und Fr. Hoffmann. Bearbeitet im auftrage der firma Schimmel and Co. in Leipzig. Pp. iv. + 919. Berlin: Julius Springer, 1899.

The issue of this work marks a distinct epoch in the history of essential oils. The nine hundred quarto pages are devoted to an exposition of all that relates to essential oils, including an historical account of their uses and methods of preparation from the earliest times. The book summarises the somewhat copious literature scattered throughout the scientific journals and provides a very interesting and complete account of a class of bodies which play a very important part in pharmacy. The subject matter is divided into three parts. Part I., consisting of 136 pages, which we learn from the preface is chiefly due to Dr. Hoffmann and is mostly historical, gives an interesting account of the *rôle* played by oils and oil-yielding substances in the trade of the world. The methods of distillations are described from the earliest historical periods up to the present day, and the numerous illustrations provide a very interesting comparison between the primitive flask and retort of the ancients and the complicated steam plant in use at the present time. Part II. contains a general account of the preparation, the constituents, and the methods of testing essential oils. This part and the following part devoted to the description of the oils in detail is mainly from the pen of Dr. Gildemeister, assisted by special contributors. The fundamental principles underlying the methods of obtaining oils by distillation are first discussed from a theoretical standpoint, showing how the best results may be attained. This chapter serves to emphasise the value of the application of scientific knowledge to technical operations, with a view to improving the product and economising materials and labour.

In another section an account is given of the more commonly occurring constituents of essential oils—the aliphatic, aromatic and hydro-aromatic hydrocarbons, the alcohols, aldehydes, ketones, phenols, acids, esters, lactones and some sulphur and nitrogen derivatives. One would have been glad to have had a summarised account of the large number of researches dealing with the constitution of the terpenes. These researches are scattered and somewhat contradictory, so that something of the sort would have been distinctly useful in the work under consideration. The authors, however, content themselves with a description of the properties, derivatives and physical constants of the chief well-recognised terpenes.

A chapter is devoted to the general methods of examination of essential oils by their physical properties and the determination of certain constituents. This includes also a section relating to the detection of substances very commonly used as adulterants of essential oils. Part III. gives a more or less detailed description of no less than four hundred and twenty-two individual oils. It comprises an immense mass of information which, taken in conjunction with the numerous references to original papers, renders the book very useful as a work of reference for everyone interested in this class of substances. The article on rose oil is a fair illustration of the thoroughness with which the matter is treated. It consists of eighteen pages treating of the history, source, preparation, properties, composition, and tests—the three last extending over nine pages—and contains all necessary information respecting rose oil. It is pointed out that one kilogramme of rose oil can be obtained from about 6,000 kilos of German roses, that the characteristic aroma of rose oil is not entirely due to the alcohols and the ester—geraniol, l—citronellol, geranyl acetate—but to a combination of them with small quantities of unknown bodies, and that the chemical and physical tests cannot be entirely relied on as evidence of purity. The chief adulterants are stated to be palma rosa oil and geranium oil. In this manner is each oil described. Throughout the book there is an air of authority that commands attention, and its issue by Messrs. Schimmel and Co. is instructive in the sense of giving additional evidence, if that be necessary, of the scientific manner in which industrial operations are carried out in Germany in contra-distinction to the rule of thumb procedure almost universally predominant in this country. Some of the information here given on essential oils may be familiar to readers of Schimmel's semi-annual reports which, while naturally not neglecting trade interests, periodically summarise results obtained in the course of chemical research, and are always of interest to chemists who are desirous of keeping in touch with the latest information on the subject of essential oils. Such scientific work in technical operations can only be possible when a research laboratory with trained chemists is part and parcel of the chemical factory.

It is with good reason that Gildemeister and Hoffmann's book, based on the practical application of the results of scientific research, forms such a valuable contribution to pharmaceutical literature, and indeed may be considered indispensable to such chemists and pharmacists as are more particularly interested in the chemistry of essential oils.

Richter's Organic Chemistry. Edited by Professor R. Anschutz. Translated by Edgar F. Smith. Third American, from the eighth German edition. Vol. I. Chemistry of the Aliphatic Series. Pp. 625. Price 15s. London: Kegan Paul, Trench, Trübner and Co., Limited. 1899.

The division of this work into two volumes has been rendered necessary by the enormous development in almost all departments of organic chemistry. Vol. I., dealing with the fatty or aliphatic compounds only, is larger than the original book published as the first American edition, which was issued in a single volume. Comparing this volume with its predecessors one must admit that great improvements have been made. Assuming that Vol. II., dealing with the cyclic compounds, is translated equally well from the already-published German text, English-speaking students will be in possession of one of the best modern text-books of organic chemistry. The errors observable in the last American edition, particularly in the formulæ and equations, are fortunately absent in the new edition. Although most of these errors were sufficiently obvious, they must have provided many stumbling-blocks for the student. The introductory portion, comprising 77 pages, gives a condensed account of the determination of formulæ, the physical constants, and the constitution of carbon compounds. Although necessarily brief, it provides a useful summary of these matters, and its value is enhanced by frequent reference to original papers. Unfortunately for English readers, most of the papers have to be sought for in German periodicals.

The difficulties which surround the systematic naming of organic compounds is recognised, and while the familiar names for numerous well-known compounds are retained, the names based upon the suggestions of the Geneva Convention are frequently added in brackets. The complete adoption of the system which was proposed by the Convention would introduce numerous difficulties apart from the unfamiliarity of the new names.

The subject matter of the present volume is brought well up to date. The system of classification adopted is based upon the alcohols, all substances being grouped under the alcohols, from monohydric to hexahydric and polyhydric, to which they are most nearly related. As in the previous editions, large and small type is employed to indicate the elementary and more advanced portions, and very numerous references are given for those wishing to have more details than are found in the text. In its present form Richter's 'Organic Chemistry' is undoubtedly one of the best text-books for advanced students, and is, in addition, a valuable work of reference.

Physics: Experimental and Theoretical. Vol. I. Mechanics, Hydrostatics, Pneumatics, Heat, and Acoustics. By R. H. Jude, D.Sc., M.A., and partly from the French of H. Gossin. Pp. xxii. + 926. Price 12s. 6d. nett. London: Chapman and Hall. 1899.

This new work on physics will be completed in a second volume dealing with optics and magnetism and electricity. Dr. Jude set out to translate into English the "Cours de physique" of Prof. Gossin, but found, like many other translators in the same department, that the translated work would not entirely meet the requirements of students in the various science schools in this country. He has, therefore, modified certain sections and added a good deal of new matter of his own.

With regard to experimental physics the present volume gives descriptions in much simpler and lucid language than is usual in books on physics so comprehensive in scope. The description of methods and apparatus is also well done; such things as the radiometer, Bunsen's calorimeter, and the specific heat of gases at constant volume and pressure being particularly well done. The popular side of physics has also been developed, and the student will find very readable descriptions of such things as weather prediction and the scientific results of ballooning.

Dr. Jude has endeavoured as much as possible to limit the mathematical demonstrations to algebra and geometry, with the result that the student, who is not familiar with the higher stages of mathematics, will probably take more interest in this side of the subject when it is presented to him in a simplified form. The illustrations are numerous and well done. One notices a good many which inevitably seem to appear in all text-books of physics, but, on the whole, the illustrations will have a distinctly fresh appearance for the English student. With regard to pharmaceutical requirements the scope of the work—apart from the mathematical treatment—is somewhat wider than is indicated by the syllabus of the Major examination. There is, however, no book on physics which quite meets the need of that syllabus, and the present work may be strongly recommended to those Major students who desire an easy and at the same time comprehensive volume on physics. As previously remarked, the mathematical treatment, which is distinctly necessary for a proper demonstration of physical theorems, is done as simply as possible. Sets of exercises with answers are also given, and a very moderate acquaintance with algebra and geometry suffices for the solution of most of the problems set.

The most conspicuous failing is the absence of any index, which makes rapid reference to any particular subject impossible. The portions relating to what may be termed chemical physics—for example, solution and chemical action—are also not very satisfactory

PHARMACEUTICAL SOCIETY.

MAJOR EXAMINATION QUESTIONS.

MATERIA MEDICA.

Tuesday, October 3, 1899.—*From* 10 *a.m. to* 11 *a.m.*

1. What are the sources of the official sennas? How can one be distinguished from the other? Discuss their relative value and indicate their active principle. Describe the characteristics of the latter body, and if it form salts, suggest one or more which you consider likely to be of practical value.

2. Mention the active constituent of Barbados aloes; describe in detail a process by which it can be obtained, and the tests by which it can be identified

BOTANY.

Tuesday, October 3, 1899.—*From* 11 *a.m. to* 1 *p.m.*

1. Write a short account of the chief modifications of the vegetative organs of plants for purposes of storing reserves of food.

2. Give a brief account of the phenomena of transpiration, and describe the mechanism by which transpiration is regulated in the plant.

3. By what characters are Bryophyta distinguished from Pteridophyta?

PRACTICAL MATERIA MEDICA.

Tuesday, October 3, 1899.—*From* 2 *p.m. to* 3.30 *p.m.*

1. Prepare transverse and longitudinal sections of the belladonna root provided. Draw and describe your preparations and leave one of each for inspection. Comment upon any peculiar features in their histological structure, and name any cell contents which you may recognise.

2. Report upon the sample of powdered belladonna root.

PRACTICAL BOTANY.

Tuesday, October 3, 1899.—*From* 3.30 *p.m. to* 5 *p.m.*

1. Make preparations to illustrate the microscopic structure of *A*, and sketch the chief features of interest in them.

2. Dissect *B* carefully—sketch your dissection and give explanatory references indicating the morphological value of each part.

3. Refer the plants *C* and *D* to their natural orders, giving reasons for your references.

CHEMISTRY.

Wednesday, October 4, 1899.—*From* 10 *a.m. to* 1 *p.m.*

Six questions only are to be attempted, and of these at least two must be taken from Part II.

PART I.

1. Indicate the nature of the experimental facts by means of which Dalton supported his views respecting the atomic constitution of compounds.

2. Give three methods by which nitrogen can be obtained in a condition free from other constituents of the atmosphere.

3. What volume of sulphur dioxide measured at 10° and 740 Mm. would theoretically be required to reduce a solution of 1 gramme of potassium dichromate in dilute sulphuric acid? [Cr = 52·5.]

4. What is the general chemical nature of glass? To what are the colours of coloured glasses due? What products are formed when a sample, of "hard" glass is reduced to powder and fused with excess of sodium carbonate?

5. A weak solution of hydrocyanic acid is suspected to contain hydrochloric acid. How would you test it for this impurity?

6. Starting from metallic lead, describe how each of the following substances may be prepared:—(*a*) White lead, (*b*) red lead, (*c*) lead acetate, (*d*) basic lead acetate, (*e*) lead peroxide, (*f*) lead nitrate.

PART II.

7. Give the constitutional formula of glycerol and discuss the evidence on which it is based.

8. Starting from acetic acid, how could you prepare (*a*) methane, (*b*) ethane (*c*) oxalic acid?

9. Write a short account of the processes by which commercial benzene is obtained. What are the common impurities in this liquid, and how would you prepare from it a sample of pure benzene?

10. Describe the preparation of salicylaldehyde.

PHYSICS.

Wednesday, October 4, 1899.—*From* 2 *p.m. to* 5 *p.m.*

Six questions only are to be attempted.

1. Explain carefully how the height of a mountain could be approximately determined by a purely physical method without the use of a barometer.

2. Find the specific heat of a substance 100 grammes of which at 90° C. when immersed in 250 grammes of water at 12° C. gave a resulting temperature of 18° C.

3. Describe the construction of a Leclanché battery cell, and state the changes that occur within the cell when it is in action.

4. What do you understand by the terms "real image," "virtual image"? Show by a figure how an image is formed in a plane mirror.

5. To what are the Frannhofer lines of the solar spectrum due? How could such lines be obtained in the spectrum of a luminous terrestrial body?

6. Describe accurately the arrangement and method of using a Bunsen photometer. What is the difference in the luminosity of two lights which show the same effect upon the photometric screen; one at the distance of one foot, the other at a distance of two feet from the screen?

7. What is understood by the critical temperature of a gas? Mention any practical points in connection with the critical temperature of a gas and the storage of the liquified gas under pressure.

8. Describe fully what happens when a constant current of electricity is passed for the same length of time successively through solutions of (*a*) copper sulphate, (*b*) silver nitrate, and (*c*) water.

PHARMACEUTICAL SOCIETY OF IRELAND.

ANNUAL MEETING.

The twenty-fourth Annual Meeting of the members was held on Monday, October 2, in the Society's House, 67, Lower Mount Street, Dublin, the PRESIDENT, Mr. R. J. Downes, in the chair.

ELECTION OF COUNCIL.

The scrutineers reported, and the PRESIDENT declared that the following seven gentlemen had been duly elected members of the Council:—Messrs. G. D. Beggs, J. J. Bernard, R. Simpson, J. E. Connor, W. J. Baxter, P. N. White, and W. Jameson.

THE PRESIDENT'S ADDRESS.

The PRESIDENT then delivered his annual address, in which he referred to the trial of The Queen (at the instance of William Boulton Conyngham) *v.* Pharmaceutical Society. He stated that the judgment given, if not in the Society's favour, was, at least, not unfavourable. The important question of the *ultra vires* of the Society's regulations was argued and decided, and although the regulations in question were decided by a majority of the judges to have been *ultra vires* at the time when they were approved by the Privy Council, it was unanimously held that they were affirmed and "set up" by the Amendment Act of 1890. The previous decision of the Queen's Bench was confirmed, that a company not entirely composed of qualified persons could not supply the requisite declaration of service, but that Hayes, Conyngham, and Robinson, Limited, being composed entirely of qualified persons, "fulfilled the conditions of a firm of legally qualified pharmaceutical chemists," one of the judges affirming that a firm did not cease to be a firm because it became incorporated—a dictum which he thought may be of considerable importance hereafter. The Society had thus recognised the applicability of the Companies Acts to pure pharmacy and pure drug business so long as the members are all qualified to transact the business engaged in, but drawing a distinct line as to the competence of the mixed company. This principle the Society hoped to see further recognised by Parliament in the Amendment of the Companies Acts. The President also referred to the refusal of the Local Government Board to recognise the Licentiates of the Society as qualified to undertake the duties of public analysts. The Council, he said, had had an interview with the head of the Department of the Local Government, and the result was to encourage the Society to seek power to hold an examination which would be recognised as qualifying for the position of public analyst, and that was now being considered by a special Committee. He then proceeded to deal with the question of company pharmacy, and gave a brief history of the Society's agitation in the matter. Referring to an article in the *Pharmaceutical Journal* of September 23 (see *ante*, page 305), the President, replying to the statement that his remarks at the last Council meeting betrayed a somewhat imperfect acquaintance with the earlier history of the matters referred to, said that he was not concerned with the "earlier history," and admitted ignorance of any move in regard to the question of company pharmacy, from the completion of the Departmental inquiry in 1895 till the Irish Society took up the matter in 1897. After speaking of the work of the Pharmacopœia Committee the President went on to review the work of the Society's schools during the past year, and of the social meetings, and wound up his address by again calling attention to the continuance of the depreciation of the "Arts and Mysteries" as a life calling, the statistics of examinations showing a falling off in every stage except that of "Assistant." The register indicated a natural but limited increase of 22 licentiates, 22 registered druggists, and 8 assistants, while the number of chemists and druggists remained stationary.

The various points touched upon in the address were subsequently discussed by the members present, Professor Tichborne speaking in favour of a post-graduate course to satisfy the requirements of the Local Government Board, but objecting to the title "Fellow" being granted in connection therewith.

MIDLAND PHARMACEUTICAL ASSOCIATION.

At a Council Meeting held on Wednesday, September 27, at Mason University College, Birmingham, the programme for the coming session was discussed and arranged.

The President announced that Alderman W. Gowen Cross, J.P., of Shrewsbury (member of the Pharmaceutical Council), had consented to give the inaugural address on Thursday, November 2.

The report of the Honorary Secretary, Mr. G. H. Brunt, on the circular issued in connection with proposed pharmacy classes at Mason University College, showed that the scheme had been favourably received by pharmacists in the Midlands and elsewhere.

Mr. Charles Thompson was appointed to represent the M.P.A. on the Executive Committee of the Federation of Local Pharmaceutical Associations, and at the unanimous request of the Council accepted its nomination of him for the local Secretaryship of the Pharmaceutical Society for the coming year.

HALIFAX AND DISTRICT CHEMISTS' ASSOCIATION.

A meeting of this Association was held at the Old Cock Hotel, Halifax, on Thursday, September 28, Mr. Cobb, President, in the chair. There was a large attendance of members, it being the first meeting of the winter session. A very interesting paper was read by Mr. Gibson Dixon, and it was afterwards discussed by the members.

Mr. Councillor Hebden, J.P., kindly offered space in his warehouse for the purpose of accommodating the library of the Association, and he was appointed the librarian. Early closing was then discussed, and it was decided that the chemists of Halifax close their establishments at 1.30 on Thursdays for the rest of the day.

The Secretary, Mr. H. C. Brierley was instructed to advertise this in the local papers for a month.

Mr. Gibson Dixon proposed:—

That this meeting of the Halifax and District Chemists' Association learns, with the deepest regret of the tragic death of Dr. J. Dick, of Eastbourne, and is of opinion that some steps should be taken to place doctors' dispensaries under the same poisons regulations as chemists' shops are now placed, and that a copy of this resolution be sent to the Council of the Pharmaceutical Society of Great Britain.

This was carried unanimously.

DEWSBURY AND DISTRICT CHEMISTS' ASSOCIATION.

On Monday evening a monthly meeting of the Dewsbury and District Chemists' Association, was held, members being present from Dewsbury, Heckmondwike, Thornhill and Batley. Mr. A. Foster occupied the chair.

Mention was made of the proposal to amend the Pharmacy Act and after some conversation the Association unanimously adopted the following resolution:—

That in view of the probable reintroduction of the Companies Act Amendment Bill into the House of Commons in the next session of Parliament, and recognising a clause in the said Bill relating to the business of a pharmaceutical chemist, or chemist and druggist, as directly antagonistic to the spirit and intention of the Pharmacy Act of 1868, and which would, if passed into law, practically annul the fundamental principles of the Statute, namely, compulsory qualification, by examination of each person carrying on business, or who assumes the title of Pharmaceutical Chemist, or Chemist and Druggist, thereby defrauding the public of the protection which the measure was intended to secure, and at the same time inflicting the most glaring injustice on those who have at great trouble and expense obtained registration under the provision of the Act, this Association earnestly trusts that the Council of the Pharmaceutical Society will use every measure in their power to prevent the said clause receiving Parliamentary sanction in its present form. The Association is of opinion that the most strenuous effort should be made to secure the inclusion of pharmaceutical chemists and chemists and druggists in the clause of the said Bill relating to the medical and dental professions, or, failing this, such radical amendment of the first mentioned clause as will render it illegal for any person or persons, individually or collectively, to take or use the title or exercise the business unless he and every person or persons have become registered under the provision of the Act of 1868. In the event of neither of these endeavours being successful, the Association would support an immediate and vigorous attempt to obtain such amendment of the Pharmacy Act as would achieve that end.

The following resolution was also adopted:—

That this Association urges upon the Council the necessity of appointing local secretaries in all Parliamentary boroughs and divisions throughout the kingdom, as we consider that this is the best means by which the work of the Society can be carried on effectively.

The Secretary (Mr. R. Gledhill) was requested to have copies of the resolution printed and sent to every member, and also to Associations in the North of England, asking of their support.

POOR LAW DISPENSERS' ASSOCIATION.

A meeting of the Poor Law Dispensers' Association was held on Thursday last at the Sessions Hotel, Clerkenwell, when Mr. C. Spencer (Marylebone) presided. There was a good attendance of members, being rather above the average number. Amongst those present were Messrs. R. E. Jones (Poplar), W. E. Miller (St. Pancras), A. Smith (St. Pancras), J. J. Smith (Marylebone), C. Spencer (Marylebone), F. N. Clark (Paddington), C. Fryer (Holborn), H. Hewitt (Holborn), E. Donnan (Islington), F. Bourke (Rotherhithe), and M. G. Smith (Lewisham), Secretary.

A council meeting having been held previously, and the order of business having been arranged, Mr. Spencer was unanimously elected to occupy the chair. The business, as a whole, rather partook of the nature of a discussion upon minor points of qualification for Poor Law Service than the conditions or terms of service, which might have better occupied the time and attention during the two hours at their disposal.

After Mr. Spencer had opened the proceedings by drawing attention to the fact of his work being nearly finished at the conclusion of two years of incessant toil along with his coadjutors on the Council, brought forward a letter received from the Poor Law Officers' Association, intimating the receipt of one from the Local Government Board on the 9th ultimo to the effect that all Metropolitan Poor Law Dispensers in receipt of a maximum salary of £140 (through the medium of their respective Boards of Guardians), can have it increased at an interval of every four years afterwards until a maximum £180 has been reached.

Mr. Jones having been called upon to say a few words, made quite a lengthy and eloquent speech (occupying about half-an-hour), in which he dwelt with especial stress upon the need of good men being let into the Poor Law Service, and that there should be more uniformity observed in the conditions of qualification so as to exclude a larger number of those who would be engaged at a minimum rate of salary.

Mr. Clark proposed a resolution to amalgamate the two kindred Associations, viz., the Poor Law Dispensers and the Public Dispensers, which, on being put to the meeting, was lost by a large majority in favour of an amendment proposed by Mr. Hewitt, to adjourn the meeting rather than to disband.

EXTRACTS FROM CONSULAR REPORTS.

The Lapse of the Patent in Antipyrine last year, as was to be expected, caused a decrease in the price of that article. Consul-General Schwabach (Germany) points out in a recent report that such an enormous fall as from 96 to 14½ marks per kilo. could not possibly lead to a corresponding consumption of that substance, and that at present it is doubtful whether its preparation is at all profitable.

British Chlorinated Lime, it is stated, is less wanted in Germany than formerly, as the electrolytic system of production provides Germany with as much as she requires, particularly as a duty of 3 marks per 100 kilos. is levied, and must be deducted from the already low prices. According to the British Consul, the past year was so unfavourable for the manufacturers of chlorinated lime that it became necessary for them to meet and consider whether it was not possible to fix the price at any rate so high that it left a margin for profit. The result of this conference was a rise of 20 per cent. The amount imported last year was 3,452 cwts., while the export from Germany amounted to 376,625 cwts. By far the greater part of the chlorinated lime used in Germany is produced by the electrolytic method, and the prejudice which formerly existed against this mode of production is nearly removed. In fact, many firms which produced chlorates and alkalis by the old method were obliged to adopt electrolysis in order to obtain anything like remunerative prices. Electrolytic works are reported to be in course of construction in the United Kingdom, Belgium, Russia, Austria, and America, so that there is a danger in the near future of over-production, unless some other additional use than those at present in vogue for chlorinated lime should be discovered.

The Glycerin Market in Germany during 1898 was, according to a recent report, much quieter than in the previous year, when a North American ring sent the price up to 120 fr. for 100 kilos. Last year, however, saw a decrease in the price of raw glycerin

to 70 fr. per 100 kilos., and this price was maintained with little variation till the end of the year. The consumption in the United States is reported to have been much less than usual in 1898 on account of the war. Within the past few months a considerable quantity has been required to supply the dynamite factories, consequently prices have gone up, and there is a prospect of a still greater rise. The price for purified glycerin was subject to the same variations as that of raw glycerin. The Association of German Glycerin Refiners found it difficult to maintain the price they had determined upon, for the reason that much foreign glycerin found its way into the German market, and was sold at a much lower rate. The quality of the foreign article, however, was not so good, but it was useful for a variety of purposes, and will eventually become a factor in competition which cannot be entirely ignored.

THE IMPORT OF RAW GLYCERIN into Germany last year was 185,614 cwts., as compared with 194,689 cwts. in 1897. Of this, 87,149 cwts. went from Great Britain. The import of purified glycerin amounted to 28,977 cwts., compared with 35,612 cwts. the previous year; of this Great Britain sent 8,432 cwts. In spite of foreign competition, however, the German glycerin production shows a decided increase principally in glycerin for making dynamite, of which Cape Colony and the Transvaal took by far the largest quantity. The export of German glycerin in 1898 amounted to 127,300 cwts., compared with 67,953 cwts. in the previous year; of this amount 8,810 cwts. came to Great Britain, while South Africa took much more than half of the entire German export.

A NEW PROCESS FOR MAKING SULPHURIC ACID has, according to a recent report, been patented by the Baden Aniline Soda Factory, whereby there is an immense saving in fuel, and the expensive platina-apparatus is no longer necessary. Another important feature is the fact that no saltpetre is required by the new process. Saltpetre is of such importance for agricultural and technical purposes that any economy in its use must be welcomed, the more so as the saltpetre fields will probably, in course of time, be exhausted.

GERMAN MANUFACTURERS OF POTASSIUM CHLORATE AND NATRON, at the beginning of last year, found business so unsatisfactory, owing to the various factories competing with each other in lowering the price, that they conferred together, and came to an understanding by which the price of chlorate productions, manufactured by the electrolytic method, were fixed at a certain rate. The result was that the price of potassium chlorate rose from 53 to 62 marks per 100 kilos., which price, it is stated, has since been satisfactorily maintained. The import into Germany in 1898 amounted to 29,725 cwts., compared with 27,646 cwts. in 1897; of this 8,259 cwts. went from Great Britain.

THE SALTPETRE INDUSTRY in Germany is reported to have experienced many changes during last year. Notwithstanding the fact that the price of raw kali saltpetre and Chile saltpetre kept up, the prices of the manufactured article went down, without any compensating increase in the sale. The cause of this unsatisfactory condition is attributed by Consul-General Schwabach to the large number of new factories and the diminished use of saltpetre in the manufacture of explosives. The export from Germany decreased. Great Britain, however, took 84,244 cwts.

A HIGH IMPORT DUTY is the probable cause of the decrease in the importation of alkali from Great Britain to Germany in 1898, the figures being 6,623 tons, as against 8,272 tons in 1897. Another reason is the increased production of soda from year to year in Germany itself. Last year the United Kingdom sent 11,742 cwts. of calcined soda, compared with 20,527 in 1897, and seeing that, as intimated above, a high duty is imposed on the import, the price for British soda must have been very low. The duty is 2s. 6d. per 100 kilos., and considering the low value of the material it is so disproportionately high that it is to be hoped that the next commercial tariff will deal with this question. Of the persulphates the most important import was kalium salts, which is used as a developer in photography. The use of natrium salts, it is stated, has greatly increased in Germany for medicinal purposes and also as an antiseptic.

PHARMACY IN AUSTRALASIA.

(From Our Melbourne Correspondent.)

WHEN I LAST WROTE we were, in Victoria, looking forward with eager interest to the further process of the Victorian Poisons Act Further Amendment Bill through the Legislative Council, feeling confident that in Mr. Grimwade (of Felton, Grimwade, and Co.) we had a representative who could lucidly explain the principles lying behind the amendments desired by the Pharmacy Board, and forcibly advocate their adoption.

UNFORTUNATELY, when the second reading came on, on August 8, Mr. Grimwade was too unwell to put in an appearance, and Sir Frederick Sargood, to whom he had entrusted his "brief," did not have the courage or inclination, when the Bill was in Committee, to move the first intended amendment, that paragraph (A) clause 4, "patent or proprietary medicines" be omitted—that is, from the list of exemptions. After this the Committee-men, in the absence of perhaps the only member of the House who could direct them, had a lot of information to give each other as to "poisons" and "patent and proprietary" medicines; and proceeded to make various alterations more or less—principally less—advisable, with the details of which it is scarcely worth while in the meantime to burden your pages, as at their last meeting the Pharmacy Board declared that the alterations made did not meet with their approval, and resolved to bring under notice of the Government before the Bill was introduced into the Legislative Assembly the amendments which the Board considered urgent and necessary in order to make it a workable measure.

AT THE LAST MEETING OF THE PHARMACEUTICAL SOCIETY OF AUSTRALASIA the Committee of the proposed Victorian Pharmaceutical Conference—respecting which see previous notes—reported that a circular had been sent to every chemist in business in Victoria, inviting co-operation and assistance, and that the Committee was now engaged in the preparation of the various formulæ to be shortly submitted and dealt with.

AT A MEETING OF CHEMISTS, held at the Melbourne College of Pharmacy on August 14, it was decided to form a Chemists' Cricket Club, and the following officers were elected:—Patrons, Hon. F. S. Grimwade, M.L.C., Messrs. H. T. Tompsitt and R. P. Francis; President, Cr. Chas. Pleasance; Vice-Presidents, Dr. Plowman, Messrs. Rankin, Strutt, and Cattach; Secretary, Mr. A. F. Vivian. So do not be surprised if at an early date you will have to entertain an Australian Eleven ready to meet, and sure to beat, any knights of the pestle in the old country that may have the temerity to challenge them.

THE RECENTLY-PUBLISHED ANNUAL REPORT OF THE AUSTRALIAN COLLEGE OF DENTISTRY, MELBOURNE, shows that although only three years established, the College has acquired an intercolonial reputation, there being among the thirty-nine students now attending the institution several attracted from other colonies. In proof of the charitable character of the institution is the fact that over 10,000 patients were attended to at the hospital during the past year.

AT THE AUGUST MEETING OF THE PHARMACY BOARD OF NEW SOUTH WALES, Messrs. Ll. Williams and H. S. Brothwood were respectively re-elected President and Treasurer for the ensuing year. In expressing his thanks, Mr. Brothwood referred to the necessity which he foresaw in the near future of applying to the Government for funds, as the receipts accruing from registrations, etc., during the past two years were now falling off, the Board had done an immense amount of work on very little money, and he expressed the hope that their efforts would be appreciated and recognised by the Government. Which remains to be seen.

IN THE MEANTIME the Board is determined to take active measures against offenders under the Pharmacy Act, 1897, and the Poisons Act, 1876, and has issued a circular to registered chemists, magistrates, and council officers with a view of obtaining their assistance in the matter by undertaking the position of district inspectors. The duties outlined by the circular are: (1) To see that chemists' shops are carried on by those persons only who are registered pharmacists. (2) To see that scheduled poisons are not sold by persons not having certificates as dealers in poisons from

the Pharmacy Board. (3) In cases of breaches of the above Acts to prosecute the offenders in Court by authority of the Pharmacy Board. The remuneration to the inspectors is allotted at one-half the fines inflicted, and a refund of the expense incurred by the inspectors on account of such prosecutions. About thirty applications have been received by the Board, and are now under consideration.

The Registered Pharmacists' Society of N.S.W. has succeeded in securing from the Government the use of convenient premises for the proposed course of popular scientific lectures. and arrangements are now being made for an early commencement. In regard to the complaint in connection with the Friendly Societies' Dispensaries, the Society has been less fortunate, its communications to the Principal Under-Secretary on the subject having so far been practically ignored. The President has accordingly been authorised to interview some suitable member of the (N.S.W.) Legislature, with a view to having the correspondence between the Society and the Colonial Secretary's department tabled in the House.

At a meeting of members of the Dental Profession, held in Sydney on August 14, it was resolved to form an Odontological Society on the lines of that already successfully established in Victoria, the principle of membership being that "a person shall be eligible for election as a member, provided that he be of good character, that he does not conduct his practice by means of the exhibition of dental specimens, appliances, or apparatus in an open shop, or in a window, or in a show-case exposed to public inspection, or by means of public advertisements or circulars describing modes of practice or patented or secret processes, or by the publication of his scale of professional charges." The following office-bearers were elected:—President, Mr. E. Reading; Vice-President, Dr. A. Burne; Hon. Treasurer, Mr. E. K. Satchell; Hon. Secretary, Mr. Donald Smith; Members of Council, Dr. Syme, Dr. F. Magnus, Messrs. P. B. Reading, Soderberg, Hunter, and Dr. Hunter.

NEW REMEDIES.

Bismuth Oxybromate and Sulphocarbolate.—Hugh Woods employs bismuth oxybromate in the treatment of nervous disorders of the stomach. It can be given several times a day in doses of 60 centigrammes, but in smaller doses of 30 to 40 centigrammes it is very efficacious. Being an insoluble yellow powder, it should be suspended by means of mucilage of acacia. Bismuth sulphocarbolate, a rose-coloured powder, slightly soluble in water, is employed by the same author in certain febrile maladies, in dyspepsia, and in abnormal fermentations in the alimentary canal; it forms a useful antiseptic. It is given in the form of a cachet in doses of 20 to 50 centigrammes three or four times daily.—*Nouv. Rem.*, **15**, 394.

Local Applications in Rheumatism.—The following application is recommended by Bourget:—Salicylic acid, 45 grains; oil of turpentine, 45 minims; wool fat, 5 drachms; lard, 5 drachms. then covered with any impervious material. S. Sterling employs This is spread over the parts, a dressing of absorbent cotton applied, the following ointment:—Salicylic acid, oil of turpentine, lanolin, of each, 1; lard, 4. This is applied to the affected joint, covered with non-absorbent cotton, then wrapped in gutta percha. When the superficial epidermis is destroyed, the turpentine is omitted.—*Pract.*, **63**, 358.

Creosote-Ichthyol.—This is the name given by H. Goldmann to a mixture composed of creosote carbonate, 15; ichthyol, 15; glycerin, 30; peppermint water, 10. The mixture is useful in tuberculosis, in doses of from 20 to 30 drops (with wine or lemonade) three times daily; for children, 10 drops three times daily is sufficient.—*Oest. Zeits. Pharm.*, **53**, 429.

Eumenol.—Eumenol is the name given by E. Merck to the extract of the root Tang-Kui, which has long been known in China as a remedy for amenorrhœa and dysmenorrhœa. The botanical origin of the root is unknown, but Harth strongly recommends its use.—*Oest. Zeits. Pharm.*, **53**, 428.

LETTERS TO THE EDITOR.

The Proposed Canadian Addendum to the B.P.

Sir,—In your comments on the proposed Canadian Addendum (September 2), you are somewhat in error in stating that the formulæ were devised, etc., by Messrs. Lyman, Sons and Co. The work was done by me, or under my supervision, in the laboratory of that firm, who kindly placed material and apparatus at our disposal to carry on the work.

Montreal, September 11, 1899. J. E. Morrison.

The Solubility of Quinine Hydrochloride.

Sir,—Having had recently to prepare a large quantity of strong alcoholic solution of quinine hydrochloride, I was led to consult the standard works as to the solubility of that salt in 90 per cent. alcohol. I find that the B.P., 1898—"our casket of natural gems more or less polished"—gives 1 in 3, and in the U.S.P., and 'Extra Pharmacopœia,' the same figures are given, but Squire says 1 in 1. From experiments I have made, I am able to confirm Squire's statement, and may add that at temperatures below 60° F. re-crystallisation quickly takes place.

North London Chemical Works, Holloway, October 2, 1899. F. Bascombe.

Ether-Soap.

Sir,—It may interest Mr. Hocking still further to know that the "surgeon's formula," which he is using and to which he refers in last week's Journal, is one communicated by me to that gentleman (who happens to be connected both with Evelina and St. Thomas's Hospitals) some months ago. I think Mr. Hocking, before writing his letter, should have consulted the surgeon from whom he derived the formula; he would then have found that the formula was given for private use and was not intended for publication by anyone into whose hands it might fall. In that case Mr. Hocking's letter and this reply would have been unnecessary. Very possibly the case of the third hospital mentioned by Mr. Hocking is similar to his own; but as the name of the institution was not mentioned, I am unable to say definitely. Comparison of the formulæ will show that the proportions of the constituents are almost the same. I have made some slight alterations which further experience suggested. The method described by Mr. Hocking was the one formerly used by me. I have, however, since changed it to the more cleanly and expeditious method described in my paper, the advantages of which over my former method, still preferred by Mr. Hocking, are sufficiently obvious. If one makes the solution according to my formula, in quantities of about 5 litres instead of a few C.c., there should be no difficuity in confirming my observations as to the rise of temperature and the formation of deposit. The occurrence and amount of this deposit will obviously depend upon the composition of the sample of oleic acid employed, commercial varieties of which are never pure, and is there any need for the employment of a very pure acid in the present case?

St. Thomas's Hospital, S.E., October 3, 1899. Edmund White.

Sodium Arseniate.

Sir,—Your "Students' Column" this week treats of sodium arseniate. My experience of the subject goes to show that as to stable-keeping qualities the crystals are the more trustworthy. I have here about 3 ounces that I can vouch for being twenty-five years old, at least, and there is no change in their appearanee whatever. The dried, on the contrary, has had to be thrown away twice or thrice during the same period because it became damp, and a specimen of the fused—as old as the crystals—has an evident tendency to return to the crystalline state. I should be happy to supply any pharmacist of my acquaintance—in proper form—with a specimen for examination upon application.

39, *Church Street, Maryletone, N.W., October* 3, 1899. J. C. Hyslop.

Poor Law Dispensers' Association.

Sir,—Now that the important question of salary is settled by the L. G. B., increasing the maximum salary to £180 per annum, I trust that the executive of the above Association, who have erected a monument of fame which will endure for ever, will take immediate steps to prevent the burial of their Association, and so avoid another resurrection of it.

The Association, as at present constituted, is not on a sufficiently sound basis to be lasting. It is but a carcase without a spirit, shell without a kernel. We do not want a thing of paper, a castl in the air, but a reality which will bear the test of common sense and with that view I advocate that we immediately amalgamate with the Public Dispensers' Association, and so promote the welfare of all public dispensers, thus opening up a wide field, with, I hope, a fertile soil, where discussions and lectures will extend intellectual culture, the fundamental principles of success.

Let us persevere and struggle to reach the apex of possibilities; it may require time, but it will be done if we are determined. Let us not pass our lives in obscurity. Let each who values himself, his intellect, and his betterment, consider the advancement of the whole craft. Join the Public Dispensers' Association, and do not grudge to trim the morning lamp, or acquire too great an affection for the pillow, and so assist in nibbling at the apple of knowledge in search of the core. Let each remember that his attendance should be regular, and that by improving the mind, obstacles will be removed that will gradually lead not only to improvement, but increasing improvement socially and financially, with the view of the Poor Law Dispensers' Association amalgamating with Public Dispensers' Association.

28, *Goring Road, Bowes Park, N.*, S. B. DONNAN.
March 3, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Sale of Business (H. K.—34/15).—Your best plan is to submit the agreement to a solicitor, and ask his opinion upon it.

Capsules (S. H.—34/25).—You should be able to obtain them through any wholesale house.

Sale of Prussian Blue (E. W. S.—34/27).—(1) Prussian blue is not a scheduled poison; (2) It hardly seems necessary to label it "poison."

Tannigen (W. H. and S.—34/29).—The substance you require is probably tannigen, which is insoluble in water, and is usually dispensed in cachets, in doses of 3 to 8 grains.

Army Medical Staff Corps (J. M.—34/22).—See the note on the subject in the *P.J.* for September 9 last, page 250, and write to the headquarters of the Army Medical Staff, 18, Victoria Street, London, S.W., for further particulars.

Pharmacopœias (E. E. H.—34/20).—(1) A 'Pocket Pharmacopœia' is published by Baillière, Tindall and Cox, price 3s. 6d. (2) Only second-hand copies of the works you name are now obtainable; advertise in the Exchange column of the *P.J.*

Medicine Stamps (W. S. A.—34/24).—All you require to do is to purchase a stock of stamps from the Inland Revenue authorities and attach one to each package in such a manner that the package cannot be opened without breaking the stamp.

Canada Balsam (A. H. B.—34/28).—The oleoresin or the spirit must have been at fault, as there is no difficulty in dissolving genuine Canada balsam, which has been evaporated to dryness, in pure benzol. The solution should not leave a sticky residue on drying.

Microscope (W. G. P.—34/26).—You can get a good student's microscope by Leitz (Stand V), with two eyepieces and two objectives, for £3 10s. Write to C. Baker, 244, High Holborn, London, W.C., for particulars. Watson's stands are, of course, much superior, and well worth the extra cost.

Photographic (J. B.—33/24).—The negative was rather fully exposed, and we should say not developed far enough. To prevent the prints losing their gloss, it is advisable to paste a piece of waterproof paper on the back of them when they are squeegeed down to the glass. We do not know the varnish, but it is probably a solution of white shellac in borax and glycerin and water. If you could send some up we might be able to tell you.

Ext. Cinchonæ Liq. (E. A. A.—2/4).—It does not at all follow that, because one fluid ounce of liquid extract is prepared from one ounce of cinchona bark containing 5 per cent. of alkaloids, the finished preparation must contain 5 per cent. of total alkaloid. According to the B.P., 1885, the residue left in the dish consists of pure alkaloids; Mr. White shows that such is not the case. If, therefore, you have been in the habit of preparing a liquid extract really containing 5 per cent. of pure alkaloids, you cannot have standardised it by the process official in the B.P., 1885.

Use of Title (C. H. B.—34/32).—(1) The individual referred to may be unaffected by the first fifteen sections of the Pharmacy Act, 1868, by virtue of being registered as a legally qualified medical practitioner. If not, send particulars of the case to the Secretary and Registrar of the Pharmaceutical Society. (2) The Privy Council can direct the name of a chemist and druggist who has committed an offence under the Pharmacy Act to be erased from the Register, but the Pharmaceutical Society is invested with no such authority. The Council of the Society can direct the removal of a person's name from the list of members, but that does not affect the position of the individual as a registered chemist.

Tinct. Iodi Decolor., B.P.C. (W. B. B.—34/10).—In calculating the iodine strength of the official tincture for comparison with other iodine preparations, you must only consider the *free* iodine present. The iodine in potassium iodide is so firmly combined with the metal that it never manifests the local action shown by free iodine. Potassium iodide is associated with iodine to assist the solution of the latter. The expression "about the same strength" must therefore be taken as referring to the 250 and 218·75 grains of iodine in the two preparations you mention. We should think the decolorised tincture would be meant by the prescriber of lin. iodi alb.; or, perhaps, the tinctura iodi decolorata fortior of the B.P.C.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

Corrections.

PERCENTAGE SOLUTIONS OF THE PHARMACOPŒIA.—At page 317, column 2, line 9 from the bottom, for "24/11 or 22/11," read "24/11 or $2\frac{2}{11}$."

THE TESTING OF TURPENTINE OILS.—At page 330, column 1, line 15 from the bottom, for "88°" read "8°."

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Anderson, Andrews, Attree, Bartlett, Bell, Bennett, Bentley, Booth, Brierley, Brunt, Cocks, Ferryman, Fox, Frame, Gamble, Gibb, Gibson, Glew, Groth, Hibbert, Hill, Hogg, Hooker, Jennings, King, Kirkby, Lake, Longstaff, Maben, McKellar, Massie, Mumbray, Nursaw, Pater, Pinson, Powell, Roberts, Roy, Rudd, Sleath, Smith, Snowden, Tuckett, Type, Tyrer, Walton, Whineray, Wilkinson, Williams.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

EFFECTS OF ANHALONIUM LEWINII.

Dr. W. E. Dixon finds that "Mescal" acts differently from any other known substance, although in isolated properties it resembles many. *Cannabis indica*, which it was at first thought to resemble most closely differs from it in producing delusions of merriment and a hypnotic effect; "Mescal" never gives rise to merriment, but rather to a condition of ideal content, and produces wakefulness. It is closely related to strychnine by its marked effect on the brain and cord, but whereas strychnine acts mainly on the cord, the effect of "Mescal" is mainly cerebral, and opisthotonos never occurs. It resembles nicotine in its effects on nerve, first paralysing nerve cells and then fibres. Other properties of "Mescal" may be compared to those of digitalis and cocaine, but in each case with marked contrasts. In its peculiar stimulation of the occipital cerebrum "Mescal" appears to stand alone. Its properties lead the author to hope that it may be of use in therapeutics: the fact that even after very small doses a feeling of well-being and exhilaration results, points to its use as a general stimulant to the central nervous system, the diminution in the kinæsthetic sensations possibly making it of special use in melancholia. Further it is possible that its effect on slowing the heart by a direct action on cardiac muscle and in small doses increasing the force of the beat may be found of use.—*Journ. Physiol.*, September, 1899, p. 69.

ALKALOIDS OF ANHALONIUM LEWINII.

Dr. Dixon points out that Heffter described (*Berichte*, 1896) a method by means of which four alkaloids — mezcaline, anhalonidine, anhalonnine, and lophophorine—could be extracted from "Mescal" buttons. E. White, of St. Thomas's Hospital, has amplified Heffter's work, and prepared the alkaloids in the following proportions from the crude "buttons":—Mezcaline and anhalonidine (about equal amounts of each), 1·16 per cent.; anhalonnine, 0·46 per cent.; lophophorine, 0·14 per cent. The alkaloids were supplied in a beautiful crystalline condition, except lophophorine, which appears to be only crystalline in the form of a salt. All were freely soluble in distilled water, alcohol, or normal saline solution, and possessed remarkable similarity in their physiological actions. Anhalonnine and anhalonidine have the same formula—$C_{12}H_{15}NO_3$—and are isomeric; their physiological effects are identical. Lophophorine ($C_{13}H_{17}NO_3$) belongs to the same series, differing only by the addition of CH_2: this addition, however, appears to have the effect of increasing the toxicity. Mezcaline ($C_{11}H_{17}NO_3$), though apparently differing somewhat in constitution, is also closely allied to the other bases, and its physiological action is almost indistinguishable from that of anhalonnine.—*Journ. Physiol.*, September, 1899, p. 71.

MELTING-POINT OF HYDROGEN.

T. Bayley points out that the value—about 16°·7 C. (abs.)—given by Professor Dewar for the melting-point of hydrogen is near a value —16°.768 C. (abs.)—which is, within narrow limits, a common measure of the melting-points of the family of alkali-metals of which hydrogen is the first member. Thus, taking the latest determinations given in Roscoe and Schorlemmer's 'Chemistry':—

	M.P. (abs.)		16·768		Diff.
H	c. 16·7	(Dewar)	X		
Li	453		27	= 452·73	— 0·27
Na	368·6		22	= 368·89	— 0·29
K	335·5		20	= 335·36	— 0·14
Rb	311·5		18·5	= 310·20	— 1·3
Cs	299·5			= 301·82	+ 1·3
—	c. 273		17·5	= 293·44	

c. 293 is the melting-point for the unknown alkali-metal (A W c. 223·7) next succeeding to Cs, independently arrived at by a graphical treatment of the melting-points of the elements in a manner similar to that employed for the A.V.'s (*Journ. Am. Chem. Soc.*, 20, No. 12). This graphical treatment clearly demonstrates an interrelation between the A.V.'s, M.P.'s, and B.P.'s of the elements, and in view of the figures given above the question may be asked whether the melting-points of the alkali-metals are not simple multiples of the melting-point of hydrogen. Also taking 0·036 (Dewar) as the maximum density of liquid hydrogen (= A.V. 11·6), the A.V.'s of the same metals are (but only approximately) simple multiples of this hydrogen value.—*Chem. News*, **80**,159.

ALUMINIUM IODIDE EXPLOSION.

P. L. Narasu received at Madras two samples of aluminium iodide in hermetically sealed glass tubes, from a German firm. Whilst one of the tubes was being passed round a class, the other—lying on the demonstration table—suddenly exploded, and its contents were thrown out. Prior to the event both the tubes appeared to be perfectly sound, and there was no reason to suspect that the volatile compound had formed an explosive mixture with air. The temperature of the lecture-room at the time the explosion took place was nearly 95° F.—*Nature*, **60**, 520.

EFFECT OF ARSENIC ON PLANTS.

According to M. R. Bouilhac, a number of freshwater algæ which he enumerates can absorb a certain amount of arsenic acid in the form of arseniates without injury; these salts partially taking the place of phosphates. Among the algæ which possess this property are *Ulothrix tenerrima*, *Protococcus infusionum*, *Dactylococcus infusionum*, and *Stichococcus bacillaris*. With *Schizothrix lardacea*, arsenic acid appears to have even a more favourable effect on its growth than phosphoric acid.—*Bull. Soc. Bot. France*, 1899, p. 61; from *Annales Agronomiques*, 1898.

MICROSPORIUM AND ALLIED FUNGI.

In the opinion of MM. L. Matruchot and C. Dassonville, all the fungi which cause ringworm, herpes, and allied cutaneous diseases—*Trichophyton*, *Achorion*, and *Microsporium*—should be placed in the *Ascomycetes* among the *Gymnoasci*. The conidial apparatus of *Microsporium* is a similar structure to those of *Gymnoascus*, *Ctenomyces*, and *Trichophyton*. The spores are solitary, or grow laterally and irregularly on the filaments. They are formed by the transport and encysting of the protoplasm, and are attached by a more or less broad surface. *Microsporium* possesses also pectinaceous hyphæ similar to those of *Ctenomyces*. Whether it should be retained as a distinct genus, or united with *Ctenomyces*, *Trichophyton*, and *Achorion*, and all sunk in *Gymnoascus*, the authors leave an open question.—*Comptes rendus*, **129**, 123.

ANIMAL AND VEGETABLE CANCER.

M. Bra records some interesting observations on the analogies presented by cultures of *Nectria ditissima*, the fungus which produces "cancer" in trees, and those of the parasitic fungus which accompanies cancer in man and other animals. In the former case the cultures produced round spores about 1 μ in diameter, displaying a brownian movement, having a strong tendency to agglomerate and multiplying endogenously by budding. The spores, spherules, conids, and hyphæ present staining reactions and biological characters identical with those of the human parasite. Inoculations of trees with cultures of the human parasite resulted in a "cancer" in all respects resembling that produced by *Nectria*; and conversely, the ingestion of rabbits by cultures of *Nectria* caused the production, in about three months, of round ulcers in the stomach similar to those produced by the ingestion of cultures of the human parasite.—*Comptes rendus*, **129**, 118.

PERCENTAGE AND OTHER SOLUTIONS.

BY HAROLD WILSON.

Pharmacist to University College Hospital.

The subject of percentage solutions is one in which, as a teacher of pharmacy, I have been much interested, and it was, therefore, a pleasure to read the paper published by Mr. F. A. Upsher Smith in a recent number of the *Pharmaceutical Journal* (*ante*, p. 317). I am in entire accord with the first of his conclusions, viz.: "True percentage solutions containing x parts by weight in 100 parts by weight are not desirable as long as liquids are measured.

True percentage solutions are useless when liquids are dispensed by measure; for, neither the weight of principle contained in a given weight of solution, nor the volume of the principle which has been mixed with a given volume of the solvent, are of any use as a basis for calculating the weight or volume of principle in measured quantities of the finished product.

As pointed out by Mr. Upsher Smith, the chief difficulty met with in using true percentage solutions is the varying specific gravity of the solvents ordered; this can be demonstrated in a very convincing manner by preparing solutions of a salt, such as mercuric chloride, in water, ether, and glycerin, each solution being of the same true percentage strength, and containing the same weight of the salt; it is then very evident that the strengths of the respective solutions are quite different if determined by the weight of salt in a given volume. This difficulty disappears where fluids as well as solids are dispensed by weight, but, so long as fluids are measured (and I hope this may always be the case), the volume of a true percentage solution required to contain a definite weight of principle can only be determined by direct experiment in each case as it arises.

Considering that we are almost compelled to regard the strength of solutions in terms of weight or volume of the principle in definite volumes of the product, it appears to me that it would be well if the British Pharmacopœia, our "uniform standard and guide," were to make some authoritative statement as to the method of procedure to be followed in preparing solutions ordered to contain definite percentages of solids or liquids. This seems all the more necessary, as undoubtedly the ordering of percentages in prescriptions is on the increase. I suggest, as the most satisfactory method of dealing with the question, that in pharmacy the term percentage, when applied to solutions, shall be restricted to indicating the parts or fluid parts of the principle contained in 100 fluid parts of the solution. This is the system under which the standardised preparations and most of the liquors of the British Pharmacopœia are prepared, though in no case are the products spoken of as percentage solutions.

Some such paragraph as the following would, I think, meet the case if inserted in the Pharmacopœia.

"Percentage Solutions."

"In preparing solutions ordered to contain x per cent. of a solid or liquid, the following rules shall be observed:—

"(1) *Solution of a solid in a liquid.*—Take x parts of the solid, dissolve and make up to 100 fluid parts with the solvent ordered.

"(2) *Solution of a liquid in a liquid.*—Take x fluid parts of the liquid, dissolve and make up to 100 fluid parts with the solvent ordered."

Another matter which may be conveniently referred to here is the necessity for an authoritative statement as to the correct interpretation of prescriptions in which are ordered solutions containing 1 part in x parts. The following is a very commonly occurring prescription of this class:—

℞. Sol. Hyd. Perchlor., 1 in 1,000.
Mitte, ʒviii.

This prescription is dispensed in one of two ways—

(*a*) By making a solution containing 1 grain of mercuric chloride in 1,000 minims. In this case $\frac{480 \times 8}{1{,}000} = 3{\cdot}84$ grains of mercuric chloride would be contained in eight fluid ounces of the finished solution.

(*b*) By making a solution containing one grain of mercuric chloride in 1,000 fluid grains. In this case $\frac{437{\cdot}5 \times 8}{1{,}000} = 3{\cdot}5$ grains of mercuric chloride would be contained in eight fluid ounces of the finished solution.

By the first method a solution is obtained which is more than one-tenth stronger than one prepared by the second method; this is surely a serious difference. I will refrain from citing the arguments of the respective adherents of the methods given; suffice it to say, that enough uncertainty exists to give colour to these arguments when a uniform and definite method should unquestionably be followed in all such cases.

I therefore also suggest that some such paragraph as the following be inserted in the Pharmacopœia:—

"Solutions Containing 1 Part in X Parts."

"In preparing solutions ordered to contain 1 part of a solid or liquid in x parts of the finished solution the following rules shall be observed:—

"(1) *Solution of a solid in a liquid.*—Take 1 part of the solid; dissolve and make up to x fluid parts with the solvent ordered.

"(2) *Solution of a liquid in a liquid.*—Take 1 fluid part of the liquid; dissolve and make up to x fluid parts with the solvent ordered."

I am perfectly aware that I have only been stating well-known facts with regard to these solutions, but I do hope my remarks may lead to steps being taken which will render it impossible for any such misconceptions to arise. We must strive for uniformity. We all know instances in which pharmacists have lost the confidence of customers through such trivial matters as the varying colour of an infusion; but what would these people think if they knew how much the strength of a solution depended on the particular views of the pharmacist who dispensed the prescription.

My reason for advocating the use of parts or fluid parts of principle in fluid parts of product, is, that made in this way, solutions will be of the same strength, whether British or metric weights and measures are employed. The fluid grain bears practically the same relation to the grain as the cubic centimetre does to the gramme, but if, on the other hand, we decide to make solutions containing grains in minims, then we destroy the connection between the British and metric systems.

Mr. Upsher Smith's second conclusion reads as follows: "Solutions containing x grains in 110 minims, are unnecessary and clumsy, because they serve no useful purpose, and do not admit of consistent and simple dosage of potent drugs."

Against this I must protest most strongly; in fact, to criticise in this way a Pharmacopœia which has adopted the metric system as an alternative in formulæ for the first time, is little short of heresy. If we go back to "percentage" solutions containing grains in minims, how are we to secure that uniformity between British and metric systems which must pave the way for the complete adoption of the latter in this country?

It is indeed unfortunate that fluids are prescribed in minims, rendering the calculation of the quantity of solid present in a small dose of the official liquors somewhat tedious. For all this we must blame the minim, and look upon the fluid grain as one of the prophets of the coming metric system. With regard to the discrepancy in dosage which Mr. Upsher Smith points out in the case of sodium arsenate, and solution of sodium arsenate, I should seek an entirely different remedy. What purpose is served by having official liquors which are merely aqueous solutions of salts? Why cannot the

salts themselves be ordered? Surely if such salts were ordered by weight the pharmacist might be trusted to select and make a solution of his own, which in his experience was most convenient for dispensing purposes. It seems to me that it would be easier, and certainly more scientific, to order definite quantities of a drug than of a solution the strength of which the prescriber frequently knows nothing.

PRACTICAL STANDARDS OF SOLUBILITY OF CHEMICAL SUBSTANCES.

BY HAROLD WILSON,

Pharmacist to University College Hospital.

It has occurred to me that the statements in the British Pharmacopœia as to the solubility of chemical substances, though scientifically accurate, might with a little extension be made much more useful both to medical men and pharmacists.

Here we find that the information takes the form of noting the number of parts of water or other solvent in which one part of the substance will dissolve. No mention, however, is made of the volume resulting from such solution. Now, in practice we require to know what quantity of the substance is capable of being held in solution at ordinary temperatures in some given volume which is the resultant of the solution of the substance in the particular solvent ordered. I, therefore, suggest that the quantity of the substance contained in a given volume (say a fluid ounce and some convenient volume in cubic centimetres) of a saturated solution at 50° F. (10° C.) should also be mentioned. In most cases it would only be necessary to treat in this way the case of solution in water. The most desirable temperature to select is a point for discussion, and it might be advisable to give figures for more than one temperature

I will give one instance of the uselessness, from the practical pharmacist's point of view, of some of the statements at present in the Pharmacopœia. In the case of sodium sulphate we are told that it "is soluble in less than half its weight of water at temperatures from 77° to 86° F. (25° to 30° C.)."

This is all very well as a fact, but the information is not of the least use to prescribers and dispensers, at any rate, in such a climate as ours. No general remarks are made showing the peculiar variations in the solubility of this salt at different temperatures. I cannot but think that such isolated statements are more fitted for a dictionary of chemistry, and that they might well be deleted from the Pharmacopœia. Let us try to make the book a really more practical one by removing statements of doubtful utility, and introducing information more fitting to those whose lot in life necessitates its constant companionship. But whence shall the required data be derived in order that such information *can* be given? Most improvements introduced into the Pharmacopœia have been the result of independent researches conducted by pharmacists. But I take it that no pharmacist will gratuitously undertake work of this kind. However useful and even necessary the results of such labours might be, the subject is too tedious and dull to be ever undertaken for love by anyone competent to obtain accurate results. Work of this description must be paid for, and it is a thousand pities that the Pharmacopœia authorities have not yet advanced so far as to appoint a body of paid workers. Such a body would find abundant employment in routine work and in checking many processes advocated by independent workers. We should then hear less of unworkable and clumsy methods finding their way into the Pharmacopœia. The latter might then come much nearer to that high standard of perfection which it is our hope and ambition to see in our recognised authority.

EXTRACTUM BELLADONNÆ, B.P.

BY F. A. UPSHER SMITH.

Demonstrator of Pharmacy, Pharmaceutical Society's School.

This note has for its object the raising of a point which has given the pharmacist some difficulty during the past eighteen months. When extractum belladonnæ is ordered in a prescription, it is not easy to decide which extract to use, since there are now two official extracts, known respectively as extractum belladonnæ alcoholicum and extractum belladonnæ viride.

Inquiries recently made among some of the leading pharmacists in the West-end elicits the fact that some use the alcoholic and others the green extract when simply extractum belladonnæ is ordered in prescriptions. It matters less which is used in making pills than in making suppositories, though the balance of evidence is in favour of the alcoholic extract for suppositories. The case may be thus briefly put:—

In support of the green extract it may be urged: (1) That the older practitioners have it in view when writing prescriptions; (2) that in the list of alterations in the nomenclature of the preparations of the B.P., 1898, extractum belladonnæ viride is given as the new name for extractum belladonnæ; and (3) that the green extract possesses better binding properties than the alcoholic when used for forming pills.

On the other hand, it may be claimed for the alcoholic extract: (1) That it is a preparation of definite strength; (2) that it is free from chlorophyll, consequently there is less difficulty in making belladonna suppositories with it; and (3) that the suppositoria belladonnæ of the B.P. are made with the alcoholic extract.

It will be seen, therefore, that each extract has something to recommend it before the other. Those who have attempted to prepare suppositories containing extract of belladonna and tannin will testify to the extreme difficulty of turning out a presentable product when the green extract is used. A strict minimum of heat is necessary to prevent an unsightly mass, and even then only the most skilful and rapid operator is successful. If the use of the green extract be insisted on, then it will be found advisable to make the suppositories in the cold. This plan was adopted in the School of Pharmacy last winter with considerable success.

In my opinion, the alcoholic extract is the most suitable for making suppositories. That it is by no means an ideal preparation has already been shown by Bird (*Pharmaceutical Journal*) [4], **7**, 163). Its disadvantages, however, affect chiefly its employment in forming pills. It is too crumbly, and lacks the binding properties of the green extract and of the alcoholic extract of the 1885 Pharmacopœia. This points to the use of the green extract in pill-making.

Further, there remains the undoubted fact that many medical men are still ignorant of the contents of the new Pharmacopœia. There are, indeed, some who are unaware even now that a new Pharmacopœia was published in 1898. There is no doubt that these practitioners, as well as others who have a preference for the green extract, intend it to be used when they simply order extractum belladonnæ in prescriptions.

Lastly, the definite statement in the Pharmacopœia, p. xxvi., that the present name for extractum belladonnæ is extractum belladonnæ viride, leaves no room for misinterpreting the intentions of the Pharmacopœia authorities. By extractum belladonnæ they certainly mean extractum belladonnæ viride. It would be well, provided they sanction the use of the alcoholic extract for suppositories and the green extract for pills, that they should insert a note to that effect, as is done under unguentum paraffini, where white ointments are directed to be prepared with the white variety of soft paraffin, and coloured ointments with the yellow.

It is hoped that pharmacists will ventilate and discuss this question. At present the existing confusion in the use of the two kinds of extract is increasing rather than diminishing, as every year another generation of students goes back to business, uncertain as to what other pharmacists are doing in the matter. Though different opinions have been held in the past, yet at all events some degree of unanimity may be attained in the future by discussing the question.

THE EARLY HISTORY OF CINCHONA OFFICINALIS.

BY G. CLARIDGE DRUCE, M A.,

(Fielding Curator in the University of Oxford.)

In the library of the Botanical Gardens at Oxford I have recently met with the following letters relating to the early history of the Loxa *Cinchona*, which it may be well to print. Although no fact of great importance is contained in them, any information about such a valuable remedy needs no apology for insertion in the pages of the Journal.

London, December 20, 1741.

Worthy Sir,—Your great learning in Botany, etc., which hath placed you in that Honourable Station you now enjoy, obliges me to take this Liberty in presenting to you the Draught of a Plant heretofore in England not known altho' the Bark which it produces is such a common and valuable commodity and one of the most noble specificks we have in Medicine. It is the representation of the distinct parts, of the very Tree which produces the Jesuits Bark. The specimens which I had to make this Draught by, where sent as a present. along with a large quantity of the Bark itself, to Dr. Mortimer, R.S.Sec., from Loxa, in Peru, by Msr. Condamine, a French Mathematician, who was then at the Place where it was gather'd, viz., in the Mountains of Cajanuma, near Loxa. The leaves, etc., where of such a thick and hard texture, and folded so intricately, as well as broken, by means of the pressure of the Bark amongst which they lay, that it was with much difficulty (by the means of hot water), I expanded them, fit to represent in this state Exposed to your view, at last I did compleat my design, and glew'd the several parts upon paper, which was presented to the Royal Society, together with my drawing from which it was made which was compared with the Specimens, was approved of, as also was ordered to be engraved purposely to place in the Philosophical Transactions. Msr. Condamine's Draught, which is published in the French Memoirs for 1739, was thought not to answer near so well, he not taking notice of several particulars, which are of the greatest Consequence. This plate is not yet finished 'cause our Learned in Botany are Dubious concerning its Genus, by reason its flowers where not expanded in our specimens (to make the draught compleat we have taken a flower expanded out of the French Memoir). The name to give is what we stay for, some will have it to be Bignonia, others a Lilack, wherefore Sir an answer from you together with your opinion concerning this Particular, will be very satisfactory, and taken as a particular favour from your Very Humble Servant

JOHN HAWKEENS,
at Mr. John Rawling Apothecarys in Silver Street
Bloomsbury Market
London.

P.S.—Sir I hope, This, my Boldness, when you know it comes from an Apothecarys Apprentice, will not be taken amiss, my design being only of propagating knowledge, when with great Labour I can obtain it, what made you known to me Sir, was your works, already publish'd & that Minute and Infinite Subject of Mosses, whereupon you now labour, and which I long to see publish'd made me think no one had more right to one of these Prints, Than yourself, which was the chief inducement for my now troubling you.

Dillenius answered as follows:—

I had yr favour of ye 20 inst together with ye Plate of ye Jesuits Bark Tree Plant, of which you desired my Opinion. From what I can collect from ye several figures & their Explications, it differs widely from ye Genus of Bignonia, nor is it a true Species of Lilac, if ye calyx stands at the top of ye embryo & seedvessel and for some other reasons too. If you could spare me some flowers & seedvessels, perhaps I could determine matters, better if you can, please to add a branch & some leafs, as good as you have them, which will oblige

Your humble servant
J. J. DILLENIUS Dec. 25, 1741.

Two years after Mr. Hawkeens sent a second letter, which is as follows:—

May 14, 1743. Chelsea.

Sir,—Some time ago I sent a print of the Jesuits Bark Tree, I have now added the Quina Quina (the Bark of which was first made use of for curing Agues), but this that we now use being found preferable, has made the other rejected. Sir I hope you'l Except it and I have my desire. I sent you a few seeds, etc. of the Jesuits' Bark, but wether you received them or no, I never had the pleasure to know. Sir I am at present a Sorting all Petiver's plants in the Possession of Sir Hans Sloan which you (in the Synopsis Raii præfat.) thought would always lie in oblivion. I wish you prosperity to go on in Your Botanical Works and particular that of the Pinax which all lovers of Botany long to see.

I am Your most obedt. Humble servt.,
J. HAWKEENS.

P.S.—Sir, If you should hear of any Nobility, etc. of the University, who are for going the Tour thro' Europe, etc, I should take it a particular favour you'd acquaint me of it, I having a great desire to see a little of the world in some station or another, I can have careful recommendation.

Please to direct to me at Sir Hans Sloan, Chelsea.

Reference to the 'Pharmacographia' will show that the M. Condamine referred to is M. Charles-Marie de la Condamine, who from 1736 to 1743 was occupied in measuring the arc of a degree near Quito, and who, on the 3rd and 4th February, 1737, visited the Sierra de Cajanuma, 2½ leagues from Loxa, and there collected specimens of the tree now known as *Cinchona officinalis* var. *Condaminea*. It will be remembered that Dillenius, the Professor of Botany at Oxford, 1734–47, edited the third edition of Ray's 'Synopsis' which was published anonymously, or to speak more correctly, without the author's name on the title page, in 1724, the work on Mosses referred to by Hawkeens was the *Historia Muscorum* a quarto volume, published in 1741. Petiver, whom Hawkeens mentions, was an apothecary, a celebrated naturalist, a contemporary and correspondent of Ray, and who contributed the list of Middlesex plants to Camden's 'Britannia'. Sir Hans Sloane was a celebrated savant, whose immense collections are contained in the British Museum.

SUGGESTIONS ON PRACTICAL PHARMACY.

The report presented by the Committee on Practical Pharmacy of the American Pharmaceutical Association at this year's meeting included a number of suggestions which should prove of interest to English pharmacists. They are grouped under two heads, suggestions received by the Committee, and others offered by that body.

Suggestions Received by the Committee.

COMPOUND CHALK POWDER.—E. R. Selzer advises the addition of oil of cinnamon directly to the compound chalk powder in proper proportion to take the place of the oil in the cinnamon water directed by the Pharmacopœia. He is of the opinion that the presence of the oil will prevent fermentation in the powder, which sometimes occurs when it is not properly dried.

COMPOUND TINCTURE OF GENTIAN.—Wm. Mittlebach says compound tincture of gentian should be allowed to stand at least a year, and to undergo varying temperatures before being filtered. This procedure will prevent the usual precipitate forming after filtration. He is also satisfied that the 1880 formula for compound soap liniment is to be preferred to the latter formula, which he thinks unsatisfactory. He is of the opinion that elixir of iron, quinine and strychnine phosphates should not be made in large quantities, and should be stored in small bottles perfectly filled to avoid the discoloration of the product, which, he says, is prone to become dark.

EFFERVESCENT SOLUTION OF MAGNESIUM CITRATE.—J. H. Schmidt has had trouble with the U. S. P. effervescent solution of magnesium citrate. He boils and cools the water just previous to using and adds the syrup of citric acid to the solution before filtering. In this way he secures a "sightlier" preparation and one which will remain clear. To save time, in making camphorated tincture of opium, he uses 40 C.c. of the tincture instead of 4 grammes of the powdered opium.

SYRUP OF TOLU.—J. F. Kiedaisch, jun., offers the following formula for syrup of tolu:—

Balsam tolu	1·28 oz.
Sugar	7 lb.
Water, enough to make	1 gal.

Place the balsam of tolu in a mortar and add 1 pound of sugar, rub them together into a coarse powder, then mix with the remaining sugar. Prepare a percolator as described under "Syrup," U. S. P., 1890, into which put the mixture, and proceed to percolate with distilled water; returning portions of the percolate until it runs through clear.

EXTRACTS IN PILL MASSES.—H. T. Cummings calls attention to the necessity of thoroughly incorporating pilular extracts into pill masses. He advises that the extract be well softened with water before it is mixed with the other ingredients of the mass. He has also found the water-bath useful in dissolving the extract of liquorice in making brown mixture.

Elixir of Ammonium Valerianate.—Chas. H. Ware suggests the use of compound tincture of gentian as an acceptable flavouring for elixir of ammonium valerianate. He finds that the sugar for syrup of wild cherry is best dissolved by percolation and has much trouble filtering the solution of liquorice for brown mixture. He asks why glycyrrhizin could not be used instead of extract liquorice.

Cold Cream.—William Gray offers the following formula for cold cream, and claims that it furnishes a product as nearly perfect as it is possible to attain. He says it will not become rancid, and that the rose water will not separate from the base:—

White wax	6 oz.
Spermaceti	6 oz.
Expressed oil almonds	3 lb.
Rose water	1 lb.
Sodium biborate	30 gr.
Oil rose	2½ dr.
Oil patchouly	5 gtt.

Suggestions Offered by the Committee.

The Committee in its further efforts begs leave to be suggestive; it will strive to offer sample notes of a kind which it believes will be interesting to active retailers. It is to such that we would call the Association's attention as follows:—

Dispensary and Laboratory.—The advantage of having these away from the public and apart from the sales department are many and are generally obvious; there are also some objections and inconveniences. Yet it is very desirable that the prescription department and the place for manufacturing be as nearly together as possible, because the apparatus and facilities of one are often badly needed in the operations of the other. The comfort of dispensers is greatly augmented if they can relieve themselves of unnecessary clothing, suiting their dress to the weather and character of the work they are doing. Salesmen can also present, continuously, a better appearance when they are entirely relieved of laboratory work. The passage of work through separate hands adds many checks to errors.

Apparatus and Facilities.—A dearth of these make quick work and good work almost impossible. A good mechanic can, it is true, work with poor tools, but it is only through necessity that he does so, and much of his valuable time is consumed thereby. Water baths of various sizes and kinds should always be at hand, and in a condition to be readily used. A small tablet machine will pay for itself in a very short time, and will add to one's reputation. A konseal apparatus is almost indispensable. Suppository moulds of sufficient number and variety should be in place, but three sizes of rectal and two of urethral are generally enough.

Containers.—Nothing adds so much to the facility of the dispenser, and nothing adds so much to the appearance of his work, as a suitable container. More than a few words regarding them will not be out of place.

It is really remarkable how many kinds of bottles can be used to advantage. Besides regular sizes, half-gallon and one gallon bottles should be washed and held in place. Twelve-ounce bottles should be among the regular stock, and a twenty-ounce bottle is sometimes badly needed. Sets of blue-glass bottles for external use remedies should be on hand, and amber bottles for solutions of silver salts, etc., are necessary; a set of moderately wide-mouth bottles with short corks to fit is stock constantly needed for tablets and granulated effervescent salts. Sets of glass-stoppered tincture bottles, flint and amber and glass-stoppered wide-mouthed bottles will be found most convenient. Full sets of homeopathic vials will not be out of place in the dispensary, and screw cap bottles and jars of every variety will be found to be of great advantage Screw-cap vials answer best for coated pills, for hard capsules filled with liquid, and for tablets, but ordinary capsules and uncoated pills look badly in these, and should be dispensed in boxes.

Pill boxes are generally had in proper sizes and in sufficient and attractive variety. If these are supplied with a label on bottom also, this under label can bear copy of prescription when required, and should invariably be numbered at top to prevent mixing of tops, as sometimes occurs.

Powder boxes of different sizes should, of course, be had, but all powder boxes should be made to accommodate the same size powders, as folded, then it is easy to select the box which will nicely contain the powders prepared. Powders naturally do not always occupy the same space, and it is difficult for the dispenser to select the proper size powder box beforehand, the necessity for which is removed by this uniformity of width.

Boxes for soft elastic capsules, plasters and suppositories, boxes for dusting powders with perforated diaphragms, boxes for medicated soaps lined with paraffin, boxes for eye solutions, holding one ounce bottle and pipette, are very attractive and convenient. Collapsible tubes of all sizes for ointments, with cartons to fit each size—necessary because the tube cannot be labelled; ointment jars with metallic caps and ointment jars with glass tops; special amber glass-top jars for ointments of mercuric oxid, etc. Containers are indeed a study, and interesting papers could be written upon the subject.

Dispensing Notes.—How prescriptions should be received, numbered, dated, and filed, and what recording notes should be made.

Every well-equipped pharmacy should be supplied with a good steel numbering machine that will triplicate. These triplicating machines have to be made especially, but cost little more than the usual ones. There should also be provided order blanks, something like the sample attached hereto, and blank checks of a convenient form; these can be used as a means of advertising if desired.

Orders are easily divided into three classes: "Waits," "Calls," and "Send-outs." If the prescription is on a "wait," it should be numbered by the machine, the order slip should receive the same, as also should the check given the customer. The order slip is simple marked "wait" if the party is unknown, and the name and "wait" if known. This same procedure is gone through with for a "call," excepting this term is substituted for "wait," and the time of calling added, if this can be ascertained. Of course, if paid for, this fact should be indicated. When these are delivered it will be necessary to mark them either paid or charged, as the case may be. The "send-out" order slip should receive, of course, name and address, and should be marked paid, charge, or collect. It should receive one number from the machine, the prescription one, and the third should be placed on a book where a memoranda of all "send-outs" should be made; otherwise they might be overlooked. This book should show time of required delivery. The prescriptions and order slip should be dated before the label is written with one of the small rubber dating stamps so easily obtained. It will be found much better to write the abbreviation for the month than to use the conventional numerals, which are not so well understood by the laity, and are much more apt to be made in error. One month is seldom if ever written for another, but one number is easily made when another should be used. Every pharmacist of any experience has been annoyed by duplicate numbers and by "skips"; frequently serious errors have occurred. A well-made machine will prevent all this, if it is not used to number the labels, which look much better numbered with a pen, and these must bear the proper figures if the checking is carefully done. The order slips are a most ready and convenient means of charging sales; in this regard they will many times save their cost and the value of time consumed in filling them out. They can be posted directly to ledger or copied in day-book; each day should be wrapped with paper bands, marked, and the packages of the several months should be bundled. They record receiver, compounder, and might be made to indicate who delivered package. Each slip should show list of other goods to be delivered with prescription, and one, indeed, should be used for every sale..

The checks, besides insuring the delivery of the proper prescription, save worlds of embarrassment, invariably following the asking for names, which in many instances the customer dislikes to give.

Notes regarding the peculiarities of the prescription or the mode of preparation should invariably be made upon the prescription itself. These notes when necessary should by all means appear. The filing of prescriptions is largely of individual preference, and is much influenced by the space at hand. No plan, however, seems to take the place of the large invoice book into which they are to be pasted.

CHECKING PRESCRIPTIONS.—This should be done in all cases where it is possible. It takes time, 'tis true, but it is not only a safeguard to the patient, but also guards one's business, and is a relief and comfort to the conscientious dispenser that is indescribable.

The label should be written first, no matter by whom; the prescription and label should be checked before the prescription is compounded, then the label should be attached to the container by the dispenser the moment the prescription is finished. The label and prescription should then be checked again. This, however, is all useless unless a lot of wooden trays are at hand—eight inches by twelve inches by two inches deep is a convenient size. Into such a tray must be placed every article used by the dispenser, the prescription and the labelled package and all handed to checker, who will certainly discover a misused drug. This tray system will work much more easily and satisfactorily than may at first appear.

Absorbent cotton, almost indispensable to the dispensing department, is scarcely more useful than is the absorbent, sterile gauze prepared for surgical dressings. Any number of uses will be found for this and it always offers a perfectly clean towel not often otherwise obtainable. The finer quality is preferable, and if kept in a box or drawer with a pair of shears handy it will be very serviceable; the cost is small. It is especially useful as a coarse strainer, for drying vessels, for wiping off capsules, etc. Once used, it is, of course, thrown away.

Collapsible tubes can be quickly and nicely filled with ointments, which must not be fused, by placing the ointment on a piece of parchment paper which has been wet, and from which the adhering water has been wiped. A long slim package should be made, as near the shape of the tube as possible, only smaller; the usual wrapping fold should be made in the paper. One open end of this package should be introduced into the tube, to the shoulder. The exposed end of the package should now be constricted and the ointment "stripped" out between the thumb and finger, filling the tube from the shoulder; meanwhile the paper should be drawn out as the tube fills. A pair of forceps, made for the purpose, are very desirable for sealing collapsible tubes. Metallic containers when used for ointments of mercurials, silver, salts, etc., should be coated with a resin. An ethereal solution of tolu will be found very satisfactory and a convenient acquisition to the dispensing department.

Percentage solutions are now comparatively common prescriptions. Pharmacists should be quite sure they fully understand the quantities required to make the percentage called for. It has been observed by members of this committee that the methods often used give weaker solutions than intended; especially is this the case with those of higher percentages. The fact that the substance dissolved goes to make up a part of the total weight should not be overlooked, as is often the case. 45.5 grains added to one fluid ounce of water does not make a 10 per cent. solution. But 50 grains to 450 grains of water does—and this will make very nearly one fluid ounce of the solution.

FILTRATION OF SOLUTIONS.—Where first-class filters are not to be had and good filtration is required, a pledget of absorbent cotton, in the neck of the funnel in connection with the paper filter, will be found effective. Especially useful for eye solutions.

Eye solutions of small amounts of fluid and of delicate alkaloids should be made by washing the bottle with filtered water—shaking out all adhering drops—placing salt in bottle and adding sufficient filtered water.

Konseals can be handled to best advantage in a regular apparatus. Not too much moisture and liberal pressure are the rules to follow. A convenient mould for gelatin lozenges can be made by placing the hinged portions of the konseal machine flat on a piece of glass. The moulds thus made can be evenly filled with the melted gelatin base, properly medicated and adjusted. When cool, the lozenges can be pushed through or out with no difficulty. Different size lozenges can be made with this improvised mould. A good base is made by using one avoirdupois ounce of French gelatin and one fluid ounce each of glycerin and water.

Gelatin bases for lozenges and suppositories can be made by dissolving the gelatin in hot water at once. It is not necessary to allow it to "soak" as is generally directed, provided the French Gold Medal product is used.

Compressed tablets can be made in a smaller way quite quickly if the proper compressing machine is at hand. The small compressors used with a mallet are not worthy a place in our stores. It is not at all necessary to granulate the substances to be compressed if the machine is fed by hand. Indeed, in almost every instance better results can be obtained when a very fine powder is used than otherwise. Often when a substance will not adhere at all, in coarse powder, tablets can be easily made if the fine powder is used.

Alkaloids, as such, are often soluble in fixed oils. This fact should not be overlooked, and when a salt of an alkaloid is prescribed in oily solution a proportionate amount of the uncombined substance should be substituted.

SPRAY.—Fluids should be dispensed as perfect and permanent solution if it is possible to be so. As these are invariably expected to be in an atomisable condition, it is thought that slight alteration of this class of prescriptions is allowable. Small or additional quantities of potassium iodide, glycerin, alcohol, alkali or acid cannot be objected to, if used with due consideration for their medicinal effect.

Waxed paper can be used to great advantage in dispensing many powders and powdered substances. When used the packages should also be wrapped in the usual white paper, since the waxed paper is unsightly.

An irrigating bottle of 2-gallon capacity, placed upon a shelf just above the level of the average eye, if fitted with a short rubber tube, a burette, pinch-cock, and a glass tube nozzle, will be found to be a most convenient holder for dispensing water. The amount required can be very quickly and accurately drawn by holding a graduate on a line with the eye.

Conclusion.

These notes, homely, perhaps, have not been offered by the committee as being in any way scientific as science is generally understood; nor is it claimed that they are representative or that the collection is by any means as large as should appear hereafter. They are simply intended to show a line of work which we believe would be profitable to a large number of the association's members. Whether or not they are of a kind that is helpful and are sufficiently new to be attractive should be fairly discussed by this body, and if such a committee is to be continued it should have the support and counsel of the association. In any event, it is only fair to remember that our trials have been the trials of the pioneers, and the same fairness will look for no more than crude results.

Not from without, but from within, does pharmacy to-day need help; help not so much of the scientific sort, but of a kind that is plain, that is practical, that can be used in the modern drug store, and make it in kind, and, to a degree at least, what the larger manufacturer is. Establish principles, principles so well formed and so well laid that no superstructure built upon such a foundation shall fail. Theories too, but easily convertible theories, to be readily applied to daily needs. Much pharmaceutical testing is above our heads, and we need beyond all things else practical tests.

So much pharmaceutical writing is even more heavenward. There is need for easily and quickly applied means for testing our purchases. Pharmacists should give more time and pains to the department of buying. Yet, withal, conscience and desire are to be our greatest helps.

Patient inquiry and personal experience confirms the belief that pharmacists of a class that is creditable to the profession are to-day largely manufacturing their galenicals. It is possible to prove, omitting extracts and fluid extracts, representative members of this association actively engaged in the retail business are preparing all preparations of the pharmacopœia used in sufficient quantities to pay, excepting perhaps four or five, viz: :—Spirit nitrous ether, spirit ammonia, solution of iron chlorid, solution of lead subacetate and mercurial ointment. If this be so, and there is still much manipulation required at the prescription counter, the times and conditions plainly point to the necessity for ample facilities and sufficient equipment. To justly judge as to the extent and limit of such requirements, one must look beyond his own narrow bounds and the possibilities of his environments and scan the larger field of possibility—the one into which ambition or desire may lead him.

In closing this report we trust it has been shown that there is yet dispensing to do, that there are still preparations to be made, and hope that through our efforts some little something has come to help the dispenser, the practical pharmacist. All of which we respectfully submit while justly appreciating the honour done us.

THE PREPARATION OF SPIRIT OF NITROUS ETHER.*

BY JOSEPH FEIL, PH.G., CLEVELAND.

For more than two centuries spirit of nitrous ether has been a standard medicament, and notwithstanding the facts that it rapidly deteriorates in quality, that the method of its production has varied with the appearance of almost every new addition of the United States and other pharmacopœias, that the strength in what some British investigators, Professor Matthew Hay, Dr. D. J. Leech, and others, regard as its essential constituents—namely, ethyl nitrite and nitrous acid, varies from the very moment of its finished preparation, and that the various pharmacopœias require different standards, it yet holds its own as a valuable medicine.

The U.S. Pharmacopœia of 1820 and of 1830 had a process taken from the old London Pharmacopœia, which produced a colourless product, yet it must have been therapeutically effective, and certainly contained much ethylic aldehyde. The 1840 and 1850 U.S.P. gave a variation of the old process, and since then every edition of the U.S.P. contained a new or somewhat varied method of preparation. Also the description of the galenical has been changed from time to time until coming down to the recent U.S.P. we have an attempt to produce an alcoholic solution of chemically pure ethyl nitrite.

All processes previous to the last one were eminently practical for the retail pharmacist, but the 1890 process is an absolute impossibility for those who are supposed to need it. The reason is readily seen: Ethyl nitrite is a highly volatile and inflammable liquid, boiling at 18°, and dangerous to prepare, except for those who are accustomed to and experienced in the manipulations of practical organic chemistry. All attempts to devise processes on this line must necessarily fail.

I believe the quality of spirit of nitrous ether is decidedly inferior to-day, owing to the present U.S.P. method of preparation. It has come about in this way, the process being an impossibility for the retail pharmacist, many tried to conform to it by purchasing ethyl nitrite and dissolving the chemical in alcohol. This procedure is open to two quite serious objections:—

1. The ethyl nitrite is probably pure when leaving the laboratory of a reliable chemical manufacturer, but no one has yet discovered a process of preventing its deterioration, and the substance when reaching the retailer through the jobber ranges in strength from 40 to 60 per cent. of the strength stated on the label.

2. It requires great care and a fair degree of skill to properly mix the alcohol with it, owing to its extreme volatility, and some loss almost invariably results. As a consequence of the above, it is common to find the average specimen, as found in retail pharmacies, to assay about 1 per cent. ether instead of 4 per cent.

With these facts in view, I have been seeking for a process which in the hands of a fairly skilled pharmacist should yield a product of good quality in a reasonably short time in quantities as needed by the average shop.

The objections to recently proposed processes will be found in a paper read by me at the Ohio State Pharmaceutical Association meeting held at Put-in-Bay, in June last.

The process here proposed requires about fifteen to twenty minutes' time, and the manipulations are such that anyone skilled in ordinary chemical manipulations can easily carry out.

THE PROCESS.

Sodium nitrite..	30 G.
Sulphuric acid	20 G.
Alcohol	Sufficient.

The sodium nitrite and 300 Gm. alcohol are placed in a litre flask with a two-hole cork or rubber stopper, in one of the openings is placed a stoppered funnel of any description, the other has a glass tube connected with an upright condenser kept cool with running water.

The sulphuric acid is placed in a funnel, the mixture is then heated until the alcohol is about beginning to bubble, the heat withdrawn and the sulphuric acid slowly added; after action ceases, heat is again applied a moment or two and withdrawn. A second repetition may again cause an action to begin; usually this does not occur, although it is best to try it.

The contents of the flask are allowed to cool, and then filtered in a well-covered funnel and alcohol added to make 450 Gm. It is of course preferable to assay the filtrate and then dilute, but a large number of experiments gave very close results at the quantity stated.

An excess of sodium nitrite is intentionally used, as molecular quantities do not act as well practically. While the ethyl nitrite is here produced in solution all attempts to prevent some escape have failed, yet a much larger quantity is obtained than in any other process that I am familiar with. U.S.P. 1898 process, my average yield has been 30 per cent. of the theoretical requirement. Scoville's process, average yield, 40 per cent. My process given above, general yield, 75 per cent.

The product obtained by this process conforms to the present pharmacopœial requirements, but has in addition an odour reminding one of the spirit obtained by the U.S.P. 1880 process. The time and attention required is so little, and the process so safe, that it is well adapted to the essential requirement that spirit of nitrous ether should be freshly made at least every two or three months.

*Read before the American Pharmaceutical Association. From the *Western Druggist*.

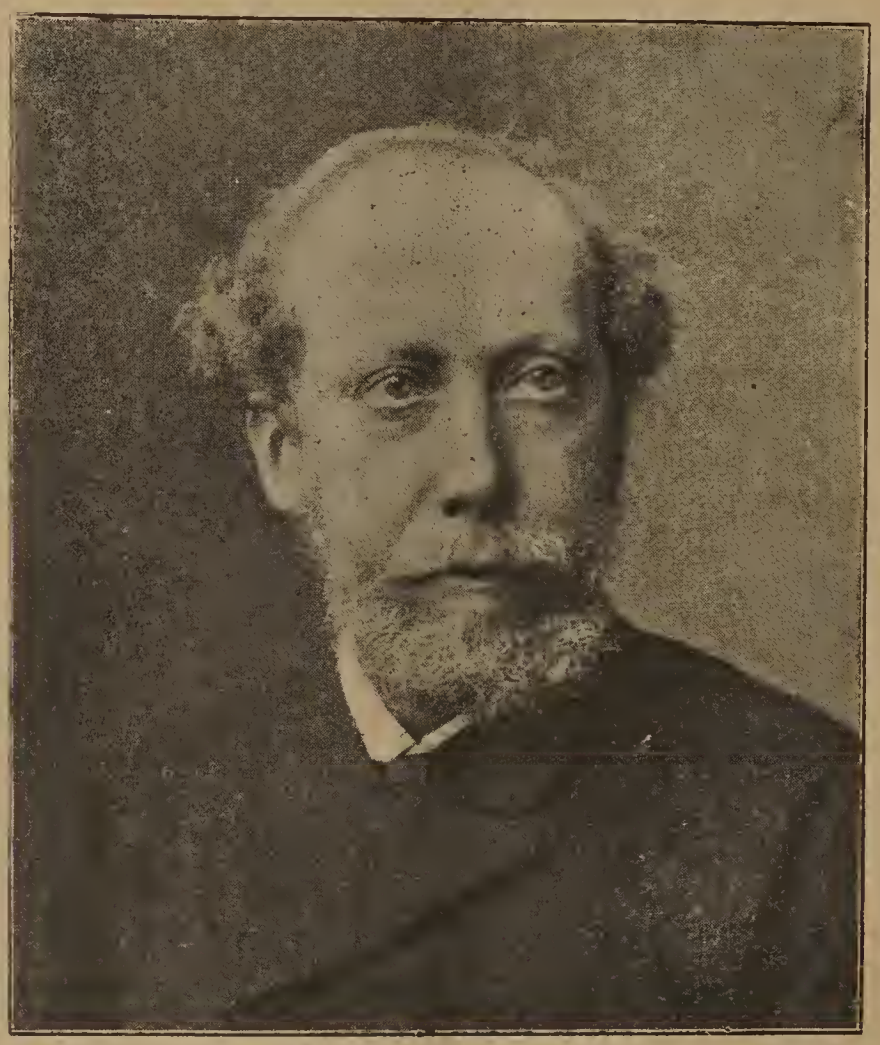
Enteroliths formed by Drugs.—Puis y Sans records a case in which he prescribed magnesium salicylate and benzonaphthol in the form of a small cachet. The next day, the author received a whitish body, hard as a stone, which had been found in the motions. It consisted solely of the drugs administered, consolidated into a stony mass. Rovisa has observed similar results after administering magnesium carbonate and salol, and Lloret has found bismuth salicylate and benzonaphthol to form intestinal concretions in the same way. *Med. and Surg. Review of Reviews.*

ALBERT LADENBURG.

A BRIEF NOTE ON HIS WORK,

BY W. HARRISON MARTINDALE, PH.D., MARBURG.

Albert Ladenburg, on whom the Hanbury Memorial Medal has this year been bestowed, was born at Mannheim on July 2, 1842. He graduated as Doctor of Philosophy at Heidelberg in 1863, and became Privat Docent at the same university in 1869. In 1873 he was called to the professorial chair at Kiel, taking the position of Professor of Chemistry and Director of the Laboratory. In 1883 he was elected Honorary Member of the Pharmaceutical Society of Philadelphia. In 1884 he was created Honorary Member of the Pharmaceutical Society of Great Britain. In 1886 the degree of Doctor of Medicine of Bern University was conferred upon him—*honoris causâ* In 1889 he became Professor of Chemistry and Director of the Laboratory at Breslau.



Other distinctions were also showered upon him, as, for example, that of Foreign Membership of the Chemical Society in 1888, and that of Honorary Membership of the Literary Society of Manchester in 1892.

To review the life-work of the subject of this article with credit to him in a few short lines is apparently an impossibility, and, indeed, even if Journal upon Journal were written concerning his work by an abler hand than mine, there would yet be left many a page unturned in the *Berichte der Deutschen Chemischen Gesellschaft*, and many a paragraph unnoticed in the *Annalen der Chemie*.

I will, therefore, content myself by culling a few facts from standard authorities, such as Ernst von Meyer's 'History,' and those which I have mentioned.

His "Vorträge über die Entwickelungsgeschichte der Chemie in den letzten 100 Jahren" (1st edition 1869, 2nd edition, 1887) is well known as a genuine historical book of reference.

His "Handwörterbuch der Chemie" is a standard work. It consists of thirteen volumes, and was issued by the chemical section of the "Encyklopädie der Naturwissenschaften," with Ladenburg as editor, in conjunction with from fifteen to twenty distinguished collaborators per volume.

His prismatic formula for benzene is well known as one of the several brought forward to explain more completely than than Kekulé's hexagon formula the chemical behaviour of benzene.

In the early days of the benzene controversy, as every student knows, it became a question to determine the relative positions of the entering substituents in the various benzene substitution products as, for example, in the three dibromo-benzenes, and Ladenburg, with his researches on terephthalic acid, was one of the ardent investigators who helped to solve the problem which resulted in the structure of the ortho, meta, and para-compounds being arrived at with comparative certainty.

Ladenburg was among those who aided the proof of the constitution of pyridine and quinoline.

His researches were particularly directed to the alkylated pyridines, especially the isomeric methyl- and ethyl-pyridines and the pyridine mono-carboxylic acids.

It was found that deductions similar to those which had been drawn from benzene could also be drawn from pyridine, namely, that only the theorctically possible methyl-pyridines and pyridine carboxylic acids were capable of preparation, and no more.

In alkaloidal research, the view was expressed that the alkaloids were derivatives of pyridine or quinoline, and this was grounded on the conversion of pyridine into piperidine, which is a decomposition product of the alkaloid piperine, and on the retransformation of piperidine into pyridine.

Ladenburg, amongst others, conducted researches which helped to prove the connection between these bases, the former containing six atoms more H in the molecule than the latter. The analogy between them—piperidine and pyridine on the one hand, and hexahydrobenzene and benzene on the other, thus became apparent.

Further, in alkaloidal work, was added by Hofmann the conversion of conine into conyrine, and on the last page (833) of his communication "Zur Kenntniss des Coniins" (*Berichte*, xvii., April 12, 1884), one reads:—

"By the conversion of an undoubted pyridine base into conine the synthesis of the latter is led a step further towards realisation. Ladenburg has applied the alkylisation of aniline to pyridine, and has succeeded in preparing ethyl-pyridine . . . ."

Turning to Liebig's *Annalen*, vol. ccxlvii., one finds 98 pages on "Pyridine and Piperidine Bases," by Ladenburg, and the few pages from 80 onwards on conine are particularly well worth reading, as they verily bristle with scientific excitement.

His ingenious condensation synthesis of conine consisted in the preparation of α-allyl-pyridine, the conversion of this by means of sodium into α-propyl-piperidine, and the subdivision of the latter optically inactive substance into its active components.

To arrive at the latter result, two courses were open to him—(I.) the fungus method; (II.) the crystallisation method.

(I.) In making use of *Penicillium glaucum*—the common blue mold—he was following in the footsteps of Pasteur, but even with

a solution as dilute as 0·1 per cent., this fungus left the poisonous alkaloid unaffected after remaining in contact with it for six weeks.

(II.) He then again turned to Pasteur for a hint—though an indirect one—and realising that he (Pasteur) had utilised *salts* in his work on tartaric acid, he borrowed a crystal or two of +conine tartrate from Schorm who had several years before obtained and analysed the same.

By means of this he succeeded in splitting up his inactive compound, and on p. 86 of vol. ccxlvii. of the *Annalen*, Ladenburg writes in italics :—

And now, therefore, the complete identity of dextro-rotary α-propyl-piperidine with natural conine is established, and in this fact the first complete synthesis of an alkaloid has been effected.

Chemists, however, disputed the completeness of this synthesis. Ladenburg therefore communicated a note (*Berichte*, xxii., p. 1403), in which, with the aid of seventeen references, he substantiated his claim; the possible steps being acetic acid (Kolbe, Melsens, Wanklyn), acetone, isopropyl alcohol (Friedel), glycerin (Friedel and Silva), allyl bromide (Cahours and Hofmann), trimethylene-bromide (Erlenmeyer), piperidine (Ladenburg), pyridine (Königs, Hofmann), α-picoline (Ladenburg and Lange), conine.

The +tartaric acid had also been synthetically prepared—authors :—Maxwell Simpson, Perkin and Duppa, Kekulé, Pasteur, Jungfleisch.

Further syntheses by Ladenburg are those of atropine from tropine and tropic acid (*Annalen*, ccxvii., p. 74; *Berichte*, xii., 942; xiii., 104, 909); and of homatropine (*Annalen*, ccxvii., 82), by heating tropine mandelate with dilute hydrochloric acid.

One cannot refrain from mentioning the "Scopolamine Controversy," in the earlier stages of which Ladenburg was conspicuous (*vide* summary, *P. J.* [4] **3,** 41). But I regret that space will not permit me to go deeply into this. (For further literature *vide P. J.* [4], **5,** 41; [4], **5,** 377; [4], **6,** 290.)

I will conclude by giving in full the *résumé* of Ladenburg's work as cited by him.

(1) In common with Ch. Friedel; Researches on silicon and compounds, and on the analogy of this element with carbon.

(2) Researches on benzene and derivatives; (*a*) constitution o benzene; (*b*) condensation products in the ortho- series.

(3) Researches on pyridine and alkaloids; (*a*) synthetic methods of forming pyridine bases; (*b*) constitution of atropine and analogous alkaloids; (*c*) synthesis of conine.

(4) Researches on low temperature; (*a*) density of ozone; (*b*) method of measuring low temperature.

(5) Researches on racemic compounds; (*a*) preparation of semi-racemic compounds; (*b*) characterisation of racemic compounds.

If any readers wish, after perusing this poor attempt of mine, to become convinced of the merit of the recipient of this year's medal, or if they do not realise the magnitude of Ladenburg's own modest *résumé*, I beg to refer them to the Royal Society's Catalogue of Scientific Papers, where will be found between the years 1865 and 1884 several pages of headings alone. And furthermore, the *Berichte* and the *Annalen* may obviously be consulted.

Egg Water in Convalescent Dietary.—A nurse contributes to the *Hospital* an article on the value of egg water as a nutrient, especially in cases of anæmia, gastric ulcer, dyspeptic troubles, obstinate vomiting, and in those cases where milk is not well tolerated. It is prepared by diluting the whites of 2 or 4 eggs with sufficient water to make a pint. Combined with whey instead of water, it forms a good food in cases of enteric fever where milk is not tolerated. It is well known and much used in France as the official "eau albumineuse."

THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.

Sodii Bromidum.—If absolutely pure, 102·23 grammes of sodium bromide require 10,000 C.c. of N/10 vol. sol. of silver nitrate.

$$\underset{102\cdot23}{NaBr} + \underset{168\cdot69}{AgNO_3} = AgBr + NaNO_3$$

$$\therefore \text{ 1 gramme NaBr requires } \frac{10{,}000}{102\cdot23} \text{ C.c. N/10 } AgNO_3.$$

$$= 97\cdot8 \text{ C.c.}$$

If more than this quantity of silver nitrate solution be required, the presence of more than traces of chlorides is probably indicated. If less than 97·8 C.c. be required, and the qualitative tests for impurities give negative results, the cause is probably the presence of adherent water. Sodium bromide absorbs moisture from the air if carelessly stored, and the lower figure, 95·8 C.c., in the official test allows the presence of two per cent. of water.

Sodii Carbonas.—Crystallised sodium carbonate readily loses water on exposure to air, the crystals falling to powder, which contains five instead of ten molecules of water of crystallisation. When taking a sample for volumetric determination a large crystal should be broken, and the desired quantity selected from the clear, glassy central portion. The official requirements indicate 98·02 per cent. purity.

$\frac{1}{2}Na_2CO_3,10H_2O$ = 142·055, and this quantity in grammes neutralises 1,000 C.c. of N/1 vol. sol. H_2SO_4

$$\therefore \text{ 1 gramme sodium carbonate} = \frac{1{,}000}{142\cdot055} \text{ C.c.}$$

$$= 7\cdot04 \text{ C.c.}$$

$$\text{and } 6\cdot9 : 7\cdot04 :: 98\cdot02 : 100.$$

When heated above 80° C. the whole of the water of crystallisation is expelled, corresponding to a loss of 62·93 per cent. For 284·11 parts (m. wt. $Na_2CO_3,10H_2O$) lose 178·80 parts ($10H_2O$) of water.

$$\therefore \text{ 100 parts lose } \frac{178\cdot80 \times 100}{284\cdot11} \text{ parts.}$$

$$= 62\cdot93 \text{ per cent.}$$

As mentioned above, the effloresced salt obtained by exposure to air at ordinary temperatures corresponds to the composition $Na_2CO_3,5H_2O$. At a slightly higher temperature more water is expelled and a salt containing one molecule of water is obtained, and this last molecule is expelled at 80°C.

Sodii Iodidum.—This salt is directed to be crystallised from warm solutions in order that it may be obtained anhydrous. From cold solutions sodium iodide crystallises with two molecules of water. The anhydrous salt is deliquescent, and being an expensive substance, the Pharmacopœia fixes the limit of water to be allowed in the commercial salt at 5 per cent. Owing to the possible presence of this proportion of water the volumetric determination is directed to be carried out with the salt recently dried at 120° C. The molecular weight of sodium iodide is 148·78.

$$\therefore \text{ 14·878 grammes NaI require 1,000 C.c. N/10 } AgNO_3$$

$$\text{and 1 ,, ,, ,, } \frac{1{,}000}{14\cdot878} \text{ ,, ,,}$$

$$= 67\cdot2 \text{ C.c.}$$

The official figure, 66·5, indicates 99 per cent. purity, but it must be remembered that the presence of either bromides or chlorides will

* Note.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J.* during 1897-8.

cause the volume of silver solution to exceed the quantity for pure sodium iodide. The absence of more than traces of these bodies must therefore be proved by careful qualitative testing.

Sodii Phosphas Effervescens.—The sodium phosphate must be rendered practically anhydrous before mixing with the sodium bicarbonate and the citric and tartaric acids; otherwise the water of crystallisation would be set free when heat was applied, and so bring about the reaction between the added acid and alkali.

Sodii Salicylas.—The student is referred to the articles on this substance, and on salicylic acid, which will be found in the Students' Columns, *P.J.* Oct. 1, 1998, p. 378.

The use of uranium nitrate, now introduced as a means of distinguishing salicylates from carbolates and sulphocarbolates, is based upon the formation of a precipitate of uranium salicylate, the uranium salts of carbolic and sulphocarbolic acid being sufficiently soluble, under the conditions mentioned, not to form a precipitate.

Sodii Sulphas.—This salt, as mentioned in the official test, is insoluble in 90 per cent. alcohol. It may also be useful to remember that all metallic sulphates, with the exception of ferric sulphate, are insoluble in strong alcohol. According to the equation:—

$$Na_2SO_4,10H_2O + BaCl_2 = BaSO_4 + 2NaCl + 10H_2O$$

319·90 parts of sodium sulphate yield 231·74 of barium sulphate.

$$\therefore \text{ 1 gramme } Na_2SO_4 10H_2O \text{ yields } \frac{231{\cdot}74}{319{\cdot}90} \text{ grammes } BaSO_4$$

$$= 0{\cdot}7244 \text{ grammes.}$$

The Pharmacopœia figure, 0·725, is, therefore, slightly in excess of the weight which can theoretically be obtained from pure sodium sulphate. Whether this is intentional or not the fact is, that under the conditions described in the official text for performing the analysis, the weight of the dried precipitate will be slightly in excess of the theoretical calculated quantity, because the precipitate of barium sulphate carries down and retains a trace of alkaline salt, which is only removed with great difficulty. In performing the experiment the sulphate solution should be just boiling before the barium chloride solution is added. The precipitate is then produced in a dense sandy condition, and is easily filtered off and washed.

Sodii Sulphas Effervescens.—See notes under the corresponding preparation of sodium phosphate.

Sodii Sulphis.—The difference between sulphites and thiosulphates should be carefully noted. When sodium sulphite solutions are acidulated the sulphurous acid which is formed remains partly dissolved, and is partly decomposed into water and sulphurous anhydride. This is evolved, and may be recognised by its odour. The proportion of the sulphurous acid so decomposed depends upon the conditions of the experiment—chiefly the concentration and temperature of the solution.

(i.) $Na_2SO_3 + H_2SO_4 = Na_2SO_4 + H_2SO_3$
(ii.) $H_2SO_3 = H_2O + SO_2$

In the case of sodium thiosulphate, the corresponding thiosulphuric acid is unstable and decomposes into sulphurous acid and sulphur, the latter appearing in the form of a nearly white, cloudy precipitate. When sodium thiosulphate solution is acidulated we get therefore the odour of sulphurous anhydride, as with the sulphite, and a light cloudy precipitate of sulphur in addition.

(i.) $Na_2S_2O_3 + H_2SO_4 = Na_2SO_4 + H_2S_2O_3$
(ii) $H_2S_2O_3 = H_2SO_3 + S$

The volumetric test is based upon the conversion of sulphite into sulphate by the oxidising action of the iodine, water, as is so often the case, taking part in the reaction.

$$Na_2SO_3 + OH_2 + 2I = Na_2SO_4 + 2HI$$

According to this equation one m. wt. $Na_2SO_3 7H_2O$ (250·38) will react with two atomic weights of iodine (125·9 × 2). The official volumetric solution of iodine is decinormal, and contains, therefore, 12·59 grammes of iodide per litre.

∴ 250·38 grammes $Na_2SO_3 7H_2O$ are equivalent to 20,000 C.c. N/10 iodine solution.

$$\therefore \text{ 1 gramme } Na_2SO_3\,7H_2O = \frac{20{,}000}{250{\cdot}38} \text{ C.c.}$$

$$= 79{\cdot}88 \text{ C.c.}$$

Since one gramme of the pure salt will decolorise 79·88 C.c. of iodine solution the higher limit allowed in the Pharmacopœia (81·7 C.c.) can only be reached by a partially effloresced salt.

Sodii Sulphocarbolas.—The Pharmacopœia now defines this as the sodium salt of *para*-phenol-sulphonic acid. In the previous series the production and relationships of the three phenol-sulphonic acids was described. See *P. J.*, Feb. 26, 1898, p. 204. In order to obtain only the para-acid, the mixture of phenol with excess of sulphuric acid is maintained for some time at a temperature of 100°--110° C. The ortho-acid, which is simultaneously formed at ordinary temperatures by the first action between the phenol and acid is by this means converted into the para variety, because at this temperature the ortho-acid which has been formed, splits up again into phenol and sulphuric acid, and the former is sulphonated again at 100°-100° C. almost entirely into the para-acid. The ortho-phenol-sulphonic acid, which has been used as an antiseptic under the name of "aseptol," is formed in preponderating quantity when the phenol reacts with sulphuric acid at *low* temperatures. The uranium nitrate test has been already noticed under sodium salicylate.

Sodium.—The quantitative determination of purity is best made in the following manner: Cut out with a sharp knife a cubical piece of the metal so that it shall have a bright metallic surface on all sides. After removing adherent naphtha rapidly by means of blotting paper, determine the weight of the selected portion without delay in order to minimise the disturbing influence of the oxidation which occurs as soon as the metal is exposed to air. For the same reason it is better to find the weight of the piece rather than to attempt to take any predetermined weight of metal the exact adjustment of which would necessarily occupy some time. The weighed portion is then cut into small pieces, which are added piece by piece to some water in a dish or beaker, allowing each piece to disappear before adding the next. The vessel is covered by a glass plate while the several pieces of sodium are reacting with the water, in order to avoid loss of solution by spurting. When the reaction is finally completed the glass plate is rinsed with water and the washings added to the contents of the beaker or dish. The weight of sodium taken may be between 0·5 and 1·0 gramme: this quantity added to about 70 C.c. of water and the solution diluted to exactly 100 C.c. may be divided into two equal parts for titration. According to the equation—

$$Na + H_2O = NaOH + H$$

22·88 grammes of pure sodium will produce sufficient sodium hydroxide to neutralise 48·67 grammes ($\frac{1}{2}H_2SO_4$) of sulphuric acid.

∴ 22·88 grammes of sodium neutralise 1,000 C.c. N/1 H_2SO_4

and 1 gramme ,, $\frac{1{,}000}{22{\cdot}88}$ C.c. N/1 H_2SO_4

= 43·71 C.c.

The official requirement that 1 Gm. of sodium shall neutralise 42·6 C.c. N/1 H_2SO_4 corresponds therefore to a purity of not less than 97·46 per cent.

THE TASK TO BE ACCOMPLISHED.

The proceedings at the Council meeting last week were in a twofold sense, especially interesting in regard to the present situation; not only on account of the action taken—in view of the possible revival of the Companies Bill of last Session—to authorise the Law and Parliamentary Committee to define the terms of a clause dealing with company trading as it affects the business of registered chemists and druggists; but also on account of the evidence afforded as to the views held by individual members of the Council in that representative capacity, and of the indications afforded as to the possible existence of some difference of opinion among chemists and druggists in respect to the line of action to be adopted when the proposed legislation comes before Parliament. So far as the remarks of some members of the Council on that occasion may be understood as having lifted the veil from the deliberations of the General Purposes Committee on the previous evening, there seems to be distinct evidence of different tendencies that may fairly be regarded as representing existing differences of opinion even among members of the Society. For the necessary adjustment and removal of any such differences, reliance must be placed upon the Committee which has been entrusted with the task of framing a clause that will—as the President tersely expressed himself—deal with the subject of company trading in a "reasonable and logical way." But attention must be drawn to the fact that on one very important point the discussion at the Council furnishes evidence of a perfect unanimity which should be received with great satisfaction, and not only meet with sympathy, but with the most hearty support from all registered chemists and druggists. Whatever difference of opinion may exist between members of Council as to other details, there is a very distinct determination to defend the right that legally qualified persons have to exclusive use of titles which are indicative of qualification for the exercise of their business and, in order to be of any practical utility, should enable the public to distinguish between qualified and unqualified persons.

The unanimity shown in regard to the defence of chemists' titles may also be taken as defining to a large extent the whole line of action to be taken in dealing with the abuse of company trading as it affects chemists and druggists. As the statutory title is the exponent of statutory qualification—the trademark of a qualified person—the use of it is to be regarded not only as a means by which the main object of the Pharmacy Act, in the public interest, is to be secured, but it should also be the means of securing to qualified persons the privilege conferred by the statutory qualification which is demanded in the public interest. The two things are really inseparable, and unless qualified persons have, and can maintain, exclusive right to the use of the statutory title, the whole structure of the Pharmacy Act must collapse; in fact, the statute would otherwise be a delusion in every sense. If restriction of the use of the title to legally qualified persons is to be of any practical value it must mean that the retailing, dispensing, or compounding of poisons can be lawfully conducted only by persons who are qualified as the Act requires, and the one obvious object of the Pharmacy Act is to place the business thus defined outside "free trade." Everything else connected with the drug trade—and unfortunately also everything else connected with pharmacy—is still left open to free trade without the least restriction. Retailing, dispensing, or compounding poisons is, therefore, the only "pharmacy" to which the Act relates and in regard to which there can now be a demand for free trade, so that the specious advocates of "free trade in pharmacy," who also profess to support restriction of the use of chemists' titles, merely exhibit themselves as marvels of inconsistency, if not as wolves in sheep's clothing. Is it possible that they can be so infatuated with their presumptuous pretensions as to be incapable of perceiving the absolute absurdity of the position they take? or do they think so meanly of the intelligence of chemists and druggists as to suppose that many of them can be gulled and misled by the preposterous and self-contradictory proposition that restriction of the use of titles should be accompanied by free trade in all that those titles represent? When such phantoms are held out as guiding lights to chemists and druggists by truculent mud-slinging critics of the Council and of pharmaceutical leaders, complicity with the pirates may be suspected, and it is time to offer a warning as to the danger of listening to the siren wiles of such fatuous or perverse misleaders.

The natural consequence of the decided opinion expressed as to the use of pharmaceutical titles would be general and uncompromising opposition to the Lord Chancellor's proposal that companies should, under any conditions, use those titles. On that point there cannot be any rational or logical dissent when the circumstances of the case are understood. The idea of a company using a pharmaceutical title is obviously absurd, because a company cannot, as an ideal individual, fulfil the condition of undergoing an examination which is essential for that purpose. Whenever that self-evident proposition is duly considered it may be expected to meet with general concurrence, and to be found unanswerable as a reasonable and logical ground for opposition to the Lord Chancellor's proposition that a company, as such, may use the title of pharmaceutical chemist or of chemist and druggist. The only obstacle to be overcome is the enabling decision of the House of Lords to the effect that companies are outside the scope of the Pharmacy Act, 1868, in the sense that they may lawfully do anything that individuals are prohibited from doing, unless they have the requisite statutory qualification. If that decision conveys a reasonable and logical construction of the Pharmacy Act there would not be any need for the provision that has been

introduced into the Companies Bill to make the use of the titles by companies lawful, and there would be an end of the matter. But that view must be disputed: for, by due consideration of all the circumstances of the case, that decision may be shown to be as inconsistent with the object and policy of the Pharmacy Act as it is with the nature of things. Lord HALSBURY, in his high position, has recently rendered important service in that direction by drawing attention to the legal and common-sense anomaly which has been created as a consequence of the House of Lords' decision, and by expressing, together with the late Lord HERSCHELL, the opinion that the prevailing interpretation of the Pharmacy Act requires corresponding legislative amendment. But the remedy he has proposed is of such a nature that neither the Government nor Parliament could be expected to support it, if the circumstances of the case were thoroughly comprehended. That, unfortunately, is not the case, for the Pharmacy Act is too generally regarded, even by members of Parliament and Government officials, imbued with free trade ideas, as an Act establishing a trade monopoly instead of being really, as it was really intended, a measure having no other object than that of providing for the safety of the public and, only with that object, abridging the liberty of the subject while at the same time conferring on qualified persons a necessarily consequent privilege. Every registered chemist and druggist who has a member of Parliament to vote for, or any other opportunity of exercising influence in educating public opinion, should therefore make a strenuous effort to secure reasonable appreciation of the true meaning and intention of the Pharmacy Act, and of the claim for more correct interpretation than it has yet received.

MONUMENT PELLETIER-CAVENTOU.

REFERENCE was made last week (see page 344*d*) to the fact that the proposed Pelletier-Caventou memorial has not as yet attracted much attention in this country, notwithstanding the publicity given to the matter some two years ago (*vide P.J.*, October 9, 1897, p. 326). Readers may be reminded that PELLETIER and CAVENTOU were the discoverers of quinine, and that it is proposed to erect a monument in Paris, opposite the Paris School of Pharmacy.

Mr. WALTER HILLS, past-President of the Pharmaceutical Society, has now forwarded to us the following subscription list:—

William Martindale, President.
G. T. Wilkinson Newsholme, Vice-President.
Samuel Ralph Atkins, Treasurer.

Charles Bowen Allen,	Walter Hills,
Thomas Bateson,	John Johnston,
Michael Carteighe,	Charles James Park,
Octavius Corder,	Arthur Ledsam Savory,
W. Gowen Cross,	Alfred Southall,
W. S. Glyn-Jones,	David Storrar,
Nicholas Male Grose,	Charles Symes,
J. F. Harrington,	William Warren,
John Harrison,	J. Rymer Young,

Members of the Council.
Total amount subscribed 21 guineas.

Mr. HILLS will be pleased to receive any other contributions from British pharmacists. They should be addressed to him, at 17, Bloomsbury Square, London, W.C. The Committee in charge of the movement is more anxious to obtain a representative list of names than to solicit large subscriptions, and is particularly desirous of securing a fair number of British names.

ANNOTATIONS

THE SLOW EVOLUTION OF IDEAS in connection with the interpretation that was put upon the provisions of the Pharmacy Act by the Law Lords who ultimately decided the case on appeal to the House of Lords, appears almost marvellous to those conversant with the circumstances of the case. But though the potent influences of misconception, deficient appreciation, and prejudice have long operated to prevent recognition of the true principle and intention of the Act, in the same manner that the acceptance of the Copernican theory was retarded by bigotted adherence to tradition, satisfactory evidence has recently been given of an advance towards reasonable interpretation of the Act. Almost at the same time that it was referred to in the House of Lords as creating "a trade monopoly," attention was directed, by two of the highest legal authorities, to the violation of common sense apparent in the fact that, in consequence of the House of Lords' decision, a company could not be made subject to penalties for infringement of the Act in the same way as an individual, and to the further consequence that an individual could, by a simple device, actually evade the statutory personal obligations connected with the business of a chemist and druggist, in such a manner as to defeat the object of the Act, and render its amendment clearly necessary.

THE ADMISSION BY THE LORD CHANCELLOR that these consequences of the House of Lords' decision are undesirable and require to be stopped, has not gone the length of disputing the construction of the Act, but only so far as to allow that the idea of a company, as an ideal personage, practising and undergoing an examination is absurd. That is, however, a very considerable advance beyond the idea that a company can be practically outside the scope of the Pharmacy Act: for if a company be incapable of those personal acts, its disability must extend equally to all other acts which can be performed only by individuals; so that, in regard to all such acts referred to in the statute, the idea of a company performing any of them, consistently with the object, intention, or policy of the statute, cannot cohere with the language of its provisions and, to that extent, a company is, in the nature of things, excluded from the purview of the Pharmacy Act.

THE MANIFEST OBJECT of the Pharmacy Act is to prevent "any person"—unqualified—from selling or keeping open shop for retailing, dispensing, or compounding poisons. For that purpose the word "person" requires, in the nature of things, to be construed as applying to a company—an ideal personage that must be, in regard to the object of the statute, in the same position as a rejected candidate or any other individual without qualification. The decision of the House of Lords is the real anomaly, serving as a legal precedent that enables any unqualified person—rejected candidates or persons convicted of breach of the Act—to keep open shop for the purposes of the Act without being liable to the penalty the Act imposes on unqualified persons. That fact is at length becoming apparent, though still only partially, as is manifest from the Lord Chancellor's proposal to allow companies to use titles indicating qualified ability to keep open shop for retailing, dispensing, or compounding poisons, a proceeding that cannot be in any way justified, and one that would be very inappropriate as a remedy for the evil created by the House of Lords' decision.

THE FALLACY PERVADING that decision is the assumption that the act of keeping open shop, etc., is in any degree more within the legal competence of a corporation than the acts which can be performed only by individuals, for the object and policy of the Pharmacy Act clearly point to the conclusion that in the nature of things all the acts to which that statute relates must be equally personal,

and must, therefore, equally require individual qualification for their lawful performance. That is, indeed, the only view reasonably and logically coherent with the language of the Pharmacy Act, and it requires the absolute shutting out of companies, as such, from the possibility of keeping open shop or performing any of the Acts for which qualification is demanded as "expedient for the safety of the public."

Keeping Open Shop, in the sense of owning the business, is the only act, referred to in the statute, which is physically within the competence of a company. The restriction provided in that respect applies only to the personal acts of retailing, dispensing, or compounding poisons, and in regard to those acts their performance is the only object of keeping open shop which requires to be considered in connection with the question whether a company is reasonably or logically to be regarded as outside the scope of the statute in the sense of the House of Lords' decision. The provision that it shall be unlawful for "any person" to retail, dispense, or compound poisons—unless such person shall be a chemist and druggist within the meaning of the Act and registered under the Act—has been admitted to be applicable only to individuals, and since the performance of the personal acts of selling, dispensing, or compounding poisons is the only respect in which the keeping open shop is restricted, the natural conclusion is that the person competent to keep open shop for those purposes must also be qualified. "Any person" lacking the required qualification would infringe the Act by keeping open shop for those purposes, and should be liable to the penalty provided in the 15th section of the Act, just as much as by performing any of the exclusively personal acts of selling, dispensing, or compounding. The inability of a company to perform any of the personal acts referred to in the statute does not appear to require consideration in regard to its object and policy. It is the inherent disability of a company, as such, to perform any of the more important acts to which the various provisions of the statute relate, that effectually puts companies outside the scope of the Pharmacy Act in every sense: that is an exclusion which is in the nature of things absolute, and cannot by any process of reasoning be made a means of enabling a company to get behind the Pharmacy Act in any way even to the extent of the somewhat absurd procedure, of keeping open shop for performing acts of which it is incapable.

Another Fallacious Argument, that the keeper of an open shop need not be qualified, is founded on the provisions of the 17th section, which, as Lord Selborne thought, must include a corporation, and, in the opinion of Lord Blackburn, show sufficient reason for extending the application of the word "person," but only in regard to that section. That view, however, cannot be sustained, for the person on whose behalf a sale of poison in the first part of the schedule is made must obviously be a natural person, to whom the purchaser can be known or introduced, as well as capable of registering the particulars of sale. The seller referred to in the 17th section is, therefore, as distinctly a person who can possess the individual qualification, and must be qualified to make the sale lawful. The indication that such a sale can be made by an apprentice also points to the necessity of the qualified person, on whose behalf the sale is made, taking such part in the transaction as would fulfil the manifest object of the Act and at the same time relieve the apprentice, or servant, from liability to penalty for breach of the law. Hence the language of this section does not, as has been assumed, indicate, or imply peculiarity of construction for a special purpose; but, on the contrary, it shows that the 17th section must be read with the 1st and 15th—that in regard to the mischief the statute was intended to prevent the person who performs any of the acts referred to, whether as master or servant, must be a person qualified as the statute requires. Here again there is the same absolute exclusion of companies from the purview of the Act, as in all other instances, and similar reason for regarding as absurd the idea of including companies as such among the "persons" capable of performing any of the functions to which the Pharmacy Act relates.

A Crucial Point in the consideration of the question as to the proper construction of the Pharmacy Act was reached when the provision of the 16th section for the continuance of a deceased chemist's business came under review. The statement there made that a person, presumably unqualified, might, in such case, lawfully carry on the business, appeared to Lord Selborne to show that such a mode of conducting a chemist's business was not thought by the Legislature "necessarily inconsistent with the object and policy of the Act." That view seemed to him supported by the further provision that, in such a case, the business should be conducted by a duly qualified assistant. But Lord Selborne failed to make allowance for the important difference between thus continuing a business and starting one without qualification, as would be possible if companies were held to be free from the restriction of the Act: therefore, the exemption provided for executors, etc., who might evidently be unqualified turned the scale against considerations tending in the opposite direction, which—as Lord Selborne said—would have made the argument against a corporation being permitted to carry on the business "extremely strong," but for the safeguard against the sale of poison by any person unqualified, which he thought was provided by the stipulation as to employment of a qualified assistant.

Lord Selborne's Judgment was in fact entirely determined by that consideration. His previously expressed view that, for the efficiency of the Act, the seller or compounder of poison whether the owner of a business or the person delegated to conduct sales, must be such a person as could be qualified, was altogether extinguished. The possibility of separating the qualified seller from the keeper of open shop, apparently afforded by the exemption of executors, proved fatal to the argument as to the manifest object of the Act being that only qualified individuals should keep open shop, or sell, dispense, or compound. Thus the necessity for qualification of the proprietor of a business was eliminated; apparently so as not to prejudice the object and policy of the Act, though in reality so as to afford a basis for complete evasion of all its provisions, inasmuch as a company—if outside their scope—could lawfully do everything that an unqualified individual may not do. Moreover, there is nothing in the Act to compel the employment of qualified assistants; consequently an unqualified and contumacious grocer could convert himself into a company and carry on business as a chemist and druggist in defiance of the law, if the House of Lords' decision be a correct construction of the Pharmacy Act.

Lord Blackburn's Judgment was largely inspired by the idea that the Pharmacy Act was intended to create a monopoly in the sale of drugs. Probably that mistaken impression may account for his declared inability to perceive anything in the object of the Legislature or in the context requiring that the provisions of the Act should be extended to companies; though he was quite clear that, in such case, the word "person" should have the more extended sense. But since that time experience of such consequences of the House of Lords' decision as were submitted to the Departmental Committee of the Board of Trade in 1895 conclusively shows that if the Pharmacy Act was not altogether frivolous legislation, it has a meaning directly opposite to that put upon it by the House of Lords in 1880 and should be otherwise construed.

LORD WATSON'S JUDGMENT was entirely founded upon the presumed inadequacy of the language of the Act, to express the intention that its provisions should apply to companies as well as to individuals. But if the foregoing arguments are reasonable or logical they will show the insufficiency of that reason for Lord Watson's acquiescence in a decision contrary to the acknowledged preponderance of "considerations of policy" in favour of reading the Pharmacy Act so as to give qualified individuals "the sole right to sell drugs"—"or to keep open shop" for that purpose—and, in that respect, altogether to shut out the possibility of defeating the object of the Act in the manner that companies have done.

THE EXEMPTION OF EXECUTORS, which chiefly led to the disastrous decision of the House of Lords, has been spoken of in a maudlin way as a "flaw in the Pharmacy Acts," that few corporations have taken full advantage of, as if it were of no more account than a hole in a Highlander's breeks; but the truth is, that exempting provision has afforded the sole basis of company trading and its interpretation by the House of Lords has been the gateway to the bottomless pit where qualified chemists and druggists, in business on their own account, are now being devoured by their own progeny. Before any hope can be entertained of securing a reasonable and logical interpretation of the Pharmacy Act, the mischief that has been occasioned by that pernicious provision must be counteracted, consistently with the manifest object and policy of the Act. Unquestionably, that will be one of the first steps to be taken by registered chemists and druggists in the task that has now to be accomplished by them.

MORE LOCAL SECRETARIES of the Pharmaceutical Society are required, according to Mr. J. W. T. Morrison (see p. 375), whose idea appears to be that every member of the Society should be directly represented by a district officer of the Society, who should "shadow" the M.P. for that district. The idea has much to commend it, but must be credited to the Vice-President of the Society, rather than to Mr. Morrison. For, in a paper read before the Bradford and District Chemists' Association, in February last (*vide P.J.*, February 25, 1899, p. 164 *et seq.*), Mr. Newsholme urged that the best method of improving local pharmaceutical organisation would be "to arrange that one registered chemist in each Parliamentary constituency throughout Great Britain shall be appointed to communicate with the representative for that constituency on all matters affecting the welfare of pharmacy." It was also suggested by Mr. Newsholme that the registered chemists delegated to perform the specified duty might with advantage be the Pharmaceutical Society's local secretaries, and that by the appointment of about one hundred and seventy extra local secretaries or assistant local secretaries—or one-third more than at present—all the country districts could be as fully represented as the larger towns now are. In fact, in the paper referred to, Mr. Newsholme not only presented a scheme, but also worked out all the details, and it is only owing to the characteristically apathetic manner in which the registered chemists of Great Britain have received his suggestions that nothing definite has yet been done in the matter.

THE SELF-INTEREST OF CHEMISTS was not directly enough touched by Mr. Newsholme's proposals. If he had drafted a scheme whereby registered chemists would have been assured of a fixed income from the day upon which they passed the qualifying examination—whatever their business capacity or incapacity—it might have been received with enthusiasm; that is to say, unless he had asked them to devote a fair amount of time, labour, and money to secure the realisation of the scheme. In the instance under notice, however, registered chemists were merely shown how their admittedly defective organisation might be improved and even perfected. But though engineers, bricklayers, dockers, and many other classes of workers would have jumped at the opportunity, and hailed the scheme with enthusiasm, the average chemist has been content to let the suggestion pass. It did not propose to secure him a monoply of the sale of drugs, a greater return on his invested capital than any tradesman has a right to expect, or any other privilege he is not fitted to enjoy. No! all that was pointed out was how he may best help himself, whereas he prefers to depend upon the provisions of Acts of Parliament.

CHEMISTS ARE ONLY MORTAL, of course, and they are afflicted with a full share of mortal weaknesses. It would be well, however, if they would realise the fact that Parliament is not likely to be influcnced in favour of any class, unless the individuals constituting it show that they are in earnest when they or their representatives ask for reforms. What member of the House of Commons cares in the most infinitesimal degree whether registered chemists are able to retain any portion of their business or not? It would be safe to say none. But no Parliamentary representative dare continue to resist reforms which must obviously tend to insure the safety of the public, and if only the registered chemists of Great Britain will agree to support reasonable demands, based on public requirements, they can soon produce a satisfactory impression. But their support must be active, persistent, and vigorous; it will not suffice to write a letter to a Member of Parliament or the Lord Chancellor, and then do nothing but talk while others work. Neither is it wise to attempt too much, and hamper the leaders of the craft by unwise displays of activity. So far as concerns the members of the Pharmaceutical Society, at least, the course of procedure is obvious. Having duly elected representatives on the Council of the Society, the conduct of affairs should be left in their hands, and not until they suggest the next move should that move be taken. If matters do not progress satisfactorily, then fresh representatives can be elected on the Council in May next.

BUT TO RETURN TO OUR TEXT, apart from what the Council of the Society is alone in a position to do—*i.e.*, negotiate with Government Departments and influential persons—much may be done by perfecting local pharmaceutical organisation. Mr. Newsholme has suggested a practical scheme, having the local secretaryship of the Pharmaceutical Society as a basis; he has also indicated an alternative scheme, based on the existence of local associations and the Federation of such bodies. If Mr. Morrison is in earnest, he might with advantage take upon himself the burden of adapting one or other of the schemes—preferably the first—to the needs of his own county, just as Mr. Newsholme has offered to do for the West Riding of Yorkshire. The response of the Hertfordshire chemists may be as tardy as that of their Yorkshire brethren, but at least something will have been done to familiarise the idea, and perhaps, in the course of time, someone in each of the remaining counties, may be struck with the appropriateness of the same idea. Whether it will be ever realised is another matter altogether, but surely the importance of the possible results is sufficient to justify the attempt being made!

AN AUTHENTIC RECORD of the number of chemists and druggists in business on their own account in different towns and districts throughout the country would, for instance, be a very useful supplement to the official register, and a similar record of qualified persons engaged in the capacity of assistants would also be worth having. For supplying such information, the Society's local secretaries have facilities which would enable them to carry out the necessary work without much trouble to themselves, and with a prospect of rendering good service.

PHARMACEUTICAL SOCIETY.

Donations to the Library and Museum.

At a meeting of the Library, Museum, School, and House Committee, on Wednesday, October 11, the Librarian and Curator, presented the following reports of Donations:—

To the Library (London).

Mr. R. T. Baker, Technological Museum, Sydney:—On a supposed new genus of the N.O. Myrtacæ. On the Cinnamoms of New South Wales, etc.

Mr. J. H. Maiden, Botanic Gardens, Sydney:—Report on the Gardens for 1898. Observations on the Eucalypts of New South Wales.

Royal Society of New South Wales:—Journal and Proceedings, vol. 32.

Dr. L. Planchon, Montpellier:—Plantes médicinales et toxiques du département de l'Herault.

Ecole supérieure de pharmacie de Paris:—Thèses par MM. Lacour, Hérissey, Guéguen, Gaudin, Lenormand et Rouchy.

M. Maurice Duyk, Bruxelles:—Sur la solubilité des huiles volatiles.

Surgeon-General U. S. Army:—Index-Catalogue of Library, 2nd ser., vol. 4.

Dr. Squibb, Brooklyn:—Ephemeris of Materia Medica, etc., vol. 5, no. 3.

University College, Dundee:—Calendar, 1899.

University College, Bristol:—Calendar, 1899.

Mason University College, Birmingham:—Calendar, 1899.

Owens College, Manchester:—Calendar, 1899.

Yorkshire College, Leeds:—Calendar, 1899.

University of Durham College of Medicine, Newcastle-on-Tyne:—Calendar, 1899.

King's College Hospital, London:—Reports, vols. 4-5.

St. Bartholomew's Hospital, London:—Statistical tables of patients during 1898.

Botanical Society, Edinburgh:—Transaction and Proceedings, vol. 21, parts 1-3.

Missouri Botanical Garden:—Tenth annual report.

Director of the Wellcome Research Laboratories, London:—Two papers by S. B. Schryver, one paper by H. A. D. Jowett.

To the Library (Edinburgh).

Editor of the *Chemist and Druggist*, London:—Proctor's Pharmaceutical Testing, 1899.

Ontario College of Pharmacy:—Annual announcement, 1899.

Dr. Squibb, Brooklyn:—Ephemeris, vol. 5, no. 3.

To the Museum, London.

Messrs. Burgoyne, Burbidges and Co., London:—Specimen of pure oil of peach kernels expressed in France.

Messrs. Stafford, Allen and Co., London:—Specimens of Canary Islands, Alicante, Malaga, Valencia, Majorca, Mogador, Sicilian ordinary, and Catanian almonds; specimens of decorticated, pure, powdered white pepper; specimens of Persian and Californian peach kernels, and a specimen of expressed oil of stavesacre seeds.

Mr. E. T. Baker, Technological Museum, Sydney:—Specimens of the barks of Atherosperma moschatum, Beilschmiedia obtusifolia, Cinnamomum oliveri, and Doryphora sassafras.

Messrs. Hearon, Squire and Francis, London:—Specimens of split cardamom seeds.

Dr. B. H. Paul:—Specimens of amber containing insects, ambroid or pressed amber, succinic acid in fine crystals, gedanite and stautienite, obtained from the West Prussian Provincial Museum in Dantzig.

The Editor of the *Chemist and Druggist*:—Specimens of Bahia ipecacuanha.

Mr. E. H. Farr, Uckfield:—Microscopial sections of Cinnamon from Annam.

To the Herbarium.

Mr. H. N. Ridley, M.A., Director, Botanic Gardens, Singapore:—Specimens of Alstonia scholaris, Cnesmone javanica, Dryobalanops camphora, Geophila reniformis, Garcinia cambogiana, Lycopodium casuarinoides, Melastoma leucadendron, Myristica intermedia, Payena leerii, Pleopeltis phymatodes, Prismatomma albidiflora, Strychnos malaccensis, S. tieute, Tabernæmontana peduncularis, Tephrosia hookeriana, Terminalia phyllocarpa, Urceola elastica, Willughbeia coriacea.

Professor Van Eeden, Haarlem:—Specimens of the leafy twigs of the trees yielding the resins Dammar Hitam, D. Kajoe alang, D. Keloekoep, D. Lagam, D. Maksa, D. Moesegah, D. Resak, and D. Tyarmin.

Messrs. Burroughs and Wellcome:—Specimen of Derris uliginosa with fruits.

Mr. G. C. Druce, M.A., F.L.S., Oxford:—Specimen of Cnicus tuberosus.

The Curator:—Fourteen specimens of rare British plants.

EXAMINATIONS IN LONDON.

October, 1899.

MAJOR EXAMINATION.

Candidates examined	15
,, failed	6
,, passed	9

Austen, John
Battle, John Cyril Marfleet
Burrell, Benjamin Lawson
Cornick, Ernest Edward
Evans, William Llewelyn
Gibson, Hubert
Moore, Richard Herbert
Smith, Arthur Richard
Wood, Edward Vivian

MINOR EXAMINATION.

Watkins, Archibald Greenwood
West, Arthur John
Whitehouse, Alexander
Williams, William Eleder
Winckler, Ernest

FIRST EXAMINATION.

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination:—

Adams, Frank Richard; London
Allen, Frank Coltman; Dudley
Aplin, John Henry; Trowbridge
Bainbridge, Archibald; Bedale
Billington, L.W.; Newcastle, Staffs
Bonner, Rupert John; Banbury
Buxton, Henry Arnold; Newark
Cole, William Henry; Buxton
Corner, Edward; Whitby
Dietzsch, Theodor; London
Francis, Edward Saunders; Wrexham
Goble, Joseph Harold; St. Leonard's
Griffiths, Richard E.; Haverfordwest
Hall, Sidney H.; Skegness
Hedley, Osborne Janion; Wrexham
Jack, Richard C.; West Hartlepool
Jackson, Ewart G.; Newcastle, Staffs
Jones, W. Bowen; Chipping Sodbury
Miller, Harry Barton; Sheffield
Osborne, William P.; Grantham
Paterson, Alex. G. C.; Scarborough
Payne, Arthur Martin; Market Rasen
Reed, Percy Stanley, Buxton
Rowlands, David Roger; Liverpool
Sandwith, Ralph Bertram; Bracknell
Saunders, Hugh F.; Walthamstow
Sayer, Thomas William W.; Leeds
Sharp, John George; St. Neots
Smith, Alfred E.; Wath-upon-Dearne
Spilman, Thomas W.; Leeds
Thomas, Arthur Reginald; Exmouth
Toy, George Harold; Perry Barr
Waldron, James Joseph; Formby
Warner, Charles Horne; Evesham
Whitehead, Andrew; W. Hartlepool
Wilkinson, Ernest E.; Otley
Willer, William; Ealing
Wilson, Tom; Manchester

EXAMINATIONS IN EDINBURGH.

FIRST EXAMINATION QUESTIONS.

First Paper.

October 10, 1899, *from* 11 *a.m. to* 12.30 *p.m.*

LATIN.

1. FOR ALL CANDIDATES. Translate into Latin :—

1. They did not plough the fields.
2. Honour the queen, my children.
3. The boys will be taught by many skilful masters.
4. Caesar and his cavalry came with the utmost speed.
5. The thiugs which make life happier are these.

2. Translate into English *either* A (Caesar) *or* B (Virgil).

A.—CAESAR.

1. Itaque prius, quam quicquam couaretur, Divitiacum ad se vocari jubet, et, quotidianis interpretibus remotis, per C. Valerium Procillum, principem Galliae provinciae, familiarem suum, cui summam omnium rerum fidem habebat, cum eo colloquitur: simul commoncfacit, quae ipso praesente in concilio Gallorum de Dumnorige sint dicta, et ostendit, quae separatim quisque de eo apud se dixerit. Petit atque hortatur, ut sine ejus offensione animi vel ipse de eo, causa cognita, statuat, vel civitatem statuere jubeat.

2. Id ne accideret, magno opere sibi praecavendum Caesar existimabat. Namque omnium rerum, quae ad bellum usui erant, summa erat in eo oppido facultas; idque natura loci sic muniebatur, ut magnam ad ducendum bellum daret facultatem, propterea quod flumen Alduasdubis ut circino circumductum paene totum oppidum cingit; reliquum spatium, quod est non amplius pedum sexcentorum, qua flumen intermittit, mons continet magna altitudine, ita ut radices ejus montis ex utraque parte ripae fluminis contingant.

GRAMMATICAL QUESTIONS.

(For those only who take Caesar.)

1. Decline throughout. in the singular, *magna altitudine*; in the plural, *ejus montis*. (Passage 2.)

2. Give the third person singular of the indicative perfect, active and passive, with the English, of *molo, impetro, demitto, decipio, neco, munio, redimo, subtraho.*

3. Give, with examples, the rule for the agreement of the verb when the nominative consists of words of different persons.

4. How must *but* be translated into Latin when it is (*a*) a conjunction, (*b*) an adverb, (*c*) a preposition?

B.—VIRGIL.

1. Quisquis es, haud, credo, invisus coelestibus, auras
Vitales carpis, Tyriam qui, adveneris urbem.
Perge modo, atque hinc te reginae ad limina perfer.
Namque tibi reduces socios, classemque relatam,
Nuntio, et in tutum versis aquilonibus actam;
Ni frustra augurium vani docuere pareutes.
Adspice bis senos laetantes agmine cycnos,
Aetheria quos lapsa plaga Jovis ales aperto
Turbabat coelo: nuuc terras ordine longo
Aut capere, aut captas jam despectare, videntur.

2. Tum sic reginam alloquitur, cunctisque repente
Improvisus ait: "Coram, quem quaeritis, adsum,
Troius Aeneas, Libycis ereptus ab undis.
O sola infandos Trojae miserata labores!
Quae nos, reliquias Danaum, terraeque marisque
Omnibus exhaustos jam casibus, omnium egenos,
Urbe, domo, socias. Grates persolvere dignas
Non opis est nostrae, Dido; nec quicquid ubique est
Gentis Dardaniae, magnum quae sparsa per orbem.
Di tibi, si qua pios respectant numina, si quid
Usquam justitiae est, et mens sibi conscia recti,
Praemia digna ferant."

GRAMMATICAL QUESTIONS.

(For those only who take Virgil.)

1. Decline throughout, in the singular, *mens conscia;* in the plural, *infandos labores*. (Passage 2.)

2. Give the third person singular of the indicative perfect, active and passive, with the English, of *gigno, inveho, muto, addo, capio, circumfundo foveo, prorumpo.*

3. Give, with examples, the rule for the agreement of the verb when the nominative consists of words of different persons.

4. How must *but* be translated into Latin when it is (*a*) a conjunction, (*b*) an adverb, (*c*) a preposition?

Second Paper.

October 10, 1899, *from* 12.30 *p.m. to* 2 *p.m.*

ARITHMETIC.

[*The working of these questions, as well as the answers, must be written out in full.*]

1. Reduce 9,123,400 sq. in. to acres, etc.

2. Taking the railway fares in Prussia at two-thirds of those in England, what will it cost to travel 320 miles in Prussia if it costs £1 2s. 6d. to travel 180 miles in Eugland?

3. Reduce $\frac{9}{11}$ of $\left(\frac{2\frac{1}{2}}{3\frac{1}{2}} \div \frac{4\frac{1}{4}}{5\frac{1}{4}}\right)$ of £15 3s. 10½d. to the fraction of £12 13s. 6d.

4. Divide 1·69 by ·013; and 13·2 by 5·6.

5. I sell goods for £46 at a profit of 15 per cent. What per cent. should I gain by selling them for £42?

6. What amount of stock in the 3½ per cents. will produce the same income as £3,560 Stock in the 3 per cents.?

The following qucstion must bc attempted by every candidate :—

7. Write out the Metric Table of Capacity. How many ares added to 55,372 deciares make 1 sq. kilomètre?

Third Paper.

October 10, 1899, *from* 3 *p.m. to* 4.30 *p.m.*

ENGLISH.

1. Analyse:—
"Well had the boding tremblers learn'd to trace
The day's disasters in his morning face."

2. Parse fully:—"Thou can'st not then be false to any man."

3. Name *two* ways in which primary derivative adverbs may be formed from other parts of speech. Write *two* sentences introducing one such adverb in each.

4. In the following passage, supply the necessary capital letters, and put in the stops and the inverted commas where necessary:—allen had started walking agaiu but the moral degradation of it he snapped out at her over his shoulder i would rather earn the meanest living at an honest trade and be free from it that may be responded sister soulsby but it isn't a question of what you would rather do its what you can do how could you earn a living allen stopped and stared at her

The following question must be attempted by every candidate:—

5. Write a short Composition on *one* of the following subjects:—
(i.) A Visit to a Cathedral or a Castle.
(ii.) The Administration of the Law in England and in France.
(iii.) The Transvaal.
(iv.) Local Attachments.

PHARMACEUTICAL SOCIETY OF IRELAND.

On Wednesday, the 4th inst., the monthly meeting of the Council was held at 67, Lower Mount Street, Dublin, at three o'clock. The members who attended were the PRESIDENT (Mr. R. J. Downes), and Messrs. Grindley, W. F. Wells, Kelly, J. J. Bernard, Simpson, Dr. Walsh, Michie, and P. N. White, J.P. (Sligo).

The PRESIDENT, after welcoming the recently elected member, Mr. Patrick N. White, J.P., read a telegram from Mr. Jameson, another recently-elected member, stating that he had received the notice of that meeting too late to enable him to make arrangements to attend.

ELECTION OF OFFICERS.

Mr. WELLS, in moving that Mr. R. J. Downes be re-elected President, said it was necessary that one who had been in harness should continue on for the ensuing year on account of the work about "company pharmacy" that was going on.

Mr. GRINDLEY seconded the motion, which was put by Mr. Wells and unanimously agreed to.

The PRESIDENT said he was very much obliged for the honour they had conferred on him in electing him for the third time to that office. He had many private reasons why he would have wished to be relieved from office, but the old adage said, "It is not good to change horses when you are crossing a stream." As regarded Parliamentary business, however, he would not be able to undertake the fatigue of lobbying, which would have to be undertaken by someone else. Nor should he be able to give the constant attendance at the evening meetings that he gave last year. He desired that the School Committee should more seriously take that up, for it was their proper work. The President then said it had been customary for the occupant of the chair to propose his Vice-President, and he

thought they could not do better than retain Mr. Beggs in that office. He moved that he be re-elected.

Mr. Michie seconded, and the motion passed unanimously.

Mr. Wells, in moving that Mr. George H. Grindley be re-elected Honorary Treasurer, regretted that he would not allow himself to be nominated for either the Vice-Presidency or the Presidency. He was quite sure that during past years they would have been ready to put him into either of those positions.

Mr. Kelly seconded, and the motion was passed unanimously.

On the motion of Mr. Kelly, seconded by Mr. Bernard, Mr. Simpson and Dr. Walsh were re-elected Auditors.

The various committees were then elected.

In answer to a question from Mr. Bernard,

Mr. Wells said it was not expected that members who resided in the country would come up to Dublin to attend the Law Committee, but they could do valuable committee work in the country, because when inquiries had to be made the papers were sent to them.

Mr. Bernard said he was not talking of the Law Committee, but of the Declarations and the Certificates Committees.

Mr. Wells said the same thing applied to them. Besides, it was desirable that the druggists should be represented on the committees.

Other Business.

A letter was received from Dr. M. R. Whitla thanking the Council for re-electing him as Examiner in Pharmacy, and expressing a hope that the Council would sanction the new method of marking in the pharmacy examination before the next examination came on.

The President said this new mode of marking had been referred to the Privy Council, who declined to sanction it.

Mr. Wells said it was sent to the Privy Council along with some other matters, and all were rejected. He would move at the next Council meeting that this mode of marking should be adopted, and that the Privy Council should be again asked to sanction it. The object was to have separate marks for prescription reading and the British Pharmacopœia. Under the present regulation a man who got no marks in prescription reading might have to be passed.

A letter from the Castle intimated that the Lord Lieutenant and Privy Council, after having fully considered the case of William Carlin, of Moville, who had been fined £5 for selling phosphorus paste without being qualified to do so, and who had memorialised that the fine should be returned to him, had decided that the law should take its course.

Mr. Wells: The man was fined £5, and after we got the money he sent in a memorial.

A donation was received from the Mason University College of a copy of their Calendar for 1899-1900.

On the motion of Mr. Grindley, seconded by Mr. Wells, thanks were voted to the donors.

Messrs. D. N. Stewart, Londonderry, and John Hartrey, Phipsborough, Dublin, were elected members of the Society.

Messrs. Arthur J. Cahill, Dublin; Thomas L. Foster, Belfast; and G. D. Dixon, Mallow, were nominated for membership.

Other business having been disposed of,

The Council adjourned.

LIVERPOOL PHARMACEUTICAL STUDENTS' SOCIETY.

At the general annual meeting of this Society, held on Thursday evening, the 5th inst., at the Liverpool School of Pharmacy, the President, Mr. Cowley, in the chair, the reports of the Honorary Secretary and the Honorary Treasurer gave evidence of the vigorous condition of the Society. The roll of membership during the year had been very satisfactory, the percentage of members present at the meetings had been larger than in the two previous years, and there was a good balance in the Treasurer's hands. The officers elected for the ensuing year were: President, Mr. Prosper H. Marsden, F.C.S.; Vice-Presidents, Messrs. Catford and Wyatt; Hon. Secretary, Mr. Patridge; Hon. Treasurer, Mr. P. G. Jenner; Council, Messrs. Atkinson, Cowley, H. B. Morgan, Park, Pickering, Smalley, Sutton, Wardleworth, and Wokes. Votes of thanks were then passed to the retiring office-bearers for their efforts to render the year's work the success it had proved to be, and it was announced that the syllabus would be issued shortly, and members desirous of contributing papers or notes were invited to communicate with the Secretary at once. The aim of the Society as regards these papers is to have them as far as possible the work of the members, and to encourage the discussion of any little difficulties of a practical nature occurring during the daily routine of business.

GLASGOW CHEMISTS' AND DRUGGISTS' ASSISTANTS', AND APPRENTICES' ASSOCIATION.

A general meeting of the above Association was held in the Masonic Chambers, West Regent Street, on Friday evening, October 6, when Mr. J. P. Gilmour, President, occupied the chair. In announcing the

Arrangements for the Present Session,

Mr. Gilmour said he felt confident that members would find the programme an unusually inviting one. The Committee had respected the old maxim that "All work and no play makes Jack a dull boy"; but that intellectual interests had not been overlooked was proved by the appearance on the list of the names of pharmacists of standing, like Messrs. J. Lothian, T. Maben, T. S. Barrie, J. R. Hill, and Dr. Coull. He was sorry to learn that an impression was current that this Association had been formed in opposition to the local Association. He warmly disclaimed any such motive on the part of the promoters of the Assistants' Association. Everyone knew that there were special practical difficulties in working a joint Association. It seemed to his colleagues and himself that there was ample space for separate Associations, and that the work of the two bodies ought not to be conflicting but complementary. It might be premature to define the Association's external policy, but he felt constrained to refer to the vexed and vexatious problem of late shop hours, an evil which more than ever harassed both master and assistant in these days when the qualification of the assistant was virtually obligatory. That was a question of immediate practical politics which ought to engage their most earnest attention.

Mr. J. Sturgeon (Treasurer) stated that the finances of the Association were already in a sound and progressive state.

Mr. J. Lothian, Ph.C., cordially welcomed the advent of the Association. He had no misgivings as to its future. The fear that it would clash with the local Association was chimerical. The greatest hindrance to the successful co-operation of masters and assistants in the same society was the constraint felt by the latter in the presence of the former. No doubt that feeling was unreasonable, but it was evidently hard to dissipate it. There were separate Associations in many provincial towns, and these seemed to help rather than interfere with each other. As a teacher he was painfully surprised by the exceptionally late shop hours in Glasgow. While in many English cities evening classes opened at seven, it was difficult to muster Glasgow students for a lecture at 9.15, and they often turned up for practical work at ten o'clock. He was not closely acquainted with the conditions of business in Glasgow, and he knew that the question was an intricate one; but some effort ought to be made to secure partial relief. Before anything could be done they must get a powerful combination both of masters and assistants.

Mr. Boyd (employer), in compliance with a call from the chair, said that he had listened with great pleasure to the statements as to the Association's prospectus. He flouted the idea that it was conceived in enmity to the older Association or that there need be friction between them. He recalled a former Assistants' Association, under the fruitful presidency of the late John Hunter, which did yeoman service to pharmacy. He hoped to see this Association live longer and go farther. He was in full sympathy with the demand for early closing. There might be formidable obstacles in the way of that, but at the very least some arrangement might be made by which employers and employees should relieve one another, so that the working day could be brought within reasonable limits. There was no sense or science in working any man up to the limit of his energy or endurance.

Mr. J. P. Taylor could see no way clear out of the *impasse*. In Glasgow one of the chief causes of late hours was the practice of keeping night bells. In such establishments, although the nominal hour of closing was nine, it was actually eleven, and it was expecting too much of human nature, in these times of desperate competition, to suppose that other shops in the neighbourhood would lock their doors and lose custom.

Mr. MacKay deprecated Mr. Taylor's views as too pessimistic. The night bells in Glasgow could be counted on one's ten fingers. The doctors' shops, with their late consulting hours, were the greatest sinners. In lieu of drastic reform, he welcomed Mr. Boyd's proposal.

The Chairman, in closing the meeting, summed up the discussion by remarking that the consensus of opinion seemed to be that strong combination was a *sine quâ non* to the effective action for the cure of the evil.

EXTRACTS FROM CONSULAR REPORTS.

THE GERMAN PHOSPHORUS FACTORIES, it is reported, are about to form a syndicate. Last year 5,928 cwts. were imported into the country, as compared with 5,831 cwts. in 1897; of this Great Britain sent by far the largest part, 5,121 cwts.

THE PROTECTION OF NATIVE INDUSTRY has been under consideration in Russia, and a scheme has been devised by which, under a law that came into operation on January 1 of this year, all foreign commercial travellers plying their avocation in Russia must, on arrival in the country, provide themselves with a licence, for which the charge is 50r. (or about £5 5s. 6d.). In addition to this they must take out a trading licence at a cost of 500r. (or about £53 4s.) for the person, firm, or company on whose behalf they are travelling. Moreover, these licences cannot be procured for the mere asking and paying. In order to obtain a commercial traveller's licence an applicant must also produce a power of attorney or letter of authority from a person, firm, or company authorising him to travel on his or their behalf; he must further, if representing a British firm, produce a certificate or licence to trade issued by a British Chamber of Commerce. Jewish commercial travellers are practically excluded from Russia, unless they obtain special permission from the Ministers of Interior, Finance, and Foreign Affairs.

THE PENALTY FOR TRADING without the above licences is treble the amount of their cost, or 1,650r. (equal to about £175). The licences in question, procurable on entering Russia from the nearest local treasury, town council, or collector of taxes, are issued for the period of one year, from January 1, and are renewable during the months of November and December for a further annual period. Commercial houses and industrial concerns which have provided themselves with the prescribed licences may employ an unlimited number of commercial travellers, on condition, however, that each such traveller pay the tax of 50r. for his licence. The operation of the new law does not extend to the Grand Duchy of Finland, where such travellers belonging to countries (Great Britain being among these) with which Russia has commercial treaties are exempted from payment of a commercial traveller's tax.

THE BENZINE CONVENTION, after much discussion, is at last stated to be an accomplished fact. According to a recent report on the trade of Germany for 1898, this convention includes thirty establishments in Germany, Belgium, Luxemburg, and Switzerland, and will last three years. It commands a production of 35,000,000 kilos., regulates the amount of production, and rules the prices. This convention is stated to be the outcome of the exorbitant prices demanded by the Standard Oil Company, and the benzine manufacturers hope to keep their prices proportionately high.

A NEWLY-DISCOVERED PROCESS for the production of ammonia is reported from Germany by Consul-General Schwabach. Formerly, gas-meters have been used in the production of the union of hydrogen and nitrogen, but by the new process a calcium metal is heated in nitrogen to 1,200 degrees, the result being a brown slag, from which, by watering, ammonia and slaked lime are obtained. At present, however, the process is too expensive, on account of the high price of calcium, but it is probable that this difficulty may be overcome, as it is considered possible to obtain calcium cheaper by means of the electrolytic process.

THE EXPORT OF SUGAR OF LEAD from Germany is steadily decreasing year by year. In 1896 the export was 1,533 tons, the following year 1,176 tons, and last year 1,119 tons. Its manufacture is also stated to have been unprofitable last year. The main reason for this retrogression is said to be the establishment of new factories in other countries with which the German manufacturer cannot compete on account of the high import duty. The difficulties in the spirit trade have intensified these unfavourable conditions, spirit being the principal raw material in the production of sugar of lead. The enormous rise in the price of spirit in the spring of 1898 caused a rise in the price of sugar of lead of six marks per 100 kilos. A fall in the price of spirits in the autumn brought about a reduction of two marks in the price of sugar of lead, but the present prospects are reported to be very gloomy, as the maintenance of high prices by the spirit "ring" render a profitable production of sugar of lead impossible.

"METHYLBENZOLSULFINID," or "SUGARINE," is a new sweetening substance which is said to be 500 times as sweet as sugar. The process of production is reported to be somewhat complicated.

THE BUSINESS IN SACCHARINE during the first nine months of last year, both in Germany and other countries, is reported to have been satisfactory. There was a slight falling off in prices, however, during the latter part of the year. This fall is attributed to the law regulating the trade in artificial sweetening stuffs which came into force in Germany in October, 1898.

ARTIFICIAL INDIGO, in the opinion of Consul-General Schwabach, is a perfect substitute for the natural product, and it is stated that the most sanguine anticipations of the German manufacturers have been realised, the consumers being convinced of the great advantages which it possesses and of its equality with the natural product. Numerous factories have been established for its production, but, as was recently pointed out by Consul Robinson (see *ante*, p. 197), seeing that the market price of the natural article is less than that of the artificial product, difficulties are likely to arise in the trade.

"CALCIDUM" IS A COLOURLESS LIQUID which is claimed to have the property of lowering the freezing point of water to 56°. It is heavier than water, hydroscopic, non-inflammable, rendering stuff impregnated with it also non-inflammable, and it does not eat into metal. Calcidum, being 500 per cent. cheaper than glycerin, is expected to have much influence on those industries in which it is necessary to work with a liquid which does not freeze. In the manufacture of acetylene gas, for instance, calcidum is likely to prove of importance, especially in Germany, where the police regulations prohibit the generation of acetylene gas in houses or in massive buildings, and consequently it is only in lightly-built sheds in which water easily freezes that its manufacture is permitted. By the use of calcidum, it is stated that the freezing point of water can be lowered to any desired depth, so that the manufacture of acetylene can be carried on in the open air with only a light roof as a protection against snow. Samples of this new substance may be obtained gratis on application to the Patent Bureau of Richard Lüders, in Görlitz.

THE IMPORT OF PALM KERNELS into Germany is reported to have nearly ceased, and the trade in palm oil has diminished by one-half. Although the largest and oldest German firm, Messrs. Gaiser and Co., in Harburg, has ceased to exist, the remaining firms, it is said, cannot do a remunerative trade. The cause of this is attributed to the fact that Great Britain, Spain, and Portugal, countries which formerly received the export of Germany, now have their own factories, which raise the price of the already scarce raw material and provide the German market with comparatively cheap oil-cake. At the present time, it is reported that a petition signed by 160 German oil manufacturers is lying before the Bundesrath praying for an increase of import duty on cotton-seed oil, which competes largely with palm oil.

IN THE HOPE OF RELIEVING THEIR TRADE, the German soap manufacturers petitioned for a decrease of the import duty on maize oil. But it was the opinion of the Chamber of Commerce of Harburg that those who supported the petition could not be aware of the capabilities of the German linseed oil industry, which amounts annually to 165,000 tons. Of the quantity produced in Germany, it is stated that at least 50 per cent. is used in soap manufacture, and should a lower duty be levied on the import of maize oil it would be a severe blow to the German linseed oil industry. The Bundesrath, therefore, declined to accede to the proposals of the soap manufacturers. Later, the combined linseed and palm oil manufacturers presented another petition. They proposed to raise the tax (4 marks) which already exists on cotton oil, a material used freely in many industries. They pointed out that the import of this oil is rapidly increasing, and expressed the opinion that the large supply is an injury to the German oil industry and to agriculture. They have hopes that this request will be granted, inasmuch as Germany imposes a lower duty on the import of cotton oil than most other countries.

SELECTED PRACTICAL FORMULÆ.

Lanolin Creams.

Toellner recommends the following recipes:—(1) Lanolin, 640, white vaseline, 220, are melted together, then mixed with a solution of borax, 5, in distilled water, 135, and the mixture perfumed with rose oil, 1, bergamot oil, 2; (2) Spermaceti, 200, yellow vaseline, 600, are melted together, then wool fat, 800, is added, and water, 1,000, the whole stirred well and finally perfumed with oil of lemon, 5.—*Oest. Zeits. für Pharm.*, **53**, 387.

Boroglyceride Lanolin.

Wool fat, 350, olive oil, 130, are melted together, and gradually a warm solution of boric acid, 20, glycerin, 100, distilled water, 50, is mixed in and stirred until cold.—*Oest. Zeits. für Pharm.*, **53**, 388.

Oily Solutions of Mercuric Chloride with Guaiacol for Subcutaneous Injections.

Lagrange advocates the use of oily solutions of mercuric chloride containing guaiacol in those cases where the internal administration of mercury has been unsuccessful, and where the use of mercurial ointments is impossible. The injection gives a little pain, but the results are prompt. E. Bazin gives further particulars concerning the preparations of such solutions. Olive oil which has been washed with alcohol to remove the free fatty acids is treated with charcoal and filtered. To remove every trace of alcohol it is heated to 100° C., and is then sterilised by further heating to 120° C. The mercuric chloride is powdered and rubbed down with the oil (5 Gm. to 100 C.c. of oil) in a mortar which has been heated by burning alcohol in it. In order to completely dissolve the mixture it is heated from 75° to 80° C. in flasks fitted with rubber corks. After cooling 3 per cent. of guaiacol is added and dissolved by shaking. The finished product is preserved in 1 C.c. bottles which have been previously sterilised at 120° to 150° C. One bottle contains one injection. The solution thus prepared is very stable, but it must be kept from the light; the guaiacol crystals which are used must be dried.

Wine for Gout.

Quinine sulphate, 1·5; alcoholic extract of colocynth, 1; alcohol (95 per cent.), 10; Malaga wine, 80.—*Pharm. Post*, **29**, 392.

Kalodont.

Precipitated chalk, 250; magnesia, 80; glycerin, 500; Castile soap, 150; cinnamon oil, 2; peppermint oil, 2. A rose colour is obtained by the addition of 3 parts of a mixture of carmine, 5, and calcium carbonate, 5, in water, 10 parts. Dahne recommends in place of carmine, blue litmus tincture, which serves the same purpose and whitens yellow teeth.—*Pharm. Post.*, **29**, 393.

Headache Drops.

The following formula is given for Frieser's headache drops. Methyl valerianate, 1; distilled water, 4; syrup of orange flowers, 6. Twenty drops are given every two hours during the attack.—*Pharm. Post.*, **29**, 393.

Seidlitz Powder Tablets.

Powdered white sugar, 60; magnesium sulphate, 18; mucilage of acacia, 7; powdered sodium sulphate, 6; sodium bicarbonate, 6; triple rose water, 2; essence of orange, 1.—*Pharm. Post.*, **29**, 393.

Ointment for Burns.

Capitan prescribes the following ointment for burns: Salol, 5 Gm.; cocaine hydrochloride, 30 centigrammes, vaseline to make 50 Gm. Incidentally, the author recommends a moist compress with a quarter to a half per cent. solution of mercuric chloride, or 2 per cent. boric acid solution.—*Oest. Zeits. für Pharm.*, **53**, 473.

Antiseptic Sticking Plaster.

Koller prepares a plaster by mixing salicylic acid, 1, gum arabic, 45, water, 55, which is spread on paper, and, to prevent the mass separating from the paper, 2 to 3 of glycerin are mixed. The paper is fastened down to a board, and the solution painted on with a broad brush, and then dried.—*Oest. Zeits. für Pharm.*, **53**, 473.

Antiseptic Mouth Perles.

According to Von Rudlauer these may be prepared in the form of cachous, each containing 0·001 Gm. of thymol, menthol, eucalyptol, saccharin, and vanillin. They may be used in place of tooth or mouth washes and gargles, especially in case of children not old enough to use a gargle. For adults, 2 perles are allowed to completely dissolve in the mouth, the solution being swallowed.—*Pharm. Central.*

LETTERS TO THE EDITOR.

The Society's Local Secretaries.

Sir,—Now that the attention of the Council is being directed to this subject, may I be allowed to make a suggestion? It is unnecessary for me to recapitulate the qualifications for the appointment of local secretaries, as they are fully defined on the circular post-card sent to every member of the Society. There are many rural districts containing numbers of chemists where there are no local secretaries. Could not the Council appoint a local secretary for each Parliamentary district, so that every member may have a representative, and every M.P. be shadowed by one? The county of Herts has local secretaries in four towns only. Are there no other subscribers to the Society in the county? If there are others why should they be debarred representation, so to speak, because under existing conditions it is impossible for their respective localities to qualify? Probably at the present time the existing body of local secretaries represents a minority of the Society's supporters for this reason.

Tring, Herts, October 7, 1899. John W. T. Morrison.

A University Degree for Pharmacists.

Sir,—To prevent anyone being misled by the President's remarks about the B.Sc. examination (I presume he means London University) when moving the vote of thanks to Professor Leech, if they will turn, as the President might to have done, to the official regulations, they will find that there is no need to trouble their heads at all about zoology. For the Intermediate Scientific Examination, the candidates must pass in four out of the following six subjects:—1. Pure Mathematics; 2. Mechanics; 3. Experimental Physics; 4. Chemistry; 5. Botany; 6. Zoology. For the Final B.Sc. Examination, three subjects (or under certain conditions two) are necessary out of the following eight:—1. Pure Mathematics; 2. Mixed Mathematics; 3. Experimental Physics; 4. Chemistry; 5. Botany; 6. Zoology; 7. Animal Physiology; 8. Geology and Physical Geography. Thus it will be seen that there is plenty of scope for the candidate without the zoology.

October 6, 1899. Microcosm (2/37).

Ether-Soap.

Sir,—Being by no means ignorant of the connection with both hospitals of the surgeon to whom reference has been made by Mr. White, I was the more careful in my letter to dissociate myself from the slightest appearance of appropriating the formula, assuming that should it prove to have emanated from St. Thomas's, a courteous intimation to that effect, on the part of Mr. White, might reasonably be expected in due course. It may also be mentioned that the surgeon intended to lay no claim to the formula. Mr. White states what he thinks I ought to have done before writing my letter; had he acted upon his own advice he would not improbably have hesitated before lecturing me on professional ethics. Further, I would point out that the "formula for private use" having appeared in what Mr. White considers an improved form the previous week, and hence available for public use, I cannot be said to have published the formula at all. Turning now to the pharmacy of ether-soap, I adhere to my preference for the method there described (uncommunicated to me, be it noted, by Mr. White), notwithstanding the "sufficiently obvious advantages" of the other. On the question of deposit my point needs no defence, for if it be necessary

to make as much as five litres before the amount is easily observable, my contention that there is practically no deposit is justified. Then as regards the temperature of the mass during neutralisation I give the following particulars:—In one case 120 C.c. of acid was neutralised and the increase of temperature was 23° C. In another case 440 C.c. of acid was neutralised, when the increase was 22° C. The temperature was repeatedly ascertained at intervals during neutralisation. Your readers are now in a position to judge as to whether it is more accurate to describe the rise of temperature as "appreciable" or as "considerable," as Mr. White suggests. After all "ether-soap" is not a very wonderful preparation, for it is common knowledge that potassium hydroxide will neutralise oleic acid and that the soap thus formed is soluble in spirit and ether; nor is the idea of dissolving soap in a volatile liquid a novel one, for I prepared a solution of soap in spirit according to a formula derived from a German medical periodical some time before "the formula for private use" fell into my hands.

Evelina Hospital, October 9, 1899. F. A. Hocking.

Federation of Local Pharmaceutical Associations.

Sir,—I should feel obliged to any local secretary who received a circular from me on behalf of the Executive, and who has not yet replied to it, if he would kindly do so by the 21st inst.

James Cocks, *Hon. Secretary.*

Stonehouse, Devon, October 9, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Embrocation for Whooping Cough (A. A. M.—34/18).—Olive oil, 3 fl. oz.; rectified oil of amber, 1 fl. oz.; clove oil, 1 fl. oz. Mix. If so desired, it may be coloured red with a little alkanet root.

Gingerbread Wormcakes (J. P.—34/23).—Treacle, 7 oz.; moist sugar, 4 oz.; butter, 2 oz.; flour, 9½ oz.; calomel, 2½ oz.; powdered jalap, 5 oz.; powdered ginger, ½ oz.; powdered pimento, ¼ oz.; powdered coriander, ¼ oz. Mix the powders together, warm the treacle and the butter, then work it into the mixed powders until a uniform paste results. Divide into 30 grain cakes, and bake for about thirty minutes in a rather slow oven.

Preliminary Examination (L. R. D.—35/2).—The examination you refer to is not at present included in the list of those recognised by the Pharmaceutical Society's Boards of Examiners, and, if it were, the fact that Latin has not been taken as one of the subjects would prevent the certificate being accepted. See page 260 of the Students' Number of the *Pharmaceutical Journal*, also the first paragraph of the article at page 259.

Book on Lacquers (P. J. P.—34/31).—Probably the most useful book for your purpose would be the 'Painters', Gilders', and Varnishers' Companion.' The following are two recipes for brass lacquer which may be useful:—(1) Annatto, 1; turmeric, 4; saffron, 1; shellac, 10; methylated spirit, 64. Macerate for seven days, with frequent agitation; then filter. (2) Shellac, 16; gamboge, 1; wood spirit, 96. Dissolve without heat, decant the clear liquid; mix, when required for use, with eight times its volume of methylated spirit.

Acetanilide in Headache Powders (A. A. M.—34/17).—The formula you allude to is of American origin, and is supposed to represent a certain proprietary preparation. It is supposed that the caffeine tends to lessen the toxic effect of acetanilide. The objection to the latter body is that some individuals exhibit a very marked intolerance towards it; in such cases, a perfectly normal dose will give rise to unpleasant symptoms. In most cases a dose of five grains of the compound powder will have as good an affect as a larger quantity.

Glaze for Gum Sweets (W. M.—34/16).—Soak gelatin in cold water for an hour, then drain off the superfluous water. Put the softened gelatin in a covered pot; stand it on the water bath until it has melted, then stir in rectified spirit, 2, and bottle off for use in a wide mouth bottle. When required for glazing stand the bottle in warm water, and coat the articles by dipping them in the liquid. If required for immediate use and not for storing, omit the spirit and add to the above mucilage of acacia, 1, and freshly boiled water, 1 or *q. s.* to give the desired consistence.

Colours for Antiseptic Solutions (E. N.—34/30).—Methyl violet, malachite green, Nicholson's blue, indigo carmine, and iodeosine have all been recommended for colouring mercuric chloride solution. Phenol solutions may be tinted with fuchsine, eosine, or safranine. Boric acid solution with methyl orange. Silver nitrate solution with fluorescine. If a universal series for colouring antiseptic dressings and solutions were adopted, it would be very convenient and tend to safeguard against error. At present there is no uniformity in the use of colours for the purpose.

Extracting Honey from Comb and Preparing Beeswax (G. G.—34/33).—Honey is separated from the comb by means of a small centrifugal arrangement called an extractor. You can probably obtain this and all other appliances requisite for bee-keeping from James Lee and Son, 5, Holborn Place, W. Wax is obtained by melting the extracted comb in boiling water, allowing the water to cool, then removing the cake of wax which sets on the surface. It is then purified from suspended matter by melting it in a deep vessel and allowing it to stand melted for some time, when all the suspended matter will sink. The pure wax is then poured out into small earthen vessels previously wiped over with a wet cloth: when cold it will separate in cakes. If you employ "foundations" care should be taken that they are made entirely of pure beeswax, otherwise the whole product of the hive will be spoilt, so far as the wax is concerned.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Alcock, Allenby, Ayrton, Bartlett, Burroughs, Clarke, Cracknell, Davies, Elborne, Ferrall, Fresson, Giles, Gilmour, Godkin, Graham, Gregson, Harrison, Hebb, Hill, Hillyer. Kirkby, Krischke, Lasey, Leadbeater, McGonigal, Maiden, Marshall, Matthews, Michie, Nutt, Platt Prescott, Skerry, Waddell, Whineray.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

DETERMINATION OF VANILLIN IN VANILLA.

W. Busse (*Arb. Kaiserl. Ges.*) does not consider that the vanillin content of a sample of vanilla bears any marked relation to its value as a flavouring agent, the aroma of the pods not being due solely to the vanillin they contain. To determine the amount of that body, a known weight of the pods, crushed with sand, is extracted in a Soxhlet tube with ether, the ethereal extract is shaken out with sodium bisulphite solution; from the latter, the vanillin is liberated by treatment with H_2SO_4, the SO_2 generated removed by a current of CO_2, and the vanillin extracted by shaking out with ether, evaporating the solvent, and weighing the residue. In East African vanilla the author found 2·16 per cent. of vanillin, in that from Ceylon 1·48 per cent., and in Tahiti vanilla from 1·55 to 2·02 per cent. Tiemann and Haarman found in the best Bourbon vanilla 1·94 to 2·90 per cent., and in the best Java vanilla 2·75 per cent. The author attributes the cases of so-called vanilla poisoning to the decomposition of the other ingredients in vanilla-flavoured foods.—*Zeits. für Unters. der Nahr. und Genuss*, **6**, 519.

TESTING OIL OF BERGAMOT.

According to A. Soldani and E. Berté, during fractional distillation of bergamot oil the dextro-rotation of the oil becomes less and less until after half the oil is distilled, when it becomes negative. In bergamot oil adulterated with 2 per cent. turpentine, the dextro-rotation of the first fraction is less than that of a pure oil. In the second fraction the rotation is the same as that of a pure oil. The authors arrive at the following conclusions:—By distilling 15 or 20 C.c. of pure bergamot oil *in vacuo* under 20 M.m. pressure the optical rotation of the first fraction (one-third of the original oil) varies from + 35 to + 45, and a very slightly optically active residue (under + 1°) is obtained. If a bergamot oil contains lemon oil, and the optical rotation of the distillate is less than + 40 C., turpentine is also present. If from 15 C.c. of the pure oil 10 C.c. be distilled off, the residue will give a slight lævo-rotation, but with an oil adulterated with 5 or 2·5 per cent. lemon oil, or as much turpentine, the rotation will be to the right; the presence of lemon oil may be confirmed by Schiff's reaction. If the oil gives a fraction of higher rotation than + 45 the presence of lemon oil is established. In both the latter cases the optical rotation of the residue will be over + 2.—*Zeits. für Unters. der Nahr. und Genuss.*, **6**, 537.

SOME MEXICAN DRUGS.

Schinus Molle.—According to M. Duyk, the leaves, fruits, and gum resin of *Schinus molle* are used in Mexico as drugs. The two former yield, on distillation, a colourless volatile oil, having the sp.g. 0·852, which may be of use in the treatment of gonorrhœa. The gum resin is white and odourless, with a bitter, acrid taste. It melts at 40° C., and forms a persistent emulsion with water. The resin, freed from the accompanying gum, is yellow, at first semi-fluid, but soon becoming hard. It is soluble in alkalis. Toussaint has found that the gum resin, in emulsion in water, is toxic, in doses of 2 Gm., giving rise to gastro-enteritis, vomiting, frequent bloodstained evacuations, followed by a marked lowering of the temperature, and ultimately by death. In therapeutic doses, Orvagnanos finds that it acts as a powerful purgative, and modifies the respiration. He gives it in the form of pills containing 10 centigrammes. Capulincillo.—This drug derived from *Rhamnus humboldtianus*, which grows plentifully in many provinces of Mexico, is a violent poison, analogous to curare, producing paralysis. It has been employed, but with little success, in the treatment of hydrophobia and tetanus. The fruits of the tree contain a non-toxic, non-drying fixed oil, free from taste and odour. A considerable commerce is done with this in Mexico. Coztic patli.—This drug, the root of *Thalictrum hernandezii*, known to the Aztecs as Llamaron Coztic-patli, or yellow root, is employed as a diuretic. It contains, besides the yellow colouring matter, a peculiar alkaloid crystallising in prisms, and a greenish resin with an unpleasant odour. Cuajiote.—The gum resin from several Burseraceous trees is included under this name; the drug is employed by the natives as a remedy for scorpion bites. It occurs in the form of white or yellowish odourless, bitter, and acrid tears or irregular sticks. Given internally, it is a purgative, approaching gamboge in its action. Chilpauxochitl.—This is the odourless, acrid, woody, branched root of *Lobelia laxiflora* var. *angustifolia*; according to Morales, it contains the volatile alkaloid lobeline. The fresh juice causes reddening when applied to the skin.—*Bull. de Pharm. de Brux.*, **43**, 269.

QUINCE SEED OIL.

H. Thoms gives the following characters for the fixed oil of quince seed, which exists in the seeds to the extent of about 15 per cent. The oil from the fresh seeds was yellow, of an almond flavour, the specific gravity was 0·922, it gave the following constants:—Acid number, 31·7; Koettstorfer number, 181·75; iodine absorption (Hubl) number, 113; Reichert-Meissl number, 0·508; Hehner number, 95·2. It contained a fluid unsaturated acid, with an OH group, as represented by the formula $C_{17}H_{32}(OH)COOH$, which was a clear yellow oil, with a feeble taste, and a specific gravity of 0·893. The ethyl ester of this acid $C_{17}H_{32}(OH)COO{\cdot}C_2H_5$ was a colourless mobile liquid of specific gravity 0·886. The oil contained at least two saturated fatty acids, one of which was identical with myristic acid; these acids were present as glycerides.—*Archiv*, **237**, 358.

CINNAMEIN.

According to the researches of H. Thoms, cinnamein consists of benzoic and cinnamic esters of benzyl alcohol and a hitherto unknown alcohol possessing a sweet odour and taste, having the formula $C_{13}H_{22}O$, to which the author gives the name Peruviol. This body was probably the so-called cinnamyl alcohol isolated by Delafontaine, which the author failed to detect in Peruvian balsam, neither could he obtain any iso- or allo-cinnamic acids, but in all the samples examined vanillin was found. Further, he separated an acid having the m.p. 79°-80° C., which is a dihydrobenzoic acid. The ratio of cinnamic to benzoic acid in eight samples of balsam was as 40 to 60.—*Chem. Zeit.*, **24**, 236.

SURINAM COPAIBA.

According to Pool, *Copaifera guianensis* and other copaibas yield a clear yellow, not opalescent balsam, having the consistence of olive oil, known in commerce as Surinam copaiba. The balsam has a sp. g. at 15° C. of 0·942, and is miscible with petroleum ether, ether, chloroform, and carbon disulphide in all proportions, and with absolute alcohol in 4 or 5 parts. Its saponification number = 34. One Gm. of the balsam combines with 94 Mgs. of iodine. The balsam yields 78 per cent. of a colourless volatile oil, having a sp. g. 0·910, boiling at 250°-260° C.; after the distillation of the oil a hard residue remains, from which copaibic acid is obtained by treatment with dilute alcohol, forming crystals which melt at 130° C. It is distinguished from similar thick fluid copaiba balsams by its solubility in petroleum ether. A carbon disulphide solution of the original balsam gives, with a mixture of equal parts sulphuric and nitric acids, a brown-red, not a violet colour. It affords a clear solution with one-third of its volume of ammonia. Bromine in 20 parts of chloroform, gives with the balsam a fine violet colour; lead acetate does not throw down a precipitate. The volatile oil gives with the above bromine chloroform mixture a bright red colour, with concentrated sulphuric acid, a brown, and with chloral hydrate, on warming, a green colour; it does not react with iodine, but evolves heat with chromic acid.—*Pharm. Central.*, **40**, 503.

THE FEDERATION OF LOCAL ASSOCIATIONS AND THE PHARMACEUTICAL SOCIETY.*

BY JOHN SMITH,
Local Secretary for Liverpool.

In the month of October members of the Pharmaceutical Society are requested by the Secretary to nominate persons who will repre ent the Society and undertake certain duties as local secretaries, and I think the present is an appropriate occasion, before the nominations are sent in, upon which to discuss the relationship of the Council to the constituents, and the general question of efficiency or inefficiency of the existing system of local representation of the Society. Whilst on this subject I will endeavour to locate such weakne ses as may exist, and consider if there are any means available which might in some measure, at any rate, supply the remedy.

The Pharmaceutical Society, by reason of its constitution, ought to be one of the finest specimens of effective organisation in existence. I need not take up time by referring to its origin and history. Its functions are administrative and educational. In endeavouring to fulfil the duties imposed upon it by the Pharmacy Act, 1868, the Council has, on the whole, I think, exercised wise discrimination, and there are not many who would deny it appreciative recognition for its efforts in the direction of advancement of knowledge. Successive members of the Council, of great ability and insight into the future, have done what men can to promote and encourage technical knowledge and research, and by raising a more highly-trained body of men in our calling, have done much to raise the status of the registered chemist. While recognising what has been done by our leaders, it is fair to aportion a proper share of the credit for the advancement of knowledge in subjects pertaining to pharmacy to the members of such associations as this. The work accomplished by the Pharmaceutical Society, through its members, should give it an influence and weight that an organisation of a mere trading body could not attain. Another great advantage the Society has is that it is

A Democratic Body.

In practice it is not as much so as it might be, but that is not the fault of its constitution. It is open to every person on the Register, whatever his views may be, to take an active part in the work of the Society, to expound and promulgate those views with all his might and energy and to occupy a seat on the Council if his brethren choose to place him there. The Council consists almost entirely of men who are engaged in retail pharmacy and having the same interests at stake as the rest of us. We have an exceptionally capable Secretary and staff at Bloomsbury Square and an ably conducted Journal which, besides recording the transactions of the Society, provides us with much useful information of a business as well as a technical character and enables us to keep abreast of modern pharmacy.

Notwithstanding the elements of success I have enumerated, can it be said that the Pharmaceutical Society is in the position it should be, or that it is truly representative? Not only is it a fact that the Society numbers among its supporters only a minority of registered chemists; but it must be admitted that many, even of those, are lacking in interest in the doings of the Society, and are imperfectly acquainted with the efforts made on their behalf. It is no part of my duty to claim perfection on the part of Bloomsbury Square; but I do not find that any notable shortcomings are placed to the debit of the Council and officials. I am speaking now of present and recent circumstances; it would be unprofitable to excite contention over real or supposed errors of twenty years ago. We are bound, then, to see how we stand as regards provincial local organisation. Here lies our weakness. Once a year members are requested to nominate a person for the position of local secretary in respective districts. I have no actual knowledge, but I am strongly of opinion that not more than seven to ten per cent. of those nomination cards are filled in and returned. In most cases it is a mere matter of form—the same person is appointed year after year until he wishes to retire. Towards the close of each year of office the local secretary receives a communication, suggesting that he should call a meeting of the chemists in his district to consult as to the most suitable person to be recommended for the office. Does anyone suppose there is sufficient interest in the matter to bring a meeting? Men would not leave their business to discuss this question only. If I am right in concluding that there is a serious

Defect in Local Pharmaceutical Organisation,

due partly to the impression in many minds that the local secretary is the representative of the Council of the Society, rather than the nominee of the chemists in the district, we must endeavour to find the remedy. Following the suggestions of the Council in large towns, there could be no more fitting occasion for the consideration of the nomination of a local secretary than a meeting of the local Association. If notices of the meeting were sent to every registered chemist in the district and only supporters of the Society permitted to vote, the nomination of the chairman on behalf of the meeting should be valid. The Council would naturally recognise the importance of such a nomination and would, no doubt, be more than satisfied in appointing the person named, especially as this would exactly carry out their wishes in having a person nominated by a representative meeting of chemists in the respective districts. The local secretary then would, actually and truly, represent his neighbouring chemists and while he would be the appointed officer of the Society he would also be the chosen of his district. It should be within the power of his fellow chemists then to question him at any general meeting respecting the duties of his office and his fulfilment of them, while he would have an advantage to which I attach great importance—that is, the opportunity of conferring with others and would be encouraged by the knowledge that others in his district took some interest in his official duties.

I do not suggest that this system of nomination could be generally adopted this year, especially as nominations must be in by October 20, and it may be desirable also that we should first have a pronouncement from the Council that a nomination in this form would receive the consideration its importance deserves. The Council could not pledge itself, under all unforeseen circumstances that may arise, to appoint a person so nominated; but a general acquiescence in the principle and an assurance that the nominations from local Associations would be accepted, would be satisfactory. The Federation could render invaluable aid in this matter and it would gladly co-operate with the Council in endeavouring to secure a larger number of energetic local secretaries. Let the Council now, or at any other time, consist of the picked men of the country and organisation at headquarters in London and Edinburgh will be as perfect as human ingenuity can make it. Its state is only rudimentary so long as organisation outside these centres is in the chaotic condition it now is. I dwell on this point. To speak of

The Necessity for Organisation

is to utter a commonplace, but it is one of those commonplaces which, because it is so obvious that it needs no demonstration, is liable to be pushed on one side.

If the Federation cannot do something to bind together, in a common interest, the many local Associations spread over all parts of Great Britain and enable them to work together to protect the rights and further the interests of their individual members, there is no reason for its existence. That is a proposition that will not be contested. Further, as every registered chemist may have power to vote in the election of members of Council and the election is by majority, the Council must be regarded as the representative body of the chemists of Great Britain and it is through them we must be heard. It follows, then, that one of the main objects of the Federation's existence is to

* Read at a meeting of the Liverpool Chemists' Association, October 12, 1899.

Strengthen and Assist the Pharmaceutical Society to the utmost of its power. It is not necessary that the Federation should hand itself over bound hand and foot; it is an essential part of its existence that it should have an independent position. As individuals have diverse opinions, so will Associations; but the Council being an elected body, the electorate consisting of men who are members of the local Associations, the possibility of friction between the Council and these Associations through this Federation may be disregarded. I repeat that it is the function of the Federation, as it is of the Society, to promote the interests of registered chemists: that can only be done effectively by conjoint action. There is no room for two organisations working for the same ends and representing the same persons, unless one is supplementary to the other. If it were otherwise we should find ourselves split up by internal dissensions when unity is most urgently needed. The Federation can be useful in many ways. It is necessary, for instance, to take some action in a Parliamentary election in a distant borough or other division and the assistance of persons familiar with the aspect of pharmaceutical affairs is desired, the Federation through some of its members will supply this assistance. Action in conjunction with such a body would be more weighty than that of a few individuals in the constituency.

Again, we have knowledge of serious divergence of opinion between associations of chemists in different parts on the question of the direction that coming amendments of pharmacy law should take. Without some action being taken by the Federation I do not see how these differences are to be adjusted. There is no other organisation available as a medium of communication between the different associations and until something better is forthcoming, I claim for the Federation that it should receive the earnest support of every local Association or local committee of chemists in Great Britain. I openly appeal also to the Council of the Pharmaceutical Society to make use of the local knowledge we possess and then accept the co-operation we tender in the spirit in which it is offered. As a local secretary of some experience, having no small acquaintance amongst others in the same position, I state my conviction that those officers of the Society are hampered and discouraged by lack of interest, on the part of those amongst whom they work and by the want of proper local support. The President said last week that some of the local secretaries could do with a little more zeal and we hear a good deal about the apathy of chemists; but it is not apathy, only another word for

Imperfect Organisation.

As one who occupies a responsible position in connection with the Federation of Local Associations, I state my belief that we can do something towards bringing the local Associations into something like affiliation with the Pharmaceutical Society and creating interest in the Society and its local representation, by the simple method of the Association nominating the local secretaries and those officers, when appointed, representing their Associations on the Federation. The Federation consists of men whose desire it is to serve the interests of registered chemists and I know none more loyal to the Society that these. Differences of opinion there must be, as long as individuality exists in human nature, but I am certain that whims and hobbies will not occupy too prominent a place.

To briefly summarise, I submit that the success of the Pharmaceutical Society is largely dependent upon local organisation; that local organisation in connection with the Society should be the business of a local Association and not alone that of a single individual appointed from London; that these local Associations should be banded together in one Federation, their representatives being principally men who are also officers of the Society and having at hand the assistance of their Associations and of the machinery of the Federation, provide an infinitely better agency than where the duties rest with isolated individuals. It is possible that the views I have expressed may not be accepted in their entirety by all connected with the Federation; it is also likely that modification and alterations, here and there, might be made with advantage; but, as far as my vision extends, there seems to be a real need for a closer co-operation between local Associations and the Pharmaceutical Society.

In conclusion, I may point out that there has been a lull in pharmaceutical politics in the last two months. The Lord Chancellor's last famous statement was made in the last few days of an expiring Parliamentary session; I believe it was the same day as the August meeting of the Pharmaceutical Council. As the Council does not meet in September, we could not have its views on the matter; but we learn that, at the October meeting, it was resolved to frame a clause for the purpose of getting it inserted, if possible, in the Companies Bill when it is again brought forward. Chemists all over the country, through their associations, have unmistakably stated their wishes and what they believe to be their just claims. The Council has also been made acquainted with those. The Council, also, in the early part of the year formulated or adopted

The Well-known Draft Suggestions.

Many of us believe that in that instance too much was asked for, and would willingly abate our demands to a more reasonable limit; but there does seem to be something underlying those suggestions which may form the basis of a policy. I realise that this is a difficult and thorny question and I have no wish to add to the difficulty. My reason for speaking of the matter is to say that whatever the solution presented by the Council, there will be work for the Federation. In order to be prepared for that, in the last two months of apparent inertia, a very important step has been taken towards organising districts which are at present unorganised. I have received from the honorary secretary of the Federation a communication and particulars respecting replies and letters received in answer to a Federation circular to local secretaries. We have here not evidence only, but, to use the secretary's words, proof of "a great amount of latent enthusiasm in the country" and a justification of the policy we have adopted. The object that the Federation has in hand at this moment is to provide available means for utilising this enthusiasm and ability in the interests of all. If that can be accomplished—a new hope on a fairly extensive scale—it will be an important step forward.

THE ASSAY OF SYRUPUS FERRI IODIDI.

BY F. H. ALCOCK.

It is not possible to precipitate the whole of the iron in this preparation as ferrous carbonate, because of the presence of the large amount of sugar. It may be possible to so add sodium carbonate that little or even no precipitation of the iron salt would take place, this being dependent upon the degree of concentration of the syrup and solution of sodium carbonate.

By proceeding as follows the operator will find that the amount of iron compound in the filtrate will be reduced to a minimum:—Into a graduated 100 C.c. stoppered cylinder 80 C.c. of distilled water are put, and in this the gramme of pure dried sodium carbonate is dissolved, and the volume made up to 90 C.c. with the water; then the syrup is added to the 100 C.c. mark, the whole vigorously shaken and the official quantity, or more, if thought desirable, filtered at once through a dry English filter paper, the texture of which appears to be suitably adapted for iron precipitates. By this plan it becomes an easy matter to filter in a very short time as much as 85 C.c. of clear liquid out of the whole quantity of liquid originally present.

For the purposes of neutralisation very dilute nitric acid should be used, or, better still, diluted acetic acid, and the titration conducted in the usual way, using white dishes in place of glass flasks. It is a good plan to limit the quantity of potassium chromate used, for an undue excess may greatly affect the result. By following the above modifications concordant results were obtained by half-a-dozen different operators. The official expression "for complete precipitation of the iodine" does not rightly express the reaction, but as this is only a "minor" trouble, a reference to it, in passing, may sufficiently satisfy the hypercritical.

THE POSITION AND PRIVILEGES OF PHARMACY AND THE PHARMACIST.*

BY J. RUTHERFORD HILL.

If we search the earliest literature of the Israelites and of the pagan races and inquire into the condition of primitive communities in ancient or modern times, we find that pharmacy is an attribute of the priesthood. The priest combines the three functions of religious teacher, medical practitioner and pharmacist. But the progress of civilisation and the evolution of society gradually lead to differentiation and specialisation which result in separation of functions originally inherent in one individual. In this way the priest gives up his medical and pharmaceutical functions and we next find these embodied in the medical practitioner. The process still continues, and in course of time the medical practitioner drops his pharmaceutical function and pharmacy emerges as a distinct profession in the person of the pharmacist. The process is always a gradual one, attended by the struggle and effort, and conflict which seem inevitable in the progress of humanity towards a higher ideal. The process is well illustrated in the history of our own country by the contendings which marked the early years of the present century before pharmacy, as a separate and independent profession, could be said to have come to birth in Great Britain, when the Pharmaceutical Society was formed in 1842. The legislative title of pharmacy to separate existence and independence is embodied in the Royal Charter of Incorporation granted in 1843. The Pharmacy Acts of 1852, 1868, and 1898 mark other important stages in the evolutionary process. The systems of examination and registration involving special education set up under these statutes have resulted in a more or less clearly defined and perfectly distinct professional function, which we call pharmacy.

The Privileges of Pharmacy?

What are the privileges of pharmacy? Some pessimists will say it has none. With that I do not in the least agree. In the Royal Charter and Pharmacy Acts the profession of pharmacy possesses the fundamental and highly important privilege of recognition by the State. This State recognition of the separate and independent position of the profession of pharmacy is the greatest and most valuable achievement of the wise and far-seeing men who led the pharmacists in the early years of this century. Flowing from State recognition pharmacy has the privilege of State protection. This is a necessary consequence of State recognition. Only those qualified to discharge the special function of the pharmacist are to be allowed to call themselves by a name which certifies their fitness. Some say this State protection does not exist. I do not believe that. It is real and effective but by no means perfect. There can be no State protection of prices, but there ought to be the most perfect possible protection of the practice of pharmacy in the interest of public welfare and safety. In this direction there is room for improvement and at the least there should be the absolute prohibition of the use of any word implying personal fitness by any individual not duly certified or by any association of such persons—for, in the nature of things, no association can possess personal fitness.

Another privilege consequent on State recognition is that of State endowment. Some may ask what State endowment pharmacy enjoys. A study of the Charter and Pharmacy Acts will show that the examination fees are a State endowment. The fees are a compulsory tax imposed, not by the Pharmaceutical Society, but by the State. It is only in virtue of and in pursuance of regulations imposed by Statute that the Pharmaceutical Society is permitted to receive fees. And it is quite a mistake to suppose that these fees are merely intended to cover the cost of examination and registration. The Charter makes it perfectly clear that the State empowers the Society to apply these fees in the promotion of the objects of the Society, that is, to the advancement of pharmacy. The same may be said of the penalties recovered under the Pharmacy Acts. Both fees and penalties are strictly public funds which the State assigns for the endowment of pharmacy.

It is the privilege of pharmacy also to be recognised as a referee in the construction of the national Pharmacopœia. This recognition is not yet placed on a perfectly satisfactory basis, but things are moving in the right direction, and the position already attained makes the ultimate full recognition a practical certainty. It is the privilege also of pharmacy to be consulted by the Imperial Government in poison or pharmacy regulations affecting various parts of the Empire. We had an example of that the other day in the case of the Pharmacy Ordinance for Gibraltar. So much for the position and privileges of pharmacy.

What is a Pharmacist?

We now turn to to the individual pharmacist. What is a pharmacist? Here I shall probably be challenged for the use of the title as a term applicable to every qualified chemist and druggist. In using the word in that sense I know I have the letter of the law at least against me. There is a very curious anomaly in the 1868 Pharmacy Act in this connection, clause 1 of the Act gives every registered chemist and druggist permission to use the title "pharmacist." Curiously enough, clause 16, which is merely meant to provide penalties for infringements of clause 1, takes away this permission and restricts the use of the title to those who have passed the Major Examination. Seeing that clause 1 is the enacting clause, and clause 16 only the penal clause of the Act, it is difficult to avoid the conclusion that the original intention of the Act was to confer the title "pharmacist" on every registered person. Whatever may be the law, in common language the title is now constantly and universally applied to all qualified practitioners of pharmacy, and it is in that broad sense that I use it here.

The pharmacist has been aptly described as "ye physician's cook." His function is subordinate to that of the physician, and his duty is to carry out with absolute fidelity the instructions of the prescriber. This is a position of very great responsibility and honour, and recent advances in medical science have greatly added to its importance and difficulty. The pharmacist is more and more called upon to show the prescriber how the appropriate remedies may best be turned to account in the treatment of disease. But he is also a most important check on the work of the prescriber All of us, I daresay, are familiar with instances in which the dire consequences of a prescriber's slip have been averted by the care and intelligence of the dispenser. In my judgment, this function of the dispenser is one of so much consequence to the public safety that, except in very exceptional circumstances, no prescriber should be permitted to dispense his own medicines, but that in all cases safety should be assured by the intervention of an independent and responsible dispenser, fully qualified for such a position. Some recent examples emphasise the importance of this.

The Pharmacist a Professional Man.

The pharmacist is also, I think, justly entitled to call himself a professional man in the same sense as a clergyman, a lawyer, a medical man, or a dentist. If we had a compulsory curriculum of study this position would be made clearer, though not actually perhaps more real. As a matter of practice, a curriculum is now universal, and the special training and education which a pharmacist must possess fairly entitle him to rank as a member o a learned profession. Moreover his duties as a pharmacist are purely professional, and pharmacy itself, as now evolved, is distinctly and unmistakably a learned profession. Pharmacy is in no sense a trade. We confuse things that should be separated when we say it is. The confusion arises from the fact that in almost all cases the

* Address delivered at a meeting of the Glasgow Chemists' and Druggists' Assistants' and Apprentices' Association, on Friday, October 13, 1899.

pharmacist is more than a pharmacist. He is a trader or commercial man as well as a pharmacist. We would not call the pharmacist in a large hospital or infirmary a trader, and yet he is in every sense of the word a pharmacist. But it remains true that most pharmacists are engaged in trade, and that is a condition which will probably continue for a long time to come.

This is an aspect of the pharmacist's position which receives too little attention. The tendency of a professional curriculum is to draw away the attention from the importance and necessity for a thorough equipment in the theory and practice of commercial enterprise. There is even a tendency in some quarters to despise and regard as unworthy and dishonourable everything that savours of commerce. My observation leads me to say emphatically that I believe a great many of the evils at present acting prejudicially towards the position and prospects of the pharmacist are due to a prevalent and undesirable neglect of the study of commercial principles and methods. Napoleon spoke in scorn of the "Nation of Shopkeepers," but it is our pre-eminence as traders more than anything else that has raised us to the front rank among the nations of the world. I would, therefore, say: To your professional equipment be sure to add a thorough grasp of the principles of commerce, for both conduce to the highest success of the pharmacist.

When I think of the position of the pharmacist I am impressed by the wideness of the field that is open to him, and the many directions in which his special training and knowledge give him distinct advantages over his fellows.

Trades Allied to Pharmacy.

In every community there is a large and constant demand for the class of goods generally designated as drysaltery. Many of those engaged in supplying this demand are ignorant, untrained, and badly equipped for such work. The pharmacist, on the other hand, is peculiarly fitted to do such work with intelligence, efficiency, and success. Many, to my knowledge, do a large and lucrative trade without in the smallest degree interfering with their higher duties as professional pharmacists.

There is also, in our time, a very widespread and constant demand for chemicals for scientific and technical purposes. Many pharmacists are fully alive to this sphere of activity, and take effective advantage of the special facility which their chemical knowledge gives them in meeting such demands, and again without, in the slightest degree, interfering with their distinctly professional work as pharmacists.

There is another public need so closely allied to pharmacy proper, that it seems almost naturally to fall within the sphere of the pharmacist. I refer to the supply of spectacles and other instruments usually included in the optician's art. The pharmacist necessarily acquires a knowledge of physics in studying for his qualification, and this knowledge gives him a distinct advantage in meeting the public demand for spectacles, etc. The sphere of the pharmacist and the optician are so close, that several instances of opticians dispensing prescriptions for eye drops as well as spectacles have come under my notice, and this is a practice which ought not to be allowed. It seems not unnatural that when a physician writes a prescription for an instrumental as well as a medical remedy for disease, the whole prescription should be dispensed by the pharmacist. I observe that many pharmacists have recently passed the qualifying examination of the Worshipful Company of Spectacle Makers, and I do not hesitate to say that it is well to do so, and previous study for the Minor makes it comparatively easy, and this line of business may be appropriately and successfully worked alongside a high-class pharmaceutical practice.

There is also another class of trade that is often most successfully cultivated by the professional pharmacist, and in which his pharmaceutical education and training give him a distinct advantage. I refer to the trade in photographic and scientific apparatus. I see no reason in the world why a very large and preponderating amount of the large volume of trade, represented by the varied public wants above referred to, should not pass through the hands of the pharmacist. I do not suggest that everyone should cultivate all these departments, but I do say it is well to have them in view, and cultivate those which circumstances and opportunities may indicate as likely to be successful.

The Pharmacist a Man of Science.

It seems to me that the pharmacist is also entitled to rank himself as a man of science. It may be that the elementary knowledge required to pass the Minor Examination is hardly sufficient to justify any great claim to such a position. But he has, at least, got a foothold, which makes it very easy for him to push forward to a knowledge that will command general respect. This he may do either on the side of botany and biology, or on that of chemistry and physics. By his training and education, the pharmacist is peculiarly fitted to occupy such a position.

Our educational status is now, or will shortly be, such that the pharmacist, like the schoolmaster, the clergyman, and the doctor, will be singled out as an educated man in any community in which his lot may be cast. This is no small honour, and gives the pharmacist many opportunities for honourably discharging many public duties and, thus, earning the esteem and respect of his fellow men. This condition is largely due to the steady and determined efforts made in recent years by the Pharmaceutical Society to raise the educational and professional status of the pharmacist. To the young pharmacist, who may yet have to face the examination ordeal, this effort may seem harsh and uncalled for. But its importance and abiding value are indisputable. It has done more than anything else to establish and protect the position of the pharmacist. This result is largely due to the courage and determination of Mr. Michael Carteighe, and it is not the least of the many services he has so conspicuously rendered to the cause of pharmaceutical progress.

Has the Pharmacist Any Privileges?

Having said so much as to the position of the pharmacist we may now ask, has he any privileges? Again, the pessimist will say he has none. But I am not a pessimist, and entertain no gloomy view as to the future of pharmacy. If we are wise, courageous, and united, things will go all right. The pharmacist possesses the statutory right to the exclusive use of certain professional titles. I know that for the moment the arrangement known as "company pharmacy" appears to infringe this monopoly. But the privilege is so obviously reasonable, and so much in the public interest, that I have little doubt we shall get the existing partial defect suitably amended. The pharmacist has also the exclusive right to sell poisons. This right is not infringed, and I do not think it can be in any way whatever without punishable breach of law. If the pharmacist is a wise man, and takes a sensible view of his position, he will associate himself with his fellows in what is the only State recognised Association of Pharmacists. By doing so he acquires the privilege of regulating the conditions under which poisonous substances are to be stored, dispensed, and sold. He also shares the privilege of determining what substances should be scheduled for exclusive sale by pharmacists. He also has the privilege of determining the conditions under which persons are to be admitted to the right of practising pharmacy. It is well to remember that it is neither the Board of Examiners nor the Council who impose the regulations for examinations. They have no power at all apart from the body of Associated Pharmacists. In England the pharmacist has the privilege of exemption from jury service if he passes the Major Examination. Perhaps in time a more just arrangement may be reached, by which all pharmacists will be placed on an equality in that matter.

The pharmacist has, in a limited and imperfect way, the privilege of dispensing medicines. This is attempted to be secured in

the Pharmacy Act, 1868, by a restriction of the title chemist and druggist. It works fairly well in bringing the public to the pharmacist to have prescriptions dispensed. But it is entirely inadequate, and we should never cease to urge that the spirit and policy of the 1868 Act should be extended by a specific enactment limiting the dispensing of prescriptions to registered chemists. There is another privilege of the pharmacist which I sincerely trust no one of this audience will ever require to exercise. I mean the right to participate in the Benevolent Fund of the Pharmaceutical Society. That is a most important and valuable fund, and I have known instances of pharmacists who had known better times receiving timely and most grateful relief in dark and difficult days. But I trust it will be your privilege to be a contributor and not a beneficiary.

So much then for the position and privileges of the pharmacist. I have by no means covered the whole ground. What I have said may furnish food for thought.

How Position and Privileges are Threatened.

There are two directions in which the position and privileges of the pharmacist are threatened. The abortive Poisonous Substances Bill of the Government last year is one. That Bill was constructed in absolute disregard of what has been the fundamental principle of poison legislation in this country ever since 1868. That principle had to be strenuously fought for, and it is not going to be lightly given up. The principle is that the education and training of the seller is the only safe basis for a Poison Bill. It is to be hoped that has been made so clear to the permanent officials that no Bill will ever again be introduced on such retrograde lines. The other direction in which there is danger is that of so-called "company pharmacy." Here, also, we may hope that matters are beginning to clear up. All must have noticed that the Council of the Society is determined to grapple manfully with the situation, and I doubt not that some satisfactory solution will ultimately be arrived at. But all these matters will require intelligent and active interest on the part of all pharmacists. We must consolidate and close our ranks, and stand shoulder to shoulder in any action that may be necessary. It is nothing short of folly to do otherwise. But let me close with one word of warning. While giving all due attention to the matters I have referred to, I would earnestly say, do not spend too much time or look too constantly in the direction of any possible legislative enactments. These, experience tells us, are too often mere "will-o'-the-wisps," on which much time and energy may be fruitlessly wasted. Some men think success depends on smartness, others place confidence in push, while some try the hazard of roguery; but the wisdom and experience of all the ages go to show that all real success is founded on morality, and that it is character alone which ultimately wins the prize. This is true of every calling. It is pre-eminently true of the profession of pharmacy. The best protection lies in steady, high-class professional work and invincible integrity. The pharmacist who thus gains the confidence of the community he serves will have established an impregnable position in which no "store" can touch him. I say this deliberately, because I have seen many proofs of its absolute truth, and it is just here that I believe security and success will be most certainly found.

A Compound for Preserving the Teeth.—A useful body for preserving the teeth is obtained by the combination of tannin and chloral hydrate in the presence of strong acids. To a hot watery solution of tannin, sulphuric acid is added until the tannin is thrown out, then a concentrated solution of chloral hydrate, which will combine to form a pasty mass. The precipitate is washed and dried; it forms a greyish brown amorphous powder which is soluble in hot water, but separates out as a fine precipitate on cooling. The solution gives an olive green reaction with ferric chloride solution. The product is the subject of a patent.—*Oest. Zeits. für Pharm.*, **53**, 429.

THE COMPANY PHARMACY PROBLEM.

BY AN ORDINARY PHARMACIST.

At the present time registered chemists are being favoured with innumerable interpretations of, and comments upon, the Pharmacy Acts, but the one solid fact which presents itself to the unprejudiced observer is that, whilst the undoubted intention of those who framed the Acts was to restrict the ownership of pharmacies to duly registered individuals or natural persons, unregistered persons without due qualification have been enabled to filch a large proportion of the business of chemists and druggists by taking advantage of the facilities afforded by the Companies Acts. For some time past a difficult problem has presented itself for solution to those who would end this anomaly, but, so far, little has been done in the matter beyond recognising that the anomaly exists.

The Intentions of the Acts.

The intentions of those who framed the Pharmacy Acts have been quoted again and again, until most of us are tired of hearing about them and, after all, no one has been able to say anything better in that respect than is clearly stated in the preambles of the Acts themselves. Thus, the preamble to the Pharmacy Act, 1852, commences with the statement that it is expedient for the safety of the public that persons exercising the business or calling of pharmaceutical chemists should possess a competent practical knowledge of chemistry and other branches of useful knowledge, and be duly registered; the preamble of the Pharmacy Act, 1868, opens in like manner with the statement that it is expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons, and persons known as chemists and druggists, should possess a competent practical knowledge of their business and also be duly registered. Those statements cannot be interpreted as implying anything short of the due qualification and registration of all proprietors of pharmacies, and the fact that subsequent legal interpretations of the provisions of the two Acts have left matters in a very different position simply proves that those who framed the Acts and those who added them to the Statute-book were alike lacking in ability to perceive what loopholes they were leaving for evasions.

Public Interests Insufficiently Safeguarded.

Whilst insisting, therefore, that it was orginally recognised by the Legislature that all proprietors of pharmacies ought to be duly qualified and registered, we are compelled by the stress of circumstances to acknowledge that the interests of the public were not sufficiently safeguarded when the Pharmacy Acts were passed. For what do we find? Any individual who has been proceeded against and fined for infringement of the provisions of the Acts may avoid further penalties, whilst continuing his illegal practices, by resorting to the simple expedient of associating with himself six other unqualified persons, and securing registration under the Companies Acts. He is not even obliged to engage duly qualified persons to conduct the transactions which the law prohibits any unregistered individual from carrying out; the penalty for not conforming with the requirements of the Acts cannot be enforced against him and his associates, but only against the unqualified servants actually engaged in the illegal transactions.

How the Public Safety may be Assured.

The problem that presents itself, therefore, is how the safety of the public may be insured by fulfilling the intention of the framers and makers of the Pharmacy Acts. What is obviously necessary is to insist upon the proprietary qualification which was thought to have been rendered necessary so long ago, and the fact that such a result may tend to the benefit of registered chemists affords no sufficient reason for shirking the issue. For more than half a century dispensers and sellers of poisons have done their utmost to fit themselves in an especial degree for the important duties which devolve upon them, and for

more than thirty years they have been legally compelled so to do. Why, therefore, should there be anything anomalous in their request that the functions for which they have especially adapted themselves—at great personal inconvenience and expense—in the public interest should be restricted to them? The word "monopoly" is freely used in this connection by opponents of the registered chemist's claim, but why should not he—a legally qualified person—have the same privilege of practising his calling as lawyers, medical men, and dentists? As matters stand, we are told that not even his title is secure—can anything more monstrous be conceived? Here we have an individual who has devoted the best years of his life to the acquirement of a proper knowledge of his business, supplemented by fulfilment of onerous legal obligations, and yet the title which it has cost him so much in time, labour, and money to procure may be freely assumed and used by any association of seven ignoramuses who may choose to register themselves as a joint-stock company.

All Compromise to be Avoided.

To such an extent has the evil grown that we find some persons in our own ranks who would compound with the devil and recognise the right of such companies to carry on the business of chemists and druggists, and also to usurp our titles. Others, again, would prevent companies using the titles, but would register and regulate associations of unqualified persons in the same manner as legally qualified persons now are. But what a deplorable frame of mind is indicated in either case—what a strange aberration from true free-trade principles and sound logical deductions! It is whispered that some of our representatives on the Council of the Pharmaceutical Society incline to those heterodox views; but, if it be so, such views are none the less fallacious, and to press them would be neither more nor less than betrayal of the interests of registered chemists and of the public at large. It is not clear from the report of the last Council meeting whether any—and if so, which—members are inclined to throw up the sponge and leave the field in undisputed possession of the enemy. It would hardly be a creditable thing to do—despite the premature jubilations of the conductors of trade journals, whose chief desire seems always to have been the extinction of the professional element in pharmacy—but I hope to find ere long that the confidence reposed by the members of the Pharmaceutical Society in their elected representatives is thoroughly justified. The Council, of course, has a free hand for the time being: but in the event of the promised clause for the next Companies Bill indicating any intention of recognising companies of unqualified persons, which carry on business as chemists and druggists, the ill effect of such action would probably be very marked before the end of May next.

The Companies Bill Not a Pharmacy Bill.

It must be recognised that the task before the Council is one of extreme gravity and difficulty; but even if the hope of fulfilling the intention of the Pharmacy Acts were of the very faintest, it would be better to fight to the bitter end and lose, than to acknowledge defeat before a blow has been struck. The task may be simplified by deciding to attempt as little as possible in connection with the Companies Bill, and reserving further efforts for the promotion of another Pharmacy Bill. For instance, it may be found expedient to seek only to defend our titles in the Companies Bill, though, in the event of success crowning such an effort, there are many in our ranks who would not hesitate to assert that, if more had been attempted, the result would have been even more satisfactory. But we must not lose sight of the fact that a Companies Bill is not a measure to regulate the practice of any particular profession or trade; all details affecting pharmacy should be embodied in a Pharmacy Bill. Personally, I am disposed to deprecate undue modesty, as it is a matter of common knowledge that, in parliamentary affairs, what is secured is, more often than not, less than was asked for. We should, at least, have no hesitation in claiming all that the Pharmacy Acts were intended to secure to duly qualified persons.

Companies should not be Recognised.

In any case, however, I most strongly protest against any proposal being advanced on our part to register and regulate drug-stores owned by companies of unqualified persons. Such a proposal would be extremely repugnant to a large and influential section of our body, and that idea cannot be too forcibly condemned or too persistently opposed. To recognise companies in any degree would be equivalent to giving away our case entirely, and the whole edifice so carefully raised on an educational basis during the past fifty years would tumble about our ears like a house of cards. We must insist just as strenuously upon the absolute restriction of all pharmaceutical titles to duly qualified persons, and I would humour the Lord Chancellor—in his desire to place companies upon a similar footing to natural persons—to the extent indicated in the following suggested clause for the Companies Bill:—

Suggested Clause for the Companies Bill.

"It shall be unlawful for any company to assume or use the title of pharmaceutical chemist, or pharmaceutist, or pharmacist, or chemist and druggist, or chemist, or druggist, or dispensing chemist or druggist, or any other title implying registration under the Pharmacy Acts; and in all other respects a company shall be amenable to the provisions of the Pharmacy Acts in the same manner as an individual or natural person; and if any company of persons not registered under the Pharmacy Acts shall assume or use any title implying registration under the said Acts, or in any way infringe the provisions of the said Acts, it shall be liable, on summary conviction, to a penalty not exceeding five pounds for each day upon which such offence happens."

Reforms Imperatively Demanded.

This clause may not please everyone, even of those in our own ranks, but it appears to me to have the merits of simplicity and clearness. Whatever we propose for inclusion in the Companies Bill should be brief and to the point, and other matters—such as modification of the "widow's clause," imposition of a compulsory curriculum of study, etc.—which are not dealt with in the foregoing clause, will be more appropriately treated in a Pharmacy Bill. For, whatever happens in connection with the Companies Bill, we look to our leaders to advance in the way of reform by promoting another Pharmacy Bill as early as circumstances may permit. We have great confidence in their discretion, and trust that it may not prove to be misplaced. But the demand for progressive reforms is imperative and must be satisfied. The world needs highly-educated and well-trained pharmacists more than at any previous period, but the modern pharmacist also needs to be assured with regard to his position, and I sincerely hope that the statesmanship of our representatives may prove equal to the occasion which now presents itself.

Silver Printing on Fabric.—The piece of silk, satin or linen is first thoroughly washed to get rid of finish, while it is drying prepare the following solutions:—(*a*) Tannin, 4; water, 100. (*b*) Sodium chloride, 4; arrowroot, 4; acetic acid, 12; water, 100. The arrowroot is made into a paste with a little water, the rest of the water is then mixed with the sodium chloride and acetic acid and heated to boiling. This is added to the arrowroot, after the latter has dissolved, mix in the solution two solutions (*a*) and (*b*). The fabric is immersed in this cold mixture, then dried, and is then sensitised by passing through the following solution: Silver nitrate, 12; water, 100. This fabric will print, tone, and fix in the same manner as Aristo paper.—*Amat. Photograph.*, **13**, 102.

C

PROCEEDINGS UNDER THE PHARMACY ACT.

Pharmaceutical Society of Great Britain *v.* Whittle.

At the Dewsbury County Court, on Tuesday, October 17, before His Honour Judge Cadman, the Council of the Pharmaceutical Society of Great Britain brought an action against Nathaniel Whittle, carrying on business at 24, High Street, Heckmondwike, for the recovery of two penalties of £5 each for infringements of the Pharmacy Act of 1868, by selling morphine contained in a preparation known as Kaye's Compound Essence of Linseed, on two separate dates, namely, July 25 and August 3, 1899, he not being a registered chemist.

Mr. R. Vaughan Williams, barrister, instructed by the firm of Messrs. Flux, Thompson, and Flux, solicitors to the Society, appeared for the plaintiff Society, and defendant was represented by Mr. T. Mitcheson, solicitor, of Heckmondwike. By consent of all parties the action was referred to the Registrar, Mr. Chadwick.

Mr. Vaughan Williams in opening the case said the Society caused inquiries to be made by an agent, who went to the shop of the defendant on July 25, and purchased a bottle of Kaye's Compound Essence of Linseed, which contained a preparation of "Morphine." He called again at the shop on August 3, and bought another bottle of the same substance, and that formed the substance of the second offence. On the second occasion, the agent also purchased some liniment, which, if it contained what it purported to contain, should contain opium, which was a constituent of laudanum. On being analysed, however, the soap liniment did not contain opium at all. He would therefore abandon that part of the claim. A letter was written by the solicitors to the Society to the defendant, informing him that by the sale of poison as contained in Kaye's Compound Essence of Linseed, he had incurred two penalties of £5 each, and stating that they were instructed. as the solicitors to the Society, to collect the same, otherwise proceedings would be taken for the recovery of the amount. No reply was received to that letter, and accordingly these proceedings were instituted. A further letter was then written to the defendant suggesting that to avoid the costs of bringing an analyst from London to prove the contents of the essence, he should admit that the articles were in fact what they purported to be. No answer was received to that, and the Society had the purchases analysed.

Evidence to prove counsel's statement was then called.

Arthur Foulds, an inquiry agent, carrying on business at Manchester, said that acting on the instructions from the Registrar of the plaintiff Society he called at the shop of the defendant on July 25. He bought a bottle of castor oil and a bottle of Kaye's Essence, and was supplied by the defendant himself. The castor oil bottle had on the label, Nathaniel Whittle, Homœopathic Stores, Heckmondwike.

Mr. Williams interposing, said the bottle containing Kaye's Compound Essence had on a label which stated that it was a preparation of chloroform and morphine, and was therefore labelled poison. On the other side there was also a blank space for the name and the address of the vendor, which was not filled in, and which, in point of fact, was another infringement of the Act, which rendered defendant liable to another penalty.

Mr. Foulds, continuing, said he took the bottles to his office, and afterwards handed them over to Mr. Moon, clerk to the Pharmaceutical Society of Great Britain. On August 3 he visited the same premises again, and purchased a bottle of glycerin, a bottle of Kaye's Essence, and asked for two-pennyworth of soap liniment mixed with two-pennyworth of laudanum, and defendant supplied him. Those purchases he also handed to Mr. Moon.

Cross-examined by Mr. Mitcheson, witness said when he purchased the goods from the defendant he did not tell him what he wanted them for. Defendant got the bottle of Kaye's Essence out of a case containing half a dozen or eight other bottles. Defendant's labels were on all the bottles he bought with the exception of the bottles containing Kaye's Essence.

Mr. Harry Moon, clerk in the office of the Registrar of the Society, proved receiving the bottles from the last witness, and sending them to be analysed. He also produced authority of the council of the Society to take these proceedings.

The order of the council of the Society authorising the proceedings was dated Aug. 2, and Mr. Mitcheson raised the point whether the Society could proceed on an order which so far as the second offence (Aug. 3.) had not, when the order was made, been committed.

The learned Registrar said this was a point upon which he would have to take the opinion of the Judge.

Mr. Vaughan Williams said it was the usual custom to leave it in an open form. They (the Council of the Society) ordered the Registrar to take proceedings, but they did not specify the dates of the offence, because the offence was conjectural, and because they were not offences until proved so.

The Registrar: They may pass a resolution on January 1 to operate throughout the year.

Mr. Williams: That is so, sir.

The Registrar: Well, we will consider that later.

Mr. Moon, examined by Mr. Mitcheson, said the bottles from the time he obtained possession of them until they were handed over to the analyst were locked up in his cupboard.

Mr. Ernest John Eastes, F.I.C., deposed to having analysed the bottles containing Kaye's Essence of Linseed, and also the bottle of liniment. They were opened by Mr. Moon, and he (Mr. Moon) kept the wrappers. The bottles of Kaye's Essence contained two scheduled poisons, namely, chloroform and morphine. The liniment contained no laudanum.

Mr. Mitcheson, for the defence, denied the whole of the plaintiffs, case, and urged, *inter alia*, that the purchaser had not even said, after he had got the samples, what he wanted them for.

The Registrar: The preamble of the Act says it is expedient for the safety of the public that samples should be taken. I don't think that should be thrown in his face.

Mr. Mitcheson said he thought if he had mentioned the matter to the defendant before he left the shop, he would have had a better chance of meeting the charge.

Mr. Nathaniel Whittle, the defendant, residing at High Street, Heckmondwike, was then called, and said when he received the letter from the solicitors asking for payment of the penalty he came to the conclusion that it was a blackmailing business.

The Registrar having read the letter which was sent to the defendant he asked him if he really meant to say that he considered it a blackmailing letter.

Witness: Yes, sir, and I can tell you why.

The Registrar: No, I don't ask your reasons.

Continuing, witness said he received another letter on September 28 in which he was asked to make certain admissions, but he had not done so, because he had nothing to admit. Up to the time of receiving the second letter he had not received any summons. He had not sold the bottles of Kaye's Compound Essence of Linseed on July 25, or any other date to anybody. He had never had a bottle of it in his shop at all. He had been asked for it, but he had always told them that he did not keep it. James Midwood, of Chappel Lane, Heckmondwike, had asked for it. The soap liniment he made himself, but he did not add any laudanum to it. The agent (Mr. Foulds) had not been in his shop to his knowledge. If he had the articles purchased would have his labels.

In answer to the Registrar, witness said he put his label upon everything he made himself.

That is your invariable rule?—Yes, sir, nineteen times out of twenty. Ninety-nine times out of a hundred.

In the course of a long cross-examination by Mr. Vaughan Williams, witness said Mr. Foulds would get his label when he purchased anything which he (witness) sold him that he made himself.

Do you remember selling glycerin on August 3?—If any glycerin had gone out of my shop it would have the label on.

Do you remember selling it or not?—I remember selling no glycerin in August.

Do you admit selling that glycerin?—I did not sell it. If it came out of my shop my name would have been upon it.

Did you make liniment?—Yes.

What did you make it with?—That's my business.

I don't want to pry into your trade secrets, but roughly speaking, what is in it—soap?—Yes, there is soap in it.

How did you colour it?—It could be coloured in making.

Is the process so dirty as that?—If you came to my place for a soap liniment, I should not get a clean measure to make it with.

Your suggestion is that it is made up in a dirty measure?—If you came to my shop and wanted some making up, and I had been using camphorated oil, I should not clean the measure.

Answering further questions, the witness said he did not know the colour of laudanum, and had never seen any in his life, while admitted having poppy-heads in his shop, which he boiled down

with marsh mallows. He had never seen any preparation made from poppy-heads alone.

You suggest that the colour is due to dirty measures. I put it to you that it is colouring matter used to give it the colour of laudanum?—No, sir.

Do you remember selling it?—I don't; because I have many score bottles like it.

Do you deny that you were asked to put twopennyworth of laudanum into the liniment?—He may have asked me to do so, but he would have been told to go elsewhere for it.

Do you suggest that the colouring has been put in by the agent of the Society?—I suggest nothing as to what they do. I have nothing to do with them. It is what I do that affects me.

Do you deny that on July 25 and August 3 you sold these bottles of Kaye's Essence of Linseed?—If I sold them there would be a bill with them. I deny that I sold them.

Do you say you have never had Kaye's Essence of Linseed on your premises?—No, never.

Not at any time?—No, never.

Not during the whole of your career as a herbalist at Heckmondwike?—I have never had any of it, and would not sell it.

Why?—Because they told me when I asked about it that it contained poison.

Do you know, then, that to sell it would be an offence?—I know that where there is poison it would be neither good for you or me.

Do you know that you would be liable to legal proceedings if you sold things that contained poison?—They told me it was so.

If Mr. Foulds swears that he bought these two bottles (Kaye's Essence) from your shop, is he swearing that which is untrue?—I never sold them.

Do you say he has come here to perjure himself?—I could not tell you that.

Is it your suggestion that he is saying an untruth when he says he bought these bottles at your shop?—I say I did not sell them.

The Registrar: I think you may leave that, Mr. Williams.

Do you admit selling poppy-heads, pursued Mr. Williams?—Yes, answered witness, to anybody that comes in and asks for them.

Do you know that you would be committing an offence against the Pharmacy Act if you did?—No, I did not know that.

Answering further questions, defendant said he sold patent medicines, and had a licence to do so. He did not know Mr. Gledhill, of Nelson Street, Dewsbury, nor did he know that he had come to his shop for Kaye's Essence. If a gentleman of that name said he came into his shop and bought a bottle he should say that it was untrue.

Martha Whittle, wife of the defendant, said she had never seen any bottles of Kaye's Essence of Linseed in the shop, and she knew all the things that were on the premises.

James Sylvester Midwood, of Chappel Lane, Heckmondwike, said he had applied to Mr. Whittle for a bottle of Kaye's Compound Essence of Linseed, and was told that he did not keep it.

The Registrar recalled Mr. Foulds, and closely requestioned him, but in no way was the witness's evidence shaken.

At the suggestion of the Registrar, Mr. Robert Gledhill, chemist and druggist, local secretary of the Pharmaceutical Society for Dewsbury and district, and Secretary of the Dewsbury and District Chemists' Association, was called by Mr. Williams. He stated that in July last he called at the defendant's shop and purchased a bottle of Kaye's Essence.

The Registrar: From whom?—Mr. Whittle.

Are you quite sure about it?—Oh, yes, sir.

Where was it got from?—From a glass case by the counter.

Cross-examined by Mr. Mitcheson, witness stated that he went because he heard that defendant was infringing the Act, and went there purposely to get a bottle.

Did you report the circumstance?—I think I reported it the same day.

Mr. Whittle was recalled, and denied that he sold the last witness a bottle of Kaye's Essence.

The Registrar, in giving judgment, said this was entirely a question of fact, and he felt no doubt about it. Mr. Foulds' statement was positively contradicted by Mr. Whittle, and inferentially contradicted by Mrs. Whittle. If he was to believe Mr. Whittle or Mr. Foulds he thought nobody would be surprised that he believed Mr. Foulds. He saw nothing throughout which called for any comment. He thought he had behaved in a perfectly straightforward way. If he did not believe Mr. Whittle, he had only himself to thank for it. Mr. Gledhill, however, put the matter beyond doubt. Mr. Whittle had come there to tell what he knew was not true. He (the learned Registrar) was perfectly certain that he had been in the habit of selling poisons, and he must pay the penalty. Turning to Mr. Williams, Mr. Chadwick asked whether he pressed for the second penalty for the offence incurred on August 3. If he did, he should consult with the judge to see whether the authority of the Pharmaceutical Council, given on August 2, covered the subsequent offence.

Mr. Vaughan Williams said he thought it was desirable for his clients to press for the second penalty, so that they would be able to see whether the order of the Council as at present drawn up ought to be amended.

Mr. Chadwick left to consult with His Honour, who was sitting in another part of the building, and soon returned to say that Judge Cadman was clearly of the opinion that there was no innovation, and judgment was then given for the plaintiffs for the two penalties and costs.

THE PURITY OF FOOD AND DRUGS.

Municipal Milk for Babies.—It is reported that the St. Helen's Corporation has opened an Infants' Milk Depôt for the sale of sterilised and humanised milk, which is mixed with cream, sugar, water, and salt. This preparation is put up in bottles with air-tight stoppers, and placed in a steriliser which heats the bottles to 109°, steam from a small boiler ascending through perforated platforms. It is stated that no microbes can exist ten minutes in the temperature thus created. The medical officer has prepared a table of quantities to suit babies of different ages, and the Corporation expects that the business, besides saving child life, will yield a profit.

Formaldehyde in Milk.—A test for formaldehyde, which has been in use in the laboratory of the Board of Health, Massachusetts, for some time past is given in the *British Food Journal* as follows:—10 C.c. of hydrochloric acid (sp. gr. 1·2) is added to an equal amount of milk in a porcelain dish. A drop of dilute ferric chloride solution is added, and the mixture heated to just below the boiling point and vigorously stirred. The presence of formalin is indicated by a violet coloration varying in depth with the amount present. It is stated that by this test 1 part of formaldehyde in 500,000 parts of milk is readily detected before the milk sours; after souring, the limit of delicacy is about 1 part in 50,000.

Retailer v. Wholesaler.—According to *Food and Sanitation*, a Birmingham grocer recently sent a sample of white pepper for analysis to Dr. A. Hill, public analyst, who found that it was adulterated with 25 per cent. of ground ginger. On receiving the certificate he commenced proceedings in the county court against the wholesale dealer who supplied him with the pepper, but withdrew the action on being paid £20 damages. If all retailers of food and drugs followed this example adulteration would probably not be practised to the extent it at present is.

Lead in Food.—Dr. C. P. Worcester, of Massachusetts, has examined the metallic foil used in packing food, and the metal stoppers of certain kinds of bottles and jars in which preserved fruits and aërated waters are sold. He found that lead was present in the form of an alloy in amounts varying from 93·5 per cent. to 0·2 per cent. of the alloy. The contents of twenty-eight metal-stoppered bottles of fruit syrups and beverages were analysed, and lead was found in all the samples. The maximum amount found was 1·05 milligramme of metallic lead per bottle, and the minimum 0·05 milligramme. The percentage of lead in the stoppers of the bottles varied from 3·5 to 50·7. While the amount of lead found in the contents of the bottles was in no case very large, Dr. Worcester thinks it is sufficient to condemn the use of lead in the manufacture of stoppers.—*British Food Journal*, **1**, 208.

Preserved Bread.—Henry A. Sevigne, of Boston, U.S.A., has taken out a patent for a method of preserving bread. The process, according to the *North-Western Miller*, is to heat the bread in an oven to a high temperature, and allow it to cool until it is at a temperature of 90° F. Each loaf in then placed in an air-tight and waterproof wrapper before the temperature of the bread has fallen to the temperature of the surrounding atmosphere. The edges of the wrapper are closed and secured upon the loaf, thus enclosing the bread in a flexible, sealed, air-tight, and waterproof wrapper, which is sufficiently transparent to enable the contents to be visible.

THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.

Spirits.—The official spirits which consist of simple alcoholic solutions of essential oils have been altered in strength for 1 in 50 to 1 in 10, with the exception of spirit of juniper, which is made 1 in 20. In alcohol of 90 per cent. strength, oil of juniper is not sufficiently soluble to yield a one in ten solution. The two "essences" of the 1885 Pharmacopœia are also omitted, and are practically replaced by the two spirits of the same name in the present edition.

Spiritus Ætheris Nitrosi.—This preparation was fully dealt with in the former series, *P. J.*, March 12, 1898, p. 266. The student should verify the official statements with regard to the correspondence of 5 and 6¼ volumes of nitric oxide to 2 and 2½ per c of ethyl nitrite. This he should be able to do by the aid of the article referred to above, remembering that the mean sp. gr. is now 0·840, and that the atomic weights are given more exactly in the 1898 than the 1885 Pharmacopœia.

The aldehyde test is due to caustic potash causing polymerisation of any aldehyde present to a brown substance of unknown but probably high molecular weight, which is called aldehyde resin. It is important to observe that spirit of nitrous ether is not unduly acid, as this indicates careless manufacture, or hydrolysis—and consequent loss—of ethyl nitrite.

Spiritus Ammoniæ Aromaticus.—Note that the sp. gr. has been slightly lowered by the use of the slightly stronger rectified spirit. Titration with sulphuric acid, using methyl-orange as indicator, gives total ammonia, *i.e.*, free ammonia and ammonia as carbonate. According to the official statement 100 C.c. of aromatic spirit of ammonia will neutralise 127·5 C.c. of N/1 sulphuric acid.

Now 1 C.c. N/1 H_2SO_4 = 0·01694 grm. NH_3
∴ 127·5 ,, ,, = 0·01694 × 127·5 ,,
= 2·16 grammes.

Taking the specific gravity of the spirit as 0·8905, *i.e.*, the mean of the official limits, 2·16 grammes in 100 C.c. is equivalent to 2·16 grammes in 89·05 grammes or 2·425 per cent. The barium chloride test is intended to show that a due proportion of the total ammonia is present as ammonium carbonate. The metric quantities given in the official formula for the preparation of the spirit will yield very nearly 4,000 C.c. Therefore, assuming that no loss of ammonium carbonate has taken place during manufacture, the 20 C.c. taken for analysis should contain 0·5 gramme, of the official salt. Let us assume that this is composed of carbamate and acid carbonate in equimolecular proportions, which by solution in presence of excess of ammonia yield the normal carbonate. Then:—

$$\underbrace{NH_4HCO_3,NH_4NH_2CO_2}_{156{\cdot}04} + NH_3 + HO_2 = 2(NH_4)_2CO_3$$

and

$$2(NH_4)_2CO_3 + \underbrace{2(BaCl_2,2H_2O)}_{485{\cdot}08} = 4NH_4Cl + 2BaCO_3 + 4H_2O$$

From this it follows that 156·04 of ammonii carbonas will require for complete precipitation 485·08 grammes of crystallised barium chloride.

∴ 1 gramme will require $\frac{485{\cdot}08}{156{\cdot}04}$ grms, $BaCl_2,2H_2O$,

and 0·5 ,, ,, ,, $\frac{485{\cdot}08 \times 0{\cdot}5}{156{\cdot}04}$,, ,,

= 1·554 grammes.

The quantity of barium chloride solution to be used for the official test is 16 C.c. Since each C.c. of this solution contains 0·1 gramme (*vide* B.P. Appendix, p. 405) the 16 C.c. will contain 1·6 gramme $BaCl_2,2H_2O$.

The student should carefully note the details for the performance of this test. In the usual scheme for qualitative analysis the metals of the barium group (Ba,Sr,Ca) are precipitated as carbonates. The complete precipitation of these carbonates takes some time in the cold. It is, however, hastened by *warming*, but the precipitation mixture should *not be boiled*, for at this temperature the reaction is partially reversed, and a portion of the precipitated carbonates go into solution again as chlorides.

Spiritus Ammoniæ Fetidus.—This contains the volatile constituents of asafetida only, the gum and resin being rejected by the distillation. The neutralisation test is stringent, for it allows of hardly any appreciable loss of ammonia during manipulation or storage. Thus, 25 C.c. of the fetid spirit of ammonia will contain 2·5 C.c. of strong solution of ammonia. The sp. gr. being 0·891, this volume should weigh 0·891 × 2·5 = 2·2275 grms. Now, by reference to B.P., p. 173, we find that 1 gramme of liquor ammoniæ fortis should neutralise 19·1 C.c. of N/1 H_2SO_4

∴ 2·2275 grammes should neutralise 19·1 × 2·2275 C.c. N/1 H_2SO_4
= 42·55 C.c.

The Pharmacopœia requires that the equivalent volume of fetid spirit shall neutralise 42·5 C.c. N/1 H_2SO_4.

Spiritus Rectificatus.—The student should refer to the article on rectified spirit in the previous series (*P.J.*, March 26, 1898, p. 310). Also to an article by Bird in *P.J.*, May 21, 1898, p. 500. The strength of spiritus rectificatus has been raised from 56 to 58 overproof, *i.e.*, every 100 volumes of the spirit contain as much real alcohol as 100 + 58 volumes of proof spirit. Proof spirit, which is used as a basis for calculation of duty for Excise purposes, has been omitted from the present Pharmacopœia, and four strengths of diluted alcohol introduced. The student should carefully note that the strength of these diluted alcohols is referred to the *percentage by volume* of real alcohol which they contain.

Strychnina.—The comparative solubility of strychnine and its commonly used salts (hydrochloride, nitrate and sulphate) in water is very different. This point is of great importance in dispensing, for strychnine is frequently given with an alkali (aromatic spirit of ammonia, sodium bicarbonate, etc.) in water, or an aromatic infusion. In such cases the strychnine is usually prescribed in the form of liquor strychninæ hydrochloridi, which is easily soluble in the proportion of water or aqueous vehicle in the prescription. If an alkali is prescribed also, then a condition of things arises which may have serious consequences. For the strychnine liberated by the free alkali acting on the strychnine hydrochloride is very sparingly soluble in water (not more than 1 in 7,000); therefore if the weight of strychnine prescribed relative to the vehicle exceed this proportion, the excess will be precipitated—probably not immediately but on standing some time, so that an excessive quantity of strychnine may be taken in the later doses of the mixture. The proportion 1 in 7,000 corresponds in round numbers to 8 minims of liquor strychninæ hydrochloridi per fluid ounce for

7,000 : 1 :: 437·5 : 0·0625

That is, if the quantity of strychnine exceed the proportion of 0·0625 grains per fluid ounce, then a precipitate of strychnine will be produced. Now 110 minims of the liquor contains 1 grain of the hydrochloride, which is equivalent in round numbers to 0·8 grain of the free alkaloid—

∴ if 0·8 grain strychnine is contained in 110 minims

1·0 ,, ,, ,, $\frac{110}{0{\cdot}8}$,,

and 0·0625 ,, ,, ,, $\frac{110 \times 0{\cdot}0625}{0{\cdot}8}$,,

= 8·59 minims.

* NOTE.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J.* during 1897-8.

LONDON: SATURDAY, OCTOBER 21, 1899.

THE PHARMACY ACT.

That unhappy legislative enactment known as the Pharmacy Act, 1868—the joint product of irrational discord among chemists and druggists, and the exaggerated popular panic prevailing at that time as to the dangers of poison—has long been made abundantly an object of various kinds of abuse and of censorious criticisms, having little better foundation than uninformed prejudice or misconception. At its inception the Act was, for a time, opposed by some medical practitioners, who feared that their professional interests might be prejudiced by the proposed new qualification of chemists and druggists; the Act has since been condemned, on the one hand, as creating a trade monopoly, and on the other as inflicting great hardship upon chemists and druggists. From the point of view of the educated pharmacist the insufficiency of the Act, as a means of regulating the practice of pharmacy, has always been apparent and, in that respect, it has been suitably described as a "wretched poisons act." At the hands of judicial authorities the Act has fared even worse, having been regarded as ambiguous, confused and unintelligible as to its language and object, besides having had a construction put upon it which entirely defeats its original intention. That such should have been the fate of the Pharmacy Act was probably to some extent a consequence of the chaotic condition existing when the Act was passed; when it was thought that the majority of the persons who then sought to obtain "the druggists' franchise" by incorporation under the Pharmacy Act were a "motley host of traders" a kind of rabble of chandler shopkeepers, stationers, perfumers and others, who dabble in death-dealing substances.

But looking backwards, the Pharmacy Act, with all its defects, may be regarded as having some redeeming points. It has been the means of incorporating and giving statutory recognition to persons engaged in an occupation requiring, even as a trade, more than ordinary knowledge of the articles dealt in and, in its more professional aspects, considerable scientific and technical training: it has established a legal qualification for the exercise of the business of a chemist and druggist, a test of fitness for carrying it on; a register which serves as an official means of ascertaining who are so qualified, and a titular description which enables the public to distinguish persons qualified from those who are not. The very essence of the Act, however, is poison, and though better things, such as pharmaceutical education, examination and certified competence are to some extent associated with the more predominant central idea of protection against poison, they are overshadowed by it and appear, as it were, only in the background, as comparatively subordinate objects. But even in the wretchedly attenuated dimensions of a mere Poisons Act the statute has some points which deserve consideration in regard to the question whether its intention and principle may not, even now, be carried out in a manner more conducive to the public interest and to the advantage of persons who have acquired vested interests under its operation. The work of formulating means to remedy the evil of company trading, upon which the Law and Parliamentary Committee are now engaged, will offer favourable opportunity in that direction and encouragement may be gathered from the fact that, in the past, the provisions of the Act have been found adequate for dealing with the sale of poisons in the form of secret remedies and patent medicines, in a manner that was not at one time thought possible.

Perhaps the worst treatment that the Pharmacy Act has received has been at the hands of chemists and druggists who have not thought enough of its provisions as capable of being made a means of protection, by establishing a sharp line of demarcation between themselves and other traders. Though the prohibitory provisions of the Act apply to only a small part of the practice of pharmacy, their strict observance by registered chemists and druggists should be the means of making those provisions the palladium of the chemist and druggist's statutory privileges to a much greater extent than has been the case. From the very first the regulations as to the sale and dispensing of poisons have been, on the contrary, in many instances regarded rather as hindrances of trade; the adoption of regulations as to the keeping of poisons has been too long resisted and the necessity of employing legally qualified assistants in branch shops was formerly too much neglected. Among other defects more inherent in the nature of the Act itself is the want of provision as to dispensing of medicine generally, for amendment of which the time should now be ripe; the loose nature of the provision for continuing the business of a deceased chemist and druggist also requires amendment. The latter defect has been the cause of that "breakdown" of the Pharmacy Act by which it has become possible to ignore altogether the demand for qualification to carry on the business; so that any unqualified person has the opportunity of setting the provisions of the Act at defiance. One of the most pressing necessities at the present time will be to devise suitable means of removing that defect which has given rise to such disastrous consequences. Now that the majority of registered chemists and druggists are qualified by examination, the desirability of such a mode of protecting their interests should carry greater weight than could be expected when that was not the case.

THE BENEVOLENT FUND.

THOSE who take an interest in the Benevolent Fund (and that should include every registered person), are invited to consult carefully the advertisement columns of the present issue, where is presented an official list of the six approved candidates for an annuity, together with a brief statement of particulars relating to each candidate. One of the objects in publishing thus early a *precis* of the circumstances of the respective candidates is to furnish subscribers with an opportunity of checking, as it were, the choice of the Council, so far as the cases in question are concerned. That body, like other human institutions, is not entirely free from liability to err, and is certainly not proof against misrepresentation, hence, while such things as plausible tales and unworthy but subtle applicants exist, it is unwise for any governing authority charged with the care of charitable funds to cultivate too exclusive an atmosphere of infallibility. The greatest care is taken by the Pharmaceutical Council in the investigation of applications for assistance which come before it, and in the selection of candidates for an annuity, especially, no pains are spared to ensure the adoption of the most deserving and most urgent cases. Notwithstanding those facts, however; in spite of the conscientious "sifting" process, there is still a possibility that someone among the subscribers may possess a fuller knowledge of certain of the candidates than the Council or its advisers can have. The Council is anxious to guard against the possible election of an undeserving person, and has decided that safety lies in taking all the subscribers into consultation in the manner adopted this week through the medium of the *Pharmaceutical Journal*.

INSTRUCTIVE READING.

ATTENTION may be directed to four communications, appearing in this week's Journal, which require, under existing conditions, most careful consideration by every registered chemist and druggist. The first is the paper by "An Ordinary Pharmacist," in which the evil that is causing so much dissatisfaction throughout the country is dealt with: next the report of the address delivered by Mr. AVERILL, at the meeting of the North Staffordshire Association, which deals with the same subject and points out that if chemists desire a remedy for the evil they will have to do something more for themselves than listen to and applaud speeches: third, the excellent address delivered to the Glasgow Chemists' Assistants' Association by Mr. RUTHERFORD HILL, in which he points out the privileges already possessed by chemists, as well as the possibility of making better use of them: lastly, the paper read by Mr. SMITH, the Society's local secretary for Liverpool, and Chairman of the Federation of Local Associations, which shows how chemists throughout the country could and should defend and promote their common interests much more effectively than has been the case hitherto. If those papers are duly digested there should be before long a very vigorous and general movement on the part of chemists and druggists for improving their position.

ANNOTATIONS.

THE PHRASE "COMPANY PHARMACY" has of late been freely bandied about, together with a superfluity of inept babble of a distracting nature. What may have been the real object of many of the lucubrations on that subject is somewhat difficult to understand; the more so as they have chiefly been conspicuous for the absence of any intelligent meaning. So far as the art of pharmacy is, in itself, capable of being the subject matter of company organisation, there does not appear to be much opportunity for disputatious discussion as to the applicability of company machinery for the practice of the art, since the primary requirement in that respect is fitting pharmaceutical qualification of the individuals so engaged, and, that being ensured, there appears to be no reason whatever against any possible advantages of company organisation being enjoyed by legally qualified persons in that business, as it need not involve damage to the manifest object and policy of the Pharmacy Act.

IF SEVEN LEGALLY QUALIFIED CHEMISTS AND DRUGGISTS found that they could carry on their business more profitably, or otherwise better, under a memorandum of association, constituting them a company with limited liability, there does not appear to be any reasonable ground for objecting to such a company carrying on the business in that way. But the matter takes a totally different aspect when the idea of shareholders is introduced, in the ordinary sense of company organisation, and the absurdity of such a position in regard to a business requiring individual qualification, both technical and legal, becomes as obvious as the absurdity of a company, or other ideal personage, practising pharmacy or undergoing an examination, for the purposes of being tested as to technical knowledge and obtaining the requisite legal qualification. Any question as to the admissibility of company pharmacy is, therefore, reduced to very narrow limits.

THE BONA-FIDE CONDUCT of the business of a company, constituted of persons legally qualified as chemists and druggists, would, in such case, be in the hands of the owners of the business—the only *bonâ-fide* managers conceivably consistent with the manifest object and policy of the Pharmacy Act or with the language of its provisions. If such "company pharmacy" be desirable, either in the interests of the public, or in the interests of legally qualified chemists and druggists, no possible objection can be raised against it, nor does it require either recognition or regulation beyond such as is already afforded by the provisions of the Pharmacy Act, rationally interpreted. Propositions as to any other kind of "company pharmacy" are therefore extraneous, and really serve only as red-herrings to confuse the simple issue as to whether or not the provisions of the Pharmacy Act are to have the application intended by the Legislature, in the interest of the public and with those consequences that are essential for their efficacy in that respect.

THE "COMPANY PHARMACY" to which legally registered chemists and druggists are entitled to object is of that spurious kind which carries on the business in violation of the Pharmacy Act and in direct opposition to its manifest object and policy. A company constituted, as the late Lord Herschell stated in the House of Lords, essentially of a person unqualified under the Pharmacy Act —who, after having been subjected to penalties for infringement, avoids the statutory obligations attaching to the business of a chemist and druggist, by associating with himself several members of his family, as nominal shareholders, so as to obtain formal regis-

tration under the Companies Acts and then continues to carry on the business as a "bogus" or one-man company—is nothing less than a fraud in every sense. There are many such existing, as a consequence of the judge-made law which has served as a legal precedent overriding the Pharmacy Act. By such "company pharmacy" the salutary provisions of the Act for public safety are defeated and the interests lawfully acquired by some 15,000 registered chemists and druggists are unjustly prejudiced. The question is not at all one as to free trade or monopoly in the sale of drugs—and if the facts of the case were properly represented to and comprehended by Parliament, there is every reason for believing that the iniquity of so-called "company pharmacy" would be promptly put an end to.

"Company Pharmacy" of the piratical kind above referred to—carried on in unnatural association with the general trade of more or less gigantic "stores"—finds its chief support in the mistaken assumption of the late Lord Selborne that its inherent inconsistency with the Pharmacy Act could be compensated by legally qualified persons acting in the capacity of assistants or managers for unqualified proprietors. Under the deluding influence of that fallacy many persons, legally qualified to carry on business as chemists and druggists on their own account, have been beguiled into participating in the brigandage that would, even now, be impossible without their aid.

Enemies within the Ranks of persons qualified under the Pharmacy Act, will therefore add to the difficulties that will have to be dealt with in attempting to remedy the evil of company trading by which the general interests of chemists and druggists are prejudiced. Though the exigencies of existence may be pleaded as some excuse, they cannot be held to justify the action of qualified persons who thus lend their services, to the detriment of the body to which they belong. Hope may, therefore, be entertained that when the question of legality of "company pharmacy" is definitely raised, a sense of loyalty will be awakened that will support the action taken in defence of chemists' privileges.

Compromise of any Kind should, however, be utterly out of the question for any but those who seek to serve their own purpose by helping "companies" to filch the small decimal fraction of professional privilege in the practice of pharmacy, which was supposed to have been secured by the Pharmacy Act and protected against the monopolising tendency of mercenary trade interests. If the failure of the broken-down Pharmacy Act must of necessity be admitted to have been so thorough that the public and the Government are disposed to regard the burglarious inroad of "company pharmacy" as more adapted to the "safety of the public" than support of the legislative provisions which were deemed "expedient" for that object: if it be held that long possesssion of stolen property constitutes, for the thieves, a respectable vested interest, there will then be nothing left for registered chemists and druggists but to join with trade journals in a chorus of exultation that, after more than forty years' struggle to obtain a professional position, the doctrine of "free trade in physic" has prevailed, and that they have again been reduced to the level of a mere "trading community." The evolution of pharmacy, imagined by Dr. Leech as desirable, would in such case be relegated to the narrow range of voluntary action, in which selfish interest of individuals would preponderate, while the interests of pharmacy as an art and the interests of every other body connected with it, would be left to whomsoever it might concern.

The Position and Privileges of Pharmacy and the pharmacist are probably as clearly explained by Mr. J. Rutherford Hill, in the address printed in this week's Journal (see p. 380), as it is possible for them to be. He shows that pharmacy is recognised and endowed by the State, and argues that a necessary corollary ought to be the most perfect possible protection of the practice of pharmacy, in the interests of public welfare and safety. To a limited extent State protection already exists, but there is room for improvement and, at the least, there should be absolute restriction of the use of any title implying legal qualification by any unregistered person, whether alone or in association with others. State regulation of prices is not asked for, but it is essential, in the public interest, that the object of the Pharmacy Acts should be fully realised. At the least, as Mr. Hill remarks, there should be protection of all pharmaceutical titles; but the public also has a right to demand that poisons shall only be dispensed and sold in shops owned by duly qualified individuals. A further benefit would be conferred upon the public if the dispensing of all medical prescriptions were restricted to pharmacists, but legislation in that direction can hardly be asked for until the medical profession and the public have been better educated on the point. The enforcement of a compulsory curriculum of study in pharmacy would doubtless hasten the desired end; but it is a question if the time is yet ripe for that.

The Pharmacist is a Professional Man, as Mr. Rutherford Hill points out, but only in the same sense as a medical man or a lawyer. That is to say, so long as the pharmacist practises pharmacy proper he is a professional man, but in other respects he is a mere trader and is likely to continue to be so for some time to come. The compounding and dispensing of medicaments are strictly professional functions, and even the retailing of crude drugs and chemicals may be removed from the category of purely commercial transactions. At most, the element of commercialism need not exist to a greater extent in pharmacy than in the case of a medical man who dispenses his own medicines and makes a charge for the same to his patients; but even to that extent it is not an essential accompaniment of pharmaceutical transactions. Properly conducted, the retailing of any quantity of the most ordinary drug or chemical may be classed as a form of dispensing, the pharmacist continually bringing to bear the results of his special training and education, and so maintaining his right to be regarded as a professional man. A thorough grasp of commercial principles is, of course, imperative, even in the case of a professional man, and in the case of the pharmacist—who is virtually compelled, under existing conditions, to engage to some extent in trade—it is particularly desirable.

Why That is So does not need explanation here, as the address under consideration may be referred to for any explanation that is not already sufficiently obvious. It is enough to say that the pharmacist ought to be, and usually is, much better fitted to supply drysalteries, chemicals for scientific and technical purposes, optical goods, scientific apparatus, etc., than any mere trader. But, apart from that, the position of the pharmacist is a privileged one in many respects. He possesses, as a rule, a much better knowledge of scientific matters than his neighbours, and he ought to find but little difficulty in securing for himself a peculiar position as one of the best educated men in the community amidst which his lot is cast. He should neglect no opportunity of sharing the burden of public duties in his district, and cannot then fail to reap a rich reward in the esteem and respect of his fellow men. It is not necessary to dwell further upon this subject of the pharmacist's position and privileges, but reference may usefully be made to Mr. Hill's warning that both are threatened. What has been gained by steady persevering work during the past fifty years may be gradually filched away unless pharmacists show a united front and sink all minor differences in the determination to protect them-

selves. Reliance upon the State will prove of no avail if the spirit of self-help is lacking, and, after all, the best protection of the pharmacist lies in "steady, high-class professional work and invincible integrity."

THE PHARMACEUTICAL SOCIETY ought, according to the local secretary for Liverpool, to be one of the finest examples of effective organisation in existence, and there is no doubt that his opinion is a correct one. But the position of the Society is far from being what it ought to be; it is not truly representative of the registered chemists of Great Britain, though it now includes a majority of those in business on their own account. The Society's weak spot is its defective local organisation, and Mr. Smith suggests as a remedy that the method of appointing local secretaries should be modified. Instead of depending upon nomination cards sent in by members of the Society, he would call meetings of the whole of the registered chemists in the respective districts, whether they happen to be connected with the Pharmaceutical Society or not. Everyone present would be permitted to take part in any discussion that might take place, but only members of the Society would be entitled to vote in deciding the claims of the proposed nominees. The person receiving the greatest number of votes would then be formally nominated by the chairman of the meeting, and probably elected by the Council of the Society in due course. By this means, it is thought, a local secretary would more truly represent his district than is now the case. At the same time, Mr. Smith promises the co-operation of the Federation of Local Pharmaceutical Associations, of which he is chairman, in endeavouring to secure a larger number of energetic local secretaries.

THE LOCAL SECRETARIES, when appointed, would also become the representatives of their respective associations in the Federation which, as Mr. Smith points out, exists only for the purpose of binding together, in the common interest, the numerous local pharmaceutical associations scattered throughout the country, besides supplementing the work of the Pharmaceutical Society. Unless it can enable the associations to work together to protect the rights and further the interests of the individual members, no sufficient reason for its existence remains. At the same time, though it is necessary that the Federation should occupy an independent position, one of its main objects is to strengthen and assist the Pharmaceutical Society to the utmost of its power. That can be largely done by bringing the local associations into an informal affiliation with the Society, and by helping to create an interest in the affairs of the parent body. One effect of that would be to make the local association responsible for the local organisation upon which the success of the Pharmaceutical Society is largely dependent, instead of leaving the whole business in the hands of one individual, who is frequently unable to cope fully with the work. Inasmuch as the representatives of the local associations in the Federation would also be local secretaries of the Pharmaceutical Society, there would be a very effective connecting link between the two bodies, and in Mr. Smith's opinion that would allow of a closer co-operation between local associations and the national Society.

THE COUNCIL OF THE ROYAL PHOTOGRAPHIC SOCIETY has decided to institute a monthly meeting specially devoted to illustrated lantern lectures. The meetings will be held on the first Tuesday in each month from November to April inclusive, and will commence at 8 o'clock p.m. The first lecture of the series will take place on Tuesday, November 7, at the Gallery, 5A, Pall Mall East, when Mr. J. J. Vezey will give a lecture upon "Some Mediæval towns of Germany," illustrated by lantern slides by Commander C. E. Gladstone, R.N. The Council wishes it to be understood that lady visitors are specially welcome on these occasions; tickets may be had on application to the Assistant Secretary, Mr. A. W. W. Bartlett, 66, Russell Square, London, W.C.

MUCH INTEREST has been excited among registered chemists and druggists throughout the country by the announcement that the Council is about to draft a clause embodying the general desire in regard to company trading. Among other indications of activity, in that direction, a correspondent has supplied the following suggestion as to the purpose which should be conveyed by a clause suitable for replacing the second clause of the Companies Bill, which was before the House of Lords last session:—

> That, in pursuance of the Pharmacy Acts in force in the United Kingdom, a company may not, as a corporate body or ideal personage, take, use, or exhibit the title of Pharmaceutical Chemist, or the title of Chemist and Druggist, or any other title indicating registration under the Pharmacy Acts, and a company shall otherwise be subject to all the provisions of the Pharmacy Acts in the same manner as individual persons.

This suggestion appears to cover all that need be attempted in connection with a Companies Bill. The proposal, in the second clause of the Companies Bill, to legalise the use, by companies, of the titles in question, obviously implies that such use of those titles is now unlawful, and that further legislation is needed only for the purpose of making the provisions of the Pharmacy Acts in that respect more effectual than they have been. Any further requisite regulation of the practice of pharmacy by persons associated together for that purpose would be more appropriate matter for amendment of the Pharmacy Acts.

THE CHEMISTS' ASSISTANTS' ASSOCIATION, having commenced the serious work of the session at the meeting last week, held the first of its social meetings on Thursday, and on November 2 the annual smoking concert will be held at the Holborn Restaurant. The chair will be taken at 8.15 p.m. by Mr. P. W. Squire, and Mr. William Warren will officiate as vice-chairman. Tickets (1s. 6d. each) may be obtained from any member of the Council of the Association, or from Mr. C. Morley, 3, Bucklersbury, London, E.C.

ANOTHER PRESCRIPTION CASE was heard at the West London Police-court last week, when a chemist was charged under the Sale of Food and Drugs Act with supplying a six-ounce mixture containing an excess of thirty-six grains of potassium iodide. The quantity ordered in the prescription was four drachms, and the analyst engaged by the defendant found that the mixture had contained an excess of nineteen grains only. A third sample was sent to the Government laboratory and the Government analyst certified that there was an excess of twenty-three grains only, instead of thirty-six as certified by the Fulham Vestry analyst. Under the circumstances, the magistrate—Mr. Rose—decided to dismiss the summons. He said there was no evidence of fraud or carelessness, and the excess of iodide present was immaterial. The magistrate also repeated what he had said on a former occasion (see *ante*, p. 257), to the effect that Section 7 of the Sale of Food and Drugs Act, 1875 does not apply to the sale of medicines dispensed by chemists from prescriptions, and containing a trifling and harmless excess of one ingredient.

DURHAM UNIVERSITY COLLEGE OF SCIENCE is to be completed, at a cost of £50,000. The College, as is well known, is situated at Newcastle-on-Tyne, and stands next to Owens College, Manchester, in point of number of students. A comparison of the cost of work, read by Earl Grey at a recent meeting over which he presided, showed that Newcastle averaged £28 per student, as against an average of £51 per student at other colleges in Britain. It is no longer possible to provide accommodation in the existing buildings of the college for the increasing number of students, and Earl Grey appealed to firms on the Tyne, Wear, and Tees to follow the example of Birmingham in contributing from their profits. He expressed the hope that before the year is out £100,000 may be raised. Subscriptions to the amount of £9,500 were announced at the meeting.

BRADFORD AND DISTRICT CHEMISTS' ASSOCIATION.

The first meeting for the session of this Association was held on Tuesday last, when the President, Mr. H. G. Rogerson, occupied the chair, and delivered an

Introductory Address.

In this he alluded to the position of the Lord Chancellor in relation to the grievances of qualified chemists, and said that it behoved chemists to maintain an attitude of vigilance and hopefulness, remembering and acting upon the old adage,

"God Helps Those Who Help Themselves."

The moment the promised signal was given by the Council of their Society, preparations should be made to circularise and interview every member of the popular Chamber. From the first it had been his conviction that the issue depended on the manner in which they impressed their Parliamentary representatives with the soundness and justice of their cause. An appeal to every member of the House of Commons by the Council should be followed by a brief circular from each local association to its Parliamentary representative, pressing home the matter of the Council's appeal, and asking for an early interview between each member and not less than three of his chemist constituents. The question of

Doctors Dispensing

their own medicines had lately been the subject of controversy both in the medical and pharmaceutical press, and had aroused much warmth of feeling. It was an abstract proposition. Few would deny that division of labour in regard to those important and responsible duties was desirable; but they had first to educate the public as to the wisdom of tolerating a little extra expense in order that their medical compounding might be performed in a more deliberate, careful, and expert manner than it had hitherto been performed—generally by an untrained compounder, and not infrequently by a menial dependent. Referring to the swelling list of

Proprietary Medicines,

which are assiduously thrust under the notice of prescribers as so many palpable improvements on the formulæ of the British Pharmacopœia, the speaker said that exploiters of those nostrums do not rely wholly on their powers of persuasion as advertisers in the medical journals. The magnitude of their trade enables them in many instances to secure the services of qualified medical men as travelling touters and persuaders of their medical brethren. Those touters presumably found this rôle more remunerative than that of their legitimate occupation. As a result, the document that was quite commonly brought to the pharmacy and handed to the embarrassed dispenser in place of the orthodox medical prescription was a signed order for a bottle of the latest proprietary fad, a typical specimen probably of what was termed poly-pharmacy, and one which any skilled prescriber ought to be able to think out for himself. This was described as a lamentable and paradoxical decadence in the art of prescribing. Happily, there are some signs of a reaction against this humiliating state of things, as the doctor discovers sometimes that his quondam patient, satisfied with the proprietary tablets prescribed for him, goes in for

Self-Medication

on the reappearance of his troubles, and also thrusts his panacea under the noses of his friends. In this way the simple-minded prescriber loses both his immediate and his prospective patients. But anything in the nature of radical reform can only be looked for in such an amendment of the medical curriculum as should recognise the necessity of a thoroughly practical acquaintance with the pharmaceutic art. Dealing next with

The Position of the Pharmacist,

the Council of the Society was alleged to have allowed to pass many opportunities of bettering the prestige of the great body it represented. It had been felt by many influential members of their body that in comparison with other scientific organisations, the Society which granted them their diplomas, and licences, and a practice, had but a barren and commonplace title to present to its graduates. They could hardly help contrasting the announcement on the pharmacy signs and labels of English pharmacists, "members of the Pharmaceutical Society," with the titles authoritatively assumed by members of bodies which could hardly claim precedence to their own in importance and dignity. He trusted that the movement for the amendment of the title would be revived when a suitable opportunity offered. It should be part of the chemist's duty to act as

Instructor to the Unwary

in regard to the great proprietary medicine traffic, and when the opportunity suggested itself, point out how each Government medicine stamp bore the words, "This label implies no Government guarantee." This vast proprietary medicine traffic was responsible for the evolution of the horde of unskilled bogus druggists who were in all the large cities and towns, taking the bread out of the mouths of the trained and duly qualified chemists. The moral to be drawn from this was that if the chemist was to maintain public respect and support he must assert himself as being something

More than a Mere Trader

and distributor of the ready-packed parcels of the advertiser. The vast majority of these quack medicines had long been a source of perplexity and embarrassment to the pharmacist. But on the part of the educated classes there was a strong reaction setting in against the absurd appeals of the ubiquitous quack advertiser. As to

Cutting the Prices of Drugs,

it seemed incredible that a qualified man should fail to realise that he thus literally gave away his status as a graduate in pharmacy, and lowered himself to the common ruck of unqualified traders. With regard to

Counter-Prescribing,

he was convinced that there were really few of them who would have the temerity and folly to treat medically a person applying to them with any semblance of a serious ailment. A pharmacist who did that was a traitor to his craft.

NEWCASTLE-ON-TYNE AND DISTRICT CHEMISTS' ASSOCIATION.

The third annual meeting was held on Wednesday evening, October 11, at the Hotel Metropole, Newcastle-on-Tyne. Mr. T. Maltby Clague presided, in the absence of the retiring President, Mr. F. Schofield. Mr. W. Kerse, Hon. Treasurer, read his report which showed a balance in hand of £1 5s., as against £8 10s. last year, the large difference being caused by heavy expenses in connection with a "Social" which had been held during the year, and which was a great success. Mr. F. Gilderdale presented the Secretary's report, which showed that six ordinary meetings had been held, the Social, the Smoking Concert, the Annual Dinner, whilst an excursion in the summer had been indulged in, besides the usual Council Meeting. An abstract of papers, discussions, etc., read before the Association during the late session showed that a fair amount of work had been got through. The Treasurer and Secretary were heartily thanked for their reports, which were very satisfactory. The election of officers was then proceeded with and resulted as follows:—President, Mr. Charles Ridley; Vice-Presidents, Mr. T. Maltby Clague, Mr. J. D. Rose, Mr. F. E. Schofield, Mr. G. F. Merson; Treasurer, Mr. W. Kerse; Secretary, Mr. F. Gilderdale; Auditors, Mr. R. Wright, Mr. G. Whitehead; Council, Mr. F. R. Dudderidge, Mr. Geo. Duncan, Mr. W. Pescod, Mr. W. Buckley, Mr. R. Cubey, Mr. W. Atkins, Mr. R. Brand, Mr. R. Graham.

The Parliamentary Committee was also re-appointed. The members present agreed to nominate Mr. T. Maltby Clague as local secretary of the Pharmaceutical Society.

Mr. Chas. Ridley, the new President, in a speech which was well received, commented on the standardisation of various drugs which the new Pharmacopœia had brought about. With regard to the new poisons regulations he considered that the same was a step in the right direction, but thought that it should be extended to doctors' surgeries, where in many cases dispensing was done in a very erratic manner. Speaking of the recent prosecutions amongst grocers for selling inferior drugs, he was pleased to see that in many cases wholesalers who had supplied the same had been heavily fined. This had caused a healthier tone in the trade and, at any rate, if these people could still sell them, they must at any rate sell the pure articles, which made competition fairer than before, where in so many instances adulterations had been sold to the public to the detriment of the chemist.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The first meeting of the session 1899—1900 was held on Thursday, October 12, in the Association's rooms at 73, Newman Street, London, W. There was a fair attendance, the President (Mr. F. W. Gamble) in the chair.—The Secretary (Mr. J. Evans) having read the minutes of the last meeting, the President explained that since the election of the Council of the Association Mr. Barlow had left London, and that Mr. Currie had been elected in his place.—Ten new members were nominated, and the President then delivered the

Inaugural Address.

Mr. Gamble commenced his address by referring to the fact that until this year no President of the Association had been re-elected for a second year since 1885, and expressed a desire to know wherein he had been at fault that he was again put into the pillory. He then went on to say that he should do his utmost to place the present session on a plane with the most successful of those preceding, but pointed out that his efforts would be of little avail without the individual help of the members. He was sorry to have to relate that the roll of membership was below the average length; that the Association was, in fact, a little run down—literally, and, as those present might perhaps have noticed, to a small extent critically. The membership now stood at about one hundred, whereas it should have been at least one hundred and fifty. The cause of this decrease he believed to be, principally, that sufficiently extensive efforts had not been made to introduce new members. To maintain their tale they must have new members for old. The Association was in need of workers—it had no place for drones. He then asked for entries for the Association prizes, pointing out that last year none were received. He deplored the absolute sterility that had overtaken a previous fecundity of original work, the reason for which appeared to be that the members of the Association were more generally engaged in retail business than formerly, and so had less opportunities for original work. To so great an extent was this the case that research workers in retail pharmacy must now indeed be placed among the *rarœ aves*. Nor was this state of things confined to Great Britain, for, according to Dr. Thoms, the same tendency was at work in Germany. It was perhaps not so much that pharmacy produced fewer workers, as that a smaller number of the workers remained in pharmacy. Paradoxical as it might seem, an explanation of this might be found, to some extent, in the levelling up of education. The pharmacist, to tower above his fellows, must now reach a higher level than formerly, and it required but a short further climb to the rarefied atmosphere of science and medicine; what was more natural, therefore, than that the effort should be made. The removal of these sources of illumination should, however, encourage the lesser lights to remove their bushel, and he hoped to see some revelations during the present session, and some efforts made to remove the stigma and reproach that the Association did no original work. The President next referred to certain criticism of the Association's work, which alleged that the scientific was being subordinated to the social. He showed that but one additional night in each session had been transferred from the scientific to the social side of the programme, the chief alteration being in the character of the social evenings, and personally he could not see that the members were guilty of a heinous crime because they occasionally danced instead of eternally singing. He believed that the work of the Association was not a whit less useful, when providing for the amusement of its members than when providing mental pabulum in the shape of a scientific disquisition. Of the future of the Association he was confident, if the members were true to themselves. They must put energy and enthusiasm into the work, that they might merit the confidence of the outside world of pharmacy, which had so far been theirs. He concluded by thanking those who, by thoughtful suggestions and kindly acts, had helped him in the discharge of his duties during the past session, and expressed his intention to rely on their assistance in the future. He extended a hearty welcome to new members.

Mr. C. J. Strother (Treasurer), in proposing that a hearty vote of thanks be accorded to the President for his very pleasant, eloquent, and genial address, pointed out that the roll of membership does not always constitute the actual number of those connected with the Association. There was a considerable number of assistants who joined the Association and attended its meetings, but omitted to pay their subscriptions. He hoped these would rectify that omission, and thus increase the roll of membership to its proper dimensions.

Mr. Currie seconded the proposed vote of thanks, and congratulated the Association on having retained Mr. Gamble in the chair, because he possessed that rare combination of great technical ability and social capacity.

The vote was carried by acclamation, and in reply the President said the extent of the Association was far larger than its members. Many had left London, but were still in touch with the Association, and in this fact lay its strength. The energy of the members was latent; it merely wanted developing. If they could stimulate it from the latent to the active during the coming winter, they would have done well. It was quite as difficult to maintain a reputation as to make it, and it was the duty of every member to strive to maintain the reputation the Association had gained in the past.

NORTH STAFFORDSHIRE CHEMISTS' AND DRUGGISTS' ASSOCIATION.

A meeting of this Association was held at the Roebuck Hotel, Stoke-on-Trent, on Thursday evening (the 12th inst.). The President, Mr. J. Averill, J.P., of Stafford, presided, and the other members present were:—Messrs. Weston Poole (Treasurer), Edmund Jones (Hon. Secretary), W. Mason, Stafford; E. H. Croydon, Newcastle; T. H. Jenkins, Stone; R. G. Emery, W. Allison, and — Bates, Stoke; T. Charles and — Waddingham, Burslem; W. Hartley and J. B. Blades, Leek; T. Bentley, J. H. Bates, and — Bottomley, Hanley; F. A. Bloor, Longton.

The President, after a few introductory remarks, said the subject of company trading and the assumption of the title of "chemists" by drug companies, which he had selected to address them upon, was an old one, although more alive to-day than at any previous time.

The Main Object of the 1868 Act

was the safety of the public, and it was thought expedient that persons keeping open shop for the retailing, dispensing, or compounding of poisons—known as chemists and druggists—should possess a competent, practical knowledge of their business. The Act, therefore, provided that all persons not already engaged in such a business should, before commencing such business, be duly examined as to their practical knowledge. That was the main principle of the Act. Section 1, said "From and after the 31st day of December, 1868, it shall be unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume or use the title of chemist and druggist, or chemist, or druggist or pharmacist, in any part of Great Britain unless such person be a pharmaceutical chemist or a chemist and druggist within the meaning of this Act and be registered under the Act." Upon that section there was a wide diversity of opinion. He, with many others, thought that a common-sense view of it and of the Charter of Incorporation and the Act of 1852, was that the intention of the Legislature and of the framers of the Act was that no persons should, individually or associated, assume the title of chemist and keep open shop for retailing, dispensing, or compounding poisons unless those persons had passed the qualifying examination and had been registered. But the construction which had been put on the word "person" by the Law Lords and upheld by the present Lord Chancellor, was that the word person should not be extended to a corporation. Although a company consisting of seven or more unqualified persons could not be qualified, those persons might practise as a company without qualification. With all due respect for the noble Law Lords, a more ridiculous construction could not, in his opinion, be conceived. If an individual was to be restricted, why should not an association of seven? Surely an Act of Parliament, passed in the interests of the public and providing that it should be unlawful for "any person" to do this or that unless he were qualified, could not be construed so as to make it legal for seven persons—by forming themselves into a company—to do that which was denied to an individual. Hence company trading had been a bone of contention for a long time: he also thought there was a general feeling that the question had not been sufficiently fought out and that there had been too much waiting for events. The Council of the Pharmaceutical Society was their representative, and thanks were due to the Council for undertaking the arduous duties which fell to its lot; but, at the same time, he was of the opinion that the Council should be urged to take immediate action

For Preventing the Assumption of Titles

and the practice of pharmacy by those who undoubtedly had no legal right to either. They did not ask, nor had they any right to ask for, restriction of the mixed portion of their business; but they had a right to ask for the privileges connected with that part of the business which constituted pharmacy proper. In order to accomplish that object they would have to do more than merely say, "Hear, hear." There must be no apathy; but every chemist and druggist in the country should join in providing a fund for the purpose and make every effort for securing the object in view. If that were done he had little doubt that their just claims would be recognised. If not, it appeared to him that they might as well do away with the Pharmaceutical Society and cancel the Act of Incorporation for the simple reason that neither will be any longer of use to those who have spent their time and money in obtaining a title which could be assumed by several unqualified traders forming themselves into a company. He saw from the Journal, which the Secretary had put into his hands, that the Council intended to take action in framing a clause to be introduced into the Companies Bill. However that might be, he thought that what he had said would only show that chemists in North Staffordshire were in earnest in what they were about, and that they wanted to urge upon the Council the necessity of taking steps in defence of their interests, so as to stop those who were practising illegally and to the detriment of chemists' interests. Previous to moving a resolution on the subject he invited discussion.

Mr. Poole said that no doubt all chemists were making up their minds to work for one end; they were determined not to allow any tinkering with their titles by outsiders. Some people seemed to think that if they got themselves included in a Companies Bill it would look as if they, as chemists, were taking companies under their wing, so to speak. He thought they ought not to allow companies to pursue the practice of pharmacy at all. It was not right that a number of persons who had not passed the examinations should be able to run a business which in the case of an individual would require years of study and preparation. He thought they would be quite

Wrong to Allow Companies to Practise Pharmacy

at all until all the members were qualified individually. He thought pharmacy should be practised only by individuals, and certainly only by legally qualified persons. Some thought they would meet much opposition in Parliament, and that they would not have any chance of getting what they asked for. But if they backed up the Society strongly and in the manner they ought to do, putting the case clearly before Parliament, showing that they do not wish to stop general trade, he was sure Parliament would see that it was not fair for a man to go to the expense of qualifying and then a body of men who had not gone to that trouble and expense should be allowed to enjoy the privileges of qualification. He thought Parliament would perceive that to be grossly unfair, and that such proceeding had also the effect of hoodwinking the public. He thought it was scandalous that people should be allowed to advertise as chemists when they were only a company of moneyed bookkeepers. The public wanted educating to the fact that all those people were not chemists. Doctors would not like a company of merely moneyed men setting themselves up as "cash doctors."

Mr. Jones said that at the present time the questions as to the misuse of titles and as to the construction of that clause in the Act of 1868 dealing with "persons" were the main pharmaceutical topics. Those questions ought to be firmly and energetically taken in hand by the Council. He had come to the conclusion that unless the Council took up those two points and dealt with them forcibly and enthusiastically the Society would be in a very dangerous position. They read from time to time, from week to week, in the journals that Associations in different parts of the country were considering those points and felt very strongly in regard to them. Perhaps some members of the Council did not feel those matters so keenly as chemists in practice outside London and in less favoured situations. But it was evident and should be patent to everyone that the irregular practice of drug companies was endangering the very life of pharmacy and that the object of Parliament in passing that Act of 1868 was being completely nullified. If the Society and the whole of the pharmaceutical body were to take up this matter earnestly they could make an impression upon Parliament which would result in their deriving more benefit from the Pharmacy Acts that they did at present. It seemed to him a farce that men had to work hard and make enormous sacrifices to pass the examinations, whilst others, unqualified and untrained, were allowed to carry on a chemist's business or a drug store by simply having a registered man in charge. He was glad to notice in last week's Journal that the Council is now coming to some definite conclusion as to the urgent necessity of dealing with these important questions. He was delighted to think that in Mr. Young, Mr. Glyn-Jones, and a few others they had some really progressive men on the Council, who were stirring up the Council into taking energetic action in regard to those vital points which so seriously affected chemists in the practice of their business. He hoped that other associations would also express their

Appreciation of the Action of the Council.

He thought it would not be a bad plan if the Federation of Associations would convene a meeting in some central place to discuss important topics like these. He thought they would thus get to know more definitely the opinions of the various associations and support more strongly the Council in dealing with those questions. He was beginning to feel with other members that it was really time that the Council took the bull by the horns and substituted this kind of work for educational work, at least, for a time. It was all right to carry education to a certain point; but in the present state of things they were very much discouraged that there was so much education with increased difficulties at examinations and so little attention given to matters which really affected their very existence, upon which they were dependent for their bread and cheese, so to speak. He hoped that Association, at least, would continue to support the Society, and urge upon the Council activity in reform and progress.

The President then moved, "That this Association protests against the combination of unqualified persons to usurp the rights of qualified persons by means of the evasive procedure of signing a memorandum of association under the Companies Act, and urges the Pharmaceutical Council to promote such legal action as will prohibit absolutely the practice of pharmacy by associations of unqualified persons as well as the assumption of titles by such corporate associations.

Mr. Poole, in seconding the motion, said he wished to emphasise the point that he did not think it fair for any person who was not qualified, to reap benefit, directly or indirectly, from the practice of pharmacy. If seven of his audience wished to form themselves into a company it would be all right, because they were qualified; but, on the other hand, it would not be right for seven unqualified men to form themselves into such a company. If unqualified capitalists wished to run a drug store they would very likely get seven qualified men to put their names down as directors, whilst it would be the shareholders, the capitalists, who would be receiving the direct benefits from the practice of pharmacy. It was not right that they should give the benefit of their brains to a lot of moneyed men.

Mr. Charles: Qualified men should not work for the companies.

Mr. Poole: And then there would be no companies; but I am afraid professional etiquette is not up to that yet.

Several other speakers spoke in similar terms, and eventually a question of supporting the Society in a practical form was talked over, Mr. Blades subsequently moved the following resolution, which was seconded by Mr. Emery, supported by Mr. Charles, and carried unanimously:—"That this Association is most anxious to render every assistance to the Council of the Pharmaceutical Society in such legal action as it may think fit to take in the interests of the chemists and suggests that a fund be established towards which every registered chemist be invited to subscribe."

Three new members were admitted.

At the conclusion of the meeting Mr. Jones said he desired to make a proposition which he felt sure would meet with their cordial sympathy and support. They had noticed that their esteemed Secretary and Registrar, Mr. Bremridge, had quite recently suffered a sad bereavement in the death of his wife. He believed that an expression of sympathy from a meeting of members of the Society would tend to lessen the pangs of his sorrow and be appreciated by him. He, therefore, moved that a vote of condolence be sent to Mr. Bremridge and his family in their affliction.

Mr. Averill said he was glad Mr. Jones had thought of this, and he willingly seconded it, though with a feeling of regret. The name of Bremridge was inseparably associated with the history of the Pharmaceutical Society, and justly held in high esteem. He had pleasurable recollections of the elder Mr. Bremridge, and he felt that they had a worthy successor in his son. He endorsed Mr. Jones's words of sympathy, and he was sure that everyone would cordially support the vote, which was unanimously carried.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first meeting of the winter season took place at the Royal Institution, Colquitt Street, on Thursday, October 12, the senior Vice-President, Mr. J. Bain, in the chair.

Two new members were elected, Messrs. A. E. Killon and A. H. Lodge.

Reference was made to the bereavement under which their respected President, Mr. Edward Evans, was suffering, and a vote of condolence was unanimously passed, at the suggestion of Mr. Bain, seconded by Mr. R. C. Cowley.

The circular from the Pharmaceutical Society respecting the election of local secretaries was alluded to, and it was resolved that the appointment of Mr. John Smith should be supported by all members of the Association, considering the good work he had already accomplished and the study he had made of the duties devolving upon holders of that honourable office.

Mr. John Smith proposed that Mr. Anthony S. Buck as President for the ensuing session, 1899-1900, having regard to the interest he had always shown in the Association and the work he had done, both as a member and as secretary. This was seconded by Mr. Hocken, and carried unanimously.

A paper was then read by Mr. John Smith on "The Federation of Local Associations and the Pharmaceutical Society." (*See* p. 378)

In the discussion following, the President said that the conjoint action of the local Association and the local secretary seemed a reasonable and workable method of perfecting their political machinery, and bringing the latent power chemists possessed more to a focus upon such subjects as might from time to time occupy their attention. He was glad to learn that the aim of the Federation was to assist and support the Pharmaceutical Society, for he had held the opinion—erroneously, perhaps—that it was at fir t rather antagonistic to the Society. However, now that the Federation was going the right way, he hoped it would have their support, and he had pleasure in proposing a vote of thanks to Mr. Smith for his paper.

Mr. R. C. Cowley seconded the proposition, which was supported by Mr. Wyatt and passed amid applause.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

The annual meeting of this Association was held on Wednesday, October 11, the President, Mr. C. J. Park, in the chair. The Secretary, Mr. G. Breeze, presented the

Annual Report,

which stated that the membership was fully maintained, the attendance at meetings during the past session had been good and interest in all matters affecting the trade had been well sustained. The visit of the British Pharmaceutical Conference to Plymouth had been a red letter week in the annals of the Association, a larger demand having to be made upon the members for time and work, and these were most freely and heartily given. During the year many subjects affecting the trade had been discussed, amongst others the necessity of increasing the membership of the Pharmaceutical Society so that it might more fully represent the entire trade. Resolutions in favour of supporting the action of the Society in making the present bye-laws for the compulsory storage of poisons were passed by the Association. Sir John Lubbock's Shop Hours Regulation Bill had also been considered, and a petition in favour of its being made to include in its regulations chemists as far as public necessity would allow was carried. The members had also considered the desirability of shortening the long hours of business observed in the locality and obtained a large amount of information on this point from other towns. Recognising, however, that different localities had different needs, they could not advise that a fixed hour for closing should be observed everywhere alike, but were, nevertheless, of opinion that every effort should be made by individual chemists to shorten the hours of business. Two very interesting lectures had been delivered by Messrs. J. D. Turney and F. R. Talbot to members of the Junior Section, both of which were much appreciated. The year was commenced with a balance in hand of £7 13s. 9d. The income had been £33 14s. 11d., and after all expenses had been met there was a small balance left. Classes had been conducted in Organic Chemistry, Pharmacy, Materia Medica, and Botany by Messrs. H. M. Morgan, O. A. Reade, and F. Hooper.

On the proposition of Mr. J. Davy Turney, seconded by Mr. Lamble, the report was unanimously adopted.

The following new members were nominated: Messrs. S. Gregory, J. M. James, J. Penrose, and W. C. Retallack, bringing the total membership up to 141.

Election of Officers.

The election of officers for the ensuing year resulted as follows:—President, Mr. F. Maitland; Vice-President for Plymouth, Mr. J. Davy Turney; Vice-President for Devonport, Mr. Lamble; Vice-President for Stonehouse and District, Mr. Downing (Launceston); Committee: Messrs. Condy U'Ren, Freeman W. Hunt, and J. Barge (Plymouth), H. D. Davey, and C. T. Weary (Devonport), J. Cocks (Stonehouse); Hon. Treasurer, Mr. W. H. Woods; Hon. Secretary, Mr. G. Breeze; Auditors, Messrs. H. P. Hearder and W. H. Austin. Committee to represent Junior Section, Messrs. H. M. Morgan and Osborne.

On the proposition of Mr. Lamble, seconded by Mr. Palmer, a cordial vote of thanks was passed to the officers for their services during the past year, and the compliment was acknowledged by the Chairman and the Honorary Secretary.

The following were appointed on the Educational Committee:—Messrs. Weary, Park, Maitland, Turney, Morgan, Barge, and G. Breeze.

Mr. F. Maitland returned thanks for his election as President, promising to do his best to forward the interests of the Association, and expressing the hope that the members would work together as comfortably and successfully in the future as they had in the past.

The following votes of thanks were passed:—To Mr. C. J. Park, for a glass presentation case; Mr. J. Maurice, for the weekly journals; Dr. John Attfield, for his framed portrait, and the British Pharmaceutical Conference handsome collection of books.

SUNDERLAND CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held on Thursday, October 12, in the Grand Hotel, Bridge Street. The President, Councillor Thompson, was in the chair, Mr. G. P. Fairman in the vice-chair; others present were Alderman Harrison and Messrs. C. Rankin, J. Mitchinson, R. Robinson, M. J. Todd, H. J. Turnbull, jun., E. R. Cherrett, R. G. Robson, A. W. Golightly, T. Walton, and R. H. Bell, Secretary.

The minutes having been read and confirmed, the Treasurer read the balance sheet, which was very satisfactory.

The Secretary reported that the committee recommended that all mineral acids and caustic poisons be only sold in poison bottles.

Alderman Harrison said that the committee which had the subject before it had come to the conclusion that, although the law demanded that scheduled poisons be sold in poison bottles, it would be a further protection to the public if the chemists themselves would undertake to comply with the committee's recommendation. After further discussion the matter was left in the hands of the Council to see if all the chemists of the town would agree to carry out the recommendation. It was decided to write to the Board of Trade and ask that they take steps to see that all ships going to sea be properly fitted out with medicines according to the regulations of the Board, and suggest that inspectors be appointed to carry out the work, also that such inspectors be competent men, and qualified under the Pharmacy Act.

Mr. Walton said he was very glad the Association had taken this matter up, as it was shameful the condition in which some ships went to sea. In one case he knew of, the chest was used for the captain's clothes, with only one or two bottles at the bottom.

Alderman Harrison said it was very desirable that all ships going to sea should carry medicines according to the scale of the Board of Trade. They had inspectors to see that they had a proper supply of lifebuoys on board of ships, and as medicine was as necessary as lifebuoys, some supervision ought to be exercised by the Board of Trade.

Mr. G. P. Fairman was elected President, Mr. Walton, Vice-President; Mr. J. Mitchinson re-elected Treasurer, and Mr. R. H. Bell re-elected as Secretary.

Votes of thanks to the retiring President and other officers for the past year brought the meeting to a close.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

The annual general meeting of this Association was held at the Westbourne Restaurant, Craven Road, Paddington, W., on Wednesday, October 18. There was a large attendance of members, the President, Mr. J. F. Harrington, in the chair.

The President, in opening the proceedings, expressed the hope that members had come up to the first meeting of the session with a good appetite for work, as there was a great deal to be done in matters pharmaceutical.

The minutes of the last meeting having been read and confirmed, the President proposed that Mr. W. S. Glyn-Jones be elected a member of the Association, and expressed the opinion that he would make a very useful member. The Hon. Secretary, Mr. H. Cracknell, seconded the nomination.

Mr. C. Young was also elected a member of the Association.

In the absence of the Treasurer the Secretary submitted the balance-sheet for the past year, showing a balance in hand of £2 8s. 5d. He said he had great pleasure in reading this report, as it recorded the highest number of subscriptions ever received, namely, 123; he regretted, however, that the balance in hand was less than in previous years. The report was adopted.

Election of Committee.

The following gentlemen were then elected as the Committee for the coming session:—Messrs. Andrews, Bowen, Cracknell, Gulliver, Harrington, Hyslop, Martindale, Mathews, Parker, Philp, Smith, Taplin, Warren, and Worsley.

Mr. Marsh next proposed, and Mr. Philp seconded, "That in future ladies be admitted to the Annual Dinner of the Western Chemists' Association." After a lengthy discussion, Mr. Mather proposed as an amendment "That the matter be referred to the Committee to bring before the next general meeting in December." Mr. Andrews seconded this, and after being put to the vote the amendment was lost by seven to twelve. The original motion was then put, four voting in favour and the majority of those present against the motion.

Messrs. Marsh and W. P. Robinson, on the motion of the President, were then appointed auditors.

Mr. Taplin then inquired if anything had been done by the Committee in regard to engaging a more convenient room in which to hold the meetings of the Association.

The Secretary, in reply, stated that the matter had not been overlooked by the Committee, but nothing definite had been done. There was rather a difficulty in getting a suitable room, and also a difference of opinion amongst the members of the Committee as to where it would be best to hold the meetings. He might say, however, that a more commodious room would certainly be engaged for the smoking concerts.

Votes of Thanks.

Mr. R. A. Robinson then proposed a very hearty vote of thanks to the President and officers of the Association for their services during the past year. They had done a great deal of good in the past, and would have to undertake very responsible duties in the coming year.

Mr. G. S. Taylor seconded, and the motion was carried unanimously.

The President and the Vice-President, Mr. Worsley, and other officers replied, the Hon. Secretary, Mr. Cracknell, remarking that he had served seven years as secretary, and it had been a labour of love but, owing to increasing calls upon his time, he was afraid his term of office was drawing to a close. He had satisfaction, however, in knowing that the Association would have an excellent substitute in Mr. Philp.

Mr. Taylor then said that, as reference had been made to the absence on holiday of the Hon. Treasurer, Mr. J. H. Mathews, he might say that he was thoroughly enjoying himself in the company of another member of the Association, Mr. S. Weston, whom he had last heard from as being at Tangiers.

The Annual Dinner.

The President announced that the Annual Dinner would be held at the Café Royal, Regent Street, W., on November 15. The price of the tickets would be 7s. 6d. each.

EXTRACTS FROM CONSULAR REPORTS.

The Systematic Planting and Cultivation of Kola Trees in the Colony of Sierra Leone, according to a recent report, gives promise of being remunerative, there being a large export trade in kola, which is an indigenous product. The cultivation of the rubber tree is also stated to be remunerative. At present the proper methods of collecting and preparing rubber for the market are unknown to the natives of the Protectorate, who, in their ignorance, cut down trees and vines in the process of collection, and so crude are their methods of preparation that the value of the rubber is said to be much depreciated.

The Two Most Important Chemical Works in Bosnia (Austria-Hungary), Consul-General Freeman states, are the "Holzverwerthungsfabrik" at Teslié, and the "Elektricitätswerke" at Jaice. At the former, methyl alcohol, acetone, pyroligneous acid, acetate of lime, tar, and charcoal are produced; railway sleepers and building timbers are also chemically impregnated to preserve them from rot. A considerable portion of the machinery in the works is at present being reconstructed, as a new patent process hitherto employed did not prove successful, and at the same time the works are being considerably enlarged. About 400 workmen are employed, their pay ranging between 70kr. and 3fl., or 1s. 2d. and 5s. per diem. When the enlargement of the works is complete it is expected that double the number of men will be required.

The "Elektricitats-Actiengesellschaft" at Jaice, it is reported, has obtained from the Government the exclusive right to employ the water power of the famous Sliva waterfall, from which, it is said, 30,000 horse-power can be obtained without detriment to the beauty of the fall. At present only 10,000 horse-power is being utilised for the production of electricity, which is employed as the motive power in large chemical works producing chiefly calcium carbide. The process employed in making the calcium carbide is a secret, and access to the works, said to be the largest calcium carbide works in Europe, is reported to be very difficult.

LETTERS TO THE EDITOR.

Percentage Solutions in Prescribing.

Sir,—In a couple of able papers on "Percentage Solutions" which have recently appeared in your columns, Mr. Upsher Smith, demonstrator of pharmacy in the Society's School, practically commends on grounds of utility the official recognition of, for solids, "grains in 100 minims," whereas Mr. Harold Wilson most strongly protests against such procedure as being little short of heresy, doing away with "that uniformity between the British and metric systems which must pave the way for the complete adoption of the latter in this country," Mr. Wilson recommending "grains in fluid grains" (practically equivalent to grains in 110 minims). The question at issue is consequently conventional utility *versus* Science. Now, the end of science as applied to medicine and pharmacy and all other arts is unquestionably utility, the particular end of pharmacy being the safety of the public as regards accuracy in the administration of medicines; and, inasmuch as affairs have to be judged by their ends, if in British medicine and pharmacy, where grains and minims by long-established custom are well understood, and where liquid medicines are invariably measured instead of weighed, if the end attained in prescribing by conventionally regarding a percentage solution of a solid as "grains in 100 minims," be attended with great accuracy and greater convenience in administration, then any attempt at innovation in the name of science likely to cause confusion becomes an unscientific procedure; and so long as grains and minims possess the field, and so long as physicians in their prescriptions *intend* by a percentage solution "grains in 100 minims," which they do, so long does it become the dutiful handmaid of medicine to so regard it too. To blame the grain and minim which, in spite of it, still bear unscathed the heat and burden of the day, is a procedure not far removed from that of the workman, say a carpenter, quarrelling with his tools, with his "straight-rule," because its straightness is not the straight line of the geometer (length without breadth lying evenly between its extreme points), with his "compasses" be-

cause their points are not points without parts or magnitude. The particular end of the Pharmacopœia being safety, uniformity, and convenience as regards the preparation of medicines, so long as medicines are prescribed in grains and minims, so long ought the preparations of the Pharmacopœia to constitute the means to the end, and be so framed as to best facilitate its attainment (prescribing and dispensing). For a Pharmacopœia to ignore such requirements is but to bring itself into contempt. If a medical man prescribe, say, a two per cent. solution of cocaine hydrochlorate, 2 grains of the salt made up to 100 minims with distilled water is surely the preparation intended; and by a 1 per cent. solution of acetic acid would be implied 1 minim of acidum aceticum, B.P., diluted to 100 minims with distilled water, and not the 1 grain of absolute acetic acid made up to 100 grains with water on a balance, as required by anyone else outside the pale. William Elborne.

Peterborough, October 16, 1899.

Percentage and Other Solutions.

Sir,—In my recent paper on the above subject (*ante*, p. 358, 2nd column, line 9 from top), read "nearly one-tenth stronger" for "more than one-tenth stronger."

London, October 16, 1899. Harold Wilson.

The Study of Visual Optics.

Sir,—Knowing that some readers of your valuable paper are interested in the classes held at Northampton Institute, in connection with the Spectacle Makers' Company examination, and seeing that the class for visual optics is held at 7 o'clock on Tuesday evenings, I should be glad to hear from anyone who would prefer a later class, of say, 8.30 to 10, as it is very inconvenient for many to attend at the earlier time. I might mention that Professor Walmsley, of the N.I., will do his best to provide a class, providing that I can get him twenty names of those who are desirous of a later class. Thanking you in anticipation,

57, *Beaconsfield Road, S. Tottenham,* T. Gardner.
October 16, 1899.

The Society's Local Secretaries.

Sir,—I am obliged by your notes in the Journal of the 14th inst., and as an earnest of the interest I feel in the matter, I enclose you a list of chemists in business in the County of Herts (excluding those in towns having local secretaries), from which you will see that there are thirty-nine chemists who (unlike Mrs. Weller, senior) have no shepherd, and twelve only of those are members of the Society. I am of opinion that the appointment of a local secretary for each Parliamentary division might bring many of these strayed ones into the fold. Local associations are all very well, but I need not tell you that chemists are a peculiar people, and I venture to think that any attempts to unite them in harmonious bonds would have greater power if it came direct from the parent Society, and certainly an official representative of the Society would have greater weight with an individual member of Parliament than one who was merely the spokesman of a local association.

Tring, Herts., October 17, 1899. John W. T. Morrison.

Sir,—In your Annotations last week you refer to Mr. Newsholme's local organisation scheme, and I regret that as yet nothing definite has been done in the matter. Mr. Newsholme not only presented, but also worked out, many details connected with it, and it is hardly to be expected that he should personally visit or write to all local secretaries to invite their co-operation in proposals that would be of immense benefit to all concerned; his time is fully occupied as Vice-President, in London and elsewhere, for the Society's benefit. Let all local secretaries in large centres take the matter up, and get one member of the Society in each parliamentary division to promise to act as assistant secretary, then notify the fact to the Secretary of the Pharmaceutical Society; the Council will then no doubt move in the matter. As soon as the Council is prepared to support the scheme we are ready to organise the West Riding of Yorkshire, and in Sheffield gentlemen have already promised to act as assistant local secretaries in each parliamentary division. As to the proposed meeting of local secretaries in London during the Conference week next year, if anything definite is arranged on the lines of Mr. Newsholme's local organisation scheme, delegates could be appointed and a very representative meeting can be got together, and good work will be accomplished.

Geo. Squire,
Sheffield, October 18, 1899. *Local Secretary.*

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Botanical (G. P.—35/8).—*Physalis alkekengi.*

Glyconin, U.S.P. (F. G.—35/7).—Rub together 45 parts by weight of the fresh yolk of egg and 55 parts of glycerin.

Apothecaries' Hall (B. and C.—35/12).—There is nothing in the Act you refer to that affects the question.

Major Examination (A. W. H.—35/13).—The examination extends over three days. The practical part comes first.

Microscopic Lamp (G. P.—35/9).—We are not acquainted with the lamp you mention.

Sale of Oxalic Acid (A. F. C.—35/11).—The law makes no special provision for such a case, and unregistered persons would be well-advised not to sell the preparation.

Hair Wash (W. J. L.—34/34).—The wash is a solution of silver nitrate, to which an excess of solution of ammonia has been added. The colour of the solution is apparently due to the presence of a very small quantity of a copper salt.

Association of Lady Dispensers (R. K. S.—35/10).—We do not know of any association of the kind you mention, and doubt whether it would be possible to attract a sufficient number of persons to form one. If, however, you were to publish an open letter on the subject in the Journal you might be able to base an independent opinion on the replies you received.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course, not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size, clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Allen, Atkins, Barrett, Bartlett, Beckett, Bell, Bevan, Breeze, Brown, Chesterton, Corder, Corfe, Downes, Eldred, Ewell, Ferrall, Gifford, Gilderdale, Gill, Hewlett, Hudson, Jones, Krischke, Leach, Meldrum, Mitchell, Mohn, Morley, Murray, Pickles, Powell, Reid, Shuttleworth, Spencer, Stokoe, Whineray, Williams.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

PILOCARPUS RACEMOSUS.

A new source of jaborandi, described by Rocher, is *Pilocarpus racemosus*, a native of the French Antilles. The leaves are stated to be rich in alkaloids, containing 1 per cent. of total bases, of which 0·6 per cent. is pilocarpine and 0·4 per cent. jaborine. The leaves also yield a greenish, very aromatic, essential oil, which is under investigation.—*Repertoire* [3], **11**, 439.

ADVENTITIOUS TREE-BUDS.

M. Casimir de Candolle finds a constant difference between the normal and the adventitious buds of trees. The first leaves of a young plant often differ in form and appearance, and even in structure from all the later leaves; and the first leaves of shoots from adventitious buds always have the same character as the young leaves of the species. M. de Candolle therefore regards such buds as new individuals, or as apogamic embryos. An illustration is afforded by the different kinds of leaf in *Eucalyptus globulus*. In the walnut the pinnæ of the young leaves are denticulate, while those of the adult tree are quite entire. In the horse-chestnut the first two leaves have the same form as those which succeed them, but always differ from them in the absence of intramedullary xylem in the larger veins. The leaves of the hornbeam present a similar variation.—*Arch. Sci. Phys. et Nat.*, 1899, p. 100.

RUBBER AND GASES.

D'Arsonval has observed that pieces of rubber tube immersed in CO_2 under a pressure of one to fifty atmospheres, swell considerably and absorb large quantities of the gas. The augmentation of volume is sometimes equal to ten or twelve times the original bulk, and the consistence is changed, the rubber becoming more gelatinous, and less elastic. On being exposed to the air, the dissolved carbonic acid is gradually given off in small bubbles, which give rise to a distinct sound. CO_2 at atmospheric pressure rapidly passes through a rubber bladder, and escapes still more rapidly from a rubber bicycle tyre. Oxygen, under like conditions, was found to behave in a similar manner. The air from a bicycle tyre kept at constant pressure by means of an air pump was examined and found to be practically free from oxygen, and to consist solely of nitrogen. It is known that oxygen traverses thin sheets of caoutchouc much more readily than nitrogen, so that by simple filtration of atmospheric air, a gas containing 40 per cent. of oxygen may be obtained. The author concludes that CO_2 passes through rubber by entering into solution with it, that oxygen does the same, but more slowly, while nitrogen remains longest under pressure in a rubber chamber.—*Comp. rend.*, **128**, 1,545.

CAUSE OF CEREBRO-SPINAL FEVER.

The subject of cerebro-spinal fever has recently been dealt with in an exhaustive manner by Dr. Osler in the Cavendish Lectures. This disease occurs epidemically in certain waves or periods of which the fourth during the present century is now prevailing in the United States. In intervals of epidemic prevalence sporadic cases occur. Weichselbaum described a *Diplococcus* with special cultural peculiarities in this disease, and the observations on the cases in Dr. Osler's clinic fully bear out the specific nature of the *Diplococcus intracellularis*, and its ætiological relation to cerebro-spinal fever. Out of fourteen cases it was found during life (by lumbar puncture) in thirteen, the fourteenth being doubtful. The organism has usually a *Diplococcus* form, and lies within the polynuclear leucocytes. It grows best on Löffler's blood serum, on which it forms round, whitish, shining, viscid-looking colonies, which attain a diameter of 1-1·5 Mm. in twenty-four hours. It can also be cultivated on glycerin-agar, but soon dies out. It does not stain by Gram's method. Sporadic cases of cerebro-spinal meningitis may also be caused by the *Pneumococcus*, but they differ in many essentials from the epidemic cerebro-spinal fever.

FORMATION OF PIGMENT BY BACILLI.

A number of experiments have been carried out by Boland on the formation of pigment by the *Bacillus pyocyaneus* (*Centr. f. Bak.*, xxv., p. 897). He finds that this organism forms only two pigments, a fluorescent one, apparently identical with that formed by many other bacteria, and the blue pigment pyocyanin, which by oxidation becomes converted into a reddish-brown pigment, pyoxanthose (pyoxanthin). A blue chloroform solution of pyocyanin becomes quickly changed to a green by sunlight. A blue watery solution of pyocyanin is likewise changed by chlorine. The green chloroform solution treated with dilute (1 : 3) sulphuric acid becomes a deep yellow; with dilute hydrochloric acid (1 : 3). The former mixture on being neutralised with an alkali again gives a green solution on shaking with chloroform, the latter by the same procedure yields a blue solution.

FORMALDEHYDE DISINFECTION.

Formaldehyde disinfection is carried out in an extremely simple manner in Chicago (*Bull. of the Dep. of Health, Chicago*, May, 1899). The room to be disinfected is sealed and prepared as usual for sulphur disinfection. All its surfaces are exposed as much as possible, cupboard doors opened, clothing hung on lines, mattresses set on end, etc. For every 1,000 cubic feet of space an ordinary cotton bedsheet (2 by 2½ yards), is suspended by one edge from a line stretched across the middle of the room—as many sheets as necessary being used and hung at equal distances. Properly sprinkled, each sheet will carry without dripping, 5 ounces of formalin—the 40 per cent. solution of formaldehyde. The operator, with a damp cloth tied over his mouth and nose, then rapidly sprinkles each sheet with this amount of formalin, by means of a special spray producer. Commencing at the sheet furthest from the exit, the spraying has to be done expeditiously, as the air becomes irrespirable in about three minutes. The room is closed and left so for not less than five hours.

EVIDENCE OF SEWAGE POLLUTION.

Some experiments have been made by the Chicago Health Department on the presence of Klein's *Bacillus enteritidis sporogenes* in water as evidence of sewage pollution. Klein and Clowes found this organism to be always present in sewage, and suggest therefore that its presence in drinking water may become one of the most delicate and valuable evidences of the sewage pollution of potable water. Dr. Gehrmann, of the Chicago Health Department, examined forty-two specimens of sewage, one hundred and thirty of city drinking water, sixteen of milk, eight of garden earth, and one of cheese. Bacteria of the species described by Klein were found in all the specimens of sewage. With the drinking water the results were practically negative, even during a recent pollution in which the *B. coli communis* was abundantly demonstrated. The method, therefore, does not seem to be of great value for the examination of drinking water. The *B. enteritidis sporogenes* was not found in the milk (*Bull. of the Chicago Health Dep.*, July, 1899). [The writer believes that the *B. enteritidis sporogenes* is a widely distributed organism and is not unfrequently present in the normal intestine. As regards the presence of this organism in milk, the writer's experience agrees with that of Klein, viz., that it can be demonstrated in a large proportion of samples.]

THE COMPANY PHARMACY PROBLEM.—II.

BY AN ORDINARY PHARMACIST.

As I explained in a former contribution (*ante*, p. 382), it was, beyond question, originally intended—both by those who framed the Bills which became the Pharmacy Acts and by the Legislature—that all proprietors of pharmacies should be duly qualified and registered. But, by the accident of judicial interpretation, it has been assumed for the past twenty years that only the actual sellers of scheduled poisons—whether proprietors or assistants—need be legally qualified, and that even they have no exclusive right to the titles which were formerly supposed to be protected by the Acts. I say advisedly "by the accident of judicial interpretation," for I think there is little reason to doubt that if the actual seller employed by the London and Provincial Supply Association had not been a duly registered person, and if all the circumstances of the case had been fully considered, the result of that case would have been the reverse of what it really was.

The Judicial Opinions.

As things were, the judges who first had the case before them, in the Queen's Bench Division, were strongly of opinion that there was nothing inconsistent in interpreting the word "person" in Sections 1 and 15 of the Pharmacy Act, 1868, so as to apply to artificial persons created by law, as well as natural persons. They also held that the danger sought to be guarded against by the Act was the keeping open shop for the compounding, dispensing, or retailing of poisons by other than registered chemists, and that it was immaterial whether the unqualified proprietors of shops were natural or artificial persons so far as liability under the Acts was was concerned. But the judges who next had the case before them, in the Court of Appeal, were just as decided in the view that there was no need for making the word "person" in the Pharmacy Act include artificial persons. They held that individuals alone could be intended by the term "person" in Sections 1 and 15, and that the danger sought to be guarded against by the Act was the actual compounding, dispensing, or retailing of poisons by individuals who were not registered chemists. With regard to the judges who heard the final appeal, in the House of Lords, they appear to have been quite of the opinion that, if the individual actually conducting the business for the company had not been legally qualified, considerations of policy might have rendered it desirable to prevent the company carrying on the business of a chemist and druggist. They seem, however, to have been unduly impressed by the fact that the actual sale was effected by a duly registered person, and they gave the fatal judgment against the Pharmaceutical Society, under the mistaken impression that the public safety was, thus, sufficiently safeguarded, their sole justification being that it was not specifically stated in the Pharmacy Act of 1868 that the word "person" should be held to include artificial persons created by law as well as natural persons.

The Resulting Position.

It seems to me, therefore, as it has probably occurred to others, that if this test case had been brought against a company which did not employ a legally qualified person to retail scheduled poisons, the House of Lords decision might have been very different. The apparent safeguard provided by the handing over of the poison by a duly registered individual would have been non-existent in such a case, and the red-herring it provided could not have been drawn across the judicial path. But it is useless to cry over spilt milk, and we have to recognise the fact that the judgment of the House of Lords was so far-reaching that companies are apparently absolutely excluded from the operation of Sections 1 to 15 of the Pharmacy Act, 1868; that is to say, of just those Sections which were formerly supposed to restrict the use of pharmaceutical titles and the sale of scheduled poisons to registered individuals. In other words, laws adopted—in the interests of the public safety—with the expressed object of preventing any but duly qualified individuals from using certain titles and keeping open shop for the compounding, dispensing, or selling of poisons, have been judicially interpreted to imply that seven unqualified individuals can combine to do what one may not, and that, by fulfilling certain trifling formalities, even an unqualified individual can occupy a position which is absolutely identical with that acquired by registration under the Pharmacy Acts in everything but the legal qualification they require.

The Question of Invested Capital.

Apologists for this state of affairs protest that it does not differ essentially from that implied in the case of a registered chemist who commences business with borrowed capital. Such, however, is far from being a reasonable view of the position. For the borrowing of capital is an affair which concerns no one but the lender and the borrower; it does not, in the least degree, affect the manner in which the chemist's business is carried on. The lender, whatever interest he receives on his money, does not share the profits of the business. If he did, that fact would constitute him a partner in the concern and, if not legally qualified, he could be proceeded against for infringement of the Pharmacy Acts. But shareholders in a company are the actual proprietors of the business carried on; they do not receive a fixed and unvarying interest on their invested capital, whether business has been good or bad, but a proportionate share of the profits, whatever those may be. Each shareholder, in fact, is in the same position as the individual proprietor of an ordinary business, and is recognised by the law as being such for all purposes except those of the Pharmacy Acts. The absurdity and unfairness of the latter position should be obvious to all unprejudiced persons.

A Qualified Manager Not Sufficient.

It is needless to say that I do not grant that the public safety is as efficiently safeguarded by a qualified manager as by a qualified proprietor. The latter has the control of the business absolutely in his own hands; he need consult no one with regard to what he may or may not sell; and he will usually be found to give full consideration to public interests, altogether irrespective of his own personal profit. A manager, on the other hand, acts under control; is not at liberty to decide upon what lines the business shall be conducted; his chief aim is to give satisfaction to his employers, increasing the business turnover at all costs and considering public interests no more than is absolutely necessary. No manager ever is, or can be, the same as the proprietor of a business, and in a case where the professional element prevails to the same extent as in pharmacy, the difference is not only one of degree but also essentially one of kind. The public interest suffers, in fact, in direct proportion to the lack of attention a pharmacy receives from its proprietor; in the case of a company carrying on the business of a chemist and druggist, it is, of course, an absolute impossibility for any personal attention whatever to be given by unqualified proprietors.

The Suggestion of Vested Interests.

Turning next to the suggestion of vested interests, we are told that such interests have been created by companies of unqualified persons, trading as chemists and druggists during the past twenty years, and must of necessity be recognised. But surely the fact that—through an oversight on the part of the Legislature or a judicial misinterpretation—an evil has existed for even twenty years is no sufficient reason for calling wrong right and, now, legalising what existing Acts of Parliament were meant to suppress—in this instance, the practice of pharmacy by unqualified persons. Moreover, we must not ignore the fact that, if the public safety in regard to the sale of poisons is sufficiently safeguarded by placing a business belonging to seven unqualified persons under the control of a qualified manager, it cannot be less satisfactorily cared for if a business belonging to a single unqualified individual is carried on under the same conditions. Those in our own ranks who now advocate recognition of companies of unqualified persons, as competent to carry on the business of a chemist and druggist, usually fail to see

how far their arguments lead them. What is right for seven individuals to do, cannot be wrong for one, and if the principle of proprietary qualification be once abandoned, we may as well ask for the repeal of the Pharmacy Acts straightway. Let us be consistent and have free trade in pharmacy, absolute and unqualified, if necessary, but do not impose obligations on individual pharmacists which are not otherwise equally binding.

A Proprietary Qualification Essential.

The pharmaceutical qualification must be an individual and proprietary one, or else fade out of existence as a legal necessity. Before Pharmacy Acts were, pharmacists occupied an honourable position in the land and, in spite of perverted Pharmacy Acts, pharmacists occupy a similar position to-day. Indeed, it is not too much to say that the leaders of our craft are men who can afford to despise all opposition, whether of companies, of drug-stores, or of any other description. Personally, I should be quite content to have my title protected; for the rest, I am prepared to depend upon my professional training and business capacity. But several thousands who have been induced to select pharmacy as a career, have done so in the full belief that the use of the titles they had to work so hard to obtain would be restricted to themselves and similarly qualified persons; they have also been imbued with the idea that, once qualified, they would be able to do what no unqualified person could do. They thought, and were justified in thinking, that the Pharmacy Act of 1868 was intended to prevent any but duly qualified individuals from using pharmaceutical titles or keeping open shop for the compounding, dispensing or retailing of poisons. In such cases, of course, a rude awakening has come; but the fact remains that the State is morally bound to do something to indemnify those persons, and the very least that can be done is to make the provisions of the Act applicable as they were originally intended to be.

What is Required.

No amount of hair-splitting by any number of legal authorities ought to be allowed to nullify the common-sense interpretation of a Statute, even if badly drawn. But if it should appear that, under present conditions, neither titles nor the practice of pharmacy can be restricted to those who have acquired the qualification required by law, the sooner the defect is remedied the better. But that must not be at the cost of concessions on our part in favour of companies of unqualified persons. Modify the "Widow's Clause" by all means; insist upon the due qualification of wholesale dealers in poisons; in fact, repeal Section 16 of the 1868 Act in its entirety if necessary; but let us, at least, endeavour to realise the ideal embodied in the preambles to the Pharmacy Acts. If care for the public safety requires no more, it certainly requires that. The suggestions for a draft Pharmacy Bill, which were submitted to the Lord Chancellor, covered much more than those preambles, but such as those suggestions were, they had the approval of all our representatives on the Council of the Pharmaceutical Society, except Messrs. Martindale and Glyn-Jones. The latter was not a member of the Council when the suggestions were agreed to, and our present worthy President was travelling abroad at the time. But nineteen out of the twenty-one members were, thereby, committed to the principle of proprietary qualification; five of them may reasonably be regarded as having been re-elected in May last on the assumption that they would continue to maintain that principle. I would be one of the last to suggest that a member of Council is a mere delegate, elected to say and do what his supporters require of him; but I am decidedly of opinion that not a single member would be re-elected to-morrow if, in offering himself as a candidate, he proposed to support a movement to register and regulate companies of unqualified persons trading as chemists and druggists.

The Irreducible Minimum.

By all means let us be content with the restriction of the use of titles if nothing more can be secured; but we must not overlook the Lord Chancellor's desire to bring companies—as ideal persons—within the law. From the pharmacist's point of view that can only be done by providing—as actually proposed by the Lord Chancellor and embodied in Clause 2 of the Companies Bill—that, in all respects, a company shall be amendable to the provisions of the Pharmacy Acts in the same manner as individuals now are. The public safety would thus be properly safe-guarded, there would be nothing to prevent a properly-constituted company from carrying on the business of a chemist and druggist, and the intention of the Pharmacy Acts would be fully realised. As I have previously stated, there is no occasion to attempt more than that in connection with the Companies Bill. But we should afterwards require to set our own house in better order, and an undertaking might well be entered into with the Government, by our leaders, to draft a Pharmacy Acts Amendment Bill which should provide for the removal of all anomalies now existing. For the present, however, our chief aim should be to prevent the recognition of the pretended right of companies of unqualified persons to assume and use our titles, or in other ways to evade the provisions of the Pharmacy Acts. Companies of duly qualified persons need not be interfered with, and even where, owing to family arrangements, part of the capital invested in such companies belongs to unqualified individuals, it ought not to be impossible to devise some generally satisfactory means of overcoming that difficulty. It may even be rendered possible for existing companies of unqualified persons to bring themselves into line by some such means; but, in such an event, no unqualified person must be permitted to enjoy any advantage from the use of our titles, nor to exercise any control over the conduct of the business. And, in any case, whether the clause to be inserted in the Companies Bill should be similar to the one I have suggested (*ante*, p. 383) or not, we must insist upon the imperative necessity—in the public interest—of preventing any unqualified person or persons from using pharmaceutical titles or carrying on business as a chemist and druggist.

SOME ANCIENT HISTORY RELATING MORE OR LESS TO "COMPANY PHARMACY."

In view of the fact that the House of Lords' decision in the case of the London and Provincial Supply Association, Limited, enabled a company, necessarily without qualification, to keep open shop for retailing, dispensing, or compounding poisons—thus providing a means by which any individual associating with himself six dummy shareholders could carry on that business without the qualification the Act requires—the circumstances which chiefly led to that decision required especial consideration by the Committee that was then charged with the preparation of an amending Bill. Those circumstances were:

First, the exemption in reference to the continuance of the business of a deceased chemist, as provided in Section 16 of the Act, and commonly known as the "Widow's Clause."

Secondly, the proviso that a business carried on under that exemption should be *bonâ fide* conducted by a person registered as a chemist and druggist under the Pharmacy Act.

The conclusion of the Judges was that such a condition would be, in any other case, sufficiently in accord with the object of the Act.

The Draft Pharmacy Bill prepared in 1881 therefore comprised a provision for limiting the period during which a deceased chemist's business could be carried on by executors, etc., who would presumably be unqualified persons. Another clause provided that the Registrar should have power to call for the names of persons keeping open shop for retailing, dispensing, or compounding poisons, or exhibiting any title implying registration under the Pharmacy Acts, and that persons failing to supply the information should be liable to penalty. A third clause specifically provided that the word "person" in the Pharmacy Act should extend to corporate bodies, and that the persons on whose behalf any assistant or apprentice acted, should be liable for the acts of their agents.

Lastly, the application of the Pharmacy Act was extended to the retailing, dispensing, or compounding of all medicines.

Those provisions struck at the root of the grievance of company trading as it affected chemists and druggists, in consequence of the House of Lords' decision, and the enactment of those provisions would have been the means of putting an end to the unfair competition of unqualified persons made possible by evasion of the Statute in that way. The importance of supporting such amendment of the Act was pointed out at the time in the Journal, as well as the necessity of impressing upon the Legislature the fact of the natural connection between the effect of that amendment and the statutory demands made upon chemists and druggists, in order to counteract the prevailing tendency of Parliament to look with disfavour upon any measure supposed to be in any degree antagonistic to free trade principles. The further necessity of making individual views subordinate to the general interest, for the sake of overcoming difficulties arising from difference of opinion within the trade and external antagonism, was also pointed out, as well as the circumstance that the contemplated appeal to public opinion, as expressed by Parliament, meant war to the knife with company trading and the simulations of co-operative stores, in regard to the practice of pharmacy and to the practical significance of the Pharmacy Acts.

The expression of opinion at that time, in correspondence and otherwise, is in many respects interesting to revert to, since it frequently shows a defective appreciation of the conditions which are most essential in the interests of chemists and druggists, as members of a privileged body, and much want of disposition to adjust differences to mutual advantage.

The first letter that appeared on the subject after the House of Lords' decision was from

JOSEPH LEAY, objecting to the practice of keeping branch shops, as an encouragement to stores.

"NO JUDGE" pointed out that while the Act requires a qualified master, and does not require qualified assistants, the judgment reversed that position for the illogical reason that a corporation cannot qualify.

"MAJOR" spoke of the practice of keeping branch shops in the charge of unqualified assistants as an effectual barrier to the proposal that only legally qualified persons should be allowed to carry on the business.

G. N., *Wandsworth*, suggested that the decision had been arrived at from a point of view too much neglected by chemists and druggists, viz., that the personal qualification of individuals engaged in dispensaries, etc., was the chief thing of importance to the public.

"WEST END" took the same view, and expressed the opinion that legal qualification was as necessary for assistants as for the owner of a chemist's business.

W. T. TUCKER, *Kilburn*, pointed to the inconsistency of allowing widows—unregistered -to carry on business while expecting legislation to prevent other unregistered persons from doing so.

Strange to say, these were the only comments on the House of Lords' decision : but, after the draft of a Bill had been adopted by the Council and published in January, 1881, a considerable number of letters appeared on the subject. The views therein expressed may be gathered from the following précis :—

G. W. SANDFORD objected to the proposed amendment of the 16th section of the Act, because it would "spoil widows' houses," and suggested as more reasonable that the exemption should apply to widows, as widows, and not to executors.

EDWARD SMITH, *Torquay*, suggested that the intention and provisions of the Act required better definition—that the Council should be relieved from the duty of adding to the poison schedule, since that invidious position afforded opportunity for imputations of bias in favour of trade interest.

JOHN TERRILL objected to the proposed amendment of the Widow's Clause as condemning to poverty the children of all chemists who die before they have been able to make adequate provision for their families.

"SEMPERVIRENS" lamented the absence of provisions compelling proprietors of branch shops to employ legally qualified assistants and making the Preliminary Examination compulsory before apprenticeship.

W. S. T. suggested that legal qualification of wholesale chemists was desirable, since it is necessary for the preparation of medicinal articles as well as for their sale.

THOMAS GREENISH (then President of the Society) suggested that it would be a mercy to the widow of a deceased chemist to be compelled to dispose of the business soon after the death of her husband—that the "Widow's Clause" permitting a qualified assistant to conduct a business, was at variance with the spirit of the Act implying personal qualification of the proprietor—the stumbling-block making the administration of the Act crooked, illogical and suicidal—a provision that opened the door for assistants to conduct a business, the owner of which was not qualified—that would be a stumbling-block in the future.

"The safety of the public, the advance of medical science, and the progress of pharmacy, with the well-being of the pharmacist, can be secured only through the personal qualification of the owner of the business being insisted upon, and this personal qualification can only be obtained by evidence of fitness shown in the examination room ; a qualified assistant is only a subordinate, and cannot as such be considered a free agent."

CHARLES SYMES urged that since the main feature of the Pharmacy Act is the safety of the public, individual proprietors of chemists' shops should be qualified—if that principle was lost sight of, the Act was not worth a straw and the chance of benefiting the trade would disappear. The writer added "The legislature is surely not so blind as to believe that the public are protected by (an unqualified) widow or executor carrying on a chemist's business by means of a qualified assistant for an indefinite period, and are not protected if a corporate body does the same thing."

W. WILKINSON, *Manchester*, supported Mr. Sandford's view out of sympathy for widows : but, with exception of the jury clause, thought the Bill would not be of any advantage to chemists and druggists, whilst adding to the vexations and annoyances they were already subject to. The writer thought the real evil to be remedied, viz., the selling of drugs and medicines by co-operative stores, grocers, etc., would not be touched, while the restrictions imposed by the amended Act would be vexatious to the chemist and druggist without being protective.

GEORGE BROWN suggested for consideration a draft clause "that it shall be unlawful for an unregistered person or partnership or body corporate to supply by retail, or to employ any servant, agent, or deputy, to act as a dealer in any of the poisons enumerated, or to compound any medical or veterinary prescriptions or private recipes containing any of the aforesaid poisons, under a penalty of five pounds for each offence. The exemptions in favour of medical men and veterinary surgeons to remain as at present."

GEORGE MEE asked whether the sympathy exhibited for widows was sincere ? and suggested that Mr. Weller's advice should not be lost—that business conducted by widows of deceased chemists was a terrible farce—that the demand for personal qualification, on the one hand, and interested laxity on the other, had made the Acts, abortive and would continue to do so until a bishop was translated and the Government took the matter in hand.

G. J. GOSTLING, *Stowmarket*, supported Sandford and widows but suggested that no branch shop should be carried on without a registered person in charge, his name to be reported to the Registrar annually, or as changes might require.

THOMAS BLACKMAN, *Stow in the Wold*, supported Sandford and

widows, suggesting also a bye-law that any chemist taking service with a co-operative society should be struck off the Register.

E. B. Vizer, *Brighton*, could see no practical good in the suggested amendments, that would improve the Act. While supporting Sandford as to widows, he doubted whether the other amendments could be considered beneficial to the general interests of the trade, and that conclusion had been supported by a canvass of the chemists of Brighton, thirty-seven out of forty-two having signed a memorial to that effect.

Henry Long considered that a deceased chemist's business ought to be continuable, if conducted under proper management, and that in every business assistants ought to be legally qualified.

M.P.S., *North Staffs.*, failed to see any plan of dealing effectually with stores; but suggested as a suitable clause that from the date of the passing of the Act no person or persons should sell or deal in drugs or chemical compounds unless such person shall be a duly registered pharmaceutical chemist or chemist and druggist within the meaning of the Act.

P.M., assistant, considered the omission of provision to deal with branch shops a mistake, and stated that out of thirty shops of druggists and doctors in his town, fifteen were in charge of—in fact, kept by—unqualified persons. Hence he suggested that there should be at least one qualified person in each shop before seeking to repress the wickedness of co-operative pharmacy.

Barnard Proctor, *Newcastle*, expressed regret that a "narrow and selfish tone" was apparent in the correspondence: agreed that public safety requires owners of pharmacy to be qualified, though legislation in favour of druggists could not be looked for or asked for—that neither widows nor co-operative stores should be allowed to carry on the business, and that if a qualified assistant was a sufficient safeguard in the one case, it should be in the other; but in any case every branch shop should have a qualified person in charge.

G. S. Woolley, *Manchester*, held that "wives" houses' were also to be considered—if executors might carry on business, there was no reason why a company should not. To ask the one and disallow the other would ruin the chance of an amended Act that would satisfy the trade.

C. B. Allen, *Kilburn*, regarded the antagonistic feeling within the Council on a vital point as not reassuring—the difference of opinion as unaccountable and likely to be disastrous, since the Act had been practically annihilated, and the proposed amendment seemed likely to share the same ignominious fate. To the general public the widow of a deceased chemist is of no importance, and the softest-hearted judge might be easily persuaded that a business could be conducted better by a miscellaneous corporation under a qualified manager than by a widow in a like position.

Fred Taylor, *Tiverton*, supported the proposed amendment of widow's clause.

Stafford thought the Bill not bold enough, and that to be consistent, all branch shops should have qualified assistants.

M. P. S. ridiculed the inconsistency of prohibiting companies or other unqualified persons while allowing widows to carry on business without qualification.

Warwickshire suggested that there might be proper means of using the name of a predecessor without actually trading under it—Employing a qualified manager, registered and represented to be the proprietor—Would compel registration of persons in business, whether alone or in partnership, and exhibition of their names over shops—Inconsistent that unqualified widows should be allowed to carry on business, since women are admitted to qualification and membership. The philanthropic view is extraneous to the consideration as to safety of public.

At the Council, February 2, 1881, various communications from the country, in reference to the proposed amendment of the Act, were read and considered.

J. Mackay, on behalf of the North British Branch of the Society, strongly opposed amendment of widow's clause, and would rather favour a special adaptation to the case of widows—otherwise no opposition or amendment.

Among the resolutions forwarded were the following:—

Edinburgh meeting thought principle of personal qualification would be more jeopardised by raising question as to widows than it then was.

Glasgow objected to amendment of widow's clause.

Liverpool approved of amendments and would support Bill.

Rochdale approved generally, and suggested that co-operative stores and widows must go together; that branch shops with unqualified assistants were contrary to the spirit of the present Act and the proposed amendment.

Sheffield cordially approved.

South Hackney, R. O. Fitch and J. A. Clark, suggested slight alterations.

Brighton sent memorial expressing decided disapproval to amendment of widow's clause.

Mr. Sandford mentioned letters from Mr. Keen, Fenchurch Street, and Mr. Balkwill objecting to amendment of widow's clause, and suggesting provision for branch shops.

Mr. Frazer's motion to omit "medical prescriptions" and substitute "containing scheduled poisons" was negatived. He objected to the extension of the Act to non-poisonous drugs in prescriptions, and to putting further chains on chemists which could not be imposed on others, leaving chemists free, and he drew the line at poisons.

Mr. Frazer moved that amendment of widow's clause be erased Sandford seconded.

J. Mackay supported, and spoke of the strong feeling in Edinburgh, adding also that the argument about stores carried no weight and no conviction, since a widow was in a totally different position to a company. Motion lost, 13 against, 8 for.

Mr. Frazer moved his remaining amendments without finding a seconder, so that the Draft substantially received the assent of the Council, and the Committee was requested to approach the Lord President of Privy Council to explain the provisions agreed to, and induce him to take charge of the Bill in Parliament.

Pelham C. Maitland, *Stonehouse, Plymouth*, expressing the views of some fatuous chemists who would make a demand for monopoly of drugs and pharmaceutical preparations, asked what else do chemists want but legislation in favour of the druggist?—that is the burden of their cry—could not understand Mr. Proctor, and thought a widow's business conducted by a qualified assistant would not be worse than the case of a business in which the proprietor is seldom seen, although it may be left to unqualified assistants.

C. M. remarks, with involuntary sagacity, that if the late law appeal had been sustained, nothing would have been heard about amending the widow's clause. The inference is not equally sagacious; that intense selfishness was at the bottom of that amendment. Council should try some other means for getting rid of co-operative stores trading in drugs, than sacrifice of the chemist's widow.

E. G. Hughes, *Gloucester*, thinks chemists jealous and narrow-minded; they had better pay a tax and place themselves under Government supervision so as to increase the confidence of the public and obtain medical practitioners' dispensing.

J. R. Cooper, *Canterbury*, did not see beyond the trade in "patents."

G. Burrell, *Montrose*, thought it not at all presumptuous of a pharmacist to take a "statesmanlike" view of pharmaceutical legislation—that it is his interest to do so if he expects his Parliamentary representative to support legislation for his benefit.

From that point of view two leading principles should be considered, viz.—

1. The safety or greater good of the public.

2. Individual qualification and responsibility of the persons instrumental in securing that object.

SANDFORD's view would be destructive to the second—legal qualification, because a personal matter, cannot be transmitted with a business—Vicarious management is against the object of pharmaceutical legislation and the real interests of the trade.

ED. PRATT, *Barnstaple*.—Retention of widow's clause would be a great mistake, for if a pharmacist's business is to be carried on by an assistant, a co-operative store cannot be prevented from doing the same. If chemists hope for amendment beneficial to them as well as to the public, they must throw "crochets" to the wind and approach Parliament as a united body, asking for what can be justly claimed—in such united action lies the only chance of sucoess.

CHEMICUS does not appear to perceive that restrictions on the exercise of the chemist's business are the only form in which its protection can be looked for.

D. H. F., *Hampshire*, overflowing with benevolence and sympathy for widows, deplores the possible sad case of an unqualified assistant of a deceased chemist, who would have to be superseded by a qualified, and perhaps younger, man so that, besides the loss of her husband, the widow would suffer the further deprivation of the services of a good servant who had proved useful for many years.

G. G. HORNSBY, *Brighton*—Is the personal qualification of the proprietor of a business the only desideratum for the public safety? If personal qualification be the principle relied on, why not a clause to prevent proprietors of branch shops carrying on business without qualified assistants? Chemists belong to a trade, and it will be time enough to have recourse to the argument that a doctor's or lawyer's widow cannot continue her husband's business when chemists have acquired a professional position. Nonsense to contend that the widow's case is the same as that of private firms, companies or individuals, established on the unqualified basis for trade purposes only.

A. J. GOWER, *Vassall Road*—Argument against a widow continuing a business is equally cogent against branch shops—if that cannot be prevented, sacrifice of the Bill would be better than injustice to widows.

A. P. S. held that it is absolutely necessary that the individual proprietors of chemists' shops should be qualified—that a qualified assistant cannot confer qualification upon his employer. That branch shops should be managed by qualified persons only. Upon those lines he urges that chemists should strive for legislation that would restrict to them the dispensing of prescriptions and the sale of poisons.

PHILOS thought those who contended that chemists could not ask Parliament to prevent grocers' companies and unqualified individuals from carrying on the business of a chemist and druggist, because the widow of a deceased chemist might do so, were engaged in a "war for an idea," and did not recognise the essentially different position of a chemist's widow and the widow of a doctor. As a means of meeting the case he suggested that a registered chemist should be appointed as trustee to carry on business for a widow.

R. L., *Peebles*, thought that, in the diversity of opinion, sentiment prevailed over argument. Holding to the principle of personal qualification, he suggested that all branch shops should be in charge of qualified persons in order to provide the desirable protection to the public, and to counteract the arguments that could be put forward on behalf of stores by a large section of the community.

T. R. GIBBONS, *Manchester*, suggested that one important factor had been overlooked—viz., what is the Legislature likely to grant? In that respect he thought a provision that widows should be enabled to continue their husbands' business would be suicidal, since there would be, for the public, no difference between a widow and a company carrying on business by proxy. Then, without a suitable provision for the evil of branch shops, there would be little chance of an amended Bill. Moreover, there is great excuse for the widow, but none for the pluralist.

H. R. insists upon the difference between the case of a widow and that of a business which never had a qualified owner, and suggests that much good might be done by better use of the powers conferred by the Pharmacy Acts as they stood.

P. MACEWAN, *Dundee*, referred to the supposition that it is expedient for the safety of the public that trading in pharmacy shoulp be conducted by persons certified to be qualified for that purpose, and pointed to the fact that the spirit of the law was to a great extent violated by carrying on branch shops which were not always managed by qualified persons, and suggested also that the practice was a source of internal weakness.

A COUNTRY CHEMIST, *Kettering*, referring to the opinion, expressed in the course of the recent litigation, that for some purposes of the Act the seller of a poison might be understood to mean the person who effects the sale, suggested that it might lead to the infliction of serious injury in some cases of an attempt to prevent apprentices or unqualified assistants from selling any scheduled poisons, but he supported amendment of the widow's clause, and thought that consistency also required restriction of branch shops.

G. P. POND dealt with the difference between the case of a widow and a company, as being in the nature of things sufficient to justify a distinction between them, and sarcastically advocated, in regard to branch shops, that they should be done away with altogether by prohibiting a chemist from leaving his shop for any purpose during the hours of business.

ALFRED JONES, *Scarborough*, writing under the impression that the Pharmacy Acts had been more beneficial to the oilman, the grocer and the stores than to the legally qualified chemist, asks "What are our privileges?" but instead of answering the question loses himself in irrelevant remarks on medical dispensing and "the patent medicine question."

VIGILANS, in the last letter that appeared on the subject, pointed out that a provision for continuing a deceased chemist's business should consider widowers as well as widows, since women could qualify and might carry on business on their own account. The writer also suggested that qualifying under the Pharmacy Act might in future become a "woman's mission," so as to provide for marriageable men unable to pass the examination, and thus there would be another way of evading the Act, in accordance with the provisions of its 16th section.

At the Council Meeting on March 2, 1881, reference was made to the Bill in connection with communications from the Privy Council Office in regard to chloral hydrate and other poisons. An official announcement was made that the Chemists' and Druggists' Trade Association would co-operate with the Council in support of the Bill.

At the Council Meeting on May 4, 1881, a letter from the Privy Council Office, dated April 6, was read, stating, in reply to the Council's application of February 16, that "after a review of the whole correspondence" on the subject, and careful consideration of the draft Bill, the Lord President was not prepared to submit the Bill framed under the direction of the Society for consideration by Parliament.

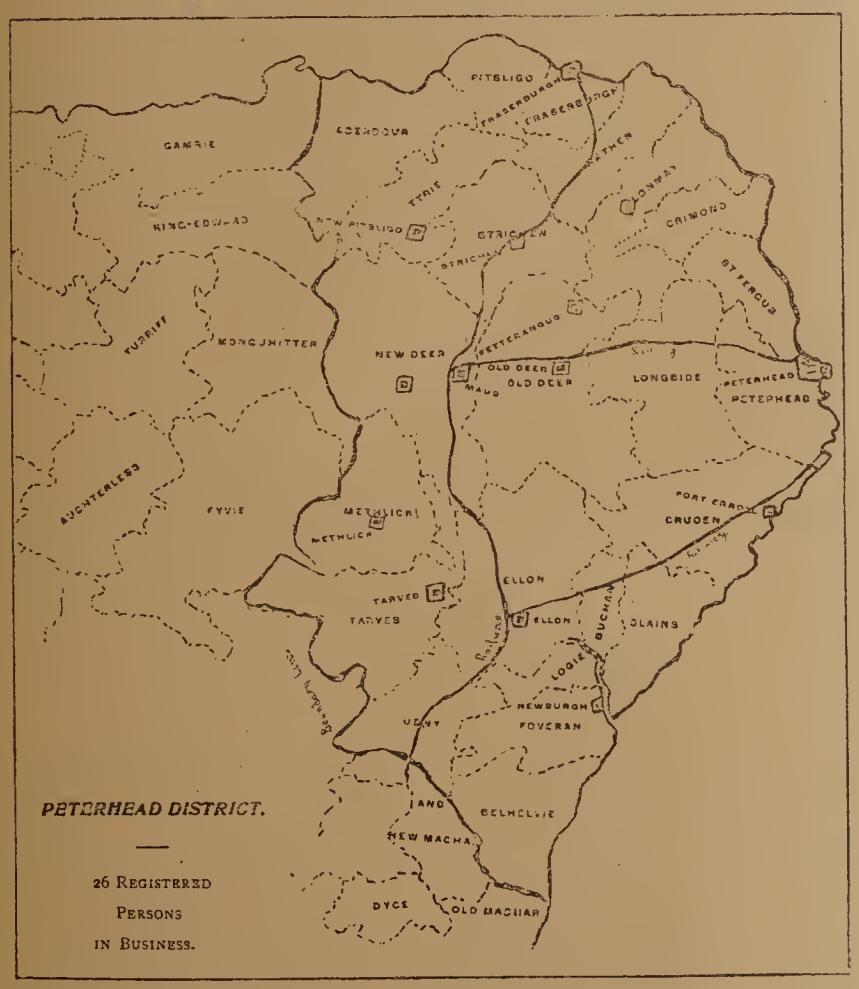
In response to a subsequent request that the Lord President should receive a deputation on the subject of the draft Bill, another letter was read, intimating that his Lordship would do so after the House of Lords met in May, but that was virtually the last that was heard of the Pharmacy Act Amendment Bill, 1881. Its fate resembled the end of a damped squib, fizzling out without igniting the powder it contains.

With some notable exceptions, the expressions of opinion in these letters show a lamentable want of appreciation for the position of the pharmacist even as a legally qualified person. Many of the views put forward are superficial, and point to such a radical incoherence of sentiment as to preclude the possibility of leadership being effectively exercised for promoting the common interests of registered chemists and druggists. Under such conditions the failure of the attempt to induce the Lord President to bring the Bill before Parliament may perhaps be accounted for, and the reference made to "the whole correspondence" in the letter received from the Privy Council Office may be taken as supporting that conclusion.

LOCAL PHARMACEUTICAL ORGANISATION.

In view of the interest at present taken in the work of local secretaries of the Pharmaceutical Society, it may prove useful to show what has been done in the direction of collating information relating to his district, by Mr. J. F. Tocher, local secretary for the Peterhead district. Mr. Tocher compiles every year a list of registered chemists in business in his district and distinguishes those who are members of the Pharmaceutical Society. He prints that list, together with a map showing the relative situation of the different places mentioned in his list.

Map of the Peterhead District.



Copy of the Printed List.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

List of Registered Persons in Business in the Peterhead District, 1899-1900.

(Peterhead District includes Belhelvie, Udny, Tarves, Methlick, New Deer, Aberdour, and the portion of the County of Aberdeen eastward of these parishes—*i.e.*, East Aberdeenshire within these limits.)

Please send early intimation of additions to this list, changes of address, etc., to the Local Secretary, J. F. Tocher, Peterhead.

Those marked * are Members of the Pharmaceutical Society.

*Mr. Robert Burnett, Broad Street, Fraserburgh (*Pharm. Chemist*).
*Mr. Wm. Cruickshank, Mid Street, Fraserburgh.
Mr. Alex. Gall, Broad Street, Fraserburgh.
Mr. J. A. Whyte, Broad Street, Fraserburgh.
Mr. C. Forrest, Lonmay.
Mr. J. Forrest, Lonmay.
Mr. J. Forbes, Broad Street, Peterhead.
Mr. J. A. B. Forbes, Queen Street, Peterhead.
*Mr. W. Pennie, Merchant Street, Peterhead.
*Mr. J. Robertson, Chapel Street, Peterhead.
Mr. J. Simpson, Marischal Street, Peterhead.
*Mr. J. F. Tocher, Chapel Street, Peterhead (*Pharm. Chemist*)
Mr. John Park, Old Deer.
Mr. G. M'Gregor, Ellon.
Mr. W. J. M'Gregor, Ellon.
*Mr. James Walker, Ellon.
*Mr. A. M. Lee, Strichen.
Mr. J. R. Angus, Strichen.
*Mr. George Thomson, New Deer.
*Mr. John Grant, Methlick.
Mr. F. C. M'Pherson, Newburgh, Belhelvie.
Mr. G. Matthew, New Pitsligo.
Mr. J. Milne, Fetterangus, Old Deer.
*Mr. W. Bremner, Port Erroll, Cruden.
*Mrs. Francis Lumsden, Tarves.
*Mr. Alexander Milne, Maud.

SELECTED PRACTICAL FORMULÆ.

Pasta Zinci Sulphurata Saccharata.

M. Hodarn recommends, as a quickly drying and healing ointment: Lanolin, 2; yellow vaseline, 2; glycerin, 1; white sugar, 2; sulphur, 1; zinc oxide, 2.—*Pharm. Cent.*, **40**, 446.

Preserving Medium for Wood.

The following mixture has been patented for preserving wood: Heat nitrophenol, from 1 to 7 parts, with a metallic basic acetate, 30 to 60 parts; creosote, 40 to 100 parts, mixed with vegetable, animal or mineral oil, 1,000 parts, and allow to cool.—*Pharm. Cent.*, **40**, 499.

Unna's Skin Paste Ointments.

Strong: Zinc paste, 40; resorcine, 40; ichthyol, 10; vaseline, 10. *Weak:* Zinc paste, 60; resorcine, 20; vaseline, 20. Either of these remedies may be used in the usual diseases.—*Pharm. Cent.*, **40**, 498.

Varnish for Laboratory Tables.

The following preparation is recommended for protecting laboratory benches from acids and alkalis:—Solution (*a*): Copper sulphate, 125; potassium chloride, 125; water, 1,000. Heat until dissolved. Solution (*b*): Aniline hydrochloride, 150; water, 1,000. Solution (*a*) is first brushed on, and then (*b*), the application being allowed to dry. Next day the bench is rubbed with raw linseed oil, this treatment being repeated once a month.—*Deutsch. Amer. Apoth. Zeit.*, **20**, 66.

Eau de Cologne for the Skin.

Lavender oil, 18; lemon oil, 18; rosemary oil, 6; cinnamon oil, 1; alcohol, 2,000.—*Deutsch. Amer. Apoth. Zeit.*, **20**, 67.

PROVINCIAL PHARMACEUTICAL EDUCATION.*

BY PROFESSOR W. M. HICKS.

Principal of University College, Sheffield.

Pharmaceutical students are connected with a calling which has a most important function to fulfil in regard to the health and bodily well-being of the community. If the *corpus sanum* contributes —as it undoubtedly does—to the *mens sana*, then the intelligence and the force of character of the community must to a certain extent depend on you for its vigour and activity. Therefore, everything that tends to bring you together, to organise you for the improvement of your craft and the technical education of your members, is not only a matter of importance to yourselves, but of the highest interest to the public outside. In early times each town had its local craft guilds, each of which looked after the maintenance of its customs, made its own regulations (including care against fraudulent workmanship), and punished its members who infringed them. With the Reformation and the disintegrating time which followed, these guilds decayed, but we now see signs everywhere of what we may call integrating forces, and in recent years the tendency to associate for common interests has become increasingly evident. We are at the commencement of a period which will see the creation of a species of national guilds in place of the ancient local guilds. They will not have grown out of the old guilds in the same way as most of our national institutions have developed by a process of natural evolution, but are new creations starting into life at a long interval after the death of the institutions which formerly did a similar work. Of course the guild comes in time after the craft, and the craft survives even if the guild goes. The craft has a continuous history. It develops and it divides with the division of labour which the constantly increasing complexity of civilisation demands. If you take your own calling of pharmacy and follow back its history, you will find its origins in something like the medicine man of the modern savages. The primitive medicine man is the depository of the tribal lore relating to the well-being or ill-being of the tribe. He knows how to appease the evil spirits, or to deal with the good spirits; he knows the medicinal powers of herbs, or charms, and the practice of incantations.

As time goes on we get a gradual separation of those who deal with the well-being of the body from those who deal with religious rites. It is only lately, after a long evolution, that the latter has divided into those whose care is the spiritual side of man's nature and those whose function it is to educate his mind. The former also grows, gets more complex, and divides. We can trace this by legislation in our own country. The College of Physicians was founded in 1815, and that of the Barber-Surgeons in 1540. Physicians prescribed, apothecaries sold drugs and also prescribed, grocers also sold drugs. In 1543 an Act was passed to protect apothecaries against their rivals, the physicians and surgeons. About sixty years later they were incorporated with the grocers, but shortly afterwards were separately incorporated, and no grocer was allowed to keep an apothecary's shop. A century later the Apothecaries' Company were empowered to enter any apothecary's shop in London and destroy drugs unfit for use. There has been a gradual separation of functions here also, and I suppose there are now very few, if any, true apothecaries in England—that is, persons who not only prescribe and dispense their own medicines, but also dispense on the prescription of others. Those who dispense their own medicines are decreasing in number, and the distinction between prescribing and dispensing is becoming every day more defined. At a time when medicines contained any number, up to sixty or seventy, more or less harmless ingredients, it mattered little to the patient or the general public whether the dispenser put in twice as many crab's eyes or an extra dose or two of moss from a human skull, earthworms or blind puppies, however much the estimation of the dispenser amongst his professional brethren might suffer. With the modern powerful drugs, however, where a gram too much or a mistake in a bottle may mean death to a patient, it is a very different matter. It is a matter of vital importance that no one shall be allowed to dispense who has not proved his competence to do so. Hence the necessity for a licensed body of dispensers, as we have had for a long time a licensed body of prescribers, and for the association of that body into a guild which shall look after the interests of the craft, the prevention of fraudulent practice, and the admission and education of new members of the craft. The Pharmaceutical Society of Great Britain is more than the beginning of such a guild. As it shows itself able and willing to do its work wisely and well, and as it gains thereby the confidence of the community, so Parliament will more and more enlarge its powers, and entrust important duties to it to perform.

In two points at least has the Pharmaceutical Society shown its wisdom and the broad-minded sense of the scope of its duties: I mean the institution of the research department for the improvement of the technique of its craft, and the institution of a course of training and examination for those who seek to enter its ranks. While the central Society alone can hold the examinations and lay down the general syllabus of instruction and experience, it is for the branch societies to organise such instruction for their localities. That has been the aim of your branch here for several years, and last year, for the first time, a trial attempt was made in connection with the University College. The result of that trial has been the institution of an organised three years' course of instruction for the Minor Examination at the College, on similar lines to those conducted at other University Colleges. This course has been drawn up after careful consideration by a joint committee of your branch and the senate of the College.

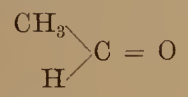
The course is confessedly a compromise between what is desirable and what is possible. We have had to recognise that your students can only attend evening classes, and that with evening study we had to guard against overloading the student We had to allow sufficient time for private study, and, may I say an occasional evening for social intercourse or recreation. In conclusion, I should like to say a few words to the students as to their study. The disadvantages and difficulties connected with evening study are obvious. You bring minds to your work jaded and bodies tired by your day's business, and the difficulty of concentrating your mind on your work and keeping interest in it is great. You have not only to bring will and determination to work hard, but you must use wisdom and judgment as well to keep your minds fresh and your interest alive. Organise your working time, and set apart certain hours which you will allow nothing else to interfere with. Set aside also certain hours for outdoor exercise or recreation—say Thursday and Sunday afternoons—and regard it as much a duty to do neither business nor study during those hours as it is to do neither business nor recreation during the hours you have set apart for study. I know it may be dangerous advice to give to any whose tendency it may be to let matters glide, but the safeguard is this: you have no duty to recreate yourselves until you have done your duty to your working hours. If this is done, then compel yourselves to work hard at resting. The time at your disposal is so small that you can only get through your study by carefully planning out beforehand how you will dispose it. Another great disadvantage of evening work is the sporadic manner in which the subjects have to be studied. You require to work continuously at a subject in order to become saturated, so to say, with it, and master it. For this reason I think you would all find it a good plan if you could give at least three months, altogether free from business, to laboratory work before entering for your examinations.

* Report of an Address delivered to the students of the Sheffield School of Pharmacy, on October 19, 1899.

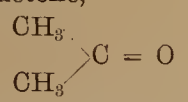
THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.

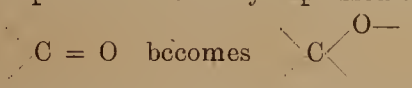
Sulphonal. — The systematic name, dimethyl-diethyl-sulphone-methane, indicates that sulphonal is a derivative of the simplest paraffin hydrocarbon methane CH_4. Two of the four hydrogen atoms are replaced by methyl (CH_3—) groups, hence the prefix dimethyl, and the other two by two ethyl sulphone (—$SO_2 \cdot C_2H_5$) groups. Although the constitution of sulphonal can thus be simply explained, it must not be supposed that it can be, or actually is, prepared directly from the parent substance methane. The process of preparation involves some reactions somewhat unfamiliar to the student, and not dealt with in the elementary text-books of organic chemistry. In order to explain them as simply as possible, it will be necessary to draw some analogies between these reactions and some of more fundamental importance with which the student should be familiar. Starting with ordinary aldehyde, whose constitution is represented thus—



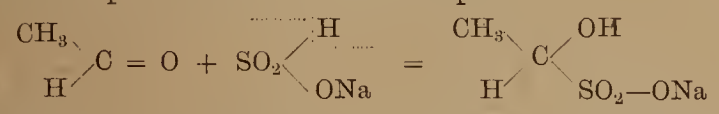
and acetone, the simplest ketone,



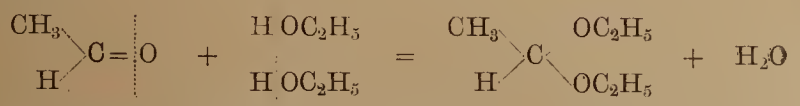
it will be observed that both bodies contain a carbonyl group $>C=O$, *i.e.*, oxygen doubly linked with carbon. The presence of this group enables both aldehydes and ketones to form additive compounds through a change in the relation of the carbon and oxygen of the carbonyl group which is usually expressed thus:—



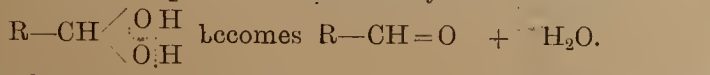
This change enables the aldehydes and ketones to take up two monovalent elements or groups, as, for instance, in the formation of the bisulphite compound with sodium acid sulphite—



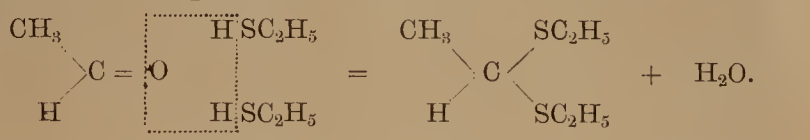
Compare also in your text-book the behaviour of aldehydes and ketones with hydrocyanic acid, ammonia and hydroxylamine. Aldehyde also condenses with two molecules of alcohol to form acetal—



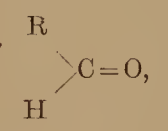
This substance, acetal, being the best known member, has given its name to a class of bodies, the acetals, which are regarded as derived from a *hypothetical* dihydric alcohol containing the two hydroxyl groups attached to the same carbon atom. As already mentioned under chloral hydrate, dihydric alcohols of this constitution can only exist in the free state when the compound contains electro-negative groups or atoms, as in the case of chloral hydrate $CCl_3CH(OH)_2$. Otherwise whenever we attempt to isolate these dihydric alcohols a molecule of water is split off and an aldehyde is obtained —



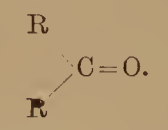
Although these alcohols are therefore unknown in the free state, we can obtain derivatives—the acetals—in which the hydroxylic hydrogen is replaced by alkyl residues. Thus ordinary acetal, referred to above, may be called diethyl acetal, because the replacing groups are ethyl, C_2H_5. The general formula for the acetal group may be therefore put as $R—HC(OR)_2$. In an analogous manner aldehyde condenses with thio-alcohols (mercaptans), which are the sulphur analogues of ordinary alcohols. Thus aldehyde gives with ethyl mercaptan a body having the constitution of a thio-acetal, and these bodies are called mercapt*als*, to recall their origin from aldehydes and mercaptans.



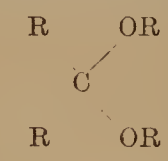
Passing now to acetone, the student should compare the similarity between the reactions of aldehydes and ketones, which are due to the presence in both classes of bodies of the carbonyl group $>C=O$. Note then the differences in their reactions, which are due to the carbonyl group of the aldehydes being connected with an alkyl group *and hydrogen*,



whereas in the ketones the carbonyl group is connected with two alkyl groups,

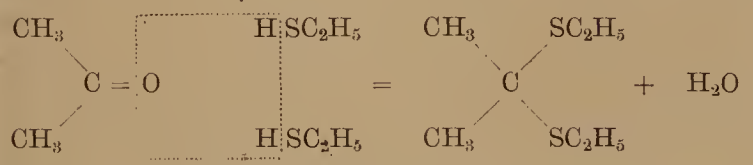


Among the compounds formed by the ketones, the group analogous to the acetals, and which would have the general formula

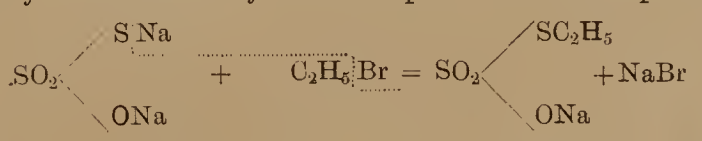


are not known.

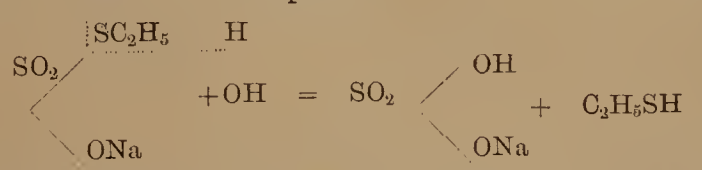
The sulphur compounds analogous to the mercaptals are, however known, and are called mercapt*ols*. The best known member is the dimethyl-diethyl mercaptol, mentioned in the Pharmacopœia, which is usually called simply mercaptol, and is obtained by the condensation of one molecule of acetone and two of ethyl mercaptan —



Mercaptan is a very volatile fluid of extremely unpleasant odour. In order to avoid the disagreeable effect of working with considerable quantities, as in the manufacture of sulphonal, it is said that sodium ethyl thiosulphate is employed. This substance is obtained by the action of ethyl bromide upon sodium thiosulphate—



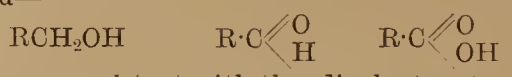
The sodium ethyl thiosulphate is heated with the acetone in presence of hydrochloric acid. Under the influence of the acid the thiosulphate reacts with water and undergoes hydrolysis into mercaptan and sodium acid sulphate—



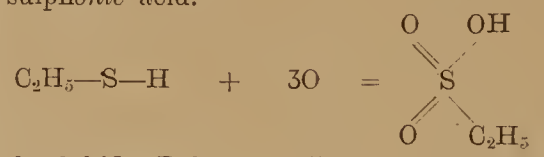
The mercaptan reacts with the acetone as fast as it is liberated, so that the disagreeable effects of working with large quantities of free mercaptan are avoided. In order to explain the next step—the oxidation of the mercaptol to a di-sulphone—compare the behaviour towards oxidising agents of alcohols and thio-alcohols (mercaptans). The former first lose hydrogen, and then take up

* Note.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J.* during 1897-8.

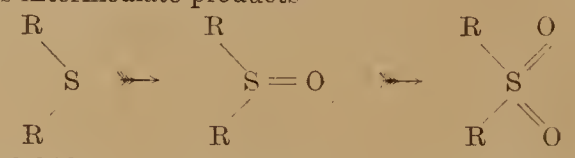
oxygen with formation of aldehydes and acids, *i.e.*, the alkyl residue is attacked—



These changes are consistent with the divalent nature of oxygen. The sulphur analogues, on the other hand, readily *take up* oxygen, due to the fact that sulphur is capable of exhibiting tetravalent and hexavalent properties (compare SO_2 and SO_3). Thus mercaptan, when oxidised by nitric acid or permanganate, is converted into ethyl sulph*onic* acid.

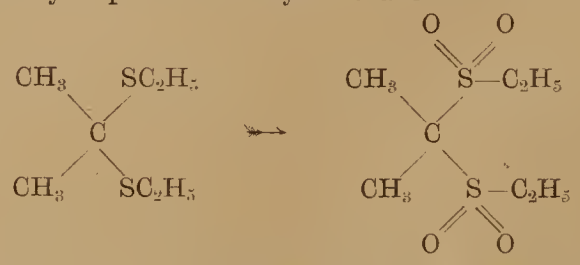


If alkyl sulphides R_2S be oxidised, two atoms of oxygen are taken up, and a *sulphone* is obtained, compounds called sulphoxides being obtained as intermediate products—

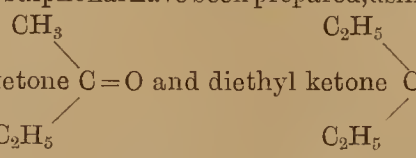


Sulphide. Sulphoxide. Sulphone.

By comparing the constitutional formula for mercaptol it will be seen to contain two sulphur atoms in the condition of sulphide, *i.e.*, each sulphur atom is connected with two alkyl residues. When mercaptol is oxidised it therefore takes up four atoms of oxygen and yields di-ethylsulphone dimethyl methane—



Homologues of sulphonal have been prepared, using in place of acetone,



methyl ethyl ketone and diethyl ketone. This leads to the production of methyl- ethyl- and diethyl-diethyl sulphone methane $(CH_3)(C_2H_5)C\cdot(SO_2C_2H_5)_2$ and $(C_2H_5)_2C(SO_2C_2H_5)_2$ respectively, which have been introduced as hypnotics under the names of trional and tetronal. If the ethyl groups in sulphonal be replaced by methyl by employing methyl mercaptan in place of ethyl mercapton, the resulting compound is devoid of hypnotic properties. In dispensing sulphonal its sparing solubility in water should be remembered. This renders it desirable to administer the remedy in the finest possible powder. Sulphonal and other sulphones are very stable bodies; they are hardly affected by boiling acids and alkalies. When heated in the dry state with potassium cyanide they are, however, decomposed. The cyanide acts as a reducing agent, and removes the oxygen of the sulphone group, causing a complicated decomposition to ensue, among the products of which the mercaptan, owing to its odour, is easily distinguished. At the same time the cyanide unites with some of the sulphur, forming potassium thiocyanate, KCNS. Hence, if the fused residue be dissolved in water and treated with a slight excess of hydrochloric acid, the resulting solution yields the red coloration with ferric chloride, which is characteristic of thiocyanates (compare iron test for acetates and meconates). It is necessary to use a slight excess of hydrochloric acid, in order to convert into chloride the excess of cyanide and some carbonate which is always present, and which would subsequently interfere with the reaction between the thiocyanate and ferric chloride.

FLORAL CALENDAR FOR OCTOBER.

There are more fruits than flowers available for examination during the present month. These will be distinguished in the following list by the letter (fr.) following their names. The list of plants in blossom being small, the names of those mentioned last month, but still in flower, are repeated here:—

Amaranthaceæ.—*Chenopodium ambrosioides* (fr.). B.G. *C. quinoa* (fr.). B.G.

Amaryllidacæ.—*Sternbergia lutea.* Fl. *Amaryllis belladonna.* Fl.

Araliaceæ.—*Hedera helix.*

Boraginaceæ.—*Anchusa italica.* Fl.

Brassicaceæ.—*Erysimum cheiranthoides, Koniga maritima.* Fl.

Campanulaceæ. — *Lobelia cardinalis.* Fl. *Campanula isophylla.* Fl.

Compositæ or **Asteraceæ.**—*Calendula officinalis.* Fl. *Anthemis nobilis, Matricaria parthenium, Tanacetum vulgare, Rudbeckia newmani.* Fl. *Aster amellus.* Fl. *Taraxacum officinale.*

Coniferæ or **Pinaceæ.**—*Taxus baccata* (fr.).

Convolvulaceæ.—*Calystegia sepium. Ipomœa purga.* B.G. *Convolvulus scammonia.* B.G.

Cucurbitaceæ.—*Bryonia dioica* (fr.). *Ecballium officinarum* (fr.) (*P.J.* [3], **9**, 241.)

Cupuliferæ or **Corylaceæ.**—*Quercus pedunculata* (fr.). *Castanea vesca* (fr.). (*P.J.* [3], **9**, p. 324.)

Dioscoraceæ.—*Tamus communis* (fr.).

Euphorbiaceæ.—*Euphorbia helioscopia* (fr.). *E. peplus* (fr.). *Ricinus communis.* Fl. (*P.J.* [3], **9**, p. 241.)

Ericaceæ.—*Arbutus unedo.* Fl. (*P.J.* [3], **9**, p. 323.) *Calluna vulgaris.*

Gentianaceæ.—*Gentiana amarella.*

Geraniaceæ.—*Oxalis rosea.* Fl. *O. corniculata.* Fl. *Tropæolum canariense.* Fl. *Pelargonium* species. Fl.

Illecebraceæ.—*Corrigiola littoralis.*

Iridaceæ.—*Crocus zonatus.* Fl. *C. sativus.* Fl. (*P.J.* [3], **8**, p. 241). *C. nudiflorus. Schizostylis coccinea.*

Labiatæ or **Lamiaceæ.**—*Teucrium chamædrys, Lamium album, Salvia pratensis.* Fl.

Leguminosæ or **Fabaceæ.**—*Ulex nanus, Lathyrus odoratus.* Fl. *Swainsonia alba.* Fl.

Liliaceæ.—*Colchicum autumnale* (*P.J.* [3], **8**, p. 241). *Scilla autumnalis.*

Malvaceæ.—*Hibiscus syriacus.* Fl.

Nyctaginaceæ.—*Mirabilis jalapa.* Fl.

Onagraceæ.—*Fuchsia* species. Fl. *Œnothera lamarckiana.* Fl.

Papaveraceæ.—*Papaver rhœas, Chelidonium majus.*

Phytolaccaceæ.—*Phytolacca decandra* (fr.). B.G.

Plumbaginaceæ.—*Plumbago larpentæ.* Fl. *P. cærulea.* Fl.

Polygonaceæ.—*Polygonum affine.* Fl.

Ranunculaceæ.—*Ranunculus repens, Anemone japonica.* Fl.

Rhamnaceæ.—*Rhamnus catharticus* (fr.). *R. frangula* (fr.).

Rosaceæ.—*Geum urbanum, Potentilla tormentilla, Rubus idæus, Rosa canina* (fr.) (*P.J.* [3], **9**, p. 241.)

Rubiaceæ.—*Lantana* species. Fl.

Rutaceæ.—*Ruta graveolens* (fr.).

Sapindaceæ.—*Acer pseudo-platanus* (fr.), *Æsculus hippocastanum* (fr.). (*P.J.* [3], **9**, p. 324.)

Scitaminaceæ.—*Canna* species. Fl.

Scrophulariaceæ.—*Linaria purpurea.* Fl. *Scrophularia scorodonia.* (Fl.)

Solanaceæ.—*Atropa belladonna* (fr.), *Solanum dulcamara* (fr.), *Datura stramonium* (fr.). B.G. *Physalis alkekengi, P. francheti* (fr.). (*P.J.* [3], **8**, p. 401.) *Nicotiana tabacum.* B.G. *Solanum nigrum.* (*P.J.* [3], **8**, p. 241.) *S. jasminoides.* B.G.

Umbelliferæ.—*Æthusa cynapium* (fr.), *Conium maculatum* (fr.), *Fœniculum capillaceum* (fr.).

Verbenaceæ.—*Caryopteris mastacanthus.*

Violaceæ.—*Viola tricolor.*

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, OCTOBER 28, 1899.

"COMPANY PHARMACY" AND THE PHARMACY ACT OF 1868.

Those chemists and druggists who believe representations that the existing prejudicial development of company trading has been the result of neglect on the part of the Council of the Pharmaceutical Society to perform the duty appertaining to it as the representative and executive body—as well as those who are not sufficiently well informed to know better—will probably be surprised to learn that the endeavour to obtain, through the medium of the Pharmaceutical Society, a remedy for the company grievance affecting registered chemists and druggists, dates back to a period antecedent to the formation of the Pharmaceutical Society of Ireland and to the inauguration of the Chemists and Druggists' Trade Association at Birmingham in 1876. At that time, the question as to the legality of Co-operative Societies selling and dispensing poison had been repeatedly under earnest and careful consideration by the Council of the Society, as a subject in which the entire body was deeply interested. Legal opinion had also been taken as to the desirability of proceedings for that unforeseen infringement of the Pharmacy Act. The result was the discovery that such procedure might open up the whole subject of pharmaceutical legislation, and reveal defects in the Act that would not be easily remedied while registered chemists and druggists included so many who were members of a trade rather than of a profession. Hence it was that the Council had, at that time, resolved that in the best interests of the general body the most prudent course would be to abstain from subjecting the Act to the tension of a trial at law, which it might be too feeble to bear, and that, for the time, such a course would be preferable to involving the Society in a costly legal process which the Council had been advised could not be other than abortive. Another probable reason for the reticence of the Council at that time was the inordinate apathy and patience that clung to the trade in reference to the infringement of the Pharmacy Act by co-operative trading, the injury it, even then, caused to their legitimate trade interests, and the prospective ruin it was likely to bring about.

A perception of this last-mentioned reason for the inaction of the Council may indeed have been the ground on which the Society—asleep and dumb—was charged at the Birmingham Conference with having forgotten that the safety of the public and legitimate trade interests were trusts that the Society is bound to take cognisance of; for that charge was made by a member of the Council thoroughly cognisant of all the circumstances. His whole address was an indictment—not of the Council, but of the Society—for failing to conserve and protect those vested interests that were the natural and anticipated outgrowth of regulations imposed by the State for the benefit of the public. The Society was exhorted to fulfil its obligations, in that respect, with a quickened conscience and sense of guardianship—to take prompt and resolute action to remedy a glaring and grievous evil that cut at the root of the Pharmacy Act and would, if allowed complete development, to a great degree render worthless and obsolete the legislation that had been the result of so much zeal and toil. That exhortation was addressed to the Pharmaceutical Society in reference to a matter endangering its safety and the stability of the calling represented by the Society. It might, therefore, have been expected to rouse every member of the Society, if not every member of the entire trade, to a sense of the necessity for such action as was suggested; to induce them to follow up such action so as to obtain amendment of the Pharmacy Act in regard to any unexpected flaw or weakness that would permit evasion and so as to establish the law, on the basis of enlightened expediency, as thoroughly efficient for the safety of the public and for the protection of those who carry on the business of chemists and druggists. But that result was not brought about and Mr. Hampson's efforts, to awaken in the minds of chemists and druggists a perception of their interests and a sense of their individual obligations, were to a great extent without effect.

The subsequent action of the Council in regard to company trading has been thoroughly representative of the position existing throughout the entire body. While some entertained a belief that the Act was strong enough to put an end to the evil complained of, indifference and lassitude prevailed with the majority. Complications arose from the desire to connect other questions, as to the need of amending the Pharmacy Act, with that of the legality of business carried on by co-operative stores. That was the extent to which "company pharmacy" had been developed until the prosecution of Mackness in 1878 was followed by the conversion of his business into the London and Provincial Supply Association, Limited; when "company pharmacy" took the form in which it is still being carried on. Immediately after the decision of the House of Lords in 1880, which made the Pharmacy Act for the most part worthless in the interest of chemists and in the interest of the public, the Council of the Pharmaceutical Society took up the question as to the requisite amendment of the Act, with the view of considering the probable effect of the decision on the future of pharmacy and whether means could be devised to secure the true object and intention of the Pharmacy Acts, viz., that in the interest of the public the individual owner or owners of a chemist's business should be registered and qualified. The Committee

appointed for that purpose presented the draft of a Bill to the Council in January, 1881. Evidence was at once given of serious absence of unanimity, even within the Committee, representing still more serious differences of opinion among those engaged in the drug trade—a desire, on the one hand, that the Pharmacy Act should protect trade interests and, on the other, to regard it as an undue restraint of trade. Widows were an additional source of trouble. The consequent discord which then found expression in correspondence addressed to the Journal, has prevailed ever since and it has been of a nature to preclude such concurrent and harmonious action as can only be secured by mutual willingness to waive individual opinions and desires for the sake of promoting the general interests of the craft.

UNFOUNDED IMPUTATIONS.

An article headed "The Adulteration of Drugs" appears in the *Hospital* last Saturday, containing statements eminently detrimental to chemists and druggists, —even raising a question as to their honesty and general trustworthiness as dealers in medicinal articles. Apparently with a view to supporting those statements, parts of a report of analyses of belladonna plaisters, signed Benj. H. Paul, was also published, in breach of a specific agreement. It will, for the present, suffice to say that the *Hospital* suppresses data in that report, which, if published, would have shown that the statements made in the article are directly opposite to the real facts of the case, and that the damaging imputations made are not in any way justified.

A MINOR COMPANY-PHARMACY PROBLEM.

In the discussion on Mr. Wilcock's paper, read before the Bradford Chemists' Association on Tuesday last, reference was made by one of the speakers to the possibility of hardship being inflicted on members of the families of registered chemists, if the law should require joint-stock companies carrying on business as chemists and druggists to consist entirely of legally qualified persons. But, as suggested by "An Ordinary Pharmacist," at page 399, it would be quite possible to devise satisfactory means of overcoming any difficulty of that kind without disregard of the intention and object of the Pharmacy Acts. For example, the capital belonging to unqualified individuals might be held in trust by a legally qualified member of the company. But whatever the means devised, so long as unqualified persons are prevented from reaping advantage from the use of a pharmaceutical title, and from exercising any control over the conduct of the business, no objection could be taken by pharmacists to the fact that the whole of the capital invested did not actually belong to persons registered under the Pharmacy Acts, any more than they could object to legally qualified persons carrying on business on their own account with the aid of borrowed money, if that were necessary for their purposes. So far as the public safety is concerned, it is not of the least consequence who finds the capital with which a business is financed, or indeed who obtains the profit; both are equally beside the question—but it is of the highest importance that no person without a proper legal qualification should be in a position to conduct the business or interfere with its control.

ANNOTATIONS.

An Evening Meeting of the Pharmaceutical Society will be held at 17, Bloomsbury Square, London, on Tuesday, November 14, at eight o'clock precisely. The chair will be taken by the President—Mr. William Martindale—and two papers will be read—one by Professor J. Reynolds Green, on "The Biology of Yeast," and the second, by Professor H. G. Greenish, on "Spurious Alexandrian Senna." The meeting will be the first of the present session, and it is hoped that the special interest attaching to the subjects to be treated may insure a good attendance.

The Company Pharmacy Problem, as put before our readers last week by "An Ordinary Pharmacist," appears to excite as much attention as ever, and it is not too much to say that registered chemists generally are more unanimous in approving the views presented to them, in the article referred to, than on any other subject. One distinguished leader of the craft, who writes privately, expresses the opinion that the views are those of nine hundred and ninety-nine out of every thousand registered chemists in Great Britain. What other leading pharmacists think on that point may be judged to some extent from the correspondence columns of this week's Journal. Notice should be taken of the fact that many of the letters are from prominent local secretaries of the Pharmaceutical Society, who are in a better position to know what views prevail amongst registered chemists than most men. Mr. John Smith, in particular, as Chairman of the Federation of Local Pharmaceutical Associations, has had special opportunities of testing the opinions of registered chemists—the warmth of his expression of approval regarding what appeared last week is, we believe, only a faint reflection of that which he has personally experienced in approaching other chemists during the last few months.

A Supplementary Article on the Same Subject, which appears this week (see p. 398), is intended to throw a little more light on the matter for the benefit of those who may not be entirely conversant with the incidents which resulted in the virtual repeal of the chemists' charter. The writer also makes it clear that his one end and aim is the prohibition of malpractice by individuals not registered under the Pharmacy Acts. Recognising that the House of Lords' decision in 1880 is irrevocable, so far as the Judicature is concerned, he would nevertheless appeal to Parliament to remedy its own oversight. The public safety requires that, and no consideration of pretended "vested interests" should be allowed to stand in the way of necessary reforms. The chief reform must be to secure full respect for the pharmaceutical qualification, like other professional qualifications, as an individual and proprietary one. Nothing short of that can effectually safeguard the public safety—nothing less, our contributor thinks, should satisfy registered chemists. He sees no objection to properly-constituted companies carrying on the business of a chemist and druggist and would not oppose internal reforms. But he asks that the Legislature should, at least, be asked to remedy its own mistakes.

Objection is Taken by Mr. William Gill, of Nottingham, to the fact that "An Ordinary Pharmacist" deals with the "Company Pharmacy Problem" simply from a professional standpoint and overlooks the commercial aspect of pharmacy. He says: "Pharmacists have to compete with unregistered trades, and should be able to raise capital in the same way as their opponents can do." That is, beyond question, reasonable. But when Mr. Gill goes on to say that "the suggested clause would prevent them from doing that," he entirely misrepresents the position, for the suggested clause would not have the effect he supposes. The objection raised by Mr. Gill rests entirely upon the mistaken assumption that the pharmacist can expect to be relieved from the necessity of competition "with unregistered traders," except in

regard to his professional functions. That is why the company pharmacy problem must be attacked in the chemists' interest from the professional standpoint—his privilege to keep open shop for retailing, dispensing, or compounding poisons. In that respect, the public well-being needs safeguarding, and for that reason every pharmacy should be under the direct personal control of a registered person who is the proprietor or has a considerable pecuniary interest in the business he controls. Mr. Gill would be in favour of permitting a company to trade as pharmacists providing the managing director were a registered chemist and the business conducted in his name; also that every open shop owned by the company were under the personal control of a registered chemist, who should hold shares to the value of not less than five per cent. of the paid-up capital of the company; and, further, that the registered person managing each shop should be the "person keeping open shop," etc., who is specified in the provisions of the Pharmacy Acts, all labels bearing his name, as in the case of an ordinary pharmacist. That might suffice for some purposes of general trade in drugs, but not for the practice of pharmacy proper. Mr. Gill's objections appear to be met, to some extent, in the second article on the subject, published this week. It must also be pointed out that pharmacy, so far as it is the subject of legislation, must of necessity be considered from the professional standpoint only. The letter signed "R. A. R." may, with advantage, be referred to with regard to the question of the capital required by pharmacists for enabling them to practise their profession.

The Conference Arrangements for Next Year were under discussion at a preliminary meeting called by the Hon. Local Secretaries—Mr. William Warren and Mr. Herbert Cracknell—at 17, Bloomsbury Square, London, on Wednesday, October 25. The chair was taken by the President of the Pharmaceutical Society (Mr. William Martindale), who was supported by the President of the British Pharmaceutical Conference (Mr. E. M. Holmes), the President of the Western Chemists' Association of London (Mr. J. F. Harrington), Mr. Walter Hills, Mr. Michael Carteighe, Mr. W. S. Glyn-Jones, and other leading pharmacists. Mr. Harrington briefly explained the position of affairs and it was decided to summon a representative meeting of London pharmacists, for the purpose of appointing an executive committee and transacting other business in connection with the Conference arrangements. The meeting will be held at 17, Bloomsbury Square, on Wednesday, December 6, and all London pharmacists will be welcome. Regarding the proposed entertainment fund, it was agreed that the maximum subscription should be fixed at two guineas for individuals or five guineas for firms. Other matters of detail were left for the consideration of the Executive Committee, which yet remains to be appointed.

The Chemists' Ball for 1900 will be under consideration at a general meeting to be held, by permission of the Council of the Pharmaceutical Society, at 17, Bloomsbury Square, London, on Monday, November 6, at 2.40 p.m. The meeting is summoned by the Hon. Secretary, Mr. William Warren, 24, Russell Street, W.C., who will be glad to hear from any gentleman who is willing to assist the Ball Committee, but is unable to be present at the meeting. The coming Ball, it should be needless to say, will actually be the last of the century, as well as the first of "the nineteen hundreds."

A Suggestion to Lady Pharmacists is submitted by Miss R. Kathleen Spencer, Cadarga, Knowle, Birmingham, who asks if the present winter session does not present a favourable opportunity to all ladies engaged in pharmacy, to form an association which would enable them to cultivate each other's acquaintance, read papers for mutual improvement, discuss matters relative to pharmacy, and from time to time hold social evenings, etc. In fact, she proposes that they should form a similar association to the many excellent pharmaceutical associations which are now in existence. In the event of such an association being formed, it is suggested that it might be desirable (bearing in mind the limited number of ladies engaged in pharmacy) to hold meetings alternately in London and Birmingham, or at any other centre likely to attract a sufficient number of members. Miss Spencer will be pleased to have the opinion of others on this subject, either through the medium of the Journal or by means of private communications.

The Plague at Hongkong provided much work for an old School of Pharmacy student, Mr. Frank Browne, who is now apothecary and analyst at the Government Civil Hospital, Hongkong; and his numerous friends will be pleased to learn that the Sanitary Board for the Colony has expressed its warm thanks to Mr. Browne for the valuable work he performed in carrying out the special cleansing and disinfecting work at Kowloon. Although Hongkong was thoroughly cleansed last year, there has been another severe epidemic more recently, causing the deaths of about fifteen hundred people. Mr. Browne again took charge of the Kowloon district on this occasion and, in sending a report to the Sanitary Board, he has felt it necessary to point out that much more drastic measures will have to be taken in order to free the Colony from the disorder. For this "very able and useful report," he has also been warmly thanked by the Board.

The Poison Regulations adopted by the Pharmaceutical Society are referred to in a note in the *British Medical Journal*, wherein it is stated that, in pursuance of the statutory powers conferred upon it by the Pharmacy Act, 1868, the Pharmaceutical Society at the commencement of this year prescribed, with the consent of the Privy Council, regulations dealing with the keeping and selling of poisons. Replying to a correspondent who writes asking how far, if at all, medical men are bound by the regulations, the editor of the *B.M.J.* observes that it appears to be quite clear that those regulations do not apply to any legally qualified medical practitioners. Since, however, the regulations prescribed by the Pharmaceutical Society are such as appear to experienced men to be necessary for the safe custody and handling of drugs, it is said to be obvious that the members of the medical profession would do well in their own interest to adhere to them.

Grant Allen or, to give him his full name, Charles Grant Blairfindie Allen, was one of the most versatile and talented writers of recent years, and his death at the comparatively early age of fifty-one will come as a great blow to the many thousands of persons who have been charmed by his work as a journalist, a novelist, or a writer on scientific subjects. He was an evolutionist of an extreme type, and carried the conclusions of Darwin, Spencer and other investigators far beyond the limits which contented them. He regarded himself as belonging to that organising class whose want was pointed out by Comte, and has been further noted by Herbert Spencer. The organising student, he pointed out, cannot also himself be a specialist in all the sciences whose results he endeavours to co-ordinate, and he must therefore depend for his data upon the original work of others. Grant Allen, himself, was not a profound scientific man in any direction, but he had a wide knowledge of the general results of scientific progress and speculation, and he had a very happy knack of lucid interpretation and exposition. Somebody dubbed him the "Darwinian St. Paul," because of his remarkable power of expounding and popularising Darwin's teaching to those who could not take it at first hand for themselves. He was an enthusiastic evolutionist in all things psychological, philological, sociological, political, and ethical, and he was specially insistent on the principle of natural selection, which he was wont to say, many professing evolutionists do not believe in and cannot understand.

SHEFFIELD PHARMACEUTICAL SOCIETY.

The annual dinner of the Sheffield Pharmaceutical and Chemical Society was held at the Wharncliffe Hotel, Sheffield, on Thursday October 19, after the new session of the School of Pharmacy had been inaugurated at the rooms of the Literary and Philosophical Society. There were about sixty gentlemen present. Mr. George Squire (President) occupied the chair, and among the company were Dr. Hicks (Principal of the Sheffield University College), Professor Addison, Drs. G. Wilkinson, Hill, and Mackay, Messrs. G. T. W. Newsholme, J. Rymer Young, William Parkin (President of the Literary and Philosophical Society), R. R. Eadon, Reaney (London), J. Austen, J. B. Pater, H. Antcliffe (Secretary), W. B. Tolputt, J. F. Eardley, S. T. Rhoden, W. Ward, A. R. Fox, Drummond, W. Harland, Paramore, C. F. Carr, Dalton, Percy Carr, G. J. R. Parkes, G. Ellinor, J. C. Gibson, C. H. Cocking, and Hands. Letters expressing regret at inability to attend were received from the President of the Pharmaceutical Society of Great Britain (Mr. Wm. Martindale) the Lord Mayor (Ald. W. E. Clegg), Ald. Batty Langley, M.P., Dr. Dyson, and others.

After an excellent meal, the President briefly gave "The Queen," which was enthusiastically honoured.

Mr. A. R. Fox, F.L.S., then proposed

The Pharmaceutical Society of Great Britain.

He said it used to be considered the duty of anyone who proposed that toast to say something in criticism of the policy of the Council, and that criticism was not always altogether favourable. Personally, he did not feel that he could say much in the way of criticism. He had been entirely in accord with what had been done of recent years by the parent Society. Had he brought the last week's issue of the *Pharmaceutical Journal* with him, and read the leading article to them, together with the "Annotations"; that would have made his speech. He had been glad to read in the Journal lately of the action that the Council of the Society had been taking with regard to the new legislation, and more especially with regard to

Company Trading.

They were all aware of the great difficulties that had been placed in the path of pharmacy by the fact that an unfortunate interpretation of the Pharmacy Act enabled company traders to do what it was quite impossible for individuals to do. Chemists had thus been very greatly handicapped in their profession. He certainly thought the Council was taking a right step in attacking the problem of company trading and with respect to the establishment of a compulsory curriculum, which would, of course, lead to a higher standard of education. It had done well, also, in instituting the use of proper regulations for the sale of poisons. Many of them had found great difficulty in carrying out the regulations, but they ought to be carried out, and more thoroughly than at present. Now, if a customer was refused poison at one shop because he had not brought a proper bottle, he could go to another shop and have poisons put into receptacles that were anything but fitted for a scientific dealer in those things to use. These complaints were coming before the Council, and he thought that body should enforce more strictly the regulations it had laid down for the guidance of pharmacists. The time was fast approaching when

A Curriculum Should be Instituted,

and he hoped that in all the large centres of the country the various University Colleges would take up the teaching of the tenets of pharmacy more than they had done hitherto. He was glad that had been done in Sheffield, and trusted the students would take every advantage of the training provided for them. He thought that the restrictions at present in force with respect to dealing in drugs should be extended. He would have a restriction attached to the sale of every article in the Pharmacopœia. If they were to have a technical knowledge of those articles, they certainly ought to have the only right of dealing in them.

Mr. G. T. W. Newsholme (Vice-President of the Pharmaceutical Society), in responding, said the criticisms of the Council which were so frequently heard were made in the best spirit, and were heartily appreciated by the Council. If it were left alone to carry out its own policy, probably it would not be as good as it was at present. The Council was about to propound some scheme for dealing with

The Important Question of Company Trading.

The Law and Parliamentary Committee had been instructed to bring up a scheme. The matter had been an important one for a great number of years, but now it had reached a critical stage on account of the clauses which the Lord Chancellor introduced into the Companies Bill last Session, and it must be dealt with in some way. At present, the Bill referred to was dead, but they had every reason to believe that the matter would come forward in the next Session of Parliament. Without indicating exactly what the policy of the members was, there was one point on which the Council were all agreed, and that was that they were going to stand, as far as they possibly could, by the Pharmacy Acts of 1852 and 1868. They were going to protect to the utmost the position they had gained. Chemists were not prepared to give up the titles which they had earned: titles which not only gave them a recognised position, but at the same time afforded protection to the public. The title of "pharmaceutical chemist" was the trade mark of the individual: it showed that he was to be trusted to carry out certain duties. He was satisfied that their best policy was

To Defend Their Titles

to the utmost. The Lord Chancellor suggested that seven unqualified persons should be able, as a company, to call that ideal personage a pharmaceutical chemist, provided they employed a qualified man. But that would be a most absurd position: it would not give the slightest protection to the public. In the preamble of the Pharmacy Act of 1868 it was expressly laid down as expedient for the safety of the public that chemists should pass examinations and assume certain titles. They had no right to go away from that now. If the Lord Chancellor's suggestions were carried out, the Pharmacy Act would be a useless thing. If a limited company was able, by the aid of a qualified individual, to usurp all the titles and the position of a pharmacist, what was the good of the Pharmacy Act at all? The whole thing would become a dead letter, and chemists had better by far go back to the position they had previous to 1868. Going on to speak of the question of

A Compulsory Curriculum,

Mr. Newsholme said he firmly believed that one ought to be established. As they had no Act of Parliament at present to enforce one, however, the next best thing was the voluntary curriculum, extending over three years, which had been agreed upon by the Sheffield Society and the senate of the University College. The Society had been met in a splendid spirit by the senate, who had been only too glad to fall in with their views. In Manchester, Birmingham, and Nottingham similar arrangements were being made, and he hoped to see the principle adopted by every University College in the country before long, because he was satisfied that until they had such a curriculum they could not deal satisfactorily with the great number of men who came up for examination. At an examination over which he presided in July, there were no fewer than 616 candidates, and only 189—less than one-third—passed. This showed that there was something wrong in the training of the men. For a great number of years it had been recognised that there was something wrong in the primary education, or, rather, in the examination that men were compelled to pass before they could go into business. The Preliminary Examination, hitherto held to be sufficient, was of far too low a character, and after July next year it would come to an end, and they would expect certificates from bodies that took a much higher standard than that examination. That was one way to meet the present difficulty, and another was that all who came up for examination should go through some curriculum, which he thought must eventually be compulsory. After referring briefly to the Benevolent Fund, and expressing his gratification at the liberal manner in which it was supported in Sheffield, Mr. Newsholme spoke of his

Scheme of Local Organisation,

propounded at Bradford in April last. His idea was that the Society should be thoroughly in touch, not only with its own people, but with every member of Parliament in the country. They ought to have at least 120 or 130 more local secretaries than they had at present, and a secretary should be appointed in every Parliamentary division, because questions affecting them—questions of legislation—were continually cropping up. He was glad that there had been a great increase in the membership of the Society since the amendment of the Pharmacy Act was passed last year, giving every man who had passed the Minor Examination the title of member of the Society, but the increase was not as great as it ought to have been. They had before them some very stiff work. "War imminent" was the position in which they were placed. At the opening of the next Parliament they would have to fight, almost for their very existence. They should be thoroughly prepared. It was desirable that they should have at the present time a greater accession of strength than they ever had before. It was sometimes said

that the Council consisted of men who had not the same feelings as those who belonged to the craft generally. He denied that. He and his colleagues had to make their own living, and to contend with the same troubles as the ordinary members of the Society. He appealed for new members, so that they might protect —not their privileges, for they wanted none—but their rights.

Mr. J. Rymer Young (member of the Council of the Pharmaceutical Society) proposed the next toast:—

The Sheffield Pharmaceutical and Chemical Society.

In the course of his remarks he referred to the question of company trading. He said the only point upon which the Council seemed to be unanimous at the present time was with regard to the protection of chemists' titles. That was a very important matter. As to how the Council should approach the thorny subject of company trading by unqualified persons, they had not one policy, but a dozen policies. One section of them would recognise that octopus-like growth, and seek to register it, regulate it, and restrict it. Another section—in which he thought he might include himself—looked upon the whole thing as unfair, unholy, uncanny, and something not to be touched by respectable people. He knew it was necessary upon many occasions to sacrifice principle in the interest of expediency, and that successful legislation was generally based upon judicious compromise. But, though he was not prepared to say at present what the Council might do, he trusted it would have nothing to do with anything which approached official recognition of company trading. If the regulation of companies was to be forced upon them by the Government, he held most strongly that they should wait until they were absolutely compelled to consider the unclean subject, but he hoped the Council would have none of it.

Mr. Squire, President of the Sheffield Society, in responding, said pharmaceutical topics were very quiet at present, but he thought it was only the calm which preceded the storm, and that before long they would enter upon very troublous times. The Council would need all the help that local associations could give, and it was for the local men to band themselves together and help members of Council in their deliberations and in framing clauses for the new Bill which they would have to promote. Above all things, they must not give away their title, and until they were absolutely obliged they must not recognise

Unqualified Company Trading.

Some time ago the Council sent suggestions to the Lord Chancellor, and if they had been passed pharmacy would have been rid of the parasitic growth of unqualified company trading, but they were doomed to disappointment. He thought company trading would always be with them, but unqualified company pharmacy they must try by every means in their power to stop. They might very well leave the matter to the Council in London, in the hope that chemists' interests would be properly cared for. Company pharmacy must not be recognised, and chemists' titles must be protected. If they gave away the title that was given them some years ago by Act of Parliament, where would they be? The Pharmaceutical Society might as well shut its doors. It would mean practically the repeal of the Acts of 1852 and 1868, and that he did not think Parliament would ever do. A company could not undergo individual examination, so why should it have an individual's title? It was important that the members of the Council should know the feelings of their brethren in the country. He was sorry that nothing definite had been done about Mr. Newsholme's scheme of local organisation. In Sheffield something had already been done, and they were waiting for the Council to give effect to the scheme.

Mr. William Ward next proposed the toast of

Sheffield University College

and the Learned Societies. He hailed with gratification and pleasure the arrangement the local society had made with the College. He was quite sure that the curriculum which had been established would meet the requirements of Sheffield students, and urged the students to avail themselves of the splendid opportunities provided for them.

Principal Hicks, in responding, expressed the hope that the connection of the College with the local society would grow stronger. It was a sign of

The Increasing Influence of the College

that the governing body was expected to take up special educational lines and to answer special educational needs. Not only had the Sheffield Pharmaceutical Society joined them, for their students, but the Incorporated Law Society had made arrangements with them to teach their pupils, and other societies in the city had also under consideration the making use of the College for their purposes —in fact, the College existed for the use of the town at large.

Mr. Wm. Parkin also responded.

The other toasts were "The Medical Profession," proposed by Mr. J. F. Eardley, and responded to by Professor Addison; and "The Visitors," given by Mr. J. B. Pater, and acknowledged by Dr. Hill.

During the evening a most enjoyable musical entertainment was given by Messrs. W. C. Newton, L. G. Reynolds, G. A. Shipman, R. C. Honey, T. Woodworth, and G. E. Hardcastle.

DERBY AND DISTRICT CHEMISTS' ASSOCIATION.

The second annual general meeting of this Association was held at Smith's Restaurant, Victoria Street, Derby, on Wednesday, October 18, Mr. Cope, President, occupying the chair. The election of officers resulted as follows:—President, Mr. J. A. Cope; Vice-President, Mr. C. W. Southern (Belper); Hon. Sec. and Treasurer, Mr. H. G. W. Dawson; Committee, Messrs. Hefford, Pembleton, Stevenson, and Warrington, the only change being that Mr. Hefford takes the place of Mr. Readman on the Committee. The Hon. Treasurer's accounts were then presented, and showed a balance in hand to the extent of £2 0s. 3d.

After other business incidental to a general meeting had been disposed of,

The circular from the Pharmaceutical Society respecting the

Election of a Local Secretary

was discussed, and after the President had explained the duties attendant upon the position, Mr. Dawson proposed, and Mr. Stevenson seconded, that Mr. Cope be re-elected. This was unanimously agreed to.

The question as to the desirability of joining the Federation of Local Pharmaceutical Associations next came before the meeting. The proposal received general support, it being thought that the Derby Association itself would benefit greatly, as well as conduce to the well-being of the trade as a whole. The Hon. Secretary was instructed to take the necessary steps towards affiliation.

At the instance of Mr. Hoare, attention was directed to the special

Classes for Pharmaceutical and Medical Students,

held at the Derby Municipal Technical College. General satisfaction was expressed that materia medica, botany, and biology were amongst the subjects now taught, and it was hoped that next year practical pharmacy would be included. The following new member was elected—Mr. W. Elmitt, Osmaston Road. This concluded the business of the evening, the subsequent proceedings taking the form of a social gathering.

NORTH-EAST LANCASHIRE CHEMISTS' ASSOCIATION.

At a special general meeting of this Association, held at the White Bull Hotel, Blackburn, on Tuesday, October 24, Mr. R. Lord Gifford, the Hon. Secretary, read a paper on

Pharmacy in 1868 and 1899.

He said: Circumstances make it desirable to come to a proper appreciation of the relative position of pharmacy on the passing of the Pharmacy Act of 1868 and of to-day, the more especially as my experience proves that the great body of chemists has not been in sympathy with official pharmacy, and that official pharmacy is lamentably ignorant of the every-day requirements of a practice of pharmacy generally suitable to the needs of the people of this country. Pharmacy is defined in most lexicons as "the art or practice of preparing medicines—the trade of an apothecary," *i.e.*, the dealing in medicinal substances. Evolution is defined as "the act or state of unrolling or unfolding." How far applicable this definition of pharmacy was in 1868, and how far it is to-day, is the measure of the evolution or unfolding that has taken place since the passing of the Pharmacy Acts, and it is, incidentally, the measure of the work effected by the Pharmaceutical Council during that period.

Pharmaceutical History Since 1841.

In approaching this subject we must bear in mind pharmaceutical history, especially since the foundation of the Society in 1841.

The Pharmaceutical Society was instituted with this special object: "To benefit the public and elevate the profession of pharmacy." Now history makes it plain that whatever may be said as to its shortcomings, the Council has kept the original intention of the Committee (of which Mr. Joseph Gifford was Chairman) constantly in view from 1841 to the present day. In the light of history this is the simple truth, in spite of the assertion made in an unfair article directed against Mr. Carteighe in a trade paper, miscalled the *Chemist and Druggist*, on May 28, 1892, that "the Council sought protection (before 1868) simply for the business of a chemist and druggist in the compounding of the prescriptions of duly qualified medical practitioners." This statement merely illustrates either the ignorance of the writer or his facility for innuendo and spite against the Pharmaceutical Society; in either case, it exemplifies the difficulties which have beset the Society from its inception in 1841 down to the present time—trade interests, working to keep, as far as possible, free trade in medicinal substances. What was the condition of the drug trade in 1868? I can only give a general idea, based upon statements made to me by men actually in business at that time, and still in full possession of their faculties. Speaking broadly, the people went naturally to the druggist for their drugs and medicinal requirements, boys were apprenticed to a calling, and it was thought the duty of the druggist to see that pupils were made proficient in this calling as practised at that time.

The Chemist before 1868—and Since.

The chemist before 1868 was looked up to much more so than now by the people generally, and he had much greater respect shown him in those days. If this is so, and every man that I know able to speak upon the subject says it is, and it is abundantly confirmed by the investigations of Dr. Attfield in 1883 that the process of degradation was going on (*vide* B.P.C. 'Year-Book' for an address intensely interesting at the present time)—then it follows that pharmacy has degraded simultaneously with its recognition. This fact, if fact it be, is very pertinent to the discussion now taking place on company pharmacy. It is also interesting to trace this decadence, and to probe into its cause. Let us begin with 1868, and we find Dr. Johnson's definition of pharmacy fairly applicable. But examinations were made compulsory, and a register prepared, which is another way of saying that our environment was made artificial. We were taken out of the grip of free trade—that is to say, Act of Parliament exempted us from free trade principles. Presently, and naturally, when restrictions were placed upon the practice of pharmacy, trespassers came, and, unfortunately, were able to trample these restrictions under foot; so much so, that at the present time the Pharmacy Act of 1868 is void and inoperative. As an example of the utter absurdity of the thing, I have a case in mind of a man endeavouring to qualify, buying a business in the market through death. Into this he put a qualified man, and prosecuted his studies. He was fined £10 for keeping open shop and using the title. Now he has on each side of him unqualified persons trading as chemists and druggists, and with no qualified person on the premises in either case. That the pharmacist can still live and thrive does not affect the argument, because it is not out of pharmacy he does so. He has to become, under present conditions, a parasite preying upon the public.

"Nay, they discover, too (their spite is such),
That health, than crowns more valued, costs not much;
Whilst we must shape our conduct by these rules,
To cheat as tradesmen, or to starve as fools."

This is not a mere fancy, but a fact, and many fortunes have been made by pharmacists because they have hit upon a good method of exploiting the public. Other men, again, hit on "good things"—many men have made wealth out of happy trade hits. Some pharmaceutical chemists have found money in "fly stickers," and so on, *ad infinitum*. My point is that from a national standpoint all this is waste and evil. The State needs its pharmacists to live out of pharmacy and to devote his life to the service of the community. If the chemist likes to go into trade, all well and good; it is alleged to be a free country, but for the devotee of pharmacy there should be a function practisable only after duly regulated qualification. Pharmacy after 1868 progressed, and it is reasonable to suppose it would have progressed and developed to this day had we guarded our rights and privileges as we ought to have done.

The Existing Problem.

But we have not done so, hence the position as it is to-day. As to what has been the cause of our apathy, or why our Council has been inactive, it is quite useless to discuss—recriminations concerning other days are waste of time. Men want to know what the problem is to-day, and what the fight is. The medical and legal professions have penal powers, and by means of these only have they been enabled to keep their barrier intact, but our case has become so glaring an anomaly that the Government recognises it, and, through the Lord Chancellor, says it must be remedied. It is natural that if it be possible to exploit a profession, traders will do it, and they have done so with us. They have recognised that the acquisition of a title by personal effort, *ipso facto*, placed chemists and druggists above the ordinary trader, and made his preserves objects of cupidity. This has been ministered to by imperfect or incomplete legislation on the one hand, and by absurd definition and our own apathy on the other. So small a field was given us that traders were able to deal in most drugs. What more natural then than flouting advertisements that "Chemists rob you—deal with us"? It then comes about that they can use the title, and it follows naturally, "We are chemists, but not ordinary chemists. They rob you, and we are philanthropists." Thus has it gone on, with the result that the title and the privileges I earned according to law are practically confiscated—that is to say, the solemn compact, most sacred the country can make, which the State made with me, has been broken; and I say, too, that we are in the right in asking, and insisting, that the State shall keep its word. That the Government shall drive out the trespassers from our land and make the restrictions operative is the merest and the barest justice. I said a short time ago that the Lord Chancellor recognises the anomaly of our position. Much twaddle, in my opinion, has been printed in reference to the Lord Chancellor; but there does not seem to be any difficulty in understanding his position if you take his actions and his statements. First, he expressly states that the idea of personal qualification does not cohere with practice by a company; secondly, he puts the case in such a way as to compel us to settle the nature of our qualification; in point of fact, he asks, Has this qualification to be for ownership or personal control—as it should be in medicine—or is it sufficient that it qualifies the actual seller on anyone's behalf? In other words, does our qualification differ from medical qualification essentially or only in degree? That it differs only in degree and equally shall not be exploited by capital is my contention, and what is infamous conduct in medicine shall not be made proper with us. Yet it is actually proposed, astounding as it seems, by members of our hitherto invertebrate body, to ask the Government to build a fence around the thieves, to allow that thieves have acquired ownership in my property by long possession. Surely the absurdity of this, which is recognised outside the drug trade, will kill it. This must be understood, however, that we insist, and the great body of chemists will insist, on our pound of flesh. We have fulfilled our share of the contract—let the State fulfil its share. In this relation I have been appalled at the shallowness of thought and want of insight into the consequences of doing this or that.

The Original Title to be Reserved.

A valued correspondent writes: "All of us are now agreed that we must insist on the title being reserved to the individual," but he strangely and utterly ignores the most vital point, which is, that we must get the original title, not a counterfeit, an emasculated, empty sound. I ask for the title I earned, and I am not prepared to accept any other. Let us be clear what are the logical consequences of claiming our title. (1) Only the person on the Register can use it. (2) That covering is equal to allowing an outsider to use it. (3) That no company of qualified or unqualified people can use it. (4) That at the present time it limits the operations of companies, as of all unqualified individuals, to substances outside the poisons schedules. There is not much to keep from them—still, a principle is at stake. (5) The "widow's clause" must go. (6) Practising under dead men's names, the worst and most damning fault of the Pharmacy Act of 1868, must cease. Gentlemen, I cannot bring this paper to an end without saying, though it is particularly painful for me to say it (but I conceive it my duty), I am heartily and sorely ashamed of some of our brethren in Scotland. They are actuated by honesty, as we are, that is patent, but for my own comrades to enter the fight with their minds made up that justice cannot be had in these British Isles of ours is too bad. I brand such comrades cowards, and I say, "Clear out, you are a clog. Leave us who have the pluck to do the fighting." Finally, then, what are our conclusions as to Pharmacy in 1868 and 1899? Whilst the examinations were voluntary natural development was taking place in pharmacy, and the people were comparatively properly looked after in the matter of its drug stuffs. The time had come for instituting a profession of pharmacy, and it is solely from adventitious circumstances that the present absurd state exists in 1899. The field of pharmacy is so trampled as to make natural development quite out of question. A pharmacist may develop

into an analyst on the one hand or a trader on the other, but that he can develop into merely an intelligent pharmacist is quite impossible at the present day. Yet the pharmacist is needed, in the interests of the people. The great mass of the nation do not want a "penny in the slot" dispenser. The bane of pharmacy, and, I believe, of medicine, is that we do not appeal openly to the public. We seem ashamed of ourselves, and our methods give them the impression that we desire to exploit them, whereas their and our interests are identical. The public cries aloud for a rational medical practice and a proper distribution of drugs. All our (necessarily futile) efforts are directed to weaving round them a network of protection without consulting them at all in the matter. I think the practice objectionable from every point of view. You tell the man in the street that a man died through taking two, instead of one, headache powders, obtained from the grocer, and he asks quite naturally why unqualified people handle such drugs, and he asks you, too, what it is you qualify for. Tell him again of the death of a woman in fearful agony through taking bitter apple—refused by a chemist, who ekes out a living, by the way, with lamp oil—and obtained from a man who has "chemist and druggist" over his door, though unqualified and having no qualified assistant. He simply cannot believe it. Prove the case, and he stands appalled at such a state of things.

Report of the Committee.

The Secretary then read the report of the general work of the Committee during the past year. Referring to the suggestions for a draft Pharmacy Bill, issued by the Pharmaceutical Council early in the year, the report stated that, given a courageous Pharmaceutical Council, the Committee believed that nothing in the world could withstand such a Bill; it would be so eminently just, straightforward, and desirable from the point of view of the public as to only need insisting upon to become law. It was acknowledged on all hands that the only obstacles to pharmaceutical legislation were sordid and capitalistic, and the Committee could not understand why chemists did not close with the opposition. The Committee was strongly of opinion that if the chemists throughout the country would interest themselves in their own affairs, the future position of the pharmacist would be an assured and honourable one.

The Company Pharmacy Problem.

Mr. W. Wells then moved:—

That companies, not being eligible for examination, cannot obtain qualification or registration and therefore, they must not use the title of Pharmaceutical Chemist, or Chemist and Druggist, and may not retail or dispense scheduled poisons.

He contended that the principle contained in the resolution was the only satisfactory and common-sense solution of the company pharmacy question.

Mr. Lomax (Darwen) seconded the resolution, at the same time expressing regret that such a thing should be necessary to protect chemists' rights and privileges. He contended that all those who refused to support the Pharmaceutical Society in such a cause were just as much traitors as those who acted as "covers" to unqualified companies.

Mr. Holt supported the motion. He said that with regard to the suggestion of compromise, that Association had consistently held that there could be no compromise where a righteous and just principle was at stake. (Hear, hear.) There was no association of chemists in the country which would support the Council more warmly than the N.E.L.C.A., provided it took immediate and energetic action to secure their titles and privileges from piratical infringements.

Mr. Brown (Burnley) also supported the resolution, remarking that no chemist could have any possible misgiving upon the matter.

Councillor Shorrock (Darwen) said they must reckon upon strenuous opposition from the companies, but he thought it could be overcome by vigorous personal propaganda.

The resolution was carried unanimously.

On the motion of Mr. Hindle, seconded by Mr. Openshaw, a vote of thanks was accorded to the retiring committee.

Antimellin.—This is the name given by Boersch to a glucoside isolated from the fruits of *Syzygium jambolanum*, which has proved useful in the treatment of diabetes.—*Oest. Zeits. für Pharm.*, **53**, 576.

LETTERS TO THE EDITOR.

The Company Pharmacy Problem.

Sir,—Permit me to say that the article by "An Ordinary Pharmacist," in last week's issue, expresses my views entirely, and, I believe, those of chemists generally. I would strongly advise our representatives on the Council to move in the direction indicated.

John Averill,
Stafford, October 24, 1899. *Local Secretary.*

Sir,—Your contributor, "An Ordinary Pharmacist," most accurately voices the opinions of fully nine-tenths of the registered chemists of the country. I do not propose to refer to his arguments; we have passed that stage, and conclusions have been definitely formed. I wish to point out, however, that during the last few months, having had more opportunities than most men of learning the views of other chemists, I emphatically say that those views are embodied in the substance of the clause your contributor suggests. There are two points of a positive kind which should be contained in the clause to be suggested for the Companies Bill. First, the restriction of the use of pharmaceutical titles to registered persons—secondly, the placing of companies of unregistered persons on the same footing as individuals in regard to liability for penalties for infringements of the Pharmacy Acts. The protection of titles is indispensable, and chemists accept the statement made at the last Council meeting that there was absolute unanimity on that point. It is equally indispensable that they should advocate the second part of the suggested clause, if only as a protest; neglect to make that claim would amount to concurrence in and acceptance of, the present law as it has been defined. I earnestly hope your correspondent's fear, that it may be proposed, in some way, to recognise unqualified company pharmacy is groundless. That would be suicidal. No one who has any conception of the intensity of feeling on this point would entertain the proposal for a moment. There is a good deal of fighting power, now dormant, which would be called into active life in opposition to the Pharmaceutical Society, and the Society would next year be less than ever the representative body of registered chemists. The mention of the bare possibility of the Council proposing to register, regulate, or in any way to recognise company pharmacy produces a heat in one's blood which can hardly find expression in words. The Council could not—as the trustee of the interests of registered chemists and in face of the fierce, determined, and now organised opposition they would meet with from within the pharmaceutical body—carry such a proposal. I recall the words of "our only orator," "if disestablishment and disendownment are to come they should come from without," and on a previous occasion "that they (the Council) should burn their boats, destroy their bridges and commit themselves to the fight." Every chemist on the Register insists upon and believes in the morality of his claim to the title he has earned and means to fight for it. Chemists also believe in the justice of their claim that all unregistered persons—whether united to form companies or singly as individuals—should be on the same level as regards the provisions of the Pharmacy Acts, and they mean to fight for that too.

John Smith,
Liverpool, October 23, 1899. *Local Secretary.*

Sir,—So much has been written and said on the above subject, that one is somewhat diffident in again trespassing on your space, but the views put forward by "An Ordinary Pharmacist" in your last issue (p. 383) so truly represent the feeling of the majority of pharmacists with whom I have had the pleasure of discussing this question, that I cannot help writing to urge all my brother pharmacists to read carefully what he has said, and to be ready to give effect to the same in every possible way. Whoever the writer may be, his article is the best thing of its kind we have had for a long time. Our organisation throughout the country is better now than at any former period of our history; we have men ready and willing to act in all parts of the country, and if the Council of the Society will adopt the suggestions put forward in the article referred to, I have no doubt that something may be done towards altering the present deplorable state of affairs. Will our Council lead us? We have justice and right on our side; why should we fear? Our right to have our titles protected is indisputable, and there is no reason whatever, that I or other pharmacists can see, why any combination of unqualified persons should be allowed to remain

outside the operation of the Pharmacy Act of 1868. Compromise has been suggested: but we cannot afford to concede anything to persons who are neither by training nor in any other way fitted to fulfil the responsible duties of a pharmacist. As for registration of companies, of such persons that is quite out of the question and I utterly fail to comprehend the frame of mind of any pharmacist who would suggest such a thing. Surely no member of the Council can be so weak-kneed as to give way on that point.

CHARLES THOMPSON,
Birmingham, October 23, 1899. *Local Secretary.*

Sir,—The article in last week's *Pharmaceutical Journal*, by "An Ordinary Pharmacist" very clearly sums up the position against company pharmacy, and clearly puts the issue before us. There must be no compromise. The Act of Parliament is the groundwork upon which a body of men have been trained and educated to discharge certain duties, and when they claim the right to discharge those duties surely "Monopoly" does not express the position! The public when they see the brass-plate "Surgeon" or "Solicitor" know they are dealing with a man qualified to use those titles, so also they have a right to expect that the use of a chemist's registered title implies qualified proprietorship.

B. KEEN,
Bristol, October 24, 1899. *Local Secretary.*

Sir,—I read with much interest the article by "An Ordinary Pharmacist" in the Journal of last week. I agree with him fully, and in saying that I know I express the views of the majority of "ordinary pharmacists" in this district. I would lay special stress on the paragraphs headed "All Compromise to be Avoided," and "The Companies Bill not a Pharmacy Bill." I would also urge the necessity of immediate action on the part of the Council in the direction of a Pharmacy Bill designed to confine to individuals duly registered according to the Pharmacy Acts the use of the titles, and the exercise of the functions of pharmacists.

FRED A. WILLIAMSON,
Preston, October 24, 1899. *Local Secretary.*

Sir,—The subject of Company Pharmacy, like the poor, may be said to be always with us. It has been talked and written about for years, and has become almost threadbare. Most chemists are beginning to think it is high time something was done, and that the Council of the Pharmaceutical Society, at least, had made up its mind how little or how much it was disposed to ask from the British House of Commons. I should like to express my sincere thanks to "An Ordinary Pharmacist" for his excellent article published by you last week. It throws an amount of light upon the question which is really refreshing, and puts the desires and aspirations of most of us in a nutshell, so to speak; it comes as a timely reminder to us not to forget our privileges and vested interests. There is also conveyed a solemn warning to be on the alert, lest by any misfortune we lose or give away any of our hard-earned advantages. He is not alone in thinking he could discern a slight shakiness in some of the members of the Council. But I trust it is only one's fancy, and that it has no real existence in fact. I sincerely hope the Council will stick to its guns, and not give way an inch; we want all the protection we can possibly get. Protection to titles is absolutely essential; so also is the protection against limited companies engaging in the sale of poisons, whether with qualified assistants or not.

"An Ordinary Pharmacist" is quite right in his interpretation of the Pharmacy Acts; they were intended to license the qualified man to conduct the business of a pharmacist personally, and not as the servant of a limited company. His desire to put as little as possible into the Companies Bill is very commendable, and the clause he drafts is excellent in conception. When our wishes are correctly formulated, we should certainly proceed by a new Pharmacy Bill. The whole paper of "An Ordinary Pharmacist" is so excellent that it were only a waste of time to comment upon each paragraph. I repeat, it is high time the Council produced a complete scheme of its own and submitted it to the members of the Society for their approval and ratification. The opinion of the thinking portion of the trade is well known, and is favourable to a Pharmacy Bill in which the chemist will receive the fullest protection to his interests. Half-measures will only disgust and dishearten members of the Society, especially those new members who have mostly joined the Society in the hope of bettering their condition. If something is not attempted on a broad and comprehensive scale many of these new men will be lost to the Society. My final words are these: Let there be no retrogressive movement, but let the Council stand fast and demand our just rights.

WALTER A. GRACE,
Liverpool, October 24, 1899. *Assistant Local Secretary.*

Sir,—I have carefully read the remarks of "An Ordinary Pharmacist" in last week's *Pharmaceutical Journal*, and therein I find that his views express in clear language what all on our Register should strenuously contend for. His proposal not to attempt to overload the Companies Bill with our grievances, and, at no distant date, to bring forward a new Pharmacy Act, is worth serious consideration. Although this world is said to be made up of compromises, compromise of any kind with company pharmacy should be opposed to the utmost. I would have nothing to do with such unfair opposition, but treat them as Pariahs. I even now cannot understand why qualified men allow themselves to act as dogs to blind men, which they do when taking service with companies. It is often said that it would be useless to attack companies because of their vested interests. If that is their only claim for immunity, may I point out the much larger vested interests they attacked when they first started their nefarious practices. Ever since they have taken from the whole community of chemists, not only those in business for themselves, but every man on the Register? There is one thing I should like to see, and that is, our Society and the Irish Society working in unison, for they have but one end in view—the safety of the public and the good of the craft—two things so interwoven that what is best for either is best for both.

Harlesden, N.W., October 24, 1899. J. W. TAPLIN.

Sir,—I have read with interest the article in your last issue on the "Company Pharmacy Problem." It is certainly asking for enough under existing circumstances, but as it is consistent with the idea of the original Act, I feel sure it would receive the support of the rank and file throughout the country.

Plymouth, October 23, 1899. JAMES COCKS.

Sir,—Our thanks are due to "An Ordinary Pharmacist" for his able, lucid, and opportune article upon the much vexed question of "company pharmacy," and to you, sir, for your "Annotations" upon the same. One ventures to hope that they are more or less "inspired" by the Pharmaceutical Society's Council itself; that they foreshadow in some degree the lines which the forthcoming suggested clause to be submitted for insertion in the Companies Bill will go upon. They seem to show me clearly the reasonableness, first, of insisting upon the protection of our titles, and, secondly, of objecting to any proposal for the registration and regulation of "drug stores owned by companies of unqualified persons."

Cambridge, October 25, 1899. E. SAVILLE PECK.

Sir,—I have read with interest and appreciation the article in your issue of the 21st inst. on this subject and I regret that "Ordinary Pharmacist" did not write under or over his name. His common sense is uncommonly well developed and I, for one, would like to know that his level head was among those which grace our Council Board. As to the suggested clause, probably a legal draftsman will want to recast it; but I think we may wisely put it forward as the embodiment of what we want,—let the draping of our figure be done in another place. In our local association we have a watching committee ready to assist by interviewing members of Parliament, etc. When the time for such action I want no better text than the suggested clause.

J. MALTBY CLAGUE.
Newcastle-on-Tyne, October 25, 1899. *Local Secretary.*

Sir,—Allow me to congratulate you on the series of four such eminently readable papers on the existing state of pharmacy as those appearing in last week's issue, a series I may say truly worthy of the denomination you apply to it, viz., Instructive Reading. Whilst not wishing to make any invidious comparison, I would earnestly commend to the notice of chemists generally the article by "An Ordinary Pharmacist" on "The Company Pharmacy Problem," if for no other reason than the bold, straightforward way in which the writer states his views and defines what he considers should be inserted in the Companies Bill. Such articles it may be hoped will have the effect of educating qualified persons to appreciate their

qualification at its correct value, while imparting a little of that necessary "backbone" which seems so lamentably wanting even in many of the younger generation of pharmacists.

HAROLD WYATT, JUN.,
Bootle, October 25, 1899. *Local Secretary.*

Sir,—Approval in its most unqualified form must be given to the article in your last issue by "An Ordinary Pharmacist." To obtain a full amount of sympathy from such a democratic body as Parliament is under our system of all but universal suffrage, we must concentrate and focus our just demands upon the point of greatest urgency. That is no doubt the unjust appropriation of our titles by unregistered persons:—upon that ground we ought to make a most determined stand against the attacks of those who would deny our exclusive right to them. Our position on the ground of common sense and ordinary justice ought to be unassailable, but partly owing to our individual carelessness, and partly to our corporate supineness, we have allowed others to filch that for which we have toiled and worked and to which they have no claim whatsoever. Therefore I venture to think the bulk of all true fellow-craftsmen is with me when I say that our Council ought, nay must, make this demand for absolute and exclusive right to our own titles the very foundation of their attack upon the "Companies Bill." We have an inherent right to them—guaranteed to us by Act of Parliament, but through stress of other matters this right has been too much invaded. It is quite beside the question to introduce a lot of side issues about "trade" and "cutting prices." Although we get our living out of trade, and have to contend with "cutting prices," yet those questions must have no place in our deliberate demands. We hold no position apart from other tradesmen—if we plead our inability to compete with them in the matter of window shows, long-haired prodigies, patent comb manipulators and waxwork shows—and it is to be regretted that so many chemists have descended to such tradesman's tricks, mainly, I believe, at the instigation of those who are the most bitter opponents of our Society, and the most active supporters of inimical journals. No recognition ought to be given to companies of unregistered persons. It is impossible for us to conceive that Parliament originally intended a personal qualification to be assumed by a corporate body, or that the personal qualification was to be concentrated in such a form that one part of unqualified person added to six parts of a cosmopolitan host should make a registered chemist according to law, let alone the fact that nowadays the ideal personage need not have any qualified ingredient at all. The lawyer, the doctor, the dentist are no more entitled to special protection than we are. Yet they are to be protected by the very justice (?) which refuses protection to us. To discuss a Pharmacy Bill, or any other matter which we should so much like to see brought forward in our interests, is not expedient at the present time. Let us by all means promote the main object with a solid front, and bear in mind the tremendous power which will shortly be presented at the next General Election, when our views on other matters connected with our profession can be formulated and explained. True, it has been said that the bulk of M.P.'s themselves are so interested in the numerous stores that their action is already compromised, but—in regard to that point—I venture to assume that the infinitesimal, and, in a large number of cases, the entire absence of dividends lately announced may not be without benefit to us all.

October 24, 1899. ANOTHER ORDINARY PHARMACIST (5/16).

Is Company-Trading Machinery Applicable to Pharmacy?

Sir,—In connection with the various points that are attracting attention on this somewhat difficult subject, there is one aspect that has not received the attention it probably deserves. It has been assumed by some persons to be undesirable to limit in any way the employment of capital, and, in support of that view, reference is made to the great developments that have resulted in many ways for the general welfare of the community by application of the principle of limited liability. It has also been suggested that the business or profession of a chemist and druggist should not be any exception to this general rule. But to those who have expert knowledge on this subject, it is quite clear that in that particular calling, large capital is not of such supreme importance which it may be in many others.

The important qualifications required for the exercise of that calling are knowledge and skill rather than much cash. The business lends itself but little to developments by the mere employment of capital, and the returns of a medium or even large business are so limited that it may be confidently asserted there is no kind of necessity in a business so essentially of a personal character for the employment of capital by the machinery of limited liability companies. And in addition, and more important still, when it is further considered that to allow the principle of limited liability, as applied to the business of a chemist, means that persons having no requisite knowledge of drugs and in particular of various poisons, are by that means enabled to evade the law requiring personal qualification. Hence it must be evident that no case has been made out for allowing any latitude or laxity in the strict interpretation of the Pharmacy Act, 1868, and that so far as regards the safety of the public and the protection of those who are legally qualified to deal in poisons, it is not expedient that capital under the protection of the Limited Liability Acts should be so employed.

October 23, 1899. R. A. R. (5/26).

A Protest.

Sir,—My attention has been directed to an article headed "The Adulteration of Drugs," which appeared in the *Hospital* last week, purporting to reproduce parts of a report by me of the results of analyses of certain belladonna plaisters, and as that report has been published in direct breach of agreement I desire to enter a protest against the use that has been made of it. I do that, moreover, because data contained in the report are suppressed, and, as published, it has been made an apparent basis for statements, contained in the article, which are damaging to the credit of chemists and druggists and, by implication, raise a question as to their honesty and trustworthiness.

13, *Fenchurch Avenue, E.C.* BENJ. H. PAUL.

Phosphorus in Pill Form.

Sir,—During the course of some chemical experiments phosphorous acid was prepared by placing a stick of phosphorus in a test tube having a hole at the bottom, as recommended by Dr. Attfield. The apparatus was placed in a somewhat lofty window, having a south aspect. After a few days it was found that all the phosphorus had melted and passed through the hole of the test-tube into the water contained in the beaker, and there formed small round beads about the size of pills and varying in weight from one to seven grains. These have been found to be very useful to hand to elementary pharmaceutical students who require to weigh small quantities of this dangerous article for making pilula phosphori and other extemporaneous preparations containing free phosphorus. It is equally available for making experimental quantities of phosphoric acid and the official hypophosphites; for, all the student has to do is to select the piece or pieces of the right weight for the operation in hand, and remove with a mounted needle. This is better than cutting the phosphorus with knives, and, indeed, better than all the curious methods (with their attendent dangers) that a long experience recalls. This suggestion is offered to manufacturers and "all whom it may concern," in the hope that others may find the same benefits as have fallen to the writer's lot in this matter. By experiment it was found that the oxidation was so slight as to be almost negligible, and carbon bisulphide dissolved the phosphorus as readily as when in the stick form.

Birmingham, October 23, 1899. F. H. ALCOCK.

Association of Lady Dispensers.

Sir,—I note the query of your correspondent in last week's Journal about a Lady Dispensers' Association. Without wishing to force the Public Dispensers' Association upon lady dispensers, I wish to draw their attention to the fact that our Association is open to all qualified dispensers, irrespective of sex, and they may rest assured of a hearty and courteous welcome at any of our meetings.

G. F. FORSTER, M.P.S.
Hon. Sec., Public Dispensers' Association
London, October 23, 1899.

The So-called Percentage Solutions of the B.P.

Sir,—My statement that solutions of potent drugs containing *x* grains of the medicament in 110 minims of solution are clumsy and unnecessary has been challenged, on the ground that such solutions are desirable because they pave the way for the adoption of the metric system. It is quite true that such solutions are equal in strength to solutions containing *x* grammes in 100 cubic centimetres, but that is only a theoretical advantage, whilst there are good reasons for preferring the present solutions containing *x* grains in 100 minims. It is unlikely that medical men will think and prescribe in terms of the metric system for some time to come, or that they will use the comparatively unknown measure known as the fluid-grain. The adoption of the metric system is a change to be welcomed, but that is no reason why error should be courted in adopting, even temporarily, the form of solution whose strength is expressed as *x* grains in 110 minims. Day by day, among both medical men and pharmacists, calculations are wrongly made through the introduction of solutions of that strength. Take the case of liquor arsenicalis. The B.P. specifies the strength of that solution as 1 gramme in 100 cubic centimetres, which is the same as 1 grain in 100 fluid grains. But the average dispenser or physician, unfamiliar as he is with the fluid-grain, misinterprets the strength as 1 grain in 100 minims. Even if he realises the B.P. statement that 110 minims contain 1 grain he cannot readily calculate the dose of potent drug, and, when that is found, the dose does not correspond with the B.P. dose of the medicament. It scarcely needs pointing out that true percentage solutions are of scientific value only. The B.P. preparations are not percentage solutions, and it would be better for everybody concerned if the term "percentage solution" were entirely abandoned in connection with pharmaceutical preparations. In conclusion, I would point out that the object of making a solution of a drug of definite strength is to obtain the drug in a form that admits of ready administration, and to avoid having solutions of varying strengths in different pharmacies, a distinct source of danger. It is advisable, for the sake of safety, that the official doses of those solutions should contain official doses of the potent drugs. That object is not attained by solutions containing *x* grains in 110 minims. It is attained by means of solutions containing *x* grains in 100 minims. That provides a practical way by which accurate and consistent doses of active ingredients may be administered. Let us for the present adhere to *x* grains in 100 minims and refrain from calling the B.P. preparations percentage solutions.

London, October 25, 1899. F. A. Upsher Smith.

ANSWERS TO QUERIES.

Liquefaction of Hydrogen (C. B. D.—35/17).—See the *Pharmaceutical Journal* for January 28 last, p. 89, June 10, p. 540, and September 16, p. 275, for full particulars.

Daffy's Elixir (W. L. B.—35/3).—The following is the formula given in Gray's 'Supplement':—Senna, 6 oz. troy; jalap, sliced; aniseed, caraway seed, of each 1¼ oz. troy; juniper berries, 2½ oz. troy; proof spirit, 6 pints. Macerate for fourteen days, then add treacle, 10½ oz. troy; water, 17 oz. troy; mix and strain.

Brine Vats for Pickling (T. C. C.—35/15).—Metals of all kinds should be avoided; well-made slate or wooden vats are far preferable in every way. The least objectionable metal would be well enamelled iron, but that would possess no advantage over slate or wood. Certainly lead is most objectionable for the purpose, and should on no account be used.

Lime Juice and Glycerin (T. S.—35/4).—Yolk of one egg; glycerin, 2 fl. oz.; tincture of quillaia, 2 fl. drms.; oil of sweet almonds, 2 fl. oz.; lime juice, 1 fl. oz.; oil of limes, 20 minims; distilled water to 8 fl. oz. Rub down the yolk of egg with the glycerin, add the quillaia; then slowly incorporate the oil and the perfume; then mix in the lime juice, and finally add enough water to make up to 8 fl. oz.

Photography in an Asylum (S. H. L.—35/1).—(1) The most useful form of camera would be the parallel bellows portable pattern, with long extension. A studio camera would be found cumbersome, and taper bellows should be avoided. If funds will allow, we should recommend the Dallmeyer Stigmatic lens, series I.; but if there is a fair amount of light the No. II. series would probably be sufficiently rapid and less than half the price. Whatever lens be chosen, the focus should be at least one and a-half times the length of longer side of the plate used. (2) All plates are so good nowadays that the choice is almost entirely a matter of personal fancy. Extremely rapid plates should only be used when absolutely necessary. A medium plate will be found to give the best average of results. (3) We do not know of any text-book which treats fully of these matters. A photographer who has been used to the class of work referred to could give more valuable information in half an hour than that contained in all the text-books put together.

Examination of Silk Fabrics (W.E.—35/14).—You will find an excellent *résumé* of all the more recent methods of silk analysis in Allen's 'Commercial Organic Analysis' Vol. 4, pp. 499 to 527. From that source we abstract the following two methods, which will probably suit your purpose. To determine the total proportion of foreign matter, a known quantity of the silk, previously dried at 110° C., is weighed off and boiled for an hour with a 2 per cent. solution of sodium hydroxide, then with diluted hydrochloric acid (2·5 per cent. of commercial acid). This treatment is repeated four times, washing the material after each bath. The silk is then dried at 110°C. For a more extended examination, the following method is employed by Von Remont:—Four quantities, A, B, C, D, each of 2 Gms. of the air dried material are weighed out. One of those, A, is kept, the other three are boiled for fifteen minutes in 200 C.c. of water, containing 3 per cent, of hydrochloric acid. The liquid is decanted, the boiling repeated with more dilute acid, the pieces are then washed free from acid and B laid aside. To remove the silk, C and D are placed for two minutes in a boiling solution of basic zinc chloride (prepared by dissolving 100 Gms. of zinc chloride in 85 C.c. of hot water, and adding 4 Gms. of zinc oxide, heating until solution is complete). They are then thrown into water and washed, first with water acidulated with 1 per cent. of hydrochloric acid, and then with pure water, until free from zinc. C is then pressed and set aside. D is next boiled gently for 15 minutes with 60 to 80 C.c. of sodium hydroxide solution, s.g. 1·02, then washed very carefully in water. The four portions, A, B, C, and D, are then dried for an hour at 100° C., and left until the following day freely exposed to the air so that they may absorb the normal amount of hygroscopic moisture; they are then weighed. The weights of A − B = dye and finish, b − c = silk, c − d = wool, d = vegetable fibre. For further specific cases you cannot do better than consult the above quoted text-book.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course, not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size, clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Branch, Breeze, Brown, Crawhall, Dawson, Delves, Dent, Dunkerton, Emary, Enke, Ennever, Evans, Ferrall, Gair, Gill, Howes, Jackson, Judge, Marshall, Nicolson, Oldham, Padwick, Rowell, Ruff, Shanks, Smart, Wallis, Whineray.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

STAINING TUBERCLE BACILLI.

An aniline colour, Sudan III., is recommended by Dorset as a stain for the tubercle bacillus (*Journ. Amer. Public Health Assoc.*, xxiv., 1898, p. 157). Cover-glass preparations of sputum, etc., are stained for 5-10 minutes in a saturated solution of the dye in 80 per cent. alcohol and are then washed in 70 per cent. alcohol for five minutes, the solution being changed several times. The bacilli so stained are not decolorised by treatment with 1 : 25 sulphuric, hydrochloric or nitric acids for two minutes. Tissues are similarly treated, and may be counter-stained with methylene blue. Dorset claims that the Smegma and other similar bacilli are not stained by this method.

FILAMENTOUS BACILLI.

Thread and branching forms have been described in cultures of the tubercle and of the diphtheria bacillus, and Valerio finds that the same occurs with the glanders bacillus. Especially in peptone broth, filamentous forms occur with true and with false branchings, and often terminated by club-shaped expansions.—*Centr. f. Bak.*, xxvi., p. 177.

SUCCINIC ACID IN TUBERCULIN.

Viquerat states that the new tuberculins TO and TR do not contain any proteid, but that a substance having all the characters of succinic acid is present, and to this the activity of the tuberculin is due.—*Centr. f. Bak.*, xxvi., p. 293.

SUPER-COOLING OF PHOSPHORUS.

E. G. Bryant points out that the super-cooling of water is a well-known phenomenon, but it is somewhat difficult to show as a lecture experiment, as a good deal of preparation is required. The supercooling of liquid phosphorus, on the other hand, is exceedingly simple to demonstrate. If a piece of phosphorus be melted under a strong solution of caustic soda or potash, as in the preparation of phosphoretted hydrogen, it will apparently remain liquid for an indefinite time; at any rate, it has been kept some four days in that condition. Its temperature can be taken roughly by immersing a thermometer bulb in it, and it will bear moderate shaking or motion without becoming solid. If violently shaken it solidifies suddenly; also if an attempt is made to pour it out of the vessel. Of course, the body of solution in which it is placed prevents any noticeable rise of temperature on solidification when dealing with only a small quantity of phosphorus. The author imagines that chemical action has largely to do with the retention of the liquid condition, bubbles of phosphoretted hydrogen being given off continually, even at temperatures of 8° or 9° C. Still, whatever be the causes, the fact remains that phosphorus can be obtained and kept in a liquid state at such a temperature.—*Chem. News*, **80**, 183.

SUBSTITUTE FOR POULTICES.

M. J. Wilbert suggests the following formula for a substitute for poultices:—Kaolin, 1,000; glycerin, 1,000; boric acid, 100; oils of peppermint and wintergreen, each 1; oil of eucalyptus, 2. The kaolin is passed through a No. 60 sieve to free it from impurities, and heated to 100° C. for an hour or more to sterilise it; then add the glycerin and continue the heat for thirty or forty minutes, stirring the mass occasionally with a spatula, until a smooth, creamy mass is obtained. Remove the source of heat, and, when the mass is nearly cool, add the boric acid and the oils; mix thoroughly, and preserve in tin or glass boxes, which are sufficiently tight to prevent the absorption of moisture from the atmosphere. Similar preparations have been sold in America under the names "Antiphlogistine" and "Antithermaline."—*Am. Journ. Pharm.*, **71**, 478.

WILD CHERRY BARK.

A. B. Stevens gives the results of analyses which indicate that the bark of *Prunus serotina* deteriorates with age. He finds that the bark is best preserved in glass or other air-tight retainers, and suggests that only whole fresh bark should be used in the manufacture of galenical preparations. He proposes now to study the keeping properties of the various preparations of the bark, as compared with the bark itself.—*Pharm. Review*, **17**, 445.

BROWN RUST OF CEREALS.

J. Eriksson gives the results of an examination, extending over many years, of the parasitic fungus which causes the brown rust of cereal crops, *Puccinia rubigo-vera*. He proposes to split it up into six species, one only of which is at present known in the æcidioform stage, viz.:—(1) *Puccinia dispersa* (*Æcidium anchusæ* on *Anchusa arvensis* and *A. officinalis*), *Uredo dispersa* on *Secale cereale* and *S. montanum*; (2) *P. triticina*, n. sp., on *Triticum compactum*, *dicoccum*, *spelta*, and *vulgare*; (3) *P. bromina*, n. sp., on many species of *Bromus*; (4) *P. agropyrina*, n. sp., on *Triticum repens*; (5) *P. holcina*, n. sp., on *Holcus lanatus* and *H. mollis*; (6) *P. triseti*, n. sp., on *Trisetum flavescens*. Of these six species the first and second only are of great importance in agriculture, the first being very destructive to rye, and the second to wheat, in Europe, the United States, and Australia.—*Ann. Sci. Nat. Bot.*, **9**, 1899, p. 241.

YELLOW PIGMENT OF LEAVES.

In all crude alcoholic extracts of green leaves, C. A. Schunck finds two yellow colouring matters accompanying the chlorophyll, viz. chrysophyll and xanthophyll, using the latter term in a somewhat restricted sense. It is the predominant substance, and is identical with the principal yellow colouring matter in faded autumn leaves. Other yellow colouring matters may also be present, Chrysophyll and xanthophyll each gives a characteristic absorption spectrum in the violet and ultra-violet regions, the former consisting of three bands, the latter of four. Chlorophyll itself also gives three characteristic bands in the violet. Phyllocyanin and phylloxanthin have bands in identical positions with these three chlorophyll bands.—*Proceedings Royal Society*, **65**, 1899, p. 177.

ACTION OF ROOTS ON GRANITE.

According to F. Sestini, the roots of many plants, especially those of certain Gramineæ and Leguminosæ, have a powerful decomposing effect on felspar, assimilating the alkaline bases and all the ingredients which serve for the nutriment of the plant, leaving behind hydrated aluminium silicate. A similar part is also probably played by the microbes in the soil.—*Atti. Soc. Tosc. Sci. Nat.*, **11**, 1899, p. 138.

FASCIATION OF PLANT STEMS.

Herr E. Küster has investigated the anatomical changes which take place in the fasciation of stems in woody plants, and especially in the fig, beech, oak, plane, and ivy. The growth of the cambium is retarded by pressure; and in *Ficus* this is accompanied by increased activity of growth, and of cell-division in the primary cortex. In *Ficus stipularis* the parenchyma of the medullary rays becomes lignified. Portions of cambium always become enclosed in the cortex and bark. In *Hedera* closed cambium rings are sometimes formed round these enclosures.—*Pringsheim's Jahrb. f. wiss. Bot.*, **33**, 1899, p. 487.

THE STUDENTS' TRAINING—PAST AND PRESENT.*

BY JOHN SPILLER, F.I.C., F.C.S.

When a fortnight ago your esteemed Profes or of Chemistry, backed by my old friend Dr. B. H. Paul, preferred a request that I should give you something in the shape of an inaugural address, I hesitated at first on the score that my knowledge was not of the newest, not feeling sufficiently in touch with the latest developments of modern chemical research; but, on the other hand, to refuse on this ground, and decline to give you, in brief, the results and conclusions of fifty years' experience in chemical laboratories, was equally unsatisfactory, especially in view of the fact that I have been the recipient of past favours from the Pharmaceutical Society of Great Britain, as represented by many of those whose names are recorded in the brightest pages of its official history, down to the honoured President of to-day. I take it for granted that you will need no further introduction, or demand from me an apology for making an attempt to interest you as members of the School of Pharmacy Students' Association in matters relating, partly, at least, to a bygone period, and compare our former aspirations with the greater advantages and realisations of the present time.

Going back to the year 1848, when I entered the Royal College of Chemistry as the youngest student, Gregory's 'Inorganic Chemistry' and the 'Giessen Outlines of Analysis' were the standard books which every student was expected to provide. A few of us possessed Fownes's delightful little volume, and later on we all worked from Fresenius's 'Quantitative Analysis.' Our work was supervised by Dr. A. W. Hofmann, the most enthusiastic of bygone professors, whose twenty years' residence in this country, successful teaching, and fertility of research, constituted a quite remarkable scientific epoch. All his students revere his memory, the Chemical Society never had a better president, and although our professor had to lecture and address us in what to him was a foreign language, his rich vocabulary and happy choice of words often amounted to oratory, so that he succeeded in investing almost every subject treated of with an extraordinary halo of interest. It was my good fortune to remain for five years under such tuition, and during two full lecture courses to act as Hofmann's assistant. The staff was a strong one, including Messrs. Abel, Bloxam, and David Price, with Nicholson and Brazier in the private (research) laboratory. It was Hofmann's practice to visit each pupil for a few minutes every working day, so there could be no wasted time or difficulties long left unsurmounted. Our professor was known to have had a preliminary legal training, and perhaps to this circumstance much of his success was due. Bearing all these facts in mind, I counsel you, then, to study so much of the elocutionary art as is needful to make your meaning clear and style attractive. If you aspire to be a science lecturer and successful teacher this is very important. In the present day there is a great demand for really efficient technical lecturers, and those are preferred who appear to possess in highest degree the power of interesting an audience and sympathising with their pupils. Many learned men have failed in this particular; they may have had the knowledge, but not the gift of imparting their information to others.

Looking back to the period just now under review, one remembers in association the grand names of Faraday, Hofmann, Huxley, and Tyndall—an ever-famous quartette, although we have good lecturers in the present day.

Shortly after I left the R.C.C. (in 1853), and accepted Dr. Percy"s invitation to come into his metallurgical laboratory at the School of Mines, and work on the 'Iron Ores of Great Britain' with Allan Dick and Edward Riley,† a coalescence was brought about which resulted in the union of the Oxford Street and Jermyn Street establishments under Government control; for Lyon Playfair was giving up his chemistry lectureship, to which A. W. Hofmann succeeded. All went well until Sir Roderick Murchison sniffed the chemical fumes, and then the savoury department was once more banished to Oxford Street, but this time into the newer (rebuilt) theatre, where Herbert McLeod began his successful career as lecture assistant, and helped to bring to perfection the elaborate system of experimental illustration afterwards published in Hofmann's 'Modern Chemistry,' 1865.

But before I leave this part of the subject let me put on record that the fees charged at the R.C.C. were £15 per term of five months, and there were only two terms per annum, so that the cost was £30 a year. This covered for lectures and practical work in the laboratory, but did not include apparatus.

Several courses were given from 1852, onwards, at Jermyn Street Museum by each of the professors in turn, at merely nominal fees, and were eminently successful. Of course, they were early attempts to inculcate the principles of technical instruction, but without opportunity of practical working; more thorough, perhaps, but of the same character as those given formerly at the Mechanics' Institutions.

I come now to a serious defect in our College syllabus at those early times. It was that of dissociating the study of chemistry and physics. We were taught only a few leading facts, such as specific gravities, the pressure of air sustaining a column of water or mercury, Mariotte's law of gaseous volume, the Torricellian vacuum, expansion by heat, and liquefaction by pressure of certain gases. In my time, as custodian of the College apparatus, I had charge of a very small collection of scientific instruments applicable to the teaching of physics. There were a few voltaic battery cells, a frictional machine, Leyden jar and eudiometer, an air pump and Magdeburg hemispheres, a compression cylinder, the ring and ball arrangement and pyrometer for showing the expansion of metals by heat, a few thermometers, hydrometers, and a box of specific gravity beads. Some of us were adepts at electrotyping, and possessed our own appliances. Crookes, Maxwell Lyte, and myself were ardent photographers, but all such hobbies were outside the laboratory course, and had to be done at home. Fownes's introductory pages, about one hundred devoted to physics, were carefully read, but we had no demonstrations, or only the scanty few already mentioned. Hence it was to some of us a great boon that we were permitted to attend here for a short course of six evening lectures on "Magnetism and Electricity," given by the late Dr. Theophilus Redwood, and admirably illustrated. I cannot now remember whether any fee was paid, but I believe not; nothing beyond recording our grateful thanks to the Pharmaceutical Society and its amiable lecturer, who was always on very good terms with our own professor.

Now-a-days the study of elementary physics and chemistry go hand in hand, for we have to use the polariscope in sugar determinations quite as often as the purely chemical tests. The tintometer is also a well-recognised instrument for matching colours and keeping to standard shades. Electrolysis is now often resorted to in the quantitative deposition of metals; dialysis performs a useful function amongst the class of bodies to which you give your attention, and we all know the practical use of the spectroscope in steel making. Who could have guessed that an alloy of potassium and sodium would remain permanently liquid like mercury, and be used in a similar way for filling thermometers? I remember Schrötter coming over from Vienna to show us how to prepare the red modification of phosphorus; now Bryant and May use it by the ton. The differences are only physical, but important, like coke and the diamond. During the last half-century a band of scientific educationalists have been hammering away to secure the recognition of science teaching in public schools. Eton, Harrow, and Rugby were slow to begin, although the City of London had

* Address delivered at the opening of the School of Pharmacy Students' Association, on October 27, 1899.

† Published in 'Memoirs of the Geological Survey,' and reproduced in Watts's 'Dictionary of Chemistry'

shown the way as early as 1847. Some fifty Fellows of the Chemical Society and nine of the Royal Society received their first scientific instruction at the school under the late Thomas Hall, B.A., F.C.S. Amongst others, Dr. Divers, Sir Wm. Huggins, Professors Kennedy, Pedler, W. H. Perkin, sen. and jun., Sir John Seeley, Professors Sollas and W. C. Unwin. Perhaps none of these might have been won over to science but for the happy circumstance of their being brought under the influence of Mr. Hall at the City of London School. Now every school has is laboratory, and elementary science classes are held even in remote country districts, the operation of the Technical Instruction Acts conducing to this end, and offering financial aid, the Department of Science and Art likewise giving encouragement of a similar character.

In the march of progress Huxley led the van, for we see in his 'Lay Sermons' and multitudinous writings continual references to the advantages and mode of presenting the leading facts and principles of science to school boys and girls. His Chapter IV. "On Scientific Education" is a veritable golden legend, and be sure and read the footnote relative to medical education, quoting the speech of Mr. Quain, the President of the Royal College of Surgeons.

Dr. John Hall Gladstone, some time member of the London School Board, is another doughty champion of the same fraternity. We spent a most delightful morning at Dover on Monday, 18th ult., receiving and discussing the British Association Report on "The Teaching of Science in Elementary Schools." It promised well, for here are the names of the Committee:—Dr. Gladstone (chairman), Professor H. E. Armstrong (secretary), Professor W. Ramsay Dunstan, Mr. Geo. Gladstone, Sir John Lubbock, Sir Philip Magnus, Sir Henry Roscoe, Professor A. Smithells, and Professor Silvanus Thompson. We were told that, according to the Education Department's reports for 1897-8, 24,000 centres in England and Wales had adopted "Object Lessons and Elementary Science," and that the London School Board, in their Evening Continuation Schools, had considerably over 20,000 scholars taking these subjects. This, in turn, threw great responsibility upon the teachers, so that we now find special classes instituted for their training at several of the London Polytechnics. We must be careful not to overdo it, but it is surely desirable to give children some idea of the nature of air, water, and common objects around them. At any rate, Huxley and Quain's objections are met, and what with the gigantic technical advances of late years no one of the rising generation ought to come to Bloomsbury Square without a fairly good preparation for the special course of study you propose to give him here.

Chemists of to-day find the area of study so immensely large and constantly increasing, without even the superadded effort of keeping abreast of the progress in physics, that the majority of us, if not all, have to be content with a general survey, and allocate to ourselves the duty of following closely some few particular directions of study in which we endeavour to make ourselves proficient. Many of us are specialists, and only consulted as such. We have our brewers' chemists, sugar experts, food and water analysts, toxicologists, assayers, textile colourists, chemical engineers, and the hundred and one representatives of certain well-defined departments, which a glance at the printed list of members of the Society of Chemical Industry will enlighten you upon. As I have said before, it is not possible for one poor mortal to make himself master of all branches; the work must be subdivided, and practically it is so to a large extent in the present day. I imagine that pharmacy is getting pretty wide, so many new therapeutic agents being constantly introduced, but your range is probably more limited than that of the general chemist. We can only strive to do our best, seek help when we want it, and, therefore, must keep on good terms with the whole profession. One step towards this is to cultivate and deserve the friendships formed here in your early days, and be ready to sympathise with other scientific men, whose work does not happen to run exactly in your own groove. I trust your Students' Association is founded for this very purpose, each contributing from his own special store of knowledge to enrich the experience of others, and in this way many a good thing is best done when you have the opportunity of comparing notes with your fellows as you go along.

How I envy you the long and useful career that we devoutly wish stands in front of every one of you—to begin where I leave off, and take advantage of all the refinements and conveniences of modern times. Rare metals and products brought within your grasp, cheap nickel and aluminium; uranium, lithium, and thallium accessible; silver at half-price; liquid air for freezing; an electric current is wanted—you take it off the house main just as easily as you get your supply of gas, but for electrolytic purposes see that it is not an alternating current. You will be working with X rays to help the surgeon and solve many a mystery. Your drugs and tinctures will be of the right strength. Always do your own analyses, and be ready to stand by the results. Lose no opportunity of seeing over a factory whenever you get the chance, and be sure and visit the foreign laboratories, museums, and botanical gardens when you go abroad. Acquire some little proficiency in glass-blowing, for we often work now with sealed joints. These are just a few hints that occur to me to offer by way of conclusion, and I suppose the student who has no research of his own to report will do as we did, and find somebody else's novelty to describe, and, if possible, submit samples.

One other thought occurs to me. Are any of you intent upon competing for the Actonian Prize in 1900? One hundred guineas was awarded to Professor Fownes in 1844 for his essay, and the septennial period will very shortly be coming round again.

ETHICS AS APPLIED TO THE PRACTICE OF PHARMACY.*

BY J. C. HYSLOP.

The agreeable task that devolves upon me now of asking your attention for a short time to the subject of Ethics as applied to the vocation we have chosen for our life's work, demands that I present to you in as terse and succinct a form as possible:—First, some historical introduction; secondly, some *résumé* of Ethics in general; thirdly, some of the most prominent cases in which we have to fall back upon the teachings of Ethics for guidance in the practice of pharmacy.

Historical Introduction.

About 400 years before the commencement of the Christian Era there lived at Athens Plato and Aristotle, two of the profoundest thinkers and most indefatigable workers of any country or time.

Plato—the instructor of Aristotle—was an idealist; Aristotle, his pupil, became a realist.

To put one on the straight road of becoming wiser than his instructor, is the aim and effort of all good tuition, and hence it is no disparagement to Plato's memory to say that Aristotle became in many respects the greater personality. Indeed, by a closer inspection than we have time to give now, there would be found in the lives and teachings of these two men an exemplification of another broad, general truth, namely, that excellence of ideal precedes, naturally, excellence of workmanship. Plato built all his castles in the air; Aristotle supplied foundations to the same, and added all necessary filling in of the splendid outlines.

The voluminous writings of Aristotle are divisible into two groups of subjects: the first (in order of time) consists of dissertations on almost every conceivable subject relative to the outward nature of things. These are termed in the Greek *τά φυσικά*, things belonging to outward nature, hence our own word "physics." The second group is an attempt to grapple in the like exhaustive manner with those inquiries which lie beyond the limit of human experience, such as the nature of the Supreme Being and the mysteries of existence itself; and also of mental and of moral science.

* Read before the Chemists' Assistants' Association, on October 26, 1899.

All these of the second group were termed *τά μετά φυσικά*, things that follow the physics for the simple reason that they were written last in order of time, from which we get our own word "metaphysics."

Now of these metaphysical writings, the one portion—those relating to the mysteries of existence and the nature of the Deity—have been totally eclipsed by the brighter and clearer light which it was the mission of the adorable founder of Christianity to bring into the world. Those who would still cling to the old notions, good and helpful as they had been in preparing men's minds for fuller light—the greatest of the Apostles does not hesitate to brand with the error of introducing oppositions of science falsely so called! The very term metaphysics is rapidly passing out of use except in a sarcastic or deprecatory sense.

But the case is widely different as respects the latter part of these truly wonderful productions.

"Man know thyself, presume not God to scan,
The proper study of mankind is man."

Our poet's idea is well illustrated by the absolute persistence—a survival of the best—of those divisions of the Metaphysics of Aristotle in which man's attention is directed to the mental and moral laws he finds written within himself, by which he himself must regulate himself, and be punished or rewarded as the case demands. These interesting researches have been resumed from time to time by some of the highest intellects and the most exemplary scholars with a progressive evolution of quite as satisfactory a result as can be claimed on behalf of any branch of human knowledge; and to-day the twin subjects—Psychology, the science of mind, and Ethics, the science of duty—are well recognised as lying within the scope of a liberal education.

Some of the Elements of Ethics.

This word Ethics is compounded of the Greek substantive *ἔθος*, custom; and that much-resounding verb—a great favourite with every student of the language because of the scores of cognate meanings it gives rise to—*τίθημι*, to place, ordain, fix, settle etc.

The aim of Ethics is to investigate and determine upon that branch of the laws of man's moral economy which relate to his duty as a responsible creature, and as a member of civilised society.

The Latin equivalent of *ἔθος* is Mos, moris; whence "moralis," and our own "moral" and "morals." "Mos" is derived from the old Latin verb "meo," akin to Sanscrit root "MA," which equals metire, to measure, with the accessory notion of one's way; used of an army—to be on the march, and also of inanimate things that proceed in an ordinary manner: so in Ovid—

"quo sidera lege mearent."

In Asia Minor they say there is a river, the Meander, named from this same root because of its intricate windings and peaceful career, and hence come our own two beautifully poetic words—"meander" and "meandering."

For the pharmacist life is, however, as it is with every active and useful career, not a meandering down quietly from its source to the grand ocean of eternity with scarce a struggle or a storm; but it is a call "to cope with enemies, and first points out a conflict with oneself the worst." As the course of Time proceeds, this struggle is not lessened, but rather intensified, and whatever our calling in life, unless we face the facts of our existence with candour and thorough earnestness, we have no right nor reason to expect anything but ignominious defeat at last.

There is a sophism current, and thus it runs:—"Man's first duty is to himself." There is no logic, no reason, whatever in such an expression. "Duty" means "debt"; a debt that is lawfully due to another, or to others. "As a vital spark of heavenly flame" man's first duty is to his Maker and Preserver, to investigate and fix those duties and the laws that regulate them is the province of religion. But man has duties with respect to those around him, on the due performance of which much of his own happiness depends. These, it is the province of Ethics to investigate, to trace to their source, if possible; to discover the laws of their evolution or development; to classify them as to their relative importance; and to enforce their due observance by appeals to man's own reason and judgment. There have been fierce contentions in every age as to the fundamentals of Ethics, as there have been also as to those of religion. These contentions have prevented many men from slumbering away their days without some regard for such important matters; that seems the main good they have done. On the other hand they have furnished an excuse for those drowsy heads who dislike action, and wish to sleep away life's little day; and so the balance seems to remain about as it was.

Ethical teachers have for ages been divided into the two opposite camps—the inductive and the experimental systems. In our own times these are best known as the "intuitive" and the "utilitarian" schools of thought. It is all a question of the criterion by which good and bad is to be determined. The results seem to come to about the same in either case. Accordingly, the popularity of these two systems has varied much with the efflux of time. Latterly the public taste has certainly been in favour of the experimental or utilitarian school, which teaches that man should make his own happiness the rule of his life, and the promotion of the greatest happiness for the greatest number the criterion of his duty. There are signs, however, that the intuitive system is again coming into vogue. It is comprised in the two following propositions:—

First, that our will is not governed exclusively by the law of pleasure and pain, but also by the law of duty, which we feel to be distinct from the former, and to carry with it the sense of obligation.

Secondly, that the basis of our conception of duty is an intuitive perception, that among the various feelings, tendencies, and impulses that constitute our emotional being there are some which are essentially good, and ought to be encouraged, and some which are essentially bad and ought to be repressed.

In support of this view we contend that it is a psychological fact that we are intuitively conscious that our benevolent affections are superior to our malevolent ones, truth to falsehood, justice to injustice, gratitude to ingratitude, chastity to sensuality; and that in all ages and countries the path of virtue has been towards the higher and not towards the lower feelings.

We cannot afford time to pursue the arguments for and against these rival theories now, but must finish this division of our subject with the remark that as to the systems of Ethics, as with the kindred and more lofty subject of religion, all who have heartily sought for truth in these regions have found it; all have been right in most of their contentions; all have been wrong in some few of their conclusions. Each succeeding generation is better equipped than the former one for settling the points of greatest importance, and it is those who are attracted to the consideration of these lofty truths by the fact that the best and noblest minds have through all ages sought to unveil them—not those who read to doubt or read to scorn—that finish their course here most happily and well.

Ethics Applied to Pharmacy Practice.

Our duties as pharmacists may be arranged under these three heads:—First, our duties to the public—*i.e.*, our customers; second, our duties to the medical man; third, out duties to our schoolmates.

The very foundation of our business consists in due performance of our duties to the public. Forgetfulness of this fact lies at the root of most failures; attention to it, and a diligent behaviour accordingly must, and always does, ensure success.

This attention to the public interest keeps a man always on the *qui vive*. You can scarcely conceive an occupation where so

much variety of minutiæ is so constantly turning up, and the pharmacist must be prepared for it all.

The aggregate of this demand—this heavy demand at first it is—varies with the locality where his services are rendered, and goes on to multiply indefinitely and most prolifically with each day's business, the serious part of the matter being that very often a man's courage begins to fail. He has not something that his neighbour requires, or he has half a dozen customers walk in for small quantities of as many different articles that ought to be ready to hand to each at once. These he has to weigh up for them in a nervous state, feeling that for once all eyes are upon him, and that although the business of his neighbourhood is improving he himself is losing ground.

This man has not attended to the *morale* of his business. A fruitful source of failure this. First he fails in the proper conception of the ideal of his own intentions, and as a consequence they soon say of him, "This man began to build, but was not able to finish." He may lay the blame upon his assistant, as the man who is mean enough will—Adam like—lay the blame upon his wife. Or he lays it sometimes upon the Pharmaceutical Society. Poor fellow, his case must be worse than that of Job, for he commits the very sin that Job would have committed had he followed his wife's advice. Whilst all the time this man's failure is due, from the first, to the incomplete idea he possessed of his own position as a public servant—of rank and importance—followed necessarily by those inattentive, slovenly habits which have at length irreparably lowered the *morale* of his own business establishment.

Wherever a pharmacist is in business, he must, in order to gain general success, keep an efficient store of drugs and chemicals, methodically arranged, ready at a moment's notice, day and night. And, so far as his petty retail trade is concerned, which, properly managed, proves often the broad, safe basis of downright success, everything in daily request should be as neatly wrapped as possible, and well stocked, ready for handing over to the purchaser in an instant. An employer is ever ready to blame his assistant for neglecting these matters, whilst in nine cases out of ten he himself has never set the good example that he wants another to adopt. That same assistant, as soon as he goes into business, gets an assistant, and makes a scape-goat of him in turn. Want of discipline of this sort brings nothing but failure in its train. Most of those who advertise often for assistants really need managers. Neither they nor their so-called assistants ever took a love for pharmacy for its own sake. Each seems to think that in life's business it is very clever to give little and take much. Hence a constant changing and constant irritation where there is so much need of a reasonable, patient performance, and a constant placidity of disposition.

The truth is that both employer and employed are groaning beneath the punishments that always accompany and follow duties neglected. Our profession, "Habenda ratio valetudinis," cannot be ignored with impunity.

There is a certain breach of duty, the punishment for which lies heavy upon the trade of the chemist and druggist; one which I might almost say is a chronic curse that he inherits from his ancestors, who used to cater for the dirty sensuality of the last century, which greed of gain permits him not to shake off even in these days of vaunted refinement and educational advancement. My own feeling of duty compels me to hint at this as lightly as I can.

Our duties to the public demand that with the greatest care and judgment we supply medicaments of the most trustworthy character, and the various surgical appliances that are necessary to cure or alleviate all the disorders that are diagnosed by the medical man. Many of these disorders have their origin in vice. That is no business of ours. But this is our business: to refuse to sell at any profit, or at any cost, appliances that are used only by the vicously inclined for the purpose of perpetuating the vice without the sequence of its normal consequences. If we do supply these appliances we participate in the crime of demoralising and debasing our fellow creatures, and lay up for them in times to come—in this world—a punishment similar to that typified in the tale of Sodom's overthrow, whose moral descendants our patrons are.

And what shall we say with respect to our duties to the public as to the abounding imposture of quackery?

> "The tincture or syrup, lotion, drops, or pill,
> Which tempt the sick to trust the lying bill;
> And twenty names of cobblers turned to squires,
> Aid the bold language of these blushless liars!
> There are among them those who cannot read,
> And yet they'll buy a patent and succeed,
> Will dare to promise dyiug sufferers aid,
> For who, when dead, cau threaten or upbraid?
> For soul or body no concern have they,
> All their inquiry—can the patient pay?
> And will he swallow drugs until his dyiug day?"

Is it consistent with truth and honesty to stock these things indiscriminately, to allow our honoured names to be placed on the handbills, almanacks, etc., got up to deceive the illiterate and to fill the pocket of the richest at the expense of the poorest part of mankind? Shall we know these things better than most do, and not raise the note of alarm and indignation for the benefit of the ignorant and the deceived? If so, the breach of duty brings condign punishment. First, a loss of self-respect; secondly, the contempt of the educated classes of society—medical men especially—who may go on using us for their own convenience, whilst they regard us as mere traders, and even speak of us as such *in camerâ*, and despise us in their hearts; thirdly, we shall have a world of worry within our own domains, a worry that no pharmacist can stand with impunity. Cares he can face as well as any man, work is his forte to any extent; but worry he must seek means to avoid, and the first preventative is a good conscience, the second a strict method in all he does.

Next to our duties to the general public come our duties to that select circle—the medical profession.

The great aim of a pharmacist should be to worthily fill the position of a responsible, confidential, and trustworthy assistant to the doctor; attempting to soar higher than this he must raise himself as a selfish individual, with stolen or borrowed wings, soon to come smash to the ground. The need for such a faithful coadjutor is great, and is largely felt by the first parties to the bargain; but is it likely that the medical profession as a whole will ever climb down from the sphere of their own arduous duties, and entrust a part of them to those who look like mere shopkeepers, the managers of fancy bazaars, or general agents for packed goods? It could never work. And as to thinking that negotiations between the one party and the other, as respects giving up dispensing on the one hand, and dispensing with prescribing on the other, will ever come to anything whilst the chemist's show is of such a flimsy, trashy, untasteful character as it is, is a mere delusion—doomed to the worst of disappointments. Let the pharmacist, in his own pharmacy, come to the light, and show that besides being qualified he is a competent man, and ever ready for his duties; all other good will follow.

Lastly, our schoolmates.

In the good time coming, sir, I can fancy I see still plenty of chemists scattered throughout the British Empire to meet all the need—pharmaceutically—of all men everywhere. And I hear the remark passing from mouth to mouth, "See how these chemists love one another."

Is one of them suddenly incapacitated from his important duties, his brother-chip close by will keep his customers together for him until the crisis is past. Or, does one seriously need a change, and is not wealthy enough to keep a permanent assistant, he will need no "locum"—who often ruins the work of years in a single month—but he will with scarcely any loss be enabled to suspend business altogether for a few weeks by a like amicable arrangement.

If anything like this is to be realised it will come simply as a virtuous reward for the recognition of our common scholarship. The pharmacist of the future must be trained for his calling as well as legally qualified to practise it, and the memory of that training, with all the forbearance and the wise nurture of the Alma Mater, the jovial times we had at times, and the hard lessons at others, which all came right at last, will be a grand source of perpetual brotherly sympathy and seasonable aid then always close at hand.

Why do I, with the least show of reason, expect such things? Why, is there not already a sound living nucleus consisting of true pharmacy men that have been trained in the School of Pharmacy and at other efficient centres of learning ready to push forward the good cause of pharmacy proper for the benefit of society, the assistance of the physician, and the honour of the craft to which they belong, because they perceive it to be an incumbent duty? The successful career of your own Association, sir, is an earnest to me that such a desideratum is quite possible of attainment, and your Association is but one of very many where the leaders—always changing—are all animated by the same spirit of unselfish devotion to the good of the general body. Men who have a conscience and fear not to admit the fact—conscience that Ethics demonstrates to hold a place among the moral powers analogous to that which reason holds among the intellectual powers of man's being; a habit of thoughtfulness as to one's duty; a determination to act on the plain dictates of conscience makes the hero—have made the heroes before us who started British pharmacy sixty years ago—on the career of steady development and substantial progress we see to-day, and such are yet to follow to reap the full harvest and scatter around its golden fruits. Say not this is too optimistic. The moral laws of the universe of man's heart are as inviolable as the laws of outward nature. One branch of the moral law is duty; this works by penalties, we may ignore the law and fail in our duty, but the punishment comes to put us right and teach us better. The other chief branch of the moral law is virtue; this works by reward. Virtue is always its own reward, and the virtuous man expects no better reward; yet,

> "All's on the side of the virtuous man,
> The good will always aid him if they can,
> The bad when interest or ambition guide,
> And 'tis at once their interest and their pride:
> But should both fail to take him in their care,
> He boasts a greater Friend and both can spare."

The remembrance that we are schoolmates, and the efforts we make in consequence to cultivate an *esprit de corps*, will tend to level many molehills that, being now magnified into mountains, prove real obstructions to the general good. The late controversy as to secret commissions is a case in point.

Have not we all known mere trading chemists who were always ready to take any mean advantage of their neighbour for their own immediate profit; and some at the present time who advertise some of the worst of quack remedies at greatly reduced prices in order to steal away their neighbour's trade—he who will not swerve from the sound business principle of demanding a fair profit for everything that passes through his hands!

And have we not also known trading doctors who have been bad enough to take advantage of the chemist's greediness for their own immediate gain? heathens, fools enough to suppose that gain is godliness, that business spells £ s. d. and nothing more.

Pray do not think these words too strong. What! do we not know that

> "Vice is a monster of such frightful mien,
> As to be hated needs but to be seen."

Then show her up in all her naked deformity. Lucid exposure is our only safeguard. Laws can never check her pestilential rule over men's affections, but truth-speaking can, and so can such associations as yours, sir; the bad can never hold together, it is those only that are well disposed that can face the necessary discipline that unites together for one common end. Selfishness is a disintegrating force; benevolent sympathy holds all together through all eternity.

AUSTRALIAN QUICKSILVER.

Although quicksilver has not hitherto occupied other than a minor position among the metals of New South Wales, there are indications that in the near future it will be found one of the most valuable of the numerous metallic products of the colony. The presence of native mercury, or quicksilver, in New South Wales was ascertained so far back as 1841, when the Rev. W. B. Clarke, the well-known Australian geologist, received a sample from a creek on the Cudgegong River, an auriferous stream, rising in the Australian Alps, and flowing through a portion of the western goldfields of the colony. Cinnabar had previously been found in the same locality. It has also been discovered in a few other places, but although Mr. Clarke, with a view to stimulating systematic search for the metal, published a popular description of the ores of mercury, little or nothing further was done. In later years mercury, in the form of cinnabar, was found at Bingara, where there are several diamond mines; in the vicinity of the Solferino goldfields; and at Cooma, at the entrance to the New South Wales snow country, where the assays of ore yielded 25 per cent. of quicksilver. The richest deposits have, however, been discovered near Yulgilbar, in the Clarence River district, one of the most fertile and beautiful in Australia, sugar cultivation being a staple industry. Some four years ago prospecting was carried on, in the hope of finding a payable quicksilver deposit, and the New South Wales Department of Mines dispatched its mineralogist, Mr. J. E. Carne, to inspect and report upon the workings, with the result that that gentleman, after a most careful examination, recommended that a portion of the Government prospecting vote be devoted to assisting the prospectors in their search for the lode which was suspected to exist, and, if successful, to ascertain whether or not the deposits would eventually become payable. Since then considerable developments have been made, and six distinct shafts have been put down on three parallel lodes. Several tons of the ore from these lodes have been brought to Sydney, and quantities of it distributed among the various Government departments for examination and testing purposes. The ore is expected to yield from 3 to 5 per cent. of mercury, and it has been ascertained that the "spent" ore contains gold and silver. The area of the ground examined by the Government geologist is about 120 acres, but it is believed that with the progress of prospecting operations other lodes, more or less rich, will be found. A further examination of the locality is being made by the Government geologist, and his opinion is being anxiously awaited. He has definitely ascertained the existence of three distinct parallel lodes, the first discovered in the colony, and improving as they go down. When the quicksilver mining industry is fairly established, a large population will become attracted to this part of the colony, which has been for many years portion of an immense pastoral property, and but little known. Machinery is being erected, and a preliminary testing of about one thousand tons of ore will be made. Should the results prove satisfactory, the New South Wales quicksilver trade will become revolutionised, as the poorest assays show the ore to be richer than those of the American and Spanish mines. They will also encourage the search for other cinnabar deposits, which, there is every reason for believing, are more numerous and richer than generally assumed. The value of the discovery in connection with the colonial gold-mining industry can hardly be over-estimated. It simply means that the work of gold production will become enormously stimulated, thereby greatly increasing the already large auriferous output of the colony.—*Journal of the Society of Arts.*

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, NOVEMBER 1, 1899.

Present:—

Mr. W. Martindale, President.

Mr. G. T. W. Newsholme, Vice-President.

Messrs. Allen, Atkins, Bateson, Carteighe, Cross, Glyn-Jones, Grose, Harrington, Harrison, Hills, Park, Savory, Southall, Symes, Warren, and Young.

The minutes of the previous Council meeting were read and confirmed.

The Late Dr. Adolph Ernst.

The President said he regretted to receive information of the death of Dr. Adolph Ernst, of Caracas, a corresponding member of the Society.

The Late Mr. Bevan.

The President then announced with regret the death of Mr. Bevan, late of Harwich, who had acted as a local secretary for forty years. The Society was indebted to Mr. Bevan for the unswerving support which he had afforded the Society for half a century.

Diplomas.

The undermentioned being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Austen, John
Battle, John Cyril Marfleet
Burrell, Benjamin Lawson
Cornick, Ernest Edward
Evans, William Llewellyn
Gibson, Hubert
Meldrum, Martin
Moore, Richard Herbert
Smith, Arthur Richard
Wood, Edward Vivian

Election of Members.

The following persons having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Beck, Albert Neve: Stroud Green
Beresford, Arthur William; Birmingham
Black, Robert; London
Boulton, Jesse; Kidsgrove
Butler, John Howard; Margate
Corke, Edward; Ticehurst
Cox, Arthur H.; Brighton
Gill, Herbert Edward; Birmingham
Hutchinson, Walter: Leeds
Jackson, Frederick William; Ashton under-Lyne
Morris, Edward Herbert; Newport, I.W
Myers, James; York
Sharpley, Major; Market Rasen
Stevenson, Arthur L.; Todmorden
Williams, Thomas; Hillingdon Heath
Winckler, Ernest; London

Election of Student-Associates.

The following persons having passed the First examination, and tendered their subscriptions for the current year, were elected "Student-Associates" of the Society:—

Martlew, Thomas Nicholson; Carlisle
Willder, William; Ealing

Several persons were restored to their former status in the Society, upon payment of the current year's subscription.

Benevolent Fund Committee.

The report of this Committee included a recommendation of grants to the amount of £71 in the following cases:—

The widow (62) of a chemist and druggist member, who himself had a grant in 1898. (London.)

The widow (62) of a member who has had an annual grant for several years. (London.)

A member and subscriber (75), formerly in business in London, who sold his business for a very small annuity. (Ipswich.)

The widow (43) of a registered chemist and druggist, who was in business for twenty-eight years and died in 1894, after ten years' illness. (Exeter.)

The widow (51) of a chemist and druggist whose name was erased from the Register in 1896. This case was deferred last month. (Walsall.)

The widow (69) of a chemist and druggist and subscriber. This case also had been deferred. (Louth.)

One case was adjourned for further information.

The Vice-President moved the adoption of the report, which was carried unanimously.

Finance.

The report of this Committee was read, recommending the payment of sundry accounts.

The President in moving the adoption of the report and recommendations, said there was nothing which required any special comment.

The motion was unanimously agreed to.

Library, Museum, School, and House Committee.

The report of this Committee stated that several donations to the Library and Museum had been received (see *P.J.*, October 14, p. 371), and the Committee had directed that the usual letters o thanks be sent to the respective donors. The Librarian had pre sented his usual report including the following particulars regarding attendance at the Library:—

Attendance.	Total.	Highest.	Lowest.	Average.
July	253	23	3	10
August	75	8	1	3
September	80	10	0	6

Circulation of Books.	Total.	Town.	Country.	Carriage Paid.
July	117	49	68	10s. 4d.
August	105	45	60	14s. 5½d.
September	88	37	51	11s. 7½d.

The Committee recommended that the undermentioned books be purchased for the Library in Edinburgh:—

Reichter, Organic Chemistry, new edition.
Thorpe, Quantitative Chemical Analysis.

The Librarian reported that at the annual examination of books in the Library in London, the undermentioned were missing:—

Attfield, Chemistry, 13th edition, 1889.
Morley, Organic Chemistry, 1886.
Valentin, Qualitative Chemical Analysis, 5th edition, 1880.
Whateley, English Synonyms, 6th edition, 1868.

The Curator's report had also been received and included the following particulars:—

Attendance.	Total.	Highest.	Lowest.	Average
July	361	43	3	14
August	63	7	1	2
September	106	15	3	9

An application from the Curator for an extension of the Materia Medica Museum was deferred until further details and an estimate had been submitted. The Librarian had made his usual annual report as to books missing from the Library. He also presented a report on the meeting of the Library Association at Manchester.

A sub-committee had been appointed to consider what, if any, modifications in the conditions of the Jacob Bell Scholarship examination were desirable. Mr. Carteighe had been appointed visitor of the Society's School. The School Staff had attended and reported on their respective classes.

The President, in proposing the adoption of the report, said the number of books reported as missing from the Library was somewhat less than on former occasions. Probably the books would turn up soon.

The report was unanimously adopted.

Appointment of a Divisional Secretary.

Mr. J. H. Smith, of 227, Commercial Road, E., was appointed divisional secretary for St. George's-in-the-East, in place of Mr Chas. Walker, who has left the district.

First Examination Attendance List.

The Secretary formally laid on the table the following list of centres at which the First Examination had been held during the past three years, with the number of candidates at each centre, and it was ordered to be entered on the minutes.

List of Centres and Table of Attendances of Candidates at each Centre.

CENTRES.	1897. Jan., Apr., July, Oct.	1898. Jan., Apr., July. Oct.	1899. Jan., Apr., July, Oct.	Total number of attendances at each centre at **12** examinations.

Correspondence.

The PRESIDENT announced that the following letters had been received :—

From Mr. Porteous, of Lerwick, asking that that place should be made a centre for Preliminary examinations. Of course, in present circumstances this could not be entertained, but the letter might be referred to the Library Committee.

From the Grimsby and District Chemists' Association, endorsing the resolution passed by the Dewsbury District Chemists' Association, and intimating that Mr. Sneath, the Secretary, had been appointed to represent the Association on the North-East Section of the Federation of Local Associations.

A circular from the British Association inviting names for a General Committee to act in connection with the Paris Exhibition of 1900. He suggested that this should be referred to the Library Committee.

From the Royal Societies Club, asking for notice of the Society's meetings and a gratuitous copy of the Journal as published. This might go to the Library Committee.

From the Hull Chemists' Association calling on the Council to apply to the Privy Council to place carbolic acid on the schedule of poisons. They would remember that the matter was at present before the Privy Council.

From the Bradford and District Chemists' Association forwarding a resolution urging the desirability of promoting legislation for the protection of titles and to extend the scope of the poison schedule, and also supporting the proposals set forth by the Vice-President a year ago with reference to the local secretary organisation.

From the East Lancashire Chemists' Association, expressing the opinion that companies cannot legally use the title of chemist or retail or dispense scheduled poisons. From the Burnley Chemists' Association urging legislation in the direction of protecting titles and requiring a qualified directorate in companies carrying on the business of a chemist and druggist. Those last three letters, he should suggest, might be referred to the Law and Parliamentary Committee.

The suggestions of the President were all agreed to.

The Waterall Legacy.

The PRESIDENT announced that a report had been received from the Solicitor recommending the acceptance of the Waterall legacy of £1,000. The conditions attaching to the legacy made it imperative that the legacy should be placed to a separate fund.

Mr. CARTEIGHE, who had read the will, stated that the conditions were a little peculiar but the intention of the donor being distinctly benevolent, he felt they could not refuse the legacy. He hoped that any of their friends who were making their wills would feel a sufficiently wide and catholic faith in their own Benevolent Fund not to impose such conditions.

The report was adopted.

Law and Parliamentary Committee.

The report of this Committee was then read. It contained a recommendation that the following clause be presented on behalf of the Council to the Department of the Government having charge of the proposed company legislation :—

"No company shall carry on the business of a chemist and druggist, or assume or use the title of pharmaceutical chemist, or pharmaceutist, or pharmacist, or chemist and druggist, or chemist or druggist, or dispensing chemist or druggist, or any other title implying registration under the Pharmacy Acts, and if any company contravenes this enactment it shall be liable to the same penalties as those enacted in the case of individuals under the Pharmacy Acts."

Mr. GLYN-JONES moved that this report be received, but that it be referred back for consideration.

A discussion ensued, which occupied some time, as to whether this ought not to come as an amendment to the usual resolution that the report be received and adopted. Eventually it was agreed that such a course should be followed.

The VICE-PRESIDENT therefore moved : "That the report of the Law and Parliamentary Committee be received and adopted." There was one point on which all members of the Council were agreed, and that was to do their utmost to protect the registered title He thought they ought to be just as much agreed with reference to the carrying on the business of a chemist by limited companies He would ask in what way their position was altered from what it was in 1852 or in 1868, when it was laid down that for the safety of the public certain individuals should pass certain qualifying examinations, and certain regulations were also laid down with reference to the keeping open shop. They had had during the last twenty years a great deal of worry and anxiety in connection with so-called company pharmacy, which had been a great curse to the bulk of pharmacists, but he did not think it would be a proper thing for them to climb down in face of the great opposition with which they were menaced. They were there as representatives of the chemists of the country. It was felt by some that there should be some regulation of company pharmacy. He maintained that it was not the duty of the Council to recognise or regulate company pharmacy at all. They did not believe it was right for a company to use the title or practise pharmacy. There were, no doubt, a few

men in their ranks who found it convenient to form their business into a limited company, but the Council represented the great mass of chemists who had to live by their titles and their qualified practice, to whom this system was a curse. Not only in their interest, but in the interest of the safety of the public, the nearer they could get to the principles laid down in the 1852 and 1868 Acts, the better.

Mr. Atkins, in seconding the motion, said he should speak very briefly, but he did so under a sense of responsibility as deep as he had ever felt during the many years he had sat at that table. It was no use saying much, because what they said would not have much influence probably on one another, or even on the country—the pharmaceutical country. There had been times when that country required education, but if he could gauge the opinion of the country—and he had received an amount of correspondence during the last month on this subject which astounded him, both from its quantity and character—the country did not require any education on this point. There were two things for which he was prepared to fight if necessary to the bitter end. The first was the protection of titles, on which they were all unanimous, but when they came to the next point they differed. He contended that companies must be placed in every respect in the same position as individuals; nothing less would satisfy him. He might be beaten, but he did not regard that as so inevitable as some of his friends. He should not believe that until they were told by the authorities that justice would be denied them. He did not believe that a Government department, if properly educated by those who knew what pharmaceutical law and pharmaceutical ethics were, would refuse them justice, but if that should be the case, he would be prepared to take off his coat and go in for a campaign throughout the country for fresh legislation. No doubt the case would be very ably argued on the other side, but though he much regretted there should be any difference of opinion, he must adhere to the two points he had mentioned.

Mr. Glyn-Jones then moved as an amendment, "That the report of the Parliamentary Committee be received, but that it be referred back to that Committee for further consideration." He could not understand why Mr. Atkins should oppose the amendment, because he thought that every member of the Council was agreed that there should be but one law for individuals and for companies. The report of the Committee was by no means a unanimous report, but the report of a section of the Committee. The proposed clause pledged the Council "that no company shall carry on the business of a chemist and druggist, or use the title," and those who thought that was going too far, took care to ascertain what those who were in favour of that clause meant by it, and they said they meant exactly what they said. The Council was, therefore, to go to the Government and ask that it should be made illegal for all limited liability companies to use the title (which he agreed with) or to carry on business. Now there were two members of the Council who, if that clause became law, would have to close their business, as they at present stood. The Council would be asking the Government to declare as illegal a practice which had been carried on by two of its own members, and several local secretaries were also guilty of this great iniquity. Before going to the Government for such a clause, surely the bounden duty of the Council was to remove the names of Messrs. Symes, Southall, Reynolds, and Woolley from the list of members. If the Committee meant what was said, why did not the Council begin by putting its own house in order; instead of that it was proposed to go to the Government and ask that no company pharmacy should be allowed. If he had the slightest hope that such a thing could be accomplished, he would hold up both hands for it, because though it might be hard on some of the Council's own members, it would be in the interest of the whole trade. But anyone who voted for the procedure embodied in such a clause ought at least to be prepared to say that he had a reasonable hope that it would be accepted by the Government, otherwise the Council would be simply encouraging unfounded expectations amongst the members at large, who looked to the Council for guidance. It had been argued that the Council had already taken up the position indicated by the proposed clause, that no company should use the title or practice, and on the invitation of the Lord Chancellor to state its views, had asked him to introduce such provisions into a Bill. What had been the result? The receipt of the suggestions was acknowledged, but the practical answer of the Lord Chancellor was shown by the Bill he introduced, in which he proposed that a company might carry on the business and use the title of chemist if it had a manager holding such a title in its shops. That Bill had practically been abandoned, but in introducing it the Lord Chancellor said he had had a number of communications on the subject, and that it was impossible to resist the propriety of submitting those companies who were at present carrying on business as chemists to restrictions such as were proposed in the Bill. Unless they were going to knock their heads against the wall, they must accept that as a complete answer to their request. The matter was dealt with in that Bill in a way which no pharmacist could allow to pass without vigorous protest. The question had been raised as to the views of the members generally, and he should be the last to disregard that, but he was not prepared to admit that the majority of them would agree to going to Government with the proposed clause. It was rather singular what a quantity of correspondence had appeared in the Journal a few days before the meeting of the Council. On October 21 an article appeared in the Journal on this subject by a gentleman who did not sign his name, and the next week there were several columns of letters approving the views of "An Ordinary Pharmacist," and saying it was what everyone was thinking. Still he should claim that all these local secretaries and others who agreed with "An Ordinary Pharmacist" would be supporters of his amendment, because in his second article that gentleman pointed out that in dealing practically with the matter there were various awkward little things to deal with. One was the fact that there were men in their own ranks running a business as a company with unqualified shareholders, and he said that "companies of duly qualified persons should not be interfered with." But the Committee proposed to interfere with them. He also said—"Even where, owing to family arrangements, part of the capital invested in such company belongs to unqualified individuals, it ought not to be impossible to devise some satisfactory means of overcoming the difficulty." That was exactly what he wanted the Committee to consider. To his mind the Editor of the Journal sought to emphasise what his contributor had said when he wrote: "whatever means were devised, so long as unqualified persons were prevented from reaping advantage from the use of a pharmaceutical title, and from exercising any control over the conduct of the business, no objection could be taken by pharmacists to the fact that the whole of the capital invested did not belong to persons registered under the Pharmacy Act." The principles of the 1868 Act could be absolutely maintained without their going to the Government and saying no company should exist. Who, in the case of Day and Son's Drug Company, would suppose that it was the clergyman in the North of England, who owned a few shares, who ran the business? Of course, it was Mr. William Day, the managing director, and the other directors associated with him. What they had a right to insist upon was that not one of their qualified men should become the servant of an unqualified master. He maintained that it made not a bit of difference whose money it was that was being controlled; what they had to consider was, that in the interests of the public it was necessary that the Government should place all shops where poisons were sold upon the basis of the 1868 Pharmacy Act, provided that

such shops were *bona fide* controlled by qualified assistants. There was not the thickness of a piece of paper between those who said that companies ought to be on the same footing as individuals and the position he wished to lay down. He wished to emphasise the fact that, practically, the people who kept open shop were not the people who found the money, but the people who controlled the business. The Government was prepared to place such restrictions upon people who used company machinery that they would not be able to conduct the business of a chemist and druggist unless the people who absolutely conducted it were qualified under the Pharmacy Act so to do. It was his firm conviction that if all the capital invested in retail pharmacy at the present time owned by unqualified people was withdrawn a third of the pharmacies of the country would be shut up. There were a large number of men who were, while controlling their business absolutely, running it with financial help received from their wholesale house, which had no qualification, or from some brother or friend, and he could see no reason in the world why that man should not carry on business with the borrowed capital if he controlled it himself. The Society had a dual capacity to some extent. It stood for the drug trade in the same position as the General Medical Council on the one hand, and on the other hand it stood, or their members thought it stood, in the same position as the Medical Defence Union. He thought the Council made a mistake in going to the Government and speaking of the Pharmacy Acts as chemists' Acts. They were Acts which provided for the public safety, and the Society was the body to carry out the Acts. They would have no chance of obtaining a hearing from the Government if they went in the capacity of men formed together to defend trade union rights. Their strong position was to say what they asked for was asked for in the interests of the public. Could they, in the interest of the public, ask the Government to stop Charles Symes, Limited, conducting their business as they were at present doing? Could it be said that his business was a menace to the public, or that Reynolds and Branson should be closed in the interests of the public? There was a way by which they could get for their people all that they could reasonably ask, and he thought all that they wanted. A restriction should be made that the moment a subscriber signed the memorandum he should become a director and, if it was necessary, that a man should be qualified to conduct one shop, surely it was necessary that a man should be qualified to conduct several. It was twenty years too late to deal with the question of recognition. What did it matter whether they recognised companies or not while their customers were recognising them? The Government had committed itself to there being some restrictions; the only point of difference that they could reasonably have with the Government was that the restrictions which they imposed did not go far enough. He asked the Council to refer the report back to the Committee on the ground that it asked for the impossible, and for more than they had a right to ask, and on the ground that it could, by adopting other methods, secure a very great step in the right direction. It was all very well to appease the demands of the present by saying they would go to the Government and ask the Government to do this, that, and the other, but if the Government refused them again their position in twelve months' time would not be so popular. He agreed with the Treasurer that what they wanted was the protection of titles and the placing of companies, so far as the 1868 Act was concerned, on the same footing as individuals, by which he meant allowing companies to employ money owned by unregistered people in the same way as they allowed individuals to employ money owned by unregistered people, but not to allow people who financed companies to take up the position of unqualified partners. If unqualified people wanted to finance pharmacy they must put their money in the hands of qualified men to conduct the business in the same way as the unqualified man who provided capital placed the sole control of the business in the hands of a qualified man.

Mr. HILLS seconded the amendment which he thought all their colleagues would agree had been most ably proposed by Mr. Glyn-Jones, who covered the ground so completely, but he felt that this was an occasion when everyone should speak out and declare plainly what his views were on this most important subject. He was sorry that they were not more unanimous in their views with reference to this subject of company trading. While he had the honour of being President he always tried to get their differences of opinion threshed out in Committee, so that they might come to something like unanimity of opinion when they came to the Council. He did not say that his successor had not done all he could in the same direction, but this was a more thorny subject than he ever had to tackle with when President. He had read the articles by "An Ordinary Pharmacist" who seemed to think that although company trading was altogether immoral, still there could be means found in certain cases of getting round it. He thought they would all agree with the general remarks of "An Ordinary Pharmacist," but questioned whether they would agree with his conclusion. The question divided itself into two parts, one was with reference to the protection of title or description, and the other with reference to the protection of trading. Mr. Glyn-Jones said they were all probably agreed on the question of titles. Probably they were in the abstract, but he was not prepared to admit that entirely. An opinion had been expressed to him by a member of a company, which was carried on on excellent lines, that it would be undesirable to say that a limited company, all the members of which were registered persons, should not be allowed to use the title. They were not absolutely at one on that question, but as far as he could gauge the opinion of others, he thought, broadly speaking, they did say that it was reasonable that the title should be restricted to the individual, and that limited companies should not use the title that belonged to persons who had obtained their qualification in the ordinary way. They found that many of their friends round the country did not universally use their title, and he was told that drug stores with cutting prices were doing quite as much harm to the pharmacist as any company. When they went to the Lord Chancellor they took up the line which was now proposed by the resolution, but he thought the condition of things was somewhat altered now. He admitted that they were justified as a Council at that time in making those representations to the Lord Chancellor, who had made a statement in the House of Lords which led them to believe that they would have support from him in dealing with this very thorny question. In obtaining any fresh legislation there were two factors that were necessary; they must have the direct or indirect support of the Government, and also very largely the support of a majority of their people. They did say to the Lord Chancellor that if they had his sympathy with their views and aims, the principles contained in the suggestions which they sent to him represented the views of registered persons throughout the country, and probably they did now. The Lord Chancellor had not done anything more than simply acknowledge the receipt of those suggestions. He had made some sympathetic remarks in the House of Lords, but the clause in the Companies Bill now before them was one which did not recognise their suggestions in any way, and did not meet with the approval of any member of that Council. The point before them was this, Were they going to knock their heads against a wall and simply put themselves in a position which was untenable, and which had a certain amount of unreality about it. The amendment which he supported was that they should send the matter back to the Committee to be reconsidered. Of course, as Mr. Glyn-Jones had said, this action ought to have been taken twenty years ago, but they could not go back twenty years, they had to deal with things as they were now. What did they see? They saw companies on all sides, and the public recognising those companies. In conversation with a member of Parliament, that gentleman had told him, in considering a matter of this kind the

House of Commons would be influenced by two considerations, first, what was for the public interest and protection, and, secondly, what interfered least with existing conditions. He agreed broadly with what Mr. Glyn-Jones had said that a certain amount of protection by the public over and beyond what was obtained by present conditions would be furnished if there was a *bona-fide* manager or director, who should be in full control of a business where poisons were sold and retailed, and he did not object to a qualified person being the servant of an unqualified person, and having to do what the unqualified person told him he must do. Then, as to interfering with existing conditions, he would refer to the Widow's Clause, which the Lord Chancellor had taken to furnish him with a text for fresh legislation. Broadly speaking, he should say that their friends were opposed to any material alteration in that clause. In the suggestions which they laid before the Lord Chancellor they proposed that there should be a limit of time; but he thought it was quite possible that there was some way out of it, and that in the case of a deceased chemist one of the executors or trustees should be a qualified man who should have control, and if he was not actually working in the business, should employ a qualified man in his absence. As his predecessor had often said, the Widow's Clause was the one great weakness in that Act. Then they had the vested interests of twenty years to deal with, which the Government would not ignore. Going round the country he saw very little pharmacy carried on. He should like to see all dispensing carried on by registered persons. He believed there would in future be less of what he called the ordinary profitable pharmacy done than in the past. Mr. Rutherford Hill had suggested that they should go in for drugs allied to photography, spectacle selling, and so on. Their practice was not protected, and he was very doubtful whether the clause affecting their professional brethren, with whom he had a great deal of sympathy, would ever pass at all. It was practically asking Parliament to say that a company should not do what an individual was allowed to do. They had a certain amount of practice which was protected, though it was very little indeed, but when they asked that all legitimate pharmacy should be in their hands he saw no enthusiasm for it throughout the country. Under the Wheeldon judgment the public at the present moment were so far protected that the hand of the person who retailed or dispensed a poison should be qualified, and he was afraid it would be rather difficult under these circumstances to make a member of the House of Commons see that he was not sufficiently protected. They only said now that they should try and help the Government at this juncture to reproduce in a limited liability Bill something underlying the principle of the Act of 1868. His friend, the member of Parliament, agreed with him that the public would be best protected by a qualified individual who had all his capital and reputation at stake in the proper conduct of that business, but he also said that that remark might be made of almost every other business throughout the country. He should be happy as far as he could to help to draw up some proposal to submit to the Government.

Mr. Young said he would not detain the Council long, but he thought it right to say that he should vote for the resolution, chiefly because the report of the Committee was in accordance with the resolutions passed eight or nine months ago, and passed unanimously. He had yet to learn what had happened since then which would justify their ignominious withdrawal from the position then taken up. If it were urged that the Lord Chancellor had not seen fit to accept the suggestions put before him, and that that was a reason for withdrawing them, he could only say that they were very easily shaken off. Was every effort in the interest of pharmacy to be dropped the instant the cold breath of opposition came upon it? That was not the spirit they would expect from their soldiers. He would be a bold man who would say that because of a defeat in the Transvaal the British soldiers should be withdrawn. Then it was said they were asking far too much. Was it too much to ask that their titles should be protected? Or that the sale of ten or a dozen poisons should be restricted to chemists? That was the only possible point on which companies could oppose such a clause. Mr. Glyn-Jones said that in a roundabout way he could so restrict companies that it would have practically the same effect; if so, would not the limited liability companies oppose any such clause with equal force? Speaking for himself, then, he looked upon the article which had been referred to simply as the expression and opinion of an individual. When it referred to the question of how far members of Council were delegates, and how far they were supposed to represent the constituents, he thought if the half-a-dozen members who were elected in May last under the new franchise had let it be understood that they were going in for doing all they could in the interest of storekeeping, there would not have been a single one elected.

Mr. Glyn-Jones said he stated distinctly in his address that he did not agree with the Council's suggestions.

Mr. Young said the Council represented the whole of the chemists on the Register, of whom not 2 per cent. had any idea or intention of becoming members of limited liability companies. They were not sent there to make things comfortable for themselves or their friends, but to protect the interests of the trade at large, and he saw an enormous danger in any attempt to regulate company pharmacy or to recognise this pernicious growth in any shape or form. If they recognised it in any way it should only be after repeated defeats. Let them go to the House of Commons, the Privy Council, and the Board of Trade, and if they were defeated in every quarter it would be quite time enough to consider how to move in the direction Mr. Glyn-Jones indicated. He thought it would be a serious mistake to give way in the slightest degree to any suggestion for regulating company trading. They had to consider the interest of the public, but they had also to consider their own interests. On these grounds he should vote for the resolution.

Mr. Allen said he was a member of the Sub-Committee who drew up the clauses which were sent as suggestions to the Lord Chancellor, and in assenting to those clauses he deferred to the general feeling of his colleagues. The moment they attempted to draw up any clauses of such a character, they departed from the principle on which the Society had always acted, and he came to the conclusion that it was not the duty of the Council to devise clauses with the object of putting those who had not, and could not pass an examination on a level with those who had. That principle he could not see his way at the present juncture to depart from. It was said, why should they not loyally assist the Government to do that which would amount to a surrender of their rights? But there was no evidence that the general body of members desired that any such surrender should be made at present. He was thoroughly in accord with the motion, which amounted to this, that no company should carry on the business of a chemist, or assume the title. When they were told decidedly that such a clause was impossible he would accept the defeat, but not before. A certain clause had been passed in the House of Lords, which might come before the House of Commons; that recognised certain professions, and there was nothing advanced yet to convince him that there was any difference between the business of a dentist and that of a pharmaceutical chemist from a professional point of view There had been no attempt as yet to educate the public as to what the business of a chemist really was. It meant trading in a certain professional way with a certain poison schedule—nothing else. 95 per cent. of the things sold by a chemist had no relation whatever to this particular question. He did not want to do anything impolitic, but he could not at this juncture, without any direct invitation from the Government, agree to assist in framing clauses which would have the effect of allowing companies to carry on the business of pharmacy.

Mr. CARTEIGHE said it was a misfortune for those who read their discussions—if there were any—that they had not before them the wonderful panacea referred to by Mr. Glyn-Jones. It was before the Committee, and it was rejected, though only by a small majority, he admitted—not because it did not fulfil many conditions which would be valuable, but simply as a matter of tactics—as Mr. Allen had said, it was purely a question of tactics. When the clause embodying Mr. Glyn-Jones' views, was drawn up he admired its ingenuity, and regretted that it had not been produced, so that a vote might be taken upon it direct. But he would ask any person of average intelligence outside, who knew anything of political life whether there was any material difference between that clause and the clause adopted by the Committee with regard to the opposition which would be aroused in either case. He objected to Mr. Glyn-Jones' clause on two grounds—firstly, as a question of tactics, because that clause would evoke as much opposition from the Government and those interested, as the direct clause which the Committee adopted. Until they were told by members of Parliament or by a Minister of the Crown having charge of the Companies Bill that they would do nothing more than was offered, he did not think the Council was justified in asking for anything less than what had been suggested as proper. In view of the clause relating to dentists and midwives, the Council ought not to reduce its demands until there was a clear expression of opinion that the members of the Society desired the Council to do so. His clear conviction was that the Council could not deal with companies by an indirect method, either by means of a qualified director or manager or otherwise, so as to be satisfactory to the public and to pharmacists. Though it was quite true that the Council had to consider the public, it had also to consider the interests of the trade. To lay down regulations by which men of capital could set up any number of pharmacies and put in a managing director—who might have his qualification supplied him—with the effect of sweeping off those who remained of their poorer brethren, was not in the interest of the public. He had had something to do with Parliamentary business, and he should vote for the adoption of the report, because he did not think the united skill of the whole Council could frame an amendment of the Companies Act which would meet all the exigencies of the case. Under those circumstances, he thought the duty of the Council was plain—to go to the President of the Board of Trade and remind him of what he had said, taking the Blue Book with them and showing how the draft Bill conflicted with his expression of sympathy. He was surprised and saddened to think that the professional side of their occupation—limited as it was—should have been practically brought down to the level of the average grocer. There was no reason in the world why a chemist should not do anything he liked. In the days of Jacob Bell a pork butcher might qualify, possibly, but he was not qualified *per se*; a pharmaceutical chemist might qualify, and was qualified for his business. A pork butcher must not become a pharmaceutical chemist, but the chemist might become a pork butcher. It would be a mere waste of time to attempt to break the principle of the old Act by introducing a clause which, when it got into the House of Commons, would be met with as much opposition as the direct clause the Committee proposed.

Mr. CROSS said if the amendment simply pledged the Council to regulate company trading he should not vote for it, because he would be no party to undertaking such a duty, but he should support the amendment, because he believed the resolution before the Council was impracticable. It was reiterating the position which the Council took up earlier in the year, when, no doubt, the members were unanimous. But what had happened since then? When the suggestions were published, and went before the country, they were received not as tentative suggestions, but almost as a proposed Act of Parliament; they were argued clause by clause at provincial associations, and the conclusion most of those associations came to was that the Council was asking too much. He believed a clause could be framed which would meet the case, and that it was better the Committee should reconsider the whole matter. If the Council could obtain a clause protecting the title, he believed a great deal of what chemists wanted would follow. It was an injustice for companies to assume the title of chemist, and on that point chemists might fairly ask for redress. Afterwards they could consider whether pharmacy—whether carried on by companies or by individuals—was in a satisfactory condition. If it was not, an amending Pharmacy Bill might be introduced.

Dr. SYMES said his name had been introduced into the discussion, but he never allowed his personal interests to interfere with his public duty, and if passing the resolution could reasonably be expected to have the effect of preventing companies carrying on the business, he would vote for it. He had hoped for many years that something of the kind might be accomplished, but most of them had come to the conclusion that it was hopeless and impracticable. It was a nice thing to talk about the higher education and the like, and was very popular. If any good were likely to result, he should be as pleased as anybody, but he knew better. Some of those who had spoken on the other side had charged their opponents with the desire to regulate company pharmacy, but he repudiated any such idea. The Council was asked by the Lord Chancellor to state what was wanted, and it did so; but not a single member of the Council ever supposed they would get all that was asked for. The only practical reply the Council got was in the opposite direction to stopping company trading. If the Lord Chancellor's speech meant anything, it meant that he did not propose to stop company trading. But he meant to impose sufficient restrictions to protect the title, and also to provide that companies should be under the same restrictions in conducting the business as individuals. He had been an advocate for the protection of titles for many years, but had been told by a past president that chemists had no title, that they had nothing to fight for in the matter of title, though to-day the title seemed to be the great thing the Council was going to fight for and he was pleased to find it was so. If an unqualified person put up a sign saying he was a chemist or surgeon or physician, that person practised a fraud on the public, and was amenable to the law; but to-day they had companies of unqualified persons writing "chemist" over their door, and it was said that because companies were not mentioned in the Act they were outside the law. There had been a good deal of abuse of the "Widow's Clause," which was made a pretext for the Government saying that the Act acknowledged an unqualified proprietor, but he contended the "Widow's Clause" did nothing of the kind. If a duly qualified man had been carrying on business and died, the executors, who might not be qualified, had to bring in qualified persons to conduct the business, but the qualified manager came into a place arranged by a qualified man and carried it on in the same way as it had been; that qualified manager controlled the business, the executors only found the capital. He believed the report of the Committee was thoroughly unpractical, and it was much better that it should go back for reconsideration, to see if something could not be done to draw up a practical clause. In this matter he thought the interests of the public and of the trade were identical.

Mr. HARRISON would vote for the amendment, not because he wished to regulate companies in any way whatever. He had as little sympathy with company trading as anyone on that Council. It was said that those who took the position which he was taking were guilty of a great surrender, but in his view if the Council were to go to the Government for restriction of the use of the title of chemist and druggist, and restriction as to practising pharmacy, it might be leading its forces into an untenable position. The Council could ask for the protection of the chemists' title on strong grounds of principle. The trouble largely arose from the fact that in the original

Act of 1868 there was a departure from this principle. Dr. Symes, with his great generosity, still defended the "Widow's Clause," but if the Council were to have any legislation which should be of benefit to chemists as a body, it should in the first place abrogate the Widow's Clause. That would benefit chemists and would be doing no injustice to the widows. The medical profession was protected as to title but not as to practice, and it appeared to him a doubtful policy to go beyond what was acknowledged in the medical profession. He hoped the Council would accept the amendment in order to ask for what was believed to be practicable, and in the meantime there might be an opportunity for the Council to approach the Government with some definite policy, and ascertain how far the Government would support the Council.

The PRESIDENT said he found himself in the dilemma of not being able to support the clause passed by the Committee. He thought it was necessary to declare the actual position, and not mislead the trade by trying to obtain something which was unobtainable. The Vice-President had said that the Council should go back to the 1868 Act, but that Act did not afford that protection which chemists desired. Chemists had enjoyed the privilege of carrying on their practice for the last twenty years, and were now beginning to assume the chemists' titles. He maintained that if they protected their title they would protect their practice. Having briefly referred to the remarks of the previous speakers, he put the following amendment :—"That the Report of the Law and Parliamentary Committee be received, but that it be referred back to that Committee for further consideration."

Ten members voted for the amendment, and eight against, the division list being as follows :—

For.	*Against.*
Bateson	Allen
Cross	Atkins
Glyn-Jones	Carteighe
Harrington	Grose
Harrison	Newsholme
Hills	Park
Martindale	Warren
Savory	Young
Southall	
Symes	

The amendment was afterwards put as a substantive resolution, nd carried *nem. con.*

A letter was read from the Board of Trade thanking the Council for having appointed Mr. Phillips to serve on the Departmental Committee having for its object the revision of the scale for ships' medicine chests.

Mr. HARRISON, as representing a seaport town, said he had paid some attention to this subject. It frequently happened that medicine chests were imperfectly fitted, both as to the quality and quantity of the drugs. They had recently sent a communication to the Board of Trade calling attention to the matter, and suggesting that it was of sufficient importance to have an inspector appointed who should hold the qualification of the Pharmaceutical Society.

Mr. SYMES and Mr. GLYN-JONES endorsed Mr. Harrison's remarks.

The PRESIDENT then called attention to an article in the *Hospital*, with reference to certain analysis made by Dr. Paul, of some belladonna plasters, a great number of which were deficient in alkaloids. Dr. Paul had reported confidentially, but the report had been made public, and some very sweeping observations had been made in the periodical to which he had referred, reflecting prejudically upon chemists as being generally in the habit of adulterating, but he wished to say that all the plasters reported upon were not the plasters of the British Pharmacopœia, but trade articles. Moreover, they were purchased from company drug stores and did not afford any basis for the statement in the *Hospital*, casting discredit upon legally qualified chemists and druggists.

Mr. HILLS announced that he had received from the Comité de Souscription du Monument Pelletier-Caventou, acknowleging the contributions which had been forwarded by the members of the Council.

Appointment of Examiners.

A portion of the report of the General Purposes Committee dealt with the appointment of examiners. In accordance with that report,

The PRESIDENT moved that the following be appointed Examiners in England and Wales for the ensuing year :—

Arkinstall, William ; London.	Phillips, Alfred James; London.
Farmer, John Bretland ; London.	Saul, John Edward; London.
Farr, Edward H. ; Uckfield.	Tanner, Alfred Edward ; London.
Harvey-Gibson, J. R. ; Liverpool.	Thomson, John Millar ; London.
Kipping, F. Stanley ; Nottingham.	Wilson, Harold ; London.
Peck, Ernest Saville ; Cambridge.	Wright, Robert ; Buxton.

and that the following be appointed Examiners for Scotland :—

Balfour, Isaac B.	Fraser, Jonathan I.
Boa, Peter	Jack, Jas.
Davidson, Alexander	Lunan, Geo.
Dobbin, Leonard	Tocher, James Fowler.

This was unanimously agreed to. It was also resolved that the Boards of Examiners should hold examinations during 1900, in January, April, July, and October, or as near to those months as conveniently may be.

Appointment of Local Secretaries.

The General Purposes Committee had also considered the appointment of local secretaries, and presented the list which is printed at page 430*a*.

THE PRESIDENT said that, after careful consideration of the recommendations submitted by local associations, and by members residing in the respective districts, it had been decided to appoint representatives of the Society in the following new centres :—

Barnard Castle	Rotherham
Beckenham (with Bromley)	Sidcup (with Chislehurst)
Cirencester	Staines (District)
Haslingden, etc.	Swindon
Macclesfield	Tewkesbury
Morley (Parliamentary Division)	Wallasey (District)
Newbury	Wallingford
Normanton (Parliamentary Division)	Workington

He had to report, with regret, the retirement of several local secretaries who, for many years, have rendered loyal service. Among the number he might mention Messrs. Goss (Barnstaple) Laurie (Blackpool), Howorth (Doncaster), Bottle (Dover), Currie (Glasgow), and Heanley (Peterborough). To all those and other past local officers who have watched over the local interests of the Society, the cordial thanks of the Council were due. It was gratifying to be able to point out that in several centres where the local secretaryship had been recently in abeyance new interest has been manifest, and the *status quo ante* restored. On the other hand there were some cases where the centre had retired into the unrepresented condition. In five instances, although nominations were recorded, the nominee had intimated his unwillingness to accept office, and, in default of other evidence of local wishes, the places had to be dropped. The towns in question were :—Chelmsford, Gateshead, Leytonstone, Uttoxeter, and Weymouth. No nominations had been received from the following places ;—

Berwick	Maldon
Bridgwater	Oakham
Cromer	Romford
Faversham	Sevenoaks
Ilfracombe	Stowmarket
Leigh (Lancs)	Stratford
Leominster	West Ham

If the present officers in these towns would, during the ensuing month, signify their readiness to act for another year, he had no doubt the Council would gladly avail itself of the opportunity of retaining the places on the list of local secretary centres. With regard to Scotland, the Council had the advantage of the aid of the North British Branch Executive officers, and the appointments for the Scotch centres had been largely made on the recommendations which had been forwarded for guidance. It was, perhaps, fitting that he should allude to what had been said and written as to the necessity for a more perfect local organisation

than the present arrangements were said to afford. He would not go so far as to say that the existing system was the best possible system they could get, but he was bound to remember that it had shown valuable capabilites in recent years, when Parliamentary pressure was called for in aid of the Pharmacy Acts Amendment Bill and in opposition to the Government Poisons Bill. The experience then acquired, however, was thought by some to ndicate that a greater political force might be exerted in time of need if the system of local representation were based upon the Parliamentary divisions of Great Britain rather than, as now, upon the number of members resident in a particular district. It might be that the time had arrived when the question of modifying their system should be seriously taken up; but a change of the kind ndicated involved many considerations apart from the vast amount of detail work, and could not be completed without considerable thought and labour. The Vice-President and Mr. Cross, as well as other members of the Council, had had the subject in their minds for some time, and his object in making that brief reference to the matter was to assure the members of the Society that the Council was fully alive to the importance of organising its local forces, more especially in view of possible Parliamentary contingencies in the near future.

Dr. Symes said he hoped those districts in which it was desirable that assistant local secretaries should be appointed, owing to the amount of work to be done, would consider the matter and send up recommendations by next month, when such appointments would be made.

The President then formally moved the appointment as local secretaries, of the gentlemen named, and that was unanimously agreed to.

Superintendents of Written Examinations.

It was resolved, according to the usual practice, that the office of Superintendents of Written Examinations be offered the local secretaries in the centres where such examinations are held.

The Council then went into committee to consider the legal portion of the report of the committee. On resuming, the report and recommendations were unanimously adopted, and special resolutions passed authorising the Registrar to take proceedings against the persons named.

Report of Examinations.

	Candidates.		
	Examined.	Passed.	Failed.
England and Wales :—

First Examination.....	316	160	156

Thirty-eight certificates were received in lieu of the Society's Examination.

NORTH BRITISH BRANCH.

A meeting of the Executive of the North British Branch was held in the Society's House, 36, York Place, Edinburgh, on Friday, October 27, 1899, at 11.30 a.m., Mr. Peter Boa in the chair. Present: Messrs. Ayre, Boa, Bowman, Burley, Cowie, Currie, Ewing, Fisher, Gilmour, Henry, Johnston, Kerr, McAdam, McLaren, Mitchell, Russell, and Strachan.

An apology for absence was intimated from Mr. Tocher, Dumfries. The minutes of last meeting were read and approved.

Evening Meetings.

The Assistant-Secretary reported that Professor J. Arthur Thomson, Aberdeen, had replied expressing a desire to have his address postponed till next year, on account of other engagements. This had been readily agreed to, and Professor Thomson had consented to give the opening address of the Session of Evening Meetings in Edinburgh in 1900. His subject would be "The Medical Aspects of Natural History." Mr. Boa had consented to open the ensuing session with an address on Wednesday evening, November 29. Other meetings were being arranged for the third Wednesday of each month, and those willing to assist were invited to communicate with the Assistant-Secretary as soon as possible.

The Chairman said he hoped they would get some support from members of the Executive for the Evening Meetings. They were deserving of every support that could be accorded to them, because they helped to sustain an interest in the scientific part of their work as pharmacists. They also brought members together to exchange ideas, and in many ways did a great deal of good. He earnestly hoped those who were inclined that way would do their utmost to assist in getting up the meetings.

Nomination of Examiners.

The Executive went into committee to consider the report of the Committee for Nomination of Examiners. Two examiners—Messrs. Ewing and Nesbit—retired by rotation. The others were eligble for re-election. After a full discussion the meeting again became open, and the Chairman announced that the following resolution had been agreed to:—

"That Isaac Bayley Balfour, Professor of Botany in the University of Edinburgh; Leonard Dobbin, Lecturer on Chemical Theory, and Assistant to the Professor of Chemistry in the University of Edinburgh; Peter Boa, Edinburgh; Alexander Davidson, Montrose; Jonathan Innes Fraser, Edinburgh; James Jack, Arbroath; George Lunan, Edinburgh; and James Fowler Tocher, Peterhead, be nominated for election by the Council as members of the Board of Examiners for Scotland for the year 1900."

The Chairman moved that the Executive record in the minutes an expression of their thanks to Messrs. Ewing and Nesbit, the retiring examiners, for their services. Mr. Nesbit had been connected with the Board for a much longer period than any of the present members. Mr. Ewing joined the Board at a very special juncture, and has done important and useful work during his period of service.

Mr. Johnston seconded the motion, which was unanimously agreed to.

Mr. Ewing thanked the Executive on behalf of Mr. Nesbit and himself. He had found his four years' period of service a very pleasant time.

Local Secretaries.

The Assistant-Secretary intimated that he had received a communication from the Secretary anent local secretaries in Scotland. A proposal had been made to have a local secretary appointed for the County of Linlithgow, and the matter was at present under consideration by the Council. Regret was expressed that in several instances again in Scotland this year there had been a want of proper attention to the nomination of local secretaries by chemists in business in the various districts. In other cases the returns were so imperfect as to be of little value to the Council as indication of the wishes of the local chemists. The Executive instructed the Assistant-Secretary to reply, giving all possible assistance to the Council in the appointment of suitable persons in the districts referred to.

Plymouth Conference.

Mr. Burley reported that he had attended the meetings of the British Pharmaceutical Conference at Plymouth. Comparatively few Scotchmen attended owing, doubtless, to the distance and inconvenient railway connection. The local committee gave them a very cordial welcome. The meetings were well attended, and the papers read were interesting and useful. The excursions were very delightful, and creature comforts were supplied in great abundance.

This concluded the public business transacted.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, NOVEMBER 4, 1899.

THE COUNCIL MEETING.

After the reading of minutes of last meeting, the President mentioned the death of Dr. Ernst, of Caracas, a corresponding member of the Society, and Mr. Bevan, who had long occupied the position of local secretary at Harwich.

The reports of the Finance and Benevolent Fund and Library, etc., Committees were adopted, payment of six grants, amounting to £71, being authorised.

Mr. J. H. Smith was appointed divisional secretary for St. George's-in-the-East.

Several communications were referred to the Library Committee, one received from Mr. Porteus asking that Lerwick should be made a centre for Preliminary examinations.

Others from the Grimsby Chemists' Association endorsing a resolution passed by the Dewsbury Association (see p. 424); from the Hull Chemists' Association, calling upon Council to apply to the Privy Council to place carbolic acid on the schedule: from Bradford Chemists' Association forwarding a resolution urging the desirability of promoting legislation for protection of titles and extension of the poison schedule, and supporting the Vice-President's proposals concerning local secretary organisation: from the North-East Lancashire Association, expressing the opinion that companies cannot legally use the title of chemist, or retail or dispense scheduled poisons—and one from the Burnley Association calling upon the Council to protect the title of chemist and druggist and to insist that the directors of every company should be qualified, were referred to the Law and Parliamentary Committee.

Reference was made by the President to a legacy of £1,000 left under special conditions by the late Mr. Waterall, of Nottingham, and Mr. Carteighe mentioned that in such cases a sufficient belief in the Benevolent Fund would make such conditions unnecessary.

The Report of the Law and Parliamentary Committee recommended a clause to be submitted to the Government department which has charge of the Companies Bill with the view of obtaining its support. Mr. Glyn-Jones moved that the report should be received and referred back for reconsideration. After some discussion as to the mode of procedure, the Vice-President moved that the report be received and adopted, urging that it expressed the unanimous view of the Council in regard to titles, and that there should be the same agreement as to the exercise of the chemist and druggist's business. He did not think it would be proper for the Council to yield to the opposition with which chemists were menaced, in violation of the principle established in 1852 and confirmed in 1868.

Mr. Atkins seconded the motion, and expressed himself as being convinced that the determination of chemists throughout the country was to defend the legal position in which they had been placed by the Legislature. On the point of title there was no kind of dissent; as to "company pharmacy" he expressed his agreement with the prevailing feeling that nothing less would satisfy chemists than seeing the Pharmacy Act applied to companies in the same manner as to individuals. He could not believe that claim could be denied wherever the circumstances of the case were made clear and understood.

Mr. Glyn-Jones then moved, as an amendment, that the report should be received and referred back to the Committee, supporting that proceeding in a long speech by the opinion that the Committee was not unanimous in its recommendation; that it proposed to ask for too much—far more than chemists have a right to—and, if granted, would involve stopping the business of many pharmaceutical chemists. In objection to the argument that no company should be allowed to use the title of chemist and druggist, or practise pharmacy, he urged that the Lord Chancellor had not adopted the suggestions of the Council as to amendment of the Pharmacy Acts in that direction, and that their adoption could not be expected. Mr. Hills seconded the amendment, and Messrs. Cross, Symes, and Harrison spoke in support of it, Messrs. Rymer Young, Allen and Carteighe speaking in opposition. On a division being taken, ten members voted for the amendment and eight against it.

The discussion was of so important a nature on both sides that it claims careful perusal of the full report (see page 424).

Attention was directed to the subject of the medicine chests supplied for the use of ships by the reading of a letter from the Board of Trade, thanking the Council for having appointed Mr. Phillips to serve on the Departmental Committee for the revision of the scale for ships' medicine chests.

The President drew attention to the statements published in the *Hospital*, on the 21st ult., reflecting upon chemists and druggists, and explained that the circumstances were such as to show that there was no ground for those statements, the plasters referred to being ordinary trade articles that were obtained from company drug stores, and not from legally qualified chemists and druggists.

The report of the General Purposes Committee reviewed the experience of the past year in connection with the office of local secretary, and a number of appointments were made in accordance with the recommendation of the Committee.

The recommendations as to the appointment of examiners for England and Wales and for Scotland for the year 1900 were adopted (see page 429).

BRITISH PHARMACY—AS IT IS AND AS IT MAY BE.

AT the present moment a question is under consideration that has been somewhat unexpectedly raised; one that concerns every individual whose name is on the Register, inasmuch as it is a question of the continued existence of chemists and druggists as a body of individuals recognised by the State and possessing privileges conferred by the Legislature, not as a consideration for, but essentially as a complement to their compliance with statutory conditions relating to their business that have been held by the State to be expedient and necessary in the public interest.

That question relates, in its present form, to "company pharmacy," or, in other words, it is a question whether the provisions of an Act of the Legislature, devised solely in the interest of the public, shall be sustained or practically repealed, so as to frustrate the intention of that Act, as well as inflict upon a large number of individuals a glaring and grievous injury.

In view of the importance of this question to all registered chemists and druggists, articles having especial reference to it have been published in this Journal during the past year in order to direct the attention of all who are interested to the nature of the issue that is now before them, an issue that calls for the most energetic action on the part of every person whose name is on the official Register. Now that the necessity for such action has become crucial and urgent it appears desirable to make the following further and comprehensive statement of the case.

In every civilised country—except Great Britain—the practice of the art of pharmacy, in its full extent, is limited by law to individuals certified by the State to possess a competent practical knowledge of their business, acquired as the result of education and technical training. The limitation of that business to such specially qualified persons does not in any degree amount to a monopoly of the sale of drugs, nor is it in any sense to be regarded as constituting a trade monopoly, since it is an arrangement that has been adopted, in the interest of the general public, in regard to the performance of important duties, its object being the safety of the public—as has been repeatedly pointed out in this Journal. Any coincident advantage accruing, as a result of that limitation, to the persons lawfully entitled to practise pharmacy is a necessary consequence of the limitation for public purposes, and an essential condition of its efficacy for obtaining the public object in view. It may be confidently stated that, to candid minds, consideration of all the circumstances of the case can lead to no other conclusion than that stated above. But at the risk of appearing tedious to those who do perceive and acknowledge the truth of that view, its reiteration is still necessary, because that truth is not fully appreciated, and also because an unworthy attempt is being made to create an impression that a monoply of the sale of drugs is the real object of the opposition to "company pharmacy" and to the proposed amendment of the Companies Acts in regard to the practice of pharmacy which has recently been brought before Parliament.

In Great Britain the practice of pharmacy, as now taken cognisance of and defined by Act of Parliament, is the retailing, dispensing and compounding of certain medicinal articles that are enumerated in a schedule to the Act, to which other articles may be added under prescribed conditions. To that extent only is the keeping open shop, for those purposes, by persons "known as chemists and druggists" unlawful for "any person" who is not registered under the Act. As compared with other countries, that limitation of the practice of pharmacy in Great Britain is therefore of very small extent—instead of applying to the entire range of pharmaceutical work it is confined to operations with those medicinal articles which are "poisons" by Act of Parliament and require on account of their exceptionally deadly as well as dangerous nature, for the "safety of the public" to be dealt in and manipulated or supplied as medicines only by persons certified to possess competent skill and knowledge for the performance of those important duties. To speak of that curtailed limitation of the practice of pharmacy as a "trade monopoly" indicates either mendacious perversity or strange want of acquaintance with the circumstances of the case. This latter condition is by far the most dangerous: the great necessity for providing against the possibility of its influence affecting legislative action, has but recently been demonstrated by an utterance of the head of that Government department which exercises statutory control over the action of the Pharmaceutical Society and has almost unlimited power to influence pharmaceutical legislation.

The present legal position of British pharmacy, as above defined, is better than it was, some fifty years ago, when the practice of the art was open to any persons however ignorant or incapable, and when the public were utterly unprotected in that respect by suitable statutory regulations. The early efforts of the Pharmaceutical Society produced some improvement; but it was regarded with suspicion from the free trade point of view—even Parliament refused to sanction the establishment of any qualification for the practice of pharmacy but one of a voluntary nature—that of pharmaceutical chemist. At a later period, when the state of pharmacy in Great Britain was declared by medical authorities to be a disgrace to the country—but not until the public were in acute dread of the danger of poison—the partial measures, now in force, were adopted for regulating the practice of pharmacy. The effect of the Pharmacy Act, 1868, was to incorporate, by registration, the persons known as chemists and druggists, as persons having the legal qualification for keeping open shop to sell, dispense, or compound poisons that was then established. So it came to pass that a recognised craft guild of "chemistanddruggistry" was created, superseding that of pharmaceutical chemist, which had been the object of the Society, as necessary for ensuring competence for the practice of pharmacy in the proper sense. Hence the operation of the so-called Pharmacy Act, 1868, did not affect the practice of pharmacy as a whole; but served only for the protection of the public against the danger of poison. The beneficial effect of the advance thus made was soon interfered with. The business carried on by persons known as chemists and druggists, generally comprises—in addition to the sale, dispensing, and compounding of statutory poisons, and the whole professional part of the business practice of pharmacy that is not subject to statutory restriction—various accessory branches of ordinary trade which

could be carried on by any persons without qualification. Considerable opportunity for encroaching upon the professional part of the business was also presented by making the chemist's and druggist's shop resemble a fancy bazaar and calling it a "drug store." The first encroachment on the chemist and druggist's privilege to sell, dispense, and compound poisons was on the part of co-operative stores, some of them carrying on business as limited liability companies, and the attempt to stop that encroachment was frustrated by the decision of the House of Lords in 1881, which virtually sacrificed the legal qualification established for the practice of pharmacy to the Moloch of free trade.

The full effect of that failure to uphold the principle of the Pharmaceutical Society—that it is expedient for the safety of the public that persons engaged in the practice of pharmacy should possess a corresponding scientific and practical knowledge of their business—was not produced until the provisions of the Companies Acts were mischievously applied for the purpose of evading the Pharmacy Acts in which that principle was embodied. By that means and by the subsequent invention of the "bogus" or one-man company, any person—unqualified under the Pharmacy Acts—could keep open shop for retailing, dispensing, or compounding poisons, without being subject to the provisions of those Acts. That invention —the apotheosis of the House of Lords' decision—utterly stultified the Pharmacy Acts, and took the practice of pharmacy back again to a legal condition which was declared in 1864 by the General Medical Council, by Sir Robert Christison, Sir Henry Acland, and many other medical authorities, to be "a disgrace to the country," a condition allowing any ignorant or imcompetent person to carry on a business for the exercise of which, the Legislature had previously decided that the safety of the public required competent knowledge and skill. Hence the question has come to be really one as to the sufficiency of the Pharmacy Acts to prevent unqualified individuals taking a position that only legal persons should enjoy, not merely one as to the admissibility of company pharmacy. That is the position, at the present time, and though the departmental Committee of the Board of Trade declined in 1895 to take cognisance of the evil as being outside the scope of its instructions to provide a remedy for defects of the Companies Acts, the mischievous effect of the existing legal anomaly in regard to the operation of the Pharmacy Acts has been perceived: two of the highest legal authorities, having pointed it out in the House of the Lords as requiring to be remedied by suitable legislation. The procedure that was suggested for the purpose by the Lord Chancellor would, however, be no remedy for the evil: it would involve entire sacrifice of the principle of the Pharmacy Acts, destroy their efficacy in regard to the safety of the public, and inflict a grevious wrong on the persons legally qualified under those Acts to practise pharmacy, by making them the prey of unqualified competition.

Such is the position to which British pharmacy would be reduced if the provisions of the clause introduced in the Company Bill were enacted. The only hope of averting that disaster—which would indeed be a national disaster—lies in impressing upon the authorities concerned the utter incompatibility of the proposed measure with the principle of the Pharmacy Acts, or with public safety, and public justice. The Lord Chancellor's original suggestion for remedying the evil that he recognised, bore evidence that he had only a partial and distorted perception of the truth that the anomalous state of the law is obviously contrary to common sense. The same deficiency is apparent in the subsequent modifications of that suggestion. The memorandum prefixed to the Lord Chancellor's Pharmacy Bill, stating that the object of that Bill was to place a company in the same position as the executors or trustees of a deceased druggist, involves the fallacious assumption of analogy between the abnormal conduct of a chemist and druggist's business by a company of unqualified persons and the continuance of a deceased chemist's legitimate business. There is really no analogy whatever: nor can the proviso as to employment of a duly qualified manager or assistant be regarded applicable in the one case as it would be in the other.

Moreover the provisions of the second clause of the Companies Bill are absolutely inconsistent with each other, as well as with the general principle of the Pharmacy Acts. If the second clause were enacted, the only provision of the Pharmacy Acts to which a company would be really subject would be the one relating to observance of regulations as to the keeping or selling of poisons. Companies do not compound medicines, but obtain them for sale from wholesale manufacturers; therefore the only other provision touching a company, viz., that as to the compounding of medicines of the British Pharmacopœia, would be of little account in the case of companies. Then again, that very slender liability to the provisions of the Pharmacy Acts, is, according to the latter part of the second clause, to be subject to the further provision implying that companies may carry on the business and use the description pharmaceutical chemist or chemist and druggist—thus conceding to companies the most essential points of the Pharmacy Acts. That provision is in direct opposition to the principle of the Pharmacy Acts: it implies that a company may carry on the business and use those titles in connection with the chemist's business and irrespective of the fact that a company, as an ideal personage, cannot be registered, and cannot fulfil the conditions, antecedent to registration, which the Legislature has declared to be essential and expedient for the safety of the public. The condition under which it is thus proposed that a company should carry on the business and use the titles indicative of qualification, is also, from the public point of view, delusive, for since a company cannot be examined as to its fitness to do either the one or the other, it follows that the conduct of a company's business by a duly registered manager would in any case only confer upon the company a reflected and not a real qualification. Such a moonshine qualification may well be regarded as insufficient to secure any object of the Pharmacy Acts, —not in any sense justifying that practical confiscation of the privileges of qualified persons which its recognition would entail. The proposed second clause of the Companies Bill is, therefore, self-contradictory and distinctively retrograde in its tendency. That such a mode of dealing with the evil of company pharmacy should be considered for a moment, is conceivable only on the supposition that its proposers do not fully com-

prehend the case, or perceive what would be the consequence of adopting such a proposition. That persons on the Register of Chemists and Druggists—to say nothing of pharmaceutical chemists—should be the advocates of such legislation, should be inclined to acquiesce in it, or to contemplate any kind of compromise, admitting companies of unqualified persons to share their privileges, suggests a state of mind which, as Mr. SMITH well expressed himself last week, does not admit of being characterised in polite language, for, unless the interests of the public and the corresponding just interests of all legally qualified persons are ignored and disregarded, the only other conclusions would be too uncomplimentary to specify.

From the point of view stated above the articles appearing in the Journal during the past year have been directed to the exposition of a common-sense view of the case, which appears to be consistent with the principle and past action of the Society. Chemists and druggists who share those views and desire to oppose the confiscation of their privileges which seems possible, should throw the whole weight of their influence individually and collectively into supporting the action of the Pharmaceutical Society on their behalf. In order to defeat the open advocates of company pharmacy, as well as its secret supporters, the Council of the Society should be placed in a position to represent a united Society strong enough to resist all opposition—a Society determined to defend the position in which chemists and druggists were placed by the Pharmacy Acts—to command the attention of the Government and of Parliament, and to secure recognition of the justice of its claim. Existing conditions are more favourable than those prevailing when such an attempt was made in 1881. The rank and file of legally qualified chemists and druggists comprise a much larger proportion of examined persons, the value set upon their professional qualification by the public is greater, and, even in Parliament, extended application of the principle of the Pharmacy Act has been spoken of as desirable in the public interest.

THE COMPANY PHARMACY PROBLEM.

THE proceedings at the Council Meeting last Wednesday and—so far as can be gathered from the report—the proceedings of the Committee, clearly point to the existence of two parties in the Council. That absence of unanimity may perhaps be a source of gratification in certain quarters, though the papers by "An Ordinary Pharmacist" appear to have disturbed the equanimity of some who are inclined to support opposite views on the subject of company pharmacy. The writer of those articles may safely be left to defend himself by reasonable and logical arguments against any opponents, without editorial assistance. It may, however, be said that the view he puts forward and the arguments by which it is supported are quite in accord with the view that has always been expressed in the *Pharmaceutical Journal*. Any weight attaching to those arguments depends on their being reasonable and logical. Knowledge of the writer's name and individuality would not enhance that value, therefore it is sufficient to say that the writer is a pharmaceutical chemist, as well as a member of the Society, and is consequently fully entitled to express his views in the pages of the Society's Journal.

ANNOTATIONS.

"PHARMACIST No. III.," whose letter appears at page 443, does not appear to remember the fact that the House of Lords' decision in the case of the London and Provincial Supply Association, Limited, is a legal precedent applying to all cases relating to the legality of "company pharmacy." According to that legal precedent a company may lawfully carry on the business of a chemist and druggist, *i.e.*, sell poisons, or keep open shop for retailing, dispensing, and compounding poisons, and use the title of chemist and druggist in connection with that business—or even the title of pharmaceutical chemist—without being subject to the penalties that an individual would be subject to in such cases of infringement—in fact, a company need not conform to any of the requirements of the Pharmacy Act, *i.e.*, need not be registered, have been examined, or conform to regulations as to keeping or selling poisons or compounding medicines according to the formularies of the British Pharmacopœia—a company, as such, is a free-lance that may do what it will—and as a company may consist of the one individual—on whose behalf it is formed—with six dummies merely to satisfy the Companies Acts, the result is that the House of Lords' enfranchisement of companies has wiped out the Pharmacy Acts from the statute book. Strange to say, many chemists and druggists do not seem to have perceived that fact, any more than "Pharmacist No. III." appears to have done. Now that a very material advance has been made—in regard to the legal position of the registered chemist and druggist—by the introduction of clause 2 into the Companies Bill of the Govrernment, a more fully rational appreciation of the case is urgently desirable.

PROCEEDINGS UNDER THE SALE OF FOOD AND DRUGS ACT, 1875, were taken during 1898 in respect of the sale of "drugs," in ninety-three cases. Sixteen hundred and forty-one samples were examined, and a hundred and ninety-six of those—nearly 12 per cent.—were found to be adulterated. There were 39 adulterated samples of sweet spirit of nitre out of 173 examined; of Gregory's powder, 25 out of 75; of sulphur, 15 out of 82; of rhubarb, 15 out of 136; of lime water, 13 out of 40; of magnesia, 11 out of 74. Eight out of 25 prescriptions were improperly or carelessly compounded. The condemned samples of "wax" numbered 8 out of 30; of cream of tartar, 9 out of 84; of seidlitz powders, 9 out of 43; and of glycerin, 2 out of 132. On the other hand, 69 samples of castor-oil, 48 of linseed meal, and 49 of quinine and its preparations were found above reproach. The twenty-eighth annual report of the Local Government Board, from which the foregoing figures are taken, is like its predecessors in not stating how many—or how few—of the condemned samples were purchased from registered chemists Possibly the reason of the omission is that the number is too small for the authorities to feel justified in attempting to classify the culprits according to the nature of their business.

GUMMED PAPER has claimed a victim during the past fortnight—a clerk who applied the adhesive edge of an ordinary envelope flap to a wound in the scalp, instead of sticking plaster, having apparently died as the result of blood-poisoning thus set up. The wound may, of course, have become septic from some other cause, but the medical testimony favoured the view that the septicæmia which caused death had resulted from the unwise practice of applying any odd piece of gummed paper to a wound. The margins of sheets of postage stamps are frequently preserved for that purpose by people who ought to know better, but it cannot be too widely known that Government gummed paper is as likely to cause mischief when applied to wounds as any other.

THE FIRST EVENING MEETING of the Pharmaceutical Society for the present session will be held at 17, Bloomsbury Square, London, on Tuesday next, November 14. Professor J. Reynolds Green

will treat of the biology of yeast, and Professor H. G. Greenish will read a paper on spurious Alexandrian senna. The chair will be taken by the President—Mr. William Martindale—at eight o'clock precisely. It is hoped that a large number of members of the Society will make a point of being present and also bring my friends who may be interested in the subjects announced for consideration.

The Policy of the Council of the Pharmaceutical Society with regard to company trading in pharmacy, in so far as such a thing can be said to exist, is substantially what it was before the Companies Bill expired in August last. That is to say, the members of the Council are at one on the point that the use of titles indicating the possession of a legal qualification should be restricted to individuals who actually hold that qualification. They are also agreed that it is essential in the public interest that companies carrying on the business of a chemist and druggist should be placed on the same footing as individuals in regard to liability for offences under the Pharmacy Acts. Those two points of agreement are sufficient to constitute the basis of a policy that should commend itself to every chemist on the Register, and but few level-headed laymen would deny the justice of the two propositions. The difficulty, however, is to arrive at a generally satisfactory method of realising the conditions implied by those propositions, and such differences as prevail in the Council have their origin in minor difference of opinion as to what is practicable.

With the Same Object in View, the twenty-one members of Council naturally approach the problem of its attainment in such differing ways as suit their personal idiosyncrasies. Each individual member of the Council would like to have the Pharmacy Acts so amended as to apply equally to all persons—whether natural persons or artificial persons created by law. But there is not the same unanimity with regard to the method of securing that amendment; in fact, there is a great divergence of opinion in the Council on that point. As will be gathered from the report of the meeting of the Council held on Wednesday last, there is a strong party in favour of attempting to prevent a company of unqualified individuals from doing anything that the law says a single unqualified person may not do. But other members of Council, whilst in strong sympathy with that party, feel that it is inadvisable to attempt so much. Some hold that company trading in pharmacy has come to stay, and must be dealt with as an accomplished fact. At the same time, they insist upon the necessity, in the public interest, of providing proper safeguards in the case of companies as well as of individuals. How that is to be brought about they are not agreed. A few would provide a remedy in a Companies Bill; another section fails to see that the matter can be properly dealt with except in a Pharmacy Bill. But the point to be noted is that, whilst those differences of opinion exist, each individual member of the Council is honestly striving, as far as lies in his power, to find a satisfactory solution of the problem which presents itself.

A Protest Must be Entered, therefore, against the ill-chosen language occasionally made use of to express the opinions of members of the Pharmaceutical Society or of local associations, with regard to the manner in which the Council of the Society is attempting to perform its very difficult task. Some of the worst offenders in that respect hail from Lancashire, and a glaring instance of the objectionable practice referred to was supplied by the report of the Committee of the North-East Lancashire Chemists' Association, which was read at a meeting reported in last week's Journal. Only a summary of that report was printed in the Journal, the language of the report itself being quite unfit for publication in the Society's official organ. Whilst every member of the Society may reasonably claim to criticise in these columns his representatives upon the Council, in a fair and gentlemanly manner, it is obviously quite out of the question to print a mass of uncalled-for abuse. Misstatements and slanders cannot take the place of argument in serious discussion, and the sooner that fact is realised generally the better it will be for pharmacy.

It Would be Interesting, by the way, to know how Mr. Wells reconciles the terms of the proposition moved by him (see *ante*, p. 413) with the following statement attributed to him by the reporters:—"He believed emphatically that regulation and registration of the companies would be a desirable settlement." He then proceeded to say that "they (registered chemists, presumably) could not admit of any regulations in the matter of title, and no regulations could meet the case. Nothing but the individual qualification must confer the right to use the title or to handle scheduled poisons." Those statements may possibly be made to appear other than antagonistic, but it is difficult to conceive how. The report of Mr. Wells's remarks seemed so contradictory when received that—though apparently in his own handwriting—they were presented in the Journal in a summarised form. He has since complained, however, that his remarks have been "suppressed" and, under the circumstances, it seems desirable that he should have an opportunity of explaining what he really meant.

The Blackburn Position appears to be the absolute prohibition of all companies, whether constituted of qualified or unqualified persons. In other words, Mr. Wells and his friends would deprive registered chemists of the right to take advantage of the provisions of the Companies Acts in rearranging their business affairs—a right denied to no other tradesman. For, to the extent that the provisions of the Companies Acts can be applied to his business, a chemist and druggist is nothing but a tradesman. But such a proposal is absurd on the face of it, and not worthy of a moment's consideration. So far as a personal qualification is concerned, the existing Companies Acts should certainly not be allowed to apply, since it is obviously impossible for a company to fulfil the requirements imposed on individuals who desire to secure a professional qualification. It is equally out of the question that a company should practise any profession; but the individuals constituting a company, if properly qualified, can practise and ought not to be interfered with in so doing. A strict line of demarcation must be drawn between the professional and trade interests of registered chemists. The former should be legally protected and inalienable, but the protection of trade interests must be left to individuals—alone or in conjunction with others. What pharmaceutical chemists and chemists and druggists must be content to ask for, at present, is that the use of their titles and the practice of pharmacy in its professional aspect shall not be permitted to any unqualified person or combination of unqualified persons.

Argument based upon assumed analogy between the case of "James Woolley, Sons and Co., pharmaceutical chemists" and "Jesse Boot, Limited, the greatest chemists in the world," does not present itself as being of that reasonable and logical nature that should characterise an argument used in opposition to the claim of legally qualified chemists to the exclusive privilege of using the title and carrying on the business of chemist and druggist. Why legally qualified pharmaceutical chemists or chemists and druggists should be debarred from taking advantage of the facilities afforded by the Companies Act—if that be possible or desirable—no one of the advocates of "company pharmacy" has yet pointed out. Until it can be shown that such a proceeding involves a necessary violation of the principle of the Pharmacy Acts the argument above referred to cannot be of much practical value.

REVIEWS AND NOTICES OF BOOKS.

THE 'PHARMACOPŒIA OF UNIVERSITY COLLEGE HOSPITAL' has been revised by Mr. Harold Wilson, dispenser to the hospital, and the new edition (London: Jas. Truscott and Son, Suffolk Lane, E.C. Pp. 63. Price 1s. 6d.) is as conveniently arranged and compact a little volume as could be desired. The sections on "Heads for Reports of Cases," "General Rules for Performance of Autopsies," and "Rules for Removal of Tumours" have been omitted from this edition, and the space is more profitably occupied by sections on the "Use and Preparation of Enemata," "Poultices," "Mustard and Cold Baths," "Treatment of Bed-Sores," "The Urine," "The Blood," "Use and Preparation of Stains," and the "Treatment of Acute Poisoning." Other additions are diet, saturation, thermometric, solubility, and posological tables. The nomenclature has been brought into line with that of the British Pharmacopœia, and several new formulæ are introduced. The size of the book is $5\frac{3}{4} \times 3 \times \frac{1}{4}$ in., the binding is flexible, and there are several blank pages for notes.

'THE CHEMISTRY OF THE HAIR, FACE, AND TEETH,' by Dr. A. B. Griffiths (London: R. Hovenden and Sons, Berners Street, W. Pp. 152. Price 2s. 6d.), is a reprint of a series of lectures delivered by the author, to which he has added numerous formulæ for toilet preparations of various kinds.

THE 'TRANSACTIONS OF THE JENNER INSTITUTE OF PREVENTIVE MEDICINE,' a second series of which is now published (London: Macmillan and Company, Limited), constitute a record of original scientific work of the highest value. The papers included in the present volume dealt with diphtheria toxin, photogenic bacteria, the fermentation of sugars by various organisms, thermophilic bacteria, the pathology of cancer, symbiotic fermentation, the technical applications of bacteriology, and numerous other interesting topics in the department of preventive medicine. There are also many useful laboratory notes, dealing with flagella and capsule staining, disinfection on a large scale with formalin, etc., etc. The notes on apparatus describe a new hot stage for the microscope, a new photo-micrographic apparatus, a method of rapidly disintegrating micro-organisms, and a new microscope lamp. The volume is prefaced by an illustrated description of the Jenner Institute, and there are several plates illustrating articles on specific bacteria. Regarded as a whole, the book forms a notable addition to the literature of the subjects of which it treats.

'A GUIDE TO URINE TESTING,' by Mark Robinson, L.R.C.P., L.R.C.S. (Bristol: John Wright and Co. Pp. 48. Price 1s.), is a slight work written "for nurses and others." It is a compilation of the simpler tests and facts concerning urine, and is of a convenient size to carry in the pocket.

AN 'INTRODUCTION TO THE OUTLINES OF THE PRINCIPLES OF DIFFERENTIAL DIAGNOSIS,' by F. J. Smith, M.A., M.D., F.R.C.P. (London: Macmillan and Co. Pp. 253. Price 7s. 6d. net), is the outcome of an attempt to arrange the old phenomena of disease in such a manner as to show more clearly their fundamental meanings and relationships. The author has utilised the data of physiology and the facts of pathological anatomy as the source from which to draw inferences and deductions, which, in their turn, constitute a critical analysis of clinical symptoms; by this analysis he has endeavoured to lead up to the underlying principles which govern disease as well as health.

'NATURAL AND ARTIFICIAL METHODS OF VENTILATION' are compared in a small book of eighty pages, published by Messrs. Robert Boyle and Son, Limited, Holborn Viaduct, London. One of the most interesting features of the book is a supplement containing reproductions in colours of diagrams illustrating the action of natural and mechanical methods of ventilation.

'KING'S COLLEGE HOSPITAL REPORTS' for 1896-97 and 1897-8. (London: Adlard and Son. Pp. 358 and 270 respectively. Price 2s. 6d. per volume), have come to hand almost simultaneously. Each volume constitutes a permanent record of the more interesting cases treated in the hospital during the year, but there is nothing in the contents of special interest to pharmacists.

'ORTHOPÆDIC SURGERY,' by J. Jackson Clarke, M.B., F.R.C.S. (London: Cassell and Co., Ltd. Pp. 454. Price 21s.), is a work of which the most that need be said here is that it has been written by one of the chief authorities on the subject of which it treats. It is described by the author as a book on the surgery of deformities, based upon their pathology, and giving in a systematised form, an outline of the various therapeutic measures applicable to their treatment.

'ASTHMA,' by Ernest Kingscote, M.B., C.M., L.R.C.S. (London: H. J. Glaisher. Pp. 183. Price 5s. net), is a record of a number of observations taken during some years' special practice. While working at the treatment of chronic heart disease, the author was able to relieve some patients afflicted with asthma, and he now suggests some possible reasons for the relief obtained.

'THE PHOTO-MINIATURE' (London: Dawbarn and Ward, Ltd. Price 6d. monthly) deals in its September issue with orthochromatic photography, in the excellent style familiar to readers of that excellent little publication. The illustrations are numerous and clearly printed.

THE 'ARITHMETICAL EXERCISES IN CHEMISTRY,' by Leonard Dobbin, Ph.D. (Edinburgh: James Thin. Pp. 52. Price 2s.), have now reached a third edition, and the changes and additions made render the book more useful than ever. The series of elementary lessons on chemical calculations which it embodies was prepared at the request of Professor Crum Brown, who has written the preface to the book. The various sections deal with the metric system of weights and measures; thermometric scales; density and densities; the laws of Boyle, Charles and Avogadro, and other principles involved in the calculations required in dealing with chemical changes. Miscellaneous exercises are given, together with much other useful matter, and the book may be commended to the notice of pharmaceutical students as one which they ought to make a point of possessing and using freely.

POTASSIUM PERMANGANATE IN DYSENTERY.—Gastinel finds that rectal injections of solution of potassium permanganate give excellent results in the treatment of dysentery. A 0·5 per mille solution is employed, made warm by mixing ten ounces of a 1:1,000 solution with an equal volume of hot water so that the temperature of the mixture is brought to 112° F. The patient lies on his left side for the first part of the enema, on his back for the second, and on his right side for the remaining third, the injected liquid being retained for from 1 to 2 minutes. If this be done at night, a second enema is given next morning, followed in a few hours by a dose of 15 grains of calomel. If the patient is seen first in the morning, one enema is given, followed by the calomel when ease has been produced. The enemata are repeated, generally every 24 hours, and as the symptoms indicate, are gradually diminished, both in frequency and in strength. The injections are somewhat painful for a time, but are followed by considerable relief. With children, a much weaker solution is used, and the dose of calomel is suitably diminished.—*Med. Press*, **68**, 350.

PHARMACEUTICAL SOCIETY.

"FIRST" EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Wednesday, November 1,

Certificates by approved examining bodies were received from the undermentioned in lieu of the Society's examination:—

Dale, Isabel Marian; London
Felice, Arthur; Malta
Johnson, Martin W., Spalding
Poole, Edward J.; Weston-super-Mare
Robinson, James Dugdale; Streatham
Senior, Arthur Alleyne; Exeter
Sharland, John Howard; Bournemouth
Spurrin, Stanley R., Bethnal Green
Thorne, Ernest George; Swindon

The report of the College of Preceptors on the examination held on October 10, was received. **316** candidates had presented themselves for examination, of whom **156** had failed.

The following **160** passed, and the Registrar was authorised to place their names upon the Register of Apprentices or Students:—

Allen, John; Grimsby
Altree, Edward; Kennington
Anderson, James Michie M.; Forres
Anderson, John Miller; Alva
Anderson, Thomas; Blackburn
Andrews, Hugh; Southport
Attenborough, T. Winfield; Nottingham
Bartleman, George Herbert; London
Bates, Thomas Harry; Birmingham
Baxter, Evelyn Mar. R.; Grangemouth
Bellringer, Harry; Denton
Bennett, Frank Hawkins, Stafford
Beverley, Thomas Latham; Notting'm
Biggam, John William; Whitehaven
Binks, Lilian Maude; St. Austell
Birkett, Robert; Fife
Bond, Francis Collins; Hull
Brinson, William John; Chesterfield
Brown, Gerald Reeves; Hull
Brown, Robert; Richmond
Bullen, Frederick Edward; Streatham
Cadman, Percy; Heckmondwike
Calvert, Sidney; Snaith
Camidge, Edgar Sydney; York
Catlow, Harry; Accrington
Clark, Harry; Settle
Clements, Llewellyn; Burnham
Colebrook, Donald; Plumstead
Collins, Charles Williams; Dorking
Cooper, Reginald; Mkt. Harborough
Cowie, John William; Tillicoultry
Craig, Frank; Inverness
Craven, George Leo; Blackburn
Croasdale, Henry Kirkby; Heanor
Cullingford, Clifford S.; Colchester
Cunningham, Duncan; Glasgow
Davis, John David; Braintree
Dickinson, R. J.; Berwick-on-Tweed
Dodgson, James; Carnforth
Dolling, Sidney John; Chard
Donaldson, John; Cullen
Duncan, William James C.; Aberdeen
Edgar, Allan Herbert; Kennington
Ferguson, Adam; Stirling
Forster, C. H. S.; Bebside Wood
Fowler, Henry; Frome
Freemantle, Frank, Woolston
Freestone, H. C. H.; Nottingham
Fryer, Raymond John; Uppermill
Gale, Arthur George; Penzance
Garbutt, Henry; Stockton-on-Tees
Garment, Wilfrid E.; Northampton
Gaze, John Edwin; Oxford
Gibson, Robert; Bishop Auckland
Greener, John Ebenezer; Shrewsbury
Hallding; Samuel Herbert; Runcorn
Hancock, Harold Holden; Lee
Harries, Evan John; Ammanford
Haycock, John; Leicester
Hedley, Joseph William; Durham
Henderson, Ernest B.; Wakefield
Henderson, Louis Burdett; Edinburgh
Herman, John Bartholomew; Liverpool
Hickson, Frederick; Gainsboro'
Hogg, Andrew; Langholm
Hollows, William Edward; Southport
Homes, Richard Gerald; Cheltenham
Hooper, Albert Edward; Cirencester
Horn, James Richd.; Wath-on-Dearne
Hudson, William; Bedlington
Hugh, William Bryce; Lochgelly
Humphry, Stephen; Dartmouth
Hutchinson, Omer Talon; Sunderland
Illsley, Thomas H.; Barnard Castle
Ingall, Mary Charlotte; Lancaster
Jackson, Edith Mary; Gainsborough
James, Thomas Hutchings; Fishguard
Johnson, Frederick Charles; Dudley
Jones, George Roberts, Amlwch Port
Jones, Rees Trevelyan; Bridgend
Jones, Thomas Ernest; Pontypridd
Jones, Vincent Hadfield; Carmarthen
Jones, Walter John; London
Juniper, Ernest; Epping
Keen, Theodore Stanley; Devonport
Lawrie, William C.; Workington
Leddra, Thomas Carlyle; St. Ives
Lee, Edwin Snow; Crediton
Lewis, Alfred Pearson; Birkenhead
Logan, Herbert Millar; Coatbridge
McDonald, Andrew; Fochabers
Macdonald, Henry W.; Middlesbrough
McLachlan, Douglas; Catford
McPhie, John; Falkirk
Martin, Clarence William; Colchester
Martindale, Leonard; Uppingham

Hull	3	3	0	Southampton	6	2	4
Inverness	5	3	2	York	7	3	4
Lancaster	6	3	3				

SELECTED PRACTICAL FORMULÆ.

Sulphur Zinc Paste with Sugar.

Menahem Hodara prepares this paste from lanolin and vaseline, of each 20; glycerin, 10; sugar, 20; sulphur, 10; zinc oxide, 20. The author recommends this paste in dermatological practice, and has found it effect rapid cures in lesions of the epidermis.—*Oest. Zeits. für Pharm.*, **53**, 390.

Zinc Gelatin.

According to H. Dik, this is best prepared with the following ingredients: Zinc oxide, 20; gelatin, 20; glycerin, 80; water, 80.—*Pharm. Post*, **29**, 383.

Zinol.

Zinol is a new remedy for gonorrhœa. It consists of a combination of zinc acetate, 1; alumnol (aluminium naphthol-sulphonate), 4; and is prepared in the form of a powder or as tablets. It is best administered as an aqueous injection.—*Pharm. Post*, **29**, 321.

Syrup of Papain.

Papain, 2; distilled water, 3; alcohol (60 per cent.), 10; syrup of orange, 180. Dissolve the papain in the water with a gentle heat, add the solution to the syrup; finally add the alcohol.—*Bullet. de Pharm. de Brux.*, **43**, 279.

Toothache Remedies.

(1) Cajuput oil, 1; clove oil, 1; chloroform, 2. (2) Camphor, 8; chloral hydrate, 8; spirit of peppermint, 120. (3) Clove oil, tincture of Indian hemp, chloroform; equal parts. (4) Peppermint oil, alcohol, ether, tincture of opium; equal parts. (5) Menthol, 8; ether, 100; clove oil, 60; extract of aconite, 4. (6) Eucalyptus oil, 4; mastic, 8; camphor, 45; morphine (alkaloid), 5·5; chloroform, 75; alcohol to produce 150.—*Pharm. Post*, **29**, 393, after *Merck's Report*.

Petroleum Insecticide.

Intimately mix 1 part each of common soft soap and tepid water, then add gradually one part of common paraffin oil, mixing the whole thoroughly with a brush of fine iron wire until a perfect emulsion is obtained. This emulsion may be diluted with 60 times its volume of water, or even more before use. If desired, tobacco juice or other poison may be added.—*L'Union Pharm.*, **40**, 412, after *Horticult. Nouv.*

MIDLAND PHARMACEUTICAL ASSOCIATION.

A meeting of this Association was held at the Great Western Hotel, Birmingham, on Thursday, November 2, 1899, when an address was delivered by Mr. W. Gowen Cross, J.P., of Shrewsbury, member of Council of the Pharmaceutical Society, on

Pharmaceutical Politics.

He said: I am constrained to preface the few remarks which I am about to make this evening with the expression of the great pleasure which the opportunity of addressing a Birmingham audience gives me. Certainly, no more fitting place could be chosen as the headquarters of Midland pharmacy than this great city, replete, as it is, with institutions which themselves constitute the types of their congeners throughout the land. Very early in the history of modern municipalisation did Birmingham exhibit such capacity for self-government that her methods obtained the truest expression of appreciation from kindred bodies, and if "Imitation is the sincerest form of flattery," Birmingham has received sincere flattery by the wholesale borrowing of her methods by other municipalities. She has so fully justified her motto, "Forward!" that whatever failures she may have encountered (and I suppose that some of these have fallen even to her lot), these have simultaneously been overwhelmed and obliterated by the magnificent successes which she has achieved. For her municipality has been the training-ground of statesmen of sufficient calibre to mould the destinies of a world-wide empire. Her School Board is at once a monument of efficiency and an exhibition of how an intelligent community can call into vitality a system of primary education which could only be shadowed (or, at least, slightly sketched) by the best drafted Act of Parliament. Her provision for secondary education is not less admirable, for I was reading only last September what was justly described a "comprehensive programme," which referred to the Municipal Technical School here, with its eight compartments, wherein are yearly granted numerous scholarships and prizes, obtained not only from the usual sources of private munificence, but also from the trade societies which flourish here. And, looking into the near future, we have the Birmingham University, which has recently been called to life, in an almost incredibly short time from its inception, which proves that the spirit of the great Mason still permeates the minds of his fellow-citizens, who would fain wish that he could see in the flesh the splendid supplement to his prescient generosity which the new University will become. Surely, upon such a soil, all that reaches toward the light should flourish and abound, and among the intellectualities which will thrive, it is not too much to hope that our own art of pharmacy will strive for and attain higher spheres of perfection as time rolls on.

It comes to my memory that nearly a quarter of a century back I, for the first time in my life, took a public office, and this was as a member of the Executive of the Chemists' and Druggists' Trade Association, which had its headquarters in Birmingham, and which I always like to believe did some useful work during its ten years of existence. This city, therefore, was for good or otherwise the starting point of my public career, and it gives me great pleasure to be deemed by you worthy to occupy the place which you have given me in your programme this evening. At the commencement of every session it is well to look ahead and consider what policy is best for the present state of affairs, and pharmacy is not exempt from the necessity of having a policy. Just now we who steer the pharmaceutical vessel are more or less pleasantly reminded that we ought to formulate and declare a policy, which the country generally can accept. It seems so easy to do this. Our wants are so obvious, and our service to the public so conspicuously desirable, that it is a matter of State urgency to afford the holders of our diplomas protection from the dangers which surround them and the public, and especially from the dangers which are inherent to the practice of pharmacy by limited liability companies. And was there not before Parliament, debated and carried by the House of Lords to its third reading, a Bill to amend the Companies Acts, which we are promised to see again next session? And was not one of its clauses devoted to pharmacy? True, the treatment proposed to be meted out to us was not the sort of treatment we desire, but that might be the result of misunderstanding, and might be remedied. But how?

The Company Pharmacy Problem.

You all know what happened last month, and of the reference which was made to the Law and Parliamentary Committee of the Council with a view to a clause being drafted in the interest of pharmacy, to amend the Companies Bill. Well, this week you will find that a majority of the committee submitted a clause which would virtually prevent a company carrying on the business of a chemist and druggist or of assuming the titles. I have discussed this proposal in my place at the Council, and it would ill become me to do so here. But I know that you will read that discussion with interest, and perhaps will agree with me that it is just as well that the matter was sent back to the committee for further consideration. For my part I wish to be perfectly just to my colleagues, and to subordinate a personal opinion to the conclusion which will sooner or later be arrived at by the majority of them. And if you ask me what that conclusion is likely to be, I simply reply: Ask yourselves what is the probable outcome of our deliberations, and you will form a pretty just estimate of what twenty-one men, similarly placed to yourselves, are likely to aim at. We cannot attain the impossible, but we hope to make the best of this and every other opportunity which is offered to us.

Criticise our actions, stimulate us with your suggestions, and rest assured that the confidence which you repose in us will not be misplaced. Our policy is to act intelligently at the exact pschycological moment. Yours, and the policy of kindred associations, to collect and provide us with material for con ideration.

The policy of the Midland Pharmaceutical Association appears to me always to travel upon the lines which I have indicated, and although, as a member of it, it would ill become me to speak its praises too loudly, I cannot forbear to congratulate its executive upon the excellences of its procedure, as especially upon its prompt action in securing the co-operation of pharmacy within its sphere of influence, for the University scheme in this city, inasmuch as the prime plank in our platform, is the securing of our educational status. That is why the parent Society still keeps her hold upon the School at Bloomsbury Square—a School she will gladly relinquish when the University centres throughout the country are ready to replace it. And we should like to feel that from the moment a student enters upon pharmacy as a calling he is ever seeking to acquire and utilise knowledge, and that "as riper years shed their snow" upon the head of the pharmacist, enwrapped though he may be with care, and enveloped in business concerns, his life's' plan is to widen and deepen the sources and channels of the huge store of knowledge which he has acquired.

Although I must not divulge cabinet secrets, there is every reason why we should discuss the amendment of the Companies Acts whenever we have the opportunity to do so, and I hope that you will agree with me that no amendment will satisfy us in the least degree which fails to secure for us the individual right to use, and style ourselves by, the titles which we have acquired by examination. It is amazing—but, nevertheless, the highest legal authority tells us so—that the judgment obtained against the Pharmaceutical Society in the House of Lords covers the use of titles. This being so, it is simply wasting powder and shot to seek out a test case and bring it before the Courts, for we should simply get blocked *ab initio*. But the justice of such a position is surely "a mockery of justice," and we have a perfectly logical case in attempting to amend the law.

The Existing Position.

You will remember that the judgment above referred to was given against us mainly upon the meaning of the word person, and it decided that inasmuch as a limited liability company is not a person of the kind referred to in the Act, it is outside the operation of the Pharmacy Act, in so far as the first fifteen clauses are concerned.

Unfortunately, our titles come within this space of the Act, but surely title is essentially a personal matter. It can only be acquired by a person, who, to acquire it, must perform certain personal services who, when he has received it, must use it personally, for he cannot transfer it. And when this person ceases to live his certificate becomes inoperative.

In other words, the Pharmacy Act, for the public good, and apparently that the public may recognise the persons who are to do certain things, distinctly invests these self-same persons with definitive distinctive titles upon their compliance with certain conditions, and surely it is illogical, if not immoral (perhaps both), for that which the law has decided to be a nonentity to assume something which can only appertain to an entity—to pose, in short, at one and the same time as a person and yet not a person.

The absurdity of the position is so apparent that in their attempt to amend the Companies Act which the Government has made, a clause was inserted to protect other titles which, under the exist-

ing judgment, are similarly affected to our own, and in the name of justice we ask for similar treatment. This is altogether different from asking a trading monopoly. It belongs to us personally, and is as useful to the public generally as ourselves that such a distinction should be drawn, and that a company, *qua* company, shall not call itself by a title which it cannot honestly acquire.

We must, therefore, in any amendment of company law, use all the power we can to obtain sole possession of our titles, and we ought to succeed in doing so. I cannot help feeling when I read the reports of meetings, and some of the correspondence which our journals contain from time to time, that a need exists for stating our case plainly. After travelling through all the Courts of law judgment has been definitely pronounced, so that it is not right, and it is certainly unwise, to accuse limited liability companies of acting illegally when they do things which this judgment, the highest in the land, has declared deliberately to be perfectly legal.

And I, for one, am convinced that we shall never prevent companies from carrying on much of the business which at one time was the exclusive property of a chemist.

As to company pharmacy, there is no such thing. It is a misnomer altogether, and but for the assistance of qualified men the pretence of such a thing would be self-apparent.

Whether qualified assistants will ever recognise that by assisting companies to keep open shops as pharmacies, and evade the spirit of the Pharmacy Act, they are cutting the ground from under their own feet, I cannot pretend to say; but we must admit two patent facts by which companies are enabled to masquerade as ourselves—(1st) They obtain assistance from within our ranks, and (2nd) they have the active support of a section of the public. So long as these conditions obtain, we cannot expect Parliament to prohibit company trading in our direction.

How an Impression May be Made.

I agree with a speaker who said recently "that if the Pharmaceutical Society and the whole of the pharmaceutical body were to take up this matter seriously, they would make an impression upon the Legislature." What a picture! The Pharmaceutical Society backed by the whole estate of pharmacy. Would that we could clothe it with living flesh. But so long as qualified men are content to accept the service of companies, it cannot be realised.

Another, in a letter some time back, recommended us to appeal to the sympathy of "the man in the street." Well, we know this gentleman by repute. One of the honourable members for this city recently spoke of his shrewdness, and perhaps rightly, in connection with the matter which he had under discussion at the time. But I am not for appealing to him for pharmacy legislation. He knows nothing about us, and could not therefore champion our cause. Left to public sympathy, our cause could not progress. It is worse than useless to appeal to those who cannot help us. Rather let us go, as we have already gone, to the permanent officials of the Privy Council, and ask that no retrogressive pharmacy legislation shall be allowed—and I do not fear the result. In my opinion it is bad policy to be continually drivelling with our grievances before the public, advertising our disabilities and appearing to seek a monopoly. If we succeed in strengthening the Pharmacy Acts it will rather be at the instance of a responsible official aiming to protect the public—in spite of themselves—than by ourselves seeking the support of popular clamour. In a word, I wish to face things cheerfully and practically. There is, no doubt, in our own ranks more than one development of method which we cannot but deplore the necessity of—which, as educated men, chafes us. An atmosphere of keen trade competition, for instance, is uncongenial with the practice of the ideal pharmacy we were wont to plan out for ourselves in our earlier days. But I would rather divert attention from this state of mind to the undoubted fact that there is a better future in store for those who intelligently seek it. Living things rise to opportunity, and the wise pharmaceutical politician will endeavour to extract the good which he can secure from his surroundings. After all, has not the more modern order of things provided many who otherwise would have become stagnant with opportunities which, under the older *régime*, would have never come in his way? Where, for instance, are the shabby, not overclean pharmacies of olden days? Most of them, I hope, appear in suitable modern garb, and are of increased and increasing value to the public, the physician, and the pharmacist himself.

What to Work For.

I make no excuse (except, perhaps, to the ladies) for introducing pharmaceutical politics to this Association at its inaugural meeting, because it is, in my opinion, the right thing to discuss before the next Parliamentary session opens. And I hope that associations all over the country will endeavour to think out for themselves, with as little prejudice as possible, the question which we have to face, when anything pertaining to company law makes its appearance in Parliament. One thing, I believe, we are all united in: We are determined to secure, if possible, the personal possession of our titles; but before we have secured this point, notwithstanding that justice is on our side, we may have a weary time of waiting, and, moreover, to perform, through our Executive, some task or other which is unpalatable. Personally, I would sacrifice much to prevent limited liability companies trading under the title of chemist, and, although I would not willingly be a party to the regulation of company pharmacy, yet, if Government were to approach the Council of the Pharmaceutical Society, and to state plainly that they were determined to impose in their Act conditions upon companies for the better protection of the public, and invited the Council to assist them in framing these, I should certainly, as a public man, holding a responsible position, not stand aloof from such an invitation. And, thinking of the public whom I am bound to protect, and thinking, also, of my brethren in pharmacy, I would do everything in my power to insure that companies should be bound by the same law as I am myself; and, moreover, that the public should have full opportunity to discern whether the hand into which it is about to place its vital concerns is the hand of a responsible person, with unlimited interests and responsibilities, or whether it is the hand of a mere hireling of a number of unqualified persons, whose responsibilities are carefully limited.

As to minute directions, such as we all observe, being codified and drawn up as regulations to enable stores to flourish, I could not help in such a work—not because my commercial interests would thereby be interfered with, but because I believe the public safety demands that such matters can only be successfully dealt with by the person who himself holds statutory qualification. There is more, after all, in pharmaceutical politics than the matters which I have been discoursing upon. You expect me to discourse upon the popular theme, and the temptation to do so is irresistible—not that I can expect to say anything more than has been said and written upon the subject by men who are better able to give expression than I am. If I may say a word of criticism to my contemporaries in quitting the matter for the present, it is to deplore that so much of what one reads evidences such a lack of knowledge of the actual, as opposed to the ideal, state of the law at the present time, and that so many of the proposed terms of settlement are so obviously impossible. And this after the matter has been discussed in all its bearings for over twenty-five years, during which time no expense has been spared to secure the best legal opinion and to demonstrate the dangers and absurdities of the position to those who alone can take the steps necessary to alter it.

The Prospect Brightening.

It has been said that "until this question is settled the Pharmaceutical Council should suspend its educational work" and "devote the whole of its attention to securing justice for chemists." That would be the experiment of the Frenchman and his horse over again, and without the nutriment so essential to its vitality pharmacy would become inanimate.

There is, however, a sign of better things. It is the movement for greater cohesion in the craft, and I am rejoiced to find that, in greater evidence as one session succeeds another, associations are becoming increasingly living organisms. Time was but few years younger when it was the generally accepted dictum that associations of chemists throughout the country, had either become the pocket boroughs of one or two leading men in their ranks, or had ceased to exist altogether. We heard of libraries being housed in other premises because their original home was closed, and of certain leaders who should and ought to be attending carefully to the good of the body corporate, neglecting golden opportunities, with the result that chemists in certain districts did not unite socially or otherwise. It has been reserved for the present generation of men in our ranks to alter this state of things. Old associations are revivified, new ones are started, and instead of being the one-horsed shows of former years, they are instinct with life, intelligence, and good-fellowship. Thirty-six meetings of the British Pharmaceutical Conference in different parts of the kingdom have largely contributed to this result, but chiefly has the Federation of Pharmaceutical Associations, which was hatched and nursed through its tender years in Birmingham, been the powerful factor in this matter, and I am hoping shortly to infuse this spirit more generally among the local

secretaries of the Pharmaceutical Society, chemists meet now to take council and to sympathise with one another in a deeper, truer sense than they ever did before, at least within my recollection; and it is only, I believe, by such means that a fuller understanding of our wants, our difficulties, and the way to secure and remedy these can be brought about. After all that is argued and debated may the developments of pharmaceutical politics be—the good of the greater number, the unfolding of the many possibilities within our reach, so that when we leave the stage upon which we have played our part, as we all, sooner or later, shall have to do, we may have the satisfaction of reflecting that we each and all at least have striven to do something for its betterment.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held at 73, Newman Street, London, W., on Thursday, October 26. The PRESIDENT, Mr. F. W. GAMBLE, in the chair. There was a fair attendance of members. The minutes of the two previous meetings having been read by the SECRETARY, Mr. J. EVANS, and confirmed, Mr. J. C. HYSLOP read paper on

"Ethics as Applied to the Practice of Pharmacy,"

which is printed at page 419.

The PRESIDENT, at the conclusion of the paper, said that it was stated in the pharmaceutical press last year that the subjects of the meetings of the Association embraced almost every subject that was of interest to pharmacy, but he thought they had that night heard Mr. Hyslop speak on a subject that had been absent from the minds of all—that of Ethics as applied to pharmacy. Mr. Hyslop was in a position so speak on such a subject to those of the younger branch of pharmacy because his venerable aspect commanded their reverence and respect. It was a somewhat curious coincidence that at the commencement of the present session the medical profession had been addressed on a similar subject by Sir James Crichton Browne, who spoke on the Attainment of the Ideal. Mr. Hyslop had put before them some ideals, which to him (the speaker) seemed very difficult of attainment. For instance, it would be very nice for the pharmacist to attain to the position of being able to leave his business in the care of his neighbour for a month or two in the same way that doctors frequently do, but he was afraid the pharmacist would find it more difficult to retain his customers under such conditions than was the case with the doctor. Mr. Hyslop had revealed in his paper a wide acquaintance with literature, and although his quotations showed that he was an admirer of Pope, he was evidently ready to deny one of his sayings to the effect that "Whatever is, is right." The address had shown that a knowledge of literature was useful even to pharmacists. With regard to Mr. Hyslop's reference to the poor assistant, it was undoubtedly the fact that he got most of the blame whenever anything went wrong. Perhapsa better state of things would exist when they had a better class of masters.

Mr. T. MORLEY TAYLOR said it had been suggested to him that Mr. Hyslop's address had been so much in the nature of the kindly sermon, that even if they found any point to discuss, they could not criticise it, at any rate not in an antagonistic sense. Mr. Hyslop had placed before them a very high ideal of pharmacy; he (Mr. Taylor) had a high ideal of his calling himself—except in the matter of getting a living—and he expected that every one in that room had too. Mr. Hyslop had hit upon a weak spot when he spoke of the strikingly ready way in which pharmacists fill their pharmacies with quack medicines. He thought the practice was to be deprecated. With regard to Mr. Hyslop's ideal of a pharmacist taking care of another's business, he was of opinion that the minutiæ of each individual pharmacist's business was such as to render that ideal almost impracticable.

Mr. C. J. STROTHER thought that the public was to blame and not pharmacists for the large business done in quack medicines. The public demanded certain articles, and pharmacists had to stock them or lose custom for other things. But, of course, in order to draw trade the real difficulty was that one pharmacist in a place exhibited these goods ticketed at a less price than his neighbour sold them; he in turn retaliated by reducing the price still lower, until finally there was no profit left. He thought the ethics of the future would tend to abolish that state of things by assisting young men to take a firm stand in refusing to deal otherwise than in a straightforward way. He believed that such associations as the C.A.A. exerted a great influence for good in that direction.

Mr. JAMES regretted that Mr. Hyslop had not pointed out the way by which the high ideals he had placed before them could be attained. Personally, he thought that the abolition of the indoor assistant—who often imbibed the peculiarities of his master, and sometimes those of the lady of the house—together with shorter hours, would go far towards producing a class of men of broader mind and better in every respect than the average pharmacist of to-day.

Mr. HYSLOP having replied to the remarks made by the different speakers, a hearty vote of thanks was accorded to him on the motion of Mr. A. Latreille.

MIDLAND CHEMISTS' ASSISTANTS' ASSOCIATION.

The opening meeting of the session was held on the 25th ult. at the Exchange Rooms, Birmingham, the PRESIDENT (Mr. F. A. Spear) occupying the chair. There was a large attendance. Mr. A. W. GERRARD (Oldbury) read a paper on

Pharmaceutical Education,

and dealt with the subject in a very interesting manner. At the outset Mr. Gerrard expressed the pleasure he felt, as a pharmacist of thirty-five years' standing, at meeting the members of an Association, the chief object of which was the betterment of pharmacy. He regarded it as a promising sign of the times that the young pharmacists of a great industrial centre like Birmingham should have brought themselves shoulder to shoulder, determined to support each other, as well as kindred associations, in matters educational, political, and social. All well-wishers of pharmacy should welcome the foundation of such societies, calculated, as they were, under wise management, to exercise a most beneficial influence upon the future of the craft. Mr. Gerrard went on to urge strongly the advantages which good education afforded as a means of betterment. In this lay the pharmacist's salvation. Every effort should be made, therefore, to raise the standard, for it was unmistakably the surest foundation on which to gain the confidence and esteem of the public and the medical profession, as well as the support of Parliament. There was a brighter outlook for pharmacy to-day in the fact that the old Preliminary Examination had had notice to quit. The amount of knowledge it required for a pass had allowed hundreds of young men to squeeze themselves into a calling for which they were totally unfitted. Such men added nothing to the dignity or advancement of the craft; they were a drag on its progress. For long years past the voices of many of their leaders had been raised in favour of this change, and to those men hearty thanks were due. The future effect and influence of the new examination could only be beneficial. The more extended knowledge it required, especially of mathematics, would be of the greatest assistance in enabling students to comprehend the problems of physics and chemistry in a way that the old examination never could. As to want of facilities for obtaining higher education, few excuses could now be offered. There were provided in every good-sized town schools or classes where studies could be pursued at very moderate fees. Only the will and energy of the individual was needed, and, this given, no youth of average intelligence who desired to be a pharmacist need fear the ordeal which was to test his intellectual power. It was cheering to feel that this new and better education must inevitably raise the tone of pharmacy and materially strengthen their claim to a professional status. Going a step further in pharmaceutical education, Mr. Gerrard next discussed the apprenticeship period. At the outset he expressed himself as strongly opposed to the present system. It was most imperfect. Apprenticeship to-day was like an ill-directed journey over a barren plain. He asked those who had taken the journey whether the duties placed upon them were of such a nature as to help them to qualify themselves as pharmacists, or whether they were taught even those elementary first principles which surrounded and underlay pharmacy in every direction? He feared not. They were taught pounding, mixing, packing, labelling, and cleaning—honourable labour, without doubt, but most of it just as well done by a porter or by an intelligent girl. What a

WASTE OF YEARS

such apprenticeship was, and at an age, too, when the brain was receptive and needed mental practice! What a chaos of surround-

ings ! What a chasm those years made between the Preliminary and the Minor ! This worn-out old method badly wanted ringing out and something new ringing in. As regarded one of his own sons, likely to be trained as a pharmacist, his endeavour would be to see that the training given was systematic, and that it continued immediately after the Preliminary. Its main features would comprise science, modern languages, and commerce. There would be no loose wandering or waste of four or five precious years ; each link of the chain would be fitted in its proper order. For apprenticeship was proposed to be substituted a curriculum—one in which the complex art called pharmacy must have a large share. The course of instruction which commended itself to him should extend over three years at the least, beginning with pupilage to a qualified pharmacist in a recognised pharmacy school or institution. The first six months might well be occupied in the pharmacy, so as to bring the youth in touch with the routine of the calling and to give him some idea of his future needs. There were many daily duties best learned at this period—duties which must not be considered undignified, as they were an essential part of the training. He referred especially to lessons in order and cleanliness, which were not only valuable in themselves, but could be made to teach other important lessons. A large share of his own knowledge of materia medica was obtained whilst cleansing a bottle or dusting a drawer. A knowledge of the weights and measures employed should also be thoroughly ground in—both the metrical and British systems, with their relationships. The adoption of the metrical system in the British Pharmacopœia made it almost essential that every pharmacist should possess a set of such weights and measures. Some reading on the subject of pharmacy should then be indulged in, and a note-book kept defining the various processes. After three months of this some of the simply official preparations might be made, such as illustrated the uses of heat, solvents, distillation, precipitation, filtration, percolation, infusion, decoction, and many others. The apparatus required for these was simple enough, and one hour a day was ample for a demonstration. What a help such a beginning as this would be in time to come. Every principal who took a pupil was honestly bound to follow some such course of training, mind. After six months of such training the curriculum proper should commence. The second period ought to occupy at least nine months, spent in attending lectures and classes on physics, chemistry, and botany at a well-equipped and recognised school. Practical classes and demonstrations were of far greater value than lectures. The man who merely attended lectures and read was never so useful at his work, or so thorough in his knowledge, as the man who experimented and read. A day a week at this period might well be devoted to pharmaceutical manipulations showing the co-relationship of the science subjects and pharmacy. Materia medica, so far as it applied to the Minor, demanded attention, but it would more properly follow after instruction in chemistry and botany. Materia medica, as commonly learnt, was almost entirely a feat of memory—more or less a cram of botanical names, natural orders, preparations, and doses. It was intermingled with so much pharmacy that it perhaps mattered little at what period of the curriculum its dry details were absorbed. At the end of the first nine months' lectures the student should be admitted to an examination on the subjects of his teaching. This might be called the first Minor, the passing of which gave no qualification, but relieved the student of some of the elementary work now comprised in the Minor. The result of such an arrangement would be equivalent to dividing the Minor into two parts—a useful and much-needed reform, not only of benefit to the examinee, but to the cause of pharmaceutical education. Speaking as an old examiner, he held that seven subjects in one day's examination was too severe an ordeal. It was an anomaly, and a positive encouragement to the cram, which examiners and others so persistently condemned. Another advantage of a half-way examination was an earlier awakening of interest in work. If the student won his first goal he was stimulated and encouraged to go on. Nearly all professions had

An Intermediate Examination,

marking a period, and suitably testing a student's progress. The pupil having passed his first Minor, a further six months could be devoted to work in the pharmacy, where, fortified with the knowledge of the science subjects, work would become easier to him. At this period galenical pharmacy, prescription readin, and dispensing should have constant attention. It was not too much to ask that the pupil be allowed to dispense, label and finish at least six typical prescriptions a day—simple prescriptions at first, finally examples of those given in the minor examinations. Some time should be devoted to the manufacture of such galenicals as might be conveniently made. A share of time should also be given to the routine duties of the establishment, so as to get a grasp of the very necessary commercial side of the calling. Materia medica must still be kept green. To assist in its study, every pharmacist who took pupils ought to possess a good cabinet of specimens. The formation of such a cabinet was easy and inexpensive, and if well made and maintained, would do service for a life-time. The histological knowledge gained in the botanical course could now be well applied to further the study of materia medica, providing at the same time practice with the microscope. The second period of the curriculum proper, or third year of pupilage, should witness an extension of lectures and classes on general chemistry over another nine months, a good amount of analytical work to be included. As organic chemistry had become so important, it must have considerable attention. Advanced lectures and classes on materia medica and pharmacy must be continued, with practical work in both subjects. As regarded pharmacy, as much as possible on the manufacturing side ought to be practically done for two reasons—first, to encourage the home-made product ; and second, to provide a class of trained men competent to take the position of manufacturers, not only on their own account, but in laboratories where the position was too often held by those outside the pale of pharmacy. A good deal of work and time had to be devoted to prescription-reading and general dispensing, and as regarded teaching the latter, the most rigid rules of accuracy, cleanliness, and neatness ought to be observed ; for the aim of their education was not only to turn out skilled and safe men, but men of order and precision. At the end of this, the last year of the curriculum, the student should enter for the qualifying examination. Whether this be successfully passed or not, there would be several months of pupilage still to run, during which period loyal service ought to be given to the principal, who had helped and encouraged his pupil in the past. That the course depicted might be faulty in detail Mr. Gerrard admitted, but in principle he said he honestly believed it to be sound, and, if patiently and industriously pursued, it would in three years turn out a vastly superior man to that of the four or five years' apprenticeship on old lines. Analysed from

The Financial Side,

such a course of instruction would show itself but little more costly than the one now commonly pursued, for the saving of time and lessening of risks of failure were factors of real value in working out cost. It might be said that what he had urged was all profession, and had no business in it. It was profession, no doubt ; that was just what pharmacy needed to be, and must be. Those were wrong, however, who said there was no business in it. Emphatically, knowledge had good market value. There were a thousand articles needed to-day by the public which few men were better qualified to manufacture than the pharmacist. If they were satisfied to stand in their pharmacies selling the productions of others, making nothing of their own, then he admitted the righteousness of the argument. But it should be borne in mind that the men who did this had mistaken their occupation. As mere factors or dealers, they would be better placed in a grocer's shop, where they would be likely to make more headway. Those who had a good dispensing practice, or had prospects of cultivating one, should give it their utmost thought and care, for good dispensing was the perfection of the art. Failing in this branch, there was still a wide field for choice. Those who turned their attention to manufacture, and pursued it with industry and honesty of purpose, were likely to reap a good harvest. In conclusion, Mr. Gerrard referred to the Birmingham University, and asked whether it did not seem to provide exactly for the educational needs of pharmacy. For the first time commerce was to take its place side by side with science and art. Science they needed, and commerce also. The pharmacist well trained in both held a strong position. Already the authorities of Mason's College had approached the pharmacists of the Midland Counties, seeking to know what measure of support they might expect if they made provision for pharmaceutical education as well as establishing a degree in pharmacy. Such an opening demanded the strongest support, and he trusted every member of the Association would do his utmost to prevent the opportunity offered being lost.

Mr. H. S. Lawton, whilst approving of the curriculum sketched out, thought Mr. Gerrard was aiming a trifle high. Mr. E. Osborne and Mr. G. H. Brunt spoke favourably of the suggestions contained in the paper. On the motion of the President, seconded by Mr. Holland, Mr. Gerrard was thanked, and the meeting ended.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of the session was held in the Lecture Theatre at 17, Bloomsbury Square, on Friday, October 27, at 7 p.m., the Dean of the School of Pharmacy, Professor COLLIE, in the chair. There was a good attendance of students.

The minutes of the last meeting were read and confirmed. A proposed amendment to Rule V., that "the Dean of the School of Pharmacy of the Pharmaceutical Society shall be President and Treasurer for the same year," signed by P. B. Gray and H. Finnemore, was read by Mr. Finnemore. This will be voted on at the next meeting.

The inaugural address, which took the form of a very excellent paper on the development of the present system of scientific education, was delivered by Mr. J. Spiller, F.I.C., and is printed in full at page 418. Mr. Spiller showed two syllabuses of the first classes in scientific subjects held in London, at the City of London School, and also a specimen of carborundum.

Professor COLLIE, in a short speech, moved a vote of thanks to Mr. Spiller for his interesting paper. This was carried with acclamation. The election of officers for the present session was then proceeded with, voting cards having been distributed before the opening of the meeting.

The following names are those of the gentlemen elected:—President and Treasurer, Professor J. Norman Collie; Vice-Presidents, Mr. E. M. Chapman, Mr. Garsed; Hon. Secretaries, Messrs. C. T. Allen and C. W. B. Heslop; Committee, Messrs. F. E. Battershill, H. Deane, F. S. Fox, W. Hellyer, J. S. Hills, and W. Wilson.

The meeting then terminated, and those present partook of refreshments in the Library before leaving the building. An enjoyable evening was spent, and it is hoped it augurs well for the success of the meetings to come.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

The seventh annual meeting was held on Friday, October 27, at the Bull Hotel. The President, Mr. Alderman Deck, occupied the chair, and was supported by Messrs. A. Sidney Campkin, J.P., and E. Saville Peck, B.A. There was a good attendance of members.

The minutes of the previous meeting having been read and confirmed, Mr. Cook (Hon. Treasurer) presented his report, showing a balance of 16s. 2d., while £2 had been added to the reserve fund.

Mr. B. SIDNEY CAMPKIN, Hon. Secretary, in his report remarked that the members of the Association had much to congratulate themselves upon, inasmuch as the chemists of the town were practically unanimous in their support, and their knowledge of each other since the formation of the Association had increased, to their mutual advantage. As a body they were more closely

IN TOUCH WITH THE PHARMACEUTICAL SOCIETY,

and individually more interested in the work done by the Council. Again, they were able to instruct themselves by the lectures and papers read from time to time by the members and friends of the Association, and the thought that they had by example assisted in the formation of similar Associations in the country.

ELECTION OF OFFICERS.

The election of officers was then proceeded with, when Mr. Ald. Deck (President), Messrs. A. Sidney Campkin and E. Saville Peck (Vice-Presidents), Mr. H. F. Cook (Hon. Treasurer), and Mr. Bernhard S. Campkin (Hon. Secretary) were all re-elected, with Messrs. C. S. Addison, G. McAvoy, W. L. White, H. J. Parson, E. H. Church, and H. Coulson.

Mr. A. SIDNEY CAMPKIN spoke of the value of the Association and the urgency of close attention to matters pharmaceutical, in view of prospective legislation.

Mr. E. SAVILLE PECK gave an outline of the matters for discussion by the Association in connection with the F.L.P.A. on the 10th of November. Messrs. White, McAvoy, Parson, and Cook having spoken, the meeting terminated with a vote of thanks to the Chairman.

BURNLEY AND DISTRICT CHEMISTS' ASSOCIATION.

The principal business of a general meeting of the chemists of Burnley and district, held on Tuesday, October 31, was the consideration of their position in respect to the proposed legislation on illegal company pharmacy, and the expression of opinion on the various proposals emanating from the trade journals.

Mr. HEATON, the President, said it was comforting to see how eager the different journals were to help them in the matter, and went on to state that the point to determine was whether they could reduce the mass of controversy to one or two concrete resolutions on which they could agree, and which would meet with the approval of the Pharmaceutical Council. Judging from the general drift and tenour of what he had read, he gathered that a spirited policy on the lines of "An Ordinary Pharmacist" would meet the views of the majority of chemists, and the suggested clause (*vide* page 383), in the *Pharmaceutical Journal*, to his mind, reduced the whole question to a succinct and definite issue, and was one on which absolute combination and support could be given. It was the duty of all qualified chemists, be they members of the Society or not, to combine on a question of such momentous importance. If that were done, and their case placed before members of Parliament, and brought prominently before the public by means of the Press, there could be no doubt as to the result. If united, they were a powerful, intellectual, and wealthy body, but unfortunately they had not learnt or wished to understand the power of union and combination. A unique opportunity had now presented itself for unanimity, and it would be interesting to see how chemists responded to the appeal. There were certain unfortunate circumstances in the past history of the Council that would deter many from supporting them in the present crisis. They could not shut their eyes to the fact that for the last twenty years the Pharmaceutical Council had directed its whole and sole attention to matters technical and educational, while in the meantime the company octopus had been allowed slowly and surely to spread his tentacles throughout the length and breadth of the land, and quietly suck the life-blood out of the poor struggling pharmacist. It was only within the last few years, when pressure was brought to bear upon the Council by a comparatively small section of the trade, that it relaxed its apathy and indifference. The introduction of new blood on the Council had been productive of good results, but he was of opinion that if chemists relaxed their efforts with respect to impending legislation and other matters, the Council would certainly relapse into its former state of lethargy.

Mr. COATES moved the following resolution:—"That this meeting of the Burnley and District Chemists' Association resolves to petition the Council to take steps to combat the Bill now before Parliament; also that the Council should be requested to endeavour to have a clause inserted in the Companies Bill to protect the title of chemists and druggists, and to insist that the directors of all companies should be qualified." In doing so, Mr. Coates spoke of the importance of the protection of their titles as chemists. Anything else that might be for the benefit of pharmacy ought to be put on one side until their titles had become protected. By the companies acting as they were doing, the Pharmacy Act was rendered null and void, and practically nothing but a farce. It was not right that any tinker, or tailor, or candle-stick-maker should be allowed to tamper with the health of the public, as was the case at present. The very essence of the Pharmacy Acts was the protection of the public, but the way in which the Companies Acts were allowed to interfere with pharmacy enabled managers and conductors of companies literally to carry the lives of the public in their hands.

Mr. DODSLEY, who seconded the resolution, believed with Mr. Coates that they ought at present to fight simply for the protection of titles.

Mr. LAWTON, of Nelson, and Mr. Stuttard, of Colne, supported the resolution, which was carried unanimously, and a copy of which directed to be forwarded to the Pharmaceutical Council.

Mr. BROWN, the secretary, in presenting his interim report, stated that November 9 would be the anniversary of the first meeting of the Association, and they had great hopes of progress during the next twelve months. Referring to the question at issue he said it was useless going into battle unless they were provided with the sinews of war equal to their opponents; therefore, it behoved every member who considered they were fighting for justice to put his shoulder to the wheel.

PHARMACEUTICAL SOCIETY OF IRELAND.

On Monday evening. October 30, the meeting for the formal opening of this Society's schools and the presentation of a silver medal to the most successful candidate at the Society's examinations during the past year, was held at the Society's House, No. 67, Lower Mount Street, Dublin. There was a numerous attendance of members and students, amongst whom were some ladies. The chair was taken by the President of the Society, Mr. R. J. Downes; and the members of Council present were Professor Tichborne, Messrs. Grindley, Beggs, Wells, and Michie.

The President of the Royal College of Physicians (Dr. J. W. Moore) and the President of the Pharmaceutical Society of Queensland were amongst the visitors present.

The Registrar (Mr. Ferrall) read letters of apology from Sir George Duffey, President of the College of Surgeons, and others who were unable to attend.

The silver medal for the best answering at the examinations held last year was awarded to Mr. W. G. Stratton.

Dr. Ninian Falkiner then delivered an address on

The Education of the Pharmaceutical Chemist.

He briefly sketched the history of the educational movement in connection with the Pharmaceutical Society of Ireland and the formation of the Society's schools, and went on to advise students as to the subjects they should study and the most useful books to use in the study of the British Pharmacopœia. He then dealt with the scientific and commercial training of chemists, and their relation to the public and to physicians and surgeons.

On the motion of the Vice-President (Mr. G. Beggs), seconded by Mr. Kelly, a vote of thanks was passed to Dr. Falkiner for his address.

Mr. Sidney J. Vaughan, President of the Queensland Society, said the Government of Queensland was closely in touch with the pharmacy bodies of the colony, so much so that their Pharmacy College received a subsidy of 100 per cent. of its revenue. They received every consideration from the Government, and were to-day in a strong financial position. They had two Boards in Queensland—a Pharmacy Board and a Pharmacy Council. The Board was under direct Government control, was paid by the Government, and enforced the Acts relating to pharmacy. The Council was appointed by the chemists to watch over trade interests. The Pharmacy Board conducted all the examinations in the colony, and received all the fees for the same. The Pharmaceutical Council and the Society were supported entirely by the contributions of the Council. In Queensland they had not the great bugbear of company pharmacy that they in Ireland and in England had to face, for the law of the Colony forbade anything of the kind. The status of the pharmaceutical chemist in Queensland was excellent.

The President said in Ireland they could not thank the Government for anything like endowment of the Society. They were, no doubt, endowed with the fines recovered in prosecutions, but the defendant usually memorialised the Lord Lieutenant to remit the fine, and he constantly did so.

The proceedings then terminated.

Rapid Method for Determination of Starch.—Potassium hydrate is recommended by D. Crispo for obtaining a solution of starch for polarimetric observation. 3·391 Gm. of the fecula is rubbed down in a mortar with a little water, and transferred to a flask graduated at 200 C.c.; 50 C.c. of 6 per cent. KOH solution is then added with constant agitation, the flask is three-parts filled with water, and heated for 45 minutes on the water bath, with frequent agitation. After cooling, the volume is adjusted to 200 C.c., and the liquid filtered, until a filtrate clear enough to transmit the light in a 200 minim tube is obtained. A slight cloudiness will not hinder this. The result observed × 6 = the anhydrous starch per cent. The suitability of the method for determining the amount of starch in seeds has not yet been experimented on, but probably the results will be vitiated by the action of the alkali on the albuminoids, which give products which are optically lævogyre. —*Annales de Chim. Analyt.* **4**, 289.

LETTERS TO THE EDITOR.

The Company Pharmacy Problem.

Sir,—Permit me to add my thanks to "An Ordinary Pharmacist" for his able contribution in the Journal of the 21st inst. Certainly his suggested clause for the Companies Bill does not go a whit beyond our just rights. Of course, we cannot logically back up that view with argument, while retaining the "Widow's Clause" as that now stands in the Pharmacy Act. There cannot be any difference to the "safety of the public" between a qualified person managing a shop for an indefinite period on behalf of one unqualified widow, and the same being done on behalf of seven unqualified widows?

Nottingham, October 28, 1899. A. Eberlin.

Sir,—I fully expected someone would have written last week to repudiate some of the statements in your leading article of October 21. I suppose all minds were concentrated on that excellent article by "An Ordinary Pharmacist." The part I object to reads as follows:—"The Pharmacy Act has established a legal qualification for the exercise of the business of a chemist and druggist, a test of fitness for carrying it on. . . . A Register . . . and a titular description which enables the public to distinguish persons qualified from those who are not." Very good, Mr. Editor, I wish it was so. But what about the numerous firms that call themselves chemists and no qualified man on the premises? In a northern city there are three large firms using our titles, and how are the public to distinguish between these so-called "public benefactors" and qualified chemists? One is a drapery firm calling themselves chemists and druggists, one a firm of grocers using the enviable title "pharmacists," and the other well-known company, of "cash chemists." If it is illegal for these to use such titles, why does not the Council move in the matter? Why don't they take proceedings against these large firms who are breaking the law in various ways every day, instead of prosecuting what may be termed "poor men" for selling a pennyworth of laudanum, etc.? These people are generally in a very small way of business, and do but little harm to anyone, while these monster firms are simply ruining all branches of our trade, some even going so far as calling ordinary chemists "robbers." The Council should direct all their energy against these "wholesale pirates." Let us have rid of the worst evil first. It is no wonder chemists do not join the Society. What a lethargic body it is! Fancy, after lying dormant adout thirty years, the "poison law" is enforced. The "company problem" has been with us about twenty years, and the members of the Council are just dreaming about it. They will probably wake shortly, but alas! when too late to mend the existing state of affairs I am afraid.

October 28, 1899. Pharmacist No. III. (6/14).

Sir,—I should like to add my expression of thanks to "An Ordinary Pharmacist" for the two able articles which he has given us in the Journal. For a long time the various associations have practically been tackling this important question of company trading, and all have been anxious to adopt some course which would result in uniting the majority of the members of our craft into one solid body throughout the kingdom. Here at last has been presented a policy which can call forth nothing but praise; here is the very idea or ideas for which we have longed, which we can all agree upon and fight for. Already we see that the writer of the articles expresses the opinions of the members in the majority of places, and there seems to be great rejoicing that someone amongst us has at last clearly dealt with this great and vexed question of company trading. What is wanted now is for the Council to act on the ideas. Let the articles be reprinted larger, small type, and copies sent throughout the length and breadth of the land, irrespective of whether the chemists are members of the Society or not. The whole question of company trading bristles with anomalies, and the more we look into the matter the more glaring becomes the injustice of it. There is no doubt, as "An Ordinary Pharmacist" says, that hundreds have embraced our calling under the

mistaken idea that it was proteeted, and have afterwards found out to their sorrow that their chief privileges can be pirated, without the pirates becoming amenable to the law. I wonder how many parents or guardians, when they bring their sons or wards to article to our profession would place them with us if we told them that seven unqualified men could usurp and claim our title without putting their nose inside a pharmacy or passing any examination. But in strict justice we ought to acquaint them with this fact; for, to my mind there is great deception in letting anyone come into our ranks blindfolded. There must be no compromise. Companies of unqualified persons which practise pharmacy are riding very near the edge of the precipice, and it is only by an accident they are able to do as they are. I feel confident, then, that it only requires our case to be thoroughly explained to find many willing hands that will assist us in giving that last push which shall send them to their destruction.

Dewsbury, October 30, 1899. ROBERT GLEDHILL,
Local Secretary.

The Supply of Medicines, etc., to Ships.

Sir,—I enclose you copy of letter forwarded to the Marine Department of the Board of Trade from the Sunderland Chemists' Association, and I shall be glad if you will suggest that all associations interested in the matter should do likewise.

Sunderland, October 27, 1899. R. H. BELL.

[ENCLOSURE.]

Sunderland Chemists' Association,
October 24, 1899.

Gentlemen,—I am instructed by the members of the above Association to draw your attention to the necessity of some means being adopted to secure that ships proceeding to sea shall be supplied with medicine, surgical instruments, and appliances, according to the regulations of your Board. It is within the knowledge of many of our members that at present these regulations are largely disregarded, and that ships are sent to sea in which the medicines are not only deficient in quantity but also of very inferior quality. Having regard to the importance of proper provision being made in this respect, and to the fact that the owners and masters of vessels have rarely the skill necessary to enable them to ascertain if this has been done, we respectfully suggest that competent inspectors be appointed for this purpose and that such inspectors shall have passed the qualifying examination of the Pharmaceutical Society of Great Britain.

I am,
Yours respectfully,
Board of Trade, (Signed) ROBT. H. BELL,
Marine Department. *Hon. Sec.*

Pas Trop de Zèle

Sir,—From the time when Mr. Gifford appeared as an exponent of views for which I have great sympathy, I have watched, with interest, his efforts to impress chemists and druggists with the necessity of asserting their claim to professional position and—as you, sir, have well pointed out—to such small consideration in that respect as the law has provided for. But I must confess that, at times, I have not been able to understand Mr. Gifford's lengthy disquisitions and to have been, reluctantly, compelled to acknowledge the justice of the statement, made by a trade journal, that they are "incoherent." As a case in point, I see in the report of Mr. Gifford's paper last week that he speaks of "official pharmacy," and refers to something different, that may perhaps by implication be termed "unofficial pharmacy." But what are ordinary mortals to understand is meant by these cryptic phrases? I confess they pass my comprehension, and I regret to think that the useful work Mr. Gifford might do towards instructing his brethren may be hindered by such exuberant eccentricities. Other instances of the same kind of obscurity occur in the paper; but I will not occupy your space further than to ask what Mr. Gifford could be thinking of in comparing the claim now made by chemists and druggists for the privileges conferred on them by the Pharmacy Acts, to Shylock's claim for his "pound of flesh"! Could indiscretion be carried further?

Liverpool, October 31, 1899. R. C. COWLEY.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Seeds (W. P. C.—35/5).—They are from *Eragrostis abyssinica.*

Liability of Company Shareholder (C. E. W.—35/28).—You should consult a solicitor on the point.

Mill and Spray (T. G. W.—35/22).—The appliances you ask about are presumably of American manufacture; we have no further information respecting them.

Value of a Business (F. D. P.—35/26).—You cannot go far wrong in purchasing on the terms suggested, especially if you employ a competent valuer.

Dental Qualification (F. W. J.—35/19).—You will find full particulars in the "Students' Number" of the *Pharmaceutical Journal*, published on September 9, last.

Dental Anæsthesia (G. A.—35/6).—A 1 p. c. aqueous solution of cocaine hydrochloride is used for the purpose, being applied by means of a hypodermic syringe. As the operation is not unattended by risk, it should not be performed except by an expert.

Oleum Macis (R. D.—35/21).—True oil of mace is a volatile oil, but the expressed oil of nutmegs is commonly known by the same name, and that is probably intended in most cases when "oleum macis" is ordered.

Toning and Fixing Solution (J. R. S.—35/20).—(1) Dissolve sodium hyposulphite, 4 oz., and ammonium sulphocyanide, ½ oz., in distilled water, 8 oz.; (2) dissolve alum, 200 gr., in distilled water, 1 oz.; (3) dissolve lead nitrate, 100 gr., in distilled water, 1 oz. Add (2) and (3) to (1), boil for ten minutes, cool, filter, and add gold chloride, 7½ gr. Dilute the finished solution with its own volume of water, and immerse the prints after rinsing them in water for five minutes.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course, not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size, clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have received from Messrs. Branch, Deck, Ellinor, Epton (Miss), Gair, Gerrard, Goodess, Hall, Houghton, Jackson, Jones, Kirkby, Krischke, Lewis, Ling, O'Halloran, Phillips, Robins, Robinson, Spiller, Summers, Wallace, Ward, White, Wilkes, Wilson, Wright, Wyatt, Zimmer.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

VANILLA EXTRACT.

According to W. H. Hess, an extract of vanilla cannot be made artificially that will exactly represent one made direct from the beans, either in respect to chemical behaviour or with regard to usefulness as a flavouring agent. Synthetic vanillin and that extracted from vanilla are identical, and other constituents of vanilla might be replaced, but the resin behaves so differently from other resins that its separation and identification go far to prove that the extract has actually been prepared from vanilla. The beans contain from 4 to 11 per cent. of the resin, which is of a dark red to brown colour, and the colouring matter it furnishes constitutes about half that of tincture of vanilla. The resin is soluble in 50 per cent. alcohol. When weaker alcohol is used for preparing vanilla extract, potassium bicarbonate or other alkali is used to effect solution of the resin, but the addition tends to impair the delicate flavour of the preparation, a disagreeable foreign odour being introduced. Simple tests that have been found useful are a water dilution test, separation and identification of the resin, and tests for caramel or an azo dye, used as colouring matter.—*Journ. Am. Chem. Soc.*, **21**, 719.

ASSAY OF HYDRASTIS.

H. M. Gordin and A. B. Prescott assay *Hydrastis canadensis* by means of standard iodine for hydrastine and standard potassium iodide for berberine. Hydrastine is quite soluble in absolute ether and forms a definite hexa-iodide when a weak solution of any of its salts is added to a large excess of iodine dissolved in potassium iodide solution; berberine, on the other hand, is completely insoluble in absolute ether. The alkaloids of the powdered root, therefore, are first liberated by the action of an ether-ammonia mixture (strong ammonia, 5; alcohol, 5; ether, 30) and, after drying, the powder is extracted with absolute ether. The ethereal extract contains the hydrastine, the amount of which is determined by any suitable method, and the berberine is subsequently extracted from the powdered root by exhaustion with alcohol. The alcoholic extract is diluted with water, the alcohol evaporated off, and the residue taken up with diluted acetic acid. From this solution the berberine is precipitated as berberine-acetone and, after that has been washed and decomposed by acid, the berberine is determined by standard solutions of potassium iodide, silver nitrate, and ammonium thiocyanate.—*Journ. Am. Chem. Soc.*, **21**, 732.

CARAWAY DISTILLATION PRODUCTS.

Schimmel and Co. find that methyl alcohol and furfurol are produced during the distillation of caraway fruits, though not in such large proportions as in the distillation of cloves and clove stems. As in the latter case, the methyl alcohol is intensely yellow in colour, and requires treatment with sodium and lime to decolorise it and free it from its aldehyde-like odour. It is thought that diacetyl is present in the coloured alcohol, for when phenylhydrazine is added the alcohol distils over at its proper boiling point, and diacetylosazone separates out.—*Bericht*, October, 1899.

CITRONELLA OIL.

Schimmel and Co. publish the results of an examination of a large quantity of oil from *Lana batu*, which possessed the following characteristics:—Optical rotation—9°36′ at 20°, s.g. 0·908 at 15°, easily soluble in an equal volume of 80 per cent. alcohol, becoming cloudy with four or more volumes, saponification number after acetylisation = 190·8, calculated on geraniol 61·1 per cent. The oil was found to contain 28·2 per cent. of citronellal, 32·9 per cent. of geraniol, and 8·0 per cent. of methyl-eugenol.—*Bericht*, October, 1899.

SYNTHESIS OF ALBUMIN IN PLANTS.

B. Hansteen has obtained the following results from a series of observations on *Lemna minor*, *Vicia faba*, and *Ricinus communis*. Light plays no direct part, at least, usually in the synthesis of albumin in the green parts of Phanerogams. Under favourable conditions of growth the formation of albumin takes place in them at any time of the year, and without access of light. Its production depends, however, on the presence at the time of special carbohydrates. The amides, amido-acids, and other nitrogenous compounds are not indifferently of use for the formation of albumin. The substance best adapted for this purpose is urea, which is rapidly transformed into albumin, if accompanied in the cell by either cane-sugar or grape-sugar.—*Pringsheim's Jahrbuch f. wiss. Bot.*, **33**, 417.

DWARF HABIT OF PLANTS.

M. P. Gauchery has made an exhaustive study of the phenomenon of "nanism" in the vegetable kingdom. His general conclusion is that the peculiarities which distinguish the external form and the internal structure of plants are, like other characters, largely dependent on the environment, and are displayed more strongly in the vegetative than in the reproductive organs. A dwarf plant is not a miniature of the species with all its organs developed in the same proportion as they are in a plant of normal size.—*Ann. des Sciences Nat. Bot.*, **9**, 61.

FORMALIN FOR ANTHRAX.

Following up the success at first obtained in the treatment of bovine anthrax with injections of formalin, J. H. Bell reports that of twenty-eight cases since treated by the method, twenty-two recovered, four of the six that died being hopeless from the first. The treatment consists of injecting 20 minims of a 1 : 1,000 solution of formalin into the anthracoid swelling in the region of the jaw. The dose is repeated morning and evening for three days, and then once for three days. A draught of cinnamon oil, 1 drachm, in water, 1 pint, is administered daily for three days. To ensure success the treatment should be begun as early as possible in the course of the disease.—*Vet. Record*, **12**, 226.

CACAO BUTTER AND ITS ADULTERATION.

The solid fats obtained by submitting coco-nut fat to hydraulic pressure are stated by A. Ruffin to be the chief adulterants of cacao butter, but other animal and vegetable fats are used for the purpose, so that to obtain a definite opinion as to the purity of a specimen the following determinations are requisite. Specific gravity, refraction index saponification number, iodine number, melting point, soluble fatty acid number. Cacao butter has, according to the author, the following constants:—Sp.g. 0·910, refraction index, 34. Saponification number, 179-180. Iodine number, 48. Melting point, 30°C. Titre of fatty acids, 23°. The addition of vegetable fats will increase the density, and the iodine number, while the other constants will be lowered. Animal fats, on the other hand, raise the melting point and the fatty acid figure, while the refraction index is lowered. Coco-nut fat, however, considerably increases the saponification number and the refraction index, while the other constants are lowered. On etherification of the fatty acids obtained in the presence of alcohol and of sulphuric acid, the characteristic odour of coccinic ether will confirm the presence of coco-nut fat.—*Annales de Chim. Analyt*, **4**, 344.

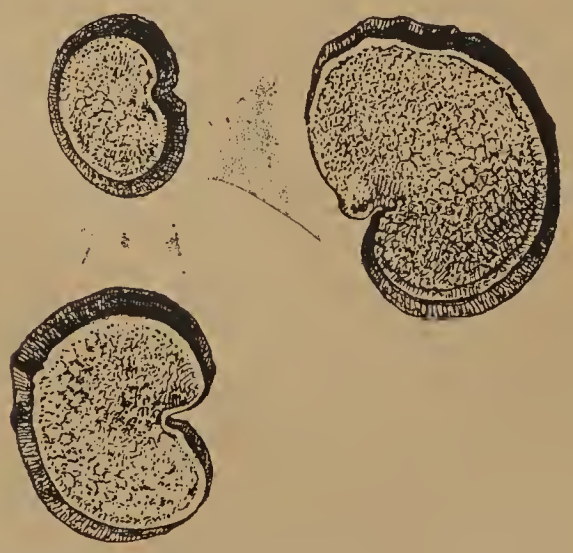
PRACTICAL PHARMACOGRAPHY.

COLCHICI CORMUS.

Macroscopic Characters.

Colchicum autumnale, Linn.—Meadow Saffron, Eng.; Colchique, Safran bâtard, Fr.; Herbzeitlose, Wiesen Safran, Germ. The fresh corm is about 35 millimetres long and 25 millimetres broad, somewhat conical, hollowed on one side where a new corm is in process of development, and rounded on the other, as shown in the illustration. The outer thin brown membranous coat covers an inner reddish-yellow one; internally the corm is white and solid, yielding when cut a bitter milky juice with disagreeable odour. The corms must be collected in early summer, before the plants flower, stripped of their coats, sliced transversely and dried at a temperature not exceeding 65°·5 C. The corm occurs in commerce in the form of dried transverse slices, varying from 2 to 2½ centimetres in the longest, and 1 to 2 centimetres in the shortest diameter; in thickness they are about 2 to 3 millimetres. The margin, which is slightly raised by the greater shrinking of the central portion in drying, presents on its outer surface a dull pale brown epidermis. The transverse surface is white and starchy, and dotted over with minute prominences which, when the surface is smoothed with a sharp knife, appear as darker dots, and are seen, under a good lens, to consist of fibro-vascular bundles. The drug has no odour, but a bitter taste; the fracture is short. Colchicum corms do not appear to be adulterated, and they do not vary much in activity, unless kept for a long time, when they show a decrease in alkaloidal contents.

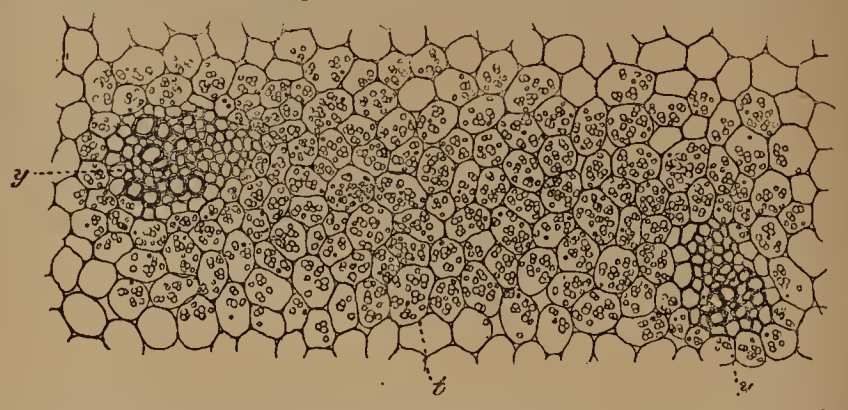
COLCHICI CORMUS.—Natural size.



COLCHICI CORMUS.—Transverse slices. Natural size.

Microscopic Characters.

Fundamental parenchyma.—This is composed of large thin-walled polyhedral, isodiametric parenchymatous cells filled with starch. In it are scattered a large number of narrow vascular bundles.

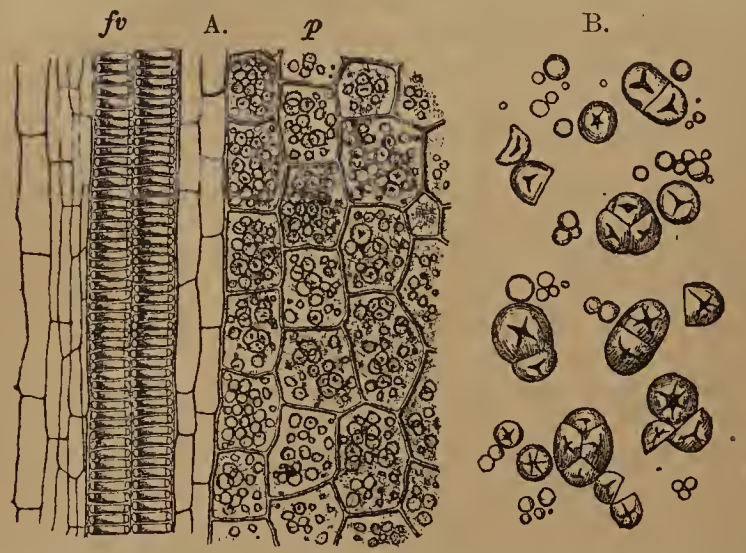


COLCHICI CORMUS.—Transverse Section magnified. *t.* Parenchyma containing starch. *y.* Scattered vascular bundles. (After Berg.)

Vascular bundles.—They consist of only two or three, occasionally four narrow spiral vessels surrounded by a sheath of thin-walled, longitudinally extended wood parenchyma.

COLCHICI CORMUS.—Transverse Section, magnified, showing vascular bundle, *fv.* with four spiral vessels surrounded by wood parenchyma; *p.* Parenchyma containing starch. (After Vogl.)

Starch.—Frequently in compound granules of from two to four grains. The hilum is almost central, star-shaped, and hollow. Well-marked radial lines pass from the hilum towards the periphery; in the compound granules two radial lines in each element unite the hilum with the points of juncture with the neighbouring granules.



COLCHICI CORMUS.—A. Longitudinal Section, magnified, showing xylem bundle with two spiral vessels, *fv.* wood parenchyma, and parenchyma containing starch, *p.* B. Starch granules, highly magnified. (After Vogl.)

Distinctive characters.—The absence of crystals, specialised receptacles of any kind, pitted vessels or cells, sclerotic cells, and epidermal tissues. The presence of the peculiar starch granules with a hollow hilum.

LOCAL PHARMACEUTICAL ASSOCIATIONS AND THEIR FEDERATION.*

BY JOHN SMITH,
Chairman of the Federation of Local Pharmaceutical Associations.

On a recent occasion I dealt with the subject of the Federation in its relation to the Pharmaceutical Society, and, arguing from well-known facts, attempted to show that the success of the Society depends upon local organisation; that this local organisation can be most successfully undertaken by the local associations; and that the Federation of these associations can be made an instrument of communication between the Society and the associations. On the present occasion I propose to deal more particularly with these local bodies and the aims and duties of their Federation, but it may be that to follow up an argument I may find it necessary to touch ground I have already covered. The objects of local pharmaceutical associations are many, and closely resemble those of the Pharmaceutical Society itself in many ways. Not the least important is the fact that their members are men who are vitally interested in pharmacy, or what used to be called the drug trade, as the means of providing a livelihood for themselves and their families. As this is affected by legislative enactments, favourably or unfavourably, and the Pharmaceutical Society is the representative body of registered chemists, with an elected council through which government and departmental negotiations are transacted, the necessity for a connecting link between the Society and the associations is obvious. There are between forty and fifty local associations having no official or other connection with each other or with the central organisation, the Pharmaceutical Society. Without a Federation clearly there is something wanting. The suggestion has often been made that each of these should become a branch of the parent body, and that a proportion of each member's subscription should be returned to the local associations to meet current expenses. I need not explain this suggestion in detail, because at the present time, looking at the financial side of things, it is scarcely practicable, though some day it may be an accomplished fact.

Mr. Newsholme's Scheme.

Mr. Newsholme, like others, has seen our defectiveness in local matters, and has elaborated a scheme which would bring a larger number of registered persons into the main organi ation, and add to the usefulness of local men in dealing with their Parliamentary representatives. This scheme has been several times alluded to lately, and I looked up the report of the address containing it. I must say I was surprised to find how closely Mr. Newsholme's plan and that of the Federation resemble each other, and if personal credit in the matter is of any importance I willingly concede it to Mr. Newsholme for being first in the field. The principal objects of this scheme are precisely those of the Federation as set forth in the rules. If there is any marked difference in method it is that Mr. Newsholme relies more upon spontaneous and individual effort, while the mainspring of the Federation scheme is collective effort. I am not discussing abstract principles, nor raising the question of collectivism as opposed to individualism, nor am I referring to any particular towns or districts when I say that in this particular matter we are considering, after years of trial, it is beyond dispute that the individual effort is not forthcoming. It is positively and unmistakably inadequate to supply the assistance needed. I may say, though, that if collectivism in this connection has any value at all it is that through it individual effort is inspired. It is better that reliance should be placed upon an association of men equally interested, who, while delegating certain duties to one of their number, would stimulate each other and help their officers by friendly interest, and even criticism, rather than upon an isolated and uncared-for individual. Our Birmingham friends hit the mark when they conceived the idea of a Federation of local pharmaceutical associations. Though not at that time connected with the Federation, I have watched its career with some interest, and I clearly recollect that in its early days it was regarded with distrust. To speak plainly, the object of its existence was believed to be to overbear the Council and its general attitude towards the Council one of hostility. Time has shown the error of that view, and I have the best authority for saying that was never at any time the policy of the Federation. Granting that the Council of the Pharmaceutical Society represents the opinions of the majority of the members, hostility would be uncalled for and mischievous. It is time enough to be antagonistic when there are antagonists to deal with. It is not the duty of the Federation to advocate any particular set of ideas nor to take charge of the interests of individual members of the Council, and so long as that body represents and endeavours to carry out the wishes of its constituents the Federation will supply a much-needed support. Good intentions may be frustrated and the work of a friendly body hindered by prejudice; but no one who has any knowledge of recent affairs can doubt that the Federation has come to stay. Year by year, in spite of doubts and misconceptions, it has grown in strength and influence and is now established on a firm foundation.

The Constitution of the Federation.

I may here refer to the present constitution of the Federation. At the last annual meeting it was decided to appoint an executive committee, and the representatives comprising it were selected from different parts in Great Britain. Each of these takes his share of responsibility for the year's work, and we are not now dependent upon the zeal of an individual officer. This arrangement is not without its drawbacks, but they are more than balanced by the gain. The plan that we are at present engaged upon is, allowing for some difference in detail, the same as that recommended by Mr. Newsholme, and we shall be glad to have the benefit of the experience of the Sheffield and Bradford Associations in the efforts they are pursuing. If the Federation can assist them in any way they may command us. I take it that the operations of the York hire Associations are to be confined to the limits of the county, but those of the Federation must cover as far as possible the whole of Great Britain. After the last annual meeting the first step taken was to inform the Council of the Pharmaceutical Society of the adoption of a resolution and of the revision of the rules in which the objects of the Federation are explained. The second was by circular to every local secretary to seek information respecting districts not so represented, and upon other matters. Following that, those who replied are asked to obtain nominations for the districts they named. When the full list of local secretaries is published, each one will probably be asked to take advantage of the assistance of the Federation to form an association of registered chemists in his locality, which it is hoped would unite with the Federation to make it a powerful representation of the pharmaceutical community. I am convinced that greater success would in most places attend this move if the outside help offered were called in. There is a choice of lines upon which these associations might be run. In some of the large centres it might be possible to adopt the rules and methods of one or other of the older associations now in existence; but the point I wish to emphasise is that in every town where five (or perhaps three) chemists can be found to take some interest, however little, in pharmaceutical affairs an association ought to be formed. It is not known from day to day what circumstances may arise to make it important that there should be local instruments at hand to deal with them. It would not be wise, perhaps, except in towns where the number of chemists is very large, to commence with the usual monthly meetings; when trade subjects have been exhausted interest would wane, and it would be difficult at a future time to restore vitality. It would be better, therefore, to meet at longer intervals, and special meetings called when

* Read before the Manchester Pharmaceutical Association, on November 8.

necessary. Besides the subjects which it will be the duty of the Federation to suggest local or other topics will no doubt arise which one or another of the members may wish to bring before his brethren in a conversational way rather than after the manner of formal meetings. A suggestion has been offered that the chemists in several small towns should unite to form an Association, and meet in one or other place in order of rotation. This plan would no doubt answer where the towns are included in a comparatively small area; but, generally speaking, I think men would soon tire of travelling any distance to attend the meetings, and it would be a serious mistake to commence on lines that would not be permanent. Neighbouring Associations could exchange courtesies, or act together on occasions of social gatherings or special meetings; but, personally, I think it eminently desirable that every Association, even if its membership be only three, should have a separate existence. I would suggest that the smaller Associations should not be too ambitious at the outset. Many have been formed from time to time, and dissolution has taken place because interest could not be sustained. When those local Associations have been formed, it may be expected that the local secretary will be the organising agent in his district, and that he will also be the representative on the Federation.

The Company Pharmacy Problem.

What has been done in the last three months, though it has involved a great deal of correspondence and expenditure of time, is little more than preparatory, but I think the most important we could undertake at the time. I hope that what is being done towards improving our machinery, in view of possible legislation in the coming session of Parliament, will meet with the approval of the Manchester Association. We have been taken to task for not formulating a programme for a year at the Plymouth meeting. Events move so rapidly, and circumstances may change so quickly, that it might be a mistake to tie the hands of the Executive Committee by setting out a definite programme. Who of the representatives at Plymouth, for instance, foresaw what would be the state of mind of some of the members of the Council as exhibited at the last meeting? It is, nevertheless, open to every affiliated association to suggest subjects for discussion, not only at the annual meeting, but to the Executive Committee, through the honorary secretary, any time during the year, and I may say that communications of that kind are desired. This committee realises that the Federation in its corporate capacity speaks not the view of one or of a few individuals, but expresses the opinions of the general pharmaceutical body through their local associations. Organisation cuts two ways. A central or elected body is nearly powerless and little more than a fiction unless it has organised support from outside, which outside organisations will claim to have a voice in the policy of the elected representatives. This is a reasonable proposition which is stated here on abstract grounds, and there appears to me but one logical conclusion in our own case—that is, that the Federation must support the elected representatives in carrying out the wishes of the pharmaceutical body, and that members of the Council should avail themselves of the co-operation and assistance the local associations are prepared to give. But suppose an occasion to arise when the Council proposes to take action to which the majority of pharmacists are believed to be opposed, it would be the duty of the Federation to ascertain as clearly and unmistakably as possible the opinions of its component parts. Never has the necessity for some such body been as urgent as now. The Council of the Pharmaceutical Society has undertaken to produce a clause dealing with company pharmacy, which it will try to get embodied in the Companies Bill. I have no authority at present to speak on behalf of the Federation, but I have a perfect right to express my own personal opinion, and I do so with full knowledge that it would be useless to go to Parliament unless we go as a united body. and therefore I say that in my official capacity I am prepared to do what I can to carry out the wishes of the majority, while in my private capacity I am free to advance my own views. The clause that has been presented to the Council by the Law and Parliamentary Committee appears to me to have been amended or constructed by those opposed to it, with the intention of making its provisions more assailable, and I am not sorry that it has been sent back for reconsideration, but I hope the principles it contains will be retained in its successor. There is an Act of Parliament—the Interpretation Act of 1889—which provides that, in the construction of every enactment relating to an offence punishable "on indictment or on summary conviction," the expression "person" shall include a body corporate; but, unfortunately, that does not apply in our case except as regards Section 17 of the Pharmacy Act of 1868, that being the only Section under which penalties are recoverable on summary conviction. It seems to me that the application of the provisions of the Interpretation Act to pharmacy law generally is what is wanted.

The Position of the Society's Council.

Previous to the last election for members of Council I advocated the claims of Mr. Glyn-Jones, on the ground of his ability and organising capabilities, and no one who has read the report of the last Council meeting can question that ability. At the same time I am convinced that if it had been known that he was going to take the position he has on the question of company pharmacy, he would not have had the opportunity of expounding his views in the Council chamber. I gather from the report of the meeting that he and those with him took good care to have the meaning of the clause expressed in plain English, and they certainly contrived to make it as blunt and unacceptable as possible. At the commencement of his speech, when moving his amendment, Mr. Glyn-Jones is reported to have said that "the Council was agreed that there should be one and the same law for individuals and companies"; but what do he and his friends mean? Is it that individuals should be permitted to practise pharmacy without registration and examination as companies do, or do they mean that those constituting companies may not carry on the business without qualifying in the same way that individuals do? The whole of his speech conflicts with that sentiment excepting where he says that "the Council had the right to insist that no one of the qualified men should become the servant of unqualified masters." His solution of the matter appears to be that the person who has ultimate control of the business (if such a position is possible where the shares are held by the public) should be a registered chemist. This proposal would meet with the same opposition as that embodied in the Committee's suggested clauses. It would be opposed with the same determination and would have the same influence against it for reasons that must be apparent even to supporters of the proposal. The situation is, I think, that when the Companies Bill is produced it will contain a clause which would place companies of unregistered persons in the same position as registered chemists in regard to the selling of poisons and the use of chemists' titles, and must be met with a counter proposal if the Council cannot get the clause replaced by one of its own. At least five different important suggestions have been placed before us, but I cannot refer to them in detail here. I may say, however, that there are two which might be called extreme proposals. One would accept and regulate the usurpation of the chemists's position by companies and the other adopts the principles of the clause referred back. The remaining plans are somewhere between these two. Now, I feel strongly that there is no halfway house. If we voluntarily surrender the principle known as qualified ownership we are driven from point to point until we arrive at a position we cannot logically evade—that is, that an individual grocer or other dealer should be allowed to carry on the business of a chemist and druggist provided he has a qualified assistant. There is some satisfaction, however, in finding that only three, or, at the outside, four, members of the Council spoke in favour of the surrender plan, and perhaps some of these will buckle up by the December meeting. I think we may infer from the remarks of the speakers at the last meeting that when the next recommendation of the Committee appears the advocates of the policy of surrender will count three in the voting.

THE COMPANY PHARMACY PROBLEM.—III.

BY AN ORDINARY PHARMACIST.

Though speech, according to Voltaire, is employed by men to conceal their thoughts, it has never yet, so far as I am aware, been authoritatively held that the written word can fulfil a similar function. I have been surprised, therefore, to find that the case which I thought I had stated plainly, for the benefit of my fellow pharmacists, should apparently remain far from clear to certain of our leaders and representatives on the Council of the Pharmaceutical Society. I have also been amused to note that the strongest arguments relied upon last week by some members of that Council, in favour of official recognition of unqualified company trading in pharmacy, were based on certain passages quoted from articles written with the object of showing the injustice and inexpediency of taking up such a position.

Where the Inconsistency Lies.

It has been somewhat rashly assumed that the views I expressed in my first and second articles are not consistent; but brief reflection will show that the inconsistency rests with those who have attempted to justify themselves in committing a grievous error, by quoting selected passages apart from their context. For example, Mr. Glyn-Jones has ventured to insinuate that the local secretaries and others who took the trouble to write to the *Pharmaceutical Journal*, expressing approval of the position taken up in my first contribution, are less likely to approve of the second article, wherein I pointed out that companies of duly qualified persons are quite different from companies of unqualified persons, and need not be interfered with. The fact that the Pharmaceutical Society's Law and Parliamentary Committee chose to adopt a garbled version of the clause I suggested for the Companies Bill, which would—as Mr. Glyn-Jones alleged—have the effect of interfering with companies consisting of legally qualified persons, does not affect my position in the least. I did not propose that registered chemists should be prevented from combining and forming joint-stock companies, nor can I see how any such proposal could be reconciled with ordinary ideas of justice.

Companies *and* Companies.

Neither have I contended, as Mr. Walter Hills suggested, that company trading is altogether immoral. I am not concerned about the morality of company trading, as such; but thought I had made it clear throughout that I was protesting against the business of a chemist and druggist being carried on by companies of unqualified persons. In the few places where I used the word "companies" alone, it is obvious to any unprejudiced reader what kind of company is referred to, and I regret that any of our representatives on the Council of the Pharmaceutical Society should have felt their case—for the surrender of chemists' privileges—so weak as to need bolstering up by an attempt to place a false interpretation upon language that is quite definite. I should have thought very little consideration is required to show that the clause I suggested for the Companies Bill (*ante*, p. 383) would not prevent properly-constituted companies—*i.e.*, associations of duly-qualified persons—from carrying on the business of a chemist and druggist; though it would prevent a company, as such, from assuming any title implying registration under the Pharmacy Acts, and would also make a company amenable to all other provisions of the Pharmacy Acts in the same manner as an individual or natural person. Companies of persons not registered under the Pharmacy Acts naturally occupy quite a different position, and unless means can be devised for enabling such companies to bring themselves into line with properly-constituted companies, they ought to be prevented from carrying on the business of a chemist and druggist in any shape or form.

Opinions Expressed by Members of Council.

I take it we may assume that to be the opinion of Messrs. Allen, Atkins, Carteighe, Grose, Newsholme, Park, Warren, and Young, all of whom voted for the clause brought up at the last Council meeting by the Law and Parliamentary Committee. With regard to the remaining members of Council, Mr. Cross has declared (see *ante*, p. 428) that he will be no party to regulating company trading; Mr. Harrington, in presenting himself as a candidate for the Council (see *P.J.*, April 22, 1899, p. 380), expressed the opinion that the Companies Bill "ought to be amended so as to prohibit the practice of pharmacy and the use of pharmaceutical titles by any association of unqualified persons"; Mr. Harrison says he has no sympathy with company trading, and does not wish to regulate companies in any way whatever (see *ante*, p. 428); Mr. Hills, some months ago, expressed his belief that the Council, in making the famous suggestions to the Lord Chancellor, was "really acting as the mouthpiece of nearly all registered persons throughout Great Britain." The question before the Council, he then said, was: What is keeping open shop? and "the suggestions now made reverted to the principle underlying the Pharmacy Act, 1868," that a person keeping open shop should be qualified and registered. (See *P.J.*, February 4, 1899, p. 104.) Dr. Symes now thinks (see *ante*, p. 429) it is "hopeless and impracticable" to attempt to prevent companies of unqualified persons from carrying on the business of a chemist and druggist, but in 1881 (see *P.J.*, January 22, 1881) he thought it was essential that "the individual proprietors of chemists' shops should be qualified, and that the employment of a qualified servant cannot confer qualification on the employer." What the present views of Messrs. Bateson, Corder, Johnston, Savory, Storrar, and Southall may be is not yet clear, but Mr. Glyn-Jones apparently desires to recognise and regulate companies of unqualified persons, while Mr. Martindale seems to agree with Messrs. Cross and Harrison that nothing beyond the restriction of titles should be asked for at present.

Opinion *versus* Action.

But, leaving the realm of opinion, we find that out of the nineteen members of Council who acquiesced in the suggestions sent to the Lord Chancellor in February last, only eight voted last week in full accord with the principle of those suggestions at the Council meeting; three among the faint-hearted were presumably re-elected, in May last, on the assumption that they would maintain that principle. Apparently, the nine members who voted with Mr. Glyn-Jones for the amendment he proposed are not all in accord as to the best means of attacking the company pharmacy problem. Most of them, indeed, seem to have objected to the proposed clause simply because they thought nothing more ought to be attempted at present than the restriction of pharmaceutical titles to legally qualified individuals. The Council ought, at least, to be unanimous as to the absolute necessity of that restriction; but the eight members who voted for the adoption of the Law and Parliamentary Committee's clause wish to go further. So does Mr. Glyn-Jones, for, according to Mr. Carteighe, the undisclosed clause drawn up by Mr. Glyn-Jones does not practically differ, so far as its probable effects are concerned, from the clause submitted to the Council by the Committee. It would be interesting, therefore, to know what manner of clause that "wonderful panacea" can be. So far as can be gathered from the report of the discussion at the Council meeting, it proposes to do, in a roundabout way, what the Committee's clause would do directly—*i.e.*, prevent companies (? of unqualified persons) from using the title and carrying on the business of a chemist and druggist. If, however, Mr. Glyn-Jones does not propose to put a direct stop to unqualified company trading, we must suppose that he aims at effecting the desired end by imposing regulations which would seriously hamper the carrying on of the business by companies—so that they would probably count the cost too great and turn their energies to better account.

What the Public Interest Requires.

But is it conceivable that such a plan would succeed? Are not the supporters of companies at least as far-seeing as their opponents? Would not the inconvenient regulations stand a fair chance of being successfully opposed; would not, also, the implied acquies-

cence in the existence of companies of unqualified persons be pounced upon with avidity and used as a weapon against us? Moreover, pharmacists, so far as I know them, prefer straight fighting, and they would rather go direct to the point than work up to it by a corkscrew path. As Mr. Carteighe said last week, our strong position is being able to say that what we ask for is in the public interest. It is undeniably in the public interest that none but legal holders of a statutory qualification should be permitted to assume any title indicating that qualification; it is further desirable, in the public interest, that all statutory poisons should be dispensed and sold by legally qualified individuals, also that no unqualified person or persons should be permitted to exercise any control over the conduct of the business of a chemist and druggist. If we would choose a selfish course and adopt the line of least resistance, we may rest content with the protection of our titles; for there is little doubt that if we protect those titles we shall maintain our hold upon the bulk of pharmaceutical practice, as is the case with medical men and dentists. Such a course would be a very easy one and success might be regarded as a certainty from the outset.

What we Should Strive For.

But, in the public interest, we ought to strive for more. Qualification to practise pharmacy is either required or it is not. If required, it ought to be vested in the proprietor of a business, whether he employ qualified assistants or not, for, as Dr. Symes has pointed out, "employment of a qualified servant cannot confer qualification on the employer." No one has yet called in question the desirability of protecting the public by imposing restrictions on the practice of pharmacy; in fact, further restrictions are continually being suggested from outside. Let us, then, insist upon equality of treatment all round. If one proprietor must be legally qualified, let all proprietors be equally qualified—permit no person of any kind, without a proper legal qualification, to exercise a controlling influence over the business of a chemist and druggist. That, at least, in addition to the protection of titles, is required in the public interest, and pharmacists who have the courage of their convictions should strive to obtain nothing less. It may be desirable for the present to abstain from asking for more; but whilst I would forcibly deprecate "crying for the moon," I would as strongly urge our leaders to eschew excessive modesty and to demand—in the public interest, as well as in the interests of those they represent—that pharmacists should "possess the earth" to a fair and reasonable extent.

THE CHEMISTRY OF ESSENTIAL OILS.

The Chemistry of Essential Oils and Artificial Perfumes. By Ernest J. Parry, B.Sc. (Lond.), F.I.C., F.C.S. Pp. i.—viii., 1—411. Price 12s. 6d. net. London: Scott, Greenwood and Co., 1899.

The group of proximate principles included by the term essential oils must always possess great interest for pharmacists. They are found in varying proportions in the tissues of many plants used as remedial agents, often constituting the odorous principles so characteristic of many articles of the vegetable materia medica. In addition to their use in medicine many of the aromatic drugs and their essential oils find important applications as condiments, flavouring agents and perfumes. The pharmacist by virtue of his training ought to be in a favourable position to command a considerable proportion of the trade in these products, and those who wish to take advantage of their opportunities should not fail to keep themselves well abreast of the rapid progress which has been made within comparatively recent years in our knowledge of the chemistry of essential oils. How rapid this progress has been can best be realised by comparing the information relating to essential oils contained in the text-books of chemistry and materia medica published ten or fifteen years ago with that relating to the same substances in the work which constitutes the subject of this review. Mr. Parry has done good service in carefully collecting and marshalling the results of the numerous researches published in various parts of the world. The outcome of his labours is the production of a fairly complete account of the oils which constitute important articles of commerce. Many of these are still subjects of contention between different chemists who have investigated them, but Mr. Parry seems to have endeavoured to give his readers a fairly balanced account of the claims of the contending parties.

As an introduction to the systematic study of the essential oils, which forms the major part of the book, several chapters are provided which deal with matters of general application. These relate to the chemical relationships of the various classes of bodies found as constituents of essential oils, and the methods of manufacture and analysis. With regard to the classification of the constituents of essential oils, one may regret that the author has not adopted a scheme founded more directly upon the modern system of classification of carbon compounds. This enables one to explain clearly the difference in behaviour of the terpenes, for example, belonging to the alicyclic or hydro-aromatic derivatives and such purely aromatic bodies as cymene and thymol. These introductory chapters will be found useful in affording explanations of the facts and figures given in the section dealing with the individual oils. To the student of pharmacy they will also supply fuller information than is to be found in the text-books of organic chemistry.

In the description of the individual essential oils, an account is given of the chief commercial varieties, their constituents, and valuation by analysis where processes are available. The author agrees in the main with the constants given in the 1898 British Pharmacopœia. The descriptions given form, naturally, an extension of and commentary upon the official characters and tests. They provide also an explanation of the official monographs, and show the bearing of the characters and tests upon the valuation of the oils and the determination of their purity.

Chapters are also given dealing with terpeneless oils and artificial perfumes. These include a useful summary of matters of scientific and commercial value relating to these bodies, which no manufacturer can afford to neglect. Many useful hints are afforded, showing the most advantageous methods which may be employed, and the book concludes with an appendix; comprising a table of constants of the more important essential oils.

DETERMINATION OF FAT IN CONDENSED MILK.

The following method has been devised by A. E. Leach for the determination of fat in condensed milk. Weigh out 40 Gm. of the sample and make up to 100 C.c.; withdraw by means of a pipette 15 C.c. of the solution, corresponding to 6 Gm. of the sample, and transfer to a 50 C.c. test bottle, with neck graduated to read to 0·1 per cent.; then pour in water till the liquid nearly reaches the neck of the bottle, and add 3·5 C.c. of an aqueous solution of copper sulphate of the strength of 69·28 C.c. per litre (Fehling's copper solution). Shake the bottle well, and allow the contents to settle. The precipitate, which consists of proteids with the fat, subsides more quickly if the bottle is cooled in iced water. Draw off the clear supernatant liquid, which contains the sugar in solution, by means of a small-stemmed pipette of a capacity of 50 C.c., the upper end of which is fitted for convenience with a piece of rubber tubing. Twist lightly about the lower end of the pipette a small wisp of absorbent cotton to serve as a filter. After the liquid is drawn up into the pipette remove the cotton wad from its lower end by lightly rubbing it against the inside of the neck of the bottle as the pipette is withdrawn. Wash the precipitate three times by decantation, and then add 25 C.c. of sulphuric acid, the usual centrifugal method being followed. The reading to tenths, multiplied by six, gives the percentage of fat in the sample. The foregoing method is employed in the laboratory of the State Board of Health, Massachusetts.—*British Food Journal*, **1**, 236.

ANCIENT HISTORY MORE OR LESS RELATING TO "COMPANY PHARMACY."

The second attempt to obtain amendment of the Pharmacy Act, 1868, was brought about in consequence of representations made to the Home Secretary and to the Privy Council as to the supply of poisons in wholesale trade and in the form of stamped medicines, as well as the sale of poisonous articles and corrosive liquids for use by grooms and farm servants.

The first step taken by the Council was to recommend the addition of several articles to the poison schedule in February, 1882. At the August meeting of the Council a letter from the Privy Council Office was read, announcing that the additions of nux vomica and its preparations was approved; but after careful consideration—and pending the consideration of the expediency of further legislation with reference to the sale of poisons—their lordships were of opinion that it was "not desirable to add to the restrictions on the sale of the acids and other articles referred to in the resolution."

At the Council Meeting in December, 1882, the President announced that a Bill was being drafted, by request of the Privy Council, to express the views of the Council as to "amendment of the law in regard to the sale of poisons," and at the meeting in January, 1883, the draft was considered and referred back to the Law and Parliamentary Committee, with power to confer with the Privy Council. At the meeting in February the Council resolved to adopt the draft Bill and send it to the Lord President as being adapted to the condition of pharmacy then existing; though not providing for all that might be desired in the interests of pharmacy and of the Society, the Bill was commended as fully and consistently meeting the requirements of the time.

The Pharmacy Act Amendment Bill of 1883 comprised provisions that were intended in the first place to remedy the defect of the 1868 Act—by specific provisions as to the application of the law to corporations—to qualification of the proprietor of a chemist and druggist's business, as the person responsible for its conduct—to the employment of legally qualified persons in all chemists' shops—improvement of the machinery of registration—extending the application of the Act to the entire professional business of supplying, dispensing and compounding medicine—establishing the one qualification of pharmaceutical chemist for the practice of pharmacy in the case of all persons passing the examination after 1886, as well as making membership of the Society open to all persons registered. The Bill also provided for regulating the sale of various articles of a dangerous nature, with a view to public safety and so as not to interfere with trade conditions of their supply—for improvement in the education and training of persons intending to take up the practice of pharmacy—and for regulation of the sale of stamped secret preparations containing poison, which has since been effected without amendment of the Pharmacy Act.

That Bill was essentially a Pharmacy Bill and not a mere Sale of Poisons Bill; several of its provisions were similar to those of the 1881 Bill, and some of them would have helped to improve the practice of pharmacy, in a manner conducive to the interests of the public and to those of persons engaged in that occupation. The following extracts from correspondence relating to the Bill will show that its advantages in those respects were recognised by many, if not by all, chemists and druggists.

B. S. Proctor—regarding "salvation by Act of Parliament as of limited value"—expressed the opinion that if chemists and druggists could clear from their minds the craving for somebody to do something for them, they would see that, in regard to the proposed regulation of the sale of poisonous articles, the Bill was fairly framed for "its legitimate work," without confounding trade transactions with work properly belonging to the practice of pharmacy. The provisions for preventing the keeping of branch shops in charge of unqualified persons, and for fixing upon the proprietor of a business the responsibility belonging to him in that capacity, were approved as tending to the advantage of pharmacists, as well as the public. Hope was also expressed that chemists and druggists might have "unity enough to sink little differences and support a measure moving them one step in advance."

George W. Sandford saw in the Bill much to advance the education and qualification of future pharmacists; but thought the means proposed to increase public safety were quite inadequate—each shop should be in charge of a qualified person, leaving no question as to "branch" or "principal."

Alex. Kinninmont thought the "measure at once reasonable and practicable"—calculated to assure the safety of the public in a still greater degree than the 1868 Act had done, without being open to the charge of "attempted monopoly"—the provision as to branch shops would "not infringe the just rights of anyone" while facilitating the discovery of the "real proprietor" of a chemist and druggist's shop.

George Mee regarded the Bill as defining the undefined, without departing from the original position of the Pharmaceutical Society.

Joseph Hallawell, *Liverpool*, thought the Bill "as nearly like a perfect Pharmacy Act" as circumstances would permit; that it would meet evils hitherto untouched, and should receive "approval by a large majority"—that the provision as to persons certified to be able and fit to dispense all medicines being alone allowed to do so, would be "appreciated by all but the incompetent and unreasonable"—affording "many a despairing pharmacist a sight of a clear and straight way out of difficulties which are now a source of danger and discontent."

B. Dickins, *Liverpool*, thought the Bill one that chemists and druggists might receive with favour—"has reasonable claims and reasonable concessions, and provides wisely for the educational needs of the future."

John Wade, *Pimlico*, thought the Bill was like the product of the mountain in labour—he failed to see "any important advantage" it would give, except to the public—expected it would have provided for many things it did not deal with.

J. Rymer Young, *Warrington*, objected to the proposal to make all future qualified persons pharmaceutical chemists and eligible as members of the Society, as practically abolishing the Major qualification.

J. Hart, *Manchester*, thought proposal as to pharmaceutical chemist qualification might excite opposition, though the educational provisions should induce Major men to take consolation that if they suffered, the future of pharmacy would "have a brighter look-out."

George Burrell, *Montrose*, thought that the proposal to give up the privilege of being the exclusive vendors of poisons was retrogressive—the objection to it "intelligible and relevant," but that under the influence of free trade principles the Council had been obliged to "yield to the remorseless logic of facts"—perhaps the true position of pharmacists would never be clearly defined until a dyspeptic Cabinet minister took a wrong dose—approved of the provision that there should be a legally qualified person in charge of every shop; but objected to making the passing of the Preliminary Examination a condition of apprenticeship.

Henry H. Pollard, *Ryde*, objected to the distinction between "poisons" and "poisonous" articles as too fine for Parliament or the public to appreciate.

Edmund Jones, *Hanley*, expressed sympathy for chemists and druggists who have to compete with drysalters and herbalists in country places where medical men dispense their medicines—desired that the sale of all British Pharmacopœia preparations should be confined to legally qualified persons; but would still feel thankful if the proposed amendments were passed.

D. Ogilvie Evans, *Bolton*, objected to the provision as to "poisonous articles" as "necessitating new labels"—also to the

absence of provision for "compulsory prosecution" of unqualified persons selling poisons under the labels of registered chemists and druggists.

JOHN J. SMITH, *Liverpool*, wished that branch shops were unlawful; but pointed out that where they were numerous, as in Liverpool, and generally in charge of unqualified persons, difficulties would be created by the provision that every shop should be in charge of a legally qualified person.

EX-PHARMACIST, in a long letter, pointed out that the operative provisions of the 1868 Act—creating a recognised grade of chemists and druggists—merely regulated the sale of scheduled poisons, and reflected "the views of the Government rather than those of the pharmaceutical body"—that in regard to the practice of pharmacy those provisions were too incomplete to prevent interloping—the worst form of competition—while the essential feature of the draft Bill was the real restriction "of the practice of pharmacy to qualified pharmacists"—characteristic of professional status, together with the prospective "extinction of the secondary grade of chemists and druggists." The Bill would provide for the realisation of the object that was the "*raison d'être* of the Pharmaceutical Society, the kernel of the policy which its founders and their successors have been labouring to consolidate for the last forty years"—on that account the Bill deserved "the loyal support" of those who should be united by "a common interest"—otherwise the favourable opportunity would be lost, and the elevation of pharmacy to professional position would be indefinitely postponed.

RICHARD REYNOLDS expressed the view that the Bill promised light where there had been darkness—should receive hearty support on all the principles by which prudent men regulate their actions—that it was on "lines consistent with the greatest chance of viability"—that while giving greater effect to the contract made by the State in 1868, it would ameliorate some anomalies, "so that unqualified persons should not usurp the functions of those who had complied with the law."

C. B. ALLEN, *Kilburn*, expressed full approval of the Bill—was convinced that "the educated public" recognised the pharmacist as having claims to consideration which no other keeper of a shop could urge—that members of Parliament would admit the same if the circumstances "were properly represented to them."

THOMAS HART, *Stockport*, thought that, though the Bill would be a disappointment to those chemists and druggists who had cherished utopian ideas of legislation securing to them a monopoly a more generous consideration of its provisions would secure the support of "all interested in the progress of pharmacy."

J. C. SHENSTONE, *Colchester*, loyally admitted that the Council in framing the proposed Bill had presumably been guided by considerations which would probably have induced him to agree more fully with the provisions contained in the Bill—acknowledged that chemists and druggists could not expect legislation creating a monopoly in their favour, and that in attempting to fling mud at the Council "most of it must come back" upon themselves—expressed the opinion that the sale of the articles requiring to be labelled poisonous would not well assort with the business of a chemist, and that those whose business partook of the nature of the oil and colourman's would not be injured by the requirement of labelling—that a chemist and druggist could not honourably take an apprentice who had not passed the Preliminary Examination.

C. J. S. THOMPSON, *Liverpool*, thought the steps taken by the Council tended to elevate the position of pharmacy in the country and would be appreciated by all who had "the true interests of the body at heart."

JOHN WADE, replying to an editorial criticism of his objection to the provision that every chemist and druggist's shop should be in charge of a legally qualified person, explained that his contention was that "if co-operative stores and corporate bodies could become proprietors on condition of having legally qualified managers of their business, orthodox pharmacists should enjoy the same privilege." [Unfortunately that view has now been extended to any unqualified individual.—ED. *Ph. J.*]

AN ASSOCIATE, *Darlington*, recalling the fact that, in different courts of law, judges had been undecided as to the intention of the Pharmacy Act—thought that the Bill would not be in danger because chemists and druggists asked "that a loophole in the 1868 Act should be stopped"—referring to Mr. Frazer's opinions, could not see "that free trade in pharmacy is at all desirable."

F. B. BENGER, referring to an editorial comment on the proceedings at a meeting at Manchester, explained that regret was felt on account of the Council relinquishing the claim that poisonous articles should be included in the schedule of poisons, that being considered a sacrifice of principle.

W. WILKINSON wrote to the same effect, and somewhat naïvely suggested that the small attendance of registered chemists at the Manchester meeting was not due to indifference, but perhaps to their not perceiving how a Bill that could be submitted "to the Legislature only on the ground of regard for public safety, should be considered necessary in the interests of pharmacy."

The provisions of the Bill met with very general approval throughout the country so far as opinion was expressed: they were very fully discussed at meetings of the trade association in Birmingham, at Edinburgh, Liverpool, Sheffield, Leeds, and Manchester, without any essential alteration being suggested. But opposition came from an unexpected quarter, and G. F. Schacht, following out the line of action he had taken while the draft was being prepared, entered a protest against the provisions for regulating the sale of "poisonous articles" and the one relating to branch shops, as involving departure from the broad principle of the Society that the sale of poisons should be confined to educated persons, and that the qualified proprietor of a business was to be responsible for the acts of his assistants.

At the Glasgow Chemists' and Druggists' Association, Mr. Daniel Frazer delivered a remarkably discursive address on the proposals of the Pharmacy Act Amendment Bill. Speaking from the point of view that regarded chemists and druggists only as traders, he expressed amazement at "the judicial blindness of the wise men at Bloomsbury Square" in proposing the changes that the Bill would bring about. Dismissing Mr. Kinninmont's approval of the Bill as due to "his usual honest impetuosity," Mr. Frazer contended that the provisions for regulating the sale of "poisonous articles" operated in the direction of grasping at a monopoly—that with exception of a dozen co-operative stores, chemists and druggists had a practical monopoly of dispensing—that the terms of the preamble—the lawyers' mode of getting at the proprietors of co-operative stores—would make unqualified assistants of chemists and druggists liable for sales of poison instead of the real seller or keeper of a shop. In conclusion, the speaker urged that at the close of the struggle into which the Council of the Society and the Trade Association proposed to enter, the protection of titles might be "the only shred of protection" left to chemists and druggists. He therefore advised withdrawal of the Bill, exhorting chemists and druggists to "rest and be thankful" for such protection and privileges as they had.

In the annual report of the Council at the annual meeting in 1883, attention was specially directed to the fact that, for any Pharmacy Act Amendment Bill to become law, thorough support of the measure by the trade at large, as well as in Parliament, was essential, while the President pointed out that, to be brought forward as a Government measure for the Bill its provisions must meet the views of the Privy Council as to the working of the law and as to the deviation from it that was considered desirable.

No progress was made for several months, until in February, 1884, when, in reply to a request that a deputation from the Council and the Trade Association should be received by the Privy Council, an intimation was received that the Government proposed to introduce a Bill confined to "the sale of poisons," and that the Lord President would receive a deputation on the subject after the

Government Bill had been introduced. Thereupon the Council expressed regret that this decision had been formed, stating its opinion that the law relating to the sale of poisons could not be satisfactorily amended "without at the same time dealing with the Amendment of the Pharmacy Acts." That was the last of the second Pharmacy Acts Amendment Bill.

WOOD-TAR CREOSOTE.*

BY LYMAN F. KEBLER.

Creosote is a complex mixture of phenoloid compounds, the proportions of which are materially influenced by the kind of wood employed for distillation, the methods resorted to for purifying and removing the creosote from the distillate and the amount of certain constituents removed from the creosote proper, by fractional distillation.

The above mixture of compounds consists chiefly of several homologous series, prominent among which are the acid methylic esters of catechol, but any of the compounds contained in the following table may be met with :—

Names.†	Formula.	Boiling Point.
MONOHYDRIC PHENOLS.		
Phenol, carbolic acid,	C_6H_5OH	182° C.
Paracreosol, cresylic acid,	$C_6H_4(CH_3)OH$	203° C.
Xylol, or phloral,	$C_6H_3(CH_3)_2OH$	220° C.
METHYL ESTERS OF DIHYDRIC PHENOLS.		
Guaiacol or methyl catecholate,	$C_6H_4\{OCH_3\}{OH}$	200° C.
Creosol or methyl methyl-catecholate,	$C_6H_3(CH_3)\{OCH_3\}{OH}$	219° C.
Homocreosol, or dimethyl-guaiacol,	$C_6H_2(CH_3)_2\{OCH_3\}{OH}$	230° C.
Cœrulignol, or propyl-guaiacol,	$C_6H_3(C_3H_7)\{OCH_3\}{OH}$	241° C.

Creosote is generally supposed to consist, for the greater part, of guaiacol and creosol, the former predominating in one case and the latter in another. This idea has become so prevalent among some that they thought guaiacol to the extent of sixty or more per cent. could easily be obtained by fractionating a good quality of creosote. Such may have been the quality of creosote years ago, but things have changed. It is claimed that when a demand arose for guaiacol and its salts, the proportion of this valuable compound began gradually to diminish, until to-day it has become difficult to purchase creosote containing 20 per cent., and an article containing 60 per cent. is a curiosity. The above demand may have had an influence, but the writer is inclined to look at it somewhat differently. The high percentage of guaiacol reported by some workers was probably due to faulty methods of analysis.

A. Béhal ‡ and E. Choay, on fractionating genuine beechwood creosote and analysing those portions coming over between 200° and 210° C., and 200° and 220° C., found them to have the following composition :—

	Boiling-Points. 200-210° C. Per cent.	Boiling-Points 200-220° C. Per cent.
Monophenols	39·00	39·00
Guaiacol	26·48	10·72
Creosol and homologues	32·14	39·98
Loss	2·38	1·30

The above analyses indicate that a specimen of creosote containing 25 per cent. of guaiacol is a fairly good one. Other recent analyses contribute towards this view. But it must be remembered that, while the larger proportion of the guaiacol distils between the above temperatures, not all comes over. This is well shown by the results of the present investigation. Those samples beginning to boil at about 210° C. (corrected) contain the largest amount of guaiacol. The probable reason for finding the guaiacol in higher fractions is that we find it almost impossible to closely separate by fractionation the various components of complex mixtures, like creosote. It has been found that a fraction of creosote coming over between 200° and 210° C. may contain a goodly per cent. of phenol having a boiling-point 20° below the lowest boiling-point. And the same fraction has been found to contain more than one-third its weight of creosol, a body having a boiling-point of 219° C.

It is sometimes very difficult to differentiate between the various creosotes. Especially is this the case when slight admixtures are dealt with. Qualitatively, beech and oak creosotes are alike. This is probably true of other creosotes. E. Hirschsohn* has compared beechwood tar with the tars of birch, fir and juniper. Apparently he has established identity tests for the several products when unmixed. But it is the writer's experience that when mixtures of the above substances are met with, many uncertainties present themselves.

Distinctive tests for creosote itself are found in books, but they are of little service in practice, where positive results only can be relied on. For example, carbolic acid, cresylic acid and creosote can readily be distinguished from one another, but it is quite a different thing if mixtures of these substances have to be dealt with. The simultaneous presence of these substances seriously modifies the identity tests.

Oak wood creosote is much more caustic than beechwood. This is due to the fact that the former contains a larger proportion of the monophenols and a correspondingly smaller amount of guaiacol than the latter. Both contain about the same amount of creosol and its homologues. Pine wood creosote distilling between 200° and 220° was found† to contain 40 per cent. of monophenols, 20·3 per cent. of guaiacol, and 37·5 per cent. of creosol and its homologues.

There is also some difference in the specific gravities of the various creosotes. The U.S.P. requires a specific gravity not lower than 1·070 at 15° C., while the B.P. is more rigid, in that the lowest limit cannot be below 1·079 at 15° C. The former can easily be met with by a creosote that does not contain any guaiacol. It seems desirable to make this requirement slightly more rigid.

From the above statements, it can readily be seen that the analyst is liable to be confronted with considerable vagueness when he attempts to identify the various creosotes and mixtures of the same. But be this as it may, we are, nevertheless, able to get at the quality of a creosote very closely by careful examination, as the data in the table below will show.

No.	Specific Gravity.	Boiling-Point Celcius.	Per Cent. of Substance Distilled Between the Following Temperatures, C.° Corrected.

No.	Per Cent. of Guaiacol.	Per Cent. of Potassium Guaiacol and Creosol.
1.....	None	60
2.....	,,	48
3.....	8	60
4.....	16	106

The six samples were obtained directly, as far as could be ascertained, from as many manufacturers. The boiling-points, as well as other tests, show that all of the samples fail to comply with the U.S.P. requirements. There was a slight residue in every case on distillation. The alcoholic potash-creosote mixture proved the most interesting. With Nos. 1, 2, 3 and 4 the mixture was made at the ordinary temperature, and the last two according to the directions of the Pharmacopœia.

The guaiacol was estimated by the following process:—Mix 5 C.c. of creosote with 50 C.c. of a 20 per cent. alcoholic solution of potassium hydrate; in from ten to thirty minutes a crystalline mass will result, due to the combination of guaiacol and creosol with the potassium. Press crystalline mass between filter paper until dry, place into a test-tube, add 5 C.c. of 10 per cent. sulphuric acid, heat mixture a moment and the guaiacol and creosol will rise to the surface of the liquid. Dilute sufficiently with water so that the oily portion will sink to the bottom, decant aqueous portion and add 4 C.c. of concentrated ammonia water. A hard crystalline compound is immediately formed with the guaiacol, and after some time a semi-crystalline mass results with the creosol. On treating the above crystalline mixture with benzin, all but the ammonium compound of guaiacol is dissolved, and separation can be effected by decantation and washing or filtration and washing. Acidulate the solid residue with 10 per cent. sulphuric, extract the guaiacol by means of benzin and evaporate in a tared vessel.

To differentiate between creosote and phenols, thoroughly agitate one volume of the creosote with diluted glycerin (three of glycerin to one of water), then set aside for separation. The diminution in the volume of creosote indicates roughly the amount of soluble impurities.

The barium hydroxide test for cœrulignol and other high-boiling constituents was also applied, but their presence was not revealed in any case.

The collodion test, the ferric chloride test, and the bromine te t did not give results on which any reliance could be placed.

In the writer's experience the pharmacopœial requirements should be based on the following points:—Physical appearance, reaction, solubility, specific gravity (not below 1·080 at 15° C.), boiling-point (200 to 220° C.), reaction with a 20 per cent. absolute alcoholic potassium hydrate solution, and a test for neutral oils, although this is indicated by the boiling-point.

THE INDIAN AND COLONIAL ADDENDUM TO THE BRITISH PHARMACOPŒIA, 1898.*

Some time since a letter was received by the Pharmacy Board and the Pharmaceutical Society of Australasia from the Premier, asking that the Imperial Government might be furnished through him with such suggestions and recommendations as might be deemed desirable in support of the project of the Medical Council. A joint committee from the Board and Society were appointed to deal with the matter. This committee invited the co-operation of the medical societies of Victoria in order that the recommendations might receive the approval of the medical profession, and Drs. D. Grant and Jamieson were appointed as representatives of the Medical Society of Victoria, and Dr. P. B. Bennie, of the Melbourne Medical Association.

* From the *Australasian Journal of Pharmacy* for September.

Several meetings of the committee were held, and the following is the report to be furnished to the Premier for transmission to the Imperial Government:—

Report of a committee appointed by the Pharmacy Board of Victoria and the Pharmaceutical Society of Australasia, consisting of Mr. Plowman, F.R.C.S., Eng., Dr. F. Hobill Cole, Messrs. H. Francis, D. McAlpine, A. W. Craig, M.A., and H. A. Woolnough, to consider the report from the Pharmacopœia Committee of the General Medical Council on the proposed Indian and Colonial addendum to the British Pharmacopœia of 1898, with a view of making suggestions in the direction of any alterations, but chiefly of replying to the queries in the draft addendum.

It has not been considered by this committee desirable at the present time to make any recommendations concerning new drugs or preparations not already made by the Victorian Branch of the British Medical Association.

It has also been decided by this committee to restrict its attention to those drugs mentioned under the head of Victoria in the report of the Parliamentary Committee of the General Medical Council.

The recommendations are also necessarily incomplete owing to want of time to carry out investigations with sufficient fulness to give definite replies to the inquiries contained in the report above alluded to.

ACACIAE CORTEX.—This committee still considers it desirable that this bark shall be made official.

The following is the description:—

Acacia Cortex. The dried bark of *Acacia decurrens*, Willd.; the Sydney black wattle; or of *Acacia mollisima*, Willd.; the Victorian and Tasmanian black wattle. Obtained from wild or cultivated trees not less than seven years old. When dried to be kept one year before use.

Description of commercial samples of barks of *Acacia mollissima*, Willd., and *Acacia decurrens*, Willd., black wattle.

In long strips from one to two inches broad, somewhat twisted and incurved, varying in thickness from $\frac{1}{16}$th to $\frac{1}{8}$th inch, external surface, greyish brown, but darkening with age, with irregular longitudinal ridges, and often with ashy-grey blotches, inner surface, cinnamon colour to ruddy, smooth; fracture brittle irregular and coarsely fibrous, light coloured when fresh; odour, faintly tan like; taste, astringent. The bark is richest in tan material when between six and ten years old.

ACONITUM NAPELLUS.—This plant is not grown for commercial purposes in Victoria. It has been grown experimentally with success in the colony, and the description of the whole plant grown here corresponds generally with that of the plant grown in England.

DUBOISIA AND DUBOISINE.—In view of the facts that our knowledge of the chemistry of duboisia is still incomplete, that salts of hyoscyamine and hyoscine are now official, and that probably duboisine so-called is either a mixed substance, or does not exist as a distinct alkaloid, it may be advisable to defer its inclusion in the proposed addendum. At the same time, in the opinion of this committee, duboisia is a drug, which may, on further investigation, be found to have a distinctive value of its own, so that the original recommendation should not be lost sight of.

EUCALYPTI GUMMI.—The restriction of this to the product of *Eucalyptus rostrata* was due to the fact that this true "red gum" is more soluble in water than exudations from other *Eucalypts*. This committee would prefer to see this true "red gum" alone official, but as a lozenge is already in the Pharmacopœia made from eucalyptus gum soluble in water from 80 to 90 per cent., this committee would not actually oppose the use of the official eucalyptus gum for the preparations already recommended.

FOENICULI FRUCTUS.—The description of fennel fruit grown in Victoria does not differ in any important respect from that of the fennel fruit now official.

Grindelia Robusta.—This committee is unaware that *Grindelia robusta* has been recommended by the Victorian authorities for inclusion in the proposed addendum. This committee does not think it desirable at the present time to make any special recommendation concerning it.

Kino Eucalypti.—This committee entirely approves of the proposed use of "Botany Bay Kino" in the Australasian parts of the empire when it possesses the characters and responds to the tests of the official Kino.

PHARMACEUTICAL SOCIETY.

Donations to the Library and Museum.

At a meeting of the Library, Museum, School, and House Committee, on Wednesday, November 8, the Librarian and Curator presented the following reports of donations:—

To the Museum.

Messrs. Hearon, Squire and Francis, London:—Specimens of small senna leaves (*Cassia obovata*), an empty civet horn, and of bright coloured Sierra Leone chillies.

Messrs. Dalton and Young, London:—Specimens of the following India rubbers:—Mollendo, Mozambique, Java, Penang, Rangoon, Central American, Mangabeira, Pemmican Ball and Pemmican Slab, and a fine specimen of seeds of Croton Tiglium.

Messrs. Lambert and Strong, London:—Specimen of *Munronia pumila*.

Mr. J. Wheeler, Ilfracombe:—Specimens of Betulin, Pyrobetulin anhydride, Pyrobetulin, Boric Acid filmed with Pyrobetulin anhydride, and specimens illustrating the application of the anhydride in pharmacy and the arts.

To the Herbarium.

Mr. W. Wilkinson, Manchester:—Fasciated flower-stem of *Chrysanthemum uliginosum*.

Mr. E. Mellor, Hemel Hempstead:—Specimens of *Euonymus europæus* in fruit.

The Curator:—Specimens of *Crocus sativus*, Linn., and *Crocus sativus*, Tenore.

To the Library in London.

City of London College:—Calendar, 1899.

British Pharmaceutical Conference:—Year-Book of Pharmacy, 1899. Two copies.

Mr. R. Bremridge;—Year-Book of Pharmacy, 1899.

School of Pharmacy Students' Association:—Papers read 1898-99, vol. 25.

Agent-General for Queensland:—Guide to Queensland.

EXTRACTS FROM CONSULAR REPORTS.

The Quantities of Rubber which weekly pass through Kumasi (Gold Coast), from Ashanti to the coast during the season, is estimated at from 70,000 to 90,000 lbs. There are other roads to the coast by which rubber is carried in large quantities from west and east, but the main supply from the west and north of the Colony now goes through Kumasi, as being the safest road to travel. The need for railways throughout the Colony is greatly felt by those interested in the rubber and timber trade. The whole of the rubber is at present brought down to the coast on the heads of carriers, ten shillings being the minimum cost of each carrier from Kumasi to Cape Coast. To bring down 70,000 lbs. of rubber requires 1,400 carriers, thus making the total cost for transport alone for an eight days' journey £700. Rubber is one of the chief sources of wealth in the Colony; the trees and vines which produce it are found in the many swampy regions of the Colony, and, as no cultivation is needed, very little skill and not much work, there is no difficulty in getting the natives to collect it. Given improved transport, it is believed that the output of rubber from the Colony could be trebled, besides releasing from the duties of beasts of burthen hundreds of human beings who could be far more profitably employed for the benefit of trade. Moreover, it is generally believed that rubber would still retain its price even if the output could be doubled in one year, because so many new applications of the material would arise that the supply would not be sufficient.

A Hydropathic Establishment has been opened this year at the mineral baths of Ilidze, near Serajevo, and is reported to be largely frequented. It is expected that the establishment will prove a further attraction to this bathing resort. The water from the hot mineral springs was formerly only employed for bathing, but during the last two seasons many patients have partaken of the water, it is said, with very successful results.

The Demand for Drugs and Medicines in Persia is reported to have been less last year than in previous years. Colonel M. J. Meade, her Majesty's Consul-General at Bushire, is of opinion that the probable cause of the diminution is the inability of the poorer classes to purchase drugs and medicines rather than because of any particular improvement in the general health.

The Supply of Persian Opium in 1898, according to a recent report, was short of the demand, the year's transactions showing a decrease of 2,03,900rs. (£12,744). Prices obtained in Hong-Kong and London, however, are said to have been remunerative, and the opium has gained much favour in Formosa. The shortage is attributed to the failure of the cultivation in Kerman and increased overland traffic with Afghanistan.

The Rose Crop in Persia last year was also much smaller than usual owing to a scanty rainfall, and the continuance of the plague in India is said to have caused a further fall in the export of rose water.

The Demand for Indigo in Eastern Roumelia, Vice-Consul McGregor reports, is on the decline, and aniline dyes are steadily coming to the front. Indigo, chiefly Madras, Bengal, and Java, is used in fair quantities, but very little goes directly from the United Kingdom, as Austrian and German merchants are said to be pushing their trade by selling half-cases, and even smaller quantities, when necessary.

Otto of Roses.—The total yield of otto of roses in Eastern Roumelia last year was about 2,000 kilos., or one fourth less than in 1897, and only about half the crop of 1896. This decrease is attributed to the changeable weather which prevailed during the winter months, it being most unfavourable for the cultivation of the rose fields; the atmospheric conditions during the period of distillation, however, were all that could be desired. According to a recent report, Europe, as well as America, bought less than usual in 1898, although prices were low, ranging from £25 to £30 per kilo.; a fact which tends to prove that adulteration of the otto is still largely practised. The system on which the production of the oil is carried on, it is stated, is to a certain degree responsible for this state of things. It appears that the peasants and small proprietors, who receive cash advances from the leading merchants in Kazanlyk, Karlovo, and other centres, usually distil the oil on their own premises without any effective supervision, and thus have every opportunity of practising adulteration with impunity, the oil of geranium being introduced into the country in sufficient quantities by Jews and gipsies from Adrianople, in spite of the endeavours of the Government to suppress the traffic.

A Central Distilling Establishment is needed for the effective prevention of systematic adulteration of the otto of roses, but although several leading merchants are fully alive to the harm which adulteration must eventually cause to the trade, the diminution in the yield, which would be the consequence of conveying the roses from a long distance under a burning sun, makes it almost impossible to entertain the idea of such an establishment. A remedy is, however, in the hands of the buyers, as a consistent refusal to purchase adulterated otto would doubtless conduce to an improvement in the primitive and unsatisfactory method of production at present in vogue.

The Import of Chemical Products into Mexico during 1898 increased by some £31,806 compared with the previous year, the total values being £344,809 in 1897, and £376,615 last year. Of this caustic soda and potash represent a value of more than £4,000 above what was imported in 1897. The increase in the imports of these articles being due to the cotton mills, bleaching works, and soap factories that have lately been established in the city of Mexico, Guadalajara, Monterey, and several others in the State of Coahuila, owned by a syndicate known as the "Compañia Industrial Jabonera de la Laguna," the local production of chemicals not being sufficient for the consumption. The remainder of the increase is placed under the heading "Miscellaneous Drugs and Chemicals," which covers the imports of patent drugs and medicines; and other special preparations not otherwise specified.

THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.

Styrax Præparatus.—The oxidation test with potassium bichromate indicates the presence of cinnamic acid. Cinnamic acid is phenyl-acrylic acid, $C_6H_5{\cdot}CH{=}CH{\cdot}COOH$. It is the simplest member of the group of unsaturated aromatic acids. Bodies containing a side-chain attached to an aromatic nucleus show very similar behaviour towards oxidising agents—the elements of the side-chain, down to the last carbon atom attached to the nucleus, being removed as carbon dioxide, and water and benzoic aldehyde or acid are formed. The aldehyde is first produced, and by further oxidation yields acid. Thus cinnamic acid,

$$C_6H_5{\cdot}C{:}H{=}CH{\cdot}COOH,$$

yields benzoic aldehyde $C_6H_5C{\cdot}O{\cdot}H$.

Syrups.—Seven new preparations have been added, and three syrups omitted. The latter include the syrups of mulberries, poppies, and subchloride of iron. The last mentioned, although introduced in the 1890 Addendum, was seldom used. Syrup of mulberries had also fallen into disuse, while syrup of poppies is now regarded as an unsatisfactory preparation, owing to its liability to variation in potency. Omitting minor changes, the following alterations may be noted :—

Syrupus Aurantii.—The use of tincture from fresh orange peel will produce a syrup of improved aroma and flavour.

Syrupus Aurantii Floris.—The use of boiled water throughout the process is presumably intended to produce a preparation as sterile as possible, in order to prevent the development of moulds which destroy the aroma of the syrup.

Syrupus Ferri Iodidi.—The strength has been increased from 4·3 grains per fluid drachm to 1 part in 10 parts by measure, *i.e.*, 1 grain in 11 minims, or 1 gramme per 10 C.c. To verify this, remember that an excess of iron is employed, and that the quantity of ferrous iodide formed is, therefore, based upon the quantity of iodine in the formula. Now, 251·80 parts of pure iodine (2I) will produce 307·40 parts (FeI_2) of ferrous iodide, and taking the metric quantities of the official formula

$$83 \text{ grammes of pure iodine will produce } \frac{307{\cdot}4 \times 83}{251{\cdot}8} \text{ grammes } FeI_2$$

$$= 101{\cdot}3 \text{ grammes.}$$

But iodum B.P. is only required to be 98·7 pure ; therefore, on this basis, we should obtain

$$\frac{101{\cdot}3 \times 98{\cdot}7}{100} = 100{\cdot}0 \text{ grammes,}$$

and this quantity is contained in 1,000 C.c. of finished syrup. The useless and clumsy performance of boiling the solution of ferrous iodide with some of the syrup is now omitted.

The test depends upon the conversion of the iodide into sodium iodide. Ferrous iodide solutions cannot be directly titrated with silver nitrate, for although the reaction between the two bodies resembles that of other iodides—

$$FeI_2 + 2AgNO_3 = 2AgI + Fe2NO_3,$$

there is no means of indicating the end of the reaction during titration, because potassium chromate forms an insoluble iron chromate when added to the iron solution. The ferrous iodide is therefore converted into insoluble carbonate by reaction with solution of sodium carbonate—

$$FeI_2 + Na_2CO_3 = FeCO_3 + 2NaI.$$

In order to avoid the trouble of washing the bulky iron precipitate in order to collect all the sodium iodide in the filtrate, the method is adopted of diluting the reaction mixture to a measured volume, and then filtering off for titration an aliquot part thereof. The 25 C.c. of filtrate in the official test is therefore equivalent to $2\frac{1}{2}$ C.c. of syrup. Taking the lower limit of volumetric silver nitrate solution, 16 C.c., and according to the equation—

$$\underset{168{\cdot}69}{AgNO_3} + \underset{148{\cdot}78}{NaI} = AgI + NaNO_3$$

$$1{,}000 \text{ C.c. N/10 } AgNO_3 \equiv \frac{148{\cdot}78}{10} \text{ grammes, NaI}$$

but by the equation—

$$\underset{307{\cdot}4}{FeI_2} \times Na_2CO_3 = FeCO_3 + \underset{2\times147{\cdot}78}{2NaI}$$

this quantity of sodium iodide is also equivalent to

$$\frac{307{\cdot}4}{2\times10} \text{ grammes of ferrous iodide.}$$

$$\therefore \quad 1{,}000 \text{ C.c. N/10 } AgNO_3 \equiv \frac{307{\cdot}4}{20} \text{ grammes } FeI_2.$$

$$\therefore \quad 1 \text{ C.c. } \text{,, indicates } \frac{0{\cdot}3074}{20}$$

$$\text{and } 16 \text{ C.c. } \text{,, ,, } \frac{0{\cdot}3074 \times 16}{20}$$

$$= 0{\cdot}2459 \text{ grammes.}$$

By the same method of calculation the higher limit — 16·5 C.c. will indicate 0·254 grammes FeI_2 in 2·5 C.c. of syrup.

Syrupus Ferri Phosphatis.—The preparation of ferrous phosphate by reaction between ferrous sulphate and sodium phosphate has been replaced by the simpler and more convenient method of direct solution in phosphoric acid. Note that sufficient phosphoric acid is employed not only to convert the iron into phosphate, but also to keep in solution the ferrous phosphate which is insoluble in water.

Syrupus Limonis—Instead of infusing the peel in the boiling juice, it is now to be extracted with strong alcohol, and the resulting tincture added to a syrup prepared from lemon juice. This change will be found a great improvement. Note that filtration of the lemon juice is not attempted, so that the resulting syrup will not be bright.

Syrupus Scillæ—The sugar has been slightly reduced to avoid crystallisation in cold weather.

Syrupus Sennæ—The senna is now to be extracted by repeated maceration with 20 per cent. alcohol in place of water. Only the third expressed fluid is to be evaporated in order to avoid the prolonged application of heat to the previously expressed and stronger portions. The use of weak alcohol as a menstruum will no doubt prevent the fermentation to which the 1885 B.P. syrup was liable.

Syrupus Zingiberis.—Owing to the omission of tinctura zingiberis fortior from the 1898 Pharmacopœia, directions are given for the preparation of a strong tincture specially for the syrup.

The new formulæ include the following :—

Syrupus Aromaticus

Syrupus Calcii Lactophosphatis.

Syrupus Codeinæ—Codeine phosphate is used for this, as the alkaloid itself is not sufficiently soluble in water.

Syrupus Ferri Phosphatis cum Quinina et Strychnina.—A syrup containing these constituents has long been known as Easton's syrup. The original formula of Easton included the preparation of ferrous phosphate by precipitation, and has not been found to possess good keeping qualities. The present official formula is more satisfactory.

Syrupus Glucosi.—This is a useful pill excipient. Its advantages are that pill masses made with it do not harden and become crumbly so quickly as those made with simple syrup, owing to the uncrystallisable nature of the glucose, while the pills so made are not so hygroscopic as those made with glycerin or syrup and glycerin.

* NOTE.—The series of articles should be read in conjunction with the series referring to the 1885 B.P., and published in the *P.J.* during 1897-8.

ATTEMPTED PHARMACY LAW AMENDMENT,

And the Causes of its Failure in the Past.

The utter breakdown of the so-called Pharmacy Act, 1868, caused by the House of Lords' decision in 1881, left the position of chemists and druggists, even as "a trading community," so precarious, that their apparent acquiescence in that decision seems, at the present time, to have been very remarkable. It certainly shows that the great majority of the body had not been inspired with the idea that chemists and druggists required in their own interests to distinguish themselves as being something more than mere traders—that they failed to perceive the full extent of the disadvantage to which they were exposed, by the Pharmacy Act being regarded as dealing chiefly with "the sale of poisons" and essentially a measure for creating a trade monopoly, rather than one for ensuring the safety of the public. Their prevailing indifference, in those respects, was due to defective perception of the fact that the professional practice of pharmacy was the only part of the chemist and druggist's business for which any kind of State protection could be expected. Owing to that deficiency, the pharmaceutical chemist has had on his shoulders, as an obstructive burden—like the Old Man of the Sea—the typical chemist and druggist, imbued with trade notions, little different from those of the grocer, the ironmonger, or the publican. The same state of mind has to a great extent prevailed with judges, members of Parliament, and Government officials, with naturally consequent disadvantage to the entire body of registered chemists and druggists; but more especially to those among them who aspire to professional status—who endeavour by qualification and conduct to assist in establishing a professional craft of qualified pharmacists.

The failure of the attempt made in 1881 by the Council of the Pharmaceutical Society to obtain amendment of the law—such as would secure efficiency in regard to public safety and the intention that it should regulate the practice of pharmacy—can scarcely be regarded as surprising, when the conditions and ideas then prevailing are considered. The very modified expression of the principle of the Pharmaceutical Society, which had to be adopted in the Act of 1868, in order to secure the great advantage of incorporating "persons known as chemists and druggists," gave an obvious preponderance to a part of their business that appeared to be distinctly of the nature of ordinary trade. The sale of the articles that were made poisons by the Statute, was thought to be of more importance than the dispensing of medicine, and to be more in need of regulation in the public interest. Among other circumstances placing the professional part of the business comparatively in the background, was the frequently mixed and miscellaneous nature of the trade carried on by chemists and druggists, as well as the very small extent to which any practice of pharmacy entered into their business. The great majority desired to be regarded as members of "a trading community" they willingly gave ear to assurances that their welfare was to be sought by assertion of free trade principles, rather than by establishing a professional status; though, strangely enough, that teaching was combined with advocacy that chemists and druggists should enjoy privileges appertaining only to persons engaged in professional occupations.

When the second attempt to obtain amendment of the Pharmacy Act, 1868, was made in 1883 the number of registered persons (13,665) was very little greater than it was in 1881, and those who had passed the qualifying examination amounted to only 40 per cent. as compared to 36 per cent. at the earlier period. It may therefore be inferred that the conditions above referred to had not been materially altered. The subjects to which the attention of Government departments had been called, in connection with amendment of the law, related to the supply of poisons and poisonous articles in various ways that were essentially trade transactions. The communications from the Privy Council and other Government departments, related specifically to the trade aspect of the matter: they showed express disinclination to allow amendment of the law as to "the sale of poison" to be trammelled by amendments relating to the practice of pharmacy and "the status or organisation of the Pharmaceutical Society," or even to take any cognisance of chemists and druggists in connection with such matters. After the lapse of fifteen years there will probably be less tendency, in official quarters, to regard persons registered under the Pharmacy Act, 1868, simply as traders, since the conditions have now become very different. Notwithstanding the discouraging influence of the fact that the slender protection of the practice of pharmacy, afforded by the Legislature in 1868, has long been extinguished, there has been loyal observance of the law in regard to qualification: for the number of persons qualified by examination, now amounts to upwards of 80 per cent. of those whose names are on the Register.—Does that altered condition furnish possibility of securing the "two essential factors" of suitable Pharmacy Law Amendment—viz., the hearty support of most registered persons, as well as their recognition, by the Government, as being something more than mere traders?—Does it admit of "protection of those who carry on the business of chemists and druggists"?

ANNOTATIONS.

TO BE ONE-SIDED is as much a reason for reproach as being irrational, or unjust—obviously the Society's Journal should uot be censurable on any one of those grounds. But there are propositions which do not reasonably admit of more than one view and the confession must be made that, under such an impression, the opinions and arguments put forward in this Journal with regard to the subject of "company pharmacy" have been those considered to be consistent with commonsense, with public interest, with the object of the Pharmaceutical Society, and with justice to legally qualified chemists and druggists. An objection has, however been made that "a one-sided position" should have been taken by the Journal, in regard to a subject on which the Council is apparently divided. Without acknowledging the implied rebuke as being merited, it may, however, admit of an invitation being given to any member of the craft who may desire to advance contrary arguments, in support of "company pharmacy," advocacy of which has—it must be admitted—been regarded as more suited to the pages of a mere trade organ, than to those of the Pharmaceutical Society's official Journal.

THE COMPANY PHARMACY PROBLEM is still to the fore in our pages, the Chairman of the Federation of Local Pharmaceutical Associations leading off with a vigorous appeal for union amongst the registered chemists of the country, and a suggestion that the provisions of the Interpretation Act, 1889, should be made applicable to pharmacy law generally. That Act—passed after the House of Lords' decision in the case of the London and Provincial Supply Association—was intended to bring joint-stock companies within the scope of other Statutes which render certain acts punishable when performed by individuals. It provides that, in the construction of every enactment relating to an offence "punishable on indictment or on summary conviction," whether contained in an Act passed before or after the commencement of the Interpretation Act, the expression "person" shall include a body corporate, unless the contrary intention appears. Unfortunately, the penalty provided by Section 15 of the Pharmacy Act must be sued for, in England, by civil process; offences under that Section are not "punisbable on indictment or on summary conviction" and, consequently, the provisions of the Interpretation Act do not apply. To put the matter briefly, if all offences under the Pharmacy Act, 1868, could be dealt with in police-courts instead of county courts, joint-stock companies would be persons within the meaning of that Act.

THE POSITION OF THE COUNCIL is summed up by Mr. Smith as being a choice of one of five different important suggestions. The extreme proposals are acceptance of the usurpation by companies of the chemist's position, on the one hand, and—on the other—absolute prohibition of unqualified company trading in pharmacy, The remaining plans are somewhere between those two, but Mr. Smith feels strongly that there can be no half-way house. "If we voluntarily surrender the principle known as qualified ownership we are driven from point to point until we arrive at a position we cannot logically evade—that is, that an individual grocer or other dealer should be allowed to carry on the business of a chemist and druggist provided he has a qualified assistant." The letter of Mr. Harold Matthews, printed at page 466, shows that the same idea is already taking shape in the minds of some grocers, and there is not the least doubt that it represents the only logical outcome of "the policy of surrender." If once the principle of proprietary qualification were relinquished, nothing would be necessary but the qualification of assistants—the individuals who actually hand over scheduled poisons to the purchaser. Behind them would be capitalists who might, or might not, be legally qualified persons, and we should be confronted with the curious anomaly of the qualified assistant conferring qualification on his employer, a position which Dr. Symes has well described as an impossible one.

"AN ORDINARY PHARMACIST" sums up the position as to "company pharmacy," defending himself against charges of inconsistency, and pointing out what reform in the law is urgently required, in the public interest. Sceptical about the feasibility of any scheme for checking the development of unqualified company pharmacy by imposing irksome restrictions and regulations, he urges registered chemists not to "cry for the moon," but to demand that they should "possess the earth" to a fair and reasonable extent. That he interprets as implying restriction of pharmaceutical titles to duly qualified individuals; the dispensing and sale of all statutory poisons by registered persons only; and the prohibition of any control over the conduct of the business of a chemist and druggist by persons who are not legally qualified. He contends that the clause suggested in the first article he contributed is fully capable of satisfying the legitimate aspirations of pharmacists, without interfering with proper business developments; while at the same time, it would prevent the usurpation of chemists' titles by unqualified persons, and put companies on a proper footing. The keynote to the article is to be found in the words "equality of treatment all round"—either free trade in pharmacy or a proper restriction of titles and practice.

THE FIRST EVENING MEETING of the Pharmaceutical Society for the present session will be held at 17, Bloomsbury Square, London, on Tuesday next, November 14, when Professor J. Reynolds Green will lecture on the biology of yeast, and Professor H. G. Greenish will read a paper on spurious Alexandrian senna. The chair will be taken by the President—Mr. William Martindale—at eight o'clock precisely. It is hoped that a large number of members of the Society will make a point of being present and also bring any friends who may be interested in the subjects announced for consideration. By an unfortunate slip the word "next" was inadvertently printed after "Tuesday" in the notice published last week; apologies are therefore due to anyone who failed to note the discrepancy in the date, and came to the Society's House with the object of attending the meeting, on Tuesday last.

THE CHEMISTS' BALL FOR 1900 will be held at the Portman Rooms on Wednesday, January 17, that date having been decided upon at preliminary meeting held at 16, Bloomsbury Square on Monday afternoon last. The Committee to make arrangements consists of the following gentlemeu:—Mr. William Martindale (Chairman), Dr. John Attfield, Messrs. J. W. Bowen, M. Carteighe, T. H. Francis, J. F. Harrington, E. W. Hill, Walter Hills, J. H. Mathews, A. J. Phillips, A. C. Preston, J. C. Umney, and William Warren (Hon. Secretary). The names of any gentlemen willing to act as stewards and assist in making the last ball of the nineteenth century a success, should be sent as early as possible to the Hon. Secretary, Mr. William Warren, 24, Russell Stree Covent Garden, W.C.

THE 'YEAR-BOOK OF PHARMACY' FOR 1899 surely establishes a record by the promptitude with which it has made its appearance—nearly three weeks earlier than last year. The contents of the book are arranged on the same familiar plan, and the numerous abstracts, formulæ, etc., should prove as useful as ever. The proceedings at the Plymouth meeting are, of course, printed at length. The only absolute novelty in the book is the list of local corresponding secretaries, which now appears for the first time. The members of the Conference may once more be congratulated on receiving such an excellent return for the small subscription they pay.

A Commonsense Judgment has been delivered by the Supreme Court of Tennessee, in connection with an attempt which has recently been made to compel pharmacists to place poison labels upon bottles, etc., containing medicines ordered by and compounded from a physician's prescription. The *Pharmaceutical Era* points out that there is a Statute in Tennessee which requires that a labe bearing the word "poison" shall be placed upon any bottle or package containing any poisonous liquid or substance, but the Supreme Court has decided that a physician's prescription absolves the pharmacist from that duty or responsibility in the matter of labeling. The decision, as might be expected, is very acceptable to both pharmacists and physicians. The latter, in particular, object to having their medicines labelled "poison," on the ground that the effect upon the patient would be harmful and that such a practice would tend to the disparagement of the physician's ability and reputation. As the *Era* remarks, the application of a poison label to medicine dispensed from a physician's prescription would afford no protection to the patient, but, on the contrary, might cause harm to all concerned. Poison laws are of the utmost value when applied to ordinary sales, and such application is, doubtless, all that was intended by any of the Statutes in force in the United States. In Great Britain and Ireland, as is well known, special exemptions are provided in the Pharmacy Acts for medicine dispensed by duly qualified persons, but it is satisfactory to find that no special legislation has been required to effect the same purpose elsewhere.

Ships' Medicine Chests appear to be considered unnecessary by the *Medical Press*, which comments on the letter recently sent to the Board of Trade by the Sunderland Chemists' Association. The question whether ships' crews are any the worse off by reason of the inability of captains to administer medicines is said to be a debatable one, and our contemporary would limit a captain's medical functions to the administration of purgative medicines (put up in suitable doses), diarrhœa mixture, ipecacuanha wine, or syrup of ginger. The administration of quinine might not prove beyond his capacity, but the prospect cannot be regarded with equanimity of the ship's master administering morphine, or mercury, "or even pilocarpine for the purpose of making the hair grow or otherwise." The *Medical Press*, therefore, would limit the contents of a ship's medicine chest to the simple remedies mentioned, in addition to surgical dressings, splints and bandages. But that is not the question. The Board of Trade, acting on statutory authority, from time to time publishes scales of medicines and medical stores suitable for different ships and voyages, and owners of ships are expected to provide those medicines and stores. But no means appear to be taken to insure the carrying out of the Board of Trade regulations, and it is alleged that ships are sent to sea with medicines of inferior quality or in insufficient quantity. The Sunderland Chemists' Association, therefore, has made the eminently sensible suggestion that competent inspectors—preferably registered chemists—should be appointed by the Board of Trade, to see that the regulations are carried out.

The Limits of Accuracy in Technical Analysis were discussed by Dr. Grossmann in an address delivered at the opening meeting of the Manchester section of the Society of Chemical Industry, last week. He pointed out that, in carrying out an observation or experiment, it is not sufficient that analysts should be able to do their work carefully. It is even more important that they should inquire what errors they may be liable to commit, and thus be able to prevent, remedy, or correct those errors. That truth has long been recognised in physics and astronomy. It has been applied to chemistry in theoretical investigations, notably in the determination of atomic weights, but it has not received the attention in technical analysis which is due to it. As an illustration, Dr. Grossmann referred to the uncertainty that exists in regard to atomic weights and how it affects analysis, and he also showed that measuring instruments are not always satisfactory. He suggested that analysts should get over those difficulties by making check tests with pure chemicals under exactly the same conditions as those under which the actual analyses will be done.

The "Kromaz" System of Colour Photography was described at a recent meeting of the London and Provincial Photographic Association by Mr. Gowenlock, who explained that the system is based upon the fact that all colours are equivalent to, or can be matched by mixtures of, the three primary colours—red, blue-violet, and green. The novelty of the system is that there are two pairs of stereoscopic images, instead of three, the right eye being made to see one colour, the left the second colour, and both eyes the third colour. There are thus four colour records. Two are due to the green, and form a stereoscopic pair, and two are due respectively to red and blue-violet, forming in themselves a second stereoscopic pair. The four records are secured upon one half-plate by two successive exposures. The red and blue records are taken together simultaneously, by the first exposure; the two green records are secured by the second exposure. In the first exposure it is necessary to equalise the exposures for the red and blue by slowing the action of the latter to the time required by the red. That is done by the insertion of an orthochromatic screen in front of the blue-recording portion of the plate, thus following Dr. Joly's process. A single-lens camera is used, and the stereoscopic effect is secured by the use of stereoscopic mirrors, which are supported immediately in front of the lens and transmit two images to the plate. To the back of the camera is attached a repeating back, taking a half-plate slide in which are placed the red, blue, and green screens. Any ordinary front-focussing camera may be used, and the adaptation required is by no means extensive. Plates sensitive to all the colours of the spectrum are necessary, and the colour screens sent out with the apparatus are adjusted to those plates. After exposure, development is proceeded with as usual. Further particulars of this interesting process are given in the *British Journal of Photography* for November 3.

Petroleum Lamp Accidents should be reduced in number if due attention be paid to the suggestions for securing safety given in a circular issued by the Public Control Department of the London County Council. In the first place the public are cautioned never to burn oil which has a flashing point of less than 100° Fahr. Then, it is urged that lamps should be strongly made, and be kept thoroughly clean. In choosing a lamp it should be seen that the reservoir is thick and strong, and not made of thin glass or china; that the burner is strong, and is securely connected to the reservoir by screwing into the collar; and that the lamp has a broad and heavy base. The wick should be soft and not tightly plaited, and should quite fill the wick tube without having to be squeezed into it. The wick should be frequently renewed, and before being put into lamps it should be dried at a fire and then immediately soaked with oil. In managing a lamp care should be taken that the reservoir is filled with oil before the lamp is lit; that the burner is kept thoroughly clean, that all oil is wiped off, and all charred wick and dirt carefully removed before lighting. When first lit the wick should be partially turned down and then gradually raised, but the wick is not to be left turned down and, in extinguishing lamps which have no extinguishing apparatus the wick should be turned down until there is only a small flickering flame—flat piece of metal should then be placed on the to pof the chimney, so as to close it entirely. Cans or bottles used for oil should be free from water and dirt, and should be kept closed.

PHARMACEUTICAL SOCIETY OF IRELAND.

Meeting of the Council.

The monthly meeting of the Council was held on Wednesday, November 1, at 67, Lower Mount Street, Dublin.

The President (Mr. R. J. Downes) was in the chair, other members of the Council present being:—Messrs. Grindley, Wells, Kelly, Michie, Dr. Walsh, Professor Tichborne, Montgomery (Belfast), Jameson (Belfast), W. J. Baxter (Coleraine), Bernard, Simpson, and Porter.

Question of Reciprocity.

The PRESIDENT, after welcoming the new member, Mr. Jameson, said there was another matter to which he wished to refer. Mr. Sidney Vaughan the President of the Queensland Pharmaceutical Society had been with them at the meeting on the previous evening. The Council of the Pharmaceutical Society of Queensland had asked him to have a conference with the Councils of that Society and of the Pharmaceutical Society of Great Britain on matters which they wished to have discussed. One of those was the question of reciprocity. His Council had sent a copy of its regulations, and also information as to the examination.

It was decided that the reception of Mr. Vaughan should be put on the agenda paper for the next meeting.

Proposed Pharmacy Act for the Isle of Man.

A letter dated October 25 was read from Mr. G. A. Ring, Attorney-General of the Isle of Man. It stated that hitherto there had been no Pharmacy Act in that island, and that he was about to introduce one based on the lines of the English Act of 1868 and the Irish Act of 1875, and intended to adopt the English and Irish registrations. The writer asked for information as to the existing pharmaceutical and chemist qualifications in Ireland and a number of other points. The reply which the Registrar had sent was also read.

The PRESIDENT: It will be an advantage to us if that is carried into effect.

Mr. BERNARD said it would be well to point out to the Attorney-General of the Isle of Man the serious flaw that existed in the Acts of the Irish Society, in consequence of which limited companies were enabled to evade the original intentions of the Act of Parliament. The expression of opinion by the Lord Chancellor of England should also be sent to him; and he might thus be enabled to frame his Act so as to prevent the occurrence of such abuses in his dominion.

Mr. WELLS: He is going to pass a special Act for himself, and they are about to accept our qualification in lieu of an examination of their own. We ought to take the opportunity of thanking him for taking us into consideration, for I think it is a very great matter for us.

Mr. BERNARD: Don't you think we should help him by pointing out the flaws and difficulties we labour under as regards company pharmacy?

Mr. WELLS: I endorse everything that you have said. I only want to add our thanks.

The draft reply to the letter of the Attorney-General of the Isle of Man was approved of, and the Registrar was directed to write thanking him for his proposed acceptance of the Irish qualification, and pointing out the disadvantages that would accrue from the recognition of company pharmacy.

The Proposed Library.

The next business was the consideration of the following resolution, which was passed at the last annual meeting, on the motion of Mr. Kelly:—

That it is desirable that a library on a practical basis be established, available to members, associate druggists, and students ofschools of botany, materia medica, and chemistry; and that books considered necessary for reference be added to the present stock, and a catalogue of same be provided.

Mr. KELLY, in moving that the foregoing resolution be acted on, said that having regard to the length of time that the Society had been in existence, it was time that such a library as that which he proposed should be formed. Besides being a benefit to their rising juniors, it would tend to bring the licentiates of the Society together more than they had been in the past. The Society had been making great strides; theoretical chemistry was about to be taught in their schools; and other branches of study bearing on the pharmaceutical profession might have to be added. It was therefore absolutely necessary to have a library, with books that could be referred to on difficult points.

Mr. BAXTER seconded. A lengthy discussion then took place, during which Dr. WALSH and Mr. WELLS—judging from the attendance at the evening meetings, at which on one occasion only three persons were present, including the lecturer and the President—pointed out the possible difficulty of getting students to make use of the library.

Finally the motion was altered by omitting the words after "chemistry," and adding "that the matter be referred to the School Committee to carry out details"; in that form it was passed unanimously.

Donations.

Donations were received from the editor of the *Chemist and Druggist* of copies of works entitled 'Diseases and Remedies,' 'Pharmaceutical Formulas,' 'The Art of Dispensing,' 'Veterinary Counter Practice,' and Proctor's 'Manual of Pharmaceutical Testing.'

On the motion of Mr. GRINDLEY, seconded by Mr. WELLS, thanks were voted to the donor.

Question of Prizes.

A report of the School Committee stated that they did not consider it expedient to award prizes for papers read at the evening meetings.

The PRESIDENT said he had proposed that these prizes should be given because he thought it would induce their licentiates to read papers, and that the education not only of the students but of the licentiates themselves would be thus promoted.

After some discussion the report of the Committee was adopted.

Other Business.

Mr. F. N. Binks was elected Professor of Theoretical Chemistry. Mr. Binks held the Young Scholarship at Anderson's College, Glasgow, for three years.

On the motion of Mr. BERNARD, it was ordered that copies of the examination papers should be placed on the table at the Council meeting next succeeding each examination.

On the motion of Mr. GRINDLEY, seconded by Mr. WELLS, the following gentlemen were elected members of the Society:—Messrs. A. J. Cahill, Dublin; G. G. Dixon, Mallow; and T. L. Foster, Belfast.

Messrs. J. T. Chamberlain (Dublin) and J. Hewton (Ballinasloe) were nominated for membership.

Other business having been disposed of, the Council adjourned.

Evening Meeting.

At Dublin, on Monday, November 6, the opening meeting of the Society for the winter session was held at 67, Lower Mount Steert, the PRESIDENT, Mr. R. J. Downes, in the chair.

The minutes of the last meeting were read by the HONORARY SECRETARY, Mr. H. O'Connor, M.P.S.I., and on the motion of Mr. D. McGREGOR WATSON, M.P.S.I., they were adopted. Apologies for non-attendance were received from Messrs. J. Tyrie Turner and J. Armstadt Ray, B.A. Mr. J. Burnett wrote regretting that pressure of business would not allow him to contribute a paper during the forthcoming session. Messrs. J. Armstadt Ray, F.C.S., J. Smith, M.C.P.S.I., and W. V. Johnston, M.P.S.I., were re-elected reporters in chemistry, botany, and pharmacy respectively, and the following were elected as a committee for the ensuing year:—Miss Ada Wyatt, and Messrs. H. O'Connor, George Brown, J. Tyrie Turner, D. M. Watson, and J. Michie. Mr. H. O'Connor intimated his intention of not further acting as honorary secretary, and Mr. W. V. Johnston kindly undertook the duties for twelve months certain.

The PRESIDENT referred briefly to the work of the past session, and paid a high tribute to the reporters—especially to Mr. Ray, who, he said, was a first-class officer. He would not call on the reporters to act as *ex-officio* members of the Committee. but he would be very glad to see them present as often as possible. The Committee formed the business part of the meetings. He must say that, good as the reporters had been in the past, he hoped for better results from them in future, and anticipated some interesting reports from Messrs. Ray, Smith, and Johnston in the coming sessions. With regard to the contemplated museum in connection with the evening meetings, he understood that an estimate for a mahogany case had been obtained from a local firm, but the price was excessive and the matter had dropped for the present. What was most wanted was for the members to rally round the evening meetings. The question of prizes was at present an open one, but it had not been overlooked. It had been suggested that the evening meetings were held with closed doors. He wanted to make it clear that those meetings were open to all licentiates and students connected with the Society's

school. He remembered when the old Dublin Chemical Society was in existence, the members of the Society had cards of invitation supplied to them to invite outsiders to the meetings. They could have similar tickets now, which could be dated and signed by the member or members issuing them. In a word, the licentiates had the opportunity of attending the evening meetings, but not of voting thereat.

Mr. Watson: If you give the licentiates the privileges of members they won't become members or pay for what they can get free.

The President feared that the evening meetings were not such as to induce the great bulk of licentiates to become members, owing to the want of interest taken by the very men concerned.

Mr. Johnston: If we give a decent syllabus and offer some instruction we may get additonal members.

The President: This room is an open one. If a licentiate comes here and offers useful information we are always very glad to get it, but when certain conditions of membership are laid down the line must be drawn somewhere. The meetings, however, are practically open, and nobody is ever questioned when he comes here as to whether he is a member or not.

Mr. Johnston said that this was not made clear in the beginning, and it kept away a number of licentiates who might otherwise have attended.

Mr. O'Connor said the matter had long since been set right and the syllabus altered accordingly.

The President, in reply to a question, said that membership conferred the right to vote at the annual meeting of the Society, entitled the member to become a candidate for a seat on the Council, and to receive a weekly copy of a trade journal. About seventy notices were sent to the members and the Council in respect of each evening meeting. It was thought that the evening meetings were at present notified too far ahead, and arrangements were made to have postcards sent about three days beforehand in future.

Mr. Johnston advocated the sliding scale of recruiting members for the evening meetings. First, he said, make licentiates of the members.

A syllabus for the winter session was approved of, after which the President moved, and Mr. Watson seconded, a very hearty vote of thanks to Mr. O'Connor for his zeal and energy while acting as honorary secretary. The resolution was carried with applause and

Mr. O'Connor having suitably expressed his acknowledgments, the proceedings terminated.

GLASGOW CHEMISTS' AND DRUGGISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

At the weekly meeting of this Association, held on Friday evening, 27th ult., the President, Mr. J. P. Gilmour, delivered an address on

The Assistant: His Fortunes and Future.

Mr. Gilmour began by saying that he proposed to present a descriptive sketch, and critical study, of what might be called the middle stage in the life-history of the pharmacist. Casting about for biological analogies to this cycle, the familiar case of the metamorphic insect had occurred to him, only to be rejected, for while there was unquestionably a close resemblance between the grub or caterpillar, crawling unhastingly and devouring every digestible and many indigestible things on its devious course, and the artless apprentice, it was preposterous to suggest that the slumbering pupa could be the analogue of the "live" assistant of advertisement fame, or that of the gorgeous imago, unless indeed, it were that of a dusty moth, flitting about in the sunshine sampling the nectar in every opening flower, was to be compared to the prosaic, bespectacled, and aproned pharmacist of our workaday world. He had been equally unfortunate in other attempts to find a good, working analogy. The promise of a canine comparison was impaired by the consideration that even the long-suffering, and long-suffered apprentice, might resent being likened, albeit metaphorically, to a puppy, and that the appellative "old dog" was hardly respectful to a M.P.S. in business for himself. As a *pis aller*, he had been driven back on a piffling parody of Shakespeare's timeworn lines:—

> "All the world of pharmacy's a stage,
> And all its men and women merely pill-layers.
> Their acts being three dru(d)gging ages."

It had cost him a poignant spasm of regret to be obliged to keep that "gay and festive cuss," the apprentice, in the background for the purposes of this address. In spite of all its drudgery and servitude, one invariably looked back on his apprenticeship with something of the tenderness cherished for the memories of school-life, of his first pair of breeches, or his calf-love. The epic or the comedy of the apprentice was still to write, but it seemed doomed to continue *in posse*, since the apprentice of the old type was a vanishing quantity.

The term "assistant" was one of those euphemisms to which our age was so weakly addicted. We might change the name, but the fact endured. This process of accommodation always reminded him of Artemus Ward's plan of transforming the figures in his "moral waxworks." He had an effigy of Captain Kidd, the pirate, which was generally very popular; but when the show visited religious towns, where unconverted pirates were at a discount, Artemus touched up the figure suitably, and labelled it John Bunyan, or John Knox, or John Wesley, according to the susceptibilities of the place. They might write "principal" for "master" and "assistant" for "servant," but that did not, and could not, alter the fundamental, legal, and moral relations of employer and employed.

There were two principal phases of assistant life:—(1) The official and economic phase. (2) The student phase. Those were, or ought to be, interdependent, but could be considered most conveniently apart.

The Assistant in His Official and Economic Capacity.

Having given some account of what he called the humours, harassments, and lessons of shop-life, with several amusing and instructive illustrations under each head, Mr. Gilmour proceeded to treat of the economics of the assistant's status. The two outstanding economic evils in the assistant's lot were:—(1) Long hours, and (2) low wages. Long hours of labour arose either from a general or a special cause, or from both. The general cause of the inordinately long working-day in all civilised countries was the redundancy of drones in the community. This was not political theory, but economic fact. The special cause in the case of the trade of pharmacy was the so-called emergency demand for medicines, a demand which, curiously enough, reached its minimum between twelve midnight and nine a.m., and its maximum between six p.m. and midnight. So much for the diagnosis of the disease. The prognosis depended on the regimen, which must be heroic, even if it ran on evolutionary lines. If we were to imitate the bees, whose social system has been the text of so many ethical formulas, we should cast out the drones and leave them to perish; but since we have a reputation for humanitarian science to maintain, we must seek to eliminate the gratuitously unproductive classes by educative or legislative methods. Such gradual movements don't promise speedy relief for the hapless victim of the present system. If we are to anticipate the course of economic development, it can only be by modifying the action of the special cause which lengthens the already excessively long working-day of the pharmacist, and this reform depends on factors which we have yet to consider.

Low Wages.

There are always some ill-informed or narrow-minded assistants who take the view that employees as a class are responsible for the pittance which they receive as a reward for their labour. Such malcontents usually refer to particular instances, and so fall into the common logical error of setting up a special case as a general rule. The public fall into a similar fallacy about druggists' profits. What Adam Smith said about apothecaries' profits is applicable *mutatis mutandis* to the present-day druggist.

"Apothecaries' profit is become a by-word, denoting something uncommonly extravagant. This great apparent profit, however, is frequently no more than the reasonable wages of labour. The skill of an apothecary is a much nicer and more delicate matter than that of any artificer whatever; and the trust which is reposed in him is of much greater importance. He is the physician of the poor in all cases, and of the rich, when the distress or danger is not very great. His reward, therefore, ought to be suitable to his skill and trust, and it arises generally from the prices at which he sells his drugs. But the whole drugs which the best employed apothecary in a large market town will sell in a year may not perhaps cost him above £30 or £40. Though he should sell them, therefore, for three or four hundred, or at a thousand per cent. profit, this may frequently be no more than the reasonable wages of his labour, charged in the only way in which he can charge them, upon the price of his drugs. The greater part of the apparent profit is real wages disguised in the garb of profit."

Independently of the element of skill, the question of magnitude of consumption comes in. This is glanced at in the above passage, but not stated expressly. The profits upon the sale of any commodity, allowing for competitive pressure, are determined by the

intensity and pitch of the effective demand. In plain terms, a consumer goes to his grocer daily and buys largely, but to his doctor or druggist only a few times a year, and buys sparingly, and to the undertaker, usually by deputy, once only, for a final outfit. In terms of the argument, therefore, these sellers must earn a nominally high profit. Now, economic doctrine gives us an equally clear and convincing account of the conditions which regulate wages in any occupation. Those are, as Adam Smith first pointed out, mainly five:—

(1) The agreeableness or disagreeableness, the honourableness or dishonourableness of the occupation.

(2) The ease or difficulty, cheapness or expense of entering upon the occupation.

(3) The constancy or inconstancy of employment.

(4) The trust or confidence reposed in the employee.

(5) The probability or improbability of success in the occupation.

These conditions never act singly, but always in combinations of two or more of this set of five factors, and it would take the higher mathematics to prove the number of combinations that are possible with such a set. In the light of these general principles the problem of the causation of the low wages of assistants in the drug trade is easily solved. The poor pay does not necessarily arise from the cupidity of employees, but is a resultant of these causes—namely, that (1) pharmacy is a fairly agreeable and honourable or genteel calling; (2) that there is no great difficulty nor expense in acquiring proficiency as an unqualified assistant, or even in getting the legal qualification; (3) that the employment is steady; (4) that the probability of success as an assistant, and even as a pharmacist in business for himself, is high. The advantage which should accrue to the assistant in respect of the trust reposed in him is practically neutralised by the combined action of the other four causes. Having detected the sources of an evil, it is always easier to suggest means for its abatement or removal. In this case palliative methods are more obvious than a course of curative treatment. To raise wages provisionally we must increase the difficulty and expense of entering the profession, and agitate for an enforcement of the law which now nominally protects the qualified assistant. Things have been drifting in that direction for some years. Nothing is more certain than that the Pharmacy Act of 1868 did not contemplate the legal qualification of the assistant. The definition of the word "seller," imported into the Act, is a judge-made formula, but the legal fiction is proving itself a blessing in disguise, since it has quickened the demand for the qualified assistant, and so improved his status. Any gain on these lines must, however, be temporary, nor will a stiffer examination and more stringent pharmacy laws do more than postpone the return to the old, low level of status and wages. The spread and cheapening of secondary education will soon increase the supply of stuff out of which assistants are made, and we shall reach the stage, at which Germany stands, where a highly-trained scientific man can be got to fill a responsible position at £100 a year. There is only one real preventive of this eventuality, and that is to raise the standard of comfort. This can be brought about in two ways:—(1) By the growing tendency towards easier and more rational conditions of life all round, and (2) by organised effort on trades' union lines by assistants themselves. The first was more likely to be stable and persistent as a product of social development; but it was too remote to be satisfying, and one had sometimes to hasten the parturitive processes of Nature The alternative course is difficult but feasible. The objections to the principle of combination to raise wages or better the employees' condition were mostly academical, or were inspired by sinister interest. What were the legal and medical professions, and all close corporations or syndicates which combined to maintain or raise fees and prices, but huge trades' unions? Surely no one could deny that in following these illustrious examples the assistant would be worthy of his masters?

The Assistant as a Student.

Even ten years ago the assistant preparing for the Minor could learn his theory at home and do all his practical work in the back shop. All that seemed prehistoric now, when it was seriously proposed that that disappearing type, the apprentice, should pass the Prelim. before he entered a shop, as if there were some sort of pre-established harmony between any person and any profession. There would be more reason in the proposal when the pharmaceutical Prelim. came to be identical with the medical Prelim., although even then it would probably be a counsel of perfection. At present, the student was the victim of a transitional movement, and evolution told them what became of intermediate forms. The present standard of the Minor was above the *sine curriculo* and below the curriculum level; hence the anomaly of day classes which inflicted all the hardships without any of the advantages of a prescribed course of study. As regards the Minor itself, it was defective alike in form and process. Now that there had been plain speaking in influential quarters about the arbitrariness and backwardness of a system of examination that compelled the candidate to pass in all his subjects or fail in all, it was to be hoped that there would be a full and fruitful discussion of the subject in all its bearings. As it stood, the Minor was about the most primitive and antiquated examinational mechanism in the country. Touching the nature and scope of the Minor as an examination, it was neither properly scientific nor adequately technical; but these defects were due largely to developmental conditions. And its *modus operandi*, especially in relation to the oral part of the examination might be vastly improved by substituting a written examination, whenever practicable, for the *viva voce* method, which had undoubted advantages, but was always heavily handicapped by the "personal equation" of idiosyncratic examiner or idiosyncratic student. The greater part of the examination in botany, pharmacy, materia medica, theory of chemistry, and prescription reading could be conducted in writing, even more efficiently than at present. The necessity for reform in these directions was all the more imperative in view of the probability that with the division of the examination and the adoption of the practice of referring a candidate in the subject or subjects in which he is deficient, the standard of the Minor will reach the level of the present Major.

Having seen the assistant safely through the Minor, it is assumed that he will seek the earliest opportunity of starting business for himself. Under the old system it sometimes happened that an assistant grew grey in service, and even died in it. In the meantime, while qualified assistants are relatively scarce, most of them can get a chance of setting up on their own account; but, as the supply once more overtakes the demand, openings will become proportionately fewer, and many assistants will have to be content to plod along the dusty road to death as assistants until the end. It is the evil fashion of the world to treat such lives as if they were failures. But it is gradually coming to see many things in a new light. The spirit of romance teaches us to expect that the hero will always attain wealth and renown, and the villain misery and death, and even the most familiar example of Hogarthian realism shows us the industrious apprentice going on from strength to strength until he is made Lord Mayor of London, while the idle apprentice sinks from depth to depth of infamy until he gets a last lift on the scaffold. The estimable persons who applaud these symmetrical models never stop to reflect that we can't all be rich and renowned, or even Lord Mayors of London. Indeed, it is just because many of us are too scrupulous or too unenterprising to compete for such dignities that they are open to the few, and these not always the most worthy. It is a laudable ambition to aspire to the Presidency of the Pharmaceutical Society, and fulfilment of it may mean moral as well as administrative merit; but worldly success doesn't always spell moral worth, and in spite of the rabid rhetoric of the cantankerous Carlyle, the world owes less to its great men than to the vast body of obscure, decent people who do their duty in a quiet but forceful way.

A short discussion followed, but the general opinion seemed to be that detailed criticism should be left to a future occasion. One member expressed the opinion that the formation of a trades union would only be a method of boycotting the masters. Increased wages must come from the public, not from the masters. As the public wished them to keep open till late he did not see how they could avoid doing it. Two or three times measures had been taken to reduce the hours, but without avail, as some masters always stood out. In reply Mr. GILMOUR stated that the reason they had to work so long was because of the number of drones in the community. It was a curious thing, however, that the demand for drugs was at its minimum between twelve midnight and nine o'clock in the morning, and at its maximum between six p.m. and midnight. He saw nothing to hinder a reasonable arrangement being come to between the druggists in a certain district to keep open by turns. The masters might not like a proposal to form a trades union; but the masters had formed a combination among themselves, with the understanding to keep wages at a certain level. Mr. Gilmour was thanked heartily for his address.

EDINBURGH CHEMISTS', ASSISTANTS', AND APPRENTICES' ASSOCIATION.

The opening meeting of the session was held on Wednesday, November 1, Mr. Fraser McDiarmid, President, in the chair.

Mr. Lennox (Secretary) read the

Prize Committee's Report,

from which it appeared that Mr. G. P. Grainger, 6, Polwarth Crescent, had gained the McLaren Prize, value £2 2s., to be expended in any course or courses of instruction in the subjects of the Minor Examination approved by the Prize Committee.—Mr. David McLaren, in presenting the prize, congratulated Mr. Grainger, and intimated his intention of presenting the prize again, when he hoped there would be a good competition.

The President then proceeded to deliver an address on

The Position of the Pharmacist in the Body Politic.

He referred to the abolition of the Preliminary Examination, the expanding syllabus for the Minor, and the increasing fees for examinations as constituting a very effectual barrier to the ingress of all but the elect, and urged that none can complain of this. Division of the Minor Examination was advocated, the speaker expressing the opinion that a candidate might be allowed to pass in two or three subjects at a time, instead of demanding a full acquaintance with six at a sitting. This is a method allowed by other examining bodies, and ensures a better equipment in the examinee. It was further suggested that the time is ripening for the enforcement of a curriculum of study. Few have the time or means for acquiring a practical scientific knowledge during the long hours of apprenticeship, and must undergo a voluntary course of study at a school of pharmacy. From the volunteer to the conscript is but a stage. Dispensing and pharmacy, of course, are best learned in the shop, in the daily round and common task. Unfortunately, in many towns, dispensing forms but a minute, even a negligible, portion of the work, and pharmacy is rapidly becoming a lost art owing, in some measure, to the great elaboration of processes imposed by successive Pharmacopœias, both in the preparation and standardisation of galenicals. The examination barrier having been passed, the registered "chemist and druggist" should enrol himself among the members of the Pharmaceutical Society. Union is strength. Medical men and lawyers, among the professions, and all the great trades, have their unions, and can largely accomplish their desires. Passing from internal affairs, the speaker next referred to the relation of chemists to the medical profession. He thought there was a tendency to adopt too menial a view of that relationship so far as chemists are concerned. The words "handmaid" and "cook" were not dignified. The ideal ever before both professions should be "prescribing by the medical man, dispensing by the pharmaceutical man," but the application of a little common sense would show that there are times and circumstances in which practice must fall somewhat short of profession. There should be an arrangement—perfectly open and honourable—whereby each participates in the cure of disease, performs the work for which he is specially trained, and receives his due share of the reward. With regard to the relationship of chemists to the public, it cannot be said that chemists have shirked the responsibility imposed upon them by the Pharmacy Act of 1868, though in recent times the privileges supposed to have been conferred by that Act have been slipping from their grasp, owing either to a defect in the Act or in its interpretation. What one unqualified man may not do with impunity it has been declared not unlawful for seven unqualified persons to do. Chemists were agreed that no artificial person should be allowed to continue to usurp the pharmaceutical titles. But what's in a name or title if the substance it implies is vanishing? Upon that point there was great diversity of opinion, and the old war was waging between justice and expediency. It behoved every registered chemist to have his opinion, and to declare it. Suppression of companies appeared to be outside the region of practical politics. Any attempt to read "limited company" or "corporate body" into the word "person" might work havoc in the ranks of friend as well as foe. It was vain also to suggest qualified directorship. The only practicable conclusion appeared to be regulation of companies, while insisting upon qualified managership. In conclusion, the speaker deprecated the growing tendency on the part of the public to doctor itself, and asked whether chemists might not with advantage do what they could to save the public from the effects of placing undue reliance upon the supposed virtues of quack nostrums. It was, he said, a difficult question, especially as not all nostrums are unworthy, some being imitated in the Pharmacopœia or otherwise. But surely it needed no training in therapeutics to be assured that remedies purporting to cure anything or everything, from rupture of the aorta to broken chilblains, should be left to the dispensing of the market cheap-jack, and not advertised as being "sold by all respectable chemists." The most effective method which any class of men can adopt for securing their political rights and advancing their professional standing consists not in disputation and warm argument, but in a steady and persevering attention to intellectual improvement, and the establishment of such regulations as are calculated to ensure collective privileges by increasing the amount of individual merit.

Mr. Harley (Vice-President) moved a vote of thanks to Mr. McDiarmid for his address.

Mr. John Bowman (Leith) seconded the motion, and in doing so mentioned that he would be glad to continue his Botanical Prize of £1 1s. for another session.

Mr. David McLaren said he had listened with much pleasure to the address. In regard to the hard battle referred to, he thought it was most unfortunate that the Society consisted of a minority of registered chemists. They were not in a favourable position for making much advance unless that minority could be turned into a majority. The majority evidently wanted a share of all the loaves and fishes, and why they did not join the Society was one of those things he had been quite unable to get an answer to. It was only when the Society was properly supported by the registered chemists of the country that the Council would be able to go to the Legislature and effectually demand the full recognition of the rights of chemists and druggists.

Mr. Boa said he had much pleasure in supporting the vote of thanks to Mr. McDiarmid for his interesting and delightful address Though he had not indicated anything very specific, he had made suggestions on several points which might develop into something useful if taken up by those who tried to legislate in pharmaceutical matters. He trusted they would have a successful session, and that the papers read at the meetings would be as good as usual.

The motion was passed with acclamation, and Mr. McDiarmid briefly replied.

Mr. J. G. Sclater was elected Treasurer in place of Mr. McCutcheon, who is leaving town; and Mr. W. F. Buist was elected assistant secretary, in place of Mr. Kidd, resigned.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The annual *réunion* of some two or three hundred members, new and old—assistants of to-day and of times long past—and a sprinkling of patrons, took place on Thursday evening, November 2, in the Throne Room, King's Hall, Holborn, Mr. P. W. Squire in the chair, his companion in the vice-chair being Mr. William Warren, member of the Pharmaceutical Council. It is an encouraging sight, and augers well for future pharmaceutical unity, to see employers and employed seated together enjoying the social pipe. This feature of the annual *réunion* evidently appealed to Mr. Warren, who, in replying to a vote of thanks—to which reference will be made later—urged the necessity for the cordial co-operation of proprietors and assistants against

The Common Enemy—Company Pharmacy.

The Committee had arranged an excellent entertainment of vocal and instrumental music, humorous sketches and recitations, which, under the efficient management of the hon. secretaries, Mr. Charles Morley and Mr. T. Edward Lescher, was brought to a successful issue. One item, not down on the printed programme, gave general satisfaction, viz., a recitation "Leetle Yawcob Strauss," by Mr. T. Morley Taylor, past-president of the Association, and a first-class amateur reciter. During an interval, after the toast of "The Queen, and Success to Her Majesty's Forces in South Africa" had been honoured and the National Anthem sung with patriotic fervour, another item—apparently unofficial—was announced by the vice-chairman; this was of a practical character, taking the form of a collection

In Aid of the Widows and Orphans

of the soldiers killed whilst fighting against the Boers. It was an appropriate finish to the enthusiastic outburst of patriotism which preceded, and although there was a suspicious murmur in at least one quarter that savoured of grumbling, like true Britons everyone seemed to contribute his mite, the sum collected for the *Daily Telegraph* Fund amounting to £6 7s.

VOTES OF THANKS.

The PRESIDENT, Mr. F. W. Gamble, then proposed a hearty vote of thanks to the Chairman and Vice-Chairman. He said that perhaps no name was better known throughout the pharmaceutical world than that of Mr. Squire. By his aid most of those present had gained their first professional knowledge. Mr. Squire having led them in their studies, his presence there that night was in the eternal fitness of things. Mr. Warren had been the very enthusiastic manager of the Chemists' Balls for several years, and was consequently well-known ; moreover, he was a member of a body to which that Association had before time extended its sympathy—the Pharmaceutical Council. It was at the present time burdened with a very great responsibility, and he hoped it would be able to carry that burden to a satisfactory conclusion, a conclusion that would be to the ultimate benefit of every member of the craft.

The CHAIRMAN briefly replied to the vote of thanks, and expressed his pleasure at being present that evening.

THE COUNCIL AND THE COMPANY QUESTION.

The VICE-CHAIRMAN also replied. Referring to the remarks made by the President, he said if pharmacy was to be a calling worth following, the cordial co-operation of proprietors and assistants was most necessary. If they were not to be led in bondage by company pharmacy, the Council must have the assistance of both wings of the pharmaceutical army. As would be seen from the report in the Journal there had been a battle royal at the Council meeting held the previous day. The question was whether company pharmacy should be abolished or regulated? If that question was to be settled satisfactorily the Council must have the support of all the forces it could command.

The second part of the programme was then proceeded with, a very enjoyable evening terminating by the singing of "God Save the Queen."

MIDLAND PHARMACEUTICAL ASSOCIATION.

This Association inaugurated the winter session with a meeting held at the Great Western Hotel, Birmingham, on the 2nd inst. The PRESIDENT (Mr. Jeffrey Poole), was in the chair, and there was a large attendance.

Alderman W. GOWEN CROSS, J.P., of Shrewsbury (a member of the Pharmaceutical Council) delivered an address on

Pharmaceutical Politics,

which will be found, printed in full, at page 438 of last week's issue. At the conclusion of the address,

Mr. A. SOUTHALL moved a vote of thanks to Alderman Cross, remarking that by the paper they had been inspired for some hard work. As pharmaceutical chemists they wanted someone to guide and lead them in the matters of which Mr. Cross had spoken. It seemed that the Council of the Pharmaceutical Society was too timid to move in such matters. The members were pretty nearly divided as to the matter of altering the Companies Act, and he hoped that Birmingham might be able to suggest something which might be helpful to the Council. Mr. Cross would be satisfied, apparently, if they kept their titles, but that would not satisfy him (the speaker). He thought they ought to be able to regulate, and regulate successfully, what companies should do, and to do something to prevent them doing harm to pharmaceutical chemists.

The vote was seconded by Mr. W. JONES, who also referred to the question of company trading, and urged that something should be done to afford pharmacists something in the shape of protection. When a man, after years of labour, had earned his diploma, he should have some better prospect than the possibility of opening a shop and being opposed by a cutting process in the adjoining shop. He was as much entitled to protection as a solicitor, for instance, and he hoped such protection would be provided in the Companies Bill.

The meeting heartily accorded the vote, and Mr. CROSS briefly acknowledged it.

A programme of music was afterwards gone through, in which Mr. S. J. Halliday, Mr. S. Stoddard, and the Moseley Quartette took part.

LEEDS CHEMISTS' ASSOCIATION.

The thirty-first annual general meeting was held in the Church Institute, on October 31, the PRESIDENT (Mr. E. Yewdall) in the chair. The HON. SEC. (Mr. W. D. Pollitt) read the following report :—

ANNUAL REPORT.

"The Committee has to report that during the past year the aim and object of the Society have been kept steadily in view. In consequence of extensive structural alterations the room formerly used as a library has been demolished. The book cases and the materia medica cabinet have been moved into a more commodious room upstairs, which is lighted by electricity, and can be readily made comfortable for students. A meeting of the members was held to consider the draft Pharmacy Bill, which was well and carefully criticised, and it was agreed that the prospect of legislation for removing some of the abuses at present existing in the State regulation of pharmacy was gratifying, and it was hoped would eventually result beneficially. The regulations for the storage of poisons which had been sanctioned by the Privy Council were discussed, and the ways and means of conforming to each regulation afforded a pleasant opportunity for the interchange of opinions. Several bottles for the storage of poisons, and labels to be attached to other bottles for preventing mistakes, were shown, and examined. The Committee is alive to the interests of the trade in connection with the proposed Companies Bill, and will carefully watch its progress, and if possible get such clauses added thereto as will meet the wishes of the registered chemists of this city. There has been a slight increase of members, although death has removed Mr. Chadwick, and Mr. E. Brown has retired into the country."

The financial statement was read, and showed a small balance due to the Hon. Sec. The report and balance sheet were adopted on the motion of Mr. BRANSON, seconded by Mr. BOWMAN. On the motion of Mr. WORFOLK, seconded by Mr. ANNING, votes of thanks were accorded to the Pharmaceutical Society for the gift of the *Pharmaceutical Journal*, and to the Executive Committee of the British Pharmaceutical Conference for the gift of the 'Year-Book of Pharmacy.'

ELECTION OF OFFICERS.

The following were elected officers and Council for the ensuing year :—President, Mr. E. Yewdall, Ph.C.; Vice President, Mr. G. W. Worfolk ; Hon. Treasurer, Mr. J. J. Anning; Hon. Secretary, Mr. W. D. Pollitt. Council : Messrs. F. W. Branson, F.I.C.; F. C. Long, Ph.C.; W. Johnson, R. Reynolds, F.I.C.; S. Taylor, and G. Ward, F.I.C. Auditor, Mr. J. H. Beacock.

PLYMOUTH, DEVONPORT, STONEHOUSE AND DISTRICT CHEMISTS' ASSOCIATION.

The Annual Dinner of this Association was held at the Freemason Hall, Plymouth, on Wednesday, November 8.

The PRESIDENT (Mr. F. MAITLAND) occupied the chair, being supported by Mr. G. T. W. Newsholme (Vice-President of the Pharmaceutical Society), Messrs. J. Davy Turney, J. A. Lamble and F. Downing (Vice-Presidents of the Association) ; Messrs. C. J. Park, W. H. Woods, F. W. Hunt, J. K. Bond, B.A., G. Breeze, J.P., C. T. Weary, H. P. Hearder, Condy U'Ren, R. F. Roper, J. H. Bailey, Martin Johnson, J. W. B. Swainson, H. D. Davey, S. A. Perkins, E. W. H. Green, F. H. Ralph, M. Ryall, G. Fairweather Lamble, Blackmore, Pote, Venn, R. R. Rodd, W. W. Blight, A. Maitland, H. Roberts, A. Debnam, T. W. Ginn, F. Mortimer, J. Balhatchet, H. Whitfield, W. W. Wakeling, J. Perry, W. Pryor, Baker, F. Mabin, S. E. Venn, W. Hartnall, F. Underhill, R. Quance, and others.

After an excellent dinner, the usual loyal toast was proposed by the Chairman and duly honoured.

Mr. R. F. ROPER, in proposing the toast of

THE PHARMACEUTICAL SOCIETY,

said its path at the present time was beset with difficulties, in meeting which it deserved the very best support, not only of its members but of every chemist on the Register. As was well known, those difficulties had arisen through the incomplete Act of 1868, supplemented by the pharmaceutical Majuba of 1881. There could be no doubt that had the Council of that day displayed the same energy in dealing with the matter, in the direction of pressing for fresh legislation, as had been

exercised by the Council of late years, the result would have been more satisfactory to the calling of pharmacy, but the Council had to deal with things as they existed, and it was a hopeful sign that it should now be so much in earnest over the necessity of an exhaustive consideration of the line of action necessary to adopt. In view of the contents of the Companies Bill he was sure that the greater extent to which the members of Council could take their constituents into their confidence the greater would be the interest and support accorded them. At the same time, he considered it obvious that the Council had not made the greatest possible use of the Society's existing machinery and that of outside organisations, so as to focus the requirements and opinions of chemists who, as a body, are somewhat difficult to get at and, when got at, are slow to realise the possibilities of a united front, the fact being that a man who spends from twelve to fourteen hours a day in the drudgery of his business is not in the best condition to take up energetically even his own defence. So long a confinement had a great tendency to take the backbone out of a man; frequently all he asked was to be let alone and exist as best he might and, of course, grumble at all things pharmaceutical. Chemists must, therefore, look to the Council, as leaders, to ascertain what is best. In the interests of those who from various circumstances rarely attend meetings, as well as those whose opinions receive more ventilation, he hoped and believed chemists would not look in vain for the adoption by the Council of a line of action best calculated to promote the well being of all; it would then remain to be seen if there was sufficient latent energy amongst the chemists of the country to give the support necessary to carry the adopted policy to a successful issue. At the last Council meeting the Council was unanimous in its determination to protect chemists' titles and, after careful reading of the speeches made, he must say, that whilst his sympathies were with the minority over the question of dealing with the stores, his judgment was with the majority. The minority were perfectly logical in the position they took up; but was it capable of practical issue? He regretted to say he thought it was not.

Mr. Newsholme, in responding, said that he had been connected with the Pharmaceutical Society for a considerable number of years, and had visited a number of associations throughout the country. He had noted particularly the progress made by the Plymouth Association, which had done work which would tell to the great advantage of chemists, not only of the district, but of the country at large. Many associations of a similar nature had sprung up throughout the country during the last few years, and he had very much at heart the question of organisation. He had advocated that there should be local secretaries in each Parliamentary division, who should be in a position to educate members of Parliament on the question of the rights and wants of pharmacists. It was very unfortunate there should be the existing anomaly in the law regarding pharmacy. He thanked Mr. Roper for his mild criticism of the Council, and should like to say, with reference to the Act of 1868 and the decision of the House of Lords of 1881, that the Council of that time did try to amend the same, and various Bills were introduced which dealt with that question and many others. Amongst other Bills, the Council introduced the Bill of 1883, which would have established a compulsory curriculum. That would have been the best thing for the present-day pharmacists. He was very glad, as a member of the minority, to have Mr. Roper's sympathy, and hoped, before very long, that the minority would be turned into a majority. He was one of those who believed that it was not the business of the Council to see that companies were regulated. With regard to the practice of pharmacy, the Lord Chancellor said he could not see why a company should be allowed to do what an individual should not do, and he took it that companies had no right to practise pharmacy, notwithstanding the decision of the House of Lords. In 1868, pharmacists were given certain privileges, and it was in the education of the vendors that the only safeguard to the public lay. They would depart from that position if they now consented that individuals who cannot pass the examinations may form a limited liability company and control the sale of poisons. Whatever was to be done, however, in any direction must receive the individual support of every chemist of the country, as it was useless going to the House of Commons to ask for anything to be done unless the Council was supported by every pharmacist in the country. They did not want more than was right, but they must try to stick to the principles laid down in 1868 for the protection of their titles and the sale of poisons.

Mr. Park also responded. He remarked that if a person representing a drug company was prosecuted, he sheltered himself under the Companies Act, and he thought it was quite time there was legislation on the subject.

Mr. Blight, in proposing the toast of

"The Local Association,"

remarked that the matters mentioned by Mr. Newsholme and Mr. Park should be supported, not only in the interests of chemists but of the public at large.

Mr. Maitland (President), responding for the local Association said it would be unnecessary to recapitulate the work of the past year, as only recently the annual report had been issued. He was pleased to say the Association was in a very flourishing condition, they now numbered 141 members, and were steadily increasing. The most important event of the past year was the meeting of the British Pharmaceutical Conference; everyone seemed pleased, and the Association could congratulate itself upon its success. In educational matters good work was still being done for the Juniors, and though the valuable services of Messrs. Reade and Johnson had been lost, they had fortunately obtained in Mr. H. Marston Morgan a splendid substitute, who was ably conducting a class in pharmacy during the winter session. The trade section is still highly appreciated by the members, and is in good working order, there being some prospects of still further developments. As to the future of the Association, that could very well be left to the members themselves, they must be watchful, and render all the help possible to the parent Society, as it is only through them that any redress could possibly be obtained. They had heard this evening of some possible legislation affecting chemists, but whatever was tried for, all members were agreed that their title must be protected.

Mr. Lamble then proposed the toast of "The Honorary Members and Visitors," which was responded to by Mr. J. Kinton Bond, after which the proceedings then terminated.

MANCHESTER PHARMACEUTICAL ASSOCIATION

The second meeting of the session was held at the Victoria Hotel, on Wednesday, November 8. Mr. Harry Kemp presided, and, introducing Mr. John Smith, of Liverpool, said that gentleman might not be so well known to many of those present as to himself. He had had the pleasure of his acquaintance for a great number of years, and as far as pharmaceutical matters were concerned his heart was in the right place. They might not always see eye to eye on matters of pharmaceutical polity, but he said emphatically that he was most energetic, most enthusiastic, and most conscientious, and whatever he said or did was done in all honesty and candour. He had been, as they knew, a candidate for a seat on the Pharmaceutical Council. Unfortunately, he was not successful. He was not going to flatter Mr. Smith, but he might say, without drawing any invidious distinctions, that, in his opinion, he would have been much better on that Council than some of their present representatives. He now had pleasure in calling upon Mr. Smith.

In his opening remarks, Mr. Smith said the Chairman had remarked upon his candidature at the last election. He did not wish it to be thought that he was on an electioneering expedition. As far as he saw at present, he should prefer to make himself useful outside the Council, and if it was thought he could do any good, in conjunction with his colleagues on the Executive Committee of the Federation, he should prefer to remain outside and in that position. Mr. Smith then proceeded to read his paper on

Local Pharmaceutical Associations and Their Federation,

which is printed in full at page 447. In conclusion Mr. Smith said: I have wandered from the subject of my paper this evening, but the importance of the circumstances must be my excuse. My views on the pharmaceutical position may be open to criticism, therefore I do not ask this meeting to commit itself by vote. An opportunity will no doubt be provided within the next week or two for your Association to make known its opinions upon the very difficult question the Council of the Pharmaceutical Society has to solve.

Mr. Kirkby said he had very much pleasure in proposing the best thanks of the meeting to Mr. Smith for his excellent paper. The subject was hardly a new one, but whilst coming to the meeting that night he could not help thinking that Mr. Smith would be tempted to deal with matters which had occupied the attention at the last Pharmaceutical Council meeting. All of them were agreed, he thought, on one point, and that was, that it is eminently desirable that, by some means or other, pharmacists through-

out the country should come into correspondence and into touch with one another, in order that their influence may be more felt in pharmaceutical politics. They all deplored that so small a proportion of pharmacists of the country were associated with the parent Society. Within their own recollection many attempts had been made to generate in the minds of pharmacists some enthusiasm for the parent Society. What the actual obstacle was perhaps hardly any one of them could indicate. No doubt a variety of causes operated against the enlargement of the Society. Mr. Smith referred incidentally to the history of the Federation. It had a history of probably five or six years, and it had occurred to him that the one thing absolutely necessary for the Federation, in order to make it more acceptable to pharmacists at large, was some kind of policy. He had looked year after year for

THE FORMATION OF A POLICY

of some kind. The utmost he had been able to gather was that it was willing to help and support the Pharmaceutical Council in everything that was good, and that it would oppose it in everything that was evil. Beyond that, he had not seen it had a mind of its own. Possibly that might be due to a change of officers year after year, but if they had one officer, a secretary or a president, remaining in office, they might be more successful in that respect, and the Executive Council which had been formed might formulate a policy. Where business had to be done by correspondence a large amount of time was wasted in getting the views of individual members If they had an opportunity of meeting two or three times a year, they might possibly draft a policy of some kind. Mr. Smith had referred also to the fact that the Federation was living down the distrust which first appeared to arise in the minds of some as to its possible hostility to the Pharmaceutical Council. He thought the members of that Council were satisfied that the aims of the Federation were in accord with their own. Concerning the thorny question of company pharmacy, he supposed they all had a little difficulty in saying just what they would like. A large amount of correspondence had taken place in the papers, and the majority of those who had written the letters had given expression to what they would like to see brought about. The time had come when, as a community, they must try and find out what it was possible for them to obtain, and not so much what they would like to obtain. He thought they might congratulate themselves as pharmacists that the policy of silence in the Pharmaceutical Council had come to an end. Many things had contributed to bring that about, but he must say that the last report of the Council was the only one he had read with satisfaction for some years past, simply because one had felt, formerly, that there was a show being enacted for the benefit of the readers of the *Pharmaceutical Journal*. That policy he hoped had passed away for ever, and he hoped henceforth they would know in what position each man stood who wanted to be on the Pharmaceutical Council. They might expect that next year a larger amount of interest would be taken in the elections, and that the members would see that every man's votes would be thoroughly criticised, and in what direction his work had tended. To come more closely to what they might hope to get,

THERE WERE TWO FACTORS WHICH STOOD OUT,

or should stand out, very plainly before them as pharmacists. One was that when the Act of 1868 was given to them by Parliament, it was undoubtedly a compromise, and was intended simply to safeguard the public in the matter of poisons. The judgments which had been obtained in the courts of law since that time had evidently been given on that understanding. The last information they had from the Legislature was that they would give nothing to pharmacists in the nature of a monopoly except what was for the public good. At the same time, he thought they were entitled to take it for granted that, when the Legislature demanded that pharmacists should undergo an advanced system of education, in order to qualify for the stiff examinations to be afterwards passed, it was thought only right they should have something in the nature of a *quid pro quo* in return. He was very much interested in regard to what Mr. Walter Hills stated in his speech last week. He said he had had a conversation with a member of Parliament, and he left it to be inferred that the member of Parliament thought they had very little chance of getting a measure passed enabling them to return to the state of things which was thought to be possible under the 1868 Act—that they had to reckon with company pharmacists on the ground that companies had got vested interests, and that those interests had so become intertwined, so to speak, with those of the community at large, that there was very little chance of their being done away with. He (Mr. Kirkby) was not satisfied that was quite the right way to put it. His experience, when he had put the facts historically before medical men and others outside Parliament, had been that they all thought it was

VERY HARD LINES FOR THE PHARMACISTS,

and he could not help thinking that if some member of their body who had the facts at his fingers' ends would write a short account of the ins and outs of the matter, and it could be distributed generally, they would feel that theirs was a case in which injustice had been done. He hoped the Federation would be able to do something on those lines. It would come even better from an outside organisation of that kind than from the Pharmaceutical Council itself. What was the best thing to be done was rather a puzzle. It was said in the Council chamber to be a matter of tactics at present; but while that might be so he thought it would be well that they, as pharmacists, should insist upon the fact that there was a principle at stake, which they must adhere to. It was a matter in which the public welfare was involved; and, secondly, it had to do with men who had a vested interest, seeing that they had to have a high education and undergo much technical training to qualify them for the work. In that way they would be more likely to obtain a larger measure of justice than if they simply left members of Parliament to understand that they were trying to obtain a monopoly.

Mr. A. J. PIDD having seconded Mr. Kirkby's motion,

Mr. WALTER GIBBON, in supporting, said Mr. Smith had emphasised in his mind the saying—organise, organise, organise. Real organisation was the thing which had been felt necessary for many years past in regard to pharmacy, and he believed that the Federation which Mr. Smith had advocated so strongly that evening had a great future before it in that respect. The Pharmaceutical Society itself was primarily an educational body, and he might add also a Parliamentary body; but they must have some other body to assist it in organisation, and that they had in the Federation. In regard to the observation made by Mr. Kirkby as to the conversation Mr. Walter Hills spoke about, his experience coincided with that gentleman as to the impossibility of obtaining a monopoly, but he contended that they could have pharmacy regulated in such a manner as to do justice to the qualified chemist, especially in connection with the dispensing department. He trusted that the Federation would initiate a policy so as to bring about that desirable organisation which had been lacking in the past.

Mr. LANE said the matter was one of very great importance from the view of the pharmacist. It was very important that the public interest should be thoroughly protected, and he believed that in going to Parliament the Pharmaceutical Society had that end in view, and that it was for the public good. They had, however, to look at the question in a practical manner, and he held it was not necessary that the actual proprietors of a shop should be qualified men. All that was necessary for the public safety was that the men in charge should be properly qualified, and he thought those seemed to be the lines on which they would have to go to Parliament. He agreed with Mr. Smith as to the work which it was within the province of the Federation to perform. Although they had not seen much result from it at present, he thought it would have an excellent growth in the future, and that it could be a great support to the Pharmaceutical Society in putting forward definite conclusions arrived at by the local associations.

Mr. GRIER said he had not come to any conclusion on the question of company pharmacy, but, to be logical, he thought chemists would have to give up branch shops if it was not legal for a company to carry them on.

The CHAIRMAN put the vote of thanks, which was carried by acclamation. Subsequently, referring to a remark of Mr. Kirkby, he said he was in at the birth of the Federation, and he had been almost afraid he was going to be in at the death; but he trusted they had now arrived at a point when that suckling would develop into vigorous growth. Mr. Kirkby had expressed a hope that the Federation would formulate a policy. He might tell Mr. Kirkby and those present that the one strong point which had been urged against the Federation from its very inception was that it should not formulate a policy, but that it should look to the different local associations to formulate that policy, and that the Federation should then try and carry it out. They were not there to hinder or to be antagonistic to the Pharmaceutical Council. Loyalty to that Council was one of the keynotes of the Federation as a whole, but that did not, of course, apply to every individual member. He himself thought the Pharmaceutical Council would make a great mistake if it attempted to legislate to regulate company phar-

macy. There could not be any reason why six or seven men should not be allowed to do what it was perfectly competent for each of them to do as individuals, but that did not say they were to admit that any six people who liked to band themselves into a company should be allowed to carry on a business which, after all was said and done, was a personal business.

Mr. Smith having replied, the proceedings terminated.

LETTERS TO THE EDITOR.

The Company Pharmacy Problem.

Sir,—Kindly correct your report of what I said at the Council meeting, in last week's issue of the *Pharmaceutical Journal*. Thus, at p. 429, left-hand column, line 18, for "unobtainable," read "unattainable," and at line 20, in place of "*chemists* had enjoyed the privilege of carrying on their practice for the last twenty years, and were now beginning to assume the chemists' titles," read "*companies* had enjoyed," etc. Wm. Martindale.

10, *New Cavendish Street, London, W., November* 7, 1899.

Sir,—I am reported in the *Pharmaceutical Journal* of the 4th inst. to have said at the last meeting of the Council that I "did not object to a qualified person being the servant of an unqualified person." I beg to point out that I distinctly said that I did object to such an arrangement. Whilst asking you to make this correction, I should like to take the opportunity of saying that I referred on that occasion to Mr. Rutherford Hill's recent address, with the object of expressing an opinion that, if it were found expedient by many of our well-trained pharmacists to develop their business in other directions than that of pure pharmacy, it was undesirable to prohibit them, by Statute, from taking advantage of the limited liability principle. I ask you to allow me to make this explanation, as the condensed report of my remarks does not appear to make my meaning as clear as I could wish.

225, *Oxford Street, W., November* 7, 1899. Walter Hills.

Sir,—As an individual pharmacist I beg to be allowed to give expression to my astonishment that ten members of the Council of the Pharmaceutical Society have yet to make up their minds whether or not it is right for companies of unqualified persons to practise pharmacy. The proceedings at the last Council meeting must have struck consternation into the heart of many a pharmacist throughout the country. Surely the Council is prepared not only to defend our titles but also to insist on the justice of restricting the practice of pharmacy to qualified persons on the lines proposed by the Lord Chancellor for dentistry, etc.! Recently in discussing the company pharmacy question with the president of one of the most influential provincial grocers' associations I was informed that if the practice of pharmacy by companies of unqualified persons is legalised the grocers of this country will inaugurate amendment of the Pharmacy Acts, their object being to gain for individuals the right bestowed on corporations, viz., to practise pharmacy by the employment of duly qualified assistants. I commend this possibility to the serious consideration of members of the Council of the Pharmaceutical Society. To abandon the principle now at stake without making a vigorous endeavour to uphold it would be to weakly betray both the interests of the public and those of every person at present qualified under the Pharmacy Acts.

Clifton, November 4, 1899. Harold E. Matthews.

Sir,—The policy of the Council in drawing up a clause for the Companies Bill should be to construct it so as to express what we think reasonable and just to all likely to be affected by its operation, and, at the same time, to be capable of modification to meet the views of others who differ from us, and are strong enough to command attention. I have no great respect for those who refuse to accept anything which falls short of what they think justice to themselves, whether they be ordinary pharmacists or pharmaceutical ex-Presidents. I think we ought to accept any move which is a step in the right direction—a step away from the legally established reading of the present Acts relating to the practice of pharmacy by unqualified companies. If we fail to draft a clause which can be passed in the Companies Bill, we may fairly be told afterwards that we cannot make a Pharmacy Bill to interfere with any Companies Act which may be in operation. Accepting the clause as proposed, and rejected at the recent Council meeting as my basis I suggest its modification as follows:—

No company shall (carry on the business of a chemist and druggist or) assume or use the title of pharmaceutical chemist, or pharmaceutist, or pharmacist, or chemist and druggist, or chemist or druggist, or dispensing chemist or druggist, or any other title implying registration under the Pharmacy Acts, *unless such company be under the direction of legally qualified men only*, and if any company contravenes this enactment it shall be liable to the same penalties as those enacted in the case of individuals under the Pharmacy Acts. The words in italics are intended not to square Southall and Symes, but in justice to them and all other companies who may govern their working in manner equally satisfactory in the interest of the public good. The words in brackets are reasonable and desirable from our point of view, but might be struck out if need be to save the ship from being sunk by over-lading. They should only be thrown overboard as a last resource. Rather than that nothing should be accomplished towards the extinction of unqualified pharmacists, I should offer registration as chemists and druggists, to all directors of legitimately constituted companies—*i.e.*, not one-man companies formed to evade personal liabilities—at present carrying on the retail drug trade. This, subject to the above clause, would eventually eliminate unexamined men from the directorate of pharmaceutical companies, and would show all the respect for vested interests which any person could reasonably look for. It would only be carrying out the same policy as was adopted in Clause 3 of the Act of 1868, which enabled any old soldier with a few packets of salts and a blue bottle in his window to claim his place on the Register. But future candidates for the directorship of any companies carrying on trade in drugs should be required to pass the Minor Examination, before being eligible for election. This may be said to be equivalent to putting the clock twenty years back; yet twenty years hence the position of pharmacy would be better than it is likely to be if the contest goes on as it has been doing since the judgment of the House of Lords. If the gradual extinction of unexamined directors was not to be thus permitted, I should strike out the words in parenthesis, and go in for the preservation of our property or titles with all the energy we can employ. The weak point in our action lies in the fact that all our motive force is derived from self-interest, and however much we may attempt to put another face upon it, this motive is apparent to acute observers from the outside. Public safety may very well be left to the public care, and when Parliament finds that danger lurks under the precautions it has enacted, it may be trusted to adopt something more effective. It will be to our credit if we put on record now any disinterested suggestions which may at a future time be found requisite. But so long as our action aims at helping the profits of legitimate pharmacy, and is taken in response to the cry of the trade, the Pharmaceutical Council must be a compound of simple bodies if it thinks it can get much help from the custodians of the people's interests. If the titles are protected, anyone incorrectly saying that an accidental poisoning, or a sale of adulterated drugs, was the fault of a chemist, when the culprit was not on the Register, should be prosecuted for slander. This would educate the public to the true sources of danger.

Bradford-on-Avon, November 6, 1899. Barnard S. Proctor.

Sir,—The summing up by the President of the discussion at the meeting of the Council is so much to the point, and so well focusses the issue, as to demand examination. There can be no gainsaying the earnestness now of every member of the Council or their determination to lift pharmacy out of the bog she is in, for, as one member of the Council stated,

> There was not the thickness of a piece of paper between those who said that companies ought to be on the same footing as individuals and the position he wished to lay down.

Let us try to see what this piece of paper is made of, and, with your permission, I propose to examine the arguments of our esteemed and accomplished President. He says:—

> (1) That the Council (I presume he means the Privy Council) has had the refusal of those suggestions, and had in plain English refused them.

This is mere surmise—we think—unlikely to be true, and unsupported by a single argument. Those suggestions undoubtedly forced the Lord Chancellor to lay bare the situation. He put the matter in such a way as to compel us to declare what we were fighting for. We did so, and he rearranged the case, at the same time going out of his way to say in plain English: "That company pharmacy and personal qualification could not cohere." He prac-

tically also said that we must assert this principle or accept another proposition—viz., that our qualification is different from a medical or a legal one, inasmuch as it may be exercised vicariously; that is to say, unqualified people may practise pharmacy through qualified persons.

(2) If they had the title protected the practice would go with it.

Upon this the whole question of company pharmacy hinges. It needs to be true. If it is true, well and good; if not, our business is to make it true. The air gets clearer. In medicine and law it applies because they have penal powers, but suppose it possible to get this cumbersome and unnatural qualified directorate, how will it be impossible for the unqualified practitioner of pharmacy to get a qualified directorate having only delegated powers? It is acknowledged that this must have "sole and absolute control." Surely the onus of demonstrating the possibility of this falls upon the authors of this scheme. The arrangement must be one which would not be "infamous" in medicine or law. Mr. Carteighe well shows up the folly of such impracticable roundabout methods, allowing something and tying it up so as to be nothing. Surely a direct claim is more dignified than an indirect one, simplicity easier than complexity. We agree to protect the title—*i.e.*, to prevent unqualified persons practising under the law. The legalising of company pharmacy in any shape or form means repeal of the Pharmacy Acts. That some of our own members may be affected by its abolition is not pertinent to the discussion.

(3) We failed in 1881, we must, therefore, fail now.

Circumstances are so different now as to make this remark inappropriate. The Council's policy of consistently increasing the rigour of the examinations is a powerful factor now. That there is a body of chemists virtually the product of over thirty-one years' compulsory examination is another essential factor. Besides, what is the attitude of the public? It wishes an intelligent distribution of drugs—dispensing and handling in every way. It cries aloud for this by incoherent voice, at inquests, in the Press, in everyday life. Yet there exists a body—examined, regulated, and trained—for the very purpose acknowledged to be so desirable.

(4) To completely stop company trading was impossible.

Company trading is not under discussion. Company practice of pharmacy is under discussion as being incompatible with the Pharmacy Acts, which ask for personal qualification to do specified work. Why does it need so much repetition that trade monopoly is "off-side." We need the travesty of pharmacy existing to be put on the only footing which will make it possible for the "practice to go with the title."

(5) It had got such a hold upon the Government that, whoever one talked to outside their own members it was hardly possible to obtain a patient hearing they were so convinced that the public was dead against them in the matter that it was hardly worth their attention.

Dear me! The public against us! We have been testing this for the last two years, and I have yet to hear of an intelligent person who will give a patient hearing to anyone who suggests that we may chop or deal in any way with our responsibility acquired by examination. Surely it is not to red-tape we are going to ask what we can or cannot accomplish! Moreover, every fact which has occurred in Parliament during the last two years relative to pharmacy refutes the assertion.

If the President can establish his arguments, the recommendation of the Law and Parliamentary Committee falls to the ground. If he cannot substantiate them, the sub-Committee gets a powerfu supporter.

R. LORD GIFFORD.

Blackburn, November 7, 1899.

Pharmacists and the Pharmacopœia.

Sir,—It seems desirable that pharmacists should show in a practical manner their interest in the improvement of each successive Pharmacopœia, and thus prove their claim to a share in the production of that work. Their interest might be made evident in an effective manner through the British Pharmaceutical Conference if those who are daily engaged in the manufacture of pharmacopœial preparations would keep a record of the difficulties met with and of possible improvements in the preparations and in the tests for the purity of drugs. It is generally recognised that the results obtained in operating upon large and small quantities vary within certain limits, so that records from wholesale druggists, pharmacists who make their own preparations, and hospital dispensers, would each possess a value of their own. Such records if summarised and presented each year in the form of papers to be read at the Pharmaceutical Conference would not only form a valuable commentary on the Pharmacopœia, but would afford incontestable evidence that pharmacists are alive to their responsibilities, and equal to the position they claim as co-workers with the medical profession in the production of the national Pharmacopœia. I would, therefore, urge upon pharmacists generally, and upon the members of the Conference in particular, the importance of recording observations upon the practical working of the present Pharmacopœia. I should esteem it a favour if those who are willing to record such observations, and present them in the form of papers to be read at the meeting of the Conference in London next year, 1900, would kindly intimate their intention to me or the Honorary Secretaries at as early a date as possible.

E. M. HOLMES,
President of the British Pharmaceutical Conference

17, *Bloomsbury Square, London, W.C., November* 7, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Gold Paint Medium (E. G.—36/3).—It appears to consist of pale quick-drying copal varnish diluted with turpentine.

Purity of Water (S. W.—35/30).—The permanganate test affords a ready means of determining the freedom of water from more than traces of organic matter.

Alleged Infringements of the Pharmacy Act (D. L.—35/27).—The particular cases you refer to should be reported to the Registrar of the Pharmaceutical Society.

Analysis of Urine (S. W.—35/30).—The best small work on the subject in Legg's 'Guide to the Examination of the Urine' (Lewis, 3s. 6d.), but you should also have Allen's 'Chemistry of the Urine' (Churchill, 7s. 6d.) for reference.

Definition Wanted (J. L.—6/23).—Decidedly the phrase requires a definition, and fame awaits the individual who can supply one. In the course of years, after you have gained some experience, you may even be able to tackle the problem yourself.

Preliminary Examination (J. W. C.—36/5).—The Oxford Junior Local Examination certificate is accepted under the present regulations for the three subjects you mention, but after August next an examination must also have been passed in a modern foreign language, algebra, and English.

Physiological Effect of Saccharin (J. T.—35/32).—It is extremely improbable that saccharin acts as you describe; it is generally considered to be practically inert, passing through the system and being excreted unchanged. In the case of delicate stomachs, it has been supposed to give rise to dyspepsia, but that is doubtful. The persistent sweet taste is unpleasant to many palates, and a continued course of the drug gives rise to a feeling of nausea, in some instances, from that cause.

Tinctura Opii Aquosa (D. L.—35/27).—It is usually prepared from "stock recipes" for veterinary use, and varies somewhat in strength; that usually met with being about half the opium strength of the B. P. tincture. It is prepared by exhausting the opium with hot water, filtering, adding about 15 per cent. of rectified spirit, and adjusting to the required volume. The following old formula for "Tinct. Opii Muriatica" (Nichol) is sometimes employed:—Powdered opium, 1 oz. (troy); hydrochloric acid, 1 fl. oz.; distilled water 20 fl. oz. Macerate for fourteen days and filter.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

TINCTURE OF STROPHANTHUS. A. C. Loewe and W. L. Scoville have experimented with a view to removing the fat from tincture of strophanthus by cooling it below the normal temperature. The most satisfactory method resorted to was cooling with a mixture of ice and salt, the tincture being maintained at a temperature of —14° C. for two hours. At the end of that time there was an abundance of a semi-flocculent greyish sediment floating in the liquid and, after filtering at as low a temperature as possible, the tincture was bright, clear and of a light brown colour. Attempts were also made to combine the strophanthus fat with a wax or hard fat before separating, but the results were not so satisfactory. Spermaceti proved very wasteful and stearic acid tended to change the colour of the tincture, though it caused the fat to separate in a condition which allowed the liquid to filter rapidly. One Gm. of stearic acid per 100 C.c. produced a tincture of about the normal colour and in other respects satisfactory, except that it retained a slight odour of the acid. Extract of stramonium from which the fat had been removed by filtration, after cooling, was found to be much smoother than usual and it made an ointment which remained homogeneous for a longer time.—*Pharm. Rev.*, **17**, 496.

TESTING LEMON OIL. A new method for determining the aldehydic constituents of lemon oil is published by J. Walther based on the well-known reaction between those bodies and hydroxylamine, resulting in the formation of oximes. A 5 per cent. (by weight) solution of hydroxylamine hydrochloride in alcohol 80 per cent. is prepared. Ten or 15 Gm. of this are weighed off, made up to 250 C.c.; 25 to 50 C.c. of this dilute solution are measured off and the hydroxylamine determined therein by titration in the usual manner, with $\frac{1}{10}$ normal NaHO solution, using first methyl-orange, then phenol-phthalein, as indicators. A similar weight of the strong hydroxylamine hydrochloride solution is then mixed with a known weight of lemon oil, and diluted with aldehyde-free absolute alcohol, until a clear solution is obtained. From 0·5 to 1 Gm. of sodium bicarbonate is then added, the mixture transferred to a 150 C.c. flask, and heated on the water bath under a reflux condenser for forty-five minutes; after cooling the product is washed into a 250 C.c. flask with distilled water, the condenser as well as the flask being thoroughly washed out. After thorough shaking out the watery layer is made up to 250 C.c.; 25 C.c. are measured off, a drop of methyl orange solution added, dilute hydrochloric acid added cautiously from a burette until a faint rose colour is produced, which is titrated to neutrality with $\frac{1}{10}$ normal NaHO solution. Phenol-phthalein is then added, and titration continued with $\frac{1}{10}$ normal NaHO in the usual manner. The number of C.c. of solution required, after the addition of the phenol phthalein, multiplied by ten and subtracted from the amount used in the titration of the original hydroxylamine hydrochloride solution, is equivalent to the hydroxylamine used up by the aldehyde. This number × 0·0152 or 0·0154, gives the amount of citral or citronellal in the weight of lemon oil taken. The citral content of natural lemon oil is found, by this method, to be approximately 5 per cent.—*Pharm. Cent.*, **40**, 621.

STORAX. For the examination of crude storax which has only been freed from water by mechanical means, K. Dieterich proposes the following scheme of analysis:—(*a*) Loss at 100° C. (*b*) Determination of alcohol soluble portion in 90 per cent. alcohol. (*c*) Determination of the residue insoluble in alcohol. (*d*) The acid number. (*e*) Ester number, and (*f*) Total saponification number of the alcohol soluble portion. (*g*) Determination of ash. The acid number is thus determined. About 1 Gm. storax is dissolved in 100 C.c. alcohol (96 per cent.), and titrated with $\frac{1}{2}$N alcoholic potash, with phenol-phthalein as indicator; the number of C.c. required multiplied by 28 and corrected to 1 Gm. gives the acid number. The saponification number is obtained by treating about 1 Gm. of storax at ordinary temperature for twenty-four hours, with 20 C.c. $\frac{1}{2}$N alcoholic potash, and 50 C.c. of benzene, and then titrating back (without the addition of water); number of C.c. multiplied by 28 and corrected to 1 Gm. gives the saponification number. The author considers this method to be of more value than those previously published. Adulteration with fatty oils reduces the acid number and raises the ester number. Turpentine, on the other hand, raises the acid number and lowers the ester number. The following table gives the results obtained by the author with authentic specimens of storax and trade samples.

	Water.	Ash.	Soluble in Alcohol 90 %.	Insoluble in Alcohol 90 %.	Acid No.	Ester No.	Saponification No.
I. Authentic samples	% 26·21 to 40·37*	% 0·5 to 0·92	% 59·14 to 65·49	% 1·45 to 2·61	59·38 to 70·70	35·42 to 74·43	104·67 to 135·36
Calculated on the dry drug		0·74 to 1·25	88·75 to 100·20	1·97 to 3·85	87·62 to 95·81	49·84 to 109·83	145·62 to 199·74
II. Trade samples	19·58 to 31·95	0·24 to 3·64(!)	64·00 to 77·17	1·66 to 7·33(!)	38·22 to 72·29	47·81 to 110·03	111·89 to 165·58
Calculated on the dry drug		0·31 to 4·75	89·62 to 99·63	2·45 to 9·56	54·96 to 106·23	72·82 to 142·47	170·41 to 233·46

* This high figure is abnormal.

—*Pharm. Central.*, **40**, 427.

SOME NEW GLUCOSIDES. H. Ryan has obtained crystalline glucosides of the β series by the action of acetochloro-glucose on solutions of phenols in alcoholic potash. *ββ-Naphthol-glucoside*, $C_6H_{11}O_5{\cdot}OC_{10}H_7$, was prepared from aceto-chloroglucose and β-naphthol. It crystallises in long needles (m.p., 184°—186°), is easily soluble in alcohol and in hot water, soluble with difficulty in acetone and scarcely soluble in benzene, ligroin, cold water, or ether. It is readily hydrolysed either by dilute acids or emulsin, reduces Fehling's solution only after hydrolysis, is stable towards dilute alkali in which it is insoluble, and has a disagreeable taste. *β-p-Cresol-glucoside* (m.p. 175° to 177°), and *β-o-cresol-glucoside*, $C_6H_{11}O_5{\cdot}OC_6H_4CH_3$ (m.p. 163° to 165°), resemble one another as well as naphthol-glucoside. They crystallise from water in needles which are scarcely soluble in ether, benzene, or ligroin, but are fairly soluble in alcohol and in water. They do not reduce Fehling's solution, are readily hydrolysed, and possess a bitter taste. *β-Carvacrol-glucoside* (m.p. 135°), crystallises from water in needles which are not readily soluble in ether or cold water. It is easily soluble in alcohol and in acetone, but scarcely soluble in benzene, chloroform, or ligroin. It does not reduce Fehling's solution, dissolves slowly in dilute alkali, and is hydrolysable by means of dilute acids or emulsin. *d-Pentacetyl-glucose* (m.p. 110°) is obtained by the action of acetyl chloride on dry glucose in an open vessel. *Acetochloro-galactose* was obtained as a colourless, semi-solid mass by the action of acetyl chloride on galactose in a closed tube, and has been converted into a galacto-side of β-naphthol.—*Proc. Chem. Soc.*, **15**, 196.

SPURIOUS ALEXANDRIAN SENNA.*

BY HENRY G. GREENISH, F.I.C., F.L.S.

Professor of Materia Medica and Pharmacy to the Pharmaceutical Society.

From the perusal of some of the text-books of materia medica it would appear that Alexandrian senna is liable to adulteration with a considerable variety of foreign leaves. Amongst those usually cited are the leaves of *Solenostemma Argel*, Hayne; *Tephrosia Apollinea*, Link.; *Coriaria myrtifolia*, Linn.; and *Colutea arborescens*, Linn.; whilst occasionally *Globularia alypum*, Linn., is also mentioned.

As a matter of fact, however, the occurrence of any of these leaves in Alexandrian senna, or substitution of them for that drug, at the present time extremely rare. Argel leaves, which at one time formed a regular constituent of Alexandrian senna, were, in Hanbury's time, rapidly diminishing in frequency, and have now disappeared; and the others that I have mentioned possess little more than historic interest. The principal admixture that I have observed has been an occasional leaflet of *Cassia obovata*, Collad; but these have been so few as to be interesting rather than important. It sometimes also happens that the leaflets of *C. angustifolia*, Vahl; collected in Arabia, find their way to London under the name of Alexandrian senna.

For some weeks past a considerable quantity of a drug imported from Suez has been offered on the London market as Alexandrian senna. It resembles Alexandrian senna in colour and general appearance, but is easily distinguished by the shape of the leaflets of which it is composed. These are sharply characterised by their obovate outline, rounded mucronate apex, and distinct pinnate venation. The upper surface is glabrous, but the lower distinctly pubescent. They attain 2 cm. in length by 1 cm. in breadth, but are usually a little smaller. They have the odour of senna, and a similar but rather more mucilaginous taste. The samples I have seen contained a few stalks, but no flowers, fruits, or foreign leaves.

In shape and general characters the leaflets agree well with those of *C. obovata*, Collad; a plant that, with its varieties, enjoys a wide range of distribution, being very common in Upper Egypt, near Luxor, Edneh, Esfou, and Syene, but extending eastwards to Arabia, Syria and India, westwards to Senegambia, and southwards to Cape Colony. Thirty or more years ago these leaflets formed a regular constituent of Alexandrian senna, which at that time was a mixture of the leaflets of *C. obovata* and *C. acutifolia*, Delile, and leaves of *S. Argel*.

As one broker alone was offering nearly two tons of these leaves, there must be a considerable quantity either already sold or now awaiting sale. They will probably eventually find a purchaser, and in that case the question arises, What is likely to become of them? They might, of course, be substituted for the official senna in the manufacture of tincture or syrup of senna, in which case their detection would be difficult, if not impossible. They might also find their way into commerce as powdered senna, either under that name or as an ingredient in compound liquorice powder, large quantities of which are sold at very low prices. I therefore endeavoured to ascertain whether their presence in powdered senna could be detected.

The transverse section of either of the official sennas shows a midrib, supported above and below by a crescent-shaped bundle of sclerenchymatous fibres. These fibres are accompanied by longitudinal rows of parenchymatous cells, each containing a prism of calcium oxalate. Beneath the epidermis of either surface there is a single row of elongated palisade cells, the spongy parenchyma being much reduced. Both palisade and spongy parenchyma contain an occasional cluster crystal of calcium oxalate, whilst some of the epidermal cells contain mucilage, and others are developed into warty hairs.

The leaflets of the drug in question present similar features.

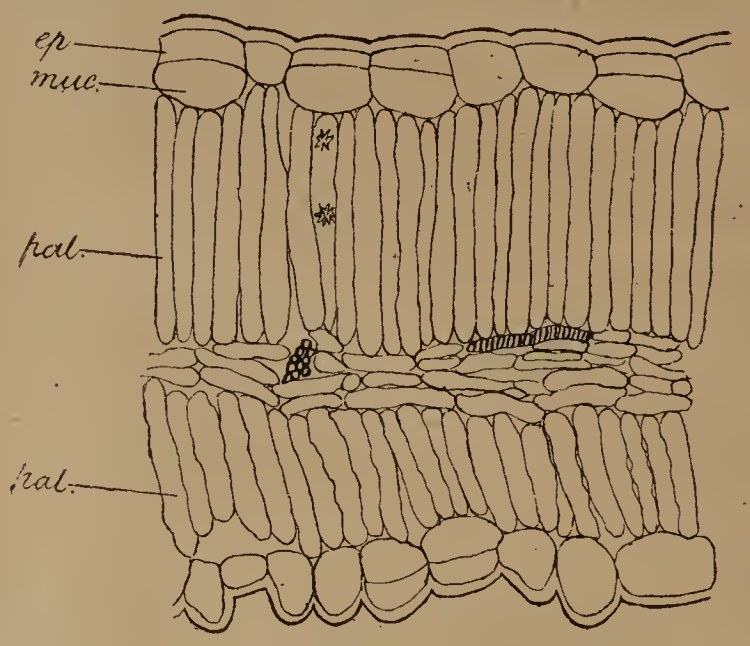

Fig. 1. CASSIA OBOVATA.—Transverse section × 200; *ep.*, Epidermis; *muc.* Mucilage; *pal.*, Palisade.

Palisade occurs on both surfaces; the spongy parenchyma is much reduced. Mucilage is deposited in some of the epidermal cells, whilst one-celled, thick-walled hairs, sometimes nearly straight, but often curved, are frequent on the under-surface. But the difference in most of the epidermal cells of the under-surface is very striking, for they form distinct projecting papillæ. When the surface of the

Fig. 2. CASSIA OBOVATA.—Portions from powdered leaf × 200; *a*, Epidermis of upper surface; *b*, Epidermis of under surface; *h*, Hairs.

lower epidermis is examined these papillæ appear as more or less distinct, but seldom sharply defined, rings. There is, therefore, little difficulty in distinguishing this drug from the official sennas, even when reduced to a fine powder, for fragments of the lower epidermis may always be found; and should the drug find its way into commerce, either in the form of powdered senna or compound liquorice powder, it could be easily identified.

I have examined several specimens of *C. obovata*, and find the leaflets regularly exhibit this character, although the prominence of the papillæ is not always equally well marked.

Such development of the cells of the epidermis into papillæ is by no means uncommon. Solereder* enumerates nearly seventy

* Read at an evening meeting of the Pharmaceutical Society, on Tuesday, November 14, 1899.

**Anatomie der Dicotyledonen*, p. 906.

orders in which it has been observed. Amongst the official leaves the coca leaf exhibits it. But in the genus Cassia it is not common, for Dellien* mentions only ten species in which he found it occur.

Obovate senna has the reputation of being much less active than either of the official sennas, but this opinion seems to be based upon some clinical experiments made by Henry in 1828 with a quantity of the drug imported for that purpose from Senegambia. This is the drug found in museums under the name of sené du Senegal. Henry states that he found this drug to be active, but a little less active than ordinary senna. But it remains to be proved whether that is true for the Egyptian drug, and as the latter seldom finds its way into commerce in such quantity, there is now a favourable opportunity for anyone who wishes to examine it.

Amongst the leaves that I have enumerated as so-called adulterants of senna are those of *Colutea arborescens*. These bear a certain resemblance to *C. obovata*, and I was therefore led to examine them. I found that they too could easily be distinguished from *C. obovata* as well as from both the official sennas. Although the cells of the lower epidermis show a slight papillose swelling, this is much less marked than it is in *C. obovata*.

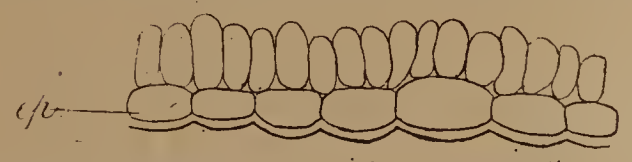

Fig 3. Colutea arborescens.—Portion of transverse section, × 200; *ep.* epidermis of under surface.

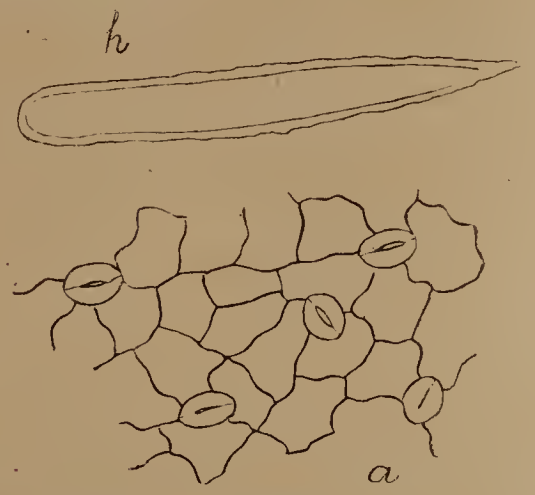

Fig 4. Colutea arborescens.—(*a*), epidermis of under surface, (*h*), hair; × 200.

The stomata on the under surface are usually surrounded by three, four or five cells, whereas in the sennas there are usually two only, and the hairs attain a much greater length; moreover the sclerenchymatous fibres of the midrib are wanting, and with them the rows of calcium oxalate crystals.

Now, *Colutea arborescens* is a native of Central and Southern Europe, and it is not easy to understand how the leaves could be used to adulterate senna, which, at the present time, is imported direct from Egypt to London. An explanation is offered by Colladon in his 'Histoire naturelle et médicale des casses,' written in 1816. Senna, says Colladon, is sent to Europe, and there sorted into the leaflets, *C. acutifolia*, *C. obovata*, and *S. Argel*, which are commonly sold separate. Sometimes the leaves of *Colutea arborescens* are mixed with those of *C. obovata*. This, he says, is attended with little inconvenience as they are nearly as active and easily distinguished; he says, further, that *C. obovata* is sold by the pharmacists under the name of sennæ italicæ, hispanicæ, alepenses, etc.

Cassia obovata was cultivated to a considerable extent in the neighbourhood of Pistoia, near Florence in the 16th century, and the drug obtained from it was known as Italian senna, to distinguish from the true or Levant senna. But all authorities agree in condemning it as inferior, and its cultivation was ultimately abandoned. Italian senna was so little known in 1694 that Pomet said "some authors have stated that a quantity of senna is found in Italy, but I think these sorts of senna are more likely the leaves of . . . . *Colutea* . . . ; it is a subject on which I shall say nothing, there being authors enough who treat of it." Lemery*, too, in 1727 alludes to it, but does not mention it as one of the three kinds of senna found in the shops, and Colladon's statement made in 1816 must therefore be received with caution.

Indeed, the difficulty of finding definite and reliable statements of the occurrence of these adulterants of senna is remarkable. Batka, who paid particular attention to the subject for years, says he found *Tephrosia Apollinea* in 1828, and again in 1840; *Coriaria myrtifolia* found its way into senna in France about 1825-28. I am not aware that *Colutea arborescens* has ever been found in the senna of English commerce, and argel leaves have practically disappeared. Of *Colutea*, *Tephrosia*, and *Coriaria* 'Pharmacographia' says they were formerly occasionally mixed with senna, but the authors have never met with any of them, and of *Tephrosia* Flückiger says later that it is not worth mentioning.

One should, therefore, be very careful in handing down these leaves from year to year and generation to generation as adulterants of senna, conveying the impression that they are at least so likely to occur as to render it desirable that the student should be acquainted with them. Does it not burden his memory with useless details and prevent concentration of the attention on the genuine drug? and when one considers that this process is repeated with many other drugs, the time that is thus occupied is very considerable. Should not the attempt be made to confine the attention of the student to the drug itself, and to compel him to study it in all its details? Should he not be educated to use his own powers of observation to detect substitution? He would then be in a position to detect not only such adulterations or substitutions as have already been observed, but such as may at any future time occur. These should certainly be recorded in the current literature and specimens preserved in museums for reference; the records collected in a dictionary would be easily accessible, and should be utilised to give the utmost precision to our descriptions. At least care should be taken to append to a statement of adulteration, the date at which it has taken place, and, if possible, the frequency with which it has recurred, and most valuable of all is the statement of an author that he has himself met with such adulteration.

ETHYL NITRITE DETERMINATION.†

BY R. C. COWLEY AND J. P. CATFORD.

An easy method of checking the percentage of ethyl nitrite in the official spirit and solution, without a nitrometer, will perhaps be welcome to many busy retail pharmacists.

We propose to demonstrate that it may be done by an adaptation of one of the colorimetric processes for determining nitrites in water analysis, founded on the reaction between nitrous acid and meta-phenylene-diamine, producing the azo-compound commonly known as "Bismark-brown," a colour so intense that one part in five million is perceptible, so that differences of 1/100th of a milligramme in 50·0 C.c. of water are distinguishable; but as for our present purpose we have only to deal with percentages, such extreme delicacy is unnecessary, and the colour produced by a few tenths of a milligramme in 40·0 C.c. will be convenient for comparison.

Standard nitrite solution has usually been prepared from silver nitrite, which is itself prepared by mixing warm solutions

† Read before the Liverpool Chemists' Association, on November 9, 1899.

of $AgNO_3$ and $NaNO_2$. The silver nitrite precipitates, on cooling, in yellow silky capillary crystals. But as there are obvious objections to using, for a permanent solution, a salt so sensitive to light, etc., as this one is, it is reconverted into sodium nitrite by precipitating the silver with sodium chloride, and diluting to a convenient strength.

Equivalent weights of these *Nitrites* are as follow:—

Ethyl nitrite	75 or 0·100	milligramme.
Silver nitrite	154 or 0·2053	,,
Sodium nitrite	69 or 0·092	,,

Years ago the above roundabout proceeding was necessary, because the commercially obtainable sodium nitrite seldom contained much more than 50 per cent., but now it is usually about 98 per cent., and as 0·092 of a milligramme ($\frac{92}{1000}$ths) is equivalent to 0·1 milligramme of ethyl nitrite, even 5 per cent. of impurity in the sodium nitrite would only diminish the colour less than $\frac{1}{20}$th, *i.e.*, 0·95, instead of 1·0 of ethyl nitrite. This may either be disregarded or allowed for by making a solution containing 95 (instead of 92) milligrammes per litre, or 19 milligrammes in 200·0 C.c.

Each C.c. is equivalent to $\frac{1}{10}$ milligramme ethyl nitrite, and the comparison standards are prepared by adding 1, 2 and 3 C.c. to successive portions of water, each containing about 10 drops of diluted sulphuric acid (1 in 3) and similar quantity of solution of *m*-phenylene-diamine (1 in 200), and finally each made up to 40·0 C.c. The comparison might be made by adjusting the standard to match the sample, as is usual in Nesslerising, but for the present purpose it is preferable to dilute the sample to match these fixed standards, which will not require preparing fresh, but may be kept for constant reference. Prepared of the above strengths they do not deposit as the Nesslerised liquid would, neither has exposure to daylight for many weeks made any perceptible change.

The sample to be tested is first diluted to contain 1·0 gramme in 100·0 C.c. The mean density of spt. æth. nit. being 0·840, dilute 1·0 C.c. to 84·0 C.c., or in case of the liquor, dilute 1·0 C.c. to 82·5 C.c.

Each C.c. of this solution contains a centigramme of the sample, and therefore $\frac{1}{10}$ milligramme of ethyl nitrite for each one per cent. of that ether contained in the sample, so that it is only necessary to treat 1·0 C.c. of this dilution with the test solutions and water to make 40 C.c., for comparison with the standard colours. An hour should be allowed for the full development of the colour. If then the colour of the sample is between standards 3 and 2, it may be considered within the B.P. limits. If paler than No. 2 it should bear dilution to 70·0 C.c. to match No. 1. If *less* than 70·0 the sample is below 1·75 per cent., *i.e.*, the B.P. minimum.

The dilution matching No. 2 if further diluted to double the volume should match No. 1.

Standard.	Dilution of Sample in C.c. to match Standards.						
No. 3.....	40	B. P. Sp. Æth. Nit.				—	—
,, 2.....	60	56	50	40		—	—
,, 1.....	120	112	100	80	70	60	40
Per cent.....	3·0	2·8	2·5	2·0	1·75	1·5	1·0

The water used should be recently distilled or boiled (air-free) and the sulphuric acid free from nitrous compounds. The sample, when diluted, should be mixed with the test solutions without delay, to prevent hydrolysis of the compound ether. In fact this test furnishes an easy proof of the instability of sweet spirit of nitre when prescribed with aqueous menstrua. Spt. æther. nit. of full strength if diluted ʒj. to ʒj. of water, and tested from day to day, will be found after the third day not to contain a trace of nitrite.

If anyone is so conservative as not to keep metric weights and measures he can use equivalent proportions in grains and minims *e.g.*,—

Sample dilution—one volume in 84 = 0·5 fl. dr. in 5¼ oz. avoirdupois. Sodium nitrite 95 in a million (or 0·019 in 200·0) may be made as follows:—

First solution, 1 grain in 1,000·0 grains (or 7 grains in 16 oz.).

Second. 19 grains of this (=0·019 grain $NaNO_2$) dilute to 200·0 grains.

For Standards Nos. 1, 2 and 3, dilute ʒss., ʒi. and ʒiss. of the second (with *m*-phenylene-diamine, etc.) to ʒxx.

ʒss. of diluted sample (1 in 84) treat similarly for comparison.

If Nessler cylinders are not at hand, comparisons may be made in white glass vials, or test tubes, *not nested*, as it is essential that the columns of liquid be equal in diameter and height. The paler colours require comparing from above.

The sodium nitrite solution keeps fairly well when not exposed to the air, but would not be required after the standards are once made.

PERCENTAGE OF ETHYL NITRITE IN SWEET SPIRIT OF NITRE AND IN LIQUOR.

COLORIMETRIC DETERMINATION.

Standard sodium nitrite solution { 0·095 in 1000. / 0·019 in 200.

Test solutions.

a—Meta-phenylene-diamine 2 grains in ʒi. water.
b—Sulphuric acid 1 vol. to 2 vols. water.

Colour standards corresponding to 1, 2 and 3 per cent. ethyl nitrite.

Add sol. sodium nitrite 1 C.c., 2 C.c., and 3 C.c. to separate portions of water, each containing 10 drops of each of test solutions *a* and *b*, make up each to 40 C.c., and keep as comparison standards.

Dilution of sample (one centigramme in each C.c.)

1 C.c.	*Aq. ad.*
Spt. Æth. Nit.....	84·0 C.c.
Liq. Ethyl Nitrit.....	82·5 C,c.

Application of test.

Add 1 C.c. of diluted sample to water containing test solutions *ut supra*, make up to 40 C.c., and after an hour compare and match with standards by further diluting sample if necessary.

e.g.—If sample (40 C.c.) is between standard Nos. 3 and 2, sample within B.P. limits. If paler than No. 2, dilute to match No. 1. If it will not bear diluting to 70 C.c. it is below the B.P. minimum (1·75 per cent.).

PETROLSULPHOLUM ALBUMINATUM.—Hummer prepares this substance thus:—Petrosulphol, 5; is dissolved in distilled water, 50; and the solution mixed with *q.s.* (about 195) of a clear albumin solution composed of dried albumin, 25; in distilled water, 170. Alcohol is then added to the solution until precipitation is complete; the coagulum is separated, washed, pressed, and dried, at about 100° C., and powdered. 6 Gm. contain the equivalent of 1 Gm. of petrosulfol. The brown, tasteless and odourless powder passes undecomposed through the stomach, and is only absorbed in the intestines.—*Oest. Zeit. für Pharm.*, **53**, 429.

COMPANY PHARMACY: ITS ABOLITION OR REGULATION

BY W. S. GLYN-JONES.

"He was anxious to impress on the members the fact that this Bill was put into the hands of the Privy Council to be brought forward as a Government measure; it was not a Bill which the Society proposed to bring into Parliament as a private measure, and, therefore, some of the provisions were drafted in such a manner as to meet the views of important Government officials, who had considered various matters connected with the working of the present law, and who thought some deviation from the law as it had hitherto been was desirable."

The above supplies me with a suitable text. It is not taken from the report of the last Council meeting, but will be found in No. 674 *Ph. J.*, page 970, May 26, 1883. It is part of a speech made at the annual meeting of the Society in 1883 by Mr. Carteighe, who was then our President. The Council had drafted a Pharmacy Amendment Bill, in which appeared several clauses which were most objectionable from the point of view of the qualified chemist, notably the formation of a Third Schedule of Poisonous Substances, which it was suggested could be sold by anyone, whether qualified or not, provided they were suitably labelled. The above sentence was, I take it, Mr. Carteighe's apology for this obnoxious clause. If the present Council drafts a clause dealing with company pharmacy which is not absolutely satisfactory to our members, the above apology could be used almost word for word. It seems to me that there are three courses open to the Council:—

(1) To draft a clause prohibiting a company using our titles, or keeping open shop for the sale of poisons;

(2) To draft a clause which would allow companies to exist, but to impose certain restrictions upon them;

(3) To do nothing, and allow the Government and those who are interested in existing companies to carry a clause which would meet their wishes.

Absolute Consistency Impossible.

If we are to be absolutely consistent with the views and principles adopted by the founders of the Society, we can be party to nothing which admits of any kind of company carrying on the business of a chemist and druggist. That is the idealistic position, but is it practicable? It must be borne in mind that we cannot expect the Government, when they deal with companies, to go beyond the principle of the 1868 Act. That Act was very far from meeting the wishes of our pharmaceutical ancestors, and was certainly anything but idealistic pharmaceutical legislation. As a matter of fact, pharmacy, as a whole, like human nature, "is a bundle of inconsistencies"; indeed, the number of registered chemists who are carrying on their business in an absolutely consistent manner in regard to the ideal conditions under which pharmacy should be conducted is infinitesimal. For my own part, I must plead guilty at once. I carry on my business under an assumed name, and in so doing am only following the example of leading pharmacists. I consider that every chemist who has a branch shop can be charged with acting contrary to a perfect code of Pharmaceutical ethics, and I therefore say that compromise comes very largely into the conditions under which pharmacy is to-day being carried on, apart altogether from the question of company pharmacy.

Company Regulation Inevitable.

I have reason to believe that the majority of our members have no desire to prevent what they call "legitimate companies," or companies of qualified persons, from carrying on our business, but the moment you allow a company of any sort to do so, and you desire to define the kind of company, you at once take up what I believe to be the inevitable position of regulating company pharmacy. I believe, therefore, that course No. 1 is disposed of, and the members have to make up their minds between some kind of regulation and the "do nothing" policy. Before agreeing to do nothing it would be well to remember that it does not rest with us entirely. The position briefly is that the Government have come to the conclusion that "chemist companies" are not properly regulated, and our Society was asked by the Lord Chancellor to offer suggestions. We did so, but our suggestions would have prohibited companies, and not regulated them. Since the receipt of those suggestions a clause has been introduced into a Government measure and certain restrictions—most unsatisfactory ones, I believe—laid down. The Lord Chancellor, in introducing those clauses, said that "it was impossible to resist the propriety of subjecting existing companies to *such restrictions as are proposed in the Bill.*" There we have the clearest indication that the Government have no intention of prohibiting companies, and it is for us now to consider whether we will attempt to get the Government to modify the restrictions they imposed in the Bill, or take up a position of absolute opposition. If the latter course is decided upon there may be one of two results. If it is argued that the Government care too little about the subject to carry their proposals in the face of opposition, the clause will be dropped, and company pharmacy will remain as at present. If, however, they are in earnest, it cannot be denied that they are sufficiently powerful to carry through Parliament any restrictions they may think fit, whether we like them or not. Looking at the matter from every point of view, can there be any doubt that our best policy will be to offer our assistance to the Government in drawing up a clause which shall, as far as possible, place companies in the same position as that occupied by individuals?

What is a Properly Constituted Company?

I have already said that I believe the majority of our members are prepared to allow properly constituted companies to carry on our business. How shall we ask the Government to define such a "properly-constituted" company? The answer which most readily suggests itself is, that every shareholder must be qualified. I do not think such a claim would be allowed, because it would be difficult to show what difference it makes to the public safety who owns the capital invested. This our Editor admitted in his article of October 28, page 408. He says: "So far as public safety is concerned, it is not of the least consequence who finds the capital with which a business is financed, or, indeed, who obtains the profit; both are equally beside the question"; and "Ordinary Pharmacist" in the same issue, page 399, puts the same view in the following words:—"Companies of duly qualified persons need not be interfered with, and even where, owing to family arrangements, part of the capital invested in such companies belongs to unqualified individuals, it ought not to be impossible to devise some generally satisfactory means of overcoming that difficulty. It may even be rendered possible for existing companies of unqualified persons to bring themselves into line by some such means; but, in such an event, no unqualified person must be permitted to enjoy any advantage from the use of our titles, nor to exercise any control over the conduct of the business."

Absolute Control by Qualified Directorate.

I think it will be necessary that our restrictions shall be in the direction of providing absolute qualified control of the business, rather than that it should be capitalised by qualified persons. I am strengthened in this view after a careful study of the judgments given in the various Courts in the case of the London and Provincial Supply Association. There are two main offences under the 1868 Act: that of transacting the actual sale, and that of keeping open shop. No company can commit the first offence in so far as Section 15 applies, and, of course, the judges made a strong point of this in showing that the public were protected by the necessity for a qualified salesman, but Lord Justice Bramwell, giving judgment in the Appeal Court, dealt with the other offence—that of keeping open shop. He said:—

It may be asked, how is the "keeping open shop" to be reached; the servants do not keep it open? No, but the directors or managers do; they are the offenders in that case. I cannot see how they could deny that they kept open

this shop. They do—they do it in fact. If they committed a public nuisance by smells, vapours or otherwise in the preparation, or (if supposable) in the sale of their drugs, they and not the corporation would be indictable.

Lord Justice Baggallay, on the same occasion, said:—

But I feel bound to add that I am by no means satisfied, that although a corporation as a separate entity be not liable to the penalty which is sought to be recovered, in this case the individual members of the corporation, whether directors of a company or otherwise, may not be liable, and thus the mischief be remedied.

Lord Blackburn, in giving decision in the House of Lords, said:—

A corporation may, in one sense, possess a competent knowledge of its business, if it employs competent directors, and so forth.

Mr. Justice Bramwell gave it as a reason for not including companies in the 1868 Act that the offence of keeping open shop by unqualified persons could be prevented by making the directors liable. I have not been a member of the Council long enough to know why the Society has not in England brought an action against an unqualified director of a drug company upon the strength of the judgments of the judges quoted above. I know that in Scotland an action was brought against seven shareholders, and that we were defeated in the Scotch Courts; but I agree with Mr. Rymer Young, who, in his address before the Manchester Association in December of last year, said:—

"The decision in the Leith Depot case—according to which the members of a corporate body cannot be sued in Scotland for trading as chemists and druggists—appears to have been too much taken for granted."

This point, however, does not affect the question at issue. I maintain that the judges I have quoted are of opinion that the qualified control in the case of companies can be supplied by qualified directors.

My "Wonderful Panacea."

Mr. Carteighe, at the last Council meeting, was good enough to express regret that what he called my "wonderful panacea" was not produced. As that clause is still under discussion by the Committee I am not in a position to publish it, but I think it can be clearly gathered, from what I said on the subject at that meeting, that the view favoured by me is that of insisting that the capital and business owned by a company selling poisons should be absolutely under the control of qualified directors. I would suggest going to the Government and thanking them for their attempt to deal with the anomaly, especially approving of their decision to provide for qualified control, but at the same time pointing out that the means proposed by them—that of insisting upon a qualified manager or assistant—would not provide the necessary control. I know that it will be argued that my suggestion would be useless, because it would be easy to provide for dummy directors; but a clause should be so framed as to necessitate directors being in absolute control. Mr. Carteighe stated that this provision would meet with as much opposition as the clause which the Committee suggested, which would prohibit company pharmacy. I do not admit this, because it would be possible for large corporations to form a subsidiary company for their drug department, and to place it under the complete control of qualified directors; but if we admit, for argument's sake, that both methods will meet with equal opposition, can there be any doubt that the clause which regulated, but did not abolish, would be the more likely to successfully contend with that opposition?

Every Critic Should Prepare His Clause.

There has, I think, been enough discussion upon the abstract principles involved in this question. The time has come for dealing with the matter practically, and I think that the Council is entitled to ask that every critic of its policy should be prepared with an alternative clause. It is comparatively easy to say what we would like or what we ought to have. It is not so easy to embody in a clause what we think we are likely to obtain. As an evidence of this difficulty I will point out that "An Ordinary Pharmacist" suggests that the clause brought in by the Law and Parliamentary Committee was a garbled version of his own. I do not know who originally drew up that clause, but I should like to point out that the clause suggested by "An Ordinary Pharmacist" could not have been accepted by any Committee. I am not sure, from reading the clause, what "An Ordinary Pharmacist" wants it to enact. This is the clause:—

"It shall be unlawful for any company to assume or use the title of pharmaceutical chemist, or pharmaceutist, or pharmacist, or chemist and druggist, or chemist, or druggist, or dispensing chemist or druggist, or any other title implying registration under the Pharmacy Acts; and in all other respects a company shall be amenable to the provisions of the Pharmacy Acts in the same manner as an individual or natural person; and if any company of persons not registered under the Pharmacy Acts shall assume or use any title implying registration under the said Acts, or in any way infringe the provisions of the said Acts, it shall be liable, on summary conviction, to a penalty not exceeding five pounds for each day upon which such offence happens."

He starts by saying "It shall be unlawful for *any company*, etc." He ends it by saying, "If any company *of persons not registered* under the Pharmacy Acts shall assume or use any title . . . it shall be liable, etc." Which does "An Ordinary Pharmacist" mean should stand? Then the clause says, "In all other respects a company shall be amenable to the provisions of the Pharmacy Act," but surely the framer of that clause knows that there are sections of the Pharmacy Act to which it would be impossible for any corporate entity to be amenable.

Plain English Wanted.

The drafting of this clause also shows the wisdom of those who at the last Council meeting particularly desired that the Committee's clause should be put into "plain English." I notice that Mr. John Smith rather scolds us for this. He says that we made it "as blunt and unacceptable as possible." It is essential that all these suggested clauses should be put into plain English, and if, as a result of that process, they are found to be, as Mr. Smith says, "blunt and unacceptable," the fault will lie with the purport of the clause rather than with the plain English. If the 1868 Act had been put into plain English we should have been saved most of the difficulties with which we have had to deal.

I have said that every critic should produce his clause, because I think it is a waste of time to discuss principles about which we all agree, and, if I may be allowed to do so, I would suggest that all clause framers should keep the following facts in view:—

(1) It is now 1899—not 1867.

(2) That it is a clause which the Government are to be asked to adopt, and here the perusal of Mr. Carteighe's remarks, which I took for my text, will be beneficial.

(3) We cannot expect conditions imposed upon companies which are not enforced against individuals.

(4) There are comparatively few men who start business who are not indebted for loan of capital to some unqualified relative or friend.

(5) Parliament will sanction nothing which savours of trades unionism.

(6) Although it need not be drawn up as by a legal draftsman, it should be put into plain English. It is useless to attempt hoodwinking ourselves, the Government, or opponents by ambiguous language. We have suffered enough from ambiguity already.

I ought, perhaps, to explain in conclusion, that by company pharmacy I mean the keeping of an open shop for the dispensing and sale of poison by a limited liability company.

Developer for Bromides.—A sepia tone for bromides may be obtained by using the following developer:—(*a*) Water, 1,000; potassium oxalate, 200. (*b*) Water, 500; ferrous sulphate, 25; citric acid, 2; potassium bromide, 2. (*c*) Water, 1,000; potassium chloride, 120. For use mix (*a*) 200 parts, with (*b*) 50 parts, and (*c*) 50 parts; the use of more of (*c*) intensifies the sepia tone.—*Amat. Photograph.*, **13**, 103.

PHARMACEUTICAL SOCIETY.

Evening Meeting.

The first evening meeting of the Pharmaceutical Society was held at 17, Bloomsbury Square, London, on Tuesday, the 1th inst., the chair being taken at eight o'clock by the President, Mr. Wm. Martindale.

Professor J. Reynolds Green, Sc.D., delivered a lecture upon

The Biology of Yeast.

He said the biology of yeast had been so intimately associated with the subject of alcoholic fermentation in general that it was difficult to realise that such a complex subject could be divided into two branches. That would appear more clearly in the course of the lecture. In early days attention was first drawn to fermentation proper, and for many years it was not known that yeast had any part to play in the process. The old researches of the alchemists and of their successors met with very little result until about 1680, when a Dutch naturalist named Leuwenhoek, who possessed no microscopical appliance except a simple magnifying glass, discovered that the scum which was associated with the process of fermentation had an organised structure and consisted of a certain number of small globules. Though that discovery did not advance the subject very materially, it was the starting-point from which they could trace the biology of yeast. It was not known for many years later that those little globules were vegetable in their nature. Indeed, there was a very active controversy about them, and the difficulty of arriving at a correct solution might be referred to the very imperfect appliances at the service of those who undertook researches.

A great many observers, particularly on the Continent, considered that those globules were animal in their nature, and that theory held its ground until the early part of the present century. A fairly long interval elapsed, between 1680 and 1820, when the discovery was simultaneously made by three people that the organism in question was a vegetable one. Those three discoverers—Cagnier de Latour, of France; Kütze, of Berlin; and Schwann, of Jena—discovered that these little globules were capable of reproducing themselves by the ordinary process known as budding. Each cell put out a small protrusion or bud from its surface, which in turn grew until it reached the size of the original cell, and then became a separate organism. That established practically the vegetable character of yeast. Subsequent discoverers had located it, until a great deal more was known about where it came from, its morphology, and so on. Perhaps the greater part of their knowledge on the subject was due to Dr. Emil Hansen, of Copenhagen. No one had thrown such a flood of light upon all the industries which depended upon the work of yeast or had done so much in that direction as Emil Hansen. Possibly from the fact that his publications were not in English, a good deal of his work had not been followed by a great many, and he was glad to be able to bear testimony to the light which Hansen had thrown on the subject. They had often been told how very largely the present century had conduced to the progress of science, and it was undoubtedly true that all they knew about fermentation had been discovered since 1820. Towards the end of the last century the

Chemical Aspect of Fermentation

was taken up by Lavoisier, and what Cagnier de Latour had done for it from a biological point of view Lavoisier started to do from the chemical side. Before his time the only discovery of any very great importance that had been made was that it was only saccharine liquids that could be made to produce alcohol. That discovery was made 100 years before, and after 100 barren years Lavoisier took the matter up, and one of his great discoveries, based upon accurate chemical analysis, was that the sugar split up into carbon di-oxide and alcohol, and that if it were possible to collect these two and put them together again, the sugar would be restored. From the old-fashioned point of view it was a great discovery and put an obscure phenomenon on a firm scientific basis. Before that time all had been nebulous and doubtful, and people made all sorts of wonderful statements as to where the spirit came from. Thus Lavoisier might be termed the founder of the accurate knowledge of yeast which was no possessed. There was a little discrepancy, however, between Lavoisier's hypothesis and his analyses. He assumed that the cane sugar was broken up into alcohol and carbon di-oxide, but the quantities which he measured of these two substances would not quite reproduce the cane sugar from which he started. It was found that it was necessary to add a certain amount of water. This remained unexplained for some time; but about 1847 Dubrunfant made the further discovery that cane sugar had to be converted into a sugar which was not crystallisable before it would ferment. This, of course, sent people again on inquiry, and it was found that the action of acids upon cane sugar split it up into two other sugars known as glucose and fructorse or till recently as dextrose and lævulose.

In 1860 what might be called the first discovery of a purely biological nature was made by the great French chemist, Berthelot. He found that in fermentation there was an enzyme presetn, now called invertase, and that the change which took place was associated with the incorporation of molecule of water into the molecules of cane sugar, with subsequent splitting with the two sugars mentioned. This explained scientifically the discrepency which existed between Lavoisier's theory and his experiments. It is known that in the ordinary processes of brewing peast was not made to work first casc upon canc sugar. The sugar which was most prominent in malt extracts, known as maltose or malt sugar, though very much like it, was not identical with it. As cane sugar had to be inverted in order to induce fermentation, it seemed probable that maltose in like manner must undergo this change. Both these sugars have the following formula: $C_{12}\ H_{22}\ O_{11}$. When split up the formula of each product is deflects the poliarised rays of light to the left and is called levulose, and the other to the right, and is called dextrose. When malt sugar was examined, the same splitting up was observed, but both sugars deflected the plane of light to the right, and they proved to be identical, so that the molecules of malt sugar split up into two molecules of dextrose or glucose. Now, as there was an enzyme which produced the first change, naturally it must be expected that there was an enzyme which produced the second, and in 1883 this was discovered by M. Bourquelot, Professor of Chemistry at the Ecole de Pharmacie. This gave a fairly large contribution to the biology of yeast.

The First Enzyme

was called invertase, that which split up cane sugar, and the second was called maltase. It was found that neither malt sugar nor cane sugar was capable of undergoing fermentation by yeast without splitting up, which was the work of these two enzymes. Then came the question, What did the yeast do to these sugars? The yeast was found, when placed in these saccharine media, to grow enormously and with extreme rapidity, and the progress of its growth was marked by the vehemence of the fermentation. The question then arose, What was the relation between the yeast itself and the sugary liquid? What was the life process in the yeast of which this curious fermentation was the expression. That was the subject of research by many chemists for many years, and gave rise to a good deal of theory, which it was not necessary now to go into. A strong controversy was indulged in, particularly on the Continent, Liebig holding very decided views in one direction, and other chemists of equal eminence holding views diametrically opposite. One of the first serious attempts to solve it was due to Pasteur, whose name was the next which must be mentioned in connection with the study of the biology of yeast. Pasteur discovered that yeast was very much more energetic in the absence of oxygen. When he took away all the oxygen from a fermenting fluid the fermentation that was going on became relatively very much intensified. Pasteur upon that formulated

A Theory of Fermentation,

which held its own for some time. Fermentation, he said, was an expression of life in the absence of oxygen; oxygen was a primary necessity for every living thing. In ordinary cases oxygen was supplied from the atmosphere, but when not so derived the organism in the progress of its life would get that oxygen from something else; it would break up some other decomposable body, with the view of getting from that body the oxygen normally supplied by the atmosphere. Pasteur's view was that the yeast split up the sugar in order to get from it the oxygen.

That was rather a bold hypothesis, and one naturally looked round carefully to see whether under any circumstances oxygen was liberated when sugar was decomposed. There was very little evidence to show that this was the case. It had been discovered that in fermentation other things besides alcohol and carbon di-oxide were formed. For instance, it had been discovered that succinic acid always occurred in the fermentation of sugar. Pasteur came to the conclusion that 96 per cent. of the sugar subjected to the action of yeast went to alcohol and carbon di-oxide, whilst 4 per cent. went into succinic acid and glycerin; still, there was no oxygen. Another chemist, named Monoyer, published a paper in which he claimed to have found that there was a small amount of oxygen given up. His paper was in the form of a thesis, which he presented to the Faculty of Medicine at Strasburg when he was a candidate for the Doctor's degree; but his views have never been subsequently confirmed, and did not seem to be accurate. The question of the action of oxygen in the metabolism of the living cell was merely an expression of the fact that the cell displayed energy. That energy was normally liberated by the oxygenation of something in the cell—it might be the living substance, or it might be some compound present; but the oxygen helped to break this down with the liberation of energy. If this could be broken down without oxygen you nevertheless got the energy liberated; and, therefore, the same purpose was served as in oxygen respiration. So that

Pasteur's Theory

came to this: the fermentation was an expression of the effort of the organism to obtain energy in the absence of oxygen. There were a great many facts which went to show that this was a characteristic feature of the vegetable protoplasm. It was found that by exposing dry fruits—not artificially dried fruits, but in their ordinary parenchymatous condition—to an atmosphere which contained no oxygen for some time, that they were capable of forming alcohol. This was discovered by two French chemists—Lechartier and Bellamy—and was confirmed by Pasteur himself, and, two or three years ago, by Gerber. All these researches showed that life, in the absence of oxygen, could be maintained by fermentative decomposition, probably principally of sugar, the effect of which was to liberate the energy which the cell wanted. This appeared to be the solution of the difficulty, but there were always people of a very sceptical turn of mind; and however prettily a theory was worded, and however nicely it was placed before them, they were never quite ready to accept it.

Such candid critics met Pasteur when he put forward his hypothesis, the most earnest of them being Schützenberger, who said that if Pasteur's theory was true, it was very evident that fermentation ought not to go on in the presence of oxygen, as the oxygen would obviate the necessity of it. Schützenberger wanted to know how Pasteur explained the fact that energetic fermentation was got in the presence of oxygen, and, moreover, that the fermentation was much more energetic in the presence of oxygen than in its absence. That, of course, was a difficulty to be got over. Schützenberger explained that instead of fermentation being for the purpose of producing energy it was for the purpose of supplying yeast with nutriment; that it was an alimentary process, and not a respiratory one. There were many things to be said in favour of that view, as, for instance, the decomposition in which the glycerin and succinic acid were produced at the expense of a certain amount of the sugar. Another curious fact was that if yeast is put in a liquid containing organic nitrogen in solution—such bodies as peptones or amides—the yeast will produce alcohol without any sugar being there at all. That led to the discovery of

A Third Enzyme,

which was now known to exist in yeast. A yeast cell, like all other resting cells, contains a certain amount of food wrapped up in its own protoplasm. This includes glycogen, a substance very much like starch, a corbohydrate, and under proper conditions it gives rise to sugar just as starch did. The alcohol which appears under these conditions is derived from the glycogen in the yeast cell under the action of another ferment, known as diastase, which has the power of saccharifying these forms of carbohydrates, the $C_6 H_{10} O_5$ group. There was thus a great deal to be said in favour of the alimentary theory, because the idea of the yeast in using up this carbohydrate would be nutrative, as in all other cells, when using their reserve, and no doubt the production of alcohol was an incident in the process. There were thus two very interesting views, each of which had a great deal to be said for it, but neither being exactly reconcilable with the other without careful thought. It was undoubted that when a vegetable cell was deprived of its ordinary supply of oxygen it would set up this alcoholic fermentation. That was found in the fruits he had alluded to, also in leaves, in buds, and recently it had been found in the interior of the wood of trees. Wherever oxygen was minimised, there alcoholic fermentation supervened. It did not seem that it need make any difference to that well-established fact if, in the ordinary course of feeding, a particular cell decomposed the sugar and the same products were evolved; the production of fermentation might in the first onset be alimentary; then, if it were deprived of oxygen, a second action would take place, and the same kind of thing would supervene, and the fermentation would be relatively intensified. In that way they might get a sort of explanation of the divergencies between the two views.

There was a certain fascination to many minds in discussing questions of this sort, but he must pass on because there were many

Other Problems

which had still to be dealt with. After the discovery of these enzymes in the yeast, the question began to excite the minds of physiologists why did not the yeast cell secrete an enzyme to do this great work of forming alcohol. A great many people set themselves to solve this question, and for years it was one of the problems in vegetable physiology whether or no the yeast cell secreted an enzyme which could carry on this fermentation, but it was not until 1896 that the question received its solution. Büchner found that there was in the yeast an enzyme which had the power of carrying this out. Many efforts had been made by filtering, pressing, and extracting with all kinds of solvents to get this enzyme out, but they had all failed. Büchner adopted a very drastic method. His argument went to this, that you must completely deorganise and crush the cell so as to destroy its entity entirely, and then perhaps the protoplasm would give up what it had held so fast. Büchner dried some yeast, powdered it and mixed it with dynamite earth or kieselguhr, and then ground it in a very fine agate mortar until he had got it into a perfectly fine powder, like flour. This disintegrated the yeast, and then Büchner extracted it, and as a final stage submitted it to the enormous hydraulic pressure of about five tons to the square inch. It was found that this extract was capable of being filtered clear, and then it was seen to be an almost translucent yellow liquid with a very yeasty smell, somewhat viscid, but still capable of passing through a filter paper. When it was boiled it deposited a marked coagulum of proteid character at a temperature of 45° or 50° C., a very low temperature indeed for coagulation. When some of this was placed in a solution of cane sugar—the best strength he found to be 10 per cent.—there was

almost at once a very vigorous fermentation set up. Bubbles began to arise, and after a short time, even at the ordinary laboratory temperature, there was a frothing on the top of the liquid.

A great many experiments were made to see if it might really be said to be the thing that everybody had been working for so long. Unfortunately for a very long time nobody could get it out except Büchner himself, and as there was no one there to see him get it out, there was a certain amount of reserve or mild scepticism for some time. However, after perhaps an interval of twelve months, the discovery was confirmed in several other places, and since that time this material had not been found very difficult to prepare. Büchner named the enzyme thus found zymase, and it might now be taken to be the active principle which split up sugar with the formation of alcohol and carbon di-oxide. Soon after Büchner found zymase it was looked for in dried fruits, and before long they found it there also, and it was apparently merely a question of knowing how to obtain and prepare it. As Büchner prepared it, it is extremely difficult to keep. In his first experiments he never succeeded in getting it to last more than two days; if it were kept in contact with sugar it might be kept for seven days if cold, but it was a very unstable thing and difficult to prepare. They could see what difficulty there was in preparing it when he told them that in an experiment which came under his own notice it took twelve hours to grind up the kieselguhr and yeast. Twelve hours sitting over over a mill with nothing else to think of, and nothing to do except see that it did not go wrong, was a sort of experiment which required a good deal of enthusiasm on the part of the operator who had to carry it out.

The Discovery of Zymase

was of immense theoretical importance, and it would be very interesting to discuss it from the point of view of whether there were such things as organised ferments at all. The old idea of a ferment after the discovery of the vegetable character of the yeast cell was that the ferment was one of those small micro-organisms which set up this peculiar decomposition, and it was only in very recent times that some people were bold enough to imagine that the ferment was not an organism at all, but the secretion that the organism prepared. The candid objector had been very much in evidence with regard to Büchner's discovery. It was said it could not be an enzyme, and the theory was advanced in all seriousness that it was the actual liquified protoplasm of the yeast cell, which had been extracted and liquified without destroying its life, and that fermentation was a function of the live cell. Without wishing to be too severe, he could not help wondering how it was possible for the human mind to entertain this view of life associated with the grinding up into a perfectly impalpable powder in the presence of dynamite earth and the subsequent pressure of five tons to the square inch. If that would not kill anything that had life in it, life was rather a different thing from what people had been in the habit of thinking, and it was certainly not easy to destroy. That hypothesis, wild as it seemed to be, had, however, to be tested, and Büchner's enzyme was subjected to a crucial test. It had been found that chloroform was fatal to the life of all these vegetable organisms or microbes; chloroform water was an antiseptic, and they would not live in it. Here was an easy way, then, of detecting whether it was an enzyme or whether it was living matter. If it were living, chloroform would put it *hors de combat*; if it were an enzyme chloroform had no effect, for the antiseptic in question had been shown to be without any deleterious influence on the enzymes with which they were more familiar. It was found then that you could saturate this liquid of Büchner's with chloroform and add sugar to it, or saturate a sugar solution and add the enzyme to it, or mix them together and saturate both with chloroform, and still fermentation would proceed perfectly well, just as well, indeed, in the presence of chloroform, as it did in its absence. Then another test was suggested, that of desiccation. It was found you could dry up this extract until you could powder it, until it was perfectly impalpable, having been filtered from all kieselguhr, and that it could then be kept for some time (and in some experiments it was kept for two or three months), and then after it was put in water again and dissolved it went to work just as before. This discovery, which as far as fermentation was concerned, was by far the most important discovery of the century, had led in turn to another, which was closely connected with the biology of yeast. He was trying to show that all this work was done from the yeast point of view, not for the production of alcohol, but for the nourishment of the yeast all, and all the processes so far had had a bearing upon that. All these four enzymes had been definitely set apart by the yeast to enable it to live at the expense of the sugar.

Now the solution which Büchner prepared contained a great deal of proteid matter. The activity of the enzyme was very difficult to maintain. It destroyed itself in a day or two, or perhaps a week, according to its condition. What was the cause of that? It was found on examining the liquid at the end of that time, when the enzymic power had disappeared, that it did not contain this proteid matter which coagulated at between 45° and 50° C., but it did contain something which it had not before, namely, a great quantity of crystals of tyrosin. Tyrosin was one of the bodies which came from the action of the pancreatic juice on the proteids, which brought about what was called the fermentation of trypsine. Tyrosin marked the final stage of digestion. Here would be seen disappearance of the proteid and the appearance of the tyrosin. At once the view suggested itself that they had in yeast another enzyme which would digest the proteid constituents of the food; in fact, the yeast appeared to show a concentration, so to speak, of all the digestive operations which were found so widely differentiated in our own bodies. This enzyme was looked for, and in due course it was found.

There was a little difference between the action of some of these enzymes. The question was whether the action, whether digestive or fermentative, took place inside the yeast cell or in the yeast cell outside it. That was discussed for some time, and it had been found that one of these ferments, at any rate, *invertase*, was excreted from the yeast cell into the liquid, and it could be prepared without any pressing by the mere filtration of the liquid which came from fermentation. A good many of the enzymes could not be got out of the cells in that way, and it was for a long time a puzzle to know how the enzyme could make its ways into the liquid. The yeast cell, the piece of protoplasm, was covered up by what looked like an impervious piece of cell wall, a transparent membrane having no holes in it as far as one could see. It appeared to be an impervious membrane except that water could diffuse through it just as you could get water osmotically through various membranes. But these enzymes which were suspected of having this power of passing through the membranes were colloidal, and it was well known that this power of diffusion was generally confined to crystalline bodies; colloids would not go through a membrane. Another discovery which had been made in recent years had enabled them to see how this could take place. This was due to the work of Mr. Gardiner at Cambridge, who showed that the cell wall was not a homogeneous membrane at all, but was permeated or perforated by delicate pores filled with protoplasm, which was so abundant in the interior. In this way they could understand how some of these colloidal bodies might pass through, but there was a great deal of difference between the colloidal bodies, of which zymase was probably another. Zymase absolutely refused to have anything to do with passing through the cell wall at all. Experiments had not yet been made on a sufficient scale to enable anything to be said about the other ones, but amongst the somewhat lengthy

group there were no doubt very distinct differences in that direction. This was a very bare outline of what was known of the biology of yeast, and dealt with it from the physiological side only. The morphological side was of equal interest, and was capable perhaps of even more discussion.

Discussion.

The PRESIDENT, in proposing a hearty vote of thanks to Professor Green, said the lecturer had been too modest to refer to his own experiments in corroboration of Büchner's discovery of the enzyme present in yeast, but he believed he had succeeded in producing a liquid which contained this enzyme.

Mr. PETER MCEWAN said this lecture might be regarded as the completion of the series given some years ago by Professor Armstrong. He should like to ask Professor Green if he could give any nformation with regard to certain foods which were now being produced from yeast, and were, from certain points of view, some of the most startling discoveries of modern science. He referred to the preparations resembling in taste, odour, and apparently in chemical constitution, extract of meat. If they could be prepared and kept in an efficient manner, the very large quantity of yeast which was now virtually wasted might be used to supply what we could not rear in our fields. He would like to know how they were prepared, and if other foods of a similar nature could be obtained from the same source?

Professor GREEN said this question could not be easily discussed without taking a great deal of time. The economic side of the matter he did not feel justified in going into. Some of these articles had been sent to him, and he had tried them, and found them really very nice. They seemed practically equal to Liebig's extract, and consisted pretty much of the same bodies. He did not like to say offhand what they contained, but they were mainly extractives of the same kind as in Liebig's and other meat extracts. There was no proteid matter in them so far as he knew. They were stimulating rather than nourishing, but they would hold their own with similar productions on the market. The man who was chiefly responsible for them was Professor Kossel, of Berlin, who had published many papers, showing how to prepare them, and giving analyses, and to those he must refer for further information. He (Professor Green) had once the ambition to try to prepare some himself, but on inquiring from Professor Kossel the right quantity to work with, and on being told it was some gallons, he decided to leave it alone. He believed, however, that the present waste of yeast was in process of being stopped, and that brewers were now considering, some of them at least, if they could not get their waste yeast turned into such commodities.

The PRESIDENT said that non-alcoholic stimulants of the kind referred to were often useful when solid food could not be taken, and if waste yeast could be converted into a marketable form it would be a great step forward.

The next paper was on

Spurious Alexandrian Senna,

by Prof. H. G. Greenish. It is printed at page 470, and gave rise to the following discussion:—

The PRESIDENT, in proposing a vote of thanks to the author, said it was very important that it should go forth to the world that this *Cassia obovata* was not genuine Alexandrian senna. He remembered when it came to London to a very considerable extent, and when in fact from one-sixth to one-eighth of the leaflets of senna were from *C. obovata*. It was interesting to remember that the Society was the means of correcting the adulteration that went on, to a very considerable extent, of Alexandrian senna with argel leaf, which was present to a very large extent fifty years ago. Jacob Bell drew the attention of Mehemet Ali to it, and pointed out that it was necessary that the adulteration should be stopped, and ultimately that was done. It was very common for medical writers on materia medica to speak of adulteration as if it were always intentional. He believed that merchants, as well as others, desired to have things as pure as possible, and he was glad to think that the day of intentional adulteration was passed. Accidental impurities, rather than adulteration, would be a better term, but they still found writers on medical materia medica adhere to the term adulteration. Those leaves should certainly not be used in medicine in place of Alexandrian senna, as they were not quite so active, and both were cheap enough now compared with what they used to be some thirty years ago. Their thanks were due to Professor Greenish for having pointed out so carefully how the two kinds differed, and how they could be distinguished by careful microscopic examination.

Mr. WALTER HILLS said he was more interested in the moral the author drew from his researches, and he was sure he would have the sympathy of all students present in saying he hoped the time was coming when examiners would not require them to know all the adulterations of the past fifty or hundred years. He recollected when he came up for examination being confronted with argel leaves, and he was rather surprised to hear that this was still a feature of the examinations. As in the moral world, so in the pharmaceutical, he thought it was better to study what was right than what was wrong. If they fixed upon a high ideal, it would be better than trying to find out what was evil. He, therefore, quite agreed with Professor Greenish in advising students to discover all they could—microscopically and otherwise—about the true senna, and leave other things to take care of themselves, only examining them as they arose from time to time.

Mr. HOLMES said he had put on the table a number of specimens of substitutions and adulterations of senna which had come to the Museum during the last forty or fifty years. In looking up the history of the matter he had come across some facts which might be interesting. *Cassia obovata* was the original senna which was brought to Europe by the Moors, and its cultivation extended from Italy to Spain. Amongst the specimens he found one which was sent about ten years ago from Barcelona; it was a very fine specimen, but did not get any sale at the time. As to the question whether it was more active than the other senna, as far as he could learn from the literature of the subject, that was dependent on the amount of extract which it yielded. *C. obovata* yielded less extract than the *C. lanceolata*, but whether it was more active depended, he thought, on the individual. The *C. obovata* was used at the Cape of Good Hope, Porto Rico, and in Jamaica. With respect to adulterations of senna, he well remembered as a student having had to deal with argel leaves, which were rather plentiful at that time. They then disappeared for some years, but in 1857 they came into the market again, and there were three specimens on the table. With regard to *Colutea arborescens* a curious fact occurred some time ago. He had some leaves sent to him, some of which he was informed had been eaten by a horse, and produced injurious, though not fatal, effects. He found on examination that they were the leaves of the *Colutea arborescens*, which was not at all an uncommon shrub. You could see it by the side of the North London Railway, in the neighbourhood of Mildmay Park. He had also placed on the table some boxes in which the shapes of the leaves were well shewn, and there were also slides showing the characteristics of the leaves. Though it might be quite true that it was better to study what was right than what was wrong, it was not always easy to know what was right and what was wrong unless the student knew exactly what to look for.

Mr. MCEWAN said that since the plague had begun to be prevalent in India senna had been rather scarce. Though an old-fashioned drug, its consumption was increasing yearly. It was in such times of scarcity that substitutions came on the market, and this paper was, therefore, especially appropriate at the present moment. The question raised was exceedingly important,

especially to British pharmacists, because the bulk of the Alexandrian senna imported into this country never went out again, whereas probably from 80 to 90 per cent. of the Tinnevelly senna was re-exported to the United States and to Germany. It followed, therefore, that if anything offered as Alexandrian senna were disposed of, the English were more likely to get it than anyone else. It should also be remembered that a large proportion of the Alexandrian senna sold was in a bruised condition, almost a coarse powder; if that were not sold in its crude state, it would be easy to turn it into the mill and re-bale it, and then Professor Greenish's investigation would come in very nicely, because he had shown them how to detect the substitution in the powdered condition. Students who took an interest in the commercial side of the question would find that adulteration had a great deal to do with the distributing market. A great deal of senna was imported into Marseilles, and at one time Trieste was a large drug distributing centre, and sent drugs to many places which were now supplied from London. Naturally, a great deal of the information which Professor Greenish had given them came from Continental observers, and was based on conditions which did not, and could not, now exist, seeing how the market had changed. There were no shrubberies in the neighbourhood of Mincing Lane, from which merchants could get a sufficient number of adulterants to mix with their bales of senna. It was not that our commercial morality was higher, but time was too valuable to allow of unbaling and repacking things of such a nature. As there was really a distinct scarcity of the cheaper kind of senna, it was very desirable that this question of the activity of *C. obovata* should be settled once for all. A good many years ago, when he was in Edinburgh, Professor Stockman made his *début* as an investigator by a paper on the active principles of senna cathartic acid. He did not now recollect what particular species Professor Stockman examined, but he thought it would be a good opportunity for Professor Stockman, now that he had plenty of students to work for him, to go into the subject from this point of view. It would also be well that its physiological effect should be investigated.

Professor Greenish, in reply, said with regard to *Colutea arborescens*, it was well known to be active, and it was stated by Colladon to be about as active as *C. obovata*, but Colladon derived his information from a pamphlet published in 1711, so that his information was 189 years old. He thanked Mr. McEwan for the excellent supplement he had supplied to his notes, and said he thought this was just the time when there was such an abundance of this senna on the market that somebody should take it up and settle the question of its physiological activity once for all. He did not care to try one or two experiments on himself, which would not be conclusive. It had been used in Porto Rico and Jamaica, but he was not aware that it was used there still.

Intensification of Plates.—P. von Janko, in Eder's 'Jahrbuch der Photographie,' compares the results obtained by the various developers. If the negative is bleached with copper bromide and then redeveloped, the intensification is very inappreciable; if after copper bromide bleaching, it is darkened with a bath of silver nitrate the result is also unsatisfactory, after intensification with mercuric iodide the negative in time becomes yellow and bleaches. A more satisfactory intensifier is mercuric chloride, the results vary as the bleached plates have been darkened with ammonia, sodium sulphite, hydroquinone iron developer, or ammonium sulphate. The best intensifier is a uranium salt; to guard against the yellow colour usually developed by this method, the intensified plate is immersed in a bath of water, 200, alum, 20, hydrochloric acid, 1, and the bath renewed three or four times. Through prolonged washing the negative is reduced. To prevent this, it is washed in half per cent. acetic acid, and for about ten minutes in pure water.—*Amat. Photograhp.*, **13**, 110.

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

The 'Organic Chemistry Appendix,' by W. H. Perkin, Jun., Ph.D., F.R.S., and F. Stanley Kipping, Ph.D., D.Sc., F.R.S. (London and Edinburgh: W. and R. Chambers, Ltd. Pp. 74. Price 1s.), consists of chapters on the subject dealing with compounds of physiological importance, which are added to the authors' original text-book with the object of rendering it more useful to medical students and general readers. The properties of the principal constituents of plants—starch, inulin, glycogen, dextrin, gums, glucosides, essential oils, terpenes and allied compounds—are therefore described, and substances found principally in the Animal Kingdom are also dealt with. The latter include lecithine and the ptomaines, uric acid derivatives, amido-acids and their derivatives, compounds of unknown constitution found in bile, hæmoglobins, and proteids. The whole serves as an excellent summary of the chief constituents of plants and animals, and pharmaceutical students, in particular, will find the little book an admirable introduction to physiological chemistry.

British Sanatoria for the Open-Air Treatment of Tuberculosis, by Percy Dunn (London: John Bale, Sons and Danielson, Limited. Pp. 50. Price, 1s. 6d. net), is a reprint, with additions, from the *West London Medical Journal*. It supplies useful information upon the subject of which it treats, and shows the progress made in connection with the open-air treatment of tuberculosis in this country. A complete list of British sanatoria is given in this book, and there are numerous illustrations.

In 'Banks and their Customers' (London: Effingham Wilson. Pp. 77. Price 1s.) we have a practical guide for all who keep banking accounts, the subject being considered exclusively from the customer's point of view. The present edition is the third and, in it, the subject is brought well up to date.

"Shall Pharmacists Become Tradesmen?" is the question asked by Mr. George J. Seabury in a closely printed volume of nearly two hundred and forty pages. The chief subjects discussed therein is the ever-fresh one of cutting prices, and that seems to be considered from every possible point of view. The author's object appears to be the securing of a final settlement of the status of pharmacy, professionally and commercially, and he strongly insists that a properly-organised attempt in that direction would not be a forlorn hope. The latter part of the book is devoted to the methods of organisation, and the answer to the question in the title is suggested on the last page, where pharmacists are urged to help in the local and general organisation of pharmacy if their answer is in the negative. The author does not desire to make any profit by the sale of the book, and copies are supplied by George J. Seabury, Maiden Lane, New York, U.S.A. at thirty cents each post free.

The 'Materia Medica Labels,' adapted for public and private collections, published and sold by Mr. H. K. Lewis, 136, Gower Street, London, are in every way admirably adapted for the intended purpose. The labels number nearly 500, and are printed in clear bold type, on gummed paper. The list of substances included has been compiled from the British Pharmacopœia, 1898, and other sources, and it is divided into two parts. The first comprises chemical materia medica, including alcohols, alkaloids, sugars, and neutral bodies; part two includes substances of organised structure obtained from the vegetable and animal kingdoms. Regarded as a whole, the book of labels is an excellent production; nothing better of the kind has yet been published.

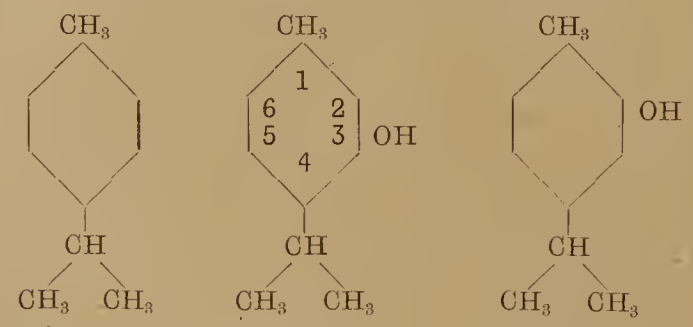
THE STUDENTS' COLUMNS.

EXPLANATORY NOTES ON THE B.P. 1898.

Suppositoria.—As prodicted in the Students' Page when dealing with these preparations in the 1885 Pharmacopœia, the soap basis for suppositories has been omitted in the 1898 B.P. Comparing the formulæ now given with those formerly official, the student should note that the necessary quantity of oil of theobroma for preparing the given number of suppositories is not stated, but in the process for tannic acid suppositories one is told to take "a sufficient quantity to form with the tannic acid a mixture which will fill twelve suitable moulds, each capable of holding fifteen to sixteen grains (or about one gramme) of oil of theobroma." Since moulds of the requisite degree of accuracy cannot be obtained, the pharmacist must therefore determine for himself the capacity of the moulds he employs if accurate results are desired. The student should consult papers on this subject which will be found in *P. J.* In the formula for phenol suppositories, a little white beeswax is introduced to compensate for the depression of melting point caused by the addition of phenol to oil of theobroma. In making tannic acid suppositories the mixture should only be heated sufficiently to just liquefy it: a higher temperature will cause the tannic acid to separate in an unmanageable clot. The melted mixtures for iodoform and compound lead suppositories on account of the density of the medicaments should be assiduously stirred in order to effect a uniform distribution of the materials, and not poured into the moulds until they begin to thicken.

Thymol.—Thymol is a phenol, *i.c.*, contains a hydroxyl group substituting one of the hydrogen atoms of the benzene nucleus. The formula given in the Pharmacopœia shows that it contains three substituting groups (OH), (CH_3) and (C_3H_7), but does not indicate the relative position of these groups in the benzene nucleus. As a matter of fact the formula applies equally well to carvacrol, an isomer of thymol, another constituent of thyme and other essential oils. Both carvacrol and thymol are phenols derived from cymene. Cymene is methyl-isopropyl-benzene, the prefix iso indicating that the C_3H_7 group is not the normal propyl group—CH_2—CH_2—CH_3, but the isomeric group—$CH\begin{matrix}CH_3\\CH_3\end{matrix}$

The graphic forumlæ for the three substances mentioned are—



Cymene. Thymol. Carvacrol.

The constitution of thymol and similar bodies may also be expressed without the aid of graphic formulæ by numbering the substituting groups, thymol being methyl-1, isopropyl-4, oxy-3, benzene, while carvacrol would be methyl-1, isopropyl-4, oxy-2, benzene. The chief rules for the arrangement of these numbers or indices is to give the index:—(1) to that substituting group in which the element directly connected with the nucleus has the lowest atomic weight. If two or more of these groups contain the same element directly bound to the nucleus (as in the case above, CH_3 and C_3H_7) then one gives the index (1) to that group in which the sum of the atomic weights of the remaining elements is least. Since thymol is a phenol it dissolves in aqueous solutions of potassium and sodium hydroxides to form soluble phenate. This property is utilised to separate thymol from the other non-phenol constituents of the essential oils which contain it. The oil is shaken with caustic lye which, after separation from the oil, is washed and acidulated with hydrochloric acid. This liberates the thymol which is precipitated. Thymol is a powerful antiseptic, and as it is much less caustic and irritating than many other antiseptic substances finds extensive use as a preservative.

Thyroideum Siccum.—The thyroid gland of the sheep is selected as the one most easily obtainable. The sheep's gland is also the one with which most of the clinical as well as experimental work was done when the thyroid gland was first introduced as a medicinal agent. We know, therefore, more about the physiological action and dosage of sheep's thyroid, although the glands of other animals have also been occasionally employed. Thyroids can easily be obtained from the local butcher, to whom they are of little value. The whole gland consists of two dark red lobes lying one on each side and closely applied to the wind-pipe (trachea). Their upper extremities are connected by a bridge of tissue running across the trachea. This bridge is often very thin and pale in colour, so as to be not readily observable. In removing the gland it is most convenient to cut out the two lobes separately, and leave the connecting bridge behind. The organ is easily found in the surrounding tissues owing to its dark red colour. By careful dissection each lobe will be found to be a broadly almond-shape, firm; yet succulent, mass of tissue, which should be thinly sliced and pounded. The pounded mass should then be spread in a thin layer and dried *as rapidly as possible* in a current of warm air, or *in vacuo*, if the means are at hand. It is important to remove the bulk of the moisture as quickly as possible. When sufficiently dry to coarsely powder, it will be found advantageous to spread the powder out in a thin layer in a desiccator for a day or two in order to dry it as completely as possible. The removal of the fat is not necessary from a therapeutic point of view: it is only done with a view to prevent the development of rancidity. This, however, does not occur in a powder which is thoroughly dried and preserved in the same condition.

FLORAL CALENDAR FOR NOVEMBER.

Owing to the mildness of the season there are still a few flowers procurable for purposes of dissection, although November usually presents the smallest number of any month in the year.

Amaryllidaceæ.—*Sternbergia lutea.* Fl. *Eucharis amazonica.* Fl.

Begoniaceæ.—*Begonia* species. Fl.

Boraginaceæ.—*Anchusa italica.* Fl.

THE "HOSPITAL" AND CHEMISTS.

Though Sir Henry Burdett has acknowledged, and apologised for, the impropriety of his manager in disregarding a clear understanding he entered into as to the publication of particulars relating to the analyses of certain samples of belladonna plasters, that personal matter is of comparatively minor importance. Objection must, however, be taken to the article in the *Hospital* of the 11th inst., inasmuch as it makes the damaging imputation cast upon chemists and druggists, in the article that appeared in the *Hospital* of October 21, p. 44, more serious, by extending it to "pharmaceutical chemists of the highest class." Evidently the writer of that article was very imperfectly acquainted with the subject on which he wrote. The title of it quite misrepresented the matter to which the analyses related, viz., the advertising of a particular firm who claim that the belladonna plasters they make are stronger than those of other manufacturers. To apply the results of the analyses "as illustrating the freedom and impunity with which the substances dealt in by chemists are apt to be adulterated," *Hospital*, October 11, p. 44, was, to say the least, inappropriate, and capable of being regarded as the kind of commercial philanthropy sometimes indulged in by sensational writers on the subject of adulteration. Reference to the British Pharmacopœia was equally out of place, since the plasters in question are trade articles—mostly made in America—which are sold like ready-made clothes; they do not profess to be manufactured according to the Pharmacopœia; they are in some instances distinctly described as being different from the official plaster, and they are not what would be supplied by a pharmaceutical chemist when belladonna plaster is prescribed.

But the most serious ground of objection to the article in the *Hospital* is the absence of any indication of the fact that the plasters reported upon were not obtained from the shops of dispensing chemists; that they were collected by the agents of the *Hospital* from "drug stores" and from the establishments of companies improperly professing to carry on business as chemists and druggists, or in some instances as pharmaceutical chemists. Unless, therefore, the writer of the article was ignorant of the difference between a legally qualified chemist and druggist, and the "drug store" of a company, improperly assuming that title or even the title of pharmaceutical chemist, the omission of those particulars was capable of a sinister interpretation. Those, however, are the data which were suppressed. The importance of them will be evident from what is stated above, and when compared with the remarks made in the *Hospital* article as to the public having to depend upon the "honesty of the druggist" as the very pivot on which hangs the life of the patient in many cases. Under the conditions to which the analyses of belladonna plasters related, there was no justification for such comments, because the comparison made was between manufacturers, and had no bearing upon the question "how far druggists were in the habit of complying with the directions of the Pharmacopœia in regard to some of the more ordinary preparations commonly sold over the counter." Neither did the results of the inquiry warrant the insinuation "that much the same sort of sophistication goes on in many branches of the drug trade, and that trusting to the absolute helplessness of the purchaser, druggists only too often supply drugs which are anything but of the nature, quality, and substance asked for." If that statement is applicable, it applies to the class of establishments from which the *Hospital* collected samples of belladonna plasters, and not to the persons lawfully entitled to describe themselves as pharmaceutical chemists or chemists and druggists.

ARGUMENT FOR REGULATION OF "COMPANY PHARMACY."

Amid the unfortunate differences of opinion prevailing as to the course to be taken in regard to "company pharmacy," the suggestion that each member of the Council is honestly striving to find a satisfactory solution of the problem finds confirmation in the paper which appears in this week's issue by Mr. Glyn-Jones. Whether Mr. Glyn-Jones' views as to "placing companies in the same position as that occupied by individuals" will meet with general acceptance or not, few will be disposed to question the opinion he expresses that the Government has no intention of prohibiting companies from carrying on the trade in drugs, proprietary articles, and other goods commonly met with in a "drug store." In addition it may be stated, with confidence, that no chemists desire such prohibition, or expect the Government "to go beyond the principle of the 1868 Act." The further opinion that the wisest and most politic course would be for chemists to offer their assistance to the Government in drawing up a suitable amending clause, will also commend itself to most minds as reasonable. But beyond that point difference of opinion might be expected, and the argument put forward by Mr. Glyn-Jones appears to be vitiated by the mistaken assumption that "practice of pharmacy" and "sale of poison" are synonymous terms representing the same thing.

The same mistake was the ground of opposition to the objectionable clause providing for regulation of the sale of "poisonous articles" in the 1883 Bill, and it overlooked

the fact that the desire of the Government was to regulate the sale of "poisonous articles," simply as a matter of trade, not in any way coming within the scope of pharmaceutical practice. Unfortunately, that trade view of the matter has been extended by the Government also to the limitations established by the Pharmacy Act. That view has prevailed until the time when the House of Lords Committee came to the conclusion that the formation of companies intended to enable an individual—by taking advantage of company machinery—to do that which the Pharmacy Act, 1868, made unlawful "should be stopped," and when the LORD CHANCELLOR admitted "the propriety of subjecting existing companies" to restriction. But "such restrictions as are proposed in the Companies Bill" take a trade view of the matter different from that indicated by the provision of Clause 3 of the Bill relating to professional practice, and are objectionable for that reason, because the matter they relate to is not a matter of trade. The whole difficulty of the registered chemists seems to arise from such confusion of trade transactions with professional functions—from oversight of the fact that the restrictions of the Pharmacy Acts do not relate to trade; but to nothing more than the professional supply and manipulation of the most potent poisons, as medicine, and to such regulation of the sale of those poisons as was deemed to be expedient for public safety. For those reasons it would appear that the principle of the Pharmacy Acts must be sustained in any legislation to remove the legal anomaly that has been created by the House of Lords' decision, with the aid of company law; unless indeed it can be shown that what was expedient in 1868 is now unnecessary.

That view is so obviously reasonable, that were it "properly represented" to the Government and to members of Parliament they might be expected to admit its cogency, and to give their support to the claim that none but legally qualified persons should be allowed to sell, dispense, or compound poisons, or keep open shop for those purposes and use the title of pharmaceutical chemists or chemists and druggists in connection with that business. At present "company pharmacy" serves as a legal back door admitting unqualified persons to enjoyment of the privileges of qualified persons—a device by which the whole object of the Pharmacy Act, 1868, may be defeated, and a burlesque of limited liability. The restrictions of the Companies Bill would not interfere in the least with the formation of "bogus" or "one-man" companies, and the dispensing or sale of scheduled poison would be open to any unqualified person with impunity.

The facts referred to by Mr. GLYN-JONES at the end of his paper should certainly be kept in view; they also suggest the following remarks:—

1. In 1867 Parliament perceived that it was expedient for the safety of the public that persons keeping open shop for the retailing, dispensing, or compounding of poisons should be legally qualified for those duties, and the Act of 1868 provided for that public necessity.

In 1899 it has been perceived that a decision of the House of Lords has had the effect of neutralising that provision, so that a legal anomaly exists enabling unqualified persons, by the aid of limited liability machinery, to do what the Act of 1868 made unlawful. The Lord Chancellor has pointed out the need for a remedy of that anomaly, by subjecting existing companies to restrictions. The conditions in 1867 and in 1899 are therefore closely analogous and might be expected to point to analogous legislative action.

2. In view of the analogy above pointed out, the clause that the Government should be asked to adopt for amendment of Clause 2 of the Companies Bill should provide for the re-establishment of the principle underlying the action of Parliament in 1868, in regard to what was held to be expedient for the safety of the public.

3. Legally qualified persons being made responsible by the Pharmacy Act they are not required to employ qualified assistants—why, therefore, should that condition be imposed upon companies?—and since "a qualified servant cannot confer qualification on the employer," what purpose would that condition serve in any case?

4. Though the financial relations of a legally qualified chemist are unimportant to the public, the individual competence indicated by legal qualification is all important.

5. The limitation of retailing, dispensing, or compounding of poisons and of keeping open shop for those purposes, to legally qualified persons, does not in any way savour of trade unionism. Tendency to trade unionism is perhaps the least reproach that could be cast upon registered chemists and druggists.

6. The claim that seven legally qualified persons have a right to carry on their business as a limited liability company is in no way unreasonable, nor is that claim inconsistent with the claim that seven unqualified persons should not be allowed to carry on that part of a chemists' business which requires qualification under the Pharmacy Act.

JANUARY EXAMINATIONS.

THE January examination arrangements have now been fixed. The Major written work will be taken on Thursday and Friday, December 28 and 29, both in London and in Edinburgh. The practical portion of the same examination will be held on Wednesday, December 27, in London, and on Saturday, December 30, in Edinburgh. With regard to the Minor examination, the practical work in chemistry and pharmacy is expected to commence on Tuesday, December 26, in Scotland, and on Thursday, December 28, in London, though a good deal depends upon the number of candidates entering for the qualifying examination at the latter place. In view of the near approach of the date when the new regulations take effect, a considerable increase in the number of candidates may be shown at the next three examinations. There may exist among students a very natural desire to escape the imperfectly known effects of the new regulations, which loom before them like gathering storm clouds; and it is possible that the encouragement of this train of thought may precipitate the student into an untimely presentation before the examiners. There can be no satisfaction in such a course, and very little economy, After all, the terrors of the new *régime* are very largely imaginary; no increase in the stringency of the examination is imminent, and the ten-guinea fee should scare no pharmaceutical aspirant worth his salt into courting rejection by coming to the examination room before his training is completed.

ANNOTATIONS.

Mr. Glyn-Jones's Suggestion, in the article contributed by him to this week's Journal (see p. 473), that every critic of the action taken by the Council of the Pharmaceutical Society should produce a clause for a Companies Bill, is exactly to the point. A number of feverishly active agitators in Lancashire and elsewhere are never so happy as when they are exercising their powers of destructive criticism in connection with what everyone else says or does. Unfortunately, however, those self-same critics are decidedly lacking in constructive ability, just as they only too frequently display their want of "sweet reasonableness." Instead of attempting to find a common ground of action and to pull together, they start out with the most vague notions concerning what is requisite or desirable, in the shape of amended legislation, and the persons actually responsible for shaping and carrying out a policy are expected to submit everything they produce to be wrangled over by persons who are ignorant both of possibilities and probabilities. The present is essentially a time for action, not for talk, and it is now as absurd for any body of British pharmacists to assemble to discuss matters of principle in connection with the company-pharmacy problem, as it would be for the British Army in South Africa to remain passive while the Houses of Parliament met and considered the desirability of meeting the attacks of the Boers.

Those who Think they Have a Mission to remedy the existing state of affairs in pharmacy should set to work in a reasonable manner and, after fully mastering all the facts, crystallise their ideas into a briefly-worded expression of opinion regarding what, according to their view, the remedy should be. That expression of opinion should then be verbally communicated at a meeting of some local association, or embodied in a letter addressed to the Council of the Pharmaceutical Society or to the Editor of this Journal. But to talk wildly at meetings or to write at random about generalities, when no definite conclusion has been arrived at in the individual's mind, is worse than useless. The first question which British pharmacists need to answer at the present moment is whether they are prepared to fight for their titles and their practice. That answered in the affirmative, the next question which presents itself is: What form shall the attack take? Every registered chemist should make up his mind on that point without further loss of time, and take care that his opinion is recorded. Is anything to be done from within or not, and, if anything, what? Are we to fight only for the restriction of titles to those who assume them by virtue of their legal qualification, or are we also to demand that the intention of the Pharmacy Act, 1868—the prohibition of the retailing, dispensing, or compounding of poisons by any persons not registered under that Act—shall be realised?

The Council of the Society has unanimously decided that titles should be restricted to duly qualified individuals, but it is as yet divided on the second point. It seems only fair, however, that those who are inclined to chafe at what they regard as unreasonable delay should abstain from reproaches until they have definitely settled the matter in their own minds. If it be desired to secure the total prohibition of the sale and dispensing of poisons by companies of unqualified persons, that should be fairly and squarely stated, without waiting for the Council to decide upon the adoption of a different course, and then proceeding to express disapproval of what has been done. Reason for non-acquiescence may exist in any case, but it is vain to grumble after the event when no protest has been entered in advance. We repeat, therefore, with Mr. Glyn-Jones, that "every critic should produce his clause," or — if he is prepared to leave that duty to his elected representatives — to wait patiently on the course of events, and be prepared to support the Council loyally when the proper time for action arrives. Further, whatever clauses are proposed should undoubtedly be expressed in clear language. If it be desired to prevent companies selling and dispensing poisons, let that be stated in plain English, without attempting to mask the issue by a mass of unnecessary verbiage.

The Position Taken Up in the *Pharmaceutical Journal* has always been that the only effectual remedy is (1) to prevent any company assuming or using titles indicating individual qualification, and (2) to prevent persons not registered in accordance with the Pharmacy Acts from taking advantage of the Companies Acts to keep open shop for the sale and dispensing of scheduled poisons. In so far as we fall short of that ideal, to that extent must any remedy fail to prove effective. Neither qualified directors nor qualified managers can properly supply the place of qualified proprietors, and every shop where scheduled poisons are retailed, dispensed, or compounded should be under the direct and unlimited control of such a proprietor. Companies need not have any directors, and, even if they had legally qualified ones, their existence would, more likely than not, prove totally ineffective as public safeguards. Managers, again, are an uncertain quantity; they may be here to-day and gone to-morrow, and the protection afforded to the public by a manager's qualification must of necessity be of the very slightest. If, therefore, the pharmacists of Great Britain are to fight, let them fight for some worthy object. The easy course, the selfish plan, is to agree that what has come about accidentally should be allowed to persist. But it is a duty pharmacists owe to the public to strive to prevent the unqualified from masquerading as qualified; and, that being so, the obvious course is to fight for both titles and practice.

The Caledonian Oracle who, over the pen-name "Pharmaceutical Chemist," disposes, with apparent ease (see p. 491), of the company pharmacy problem, appears to possess a peculiarly constituted set of logical faculties. The object of his letter is, he states, to clear the ground of much debatable matter, yet he proceeds to accomplish that desirable end by dishing up proposals discarded by the medical, dental and pharmaceutical authorities long ago. In fact, the clause quoted by our correspondent as not being an original suggestion, emanated from the joint committee of professional corporations which the Council convened some years back to devise a remedy for the evils created by the House of Lords' decision in 1881. It is incorrect to suggest that the associated bodies were at any time enamoured of the clause, but it received, perhaps, a longer period of consideration than its contemporaries. Why should "Pharmaceutical Chemist" imagine that exhuming the clause from the "mass of details" in which it was comfortably buried would conduce to a clearer perception of our position? With regard to tactics—seemingly a strong point with our correspondent—if it be manifest, as he says it is, that the Lord Chancellor is determined to put a stop to the abuse of company machinery in relation to medicine and pharmacy, what subtle wisdom lies in the proposal to limit his lordship's action to the question of titles? What special degree of statesmanship lurks in the suggestion that chemists should ask for less than the highest officer of the Crown has expressed his willingness to give? Such tactics are, we understand, not generally practised in the commercial and political life of Scotland, and it is somewhat startling to find them advocated by a chemist who writes from Edinburgh. Another argument put forth as favouring the restricted policy, is that it could not reasonably be objected to even by those interested in companies. Why the interests of the public and of fifteen thousand registered persons should be subordinated to the susceptibilities of unqualified traders is a species of distorted logic which we must leave others to untwist; but one thing is tolerably clear, no thoughtful pharmacist will believe that much advantage is likely to accrue by considering the "company" question in a timid or "kid-glove" sort of spirit.

THE COMPANY PHARMACY PROBLEM is referred to in the *British Medical Journal* of last week, and entire agreement is expressed with the pharmaceutical demand that anything which extends the use of titles implying qualification beyond those persons who have actually received the qualification should be strenuously resisted. It is said to be obvious "that anything of the kind would be a most dangerous precedent, not for the pharmaceutical chemists alone, but for the medical profession. It is clear on all sides that the protection afforded to the public by preserving a proper significance to titles, inadequate though this protection may be, must not be weakened." But with regard to the contention that pharmacists should not be parties to the regulation of company practice, and so indirectly to its recognition, the *B. M. J.* thinks it loses much of its force, since there are already "so many perfectly legitimate businesses" conducted in this form that the thing must be acknowledged as existent and must therefore be grappled with. Apparently, our medical contemporary is of opinion that the Council of the Pharmaceutical Society should produce a clause which would prevent the use of pharmaceutical titles by companies and insist upon a board of directors consisting of individuals registered under the Pharmacy Acts. If that were done, it is thought that the medical profession would be prepared to give every assistance in its power to enable the Society to get the clause adopted when the Companies Acts Amendment Bill again comes before the House of Commons, an event which is understood to be likely to happen at an early period in the ensuing session.

THE TITLE "CHEMIST" is degraded sufficiently by joint-stock companies of unqualified persons which usurp it, but the ordinary newspaper reporter does not spare further degradation, and, as frequently as not, any case of an objectionable nature against an individual who sells drugs is promptly assumed to involve a chemist and druggist. Such a case was brought last week against a Wolverhampton herbalist, who had sold spirit of nitrous ether deficient in strength, and "paregoric" prepared without opium. He was fined 40s. and, in default of payment, committed to prison for four months. Needless to say, he is not a registered chemist, but he is described as such in several newspaper reports, and others refer to him as that impossible creature—"an unqualified chemist." Obviously, a protest against the misapplication of their title should have been addressed by the chemists of Wolverhampton to every newspaper which was in error, but so far we are unaware of anything of the kind having been done.

THE EXPLOSION AT ST. HELENS is reported upon in a Blue Book which has just been issued. Colonel A. Ford, C.B., her Majesty's Chief Inspector of Explosives, had the assistance of Dr. Dupré, F.R.S., in his inquiry, and inquiries on the spot appeared to establish the fact that a quantity of potassium chlorate exploded, but so far as could be ascertained such an explosion has hitherto been unknown either here or abroad. It became necessary, therefore, to conduct a number of experiments in order to discover if potassium chlorate really would explode under favourable conditions. The experiments seem to prove that the chlorate will not explode as the result of detonation, but that, whilst it gradually decomposes when subjected to heat, it ultimately gives off oxygen suddenly, exploding with violence when a certain temperature is reached. In view of the result of the experiments, Colonel Ford states that it cannot be doubted that an explosion of a small portion of chlorate actually did take place at St. Helens, and he considers that the buildings in which potassium chlorate is stored, as well as the kegs which contain it, should in future be made of non-inflammable materials.

THE USE OF BORIC ACID AS A PRESERVATIVE was the subject of a prosecution by the St. George's (Hanover Square) Vestry at Westminster Police Court last week, when several important firms were summoned for selling clotted cream preserved with the acid. In the case which was argued, that against Messrs. Hudson Brothers, counsel for the Vestry said that the real point was whether the vendors of clotted cream were entitled to put any preservative into it, and that there had been decisions given by magistrates against the use of boric acid in milk. Mr. Gill, who appeared for the defence, said the magisterial decisions had nothing to do with the present issue; the acid was used in clotted cream as it was in the preparation of hams. The magistrate (Mr. Sheil) said he had previously given a decision about preservatives in milk; he thought there was a clear distinction between milk from the cow and clotted cream, as the latter was the result of a process. The experts called for the prosecution included Dr. Corfield, who stated that the use of boric acid had been largely discontinued in medicine, because of its irritating effect on the stomach and intestines; it also occasioned skin eruption. The half-pound jar of Devonshire cream sold by Messrs. Hudson contained about sixteen grains of boric acid—the maximum single dose of the drug for an adult, and, as clotted cream was now largely prescribed for children instead of cod liver oil, the effect was likely to be mischievous. For the defence Mr. Thomas Bond, consulting surgeon of Westminster Hospital, said he used boric acid largely in his practice; it was only injurious to the digestion in very large doses. For the purpose of giving evidence before a Board of Trade commission, he had experimentally taken three ten-grain doses of boric acid daily for the last six weeks, and the drug had produced no ill effect whatever. He thought it was absolutely necessary to use boric acid, or other preservative, in cream sent a long distance by railway. At this point, after the statement had been made that other well-known experts were to be called for the defence, the case was adjourned.

"PILLS AND POTIONS, LIMITED," is the heading given by the *Financial News* to a critical article dealing with the prospectus of the Midland Apothecaries, Limited—a company formed, with a capital of £25,000, to take over the business of two well-known Birmingham chemists, and to add a wholesale department. The sub-heading of the same article—"A 'Brummagem' Company whose shares may be a drug in the market"—accurately indicates the tone of the criticism which follows. The prospectus states that the directors "feel justified in assuming that under their guidance the wholesale department will earn fair profits," but the *Financial News* objects to the very qualified nature of that opening statement, and infers that the position is such that only the special abilities of the directors—which the public must take on trust—can do justice to it. Again, it is asked, what are "fair profits"? Why do not the directors give some figures? But more extraordinary still, it is observed, is the latter part of the paragraph. "The vendors guarantee to medical practitioners who become shareholders 7½ per cent., 'provided their accounts amount annually to 10 per cent. of their holding.' This is the introduction of a species of 'tied house' system, which has been said to be objectionable in the licensed trade, but will be a thousand times worse when applied to doctors' prescriptions. What a pleasant prospect for the shareholders, if they receive no dividends in the first three years, to know that the medical members among them are receiving 7½ per cent.! However, if any doctors are inclined to take this chance they might ascertain who guarantees the vendors." In conclusion, it is suggested that, if the enterprise is good enough for Birmingham, subscriptions should be taken up locally, as they are not likely to come from anywhere else. The *Manchester Courier* also states that several very serious flaws in the prospectus might be pointed out, but it does not indicate them.

AN EVENING MEETING of the Pharmaceutical Society will be held at 36, York Place, Edinburgh, on Wednesday, November 29, at 8.30 p.m. Mr. Peter Boa, the Chairman of the Executive of the Society's North British Branch, will occupy the chair, and will deliver the Inaugural Sessional Address. The Assistant Secretary will afterwards describe the recent additions to the Library and Museum.

LINNEAN SOCIETY.

At a meeting held on November 2, Dr. A. Günther, F.R.S., President, in the chair, Professor Stewart, F.R.S., exhibited and made remarks on a preparation of

The Leaves of Mimosa Pudica

showing the diurnal and nocturnal positions. He also exhibited the embryo and egg-cases of *Cestracion philippi*.

The Rev. G. Henslow next read a paper on the proliferous state of

The Awn of Nepal Barley.

After describing the two varieties *Hordeum cœleste*, vars. *ægiceras* and *trifurcatum*, he showed that the inverted flower-buds (which constitute the peculiarity of the monstrosity) were different in the two varieties. In *H. ægiceras* it commenced at a bend in the flattened awn, with an axial protuberance arising from the middle point; in *H. trifurcatum* the hastate form began with two protuberances, one on each side. In Prof. J. S. Henslow's figures (Hooker's *Kew Journ. Bot.*, i., 1849, pp. 33—40, pls. 2—3) the arrested awn widens, the edges folding over until it forms a "cucullus," while the lateral processes of various shapes grow out at the base (really inverted summits) into what he termed "wings." His material, however, was not sufficient to enable him to interpret either the cucullus or the wings. The Rev. G. Henslow's specimens showed that the former often assume the form of two glumes more or less coherent by their edges, while the wings became their awns.

Dr. W. G. Ridewood then read a paper on the Hyobranchial Skeleton of

The New Aglossal Toad,

Hymenochirus boettgeri. The hyoidean cornua of this animal was shown to be ossified, a fact unique among tailless Amphibians. The hyobranchial skeleton is severed into an anterior and posterior portion; and, as in *Pipa* and *Xenopus*, the throhyal bones are intimately related with the laryngeal cartilages. The author considered that the anatomical features presented by *Hymenochirus* tended to confirm the view that *Pipa* and *Xenopus* are genetically related and not convergent types.

Mr. Harold Wager also read a paper on the Eye-spot and Flagellum in *Euglena viridis*. He showed that the principal vacuole at the anterior end of

A Euglena-Cell

is in communication with the "gullet." The eye-spot, which consists of a mass of pigment-granules, is curved around the gullet in the region of the vacuole. The flagellum expands just beneath the eye-spot into an oval or nearly spherical enlargement, and below it is attached to one side of the principal vacuole by means of two basal filaments. The enlargement beneath the eye-spot is probably functional in controlling the movements of the flagellum, and may be stimulated by the light absorbed by the eye-spot.

CHEMICAL SOCIETY.

The first meeting of the winter session was held on November 2, Dr. W. H. Perkin, F.R.S., the Vice-President, in the chair. After the routine business had been gone through, the Chairman spoke of the loss which the Society had recently experienced in the death of Sir Edward Frankland (a former President) and Professor Bunsen (a foreign member).

The first paper, by A. Vernon Harcourt, dealt with

Mixtures of Gaseous Chloroform and Air.

The methods of determining the relative proportions of gaseous chloroform and air in a mixture of the two were considered, and a method was given for producing a mixture of air and chloroform in any desired proportion.

The amount of chloroform that should be mixed with air to produce an anæsthetic has not yet been accurately determined, owing to the fact that so far a good chemical method of making this determination is wanting. Of the known methods the reaction between chloroform and hot alcoholic potash appears to be the best. It is found, however, to give results that are invariably 4 per cent. too low. The equation expressing the reaction is as follows:—

$$CHCl_3 + 4KOH = 3KCl + HCOOK + 2H_2O.$$

This reaction is open to the objection that differences of opinion exist as to whether all the chlorine of chloroform can be converted in this way into chloride.

The author has worked out a method depending on what he thinks is a new reaction. The mixture of chloroform vapour and air is made to undergo combustion in the presence of air and steam, a heated platinum wire in a state of incandescence being placed in contact with the mixture. The chloroform reacts according to the equation:—

$$2CHCl_3 + 2H_2O = 6HCl + 2CO_2.$$

The reaction is effected in about an hour, and the amount of hydrochloric acid is determined by means of a standard ammonia solution. Precautions are necessary to avoid the production of free chlorine; thus, a sufficient quantity of steam must be present, plenty of time must be given, and the platinum wire must be maintained at a dull redness.

It was found that chlorine, on being similarly treated, was converted into hydrogen chloride. The reverse action may possibly take place, but as soon as hydrogen chloride is formed there is a tendency for it to be abstracted by the water. The reactions are:—

$$2H_2O + 2Cl_2 \rightleftharpoons 4HCl + O_2$$

The mixture of air and chloroform vapour for anæsthetic purposes is obtained by blowing air through a mixture of chloroform and alcohol. The vapour is then passed through sulphuric acid, then through water, contained in wash-bottles. In this way the alcoholic vapour is removed. The strength of chloroform in the vapour is regulated by observing the density of the chloroform and alcohol during the passage of air through it. To effect this two specific gravity beads are immersed in the liquid, so adjusted that at the right density one floats and the other sinks. The liquid may be maintained at the density required by occasional additions of chloroform. The amount of chloroform taken up by the air is constant when the density and temperature remain constant.

Mr. Hehner and Dr. Perkin joined in the discussion. In reply, Mr. Harcourt said that the density of the liquid afforded a good means of ascertaining the proportion of chloroform vapour present on account of the marked difference in specific gravity between chloroform and alcohol. A liquid might be used that was less volatile than alcohol, but for the present alcohol was satisfactory, from the harmlessness of its vapour and its purity.

The next paper was read by Mr. J. Lewkowitsch, on

The Theory of Saponification.

The author's experiments lead him to the conclusion that the hydrolysis of triglycerides must be considered a bimolecular, and not a tetramolecular, reaction. This theory being correct, it follows that partially hydrolysed fats should contain diglycerides and monoglycerides. They have been so found by acetylating the intermediate products, freed from glycerol, and proving that the acetylated products exhibit considerable acetyl values, which rise and fall with the progress of saponification.

Mr. Bertram Blount and Mr. Hehner criticised the methods employed. The former was anxious to know whether the samples worked on truly represented the bulk from which they were taken. The author assured him that the samples were truly representative, and remarked that much of what had been said was not relevant to the point at issue.

Mr. F. G. Edmed, B.Sc., then came forward with a note on

The Action of Dilute Nitric Acid upon Oleic and Elaidic Acids.

The conversion of oleic acid to elaidic acid by the oxidising action of nitric acid—a reaction so familiar to pharmacists—appears to have come as a revelation to the author. He finds that if the density of the acid does not exceed 1·25, and the action takes place in the cold, the yield of elaidic acid is quantitative. The yield is diminished by increasing the strength of the nitric acid and by a rise in temperature. The purity of the oleic acid affects the rapidity of the change. The dilute nitric acid used was freed from nitrous acid, which brings about a similar change. Nitric acid of strength ranging between 1·2 and 1·3 has no action in the cold on elaidic acid; hot nitric acid decomposes it only upon prolonged boiling.

A paper on

The Formation of Tetrazoline,

by H. E. Stapleton and S. Ruhemann, was then read. This was followed by the most important contribution of the evening, in the shape of a paper by W. J. Pope and S. T. Peachey, on

Asymmetric Optically Active Nitrogen Compounds.

These compounds, the dextro- and lævo-benzyl-phenylallyl-methyl ammonium iodides and bromides, have been prepared, and their

isolation proves that dissolved substances may owe their optical activity to the asymmetry of nitrogen.

The paper drew a warm appreciation from Dr. ARMSTRONG, who considered it the most valuable contribution made to stereochemistry since the introduction of the geometrical considerations of Le Bel and van't Hoff. The discovery of a method of preparing asymmetric nitrogen compounds, besides being of intrinsic importance, afforded a means of investigating the disputed problem as to the valency of nitrogen in ammonium compounds.

Dr. LEWKOWITSCH also spoke, and referred to his attempt some time ago to prepare silicon compounds possessing optical activity.

The following papers were then taken as read:—"Ethylic Dibromobutane-tetracarboxylate and the Synthesis of Tetrahydrofufuran-α-α'-Dicarboxylic Acid," by Bevan Lean, D.Sc., B.A.; "Camphoroxime, Part III.; Behaviour of Camphoroxime towards Potassium-Hypobromite," and "Optical Influence of an Unsaturated Linkage on Certain Derivatives of Bornylamine," by M. O. Forster, Ph.D., D.Sc.; "The Interaction of Sodium Hydroxide and Benzaldehyde," by C. A. Kohn, B.Sc., Ph.D., and W. Trantom, B.Sc., Ph.D.; "Electrolytic Preparation of Induline Dyes," by E. C. Szarvasy, Ph.D.; "The Heat of Combination of Copper with Zinc," by T. J. Baker, B.Sc.; "The Action of Sulphuric Acid on Fenchone," by J. E. Marsh; "On Glucosides," by Hugh Ryan, M.A.; "Notes on Poly-azo Compounds," by Raphael Meldola and W. A. Williams; "The Application of Powerful Optically Active Acids to the Resolution of Externally Compensated Basic Substances; Resolution of Tetrahydroquinaldine," by W. J. Pope and S. T. Peachey; "The Application of Powerful Optically Active Acids to the Resolution of Feebly Basic Substances; Resolution of Camphoroxime," by W. J. Pope; "The Application of Powerful Optically Active Acids to the Resolution of Externally Compensated Basic Substances; Resolution of Tetrahydroparatoluquinaldine," by W. J. Pope and E. M. Rich; "Homogeneity of Dextro-lævo-α-phencthylamine-dextrocamphor-sulphonate." by W. J. Pope and A. W. Harvey; "The Characteristics of Racemic Liquids," by F. S. Kipping and W. J. Pope; "A Method of Discriminating Between 'Non-racemic' and 'Racemic' Liquids," by W. J. Pope and S. J. Peachey; "On Two Hydrated Cobalt Oxides, Green and Buff-coloured," by W. N. Hartley, F.R.S.; "A Method of Separating Isomeric Xylidenes from the Commercial Product," by W. R. Hodgkinson and L. Limpach; "Action of Hydrolytic Agents on α-dibromocamphor, and the Constitution of Bromocamphoronic Acid," by Arthur Lapworth, D.Sc.

The meeting then adjourned.

LIVERPOOL CHEMISTS' ASSOCIATION.

The usual meeting was held on Thursday evening, the 9th instant, at the Royal Institution, Colquitt Street, Mr. H. WYATT, jun., one of the Vice-Presidents, in the chair.

Mr. James Mercer was proposed as a member by Mr. DUTTON and accepted.

Among the "miscellaneous communications" was one from Mr. ANTHONY S. BUCK, who, showing a sample of

PURIFIED AND SCALED GUM ARABIC,

asked if any member had had experience of its applicability in pharmacy. He should not, of course, think of using it himself for dispensing purposes, but was of the opinion it might come in useful for making mucilage for cough mixtures and other preparations.

In reply, Mr. A. C. ABRAHAM said that he could not claim to have used the article, but from its appearance he should say it was probably a poor gum acacia, purified by solution, filtration, and probably decolorisation. As the solution would most probably be heated so as to scale it, the resulting scales would make a solution or mucilage not liable to the same amount of change as the ordinary gum was.

The CHAIRMAN said it was rather a pity that Mr. Buck did not satisfy himself that the gum shown answered the Pharmacopœial tests. Providing it was of good flavour, without odour, and answered the requirements of the B.P., he (the Chairman) should not have the least hesitation in using it, both for dispensing and for other uses, in place of gum acacia. Centrifugal separators were now largely used for clarifying thick solutions, like that of gum, for jujube-making, so that these solutions could be made, purified, and evaporated in about a third the time formerly required—a consideration where the solutions were liable to change in the way mucilage does.

Mr. HOCKEN wished to know if there was a good ready test by which one could ascertain

THE PURITY OF BEESWAX.

He had had a sample lately which was quite brittle, so much so that he had refused it.

The CHAIRMAN said that on the authority of the late Mr. Conroy there were only two tests readily applicable to beeswax—namely, the taste, and the feeling when rubbed in the palm of the hand. These were a matter of experience, so that the only way to be absolutely certain was to make a complete analysis.

Mr. COWLEY also confessed his ignorance of a good ready test—such a thing was indeed a desideratum. The easiest test for fats was that of saponification, but as regards the sulphuric acid test, it was easy but by no means certain.

Mr. A. C. ABRAHAM was surprised to hear from Mr. Cowley complaints of the sulphuric acid test—a test which had been introduced, he believed, by their friend Mr. Edward Davies, and one which had given such good results. In his opinion the melting point of beeswax was an important item, and was curiously constant in English wax, and in other waxes from various sources it was equally constant, with all genuine samples from the same source.

Mr. A. S. BUCK said he had experienced trouble with some

CACHETS CONTAINING CALCIUM, SODIUM, AND POTASSIUM GLYCEROPHOSPHATES,

owing to the deliquescence of the salts. He would like to know if this could be prevented. The prescription was altered by the medical man to a mixture instead of cachets when his attention was called to it.

The CHAIRMAN thought a mass might have been made with cacao butter or other substance, cut into lozenges, and then enclosed in cachets.

Messrs. Catford and Cowley were then called upon to read their paper on

THE DETERMINATION OF ETHYL NITRITE IN SWEET SPIRITS OF NITRE AND IN MIXTURES,

which is printed in full at page 471.

At the conclusion an animated discussion took place, in the course of which the CHAIRMAN remarked upon the practical value of the paper and the ease with which these estimations were carried out when Messrs. Cowley and Catford's method was used. The hydrolysis of ethyl nitrite of sweet spirit of nitre in aqueous mixtures was an important fact to be borne in mind by prescribers; still, at the same time, he should say that provided an alkali were present, as was generally the case in mixtures containing sp. æther. nit., the nitrite would not entirely disappear, but would be permanent from its becoming, instead of ethy nitrite, a nitrite of the alkali present and ethyl alcohol.

A vote of thanks was proposed to the authors by Mr. A. C. ABRAHAM, who complimented them on their work. He was inclined to the opinion of the Chairman, that in alkaline mixtures it would be found that the nitrite was permanent. Of course, the therapeutic action of sp. æth. nit. would become rapidly *nil*, as Messrs. Cowley and Catford had pointed out, if the menstruum were purely aqueous. The decomposition of ethyl nitrite in contact with water was known, and had been alluded to before.

In seconding the vote of thanks, Mr. BUCK said he could only see one objection to the test, and that was that it could not be used by persons who were in the slightest degree colour blind.

Mr. WOKES supported the vote of thanks, and gave his opinion that it was by no means certain that the activity of sp. æther. nit. was due to the ethyl nitrite it contained. The other bodies present had a good deal more to do with it than was generally credited.

Mr. COWLEY, in acknowledging the vote on behalf of Mr. Catford and himself, agreed that this hydrolysis of ethyl nitrite was common knowledge, but it needed emphasis. Alkalis might serve to retain the nitrous acid as nitrites, but scarcely ammonium carbonate and hydrate. As far as sugars went, his knowledge did not extend to what their effect might be in retarding or preventing the change. He was down with his friend Mr. Catford for a note on liq. bismuthi, but in consequence of further experiments their work had led them into, he would ask leave from the meeting to postpone the reading of their results until the next meeting, when he could promise them something more worthy of their attention.

Greatly to the convenience of their hearers, Messrs. Cowley and Catford had tabulated their method of working the nitrite determinations, and had had printed copies distributed among the audience, who were thus enabled to follow the process closely. Any pharmacist wishing for one of the printed tables may have one on forwarding a stamped directed envelope to Mr. Cowley, at the Liverpool School of Pharmacy.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The President, Mr. F. W. Gamble, occupied the chair at a meeting of this Association, held at 73, Newman Street, London, W., on Thursday, November 9. The Secretary, Mr. J. Evans, having read the minutes of two previous meetings, several new members were proposed, and an impromptu discussion then took place. Each person present had the privilege of writing on a slip of paper a question on any subject; the slips were folded, placed in a hat, shaken together, and handed round again, everyone being expected to draw a slip from the hat and to answer the question written thereon. After allowing a brief interval, the President called upon Mr. T. Morley Taylor to answer the question put to him.

Mr. Taylor said the writer wished him to express his opinion on a proposal recently made in one of the trade papers with regard to the advisability of establishing

Suburban Branches of the C. A. A.

He had not given much thought to the subject, but answering "straight off the reel" he should say that the idea was not only unworkable but would not be to the interest of the Association, because notwithstanding excellent facilities for travelling, they had even now great difficulty in getting a large regular attendance at the meetings. What was needed was to get members to attend at 73, Newman Street, and not anywhere else.

Mr. T. Edward Lescher echoed the previous speaker's remarks. Decentralisation would not be to the advantage of the Association. The present rooms were within easy reach of seven-eighths of the assistants in London, and he did not see why their arrangements should be upset to cater for the remaining eighth.

The President was of opinion that the idea was totally impracticable. This was also the opinion of Mr. C. Morley, who pointed out that although the trade paper referred to had put forward the suggestion as a new idea, it really had been made several years ago by a gentleman connected with the editorial staff of another paper.

How to Abolish Company Pharmacy.

Mr. George Pearson said the question put to him was quite a simple one in its way, consisting of but a few words—viz., "How are we to abolish Company Pharmacy?" He could only suggest that the questioner should read the report of the Council meeting published the previous week. That might throw a little light on the subject. It appeared to him, however, that by abolishing the Widow's Clause the chief difficulty might be overcome.

The President was not sanguine enough to hope that company pharmacy would ever be abolished. He thought the question would finally resolve itself into one of regulation instead of abolition. The company pharmacy problem appealed to the ordinary pharmacist simply on the ground of competition, and if companies were prevented from carrying on the business, competition would still exist, and matters would be little better than at present. He was pleased to note that since the last Council election there had been a healthier and stronger tone prevailing at the Council meetings.

Town *versus* Country Apprenticeship.

Mr. J. Fothergill was asked to state whether an apprenticeship in the country was more preferable from a pharmacist's point of view than in town. He thought that inasmuch as apprenticeship was usually the commencement of the would-be pharmacist's studies for the Minor, the country was to be preferred, because there the apprentice would have more time for study than he would in town. On finishing his apprenticeship, however, he certainly ought to obtain a situation in town as an improver, and so gain a wider practical experience.

Mr. Langford Moore thought the period of time usually occupied by apprenticeship might with advantage be considerably reduced.

Mr. A. Latreille was inclined to favour a situation approximate to a fair-sized provincial town possessing a good technical school. A country apprenticeship, in his opinion, had its advantages which better fitted the apprentice for his after life.

Mr. Pearson agreed with the last speaker. A country apprentice, he believed, as a rule made a better all-round assistant and a better pharmacist. He had more opportunities of learning the practical part of his calling.

The President, as a town apprentice, held the view that although a country pharmacist becomes acquainted with a different class of business than in town, there are plenty of places in and around London which possess as good opportunities for acquiring a thorough knowledge of the pharmacist's business as can be got anywhere. If he had to choose again, he should certainly become a town apprentice.

Mr. T. Morley Taylor was strongly of opinion that no man ought to take an apprentice who does not manufacture most of the B.P. preparations, because it was of no use sending a youth up for examination who had not opportunities of gaining his pharmaceutical knowledge by practical experience. He believed that was the chief reason why most of the ladies who present themselves for the Minor examination fail.

Botany and the Pharmaceutical Curriculum.

Mr. Latreille was requested to state his opinion as to the value of botany in the pharmaceutical curriculum. He did not pose as a botanist, but at the same time he believed that a good fundamental knowledge of botany was most necessary for a true understanding of materia medica. He thought it would be a great advantage to students of botany if the botanical gardens were opened on Sundays.

Mr. Lescher, while recognising the necessity for a knowledge of botany, thought there was a tendency on the part of the examining authorities to put the cart before the horse. Too much stress was laid on botany—more so than materia medica—and too little on other matters of more importance to the every-day work of the pharmacist.

Mr. Morley did not agree with Mr. Lescher. He thought it was most essential that pharmacists should have a complete and thorough knowledge of botany in order to properly understand the nature and properties of the drugs they have to handle, and to be able to speak with some certainty as to the probable value of newly-discovered medicinal plants.

Mr. Morley Taylor, although partly in accord with the anti-botanists on the ground that in actual practice the pharmacist does not require so much botany, was of opinion that as it is only by the study of botany from the biological side that the pharmacist gains a knowledge of physiological processes, botany was a very good subject in the pharmaceutical curriculum, and he should be sorry to see it deleted.

The President said botany was one of the most interesting subjects they had to deal with, and he thought thanks were due to the Pharmaceutical Society for having kept the standard as high as it has.

Is Substitution Justifiable?

Mr. Langford Moore was asked whether in retail practice substitution is justifiable to a certain extent. From a retail point of view he could not answer, but from a moral standpoint he should say that a pharmacist was justified in substituting an article which he knew to be better than the one asked for, and one which would do more good.

Mr. Pearson was impelled by the last speaker's remarks to rise immediately to denounce most emphatically the practice of substitution. The substitutor simply sucked another man's brains and reaped the reward of his labour. He classed him as a man who as a boy would substitute a penny for a shilling in his master's till.

Mr. Morley sympathised with the view taken by Mr. Pearson. Still, he thought that if a pharmacist substitutes an article that he considers to be quite as good as the one asked for, and answers the purpose just as well and the customer is satisfied, no harm was done.

The President said there were two classes of substitution, one in retail work and one in regard to prescriptions. While the former might be permitted if the customer was consulted, the other was strongly to be deprecated. But he did not think it existed in regard to prescriptions.

Mr. Lumley did not agree with the President that substitution in respect to prescriptions does not exist. He could give an instance where, in a very large firm of dispensing chemists, substitution was largely practised.

Is the B. P. a Legal Standard?

Mr. J. Evans (Secretary) was asked to state whether the B. P. is a legal standard under the Food and Drugs Act. He was not quite certain on the point, but it was usually recognised by magistrates as a legal standard, and he thought it ought to be. A pharmacist should not sell anything that was not in conformity with the B. P.

Mr. Lescher said the B. P. was not legally recognised as a legal authority. Dr. Attfield had himself stated so definitely. Whether it should be or not was a question that ought to be settled. Some of the proceedings taken under the Food and Drugs Act were most trivial. He knew of cases where people in old-established businesses had sold a certain article under a certain name for forty years, and

it had given general satisfaction. When customers asked for that article they expected to get a certain thing, and got it. But a representative of the law stepped in, and because the article in question was not what the B. P. said it should be, although it was what customers wanted, penalties were imposed for what the magistrates in their wisdom—or ignorance—regarded as serious offences.

Mr. MORLEY TAYLOR pointed out that although the B. P. is not a legal standard under the Food and Drugs Act, there is a neglected section of the Pharmacy Act, 1868, which makes it a penal offence for anyone to compound medicine not in conformity with the B. P. If that section was put into force it would be a good argument why a pharmacist should charge a higher price for his medicines, because they would be of a higher standard.

The PRESIDENT said there was undoubtedly a discrepancy between the law as to retailing and dispensing. The subject was beset with difficulties, but was a very suitable one for discussion.

OTHER QUESTIONS.

Several further questions were put, chiefly relating to the method of dealing with doctors' prescriptions and various preparations of the B. P., and were answered by Mr. Meynell, Mr. Lumley, the President, and Mr. Dewhirst. Mr. Morley was asked to say whether prescriptions should bear the name and address of the doctor. He said emphatically Yes, and stated his reasons.

"Is Company Pharmacy declining?" was the question put to Mr. Lescher, who said it was one easy to put but hard to answer. Without a lot of statistics he could not venture to express opinions on the matter.

The PRESIDENT, in declaring the meeting adjourned, said he thought the discussions had been fruitful in many points that had been beneficial to those present.

FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

A meeting of the Executive Committee was held in London on Thursday, November 9, Mr. J. SMITH (Liverpool) in the chair.

It was decided that the opinions of pharmacists throughout the country should be ascertained upon the different suggestions, for a course of action to be taken. With reference to the clause relating to pharmacy in the Companies Bill, to obtain as wide an expression of opinion as possible, it was resolved that a communication be sent to all local secretaries of the Pharmaceutical Society, as well as to the secretaries of all associations, with the request that answers for or against the suggested clauses be sent to the Secretary of the Federation on or before the 30th instant.

Since many of the local associations are entitled to larger representation on the Federation, in accordance with the amended Rules, it was further resolved that the Federated Associations be requested to appoint their additional representatives for the year ending 1900.

It was also decided that the Honorary Secretary should endeavour to procure a list of the names and addresses of the members of the local associations. Since one of the objects is, as stated in the rules, "to advise and assist in the formation of local associations and other organisations of chemists," it was resolved that existing associations be asked to furnish a copy of their rules, to provide the Executive Committee with the experience of the local bodies in different districts, so as to enable them to offer suggestions applicable to the necessities of each district.

A discussion on the policy of having a whole day for the annual meeting, and as to reportersbeing present, was adjourned.

The HONORARY SECRETARY (Mr. J. Cocks) reported that five more associations had become affiliated since the last annual meeting.

The following is the text of a communication sent to all local secretaries of the Pharmaceutical Society and to secretaries of al local associations:—

THE FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

Mr.....

.....

DEAR SIR,—You have no doubt observed that at the last meeting of the Pharmaceutical Council there was a wide divergence of opinion between members of the Council on the question of Company Pharmacy in connection with the clause to be submitted for embodiment in the Companies Bill. It is of the greatest and most urgent importance that the Council should be informed, before next month, of the opinion of the Pharmaceutical community upon this subject, which vitally affects the general interests of chemists, and we ask you, as the centre of organisation in your district, to furnish us with the views of those residing therein. If there is a local association in your district, will you please communicate with the president or secretary, at once, in order that the question may be discussed during the month of November? In the absence of any association of chemists will you invite a meeting of the chemists in your locality, in order to get an expression of their opinion?

Signed by the Executive Council,
JOHN SMITH.
W. L. CURRIE.
CHAS. THOMPSON.
E. S. PECK.
JAS. COCKS, *Hon. Secretary.*

It is earnestly requested that meetings be called and resolutions adopted and forwarded to the Honorary Secretary not later than November 30th inst.

Communications to be addressed to
JAMES COCKS,
8, Edgcumbe Street,
Stonehouse, Plymouth.

November 13th, 1899.

Each of the following suggestions have received more or less support:—

1. To protect chemists' titles and make it illegal for companies of unregistered persons to keep open shop for selling poisons, as in the case of individuals.
2. To apply for protection of titles only.
3. That all the directors of a company shall be qualified.
4. That the managing director only need be qualified.
5. That a company shall be allowed to carry on the business with a qualified manager or assistant, who shall be registered for the purpose, and whose name shall appear in connection with the business.

The Honorary Secretary has also sent the following letter to each of the local secretaries of the Pharmaceutical Society who gave information respecting localities unrepresented:—

THE FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

Mr.....

DEAR SIR,—I have to thank you for your courteous reply to the recent circular sent out by me on behalf of the Executive Committee of this Federation. So many replies have been received that I am sure you will pardon me for not writing you a personal letter.

This organisation is entirely dependent on voluntary workers, and beside the fact that, generally speaking, we are widely separated by distance from the localities you name, we are very fully occupied just now with the business of the Federation. I therefore feel that we may venture further to trespass on your good offices. In the districts you mention where there are no local representatives of the Pharmaceutical Society, viz., ...

.....

if you will get some members of the Society residing in the respective localities to nominate suitable men for the position you will materially assist in the better organisation of the pharmaceutical body. It may be done by letter or post-card, addressed to the Secretary of the Pharmaceutical Society at Bloomsbury Square.

A supplementary list of nominations will be submitted to the Council at the December meeting, but nominations should be in not later than November 20th.

Yours truly,
JAMES COCKS,
Hon. Secretary.

Edgcumbe Street,
Stonehouse,
Plymouth.
November 6th, 1899.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The second meeting of the session of the above Association was held on Friday, November 10, at 17, Bloomsbury-square, Mr. E. Chapman in the chair. The minutes of the first meeting having been read and confirmed, Mr. Finnemore brought in the amendment concerning Rule V. of the Association, notice of which was given at the last meeting. The amendment was defeated. Mr. Upsher-Smith's amendment—"That the time of meetings be altered from 5 p.m. to 5.30 p.m."—was then brought forward by the CHAIRMAN, seconded by Mr. WILSON, and carried unanimously. Mr. GARSED gave notice of an amendment as follows:—"That the officers of the Association and six other members shall be elected annually, at the first meeting in each session, to form an Executive Committee. Of the six other members, two shall be major students and four minor students." The CHAIRMAN then called upon Mr. P. E. F. Perrédès (a former student in the School of Pharmacy, and member of the Association) to read his paper upon

METHODS OF DRAWING MICROSCOPIC OBJECTS.

Mr. Perrédès confined himself to showing the construction of the principal plant tissues, and illustrated his remarks

by sketches upon the blackboard. The Chairman thanked Mr. Perrédès for his interesting paper, and invited members to put questions. Messrs. Upsher-Smith and Garsed responded, and were answered by Mr. Perrèdés. The proceedings then terminated. The next meeting of the Association will be held at 17, Bloomsbury-square on Friday, November 24, at 5.30 p.m. Particulars will be issued to members in due course.

CAMBRIDGE PHARMACEUTICAL ASSOCIATION.

At a meeting held at the Bull Hotel, Cambridge, on Friday, November 10, Mr. Alderman Deck, F.C.S., presided over a large attendance of members, when Mr. E. Saville Peck, B.A., delivered his reports as delegate to the British Pharmaceutical Conference and Federation of Local Pharmaceutical Associations at Plymouth last July.

Mr. Alderman Deck thanked the members for his re-election to the presidential chair, and expressed a hope that the support of the members might continue to increase. He then called upon

Mr. Peck, who said, referring to the Conference, that as there seemed some doubt or misapprehension as to what it really was, he should give a brief outline as to its constitution and aims. It was, he said, "an organisation established in 1863 for

The Encouragement of Pharmaceutical Research

and the promotion of brotherly feeling and mutual goodwill among those interested in Pharmacy." Its objects were (1) To hold an annual conference of those engaged in the practice or interested in the advancement of pharmacy. (2) To determine what questions in pharmaceutical science required investigation, and when practicable to allot them to individuals or committees to report thereon. (3) To maintain uncompromisingly the principle of purity in medicine. (4) To form a bond of union among the various associations established for the advancement of pharmacy. He detailed the programme of the meeting of the Conference at Plymouth, the kind reception accorded by the Mayors of the Three Towns; the number of interesting papers read, and the right royal welcome and entertainment extended to the Conference by the Local Association at Plymouth. To him the Conferences were year by year increasingly interesting and enjoyable. He urged those present, especially the younger ones, to join the Conference as it was both an object and incentive to keep up their work after qualifying for the practice of pharmacy, besides affording them an opportunity of meeting old associates. Referring to the statement sometimes made that the Conference seemed almost entirely given up to pleasure, and that very little real work was accomplished, he reminded the meeting that the Conference was not the annual meeting of the Pharmaceutical Society, where the year's work in pharmaceutical politics could be criticised, but it was a purely voluntary body, having no official connection with nor forming any integral part of the society in question; the latter gave it its hearty moral support. He hoped that, as the next meeting was to be held in London, many of the Cambridge pharmacists would join, and he assured them they would not be disappointed. Mr. Peck then went on to refer to

The Work of the Federation,

and stated that it had been viewed in the past erroneously, he submitted, rather in the light of a political caucus somewhat hostile to the Pharmaceutical Society, but, on referring to the rules, it will be seen that its objects are to assist the Council, and promote the interests of the Pharmaceutical Society and local associations, in every possible way to bind together the various associations throughout the kingdom, numbering between 40 and 50, having no official or other connection with each other, or with the central organisation, and by this means form a connecting link, which at the present time is clearly wanting between Associations and the Pharmaceutical Society through the local secretaries. It had been advanced by some that the work of the Federation was clearly the work of the Society itself, and would be much better done by the members of Council. He was not adverse to that view, but for reasons—no doubt wise ones, and best known to that body—they had not at present seen their way clear to do this, and thus followed the *raison d'être* of the Federation. He briefly alluded to the annual meeting of the Federation at Plymouth. The alteration of rules, the appointment of an executive, the forthcoming request by the Federation to various local associations to discuss the questions of the protection of chemists' titles, and company pharmacy generally.

Mr. A. Sidney Campkin, J.P., had much pleasure in proposing a hearty vote of thanks to Mr. Peck for his interesting report of the proceedings of the last conference at Plymouth, but before proceeding to speak in detail on the general subjects he asked one and all to join with him in congratulating Mr. Peck upon his recent appointment as an examiner of the Pharmaceutical Society. He had set up a high ideal, and with patience and perseverance had succeeded in reaching it. Such was not the lot of all, but they were all better for having attempted, if they did not succeed in reaching their ideal. He felt sure he should carry all with him when he said the Council had made an excellent appointment.

He thought the Conference would be of service if it acted in concert with the Society, and not as an independent organisation. He approved of the principles of the Federation. Its machinery was excellent. Its proposals for organisation were perfect, and all that was needed to secure the success of the Society, and the desires of the body of chemists, as a whole, was unity of action and complete co-operation. He trusted the points mentioned by Mr. Peck would be discussed in detail at a subsequent meeting, as their time was limited that night; but, as his opinion had been asked, he would briefly state that he considered it a primary duty to secure the insertion of a clause in the Companies Bill, having for its object

The Protection of the Qualified Chemist

against the unqualified trader and company promoter, and in this connection he had no faith whatever in those proposals which had for their object the legalising of trading companies under the cover of either the qualified manager or a qualified directorate, either of which would make their position as qualified and registered chemists worse than now, for at present no store could be carried on as regards sale of poisons (legally) without a qualified man, and if no one would lend themselves to it they could not exist. But what was essential to them was to secure the protection of title, and the same protection as existed with regard to the legal, medical, and other professions. The chemist should be rewarded in return for his long and expensive preparation, and the public interest demanded this, too, for its own protection and safety at the hands of the Legislature, and he thought the proposed clause of the Law and Parliamentary Committee went a long way in the right direction. He, for one, did not object to asking for too much; it was infinitely preferable to asking too little, for their experience was that when once an Act was obtained it was for good or ill for a long time, and it was most difficult to again reopen the question, at all events, for a generation or more. He would only point to the Pharmacy Act of 1868, which they had never been able to amend even in view of the injustice of the decision with regard to limited companies years since. Such decision was never contemplated by the framers of the Act. It had been fraught with mischief to the registered and qualified men under that Act and subsequently, and they should not rest until the Act has been so amended or a clause in the companies inserted, which should place every member of a company upon the same footing (as to responsibility) as is expected from a qualified chemist, and the acts of a company treated as the acts of an individual, which is not now the case, as both themselves and the public knew to their cost.

Mr. E. H. Church seconded the vote of thanks to Mr. Peck, which was put and carried with acclamation, after remarks had been made by Messrs. H. J. Parson, W. L. White, C. J. Addison, and B. Sidney Campkin. Mr. Peck replied to a remark that there were too many organisations at work—the Pharmaceutical Society, the Conference, the Federation—and stated he would heartily welcome a movement towards the combining of forces and the holding of the annual meeting of the Pharmaceutical Society, the sessions of the Conference, and the meetings of the Federation at one and the same place, not necessarily headquarters, on the lines of the Apotheker Verein in Germany.

On the proposition of Mr. Addison, seconded by Mr. W. Turner, it was decided to hold a meeting on December 1 to discuss fully the items suggested by the Federation in reference to the Companies' Bill.

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

The ninth annual dinner of this Association was held on Wednesday evening, November 15, in the Café Royal, Regent Street, W. The President (Mr. J. F. Harrington) occupied the chair, and was supported by Mr. W. Martindale, President of the Pharmaceutical Society; Mr. E. M. Holmes, President of the British Pharmaceutical Conference; Mr. F. W. Gamble, President of the Chemists' Assistants' Association; Dr. A. P. Luff, Dr. B. H. Paul, Mr. Walter Hills, past-President of the Pharmaceutical Society; Mr. R. A. Robinson, Mr. E. N. Butt, and others.

After an excellent dinner and the usual loyal toast, Mr. R. A. ROBINSON proposed the toast of the

WESTERN CHEMISTS' ASSOCIATION (OF LONDON).

MR. ROBINSON said the Western Chemists' Association was well worthy of the approval and enthusiastic support of every chemist in London. It was established some ten years ago by Mr. Henry Long with the object of bringing together the chemists of the district to meet and discuss matters bearing upon their craft, and so establish a bond of friendship amongst them, and also to try to shorten the hours of labour. These were admirable objects for the Association, and he congratulated its members that it had lived so long and attained to its present flourishing condition. They could not all become members of the Pharmaceutical Council; some, although they might think themselves well qualified for the position, would have difficulty in persuading a sufficient number of others to think likewise; others, again, could not spare the necessary time. But they could all join the Western Chemists' Association, where they would have opportunities of expressing their opinions. Mr. Robinson then went on to speak of the burning question now before the pharmaceutical community, suggesting that although this was not exactly germane to the toast it might be advisable for the Association to discuss the question that night. The Pharmaceutical Society, he thought, might be compared to the Church, having a great many in its fold holding different views, some high, some low, and there was a crisis impending. But he ventured to say that if the Society strives only for what is just and right and best in the interests of all concerned, the crisis would have a satisfactory termination. It was a most difficult question, but he should like to express his opinions upon it. In the first place, he should hesitate very much indeed before disturbing the *status quo* the chemists of this country were placed by the Pharmacy Act of 1868. Under that Act it was made indispensable that the proprietor of a business should be a qualified person. Before that was allowed to be altered they must know what they were going to have in its place. He had heard the question asked, What does it matter who is the owner of a business so long as a qualified man is behind the counter? That really was the point to be settled. For the safety of the public, either the person who sells dangerous drugs must be qualified or the person who owns the business. In his opinion the greater safety was in having a qualified person as the owner of a business. If that principle was not upheld, what would it lead to? Suppose a company of seven unqualified persons was allowed to carry on the business of a chemist and druggist, how could they logically refuse to allow an individual to do the same? If pharmacists agreed to that they deliberately threw away the position given to them by the Act of 1868. There were difficulties in the way of a satisfactory termination to the question, but he thought they would be doing wisely and well in putting before the responsible Government what they believe to be the right course. He ventured to say that the Western Chemists' Association might very well consider the question that night, and boldly assert that inasmuch as a large number of persons have spent a considerable amount of time and money in order to comply with the provision of the Pharmacy Act, 1868, they are not lightly or easily to be deprived of the rights granted by that Act. But in anything that was done they must be unanimous. It was because a great many were of opinion that they cannot obtain their just rights that there was so great a rift in the Council of the Pharmaceutical Society. He had great pleasure in proposing the toast, and coupled with it the name of the President, Mr. Harrington.

THE PRESIDENT, in responding to the toast, said with reference to the suggestion made by Mr. Robinson, that as they had met there that evening to enjoy themselves, he did not think it would be advisable to have a discussion. Immediately after the last Council meeting he consulted with the Committee of the Association, and it was decided to have a discussion on the company problem at the December meeting. He should like to add to Mr. Robinson's remarks about their old friend, Mr. Long, who founded the Western Chemists' Association in the year 1890. It was due to his hard work that a small number of chemists were brought together to form the Association, which has gradually swelled to its present number of 130 members. He had heard from a friend that night that Mr. Long was suffering from a very severe illness, and he was sure all present would join in wishing him a speedy recovery. The President then went on to review the work done during the past session, and announced that the annual subscription to the Association was 2s. 6d., and that it was open to every chemist in London and the surrounding districts. The Association was of very great use, in that it gave the ordinary pharmacist an opportunity of speaking openly and publicly on matters of interest. He hoped there would be a good discussion at the meeting in December.

The PRESIDENT then gave the toast of

THE PHARMACEUTICAL SOCIETY AND ITS PRESIDENT.

He did not propose to say much about the Society, and as to the President, Mr. Martindale's name was known all over the world wherever an English pharmacy was to be found. As a member of the Council, he (the speaker) had a better opportunity than most of the members of the Society of knowing their President, and he could assure them that anything that Mr. Martindale puts his hand to he will carry through in an enthusiastic, thorough, and truly British fashion.

The toast was then honoured, followed by the enthusiastic singing of "For He's a Jolly Good Fellow."

MR. MARTINDALE, having thanked the President and those present for the kind and cordial manner in which the toast had been proposed and received, proceeded to give a brief sketch of the work carried on by the Society. In respect to the onerous duty of the Pharmaceutical Society with regard to the prosecution of offenders under the Pharmacy Act, he said there were many offenders against the Act who had to be prosecuted in the interest of the public and the craft; not only grocers and unqualified persons in stores and branch shops, but also qualified persons who do not follow their calling as they ought to do. With regard to pharmacy, it had three sections which are outside the Pharmacy Act, 1868—*viz.*, the wholesale trade in poisonous drugs, and dispensing in hospitals and surgeries. None of those sections were under the restrictions of the Act, but he thought that in order to be in strict ethical accord with the Act all should be under its control. Then, too, company pharmacy was referred to some years ago as being outside the Act. The result of that decision affected pharmacists deeply, for it entrenched on their domain in respect to retailing and dispensing, and was a great barrier to true individual pharmacy, that personal supervision in the pharmacy which the Act was called into existence to regulate. That decision had stood for twenty years, but the Law Lords now see and acknowledge the difficulties of the position, and the Pharmaceutical Council is considering a way out of the difficulty. It was a delicate subject to discuss at the present time, but he might say that the members of the Council are agreed upon two great points—*viz.*, to protect the titles and uphold the principles of the Pharmacy Act, 1868. He again thanked those present for the kind manner in which they had received the toast, and expressed the hope that all would work unanimously for one object—the general good of the craft.

The PRESIDENT, in giving the toast of

THE VISITORS,

coupled with it the names of Dr. A. P. Luff, Mr. E. M. Holmes, and Mr. F. W. Gamble, and stated that they had expected to have present a distinguished visitor, Mr. Mee, the past-President of the Pharmaceutical Society of New Zealand, but he regretted to say he was indisposed, and consequently was not able to be with them that night. He was sure that all would have been pleased to welcome Mr. Mee amongst them.

Dr. LUFF responded, and in a very interesting speech referred to his connection with pharmacy as a member of the Pharmaceutical Society and an honorary member of the Western Chemists' Association. He also spoke of the deplorable decline in the art of prescribing amongst the younger portion of the medical profession, and announced his intention to start a crusade to revive the art, in the interest of the public and of the profession.

Mr. HOLMES also responded, and, taking the risk of being termed a "Boer," took the opportunity to urge the claims of the British Pharmaceutical Conference for more general support by pharmacists. At the present time he believed it comprised only about one half the members of the Pharmaceutical Society, and one-eleventh of the pharmacists on the Register. He contended that the Conference should represent the scientific side of pharmacy in the same way that the British Association represents the country. He hoped that at the forthcoming Conference in London there would be a very large accession of members.

The last toast was that of "The Dinner Committee," proposed by Mr. WALTER HILLS, who coupled with it the names of Messrs. Cracknell, Mathews, and G. S. Taylor, each of whom replied. Mr. Hills went on to criticise Mr. Robinson's remarks at length, and expressed as his opinion that Mr. Robinson was aiming at impossible ideals. He also congratulated the President of the Pharmaceutical Society upon the skilful manner in which he had concealed his views upon the company pharmacy problem.

The arrangements for the dinner were admirably carried out under the supervision of the hon. secretaries, Mr. H. Cracknell and Mr. W. J. Philp, the musical programme being greatly appreciated.

LETTERS TO THE EDITOR.

The Company Pharmacy Problem.

Sir,—I am convinced that a very large number of pharmacists rejoice to see the reasonable and sensible course adopted by a majority of the Council at last meeting. Those who have carefully watched the course of events and tried to appreciate the existing situation, must have been convinced that not only pharmacists, but the Lord Chancellor and the House of Lords Committee, clearly see that some practical steps must be taken to fill up the legislative gap in company law in relation to the practice of medicine, as well as pharmacy. This, manifestly, is going to be done, whether we take a hand in it or not. Surely it is not only good tactics, but an imperative and inevitable duty on the part of pharmacists to secure that they should have the utmost possible influence in determining the shape of any legislation on a subject which so vitally affects them. I cannot understand the policy of those who take up the hopelessly impracticable position of saying they will have nothing to do with any proposals for the regulation of company pharmacy. I am equally at a loss to understand the position of those who accuse those who suggest regulation of company pharmacy of a desire to advocate that particular form of pharmaceutical practice.

I have attempted to read carefully all that has been published on this difficult and complicated subject. I feel we are in danger of losing ourselves in a mass of details. We badly need to look around, narrow down the situation, and concentrate our efforts on one thing at a time. We have to remember that for the present we are dealing with an amendment of the Companies Acts, and not with an amendment of the Pharmacy Acts. What may we reasonably attempt to accomplish in this connection? I have grave doubts about importing into a Companies Bill any provision of the nature of regulation of the practice of pharmacy. It appears to me to establish a dangerous precedent. Regulation of the practice of pharmacy should only be dealt with in a Pharmacy Bill, and I feel convinced that we would act wisely in adhering to a policy on that line. It is not reasonable to expect to accomplish all we may justly ask for in any mere Companies Bill. We should seek and never lose sight of a very substantial amendment of the Pharmacy Acts. But for the moment that must be allowed to stand aside.

How do we stand from this point of view? We are absolutely agreed that no company should be permitted to apply to itself any professional statutory title implying personal qualification. The ground for this view is very clear and simple, and readily commends itself to the judgment of any thoughtful person. That ground is that the general use of such personal titles by parties not possessing and incapable of acquiring the qualification implied therein destroys the statutory significance of the said titles, and proves misleading to the public, for whose safety the Legislature confers and protects them. I have had the honour of explaining this contention to several members of Parliament, and without exception they agreed that it was just and reasonable. A general provision against the use of certain titles by companies would be a relevant clause in a Companies Bill. Would it not be well to limit ourselves to this in the meantime on grounds of both principle and tactics? I entirely agree with those who believe that Clause 3 of the Companies Bill relating to medical practice has not the remotest chance of passing the House of Commons. I do not stay to argue the point, but I think it can easily be shown to be contrary to the public interest in its present form. Would it not be well for us to seek the withdrawal of Clause 2 of the Companies Bill and co-operate with medical and dental practitioners in securing such an amendment of Clause 3 as might be expected to reecive legislative sanction? Some such clause as this might do:—

> No company shall be registered under a name which shall include or consist of a name, title, sign, description, or addition which cannot by law be taken, used. or exhibited by a natural person, unless such person has a personal qualification; if any company shall take, use, or exhibit any name, title, sign, desoription, or addition which cannot by law be taken, used, or exhibited, unless the person taking, using, or exhibiting the same has a personal qualification, such company shall—(1) be deemed to be carrying on business for an illegal purpose within the meaning of this Act, and shall (2) be subject to the same consequences in all respects as though the company were a natural person taking, using, or exhibiting such a name, title, sign, description, or addition without having such qualification.

The above is not an original suggestion, but is well known as one which, a few years ago, commended itself to the medical, dental, and pharmaceutical authorities, and you will observe it founds itself entirely on the question of titles. It is also perfectly general in its terms, and not limited to the titles represented by these authorities.

But our object would be equally well, perhaps better, attained, and with less risk of effective opposition, by withdrawing Clause 2 and making Clause 3 read:—

> It shall be unlawful for a company to apply to itself or to any person not registered under the Medical or Pharmacy Acts the titles physician, surgeon, dentist, medical practitioner, chemist, pharmacist, midwife, or any word implying a medical or pharmaceutical qualification; and if any company contravenes this enactment it shall be liable, on summary conviction, to a fine not exceeding five pounds for every day during which the contravention happens.

This suggestion could not reasonably be objected to, even by those interested in companies. It may not safeguard the practice of medicine and of pharmacy so completely as public safety requires, but it does accomplish one important object on which there is absolute unanimity among practitioners of medicine and pharmacy both, and other objects would be more appropriately dealt with in Medical and Pharmacy Acts respectively. I venture to submit this proposal as a means of clearing the field of much debatable matter, and securing that general agreement and concentration of effort which are the indispensable perquisites of effective action.

PHARMACEUTICAL CHEMIST (8/15).

Edinburgh, November 13, 1899.

Sir,—I am sorry that a large number of chemists believe that a qualified directorate should suffice in the case of limited companies. I don't think companies would object to that in the least; dummies could easily be nominated, and there are plenty of traitors in the camp. I wish to point out that it would be the "Wdiow's Clause" over again, and that we have hardly forgotten the "Grosvenor Hotel" scandal yet. Regarding your comment, Mr. Editor, on my letter published November 4, I thought it was plain enough for anyone to understand what I meant when saying "the companies' problem had been with us about twenty years." I was referring to the decision of the House of Lords. I still maintain that the members of the Council have not done their duty, and even now, when a little stir is made, the majority of them rush out through the back door.

November 11, 1899. PHARMACIST No. III. (8/16).

Sir,—I regret I was unable to attend the last meeting of the Council. I feel I must most firmly protest against the members of the Pharmaceutical Society giving up one iota of their right to titles which have been conferred on them after long and onerous examinations. I cannot but think that, when the question comes before members of Parliament (as I suppose it will during the next Session), all right-thinking men in that body will at least allow that—even in these days of free trade, with all its brazen effrontery—there is such a thing as fair trade, and that a company of men with one qualified assistant should not be able to commit an act which a single individual is not permitted to do. Under no circumstances should we be willing to allow that any set of men be allowed to *pirate* the word chemist or pharmaceutical chemist unless every individual member is qualified.

Norwich, November 11, 1899. OCTAVIUS CORDER.

Ethics as Applied to the Practice of Pharmacy.

Sir,—I hope the well-chosen remarks of Mr. J. C. Hyslop, addressed to the Chemists' Assistants' Association on the 26th of last month, and reported in the Journal of the 4th inst., anent the sale by pharmacists of specialities for immoral uses will find a deep echo in the consciences and minds of many amongst us. It seems altogether incongruous for those who deal in such things to be seeking increased state protection when the sale of the goods in question tends and can only tend to national demoralisation. To supply the best remedies for diseases brought on by personal vice or otherwise is the honourable work of the pharmacist, but to make himself the channel through which the abominable goods referred to reach the public is unworthy of one who asks for recognition at the hand of his fellows as a qualified and professional man, and one to whom state protection is befitting. The smallest amount conceivable of the "Fear of the Lord, which is the beginning of wisdom," would surely correct this growing evil. That young men, especially apprentices and improvers, should be trained to regard such training as a necessity is a disgrace to our calling.

Exeter, November 8, 1899. CHARLES FLINT.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Students' Books (T. E. B.—35/31).—Order the books as you require them through a local bookseller.

Latin Grammar (H. S.—36/12).—Ince's 'Latin Grammar of Pharmacy' (Baillière, 5s.) is the best for the purpose.

Malt Extract and Hypophosphites (G. T.—36/10).—The preparation is not a very stable one; however made it will not keep indefinitely, possibly from the action of the malt sugar on the hypophosphites. On keeping, a marked odour of phosphoretted hydrogen is developed. To obviate that, partially mix the ingredients in the cold, and keep in well closed bottles in a cool, dark place. It is important that the hypophosphites used should be free from sulphates. Bird finds that the presence of sulphates as impurities gives rise to an unpleasant odour. See *P.J* [3] **25**, 159.

Polarimeter for Essential Oils (H. C. T. G.—36/2).—An excellent small, portable and cheap instrument which would probably be sufficient for your purpose is Zeiss' Saccharimeter, which you can obtain from Messrs. Chas. Baker and Son, opticians, 244, High Holborn, W.C. Order it with a 100 Mm. tube, as the ordinary saccharimeter tube, which is 200 Mm. long, takes too much oil, and with some dark oils renders the reading less distinct. For more delicate work, you should obtain a "half shade" instrument of the Laurent type. Messrs. Watson and Co., 313, High Holborn, W.C., make an excellent polarimeter of this description.

Registering a Trade Mark (J. E.—35/25).—Having filled in a form of application, which may be obtained at the nearest money order office on payment of five shillings, you should send it to the Comptroller, Patent Office, Trade Marks' Branch, 25, Southampton Buildings, Chancery Lane, London, E.C. If he accepts the mark for registration, you will be required to pay a further fee of twenty shillings for the registration form and, if there is no opposition the mark will be placed on the Register without further fee for fourteen years. Refer to the Pharmaceutical Society's 'Calendar' for further particulars.

Meat Extract Lozenges (R. C. C.—35/35).—This is a subject which can only be solved by experiment. Probably something on the following lines will suit you:—Treat lean beef, as in making "beef tea," avoiding too high a temperature; strain and press the meat fibre left; dry it in an oven, and grind it in a coffee mill. Meanwhile evaporate the watery portion to an extract, incorporate sufficient of the ground meat to form a paste, add sufficient salt to keep it, and cut into lozenges. When set, dip them in a little melted beef dripping so as to coat them and protect them from the atmosphere. This is only a suggestion of lines on which you may experiment for yourself.

Vacuum Still without Pump (A. W.—35/34).—Probably you might succeed by one of the two following methods:—(*a*) Connect a receiver, fitted with a vent cock, air-tight on to the condenser, and let the condenser jacket be empty, *i.e.*, not surrounded by water. Connect with the still, open the vent cock, and heat. When vapour issues freely from the vent, shut it off, and immediately let water into the condenser. You should have a mercury safety tube attached to the receiver, as a precaution against undue pressure. (*b*) Fit up the apparatus as before, but with a receiver as large as possible, and fitted with a bottom tap. Fill the receiver with water. Introduce the liquid, preferably warm, into the still. Make all tight, then run out nearly all the water in the receiver.

Effervescing Saline (W. W.—36/7).—The ingredients you mention appear to suit the label very well; we fail to see that the addition of citric acid would make the description of the article more "truthful"—as you put it. That is a matter between yourself and your conscience, on which we do not feel competent to advise. The connection which you seem to make between truth and citric acid is not very obvious. It would almost seem that the real truth of the matter is that you want to make as cheap an article as possible to accompany the "truthful" label. If that be so use no citric acid, as it is not necessary; but, on the other hand, the substitution of a portion of the tartaric acid with an equivalent quantity of citric acid, will give you a slightly more palatable article. The tartarated soda should not be omitted, unless neutral sodium tartrate—which is preferable—is substituted. The following is the recipe you should use:—Tartaric acid, 14; sodium bicarbonate, 23; neutral sodium tartrate, 63. Potassium chlorate should be avoided in compounding salines. In the presence of the faintest trace of damp it causes the bottles to burst, and also, when this does not occur, often imparts a peculiar unpleasant odour to the powder.

Cider and Perry (J. T.—35/33).—Unfortunately, cider varies so much that no general analysis will convey much information; the amount of alcohol alone varies enormously; some of the old "Foxwhelp," or other strong bottled Herefordshire cider is strongly alcoholic, so much so that a relatively small quantity will produce intoxication. Those, however, are special brands. As a rule, the amount of alcohol is not very high, but is greater in the Hereford than in the Devonshire variety, hence Herefordshire cider keeps better in bottle than Devonshire. An analysis of Brittany cider by Rousseau, quoted in Allen's 'Commercial Organic Analysis,' vol. 1, p. 99, gives the following figures:—Alcohol by volume, 2·05 per cent.; residue on evaporation, 1·93 per cent.; sugar, 0·25 per cent.; ash, 0·152 per cent. Rabot, however, gives widely different figures: According to him, good cider one year old contains from 5 to 6 per cent. of alcohol and 3 per cent. of extractive; 0·28 per cent. of ash; of which 0·215 is soluble in water. So far from cider being objectionable for gouty patients, it is now much prescribed in those cases. Probably, however, very "hard" cider would not be suitable, since it would be apt to derange the digestion. We are not able to find any analysis of perry. It is generally supposed to have a decided diuretic action on those who are not inured to its use. Possibly that may be the reason why your professional friend considers it specially useful to gouty patients. Perry is usually less acid, but more alcoholic than ordinary cider. An analytical comparison of several good brands of the two beverages would prove interesting, and is a subject that West of England pharmacists might investigate.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course, not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size, clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Austen, Barker, Bell, Bennison, Boisselier, Branch, Brown, Brunt, Campkin, Cocks, Cowley, Davis, Duncan, Elborne, Flockhart, Gaumont, Harrington, Haslegrave, Henderson, Hyslop, Kirkpatrick, Kraemar, Leete, Lennox, Linton, Luman, Maben, McWalter, Martindale, Mills, Mitchell, Morris, Naylor, O'Counell, Phillips, Philip, Scott, Sargeant, Simpson, Smith, Southall, Stoul, Thorpe, Treloar, Turner, Wallace Welcome, Wyatt.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

CONSTITUENTS OF POWDERED DRUGS.

M. W. Bamford has examined powdered senna of different degrees of fineness. The senna was exceptionally clean, and the percentage of ash was not found to vary appreciably in powders passed through sieves of varying mesh. A No. 8 powder yielded from 9·89 to 10·19 per cent. of ash, and a No. 80 powder from 9·93 to 10 50 per cent. A coarsely ground powder was separated into three distinct fractions by sifting—the No. 8 yielded 10·17 to 10·20 per cent., the No. 30 from 10·64 to 10·85 per cent., and the No. 80 from 10·70 to 10·96 per cent. Some ipecacuanha was also examined, after separating the bark (80 per cent.) from the wood; the bark yielded 2·44 to 2·45 per cent. of ash, and the wood 1·47 to 1·69 per cent. The larger proportion from the bark was due to the presence of calcium oxalate and adhering particles of sand. Coarsely powdered ipecacuanha was then divided into fractions of different degrees of fineness; that which did not pass through a No. 20 sieve yielded 1·90 to 2·14 per cent. of ash, and that which passed through a No. 80 sieve from 12·35 to 12·54 per cent. A microscopical examination showed that the coarse powder consisted principally of woody tissue and a small proportion of bark; the No. 80 powder consisted chiefly of bark with a larger percentage of sand and other foreign matter.—*Am. Journ. Pharm.*, **71**, 511.

ARTIFICIAL SUGAR-FREE MILK.

In a treatise on the treatment of diabetes, R. T. Williams has recommended the following method of preparing a milk which is practically free from lactose. A pint of water is placed in a tall vessel, and two or three tablespoonfuls of fresh cream is well stirred up with it. The mixture is allowed to stand for twelve to fourteen hours, when most of the fatty matter of the cream rises to the top and may be collected. This is practically free from milk sugar. It is then mixed with water, and the white of an egg added, then more water to bring the mixture to the colour and consistence of milk. A little salt, or a trace of saccharin may be added, which will produce a palatable and nutritious beverage. Lauritzen has slightly modified this, omitting the egg albumin and the saccharin. He mixes 100 C.c. of cream with three times its volume of water, allows it to stand for twelve hours, then, every 50 C.c. of the separated and washed cream is diluted with 200 C.c. of cold water. He has obtained good results with this beverage in eight cases of diabetes.—*Med. Chron.*, **2**, 97.

CHLOROGLOBIN.

According to Tsvett, chlorophyll and xanthophyll exist in the living plant in a state of loose combination with an albuminoid, the compound formed being analogous to the hæmoglobins of animals; he has, therefore, named it chloroglobin. To obtain it, a saturated solution of resorcin is employed in which it is readily soluble. After removal of the resorcin by washing in water, the chloroglobin obtained is soluble in alcohol, ether, benzol, chloroform, and carbon disulphide, and in strong aqueous solutions of chloral hydrate, but after treatment with certain coagulating reagents, such as mercuric chloride, tannin, formaldehyde, it ceases to dissolve in these solvents; like the albuminoids, it has a great affinity for certain colouring matters, such as fuchsine, chrysoidine, and methylene blue. The solution in neutral aqueous resorcin decomposes in a few hours, throwing down a deep green granular deposit, and crystals of xanthophyll.—*Comptes rend.*, **129**, 607.

COLOUR OF ESERINE SOLUTIONS.

O. Hallauer finds that, although solutions of eserine salts which have become coloured are quite as active myotics as those which are colourless, yet secondary results are produced by them, which render their use undesirable. He finds that there are no perfectly stable preparations of eserine on the market, the decomposition being caused by the blue rays of the spectrum. The stability of the specimens may be tested by adding ammonia and heating the solution to a temperature of over 80° C. Development of the colour may be prevented, either by the use of sulphurous acid or of a 4 per cent. solution of boric acid; these additions do not affect the physiological action of the alkaloid. The salicylate is a more stable salt than the sulphate. —*Therap. Monats.*, **13**, 561, after *Zeits. fur Augenkeilk.*

ANHYDROUS MAGNESIUM CARBONATE.

On heating the double carbonate of ammonium and magnesium $(NH_4)_2CO_3MgCO_34H_2O$ in a current of dry air, gradually raising the temperature to between 130°-140° C., the residue consists, according to R. Engel, of practically pure anhydrous magnesium carbonate, which retains the crystalline form of the double carbonate. It has a great affinity for water; when exposed to the air it becomes hydrated as quickly as lime under the same conditions; the amount of water thus combined is a little more than 1·5 molecules for each molecule of the neutral carbonate. It is soluble in water to the extent of 0·2:100, whereas the hydrated carbonate is only dissolved in the ratio of 0·1:100, and the natural anhydrous carbonate is insoluble in water. Mixed with a little water, it sets like plaster, and when suspended in a large quantity, it rapidly forms crystals of the composition $MgCO_33H_2O$. Exposed to gaseous ammonia, it absorbs a little more than one molecule for each two molecules of magnesium carbonate. In all these properties it differs so markedly from the native magnesium carbonate that the difference can hardly be attributed to its physical condition. If, during the course of preparation, the temperature is allowed to rise to between 160°-180° C., the salt undergoes decomposition, with the loss of CO_2, whereas the native carbonate may be heated to dull redness without decomposing. The double carbonate of magnesium and ammonium is obtained by mixing solutions of magnesium bicarbonate and of ammonium bicarbonate both saturated with CO_2 and exposing the mixture to the air. The double sesquicarbonate, $MgCO_3NH_4HCO_34H_2O$ does not exist.—*Comptes rend.*, **129**, 598.

SODIUM METAVANADATE.

Pécourt points out that to obtain sodium metavanadate in the most active form, the following details must be strictly observed:—Pure vanadic acid, obtained by calcining ammonium vanadate, is dissolved in excess of caustic soda; then, while boiling, the excess of alkali is neutralised with acetic acid, and the boiling continued until the liquid is concentrated as far as possible, without the separation of crystals. It is then precipitated with strong alcohol, which removes the greater part of the sodium acetate. The yellow precipitate is redissolved in boiling water, and reprecipitated with alcohol, until free from acetate. This should be effected rapidly, since prolonged boiling with alcohol materially reduces the vanadate. With regard to vanadate of lithium, which has been recommended, the author remarks that the salt must necessarily be administered in such infinitesimal quantities, that the amount of the metal absorbed could have no notable effect. He also expresses doubt as to the existence of true vanadates of the alkaloids, in view of the extreme instability of vanadic acid in the presence of organic matter. For this reason too, the acid or its salts should not be prescribed with sugar, syrups, or wines. Organic matter of any kind should be avoided.—*Repertoire* [3], **11**, 487.

THE PREPARATION OF BETULIN BY SUBLIMATION.

BY J. WHEELER.

Although the eupyreumatic oil of birch has long been used both in medicine and the Arts, the employment of betulin and pyrobetulin as such do not appear to have received attention in medicine. The antiseptic and insect-repelling properties of the oil as utilised in Russia leather have, however, long been known.

My attention was directed a few years ago to the remarkable resistant power that the epidermis or outer bark of the white birch presents to decay. This is illustrated by the fact that the Lapps and Samoyedes (according to Mr. H. Cooke, H.M. Consul at Archangel) cover their tents with it, and that in Archangel it is largely employed in the form of large deep boxes for carrying milk.

The properties of betulin are as follows: — Formula $C_{36}H_{66}O_3$. When heated to 266°F. it gives an anhydride. It is tasteless, inodorous, melting slowly at 496° F. to a yellow oil, subliming readily in a current of air. It is entirely insoluble in water and does not combine with either alkalies or acids. It is sparingly soluble in alcohol, but readily in ether, oil of turpentine and almond oil. It dissolves rapidly but quietly in oil of vitriol, forming a solution which solidifies and turns white with water. Hufeland estimated the yield at 10-12 per cent. of the bark. He obtained it by boiling the bark in the strongest alcohol and purification of the tincture, so obtained.

The method I adopt for obtaining betulin is as follows:—

(1) The tough outer bark or epidermis of *Betula alba*, after reduction to a powder of not less than 60 fineness, is mixed with from 1-8 per cent. of potassium nitrate, according to the result to be obtained, and is then compressed into tablets or blocks. These are burnt, without flame, in a closed chamber, the proportion of oxygen-carrier and air currents passing through the lamp containing them being regulated, according to the degree of conversion into anhydride that may be desired. The vapour of betulin thus obtained is employed for producing on articles or materials, porous opaque films, or reticulated transparent films of, or containing pyrobetulin or pyrobetulin anhydride in different degrees of conversion. The character of the film obtained depends upon the proportion of nitrate of potassium employed and the amount of air allowed to circulate between the tablets when undergoing ignition, as follows:—

(1) Tablets containing 8 per cent. of this salt with free supply of air give a film of a porous opaque character.

(2) If arranged in close contact they give a transparent non-porous film which, deposited on glass or metal, prevents the action of hydrofluoric or nitric acids.

(3) Tablets with only 1 to 1½ per cent. of nitrate, burnt in close contact, give a glistening transparent film of a reticulated appearance, which, treated with hydrofluoric acid, gives a similarly reticulated surface to glass. This can be employed for imparting grain to process blocks, etc.

Experiments made with the pyrobetulin-anhydride film showed that it was successful in preserving eggs in a fresh condition, and that an alcoholic solution of it acted as an antiseptic for readily putrescible fluids, such as urine, etc. Fifty minims of an alcoholic solution containing rather less than 1 grain of the anhydride indefinitely protecting 4 ounces of urine exposed to the air. For rendering plasters more resistant of moisture, with greater holding power and antiseptic property, No. 1 process should be followed. The process No. 3 is most effective for depositing a film on lint or on boric acid powder, or on other dressing material. Lint furnished with such a film is found to be perfectly sterile of pathogenic organisms, no matter how long the incubation be prolonged. When the lint was exposed film side downwards on a gelatin (agar-agar) plate and various organisms as occurring in suppurative discharges were poured over the lint, no growth resulted. Both the lint and filmed boric acid have been proved by surgeons having large hospital practice to act as reliable antiseptics and bactericides, and to possess quite characteristic healing powers. The anhydride also forms a most dependable insecticide.

The average yield from the bark by my No. 1 process is 20 per cent. of pyrobetulin; by No. 3 process, 25 per cent. of pyrobetulin anhydride; but the bark percolated by ether for several days gave 30 per cent., the percolate still exhibiting in a slight degree the characteristic irrdescence which is so striking a feature of weak betulin solutions when rapidly evaporated. The small proportion of pyrobetulin obtained, in proportion to pyrobetulin anhydride, I attribute to the more rapid combustion by the No. 1 process.

The above processes and their application have been patented in most European countries, and in the United States.

The following embody the forms of utilisation, based upon adequate trials by medical men in hospitals:—(I.) "Listulin Filmed Lint.—A dry, non-irritating, bactericidal dressing of lint filmed with pyrobetulin anhydride, by which perfect asepsis may be secured. (II.) Boro-"Listulin."—A sterile, non-irritating, powder of finely-levigated boric acid filmed with pyrobetulin anhydride, for dusting purposes; also with insufflator into cavities; mixes readily with an oily, vaseline, or lanoline basis. (III.) "Listulin" Strapping Plaster.—Filmed with pyrobetulin. The filmed antiseptic surface having a high melting point, and being unaffected by moisture, the surface is thereby rendered less likely to shift or become dislodged. "Listulin" Collodion and "Listulin" Oil are also prepared.

THE ASSAY OF EXTRACTUM IPECACUANHÆ LIQUIDUM.

BY F. H. ALCOCK.

EXPERIMENT I.—If five cubic centimetres of liquid Extract of Ipecacuanha be mixed with ten cubic centimetres of ether and vigorously shaken, a slimy precipitate of a dark reddish brown colour is formed which adheres to the sides of the vessel, and the liquid portion becomes nearly clear and has a slight yellow colour.

EXPERIMENT II.—If five cubic centimetres of Liquid Extract of Ipecacuanha be mixed with five cubic centimetres of B.P. dilute sulphuric acid and ten cubic centimetres of ether, and well shaken and then allowed to rest, the liquid separates into two clear layers—an upper ethereal layer of a yellow colour, a lower layer of a deep reddish brown colour.

Based upon these two experiments, the following method of assay is suggested which possesses several advantages over the official process, in that it is quickly performed, is more accurate, and is not so "messy," and even in unskilled hands yields concordant results when quantities of from one to five cubic centimetres are operated upon.

Proceed as in the second experiment, which may be conducted in a well-corked bottle, remove the ethereal layer by a teat and pipette, and wash the lower layer with five cubic centimetres of ether, mix these solutions and wash them twice with small quantities of water and add these washings to the alkaloidal solutions if thought desirable.

The ethereal solution on evaporation shows the amount of fatty matters, and does not contain any alkaloid.

To the alkaloidal solution contained in a separator add seven and a half cubic centimetres of ether-chloroform (one volume of former and two or more volumes of the latter), render alkaline with ammonium hydroxide, shake well, warm to 120° F., separate the lower layer, wash a second time with the alkaloidal solvent in suitable quantity, remove and repeat the washing if necessary, and evaporate the alkaloidal solution in a tared dish in the usual way. A flocculent precipitate of a brown colour appears after the addition of the alkali and alkaloidal solvent, which sometimes interferes with the separation, but this can be overcome by aspirating the whole liquid through cotton "wool," washing the "wool" with a few cubic centimetres of ether-chloroform afterwards.

BITTER ORANGES.*

BY H. H. ROBINS.

In the London market this fruit is known under the name of "Sour Oranges."

They are chiefly imported from Malaga, Seville, and Messina. In this order they arrive. The Malagas have just now commenced, but they are very pale in colour, the Sevilles reach us about January, and the Sicilians February and March. Malaga supplies the largest quantity, and Seville the smallest, but no statistics are obtainable. There is in certain quarters an impression that only this latter fruit is the official variety. This error probably arises from the Seville district being the first to put on the market bitter fruit.

I was shown this week by a firm of City brokers a catalogue of a fruit sale in the year 1776; it contained a lot of six cases of Sevilles, but no mention of any other kind.

It was customary twenty years ago to speak of all bitter oranges orange or Seville orange."

In Bentley and Trimen it is stated that "the fruit is imported from the South of Europe, and is known in London as the bitter orange or Seville orange.

The London Pharmacopœia, 1857, orders peel dried in February, March, and April to be used."

The B.P., 1864 and 1867, describes ripe fruit imported from the South of Europe.

In the additions to the B.P., 1874, ripe fruit, under the name of bitter orange, was introduced, of which tinct. fresh peel was then ordered for the first time. The present B.P. simply mentions the peel of bitter oranges, and from the description given of the fruit only the fully matured is intended.

The bulk of the fruit imported is used by confectioners for making orange marmalade and preserved peel. Distillers are large users of both the dried and fresh peels in the manufacture of cordials, liqueurs, orange wine, etc. The drug and mineral water trades consume comparatively a small quantity. The outer part of the pericarp is the only official portion of the fruit used, so producers of this are left with the remaining pulp and pith.

These are known by them as "dummies," though they nevertheless help to produce a special transparent kind of marmalade, much in favour with the Scotch. It is important to use peel from ripe fruit in the official preparations, for then only is the full flavour of the essential oil obtained.

The present tincture is a good preparation, but it would be improved if it contained more of the peel.

Last season I secured representative samples of ripe fruit from each of the before-mentioned sources, and the tinctures shown were made respectively from them.

The specific gravities and extracts obtained by evaporating the tinctures in a water-bath until they ceased to lose weight are as follow:—

Source of Fruit.	Sp. G. Temp: 60° F.	Grains Extract per Fl. oz.	% Extract.
Malaga	0·8808	9·05	2·35
Seville	0·8808	8·47	2·20
Messina.....	0·8811	9·04	2·35

It will be found that the tincture made from Messina fruit has the finest aroma, and this when diluted with 500 times its bulk of water still possesses an orange odour. This under similar conditions is not perceptible in either of the other samples.

There is apparently no difference in their relative bitterness. This property of the peel is fully developed in its unripe stage, and preparations made from such fruit are doubtless as useful for tonics as those made from the ripe, but they are certainly not so pleasant.

The percentage of extract in these tinctures is no guide to their strength.

The pith from lemons will yield more extract to 56 o/p spirit than the rind (the outer part of the pericarp), and the same is no doubt true of the orange.

Oil of orange is almost entirely volatilised at the temp. of a water-bath, and any results obtained by such a method are absolutely misleading.

I probably ought to mention a variety of bitter orange that comes in small quantities from Jaffa. This fruit is better grown and finer in every respect than that from any other district.

* Read at a meeting of the Chemists' Assistants' Association on Thursday, November 16.

THE MATERIA MEDICA OF THE SOCIETY'S MUSEUM.

BY E. M. HOLMES, F.L.S.,

Curator of the Pharmaceutical Society's Museums

Tea Leaves.

Camellia Thea, Link.—The specimens in the Museum consist at present of (1) The leaves of the plant dried; (2) Black tea of commerce; (3) Green tea of commerce; (4) "Flower" of tea; (5) Chinese "old man's eyebrow" tea; (6) Brick tea used by the Tartars. None of these, except perhaps the "flower" of tea, represents the form of tea used for the extraction of caffeine, which is obtained from much cheaper sources. The tea damaged in sea voyages, and the tea-dust consisting of the sweepings of the sifting rooms, etc., in the manufactories and warehouses, are used for the purpose, after being "denatured" by the Customs authorities in this country by the addition of asafœtida and lime. Black tea differs from green tea in being fermented before drying, whereas green tea is dried before being fermented, and thus retains its colour (Greenish, 'Mat. Med.,' pt. 3; Fortune, 'Wanderings in China,' vol. ii., pp. 232—246). Indian tea yields more caffeine than Chinese tea and also more tannins, Chinese affording 3½ to 3¾ per cent. of caffeine, and Indian, including Assam and Ceylon, on the average 4¾ per cent. The average amount of tannins is 9 per cent. in Chinese, and 13 per cent. in Indian teas. Indian tea is apt to produce in those unaccustomed to its use symptoms resembling those of gastric catarrh, but whether this is due to the excess of tannin or of theine has not been determined. In the manufacture of Indian tea, the juice which exudes on rolling the tea-leaves is reabsorbed by the balls into which the rolled leaves are made—but this is not done in China. The commercial value of tea does not depend on the amount of caffeine present, but on the odour and "body" of the infusion. The odour may be formed in the process of fermentation, or may be the result, in high-priced Chinese tea, of contact with fragrant flowers. Those chiefly used for the purpose are the flowers of rose, jessamine and *Chloranthus inconspicuus*, *Aglaia odorata*. and *Murraya exotica* (Fortune, 'Wanderings in China,' vol. i., p. 293, 1853). Specimens of these exist in the Chinese collection of drugs. The "body" of tea is indicated by the opacity of the infusion as it cools, due to the formation of a cloudy precipitate, which is less soluble in cold than in hot water, and is supposed to be a tannate of caffeine, but its exact composition does not appear to have been determined. There is probably more than one form of tannin present in tea (Winter Blyth, 'Food').

Besides caffeine (trimethyl-xanthine), tea yields traces of theophyllin, an isomer of theobromine (dimethyl-xanthin), but differs from it in the amount of water of crystallisation and solubility in water, and in melting at 264° C., theobromine subliming without melting at 290° C. See *Pharm. Journ.* [3], **19**, p. 41.

Flower of tea consists of the hairs of the unopened leaf-buds in making flowery Pekoe tea, for which only the two youngest leaves of the twigs, besides the unopened leaves, are employed. A description of this article was given in *Year-Book Pharm.*, 1876, p. 609. The hairs are whitish on the fresh leaves, but become brown in the process of firing the tea. (See Money, 'Tea Cultivation,' 3rd edition. London, 1878; pp. 132—143.)

Chinese "old man's eyebrow" tea is a fancy tea; it is in the form of small bundles or faggots of a brownish tint, composed of twelve or

more twists of tightly screwed leaves. The bundles are about five centimetres long, and two in diameter, and are sold at a high price. These may be seen in the Hanbury collection, and were made in Yunnan, and presented by Mr. A. Fortune to Mr. D. Hanbury in 1852.

The Brick tea is a specimen brought home from Russia by Professor Greenish. It is a portion of a hard, flat, solid cake, about 1½ centimetres in thickness, and possesses considerable fragrance. It differs entirely from the large bricks composed of loosely compressed leafy tips exhibited in the No. 1 Museum at Kew, where an excellent collection of various forms of tea may be seen. These are described in Cooper's 'Travels of a Pioneer of Commerce,' London, 1871, pp. 171—173, 201. See also 'Encyclopædia Britannica,' Art. "Tea."

Besides these forms of tea there are in the Museum specimens of tea fruits imported under the name of "Tanne" seed, and a fixed oil, derived from the seeds of *Camellia japonica* and *C. oleifera* (*P.J.* [3], **15**, pp. 634—637), as well as the cake left after the expression of the oil. The seeds contain about 10 per cent. of saponin, (*P.J.* [3], **14**, p. 21). The oil is a non-drying oil and, examined by Mr. R. W. Davies, was found to contain 83 per cent. of oleic acid. It is used by the Chinese for hair oil. The seed cake (presented by Mr. H. Humphreys, of Hongkong) is used by the Chinese as an insecticide for garden insects and worms (in the form of infusion or decoction), and as a fish poison, also as a soap for cleansing the person and clothes.

There are specimens of the China and Assam tea plants in the Herbarium of the Society.

The microscopical structure of tea leaves and the distinctive histological characters of other leaves used as substitutes of tea are well illustrated in Tschirch and Oesterle 'Anatomischer Atlas,' taf. 3. The idioblasts found in true tea leaves do not occur in any of the substitutes at present known.

Other so-called teas in the Museum collections are classed under the respective countries in which they are employed, viz.: —

Abyssinian or Arabian Tea (*Catha edulis*, Forsk., Celastraceæ), described in *Pharm. Journ.* [1], **12**, p. 269, and its active constituents in [3], **18**, p. 1009.

Batoum Tea (*Vaccinium arctostaphylos*, Linn., Ericaceæ), an account of which is given in *P. J.* [3], **15**, pp. 573—771.

Bourbon or Faham Tea (*Angræcum fragrans*, Thon., Orchidaceæ), 'Gard. Chron.,' 1850, p. 599; 'Kew. Bull.,' 1868, p. 181; Bouton, 'Flore Méd. de Maurice,' p. 129.

Brazilian Tea (*Stachytarpheta jamaicensis*, Vahl. Verbenaceæ), Lunan, 'Hort. Journ.,' **2**, pp. 257, 258; 'Treas. Bot.,' **2**, p. 1090.

Cape or Bush Tea (*Cyclopia genistoides*, Vent., Leguminosæ), *P.J.* [3], **11**, p. 549; Pappe, 'Fl. Med. Cap.,' p. 9.

Labrador Tea (*Ledum latifolium*, Jacq., Ericaceæ), 'Amer. Disp.,' 1895, p. 478.

Mountain Tea (*Gaultheria procumbens*, Linn., Ericaceæ), 'Nat. Disp.,' 1886, p. 724.

New Jersey Tea (*Ceanothus Americanus*, Linn., Celastraceæ), 'Nat. Disp.,' 1886, p. 407.

Oswego Tea (*Monarda didyma*, Linn., Labiatæ), 'Nat. Disp.,' 1886, p. 987.

Paraguay Tea (*Ilex paraguensis*, A. St. Hil., Aquifoliaceæ), 'Nat. Dis.,' 1886, p. 810. This tea is employed in two different forms (1) Broken leaves, (2) powdered leaves and stalks. The first is employed in Brazil, the second in the Argentine Republic. Specimens of the gourd and the pipe-like strainer or "Bombilla" used in making and drinking the tea are also shown in the Museum.

West India Tea (*Capraria biflora*, Linn., Scrophulariaceæ).

None of these except *Ilex paraguensis* contain caffeine, which, however, is found in cola (*Cola acuminata*, Schott and Endl., Sterculiaceæ), and Guarana (*Paullinia cupana*, H. B. and K., Sapindaceæ). An interesting specimen of the latter drug moulded in the form of the fish Piraruccu, and of the dried tongue of that fish, which is used for grating the drug, may be seen in the Museum, presented by Sir Samuel Wilks, Pres. R.C.P.

Coca Leaves.

ERYTHROXYLON COCA, LAM.—The specimens of coca leaves in the Museum include (1) Peruvian or Truxillo coca, derived from *Erythroxylon coca*, var. *novo-granatense*, Morris, and an original package of the leaves, (2) Bolivian or Huanuco coca obtained from *E. bolivianum*, (3) Coca leaves from a plant cultivated in Java under the name of *E. coca*, var. *Spruceanum*, Burck., (4) Specimen of Bolivian coca cultivated in Ceylon. Botanists are not agreed as to the specific rank of the three plants, some considering them as varieties of one species (*P.J.* [3], **22**, p. 874). The leaves are, however, distinctly different in appearance, those of the Bolivian plant having a brownish-green tint, a thicker texture, a reddish midrib, and a slender ridge in the centre of the upper surface of the midrib, and are about twice as long as broad. The Peruvian leaves are of a pale green colour and thin texture, are very brittle, the midrib is greenish, and has no ridge on its upper surface, and the two lateral lines, marking where the leaf is folded in vernation, are less marked; they taper considerably to the base, and are about three and a-half times as long as broad. The Java leaves are about two and a-half times as long as broad, but otherwise resemble the Peruvian leaves, except that the apex is not rounded but acute. It, however, differs in habit of growth (*P.J.* [3], **22**, p. 818) and in the proportion of its alkaloidal constituents, containing more cinnamyl-cocaine and truxilline (or isatropyl-cocaine or cocamine) than the other varieties. It also yields benzoyl-pseudotropeine (*P.J.* [3], **23**, p. 241). Truxilline is the alkaloid to which the occasional poisonous effects of cocaine have been attributed (*P.J.* [3], **22**, p. 874), and is also found in Peruvian coca. Benzoyl pseudotropeine is less toxic than cocaine, and is better adapted for use in operations on the eye. Coca leaves rapidly lose in cocaine percentage if exposed to damp air. Hence crude cocaine is now largely imported from Peru, and purified in this country (*P.J.* [4], **5**, p. 78), and will in future probably be imported also from India and other countries where the plant is cultivated. The natives of Peru chew the leaf with an alkaline ash sprinkled over it, and as alkalies readily split up the alkaloid into ecgonine, methyl alcohol, and benzoic acid, it appears probable that the supporting property of the leaves under strenuous exertion must be due to ecgonine rather than to cocaine, the latter alkaloid acting as an anæsthetic rather than as a cardiac stimulant. The fact that benzoyl-ecgonine acts as a stimulant like caffeine without producing anæsthesia seems to support this view.

For the microscopical characters of the leaf see *P.J.* [4], **8**, p. 484-5. The alkaloid is represented in the Museum by the hydrochloride of cocaine. The test for its purity is given in *P.J.* [3], **18**, p. 781; [4], **6**, p. 586. The presence of another alkaloid in small quantity, viz., hygrine, has been disputed, but it was found by Dr. R. Stockman in tincture made from fresh leaves.

In the Herbarium there are specimens of the wild or nearly wild *E. bolivianum;* of the finest sort in cultivation (much resembling *E. spruceanum*, having a rather thinner and narrower leaf than *E. bolivianum*) collected by Dr. H. H. Rusby in Bolivia; specimens of *E. novo-granatense* cultivated at Kew, and by Mr. T. Christy, at Sydenham; specimens of Bolivian coca cultivated in Ceylon; and of both, cultivated in India, from Dr. Prain. These specimens show that the flowers of *E. bolivianum* occur in thicker clusters and with shorter stalks, and have a darker brown fruit than those of *E. coca*, var. *novo-granatense*. The plant appears to be a trimorphic, since Benth. and Trim., 'Med. Plants,' p. 40, represent the flowers of *E. coca* (var. *novo-granatense ?*) with short styles and long stamens, and Koehler, 'Med. Pflanz.,' i., p. 82, *E. coca*, var. *spruceanum ?*), with long styles and short stamens. See also *P.J.* [3], **22**, p. 875.

Dr. Prain remarks, concerning the plants, "The one that grows well in the gardens at Calcutta is one with thin pale green leaves (the colour of beech leaves as they are coming out); this colour they retain all the year round. It is a sparse flowerer, and its berries become *red almost at once*. It is found that it gives far more leaf per plant than the other kind, although at the elevation where it is planted here it does not thrive so well as in the plains below. Its branches are very slender and twiggy, but it retains in spite of this a fairly compact bushy habit. (This description apparently refers to *E. coca*, var. *Novo-granatense*, Morris.) The second kind of coca grown here (Sureil Kurseong) thrives much better. Its leaves are decidedly larger and are dark olive green, it flowers and fruits profusely, the berries remaining yellow till they are just ripe. As they ripen off they turn red, not so brightly cherry red as the last kind, but more orange red. This kind of coca we cannot get to thrive at Calcutta." (The writer here describes the *E. bolivianum*.)

Excellent illustrations of the leaves and of their microscopical structure are given in *Ph. Journ.* [4], **8**, p. 484, and [3], **22**, pp. 818-9.

THE CHEMISTRY OF ESSENTIAL OILS.*

Anethol.—Like other phenol ethers containing the side chain $CH:CH\cdot CH_3$, Klages finds that anethol when treated with sodium alcohol takes up two atoms of hydrogen, forming the methyl ether of *p*-propyl phenol—

Or Dihydro anethol, which boils at 210°—211° C., has an anise odour, and when saponified with hydriodic acid yields *p*-normal propyl-phenol, and with sulphuric acid a crystalline sulphonic acid, from which the phenol ether may again be obtained by separating the sulphon group. The isomer of anethol—ertragol—containing the side chain $CH_2\cdot CH:CH_2$ does not take up hydrogen under the influence of reducing agents, and the product of reaction is readily converted into anethol by boiling with alcoholic potash.

Calamus Oil.—The higher boiling portion of this oil that had been kept for a long time was found to have deposited laminar crystals, melting at 167° C., and probably consisting of a sesquiterpene hydrate or some allied compound.

Carraway Oil.—In the distillation of this oil methyl alcohol and furfurol are produced as in the distillation of cloves and clove stalks, though not to the same extent. The persistent yellow colour of the first distillate and the abnormal boiling point of the methyl alcohol in this case, as well as in the distillate from cloves, is attributed to the presence of diacetyl ($CH_3\cdot CO\cdot CO\cdot CH_3$), since on addition of phenyl-hydrazine to the yellow methyl alcohol distillate, diacetylosazone, melting at 243° C., was formed, and the boiling point of the methyl alcohol became normal.

The success of the method of determining carvone by conversion into its oxime is shown to be dependent on the conditions under which the operation is conducted. A very capacious flask should be used and the volatility of the oxime when dried in a glass dish on the water bath may occasion loss of material. In the case of old resinified oil, the results may be too high, in consequence of admixture of resin with the oxime.

Citronella Oil.—The great differences presented by this oil in the specific gravity, optical rotation, solubility in alcohol (80 per cent.), and amount of acetylisable constituents, are attributed to its being the produce of distinct varieties of *Andropogon nardus*, L. One of these, known as *Lana Batu*, yields the ordinary oil of commerce with specific gravity over 0·905, rotation up to — 20°, small amount of acetylisable constituents (65 per cent.), and imperfect solubility in 80 per cent. alcohol. The other variety, known as *Maha Pangira*, yields oil of finer quality, specific gravity to 0·890 rotation as low as — 3°, up to 91 per cent. acetylisable contents and is much more soluble in 80 per cent. alcohol. This variety is said to have been introduced into Ceylon from the Malacca peninsula, is cultivated near Baddagama, and is also grown in Java and the Straits Settlements.

Examination of the oil made from *Lana Batu* gave its specific gravity 0·908 at 15° C., rotation 9° 36′ at 20° C., soluble in equal volume 80 per cent. alcohol, and becoming turbid on adding four or more volumes of alcohol, saponification number after acetylisation = 190·8, calculated as geraniol 61·1 per cent.[1] The oil was carefully tested as to the possible presence of petroleum with a negative result, nor could any fat oil be detected. But the portion of highest boiling point (over 250° C.) amounting to 10 per cent., was found to be insoluble in 80 per cent. alcohol, and not to form a clear solution with ten volumes of 95 per cent. alcohol. It was subsequently ascertained to be a normal constituent of the oil.

For the qualitative examination of this oil 100 kilo. was heated to boiling with two parts caustic potash and ten parts of alcohol for twelve hours in a vessel fitted with reflux condenser. After separating the alcohol the oil was distilled with steam, and separated into eighteen fractions of 5 kilo. each, having the following characters:—

	Sp. Gr. 15° C.	Rotation 20° C.		Sp. Gr. 15° C.	Rotation 20° C.		Sp. Gr. 15° C.	Rotation 20° C.
1	0·873	—29° 48′	7	0·906	—7° 45′	13	0·912	—5° 17′
2	0·877	—28° 5′	8	0·908	—7° 1′	14	0·914	—4° 27′
3	0·883	—23° 20′	9	0·910	—6° 42′	15	0·917	—4° 4′
4	0.890	—18° 0′	10	0·910	—6° 38′	16	0·923	—3° 7′
5	0·897	—12° 30′	11	0·910	—6° 16′	17	0·934	—1° 40′
6	0·904	— 9° 20′	12	0·911	—5° 55′	18	0·934	+0° 53′

The fractions 1 and 2 consisted chiefly of terpenes; they were mixed and distilled at first under reduced pressure; then over sodium at normal pressure: two fractions of different boiling point were thus obtained, the first consisting of camphene, the second of dipentene and limonene.

Camphene.—Sp. gr. 0·8642 at 15°, rotation —62° 3′ at 15° C., n_D at 16° C. = 1·46367, boiling point 159°—161° C. By hydration with glacial acetic and sulphuric acid and saponification readily yielded iso-borneol, melting at 212° C.,[2] a solid nitroso compound could not be obtained by Jagelki's method.[3]

Dipentene.—Sp. gr. 0·847 at 15° C., rotation — 54° 21′ at 22° C., n_D = 1·46912 at 22° C.[4] By treatment with bromine in ether solution, dipentene tetra-bromide was readily formed, and after recrystallisation from acetic ether it melted at 125° C. By fractional crystallisation limonene tetrabromide, melting at 105° C., was obtained from the mother-liquors.

For separating the geraniol the fractions 3 to 16 were treated with powdered calcium chloride until reaction ceased, and then the whole residue was treated with phtalic anhydride,[5] so that the geraniol and any citronellol present would be combined with phtalic acid as semi-esters, and dissolved as soda salts, while the secondary alcohols (borneol) are but little acted upon, and the tertiary-alcohols (linalol and terpineol) are not at all affected.

The aqueous solution of semi-esters was three times shaken with ether acidulated with sulphuric acid, and the ether solution of acid ester separated; ether entirely distilled off the residue mixed with twice its volume of petroleum spirit, and kept for several days at a temperature below —5° C.,[6] the abundant crystals of geranyl-phtalic acid separated by filtration. The filtrate, saponified with alcoholic potash, gave about 20 Gms. of an oil which was distilled fractionally with steam under reduced pressure (15 Mm.). Almost the whole

distilled between 118° and 120° C., and had a sp. gr. 0·882 at 15° boiling point 228°—230° C. at 760 Mm., formed a solid compound with calcium chloride, by oxidation with chromic acid yielded citral, by treatment with diphenyl-carbamine chloride yielded geranyl-diphenyl urethane, melting at 80°—81° C., and when boiled with concentrated formic acid, it was almost entirely converted into terpene. The oil was therefore geraniol, and citronellol could not have been present in the oil operated upon. The geraniol separated from the crystals of geranyl-phtalic ester acid deposited from the petroleum spirit had a sp. gr. 881 at 15° C., rotation ± 0° at 20° C., boiling point 229°—230° C. at 760 Mm. n_D at 23° = 1·47392.

The acid geranyl-phtalic ester is not entirely insoluble in petroleum spirit, and the statement of Flatau and Labbe[7] as to the presence of citronellol in citronella oil is to be attributed to that circumstance.

The portion of oil uncombined with phtalic acid was mixed with the oil, washed out by ether, and three times washed with warm water to separate the phtalate dissolved by ether and prevent some admixture of geraniol. The washed oil was then fractionally distilled under a pressure of 12 Mm.

Fraction.	Boiling Point.	Sp. Gr.	Rotation.	Yield.
				Cub.Cent.
1	70°— 91°	—	—12° 40′	5·5
2	91°—101°	0·910	—10° 13′	14·0
3	101°—107°	0·922	—16° 25′	73·0
4	107°—111°	0·917	—16° 47′	75·0
5	111°—115°	0·900	—11° 10′	37·0
6	115°—122°	0·908	—6° 2′	32·0
7	122°—134°	0·961	—1° 37′	61·0
8	134°—139°	0·967	—4° 53′	59·0
Residue				5·0
				361·5

The first two fractions contained little or no linalol or terpineol, and in the later fractions borneol could be detected by its smell. Fractions 6 and 7 contained other substances which were also present in later fractions. To separate the borneol the first six fractions were mixed with an equal weight of benzoic anhydride, the mixture heated for four hours on the water bath, then neutralised with warm soda solution, the benzoate driven off by steaming, and the oil passing over fractionated under a reduced pressure of 14 Mm.

	Boiling Point.	Sp. gr.	Rotation.	Yield.
				Per Cent.
1	84°— 95°	0·883	— 7° 22′	8·8
2	95°—101°	0·903	—12° 40′	22·0
3	101°—105°	0·911	—20° 00′	13·2
4	105°—110°	0·914	—26° 14′	12·9
5	110°—120°	0·906	—20° 12′	20·5
6	120°—125°	0·906	—13° 12′	15·6
Residue				5·0
				100·0

In fraction 1, linalol could be detected by the formation of citral on oxidation with chromic acid, but the amount of that alcohol in citronella cannot be much more than one-thousandth. Terpineol, which, according to the boiling point, would be in fractions 2 and 3, could not be detected. In fractions 4 to 6 there was in addition to some borneol that had escaped the action of benzoic anhydride, and may have caused the high rotation of those fractions, an oil smelling like mint or pulegone, which had possibly been formed through the alteration of citronellal by alcoholic potash, as the quantity (10 C.c., about) was trifling. From the benzoic compound borneol could be readily obtained, and it had the normal character melting at 203°, $[\alpha]_D$ at 20° C. = — 33° 19′ (chloroform solution) 8·23 per cent., borneol sp. gr. 1·415 at 20° C., 100 Mm. tube length, observed rotation — 3° 55′ at 20° C. By treatment with carbanil the borneol phenyl-urethane, melting at 138°–139°, could be easily obtained.

The steam fraction 17 yielded, on oxidation with permanganate, veratric acid melting at 180° C. That indicated the presence of methyl eugenol, and that body was isolated in the following manner:—A residue of geraniol was removed by distillation under a reduced pressure of 18 Mm., and the residue was well shaken with ten volumes of 60 per cent. alcohol. Methyl eugenol dissolves in ten volumes of 60 per cent. alcohol, though the sesquiterpene present in the oil does not freely dissolve. After the mixture had become clear the alcoholic liquor was separated, and the oil containing methyl eugenol was salted out. It had a sp. gr. 987 at 15° C., while pure methyl eugenol has a sp. gr. of 1·055, so that it still contained much sesquiterpene, which was afterwards found to have nearly the same boiling point as methyl eugenol (145° at 12 Mm.), and cannot, therefore, be separated by fractional distillation, but is readily altered by acids or alkalies. To destroy the sesquiterpene and convert the methyl eugenol into methyl isoeugenol, the oil containing methyl eugenol was heated for three hours to 230° C. with a 5 per cent. solution of sodium alcoholate. After distillation under reduced pressure of 12 Mm., the following fractions were obtained :—

	Boiling point.	Sp. Gr.	Yield.
1	78°—110°	—	2·6
2	110°—140°	0·948	12·9
3	140°—142°	1·004	10·2
4	142°—143°	1·017	27·6
5	143°—145°	1·023	40·7
Residue			6·0
			100·0

Fraction 5 had the boiling point of iso-methy engenol 268°—270° C. and the smell of that body, but it was not quite free from sesquiterpene, as shown by the low specific gravity.

The dibromide melting at 102° C. was prepared, and found to contain very nearly the proper amount of bromine.[8] Oxidation yielded a satisfactory amount of veratric acid, and its silver salt gave 37·41 per cent. of silver, against 37·61 per cent. calculated.

The presence of methyl eugenol in citronella oil is proved by those data.

The oil from which methyl eugenol had been separated by washing with 60 per cent. alcohol was further washed with 70 per cent. alcohol, and then separated by distillation under reduced pressure into fractions; in that way an apparently homogeneous body was obtained having a boiling point of 157° C. at 15 Mm., and under normal pressure 270° — 280° C. with distinct decomposition, sp. gr. 0·8643 at 15° C., rotation at 15° C. = + 1° 28′, index of refraction at 15° C. = 1·51849. It still contained some methyl eugenol, but was evidently for the most part a sesquiterpene of lower specific gravity than usual.

In the fraction 18 the presence of a second dextrogyre sesquiterpene, sp. gr. 0·912, at 15° C., boiling point 272°-275°, rotation + 5° 50′ at 17° C., was ascertained, but owing to the slight difference in its boiling point it could not be completely separated. This citronella oil therefore contained, in addition to the alcohol geraniol and the aldehyde citronellal, l-limonene, traces of linalol, methyl eugenol, a light sesquiterpene, and a dextrogyre heavy sesquiterpene, and the proportion of the chief constituents was found to be :—

	Per cent.	
Citronellal	28·2	= 69·1
Geraniol	32·9	
Methyl eugenol	8·0

INCOMPATIBILITY AND SOME OF ITS LESSONS.*

BY WALTER G. SMITH, M.D.

Ex-President Royal College of Physicians, Ireland; Physician to his Excellency the Lord Lieutenant; King's Professor of Materia Medica and Pharmacy, School of Physic, T.C.D.

Part I.—General.

The decline in the art of prescribing has been a frequent subject of lament of late years, and with some practitioners it is to be feared that the atrophy of disuse has almost blighted their capacity to think out and indite a good prescription.

To some extent this is inevitable, owing, partly to the rapid changes which have swept over modern pharmacy, and in part to the hurry-scurry of active practice, and to the ultra-fastidiousness of the public, who have learned to insist on being delicately catered for by the pharmacist.

But there still remains some scope for the educated practitioner who, while not disdaining convenient and palatable forms of medication. prefers sometimes to soar above soloids, tabloids, and bipalatinoids, to choose his own combinations, and to use his judgment as to the forms in which these shall be cast.

Knowledge of this kind, "*quamvis non faciat medicum, aptiorem tamen medicinæ reddit.*"

Apart from stupid and sometimes ludicrous mistakes, serious inconveniences, dangerous accidents, and even loss of life have been the penalty of contravening simple and fundamental principles.

Hence it needs no apology to the readers of a journal whose title seems to invite such communications, to offer some remarks upon the correct formulation of a prescription, regarded from a chemical point of view.

And it may be safely said that this subject is either ignored or inadequately discussed in text-books upon materia medica, and even in manuals of practical pharmacy it scarcely meets with that systematic exposition which its merits demand.†

For example, what is the use or meaning of such a list of incompatibilities as the following, taken from a well-known text-book :—

"Corrosive sublimate with carbonates, lime water, iodide of potassium, opium, vegetable infusions, tannin."

Students are very prone to misunderstand formulæ and equations, and sometimes interpret them in a way that is comical enough :—

For example, take these answers :—

"How would you prepare quicksilver?

"$2NO_2AgO$ + CaO = N_2O_4CaO + Ag_2

Nitrate of Silver. Quicklime. Nitrate of Lime. Quicksilver.

"How is phosgene gas prepared?

"By the action of hydrochloric acid on metallic cobalt, as is shown by the following equation :—

"$Co + 2HCl = H_2 + COCl_2$"

(*Pharm. Journ.*, Dec. 7, 1895.)

These are, no doubt, extreme cases. It is, however, true that our mode of regarding chemical changes has altered much within the last twenty years. We are not content to worship the fetish of mere formulæ, but strive to go deeper, and to inquire into the dynamical processes that underlie all chemical change.

Hence I shall, by way of introduction, briefly advert to some general considerations which help us to better understand the inner meaning of a chemical equation in accordance with modern ideas.

The two broad subdivisions of theoretical chemistry are :—

(1) *Chemical Statics.*—This deals with single substances; with views upon the structure of matter; the conception of atoms and molecules; and the determination of molecular configuration.

(2) *Chemical Dynamics.*—This branch discusses the actions between two or more substances, *i.e.*, chemical change, velocity of reaction, and chemical equilibrium, *i.e.*, the result of chemical change.

Chemical dynamics has assumed the foremost place in chemical philosophy within the past ten years, and it is to some topics in relation to it that I wish to invite attention.*

Chemistry has to do with ponderable matter, and atoms are the building-stones of chemistry. Our idea of what we call matter is inextricably bound up with the notion of some form of motion, and every phenomenon we can perceive can be traced to motions going on in the world around us, *i.e.*, to kinetic energy, and this seems to be dependent upon temperature. Since at absolute zero, *i.e.*, −273° C., all atomic motions would stop, it is an attractive subject for the mind to try and imagine what would be the properties of matter at that paralysing temperature. Results of extraordinary importance will surely accrue if investigations are made upon the properties of bodies near the absolute zero.

The temperature of the upper air is about −66°, but Professor Dewar has shown that liquid hydrogen boils at −253° in a vacuum, and this is only −20° above absolute zero. By exhaustion he was able to attain a temperature of only −15° absolute T.

Cold retards chemical reactions. At temperatures below −120° such reactions as those between sulphuric acid and caustic soda do not take place, and even the coloration of litmus by acids commences only at temperatures above −80°. Metallic sodium has no action upon dilute alcohol at −80°. Metallic sodium and HCl do not act upon one another visibly at −80°. But a more exact study shows that it is really a *retardation* which occurs. The HCl, after having been (apparently without reaction) in contact with Na, is actually found to contain Na (van't Hoff). Liquid fluorine boils at −187°, and at −210° it has no action upon oxygen, water, or mercury, but explodes with hydrogen or oil of turpentine.

Conversely, it is easy to see how a rise in temperature generally accelerates chemical change because it acts in three ways :—

(1) It alters, usually diminishes, the cohesion of the molecules.

(2) It increases the motion or the store of energy of the molecules, and brings about a greater number of molecular collisions in unit of time.

(3) It probably effects the motion of the atoms themselves in the molecules.

A parallel kind of change is accomplished by the act of solution, and dilution with water operates like heat in favouring chemical change.

In short, chemical change cannot otherwise be explained than as change of motion.

Every chemical reaction requires certain limits of temperature for its accomplishment, and doubtless many of the chemical changes observed by us cannot take place in the sun where the temperature is very high, or in the moon, where it is very low.

The study of the influence of change of temperature upon chemical equilibrium leads to the following generalisation :—

Rise of temperature favours the system formed with absorption of heat. Therefore, all equilibria are displaced at high temperatures towards the side that is formed with absorption of heat; whilst at low temperatures displacement in the opposite sense takes place.

When we remember that the temperature of our surroundings is comparatively low, only about 273° removed from absolute zero, it is clear that, under the conditions usually obtaining, the majority of chemical equilibria tend to the side of the system formed with

* Reprinted, by special permission, from the *Practitioner*.

† The best and fullest account I have met with is given in Scoville's 'Art of Compounding,' 1895. It includes an instructive illustrative collection of incompatible prescriptions

* In penning these introductory observations (intended chiefly for students and junior practitioners) I have freely borrowed, sometimes the language, from the writings of Nernst, Mendeléeff, Ostwald, and van't Hoff.

evolution of heat (exothermal). Consider more exactly the equilibrium :—

$$2H_2O \rightleftharpoons 2H_2 + O_2.$$

Water is partially decomposed at 1000°. Upon cooling, this equilibrium must be displaced, in accordance with the above principle, towards the side formed with evolution of heat, *i.e.*, water, and this has been experimentally verified.

This displacement implies that at ordinary temperatures water is the stable form of a mixture of oxygen and hydrogen, and accordingly the latter is, under the most varied circumstances, completely transformed into water.

Hence it will be seen that such chemical changes as take place at ordinary temperatures are, for the most part, accompanied by evolution of heat.

Analogous considerations lead to the conclusion that the reverse must be true at high temperatures.

Both conclusions are most completely verified by experience.

This is not quite the same expression as Thomsen and Berthelot's "principle of maximum work," which was claimed to be the guiding principle of chemical mechanics.

For although this is mostly true under ordinary circumstances it would only be strictly true at the absolute zero.

At the absolute zero point compounds formed with evolution of heat replace the others fully, *i.e.*, reactions are complete and exothermic.

It will now be perceived that we are compelled to renounce the idea of any substance being in a condition of absolute rest or stagnation, and we grasp the conception that chemical equilibrium is not static, but dynamic.

It must be admitted that we know scarcely anything definite either about the nature of the forces which bind the atoms together in the molecule, and which hinder them from flying apart, or regarding the laws of action.

It seems clear, however, that our whole conception of affinity requires to be completely reconstructed, and we fix our attention not on potential, but upon kinetic energy.

The mutual action of atoms evidently varies with their nature, and the case is very rare where the course of the reaction can have but one issue depending solely upon the chemical forces.

The affinity certainly changes with external conditions of temperature and pressure in all cases.

Thus, Spring has shown that some finely powdered solids which do not react upon each other at the ordinary temperature may do so under an increased pressure, *e.g.*, sulphur and metals. He also proved that the powder of solid metals, when exposed to a pressure of over 1,000 atmospheres, gave by its homogeneity, crystalline structure, etc., quite the impression of having been melted.

In the case of gases* we have little difficulty in recognising the freedom and velocity of molecular movement,† and the kinetic theory of gases must be considered as one of the most brilliant acquisitions of the latter half of the present century.

In the case of liquids, also, we can easily comprehend the comparative freedom of molecular interchange, and hence most chemical experiments are carried out in a state of solution.

The possible interaction of gases with liquids, and of liquids with insoluble solids, can be foreseen, and of the latter event we have a familiar example in the preparation of Lotio Nigra.

But it requires some effort to firmly implant in the mind the doctrine of the universality of molecular motion, and to realise that it is applicable not only to gases and liquids, but also to solids, and this whether they be elements or compounds.

Let me refer to a simple and convincing experiment by Sir William Roberts-Austen, who has investigated the diffusibility of metals into each other.

He maintained cylinders of lead and gold at a constant T., far below the melting point of lead, for several days. Analysis showed that solid gold placed at the bottom of a cylinder of lead about three inches long will diffuse to the top in notable quantities in three days. He has also lately shown, by investigations on the cooling curves of metals and alloys, that steel and cast iron (carburised iron alloys) behave exactly as certain saline solutions do. (*Nature*, April 13, 1899.)

The ancient dictum—*Corpora non agunt, nisi fluida*, no longer holds good.

It is easy to give examples of the mutual interaction of solids in the absence of water or any other liquid. Some of them are of interest to pharmacists.

I divide them into two groups :—

(*a*) *Formation of Molecular Complexes.*—These are unstable liquid or pasty compounds, easily resolved into their components. The "valence" hypothesis does not embrace such facts as these, viz. :—

Camphor and chloral.
" " menthol.
" " phenols (carbolic acid ; resorcin).
Phenacetin, exalgin, or acetanilide and salicylic acid.
Acetanilide + antipyrin.

(*b*) *Double Decompositions.*—Alum (or zinc sulphate) and acetate of lead, *e.g.*—

$$ZnSO_4 7H_2O + PbAc_2, 3H_2O = PbSO_4 + ZnAc_2, 3H_2O + 4H_2O.$$

The mass becomes moist when triturated, owing to liberation of some of the water of crystallisation.

Similarly, potassium nitrate and sodium acetate—

$$KNO_3 + NaAc, 3H_2O = KAc + NaNO_3 + 3H_2O.$$

Iodoform left in contact with calomel or grey powder, slowly reacts and forms red iodide of mercury.

Every free element, every acid, and every base seems to contain a fixed amount of energy, which, in the act of combination, may in part be utilised in the production of change or liberated as heat.

A chemical change is invariably accompanied by changes of energy, and the energy is not produced by the chemical affinity but rather is set at liberty by it. Chemical energy passes most easily and completely into heat.

A chemical change is a complicated problem, and the chief problem of theoretical chemistry is to express the mutual reactions between substances by means of certain characteristic numerical coefficients; but we are, as yet, far distant from having a clear conception of the precise course of chemical combination. When this is feasible, we may feel pretty sure that it will be on a kinetic basis, probably including electrical actions.

So far as the number of reacting molecules has been investigated, it appears that the mechanism of reaction is, in general, very simple, and is nearly always mono- or bi-molecular. If an equation, in order to express a reaction, quantitatively shows the interaction of several molecules, it is probably in reality a combination of processes taking place consecutively. Thus—

$$2HI + H_2O_2 = 2H_2O + I_2$$

probably should read as

(*a*) $HI + H_2O_2 = HIO + H_2O.$
(*b*) $HIO + HI = I_2 + H_2O.$

Kinetically, the rarity of polymolecular reactions is quite intelligible. The probability of a simultaneous collision between three molecules and those of specified kinds is a very small one; so the reaction proceeds, if it is possible, by the actions taking place within a single molecule or on the meeting of two molecules (van't Hoff).

* The derivation of the word "gas," invented by Van Helmont has been differently given, but the truth is that it was suggested to him by the Greek word "chaos." For, he says, "Halitum illum 'gas' vocavi, non longe a Chao veterum secretum."—(*Historical English Dictionary.*)

† A molecule of H if it moved in a straight line and unimpeded would travel 1¼ mile in one second. Similarly, oxygen ¼ mile, about, *i.e.*, inversely as quare roots of densities, viz., 16 : 1

Let us consider for a moment more closely the common case of double decomposition. The general equation will be

$$\overset{+-}{A}B + \overset{+-}{C}D \rightleftharpoons AD + BC$$

Iron Chloride + Sodium Acetate = Iron Acetate + Sodium Chloride.
Red solution.

Silver Nitrate + Sodium Chloride = AgCl + $NaNO_3$.
Ppt.

We will assume that neither AC nor BD nor any other substance is produced, and this may be admitted as commonly true in cases of double decomposition of salts in which A and C are metals or alkaloids.

But this is just the class of decompositions which most concerns practical pharmacists.

If all the products are soluble, or if nothing separates out from the sphere of action (*Homogeneous System*), the decomposition will presently cease, because a state of mobile or dynamic equilibrium will be established, and, instead of two, there will remain four substances in the mass, viz., a portion of the original bodies AB and CD, and a certain quantity of the newly-formed substances AD and BC.

Next consider what will happen if one of the new substances is capable of being removed from the sphere of action. Suppose one of the new products to be (*a*) a gas, while the others are liquid or solid; or (*b*) an insoluble solid, *i.e.*, a precipitate, while the others are liquid (*Heterogeneous System*). Then, under the influence of mass action, the reaction will evidently go on to the end, *i.e.*, until all the removable product is subtracted.

(*To be continued*).

SELECTED PRACTICAL FORMULÆ.

Collutoria for Infantile Thrush.

(1) Borax, 4; tincture of benzoin, 4; syrup of raspberries, 40. Applied with a camel's hair pencil to the affected parts. (2) Potash alum, 1; tincture of catechu, 4; honey of roses, 30. —*Formulary of Nouv. Rem.*

To Check Lacteal Secretion.

Atropine sulphate, 3 centigrammes; magnesium sulphate, 90 grammes; infusion of gentian, 240 grammes. A tablespoonful every two hours, until four such doses have been taken.—*Rev. Med. Pharm.*, **6**, 208.

Guaiacol Syrup.

Crystalline guaiacol, 7·50; glycerin, 92·5; simple syrup, 900. A dessertspoonful five or six times a day with food.—*Rev. Med. Pharm.*, **6**, 207.

Creosote Syrup.

Beechwood creosote, 5; glycerin, 80; simple syrup, 915. A dessertspoonful five or six times daily with food.—*Rev. Med. Pharm.*, **6**, 207.

Anti-rheumatic Liniment.

Oil of turpentine, 200; sodium salicylate, gamboge, myrrh canella bark, in powder, of each, 10. To be rubbed in thrice daily, and then covered with wool.—*Pharm. Post*, **32**, 407.

Essence of Buckthorn.

Rhamnus frangula bark, 10, is heated with water, 50, on a water bath, pressed, and the expressed liquor evaporated to 9; tincture of orange, 1, is then added. To prepare the essence extemporaneously, fluid extract of rhamnus frangula, 10, may be mixed with tincture of orange, 1.—*Pharm. Post*, **32**, 407.

Impermeable Paper.

The paper is treated on both sides with a solution of gelatin, 1, and glycerin, 1, in water, 4. After drying it is dipped in a 10 per cent. solution of formalin and again dried.—*L'Union Pharm.*, **40**, 411, after *Rev. Chem. Indust.*

THE COMPANY PHARMACY PROBLEM.—IV.

BY AN ORDINARY PHARMACIST.

At last, and in spite of all precedent, we have been favoured with the views of a member of the Council of the Pharmaceutical Society and of the Law and Parliamentary Committee of that body; of one, also, who is understood to lead that section of the Council which favours recognition and regulation of companies of unqualified persons carrying on the business of a chemist and druggist. A more capable leader could not well be conceived, and we have it on the authority of Mr. Michael Carteighe that his scheme is a "wonderful panacea" of great ingenuity. But a careful perusal of Mr. Glyn-Jones's article confirms me in the view—originally based on a careful study of the report of the last Council meeting—that his plan of dealing with the problem presented to us, though admirably conceived and honestly intended to benefit the craft, is nevertheless fraught with mischief. It is, however, impossible to speak with certainty on that point until we have the draft of the scheme before us. For the present, therefore, we are limited to the report of the author's remarks at the Council meeting, and to his article published in last week's Journal.

That "Wonderful Panacea."

Briefly, Mr. Glyn-Jones asserts that absolute consistency is impossible and that company regulation is inevitable. He would provide, therefore, that a board of directors must exist in the case of any company carrying on the business of a chemist and druggist, and that each director must be a person duly registered under the Pharmacy Acts. Moreover, those directors must have absolute control over the conduct of the business, the other shareholders presumably being allowed to have no voice in the management of affairs, except such as the law specifically allows them at annual meetings. As a general comment upon Mr. Glyn-Jones's statement, I will merely remark that his "wonderful panacea" appears to be little more than a carefully thought-out scheme on the lines suggested in the concluding words of my second article. But, whereas I proposed such an arrangement only as a means of enabling existing companies of unqualified persons to bring themselves into line, he would make it apply generally, and in such a manner as would result, indirectly but virtually, in preventing companies of unqualified persons from carrying on the business of a chemist and druggist. Under the circumstances, I can only echo Mr. Carteighe's expression of regret that the "wonderful panacea" has not yet been published.

Courses Open to the Council.

But, to return to its creator's modest exposition of his views, as presented all too briefly—so far as concerns original matter, apart from quotations—in last week's Journal. According to Mr. Glyn-Jones there are three courses open to the Council of the Pharmaceutical Society. It seems to me, however, that those three do not cover the whole ground, nor are they complete in themselves. In my opinion the Council might—

(1) Draft a clause simply prohibiting the use of pharmaceutical titles by companies or other corporate bodies;

(2) Add to that clause words making companies or other corporate bodies liable for offences under Section 15 of the Pharmacy Act, 1868, in the same manner as individuals, and likewise prohibiting the keeping of open shop for the retailing, dispensing, or compounding of poisons by companies of unqualified individuals;

(3) Recognise the expediency of permitting companies or other corporate bodies to retail, dispense, or compound poisons, provided the directors or managers are duly qualified under the Pharmacy Acts;

(4) Wait to see what the Government proposes to do in the next Session of Parliament, and then oppose what seemed to be antagonistic to the interests of registered chemists, whilst not conferring any real benefit on the public;

(5) Pass a formal resolution, expressing the views of the Council, and depute a limited number of members to negotiate with the Government on that basis, after which a clause embodying what seemed feasible might be drafted and submitted to the Council for approval.

(1) Protection of Titles Only.

The first plan, as I have previously explained, is the easiest one to adopt, but it involves opposition of Clause 2 of the Companies Bill, if that clause should be re-introduced next Session, and it will not satisfy the Lord Chancellor, nor will it commend itself to the majority of registered chemists. The Lord Chancellor's chief concern, as expressed by him at the outset of the present agitation, is that all medicines should be dispensed for the public by competent persons. He evidently does not care in the least whether chemists' titles are protected or not, and if nothing more than that should be proposed he might almost certainly be expected to decline to insert such a clause in a Companies Bill promoted by the Government. Now, it is a simple matter to oppose the Lord Chancellor with all our forces if he should again propose an objectionable clause ; but if we desire his assistance we must be prepared to submit something which may strike him as being worthy of his consideration. And that, a clause simply restricting the use of titles most certainly is not. For, though Lord Halsbury is chiefly concerned about the proper dispensing of medicines, his attention has also been directed to a notable defect in the Pharmacy Acts, which enables an association of unqualified persons to evade the operation of the law, and he has displayed some little anxiety to secure a remedy for that defect. He has gone to the extent of introducing a Pharmacy Bill with that object in view and, more wonderful still, he has since secured the insertion of a clause dealing with the subject in a Companies Bill promoted by the Government, in spite of the fact that the Council of the Pharmaceutical Society had been assured repeatedly that the matter could not, under any circumstances, be dealt with in such a measure.

Not Likely to Satisfy the Lord Chancellor.

Now, a Lord Chancellor does not take all that trouble for nothing, and it would be absurd to imagine that he will drop his intention of making companies amenable to the law because the Pharmaceutical Society prefers to shirk the point and asks him to help to secure protection for chemists' titles only. I grant that there should be but little difficulty in persuading him how undesirable it is, in the public interest, that associations of unqualified individuals should be permitted to assume and use titles which the law says shall only be assumed and used by individuals when they possess the proper qualification to perform duties for which that qualification is requisite. But, he may not unreasonably ask how far that will help him otherwise to secure that anything which would be an offence under Section 15 of the Pharmacy Act, 1868, if committed by an individual, shall be equally an offence if committed by a company. He would probably argue that restriction of the use of titles to legally qualified individuals is primarily a personal matter with chemists, and ask how that provided for the safety of the public as affected by the sale and dispensing of poisons by incompetent persons. The answer to that question must, of necessity, be a distinctly unsatisfactory one, and I think we may safely assume that his Lordship would subsequently proceed to deal with the matter as he thought fit, without devoting much further consideration to any views held by the Pharmaceutical Society on the subject. The position would then be a decidedly awkward one, for—if opposition to any clause subsequently drafted became necessary—we should be open to the charge of being unwilling either to do anything in the direction of reform ourselves or to permit anyone else to do anything. The value of our opposition would then be largely discounted, and the last state of British pharmacy might not inconceivably become very much worse than the first.

(2) Prohibition of Unqualified Companies.

The second course is, in my opinion, the only fair and logical one for the Council to follow. The use by companies or other corporate bodies of titles implying qualification under the Pharmacy Acts, must be as strenuously resisted as in the case of unqualified individuals. As pointed out by the *British Medical Journal*, a certain measure of protection is afforded to the public by preserving a proper significance to professional titles and, inadequate though that protection may be, it must not be weakened. But, over and above the public value of pharmaceutical titles, the legitimate holders of them are quite in order in demanding, on purely selfish grounds, that they should be restricted to themselves. Those titles can only be acquired after arduous labour, and the expenditure of much time and money. It is, therefore, quite beyond the limits of what is reasonable that others, who have not so qualified themselves, should be able to benefit by the use of chemists' titles. The restriction of those titles must be defended, therefore, on two distinct grounds: (1) because a certain measure of protection can thus be afforded to the public, and (2) because only those who have paid the proper price for a thing are entitled to possess it. In addition to that, if the pharmacy law of this country is to be logical and consistent throughout, all corporations carrying on the business of a chemist and druggist must be made amenable to the provisions of Section 15 of the Pharmacy Act, 1868, in the same manner as individuals. It is necessary, in any clause that may be drafted, to make specific reference to Section 15 in this connection, in order to avoid the constant reiteration of the almost stupid objection that, inasmuch as companies cannot fulfil the requirements of the first fifteen Sections, they must, of necessity, remain outside the purview of an Act intended only to regulate the position of individuals. The obvious retort is that companies, if they cannot fulfil the legal requirements of the situation, should cease to usurp chemists' titles and to retail, dispense, or compound poisons.

Discrimination to be Avoided.

It is not desirable to make invidious distinctions between companies consisting of qualified and unqualified individuals respectively. No company can be examined and registered as required of individuals registered under the Pharmacy Acts ; no company, therefore, should be permitted to assume or use any title implying qualification under those Acts. Whilst, therefore, nothing need be done that will prevent registered chemists from taking advantage of the provisions of the Companies Acts if they should desire to rearrange their business affairs on a joint-stock basis, all companies must be rendered liable to penalties for doing what would be an offence under Section 15 of the 1868 Act if done by an individual. No registered chemists could reasonably object to that provision, which is absolutely necessary in the public interest and should specially appeal to the Lord Chancellor's sense of justice. Finally, no association consisting of individuals who are not registered under the Pharmacy Acts should be permitted to keep open shop for the retailing, dispensing, or compounding of poisons. There are, then, three points to be embodied in a complete clause, the first of which is imperatively demanded if qualification of chemists and druggists is to continue of any value, whilst the second and third are necessary in the public interest, besides being both reasonable and just. There are doubtless many real difficulties in the way of drafting, and securing the adoption of, a clause that would satisfactorily embody those requirements, but the difficulties are not insuperable. Moreover, it is the duty of the Council of the Society to meet and overcome such difficulties, not to invent imaginary ones and despairingly shirk the issues that do present themselves. The Council has both public and private interests to protect, and, having decided upon a clear and settled policy, must be prepared to

do its utmost to persuade the Government to do what is right and fair.

(3) Recognition and Regulation of Companies.

Coming next to the third course which is open, so far as recognition of the principle of joint-stock trading is concerned, the Council has no option, as the thing is an accomplished fact and will remain so. But it is neither necessary nor expedient that our leaders should sanction any step which can be construed as recognising the right of companies consisting of unqualified individuals to assume pharmaceutical titles or keep open shop for the retailing, dispensing, or compounding of poi ons. It must be borne in mind that regulation of companies means admitting any unqualified individual to the privileges of qualification, without the preliminaries of study and examination. Nor must any excuse be admitted for granting specially favourable terms to companies consisting of qualified individuals. What the individuals constituting any company may do, irrespective of assuming a title indicating qualification under the Pharmacy Acts, the company should be permitted to do, but nothing beyond that. I repeat, with insistence, that we cannot afford to yield an iota of our claim that no unqualified person shall be permitted to benefit by the use of pharmaceutical titles or to exercise any control over the business of a chemist and druggist. If once we offer to negotiate on the basis of allowing that the appointment of qualified directors or managers might meet the necessities of the case, we shall have abandoned our main position, and nothing that we can do afterwards will enable us to regain it. For, if we give the Lord Chancellor the impression that we should be satisfied with the appointment of qualified directors or managers, under certain conditions, what is to prevent him regarding the concession as an absolute one and arranging the conditions to meet the views of the companies rather than of ourselves? Let us then refuse to concede anything in that direction, and continue to maintain our position intact and unimpaired. It is useless to shut our eyes to the fact that the position of pharmacy as a profession cannot be established on a sure basis in this country unless we secure a reversal of the House of Lords' decision in the case of the London and Provincial Supply Association. That, apparently, can only be done by Act of Parliament, and the initiative must be taken by ourselves. The Lord Chancellor's efforts seem, so far, to have been exerted in the direction of establishing the House of Lords' decision upon a clear statutory basis, but what pharmacists desire, and the public safety needs, is that the decision should be upset. That is the clear issue, plainly stated, and we look to the Council to repudiate any intention of encouraging the Lord Chancellor in his retrograde policy.

(4) Waiting upon the Course of Events.

If all attempts to secure practical unanimity in the Council should fail, nothing useful can be done now. We must wait to see what the Government proposes to do in the next Session of Parliament, and then decide whether or not to oppose any clause that may be published in a Companies Bill. The chief disadvantage of this fourth course is that we are thereby precluded from having a share in the drafting of the clause, and may have to accept or reject it as it stands, without being able to secure its modification in any degree. On the other hand, our opponents are not likely to allow similar scruples to affect them, and they will probably miss no opportunity of helping to shape the clause so as to meet their views. Unless, therefore, the direst necessity should indicate a policy of waiting to be the only one possible under the circumstances, I fail to see anything but weakness in the recommendation that such a course should be adopted. If we are assured of the justice of our cause—and I take it that every member of the Council most certainly is—why should we be ashamed of taking up a pronounced and definite position, or be backward in advancing arguments in support of that position? Surely the Council is not as lacking in constructive ability as the Editor has accused many of its critics of being. If not, let matters be fairly placed before the Lord Chancellor and other members of the Government, with some definite exposition of policy. Otherwise, Lord Halsbury may be driven to assume that the now historic "suggestions" exhausted the possibilities of the case, from the pharmaceutical point of view, and that the field is now left clear for displays of ingenuity on the part of himself and the companies affected, in endeavours to knock the bottom out of the Pharmacy Acts.

(5) Desirability of an Expression of Opinion.

To prevent the possibility of such a mistaken notion gaining ground in Government circles, I would recommend the fifth course as being alike expedient, dignified and proper. Something ought to be done forthwith, but there is no occasion that what is done now need partake of the inelastic nature of a clause for a Companies Bill. Some measure of freedom of action should be reserved, and for the moment I see no actual necessity for anything beyond a sincere confession of pharmaceutical faith by the Council. Failing immediate agreement regarding the details of a suitable clause—a non-essential point at the present juncture—why should not the Council, as representing British pharmacy, formally pass a resolution stating that, inasmuch as a company cannot be examined and registered in accordance with the provisions of the Pharmacy Acts, it should be unlawful for any company or other corporate body, as such, to assume or use any title implying registration under those Acts; that all companies or other corporate bodies should be liable to penalties for doing what would be an offence under Section 15 of the Pharmacy Act, 1868, if done by an individual, and that it is not desirable, in the public interest, that any individual who is not registered under the Pharmacy Acts should be permitted to exercise any control over the retailing, dispensing, or compounding of poisons? The references to "other corporate bodies" are necessary to cover the case of firms in Scotland, which are held to be bodies corporate. Such a resolution would include the three points which I have suggested should be embodied in a complete clause of a Companies Bill, and to pass it would clear the air and provide a definite basis for the Council or its Law and Parliamentary Committee to work upon.. I doubt whether a single member of the Council could conscientiously decline to vote for that resolution, and a useful degree of unanimity would thus be attained at the outset. It has been a matter of surprise to me that some such resolution was not passed by the Council long ago, before the discussion of the company pharmacy problem reached its present acute form. But it is not now too late to adopt that course in good time to provide a definite basis of operations for next year's Parliamentary campaign, and I commend this suggestion to the serious consideration of our representatives on the Council. In fact, taking everything into consideration, I am disposed to think that the passing of a formal resolution, and the appointment of a small deputation to lay the views of the Council before the Government, should precede any further premature experiments in clause drafting. Mr. Glyn-Jones has appealed to every critic of the Council's multi-policy to draft and submit a clause suitable for a Companies Bill, and he has rightly stated that it is easier to say what we would like than to embody our views in a presentable clause. My previous attempt in that direction is admittedly imperfect, but it has, at least, served as a useful basis for discussion—at the last meeting of the Council as well as elsewhere. The attempts of others may serve a similarly useful purpose, but the Council would be better occupied in striving to agree, if possible, upon a single definite line of policy, rather than in restricting its freedom of action by committing itself—at present—to the hard and fast lines of any clause.

ANOTHER SUGGESTED CLAUSE.

In conclusion, however, I venture to suggest another clause for the consideration of Mr. Glyn-Jones and his colleagues, as well as the pharmacists of Great Britain and Ireland generally. It follows the lines of the Lord Chancellor's clause in the Companies Bill, 1899; would apply to the whole of the United Kingdom; is consistent with the intentions of the Pharmacy Acts; expresses, I believe, what pharmacists want; and means exactly what is stated. Thus:—

"A company or other corporate body may not assume or use any title implying registration under the Pharmacy Acts of Great Britain or Ireland, and if any company or other corporate body contravenes this enactment it shall be liable, on summary conviction, to a fine not exceeding £5 for every day during which the contravention happens; and anything which would be an offence under Section 15 of the Pharmacy Act, 1868, or under Section 30 of the Pharmacy Act (Ireland), 1875, if committed by an individual, shall be an offenee if committed by a company or other corporate body; provided always, that nothing in this Section shall prevent the formation of a company of persons registered under the Pharmacy Acts of Great Britain or Ireland, to retail, dispense, or compound poisons."

IS FREE TRADE IN DRUGS DESIRABLE?

BY J. C. HYSLOP.

With the advance of civilisation there is to be seen an important difference in the evolutionary processes of commerce on the one hand and those of science on theo ther. The trend of commercial progress is always towards the accumulation of various branches of trade around a common centre; that of science, on the contrary, is of an opposite tendency, being distinguished by a differentiation of functions, almost *ad infinitum*. Hence the great advantage to the public welfare derived from the working of the Joint Stock and Limited Liability Company Acts, when honestly taken advantage of and applied, to facilitate commercial prosperity, as it was originally intended they should be. Hence, likewise, the disadvantage that must accrue to the public service when it is attempted to divert the machinery of those Acts from its proper sphere of action, and cause it to intermeddle with such strictly scientific pursuits as medicine and pharmacy.

A thriving commerce demands that stocks be accumulated and dispersed abroad with the utmost rapidity and with the minimum of cost as between producer and consumer. This rapid interchange of value for cash is equally good for both parties—small profits—quick returns. Accordingly, by the operation of the Limited Liability Acts, a wonderful change has been wrought in the character as well as the bulk of British commerce. And this change is still proceeding. No longer can we be taunted by our neighbours aeross the Channel with being a nation of petty shopkeepers, for the small shopkeeper is being rapidly wiped out of existence. The rapid character of his decadence is largely due to the arrogant extortion he was wont so long to inflict upon the public, that is a vice to which both he and the big store that has supplanted him seem equally addicted, only the bigger offender can stand his ground whilst the weaker one must go the wall. So it comes about that the British nation bids fair to become one of the big companies financed by those who know nothing of the business carried on in any of its departments; but depending for general success upon an army of branch managers, recruited largely from the ranks of the original shopkeepers, these being usually unknown men in the respective neighbourhoods where they are told off to transact business, always a mixed one, sometimes a very mean, at others a thriving one, but mean because badly managed, or thriving for the opposite reason matters little to the directorate, these branches and these managers being kept going mainly as an advertisement for the large concern which lays claim on paper to the ownership of such a gigantic list of depôts.

One would have thought that a moment's reflection was enough to bring home to any reasonable mind the wide differenee that exists between the two functions. First, that of the daily distribution of the ordinary necessaries of life and the comforts of healthy existence, and, secondly, those of the fitful and petty but onerous duties connected with the distribution of drugs and the compounding of medieines for the sick, with the supply of the various, often fantastie, aceessories that suddenly become needful, night and day, at times when ordinary traders are all closed for rest or holiday, for the benefit of all sorts and conditions of men.

Here, on the one hand, we have a steady and a rapidly flowing current, becoming more rapid and more extending still by taking a greedy advantage of every discovery and invention of science to supply the need of hungry mortals with a speed and a cheapness that is ever on the increase. Hurry of method and blatant self-assertion its native charaeteristic: a raee that does appear to be to the swift and a battle to the strong, where competition is the great watchword—fairness or unfairness being seldom regarded in this struggle. There, on the other, we have a dammed-up reservoir of all that is needed to alleviate the miseries of sickness, to cure where possible, and to sustain in as much comfort as we can the life that is fast ebbing away. The output here is under the control of men that have passed a statutory examination, and are sent forth with legal qualification for the fulfilment of their important duties. These are practically, as of old, the medical man and his store-keeper—a "pharmaceutical chemist" or a "chemist and druggist." These are supposed to spend their lives in awaiting the calls of duty. Engaged meantime in constant attention to the orderly arrangement and availability of his own individual system of things, somewhat as is the military man in attending to his proper drill, and keeping in order his ammunition and aceoutrements, in the event of a sudden call to arms.

Where you had before rapid disposal and ehange of stock, here you have a fixity of tenure ready for the rising emergency. The stock of a pharmaceutical chemist, though large and varied, need not be of a bulky kind, nor planned on an ostentatious scale. Nor is it likely to deteriorate with age if only its items be properly located and revised from time to time.

Here a man has no scope for competition in a trade sense, indeed the word need scarcely enter his business vocabulary. As to his profits and his returns, moreover, the latter can never be "quick;" the former must and ought to be large. "Business" in the case of the pharmacist is not a mere clearance of stocks of differing values for various qualities, it is rather a case of the aceurate selection of the very best picked articles of their kind, for rich and poor alike, that whether he dispenses prescriptions therewith, or sells them in doses or otherwise, he can with unerring technical skill certify their entire suitability for the purposes intended. He spends his life not in seizing upon all the appliances of science to outstrip his neighbours in the race for notoriety or for wealth, but in the application of science as science to the duties of that higher sphere of unlimited responsibility into which he is called to act.

Here there is no occasion for large capital; after the initial outlay of the man's educational equipment a small purse, a large mind, and individual industry is all that is needed.

In the wish to ignore these facts, people who should know better fall into curious mistakes. What can be more absurd, for instance, than to advise a young man fresh from the examination-room to get an assistantship in some of the large company stores, so as to gain an insight into business matters there? As if the mysteries of money taking in a big concern, the check-till with its accessories and the balancing of large accounts, were of such importance as to make a break of a year or two necessary in the pursuit of those scientific and artistic studies he has just obtained enough proficiency in to get through his qualifying examination.

Such advice as this, however well meant, will serve but to the overthrow of many, and perpetuate that block that for years past has impeded the course of pharmacy progress, and hindered man

who had the desideratum well in view from entering the land of rest and plenty.

It cannot be too earnestly pressed upon every successful examinee that the safe road is to go on cultivating still further the subjects mentioned in his examination syllabus, and that whether he start in business on his own account or not he should make it a *sine quâ non* of his arrangements to have in his map of life a certain daily amount of leisure for further study of the subjects in which he is certified to have gained a certain amount of proficiency, that otherwise the course of things will in a very few years pass him by and leave him stranded.

Besides these radical differences between those callings to which the machinery of the Limited Liability Acts may be applied with advantage, and that of pharmacy, which we have seen to be *sui generis*, and pre-eminently of a personal character, there are many offshoots of an interesting kind that might be noted did space and time permit. One only can be specified here—one of very great importance. The pharmacist by keeping strictly to his duties has to meet with a daily commercial loss of a kind unknown to others who are in touch with simple trading. He is daily obliged to limit his own returns in deference to the public convenience or the public safety. The risks indeed which attend the performance of his duties are many and serious. For instance (putting aside for the moment the responsibilities involved in the dispensing and sale of scheduled poisons), the misuse and the extravagant use of what are supposed to be harmless drugs call for his constant attention. This matter is more urgent now than ever, because of the mendacious assertions of advertising quacks, who are always seeking to make a cat's-paw of the chemist, and the risky advise to inquiring simpletons that is found in the "Answers to Correspondents" in many daily and weekly journals of a popular character.

First ought to be mentioned the large class of emmenogogues that are used in excess by foolish women for ecbolic action. Respecting those, one has to be on the daily *qui vive*. There is no law to prevent or restrict their sale; they have their legitimate uses, and only the conscientiousness of the chemist and druggist stands in the way of their application to the purposes of vice and crime.

Again, in every neighbourhood, but more especially in one densely populated with illiterate people, the chemist has often perforce to be a "first aid" in cases of accident or sudden emergency; a mother, for instance, will run to the chemist for a powder for her child who has had a fall, hurt its head, and is sick; a powder she will have unless the chemist knows his duty enough to refuse to supply her, and soundly caution her as to her own duties in such a crisis. Again, as to the harmless medicines taken to excess, a chemist only can estimate the amount of trouble caused thereby, for if the worst comes to the worst, it is all kept from the doctor and from the coroner. He is the only one in a position to check the evil; store and company pharmacy does but promote it by its cheap, rapid, and promiscuous methods of doing business. The two ounces of Epsom salts for a dose which has again and again proved fatal; the whole ounce of compound liquorice powder which is often taken at a dose, a teaspoonful being given to very young infants, especially after a fall, are but specimens of the injurious misuse of otherwise harmless drugs which a chemist is called upon daily to check at his own loss of pecuniary profit, supposing this to be his main consideration in business life.

Is it safe then, wise, or right that free trade principles should be applied to the distribution of drugs? *Caveat emptor* is a good motto as to buying food, clothing, or house furniture, but *caveat venditor* is surely the motto for the pharmacist with his knowledge of human nature and of the heavy responsibilities that rest upon him in the conduct of all his business.

THE LAW AND PHARMACY.

BY J. F. BROWN, PH.C.

Apparently the question now said to be hopelessly dividing chemists into two camps is the expediency or otherwise of recognising the fact that companies do actually carry on business as pharmacists.

The clause brought up before the Council on the 1st inst. by the Law and Parliamentary Committee assumes its present shape because it is intended to be an integral part of a measure dealing with companies generally, hence it is a simple prohibition having nearly the same force as extending the application of the word "person" to companies would have.

But not quite. A company formed only of registered chemists would, apparently, be forbidden by the clause to do that which the original Act, if amended as above, would allow them to do.

If that prohibition became law, the arrangement adopted by some of the older co-operative stores of having an individual chemist as part of their system and printing his name upon all labels would probably be generally adopted.

Such an arrangement as that would satisfy the aspirations of those who would limit their efforts to the protection of title, as distinguished from any attempt to confine the conduct and control of the business, as well as the profits, to the hands of qualified men.

The danger of concentrating our attention on the title only is that which attends all steps towards divorcing a name from the thing properly signified thereby.

Sooner or later crude popular common sense decides that whoever does the thing shall bear the name, and that if grocers and storekeepers do supply drugs, chemicals, and medicines, they are to all intents and purposes chemists.

To try and enforce the nominal distinction after the actual barriers of practice had been broken down would be as fruitless as to attempt to teach the public that not every medical practitioner is correctly a doctor, but only one who bears the title of M.D.

The wisdom and equity of reserving titles to those who have attained them by their personal exertions and sacrifices rests upon the assured foundation of natural justice.

But something more than this is needed to ensure the welfare of pharmacy: A proper share of the control and management of a business would necessarily carry with it a sufficient proportion of the profits to reward the exercise of proved ability.

Modern writers on economics fully recognise the distinction between the owners of capital merely and the captains of industry, or men of ability, by whose personal qualities, talents, and industry the capital is made productive.
