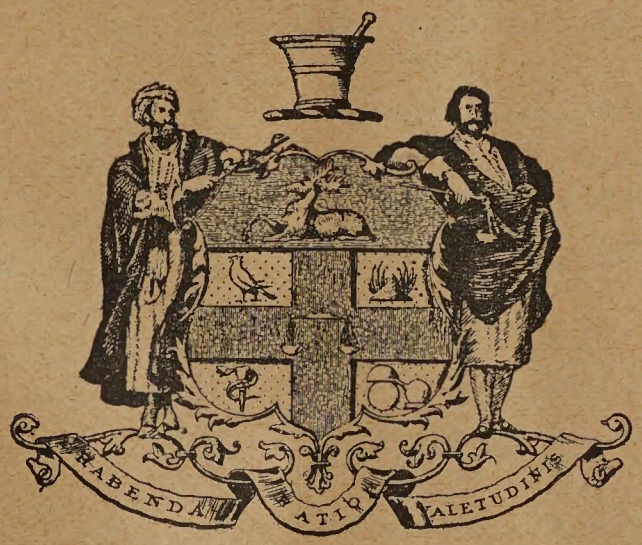
THE

PHARMACEUTICAL JOURNAL

ESTABLISHED 1841.

A Weekly Record of Pharmacy and the Allied Sciences.



VOLUME LXIII.

FOURTH SERIES—VOLUME IX.

JULY TO DECEMBER, 1899.

LONDON:

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN,

17, BLOOMSBURY SQUARE, W.C.

CONTRACTIONS OF TITLES.

The following is a list of the contractions and the corresponding full titles of Journals from which abstracts are most frequently prepared for the "Pharmaceutical Journal." The titles prefixed by an asterisk (*) are those of official Journals.

Amer. Journ. Pharm. = American Journal of Pharmacy. Philadelphia. Monthly.

Annalen = Justus Liebig's Annalen der Chemie. Leipzig. Monthly.

* *Apot. Zeit.* = Apotheker-Zeitung. Organ of the Deutsche Apotheker-Verein. Berlin. Twice a week.

* *Apot. Zeit. Rep.* = Repertorium der Pharmacie. Supplement to the Apotheker-Zeitung.

* *Archiv* = Archiv der Pharmacie. Berlin: J. Greiss. Monthly.

* *Berichte* = Betichte der deutschen chemischen Gesellschaft. Berlin. Once or twice a month.

* *Brit. Med. Journ.* = British Medical Journal, London. Weekly.

Bull. Com. = Bulletin Commercial. Supplement to L'union Pharmaceutique. Paris: Pharmacie Centrale de France. Monthly.

* *Can. Pharm. Journ.* = Canadian Pharmaceutical Journal. Toronto Monthly.

Chem. News. = Chemical News. London. Weekly.

Chem. Zeit. = Chemiker Zeitung. Cöthen. Twice a week.

Chem. Zeit. Rep. = Chemisches Repertorium. Supplement to the Chemiker Zeitung.

* *Comp. rend.* = Comptes rendus des séances de l'Académie des Sciences. Paris: Gauthier-Villars. Weekly.

Deuts. Am. Apot. Zeit. = Deutsch Americanische Apotheker Zeitung. New York.

Int. Photo. Monats. = Internationale Photographische Monatschrift fur Medzin. Düsseldorf. Monthly.

* *Journ. Chem. Ind.* = Journal of the Society of Chemical Industry. Monthly.

* *Journ. de Pharm.* = Journal de Pharmacie et de Chimie. Paris: G. Masson. Twice a month.

Journ. Pharm. Elsass-Loth. = Journal der Pharmacie von Elsass Lothringen. Strassburg. Monthly.

Journ. Zahnheil. = Journal für Zahnheilkunde. Berlin.

Med. Press = Medical Press and Circular. London: A. A. Tindall. Weekly.

Mod. Med. = Modern Medicine and Bacteriological Review, Battle Creek, Mich., U.S.A. Monthly.

Mon. scient. = Moniteur Scientifique. Paris. Monthly.

Münch. med. Woch. = Münchener Medicinische Wochenschrift. Munich. Weekly.

Nouv. rem. = Les Nouveaux Remèdies. Paris. Twice a month.

Pediat. = Pediatrics. London and New York. Weekly.

Petit. Mon. Pharm. = Petit Moniteur de la Pharmacie. Paris. Fortnightly.

Pharm. Centralh. = Pharmaceutische Centralhalle. Dresden. Weekly.

Pharm. Post = Pharmaceutische Post. Vienna. Weekly.

Pharm. Woch. = Pharmaceutische Wochenschrift. Berlin. Weekly.

Pharm. Zeit. = Pharmaceutische Zeitung. Berlin: J. Springer. Twice a week.

Pharm. Zeits. für Russ. = Pharmaceutische Zeitsch rifte für Russland. = St. Petersburg. Weekly.

Photo. Arch. = Photographisches Archiv. Düsseldorf. Monthly.

* *Proc. Chem. Soc.* = Proceedings of the Chemical Society. London. About twice a month.

Répertoire = Répertoire de Pharmacie, Archives de Pharmacie, et Journal de Chimie Médicale Réunis. Paris. Monthly.

Scient Amer. = Scientific American. New York. Weekly.

Schweiz Woch. = Schweizerische Wochenschrift für Chemie und Pharmacie. Zurich. Weekly.

Therap. Monats. = Therapeutische Monatshefte. Berlin.

Union Pharm. = L'union Pharmaceutique. Paris: Pharmacie centrale de France. Monthly.

Wiend Klin Rund. = Wiener Klinische Rundschau. Vienna: A Hölder.

Zahn. Rund. = Zahnaertliche Rundschau. Berlin.

Zahntech. Reform. = Die Zahntechnische Reform. Berlin: R. F Funcke.

LONDON: SATURDAY, JULY 1, 1899.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

A Sugar Bacterium.

H. Marshall Ward and J. Reynolds Green have followed up the observation of the former, which was recorded in the 'Annals of Botany' for 1897, that a curious association of organisms had been obtained in Paris, from an excrescence on the sugar-cane, said to have come from Madagascar. It consists of a bacterium associated with at least one yeast, which is probably a variety of *Saccharomyces cerevisiæ*. The organisms grow together in saccharine solutions, producing clumps very like the ginger-beer plant. These clumps induce a powerful fermentation in 14 to 20 per cent. aqueous solutions of common brown sugar, resulting in the liberation of carbon dioxide and the production of some acid. The saccharine liquid is thus converted into a not unpleasant acid drink, with some resemblance to lemonade or ginger-beer. Experiments show that in the association of organisms there is an agent capable of setting up active fermentation in various saccharine liquids, such as sugar and water or soda-water, beer-wort, milk and sugar, or an infusion of vegetable substance, *e.g.*, lemon-pulp. The fermentation results in destruction of the sugar and production of carbon dioxido, and is anaërobic. Plate cultures of the bacterium were obtained as circular, raised, dome-shaped, watery-looking colonies, stiff, like a firm jelly. The behaviour of the organism was tried in all the various media known to bacteriologists. A striking fact comes out, on surveying these cultures, viz., that the schizomycete practically refuses to grow in or on any pabulum devoid of sugar. Further, only certain sugars are capable of supplying it with the necessary food. No growth at any temperature could be obtained in normal gelatin-peptone media, or in broth, milk or other animal extracts, *e.g*, serum-agar, such as is used by the animal pathologists.—*Proc. Roy. Soc.*, 65, 65.

Choline and Neurine.

F. W. Mott and W. D. Halliburton have studied the physiological action of choline and neurine. The cerebro-spinal fluid, removed from cases of general paralysis of the insane, produces, when injected into the circulation of anæsthetised animals (dogs, cats, rabbits), a fall of arterial blood-pressure, with little or no effect on respiration. This pathological fluid is richer than the normal fluid, and, among the proteids, nucleo-proteid is present. The fall of blood-pressure is not due to proteid, nor to inorganic constituents, but to an organic substance which has been identified by chemical means as choline. It is soluble in alcohol, and is precipitated by phospho-tungstic acid. The crystals of the platinum double salt obtained from 15 per cent. alcohol are characteristic octahedra; this is the most convenient test for the identification of the base. Choline, together with the nucleo-proteid, doubtless originates from the disintegration of the brain tissue. The presence of choline in the pathological fluids will not explain the symptoms of general paralysis; it is, however, an indication that an acute disintegration of the cerebral tissues has occurred. Physiological tests also prove that the toxic substance in the cerebro-spinal fluid is choline. Neurine, an alkaloid closely related to choline, is not present in the pathological cerebro-spinal fluid; its toxic action is much more powerful, and its effects differ from those of choline.—*Proc. Roy. Soc.*, 65, 91.

Protection of Plants against Fungi.

Dr. Th. Bokorny enumerates the various substances which serve to protect plants against the attacks of fungi and schizomycetes. The most widely distributed of these substances are tannins, but Dr. Bokorny states that more than 1 per cent. of tannin is necessary in order to give the parts of living plants immunity against the attacks of fungi or bacteria. Tea-leaves contain 12 to 15 per cent. of tannin, oak-bark in the spring from 4 to 20 per cent. Bacteria offer less resistance to tannin than mould-fungi. Salts of oxalic acid are not poisonous to the lower fungi, while any free acid is injurious to the growth of all fungi, but oxalic not more so than tartaric or malic acid. Essential oils afford an effective protection against the attacks of all parasitic organisms.—*Biol. Centralblatt*, 1899, 177

Production of Pure Chlorophyll.

In the *Botanisches Centralblatt*, 77, 81, Dr. G. Bode describes an elaborate process by which he obtains pure chlorophyll or its potassium salt from green leaves. He emphasises the fact that an acid reaction alcohol, even if only slight, decreases its power of dissolving chlorophyll as contrasted with the solvent power of benzin, while an alkaline reaction has the opposite effect. He points out also the mistakes that have resulted from confusing between benzin and benzol, two substances which have nothing to do with one another except the similarity of their names.

Oleo-resin of Dacryodes Hexandra.

According to A. More (*Proc. Chem. Soc.*, 15, 150) the oleo-resin of *Dacryodes hexandra* consists of essential oil, a resin, and a white crystalline substance, $C_{15}H_{44}O$, which melts at 166-167°. The essential oil contains lævorotatory pinene and lævorotatory sylvestrene, which is the optical isomer of the sylvestrene described by Atterberg. The crystalline substance is insoluble in water, and only sparingly soluble in strong alcohol. By the action of acetic anhydride, it yields a crystalline mono-acetate, m. p. 200°, and it therefore appears to be an alcohol. It is unaffected by potash and by all ordinary reagents. A tetranitro-derivative is produced by the action of fuming nitric acid. Chromic acid in acetic acid solution, while oxidising it, appears to cause two molecules to combine; the product is a feeble acid, the molecular weight of which was determined by the cryoscopic method. The substance is probably identical with Personne's ilicic alcohol (m. p. 175°), with which it agrees in composition.

BOTANIC GARDENS OF THE WORLD.

DUBLIN BOTANIC GARDENS.

Dublin has two Botanic Gardens—the Royal Botanic Gardens at Glasnevin and the Botanic Garden of Trinity College, Dublin. As far back as the year 1711, there was a botanical lectureship in connection with the Trinity College Medical School, and there seems to have been at that time a Physic Garden available for the purposes of the School. Dr. Nicholson, the first lecturer, published a little pamphlet of about forty pages in 1712, "Methodus Plantarum in Horto Medico Collegii Dublinensis jamjam disponendarum Dublini." During the lectureship of Edward Hill the garden was transferred to the neighbourhood of Harold's Cross, and was partly the private property of the Curator, though assisted by a grant from the College. The salary of the Curator, appointed first in 1801, was fixed at £130 yearly in 1805. Out of this sum he was to employ two labourers all the year round, and two additional labourers in March and December.

In July, 1806, the Board of Trinity College leased a small piece of ground near Ball's Bridge for the purpose of a Botanic Garden. Situated about a mile from the College, it comprised about three acres and was held for 175 years at a rent of 15 guineas an acre. The first Curator of this College Garden was James Townshend Mackay, an excellent botanist and the author of the 'Flora Hibernica,' published at Dublin in 1836. Harvey named a beautiful acanthaceous plant after him—*Mackaya bella*. In 1807 the Garden was walled round and its planting was begun. In 1832 two more acres were added along the Blackrock Road, and the present entrance gates and a strong iron railing were put up. In 1848 two more acres were added as a shelter belt along the Landsdowne Road, formerly Old Watery Lane, making the garden altogether about eight acres in extent. The College Gardens became well known under Mackay, and were visited by Sir William Hooker, Lindley, Paxton Veitch, the McNabs, Loudon, and other distinguished gardeners and botanists. Several of Mackay's pupils became famous, *e.g* , Dr. David Moore ; Fraser, the landscape gardener ; Balfe, for a long time the energetic Secretary of the Dublin Horticultural Society ; Charles Moore, Director of the Sydney Botanic Gardens ; and Mackay's successor in the Curatorship, Bain. The Gardens are now surrounded on all sides by trees and houses, and the electric tramway runs past the gates. The roads are very level and symmetrical, all the walks being straight and running at right angles to each other. The outer garden, which runs along two sides of the ground originally enclosed, has been very judiciously planted with trees and shrubs. The hollies are especially luxuriant. The wall which surrounds this garden is covered with many choice creepers, *e.g.*, fine plants of *Magnolia grandiflora*, which often flowers profusely, *Colletia ferox*, *C. crucialia*, large plants of *Pyrus japonica*, *Wistaria sinensis*, *Chiminanthus fragrans*, *Choisya ternata*, *Smilax latifolia*. In the inner garden is a well-arranged collection of the principal natural orders of plants, a large storehouse, greenhouses, an orchid and a fern house. The soil of the Garden is a light sandy loam, resting on old river beds, on creeks that at one time extended inland from the shore. It is thus deep and warm. Owing to this fact, its sheltered position, and its nearness to the sea, many plants which are usually only half hardy can be grown there for many years consecutively out of doors. The Gardens have some remarkable trees, including a dwarf Cedar of Lebanon, which was thirty years old when it was moved into the old garden in 1807. Many rare thorn trees fruit freely, *e.g.*, a fine specimen of *Crataegus tanacetifolia*. There are also very large specimens of *Garrya elliptica*, the Japan wax tree, *Ligustrum lucidum*, *Diospyros lotus*, and *Magnolia acuminata*. Another remarkable tree is the Himalayan paper birch, *Betula bhojpattra*, two specimens of which were grown from seeds presented to the Gardens by Sir John Hooker, shortly before he retired from Kew. The Gardens are well supplied with water. Opposite one of the greenhouses there is a small pond, the water in which comes from the river, and there is a supply under pressure from the City of Dublin Waterworks. The Gardens are open daily from sunrise to sunset, as far as the officers and students of the College are concerned. The general public are admitted by orders obtainable from any of the Fellows of the College, or from the Professor of Botany. Lectures are given in the Garden during Trinity term to the Medical School class and to students working for the Natural Science Medal. The Herbarium of Trinity College may be considered the foundation of Dr. Harvey. Between the years 1843 and 1844 there was only a small collection of plants kept in presses, which mainly consisted of specimens gathered by Dr. Coulter in Mexico and California. In 1844 the post of Curator of the Herbarium was specially endowed for Dr. Harvey, who had spent several years at the Cape of Good Hope and had made large collections of native plants there, supplying from time to time many descriptions of new and rare forms to Hooker's 'Journal of Botany.' He presented his large collections to the herbarium, and added largely to it from Sir William Hooker's duplicates, from Drummond's collections in the Swan River Colony, and by collections he purchased. In 1858 a herbarium was purchased for £237. A visit made by Dr. Harvey in 1849-50 to the United States enriched the College collections, and a longer tour made by him during 1853-55 in Australia and the South Sea Islands, chiefly undertaken for the purpose of collecting algæ, resulted in making the College herbarium so rich in these forms that it has become a necessary resort for all students of this group of plants, containing, as it does, the types, as well as the finest series of specimens collected by one who was during his lifetime the chief authority upon these plants." He died at Torquay, May 15, 1866.

The Royal Botanic Gardens, Glasnevin, originated in a resolution of the Dublin Society in 1790. In that year the Irish House of Commons voted a considerable sum towards the cost of providing a Botanical Garden, and subsequent grants were made for this purpose, amounting in 1794 to the sum of £1700. A chief part in founding the Garden was taken by Dr. Perceval Hill and Dr. Wade. The former was the Dublin University Professor of Botany, the latter the Lecturer on Botany to the Dublin Society and the author of the first published 'Catalogue of Dublin Plants' and of 'Plantæ Rarores in Hibernia Inventæ.' Various sites were examined for the projected gardens, but the Society's Garden Committee was unanimous in reporting the most suitable to be the ground held at Glasnevin by Major Tickell by a *toties quoties* lease from the Dean and Chapter of Christ's Church. "The demesne had been that of Tickell, the poet, who is known to have planted many of the trees. The house in the grounds" (which enlarged and improved became the residence of the professor of botany, and later of the Curator) "was that in which he had enjoyed the society of Addison during the time the latter acted as private secretary to the Marquis of Wharton, in 1714. Near at hand was Delville, the residence of Dr. Delany, the friend of Swift, where Stella resided for a short time. Steele and Parnell were also residents in the neighbourhood of Glasnevin."

The Society speedily acquired the ground, and the formation of the Garden was rapidly proceeded with, Parliament voting for the purpose a sum of £1300 both in 1798 and 1799. In 1800 £1500 was

assigned to the Committee of Agriculture of the Dublin Society for that purpose, and the payment of the salary of the Professor of Botany. With Dr. Wade as professor and Mr. John Underwood as head of the practical department, the Gardens soon became available for purposes of technical instruction. Among the different departments of the Garden that were instituted were "the Linnæan Garden for the scientific botanist, who studies the plants systematically; the Cattle Garden; the Hay Garden; the Esculent Garden; the Dyers' Garden; the Irish Garden, etc." Lectures on general botany were given by the professor, "and also separate lectures on the Cattle and Hay Gardens for the instruction of the common farmers, their servants and labouring men," all of whom were admitted to the lectures without payment. Similar lectures were given "for the dyers' use and for the purpose of extending practical knowledge, particularly in husbandry."

Underwood published in 1801 'A Systematic Catalogue of Greenhouse and Hothouse Plants in the Dublin Society's Botanical Garden at Glasnevin,' which contains a plan and elevation of the hothouses and greenhouses existing at the time. They comprised a large central conservatory, with two Greenhouses on the one side and a hothouse and stove on the other, and were situated with their ends facing the south, where the walk now leads from the entrance gate to the Octagon House. They were connected by a corridor with the house now occupied by the Curator and to the south-west end of which a Greenhouse was also attached. A systematic catalogue of the Arboretum, Fruticetum, and Herbarium was published by Mr. Underwood in 1802.

By the year 1813 the exotics cultivated at Glasnevin had increased so that a range of three additional small houses was erected near the entrance gate, and two years later two handsome entrance gates were presented to the Gardens by Mr. Pleasants, one of the members of the Dublin Society. The principal range of hothouses was found to be both unsuitably situated and badly constructed. It was therefore moved in 1817-1818 to the spot where the large palmhouse now stands, and in 1819 the Octagon House, forty feet high, was built. On the death of Dr. Wade, Dr. S. Litton was appointed Professor of Botany.

In 1830 the Botanical Committee instituted some very extensive alterations and improvements. The Cattle and Hay Gardens were abolished, thus leaving more ground directly available for scientific purposes, the Arboretum was enlarged, and more space was devoted to the arrangement of plants in their natural orders. It was decided to take down the worst houses and erect a range of cast-iron houses in their place. Mr. Ninian Niven became Superintendent of the Gardens in 1834, and during the four years he was at Glasnevin the plan of the Garden was entirely changed. The hothouses were repaired and stocked with new introductions, a different class of assistants was introduced, and a general system of professional instruction instituted.

When Mr. David Moore became Superintendent in 1838, very extensive alterations were carried out by him. All the old houses, except the Octagon, were removed, and a splendid range of curvilinear wrought-iron conservatories were built in 1843, partly at the cost of the Government, which voted four thousand pounds for the purpose, and partly by the Royal Dublin Society. Dr. Litton, the Professor of Botany, died in 1846, and was succeeded by Dr. Harvey, who gave two courses of lectures annually, one at the Royal Dublin Society's House, Kildare Street, the other at the Botanic Garden, till 1854. In this year the Botanic Garden was placed on a new footing, so far as the Government was concerned. Instead of the Gardens receiving aid from the sum annually voted for the Royal Dublin Society as heretofore, it was included in the vote taken for educational purposes in connection with the Science and Art Department of the Committee of Council on Education, the grant being administered, however, by the Dublin Society. The first Palm House was built in 1862.

The Orchid House was built in 1854, Parliament voting a special sum of £1000 for the purpose, and the Victoria Regia House was built by the Royal Dublin Society in 1854-5. The gardens at Glasnevin entered on the third period of their history in 1877, when by special Act of Parliament the Royal Dublin Society transferred the control of their Garden Museum and School of Art to the Science and Art Department. Two years later Dr. Moore died, and was succeeded by his son, Mr. Moore, the present Curator. In 1880 Dr. M'Nab, Professor of Botany at the Royal College of Science, was appointed Scientific Superintendent and Referee—an office abolished on his death in 1889. The severe gales of the autumn of 1883 having seriously injured the Palm House, it was removed, and a new one built during the next year at a cost of £5000. There were 330,203 visitors to the Gardens during the year 1885, and a large part of the Director's time and attention was occupied by the laying out of new beds and of walks through the pleasure ground. About 300 hardy plants were sent from Glasnevin to the Regent's Park Botanic Gardens. During the year 1886 the Gardens had greater demands made on them than hitherto for botanical teaching. Students from the Royal College of Science were allowed to work at the Gardens. Among the investigations carried on in the laboratory during the year were: (1) A comparative examination of sisal, manilla, and phormium fibre as met with in commerce; (2) the examination of ergotised grasses; (3) the examination of diseased potatoes and of potato tubers produced above ground; (4) a careful examination of many fungi and myxomycetes growing in the garden. Many specimens were prepared for lecture illustration and histological work at the Royal College of Science. It was decided that the Octagon House should be replaced by a new fern house. Many scarce and new plants were purchased for the Gardens. These included *Zamia calocoma*, *Brahea glauca*, *Alsophila crinita*, *Trichomanes attenuatum*, *T. luschnathianum pulchrum*, *Phalænopsis mariæ*. Musical promenades, at which military bands performed, were held in the Gardens.

The year 1887 was one of great drought. Newly moved plants and herbaceous plants generally suffered severely. On the shallow, gravelly soil of Glasnevin moisture quickly disappeared, and although several men were constantly employed in watering them, herbaceous plants only attained to about one-half their normal development, and many of them did not flower. Several large trees throughout the Gardens died, and it was only by constant watering that newly-planted trees were kept alive. Considerable changes were made in the walks and grounds adjacent to the new Fern House. The main walk leading from the entrance gate was altered, widened, and re-made. The herbaceous border in front of the new house was remade, all the plants in it being lifted, the ground well trenched and manured, the former occupants being replanted and many additions made to them. The Rose Garden, too, was remodelled. All the plants were regrouped and classified, the old plants replaced by a fresh stock, and the beds renewed. In the new Arboretum a piece of ground in a suitable position was levelled, cleared, and dressed, and the grass kept short through the summer for the musical promenades. Additions were made to the poplars, maples, walnuts, hollies, thorns, and hickories. A large collection of 192 species of hardy plants was sent to the Queen's College, Cork, and 110 species of hardy plants were supplied to the Royal University for the new plant ground. A collection of scarce Cape bulbs was forwarded to the Sydney Botanic Garden.

During the year 1888 many changes were carried out in the Glasnevin grounds. The central walk was entirely remade and widened as far as the new Palm House, and the walk from the rockwork to the centre of the new ground was also re-made and widened. In the Arboretum a large number of young trees were planted in almost all the classes. Among the interesting and valuable plants purchased for the Garden were *Angræcum chailluanum*, *A. sedeni*, *A. kotschyi*, *Cocos marie rose*, *Cypripedium sanderianum*, *C. elliottianum*, *Licuala veitchii*, *Masdevallia elephanticeps*, *M. spectrum*, *Sobralia elisabethæ*, and *Zamia obliqua*. During the months of June and July a class of women students met on Fridays in the Gardens for landscape study from nature.

During 1889 a great deal was done in the Gardens. Some of the old walks were remade, widened, and repaired, all the necessary material coming from the gravel pit in the Garden. All the plants in the left herbaceous border were lifted and sorted to the number of several thousand, the less interesting being replaced by others. The very complete collection of species of *Pæonia* in the Garden were all collected together and the nomenclature as far as possible corrected. A great deal of work was done in the Arboretum. Some of the shrubberies were remade, and collections of elm, birch, and lime planted. Among the most important purchases made during this year were (1) the succulent plants purchased at the sale of the "Peacock Collection," (2) the "Grant Collection," of kniphofias, (3) some fine specimens of rhododendrons from the "Crawford Collection" at Cork.

The right-hand herbaceous border was remade and stocked with good hardy plants in 1890, and the renamed collection of Glasnevin Pæonies was placed in a new border 250 feet long near the enclosed garden. The bed for bog plants and the island in the lower end of the pond had both got quite overgrown with coarse grasses and sedges, and had to be remade. A good collection of moisture-loving plants was placed in the peat bed made on the island. Since there was no good representative collection of wall plants at Glasnevin, the wall round the enclosed garden was raised and repaired, all unsuitable plants removed from it, and a good selection of useful plants and of plants requiring the protection of a wall were planted and trained in it. Two magnificent specimens of *Philesia buxifolia* from the Lakelands Collection, Co. Cork, were acquired for the Gardens. New offices were completed near the entrance gate, consisting of Curator's office, clerk's office, and library on the ground floor, laboratory, herbarium, and plant room, and a room for the Professor of Botany at the College of Science on the upper floor.

During the year 1891 several new works were carried out at Glasnevin. A path joining Addison's Walk with the boundary walk by the river, so forming a connection between most of the main walks of the Garden. Many rare species were added to the collection of roses. The "Grant Collection" of kniphofias was placed in a sheltered corner, and all the most distinct sorts were planted out in small beds in the grass. The bed for arborescent and shrubby plants belonging to the natural order Leguminosæ was remade, and replanted, and a new collection of plants begun, the unique collection of varieties of *Nelumbium speciosum* originally purchased in Japan for Sir George MacLeay. During the summer months Professor Johnson gave demonstrations in botany in the new laboratory.

The chief work carried on in the grounds during 1892 was the construction of a new rockwork for ferns made of stones from Finglas Quarry. The botanical arrangements in the Garden were carefully looked to and all the plants were seen to be clearly and accurately labelled.

The year 1893 was rather a busy one in the Gardens. Many of the old walks in the Garden had no foundations and consequently got very soft in wet weather. These were remade with stones and gravel from the sandpit in the Garden. For the new fernery E. J. Lowe, Esq., of Chepstow, presented eighty-six plants of rare and fine varieties of ferns, many of which existed only in his collection. A valuable contribution was received from Mr. P. Neill Fraser, of Edinburgh, and fifty-two varieties from the Bristol and Clifton Zoological Gardens. Some of the beds of rhododendrons and hardy azaleas near the pond were renewed with suitable compost. The new varieties of hardy water-lilies in the tanks outside the Aquatic House flowered freely. Some of them grew so much that they filled the tanks, and portions had to be taken off them and planted in the pond, where they continued to thrive and flower. Many additional specimens were added to the collection of Glasnevin. Large collections of plants were sent to the Botanic Gardens at Kew, Glasgow, and Cambridge. The musical promenades were discontinued during this year. At the laboratory Miss Hensman worked steadily at investigations in the Irish marine algæ, and two Belfast students obtained leave to work there during the summer months.

In 1894 the gardeners and labourers of the Botanic Gardens were placed by the Lords of the Committee of the Council on Education, with the sanction of the Treasury, on a considerably improved footing with regard to wages. The new rockwork for ferns was almost entirely planted. E. J. Lowe, Esq., of Chepstow, presented a large collection of over 100 varieties of his choicest ferns, and the beds containing agricultural grasses were entirely remade. The collection of species and varieties of *Iris* was also renewed, and over 100 young trees were removed from the nursery ground to the various classes. A collection of 100 hardy plants was sent to Queen's College, Galway, and 4193 packets of seeds were sent from Glasnevin. Several students from different parts of Ireland worked at the laboratory during the year.

During the year 1895 the whole collection of species and varieties of *Narcissus*, which occupied fifteen beds in the nursery grounds, was lifted, rearranged, added to, and replanted. Many additions were made to the species and varieties of *Rosa*, and extensive alterations were made to the collections of ferns. The formation of a wild garden was commenced. A small railing was erected round a portion of the sloping walk leading to the pond, and under the trees in this railed-in portion large numbers of bulbous and other plants were planted in the grass. A collection of 468 hardy plants was forwarded to Dr. J. McFarlane to assist in the formation of the new Botanic Gardens in Pennsylvania, also a collection of 387 packets of seeds of hardy plants.

During the year 1896 the very fine collection of succulent plants was overhauled, cleaned, and potted, the nomenclature revised, and the plants labelled. Valuable additions were also made to the Arboretum.

In 1897 the new house for succulents which had been desired for years became advisable. Out of doors the river bank was raised to prevent floods, and much was done to improve the wild garden, over 30,000 bulbs being planted there and through the grounds. An immense amount of work has been done in the Arboretum, unsound and duplicate trees have been removed, and fifty-nine young trees, carefully prepared, were planted out; where the soil was deficient deep trenches were dug round specimens in the Pinetum, and fresh clay filled in. Ninety-eight hardy ferns were presented by E. J. Lowe, Esq., of Chepstow, some novelties of his own raising, and the rest the choicest varieties in his collection. An interesting collection of New Zealand seeds and some rare species of *Rhododendron* from Cornwall were received.

LESSONS IN PHYSICO-CHEMISTRY.

Solutions and Their Properties.

In a previous article (see last volume, page 316) reference was made, in connection with heats of neutralisation, to the current theory of solutions; and it will be well here to say something further about their properties.

The dissolving of a solid substance in water or some other solvent is probably the commonest of all operations that the pharmacist is called upon to perform. Naturally, a knowledge of the extent to which different substances can be dissolved is of considerable importance to him, and in the new British Pharmacopœia more attention is given to the solubilities of chemical substances than in previous pharmacopœias. As the exact determination of solubilities requires attention to several points, a few remarks on the subject may not be out of place here. For a correct determination of solubility, it is important, in the first place, that the substance to be dissolved and the solvent should both be quite pure. The solubility of nearly, though not quite, all substances varies according to the temperature, and this must accordingly be maintained constant and be accurately noted. For this end, the vessel containing the substances under experiment is immersed in a bath of water or other liquid, which is kept at a steady temperature; if this temperature is above that of the surrounding air, an automatic regulation of the heat supply is best; such an arrangement is called a thermostat. Several kinds of thermostat are in use; they are obtainable from makers of scientific apparatus, and need not be described in detail here; the principle on which the heat is regulated is the same in all of them. The gas supplied to the burner by which heating is effected has to pass through a tube which is in connection with a reservoir containing some very expansible substance, immersed in the bath itself. The connections are so arranged that expansion of the substance in this reservoir partly closes the tube through which the gas is passing, and so diminishes the supply, while contraction again increases it.

The substance whose solubility is to be found is reduced to powder and added to the solvent until a good deal remains undissolved; the mixture is now put into the constant temperature bath and kept in a state of continuous or intermittent agitation for a long time. When no more appears to be dissolved, the excess of the solid is allowed to subside, or, if necessary, it is removed by filtration. A portion of the solution is then removed, weighed, and carefully evaporated to dryness, and the residue again weighed; in this way the exact strength of the solution is found. To check this result, the remainder of the solution and the excess of the solid are again agitated together for some time at the same temperature as before, and the strength of the solution again found, as before. Or the temperature may be raised and solution effected at the higher temperature, and then the whole allowed to gradually cool down to the required temperature and kept at this for some time, the strength being then found as previously. The results found in these ways ought to agree very closely.

When dealing with a substance of which a solution cannot be evaporated down without loss or decomposition, the strength must of course be found otherwise; the particular method to be followed then will depend on the particular case. Ordinary volumetric analysis, carefully performed, is often a useful method. Another way is to dilute a given quantity of the solution with a known quantity of the solvent, and find the specific gravity of the diluted solution. The specific gravities of a number of unsaturated solutions of known strengths are previously ascertained, and the solution in question is so diluted that its specific gravity in the diluted state shall fall among these; the strength of it is then found by interpolation. This method is especially useful when the solubility of a salt at a large number of different temperatures is to be ascertained.

In finding the solubility of gases in liquids, points to be specially attended to are that the liquid should be quite free from dissolved gas at the beginning of the experiment, which condition is obtained by long boiling; also that the gas is perfectly pure. The amount dissolved is generally found by bringing an excess of gas into contact with the liquid and measuring its volume before and after solution. In addition to keeping the temperature constant, it is also important that the pressure should be the same at the final reading as at the first; this is secured by adjustment of the height of a tube containing mercury and communicating with the vessel in which solution is effected. Determinations of this kind do not frequently have to be made, and accordingly further details will not be given here.

In proceeding to give a short account of some of the chief properties of solutions, it may be remarked that there exists at present considerable divergence of opinion among scientists as to the actual condition in which dissolved substances exist. The two opposing theories that are upheld are generally known respectively as the "dissociation theory" and the "hydrate theory." According to the former, reference to which has already been made (see last vol., 318), when a salt is dissolved in much water it undergoes separation into two parts, the ions, which exist in the free state in th liquid. On the other hand, supporters of the hydrate theory consider that, far from being itself broken up, each molecule of the salt enters into combination with a number of molecules of the solvent, forming compounds of greater or less stability. By far the greater number of observed facts find at least a very plausible explanation on either theory. A discussion of the merits of the two would be outside our present scope,* and we shall content ourselves with a brief account of the more important facts. Our remarks will mainly deal with solutions of solids in liquids, and although aqueous solutions will mainly be referred to, what is said of the latter holds in many cases also for solutions in other liquids.

Osmotic Pressure.

It can readily be seen that when a solid substance, such as sugar, for instance, is dissolved in a large quantity of water so that there exist in the solution, say, a hundred or more molecules of water to every one of the sugar, the molecules of the latter will be separated by comparatively large spaces; since also these molecules have free motion within the liquid the state of the sugar very closely resembles the gaseous state. In these conditions the behaviour of the dissolved substance is very similar to that of a gas.

First, corresponding to the pressure exercised by a gas, we have what is called the osmotic pressure of the dissolved substance. A gas expands and fills any space that is offered to it, distributing itself equally through it, and moving, if need be, against the force of gravity. In just the same way the dissolved substance spreads itself through the whole space occupied by the solvent; if a layer of pure water is carefully put on the top of the solution the molecules of the sugar or other substance will penetrate into this against the action of gravity till they are evenly distributed throughout the whole. If, however, they are prevented from doing so, by putting between the water and the solution a partition through which the sugar-molecules cannot pass, while water-molecules can, there will be a passing of water-molecules through into the solution.

* Anyone who wishes for a summary of the arguments on the two sides cannot do better than read the two articles on solution in the latest edition of Watts' Dictionary, by Arrhenius and Pickering respectively, the leaders of the two schools.

If the vessel is arranged as in Fig. 1 the increased pressure which is thus produced causes the liquid to rise in the side tube; this goes on up to a certain definite point, when equilibrium is reached. At this point, the pressure of the column of liquid in the side tube above the level in the main vessel is equal (and opposite) to the "osmotic pressure" of the dissolved substance, that is, to the force with which water tends to pass through the partition into the solution. The osmotic pressure of a solution of a substance may therefore be ascertained by putting it into such an apparatus. The height of the liquid in the side tube above the liquid in the main vessel, after equilibrium has been reached, combined with the specific gravity of the liquid, is a measure of the osmotic pressure. The pressures obtained in this way are very considerable. Like ordinary gas pressures, they increase with rise of temperature. In fact, in this and other respects osmotic pressure is not only similar to gas pressure, but both obey the same laws. For instance, for every degree of rise in temperature osmotic pressure increases by 0 00367 times its value at 0°, which is exactly the proportion in which gas pressure increases. At common temperatures the osmotic pressure of sugar in 1 per cent. solution is equal to that of a column of mercury about 50 Cm. high, while that of potassium nitrate in 1 per cent. solution is equal to more than three atmospheres.

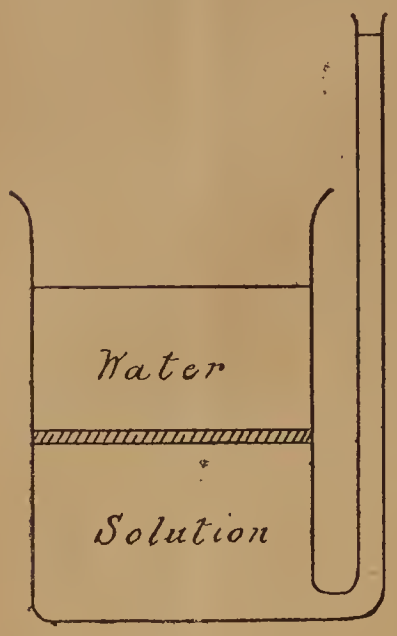

FIG. 1.

It has been found that the osmotic pressures of solutions of widely different substances are the same, when the quantity of each substance present in a given volume of the solution is proportional to its molecular weight; or, in other words, when equal numbers of molecules of the different substances are contained in equal volumes of the solutions. In this respect also the analogy to gas pressures is maintained, since the latter depend only on the relative number of molecules in a given volume, and not on the nature of the gas.

Boiling Points of Solutions.

Very important relations have been found to hold with regard to the boiling and freezing points of solutions. When a pure liquid is compared with the same liquid in which another substance has been dissolved, it is always found that the effect of the dissolved substance is to reduce the vapour pressure of the solvent liquid. If the dissolved substance forms vapour, the total vapour pressure of the solution may or may not be higher than that of the solvent alone; but in all cases where the dissolved substance is one that cannot be vaporised, such as sugar, the vapour-pressure of the solution is less than that of the solvent alone. It therefore requires a higher temperature in order that the vapour pressure may be equal to the atmospheric pressure—in other words, the boiling point is raised. The extent to which the boiling point is raised depends on the relative amount of the dissolved substance present. By comparing the effect of different substances, it has been found that in two or more solutions containing different dissolved substances (the solvent being the same in all), if to any constant amount of the solvent there are present amounts of the dissolved substances respectively proportional to their molecular weights,* the boiling points will be identical. In other words, the extent of the alteration of the boiling point depends on the ratio between the numbers of molecules of the solvent and the dissolved substance, and is independent of the nature of the latter. This conclusion has been arrived at both from theoretical considerations and from actual experiments. It is clear that by observing the alteration of the boiling point caused by dissolving any substance in a given proportion in a pure liquid, the ratio between the numbers of molecules of the two can be found by comparison with solutions of substances of known molecular weight, and from this the molecular weight of the substance in question is ascertained. We shall refer to this point again.

Freezing Points of Solutions.

The temperature of solidifying of a liquid, or, what is the same thing, the melting point of a solid, is, as we have seen, a perfectly definite and constant characteristic of a pure substance; when, however, a second substance is present in solution in the first, it exercises a lowering effect on the freezing point. The extent to which this lowering occurs is proportional to the amount of the substance present; and, as with the osmotic pressure and alteration of boiling point, an equal effect is produced by different substances, when they are present in amounts proportional to their molecular weights. If we find by experiment the extent to which the freezing point of a liquid is lowered by different proportions of a substance whose molecular weight is known, as well as that of the solvent, we can calculate the ratio existing between the numbers of molecules of the substance and the solvent, corresponding to any observed depression of the freezing point; or, since the relative number of molecules of the dissolved substance and the depression are proportional, we can make the calculation for any depression. If now we take another substance, whose molecular weight we are ignorant of, dissolve a known weight of it in a known weight of the solvent, and observe the resulting depression of freezing point, by comparison with the previous result we know the ratio of the number of molecules of the new substance to the number of molecules of the solvent. Knowing also the ratio of the actual weights of the two, and the molecular weight of the solvent, the molecular weight of the new substance is at once found. Thus, calling this substance A and the solvent B, and denoting by r the ratio of the number of molecules of A to those of B, we have

$$\frac{\text{mol. wt. of A} \times r}{\text{mol. wt. of B}} = \frac{\text{weight of A}}{\text{weight of B}}, \text{ from which}$$

$$\text{mol. wt. of A} = \frac{\text{wt. of A} \times \text{mol. wt. of B}}{\text{wt. of B} \times r}$$

This is exactly analogous to finding the molecular weight of a substance by observing the elevation of the boiling point of a liquid in which it is dissolved. Both methods are actually used for substances that cannot be obtained in the gaseous state, but in many ways the freezing point determination is more convenient; in practice a formula is employed by which the calculation can be made directly from the observed depression. The apparatus devised by Beckmann is used for this determination; it is represented in Fig. 2. The outer vessel c contains the freezing mixture to reduce the temperature below the freezing point; b is an air-jacket to prevent too rapid or irregular cooling; a is the tube into which the solvent is put, the exact amount being found by weighing in the tube; through the cork passes a thermometer, graduated in hundredths of a degree, and a wire

* Such solutions are commonly called equi-molecular.

bent at the lower end into a circle, for stirring the liquid. In carrying out a determination, the freezing point of the solvent is first ascertained; to do this, the freezing mixture is put into *c*, and occasionally stirred, the tubes *a* and *b* are put in place, and the liquid in *a* kept constantly stirred and carefully watched. Solidification does not usually commence until the temperature has fallen slightly below the actual freezing point, and at the moment when crystals begin to form the temperature rises slightly, and then remains stationary while freezing continues; this point at which it stands steady is the required one. On lifting the apparatus out of *c*, melting soon occurs; the observation is repeated several times, and the readings obtained should be the same. The cork in the side tube of *a* is now momentarily removed and a small amount of the substance under experiment is introduced from a weighing tube, which is so narrow that it can pass through the side arm, allowing the substance to fall straight into the liquid; by weighing the tube before and after the weight of substance taken is found. The substance that has been added is stirred about with the wire until it dissolves, and the freezing point of the solution is then found in exactly the same way as before. The molecular weight required is equal to

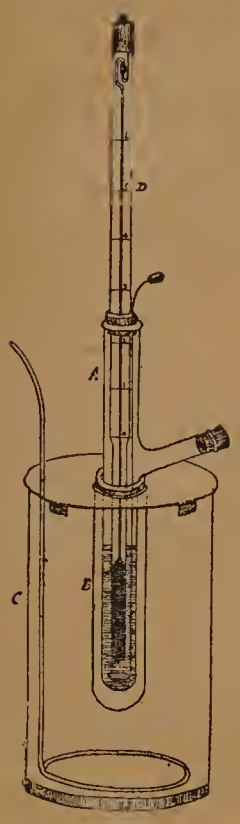

Fig. 2.

$$\frac{\text{weight of substance taken} \times \text{a constant number}}{\text{weight of solvent} \times \text{observed depression}}$$

The constant of course depends on the nature of the solvent, being always the same for the same solvent; it is found by experimenting with substances whose molecular weight is already known. If the weights are in grammes and the depression in degrees the values of the constant are :—

For water	1890.
For acetic acid	3880.
For benzene	4900.
For phenol	7500.

These are the solvents most generally used. The method is commonly called the kryoscopic method of determining molecular weights.

What has been said above about osmotic pressures, elevation of boiling points, and depression of freezing points, only applies completely to solutions of substances, such as sugar, which are not of the nature of a salt. In the case of aqueous solutions of salts, that is, substances consisting of a basylous and an acidulous portion, and including acids, in which hydrogen takes the part of the basylous radical, and bases, in which hydroxyl plays the part of an acidulous radical, the values found for these three quantities (osmotic pressure, etc.) are in all cases greater than would correspond to the relative number of molecules of the salt present. This is explained by supposing that in such solutions of salts the two parts of the molecule, termed ions, exist to a greater or less extent independently of each other, thus increasing the number of particles of the substance present with the solvent, and so causing the observed higher values. It is further supposed that when a solution of a salt is electrolysed the passage of the electric current simply directs the movements of the two ions to the two electrodes. The power a solution possesses of conducting electricity should therefore depend on the number of free ions present, and the conductivity of a solution furnishes a measure of the degree of "dissociation," or separation of the ions existing in it. The results obtained from determinations of conductivity agree perfectly with the conclusions as to degree of dissociation in a solution, drawn from its osmotic pressure, boiling point, etc.

It is only in the case of definite bodies having a limited solubility that these various relations hold. There are certain substances that are able to mix with water in all proportions, forming more or less thick liquids, or even solids; such are gelatin, gum, etc. These mixtures with water must be regarded as a kind of solution; they are spoken of as colloidal solutions, and the above statements about solutions do not apply to them.

BOTANICAL NOMENCLATURE.

BY E. M. HOLMES, F.L.S.

(*Concluded from last volume, page 568.*)

Specific Names of Plant.

4. Specific names should be adjectival, and agree in gender with the generic name, and should, if possible, be derived from Greek or Latin, but hybrid names formed from both languages are not admissible.

5. If possible, specific names should express some specific character as in *Conium maculatum*; striking property—*Physostigma venenosum*; general aspect—*Chondrodendron tomentosum*; resemblance to other plants—*Clechoma hederacea*; native country—*Hamamelis virginica*; situation—*Arnica montana*; time of flowering—*Colchicum autumnale*; the duration of life—*Mercurialis annua*; smell—*Ruta graveolens*; taste—*Fœniculum dulce*; or uses—*Indigofera tinctoria*. Resemblance to other plants is indicated in specific names derived from Latin by *pseudo* placed before the word, as *Narcissus pseudo-narcissus*, *Smilax pseudo-china*; or by *formis* placed after it, thus, *Carya olivæformis*. In words of Greek derivation *oides* is placed at the end of the specific name, as *Helminthia echioides*.

6. When a specific name is intended to commemorate the name of the discoverer or describer of a plant, it is made to end in *i* or *ii* as *Drimys Winteri*, *Aconitum Fischeri*, *Garcinia Hanburii*, but if it is only named in honour of someone, it ends in *ana* thus, *Aloe Hanburiana*, *Remijia Purdieana*. If the name is derived from a country or district it may end in *ensis*, as *Hydrastis Canadensis*, or in *ica* as *Hamamelis Virginica*, *Citrus Medica*, *Cetraria Islandica*, or in *us* as *Euonymus Europæus*, or in *a* as *Cuscuta Europæa*, according to the gender of the generic name. Sometimes the specific name consists of a noun in the nominative or genitive case, as *Pterocarpus marsupium*, *Pinus pumilio*, *Eucalyptus globulus* or *Vicia sepium*; but such names are exceptions to the Linnæan rule that the specific name should be an adjective, and are only retained on the ground of long usage or priority. Nouns employed as specific names are often printed with an initial capital letter, but this practice tends to confusion, since there is often nothing to indicate that they are not old generic names.

7. Specific names are sometimes formed of old generic names. When this is the case they are always printed with an initial capital letter, and usually differ in termination or gender from the generic name, thus *Delphinium Staphisagria*, *Pistacia Lentiscus* and *Daphne Laureola*; but sometimes, as in *Rhamnus Frangula*, this difference is not so evident, since trees are usually feminine in Latin.* When a vernacular name is used as a specific name, as *Strophanthus kombe*, *Pilocarpus jaborandi*, *Ægle marmelos*, etc., it is treated as indeclinable, unless the termination is conformable to Latin, or is

* Herbs and shrubs ending in *us* in Latin are masculine, *e.g.*, *Hyoscyamus niger*.

made so, as *Erythroxylon Coca*, *Jateorhiza Calumba*, *Quillaia Saponaria*, or *Citrus Bigaradia*.

8. A few specific names are composed of two words, thus, *Adiantum Capillus-veneris*, *Asplenium Ruta-muraria*, *Prunus Laurocerasus*, *Capsella Bursa-pastoris*. These are exceptions to the rules of Linnæus, which he himself allowed on account of long usage, and of the importance, whenever possible, of preserving the common and widely known name of a plant in its specific name.

9. Specific names formed of old generic names, nouns, vernacular words or names, as well as proper names of persons used as nouns or adjectives, are usually written with an initial capital letter, but by some authors, including Linnæus, adjectival proper names were written with a small initial letter, thus *Hookeri* would be written with an initial capital and *hookeriana* with a small letter. In some cases the correct orthography would be clear enough, but if the adjectival name happened to have two meanings as in *medica*, it is absolutely necessary to write it with an initial capital, *e.g.*, *Citrus Medica* (*i.e.*, the citron of the Medes), if written with a small initial it would mean the medicinal citron.

For this reason all adjectival names, used as specific names, should be spelt with an initial capital, as *Citrus Medica*, *Aloe Hanburiana*. This practice was followed by A. P. de Candolle in the *Prodromus*, and by other botanists, and conduces much to clearness. It would also prevent mistakes if nouns which are not proper nouns were spelt with a small initial letter, thus: *Pinus pumilio*, *Eucalyptus globulus*, *Vicia sepium*, since a reference to the Latin dictionary would show the real character of the words, which could not possibly be the case with all proper adjectives.

To avoid the difficulty of ascertaining whether a specific name is a Latin-like or Latinised vernacular name, or an old generic name, it has been suggested (*Atti de Congresso Botanico Internazionale de Genoa*, 1892, p. 123) that the usual methods followed in printing should be applied, viz., that old generic names used as specific names should be written in italics, with an initial capital letter, thus, Rhamnus *Frangula*; that vernacular names similarly used should be written in ordinary type, with quotation marks, and with an initial capital, thus: Erythroxylon "coca," Pilocarpus "jaborandi," and that all adjectival proper names should be written in ordinary type, with an initial capital, as Clematis Caripensis, Thea Chinensis, but as yet the suggestion has not been well received.

In the 'Kew Index' a rule has been followed of spelling every name exactly as it was spelt by the first person who published it, thus throwing the responsibility on the author, or the printer, as the case may be. Thus the question whether Zanthoxylum should be spelt Zanthoxylon, Xanthoxylon, or Xanthoxylum, would be decided by the first mode of spelling it; and Chondrodendron would be spelt Chondodendron, although the first syllable would lose its signification thereby; and *Jateorhiza Calumba* would be spelt Columba, although the native name is Calumb.

To make a *reductio ad absurdum* of this rule, it may be mentioned that a year or two ago a species of seaweed was named after a Dr. Becker, but was printed *Tyleiophora Becheri*; accordingly the incorrectly spelt name (either through a misunderstanding of the proper spelling, or by a printer's error remaining unnoticed) would have to be retained. The better plan in such cases perhaps would be to follow the rule of Linnæus and De Candolle, that names should be in accordance with the rules of the Greek and Latin languages, and where there is more than one form of spelling extant to chose the correct form, as *Xanthoxylum*, and in the second case to allow no incorrect spelling, like *Chondodendron*, that can lead to confusion or error. In the case of Calumba it is evident that confusion might arise, as there is a Colombo in Ceylon, whence a root called Colombo wood has come into commerce. In a few cases, as in *Rhododendron* and *Cinchona* (properly *Rhododendrum* and *Chinchona*), exception would have to be made on account of long and widespread usage, and the fact that no difficulty as to the meaning or origin is possible.

10. With respect to botanical names derived from the names of French botanists, whose names the words De, De la, Des, etc., enter, the rule is that they are only used when they form a part of the name, as in *Duhamelia*, *Lapeyrousia*, *Desvauxia*. But where it is not so, as in the case of A. de Candolle, it should be omitted, as in *Candollea*. De la Fontaine makes *Fontainesia* and L'Héritier, *Heritieria*. When a name already ends in *a*, as Colla, the *a* is changed into *ae* thus, *Collaea*.

Synonymy.

With respect to synonymy, the following rules are generally followed:—

11. The generic name to be upheld is, as a rule, the one given by Linnæus in his 'Species Plantarum,' A.D. 1753, if there is no valid reason against using it, such as the genus having subsequently been divided into two genera (in which case the old generic name is, if possible, retained for the oldest known plant in it), or imperfectly described.

12. If the genus has been published since the date given above (1753), priority belongs to the first subsequent genus in which the description of characters is complete, *i.e.*, if the generic description omits flowers and fruit it should not be upheld. The specific name to be upheld is, according to the majority of botanists, the first name that has been published in connection with the correct generic name, provided, of course, that the description of the plant is complete as regards all its organs.

But some German and American botanists, actuated by a desire not to do injustice to the first person who described the plant, maintain that the first specific name should be retained no matter what genus the species may be transferred to. This is impracticable for two reasons. First, because a large number of the Linnean binomial names were simply adopted from previous writers, such as Brunfels and others, who wrote 200 years before the time of Linnæus, and as all Linnean names published in 1753, in the 'Species Plantarum' of Linnæus, are always written with Linn. after them, as if he was the author, it would involve endless confusion to go back to the original description. In the second place, because in some cases the same specific name has existed earlier in the genus to which a species is transferred, and it would be utterly impracticable to have two different species under the same name in the same genus.

13. Nevertheless, it is generally accepted by all botanists that the specific name should always be retained wherever it is possible. This cannot, however, be an absolute rule, nor can a name that has been in extensive use for a long period of years be changed without the greatest inconvenience. It would also happen in some cases that the oldest specific name would be identical with the oldest generic name, and such absurd names as Benzoin Benzoin, Sassafras Sassafras, etc., would be the result of rigidly following the rule of retaining the oldest specific name.

14. In order to prevent confusion, it is usual to give, after the name of a plant, the abbreviated name of the botanist who first described it. The abbreviation is sometimes limited in the case of authors of classical works to the initial letters of the name only, as L. for Linnæus, DC. for De Candolle, and H. B. K. for Humboldt, Bonpland, and Kunth. A better plan, and one followed by many botanists, is to give the first syllable of the name, and where such would be of doubtful meaning, *e.g.*, Dec. for de Candolle, and Dec. for Decaisne, etc., it is usual to give either the first letter of the second syllable, or as much of the word or of the principal con-

sonants of the word as will serve to indicate without doubt who is meant. Thus Decne. or Decsne. would stand for Decaisne, Linn. for Linnæus, and Reichb. for Reichenbach. In some cases where there are two botanists of the same name—as Sir W. J. Hooker and Sir J. D. Hooker (father and son)—they are usually distinguished as Hook. and Hook. f. (filius); or when there are three, as in the case of the de Candolles, they are written DC. or De.C., A. DC. Alph. DC , and C. DC. (In this case the particle is written with an initial capital by general custom.)

The most satisfactory plan to prevent any possible error is to write the initials of the Christian as well as the surname, *e.g.*, D. Don, G. Don; C. Agardh, J. G. Agardh; Aug. de Cand., Alph. de Cand., Cas. de Cand. These abbreviations may be employed in works used by botanists, but in such works as the Pharmacopœia, or others in which a knowledge of botany is not necessarily implied on the part of the readers, the name of the authority should be given in full.

The object in giving the name of the authority is to indicate the particular plant intended by the writer. Thus there are seven plants that have been named *Solanum scabrum* by different authors, viz., Jacquin, Miller, Ruiz and Pavon, Zuccagni, Vahl, Lamarch, and Humboldt, Bonpland and Kunth, and the only way to indicate which of the seven species is intended is to place the name of the author after the plant name.

A custom exists amongst some botanists of giving two names of authorities when the genus of the plant has been changed, the first being enclosed in parentheses after the name of the plant. Thus a plant was described and named *Andira Araroba* by Dr. Aguiar, and as it was the first name published for the plant in the correct genus, it should be written *Andira Araroba*, Aguiar, which serves to indicate that the description of the plant will be found in the writings of that author. (In any flora in which that name is used, a reference to the books and the page in which it occurs should be given.) But an older name, *Vouacoupoua* (1775)* was given by a previous writer (Aublet) to the genus now called *Andira*, and a third botanist, Mr. G. C. Druce, suggests that the *Andira* should therefore be called *Vouacoupoua Araroba* (Aguiar), Aublet, to indicate that Aguiar's plant was placed in Aublet's genus. Those who use parentheses would write it *Vouacoupoua Ararobe* (Aguiar) Aublet.

But such a representation of the facts is utterly misleading, for anyone who searches the index of either Aublet's or Aguiar's works will not find that name. The proper way to write this name would be *Vouacoupoua Araroba*, G. C. Druce. Anyone looking through the writings of Druce would find the name and the reasons given for so combining the two words. The practice of giving a name in parentheses is a bad one (1) because it is misleading; (2) because it adds unnecessarily to the length of the name; (3) it is quite easy to find the history of the name in the synonymy of plants which is given in all good floras.

A list of the abbreviations of the authors' names may be found at the end of the second volume of Steudel's 'Nomenclator Botanicus' and in Asa Gray's 'Structural Botany,' pp. 385-390, and the lists of the works of botanical authors alphabetically arranged in Pritzel's 'Thesaurus Literaturæ Botanicæ,' or of later works since in the Royal Society's Catalogue of scientific papers.

The signs used to indicate whether a plant is annual, biennial, or perennial, or the flowers male or female, etc., are given in Gray's 'Structural Botany,' pp. 390–392, except the modern sign for a micromillimetre, viz, the Greek letter μ.

In conclusion, I may direct attention to the very weighty declaration made by some of the leading American botanists on the subject of botanical nomenclature as follows (*Journ. Bot.*, 1895, p. 212):—

"The nomenclature of systematic botany must be subject to constant modification with varying ideas of plant affinities. Its real developments, especially with regard to generic names, is largely determined by usage. By judicious recommendations greater and greater uniformity in the application of botanical names may doubtless be obtained, but to make rules at serious variance with the customs of the past and to give them retro-active effect can only tend to complicate botanical language. For if we depart from the nomenclature of former writers, we can by no means avoid the constant necessity of using their works.

"The result of any serious change would be the necessity of acquiring two sets of names instead of one. One of the most essential features of an efficient botanical nomenclature is its cosmopolitan character. It is very unlikely, therefore, that any lasting or satisfactory modifications of the present system can be effected without international agreement." Some excellent remarks on the same subject by the past and present Directors of Kew Gardens are quoted in the *Journal of Botany*, 1896, pp. 114–116.

* This genus being imperfectly characterised could not be maintained.

EXTRACTS FROM CONSULAR REPORTS.

The Cultivation of Colocynth (*Citrullus colocynthis*) is likely to become an important industry in several of the villages of Cyprus. The fruit is collected from June to August, and is spread in the sun, being stirred two or three times a day that it may dry uniformly and quickly, after which it is peeled by the women of the villages, who are trained to the work. For this purpose the dried fruit is sprayed the previous day with a little water. A woman can peel about 500 fruits within a day, and is paid 3½ to 4½ c.p. a day and her food. Peeling is a delicate work and requires great care in order that the naturally friable fruit may not be broken and rubbed, otherwise its value is lowered. The colocynth of Morphon and Papho is considered to be of a higher quality than from some other parts of the island. The dried, peeled, and sound fruits form the first quality, and are called "apples." They are sold to the merchants, who export this product, at 12 to 20 c.p. per oke, whilst the broken and somewhat badly peeled pieces of fruit, which are called "psicha," represent the inferior quality, and are purchased by the merchants at 6 to 10 c.p. per oke.

The Production of Essential Oils in Cyprus is receiving attention at the hands of the Director of Agriculture, Mr. P. Gennadius. Cyprus formerly was famous for its perfumes, the preparation of which, according to tradition, was introduced in the island by Venus, the goddess of beauty, and Mr. Gennadius is hopeful that its fame for perfumes may be restored. That the ancient fame of perfume-making in Cyprus is justified, he thinks, is shown not only by the fact that the Cypriotes were very rich and much advanced, but also by the fact that the flora of the country is rich in aromatic plants. In addition to the native aromatic plants which abound in Cyprus, the following are very common and grow almost without any special treatment:—Violet, jasmine, citrus trees, *Pelargonium odoratissimum*, Damascus rose, lavender and rosemary plants, the essential oils of which form in other places one of the principal reasons of their propagation and cultivation. Taking the foregoing facts into account, Mr. Gennadius hopes that the development, in certain villages at least, of the perfume industry will be of advantage. With this object in view, last year he prepared samples of essential oils which were sent to England and submitted to various wholesale houses for examination as to their quality and value, the reports on which are

published in a recent report on agriculture in Cyprus. Judging by the total results of his effort, Mr. Gennadius is of opinion that there are in the island all the elements to found an important and profitable industry.

As a Guarantee of His Good Faith in the project, it may be mentioned that Mr. Gennadius has agreed with the villagers of Kambos to prepare this year for his account as large a quantity as possible of oil of marjoram—one of the kinds most favourably reported on by the London dealers—for which he will pay them at the rate of 4*s.* 4½*d.* c.p per oke (about 3 lbs.). The oil will then be filtered and properly packed, and sent to London, where he hopes to get from 6*s.* to 9*s.* per oke. If there is any surplus from the sale, it will be distributed to the villagers proportionally to the quantity of oil which each has supplied.

ANALYTICAL NOTES.

Delicate Reaction for Tannin.—Gold salts are reduced by the barest trace of tannin, giving rise, in very dilute solutions, to a red colour. So delicate is the reaction that after standing for about thirty minutes it will indicate the presence of tannin in red wine when diluted so that its colour is not visible.—*Pharm. Central.*, 40, 75.

Adulterated Light Calcium Carbonate.—P. Hamburger has detected the presence of magnesium carbonate in commercial light calcium carbonate, certain samples containing as much as 15 per cent. This impurity may be detected as follows: 1 Gm. of the sample is shaken repeatedly for five minutes with ammonium chloride solution, 10 C.c., and solution of ammonia, 1 C.c. After standing, the mixture is filtered. The resulting filtrate should develop only a slight opalescence on the addition of 8 drops of sodium phosphate solution.—*Oest. Zeit. für. Pharm.*, £4, 36, after *Pharm. Centralh.*

Assay of Pomegranate Bark.—According to Ewers, the fresh bark of pomegranate contains from 0 5 to 0 7 per cent. of total alkaloids. When the bark is kept this percentage decreases to 0·33 or 0·4. The powdered bark deteriorates more rapidly. The root bark is slightly richer in alkaloids than that of the stem, but the difference is not very great. To determine the total alkaloids, Ewers employs the method of Keller for the determination of nicotine in tobacco. Six Gm. of the powdered bark are placed in a flask and treated with 120 Gm. of a mixture of equal parts by weight of ether and of petroleum ether, 10 C.c. of solution of soda or of potash are added, and the mixture is shaken thoroughly several times in half an hour. It is then set aside for four hours, when 100 Gm. of the solution is filtered off. A few drops of methyl-orange solution are added to this filtrate, a known excess of $\frac{1}{20}$ normal sulphuric acid is then run in, and the uncombined acid titrated back with $\frac{1}{50}$ normal soda solution, each addition of the latter being followed by vigorous shaking. The number of C c. of $\frac{1}{20}$ normal acid used up by the alkaloids × 0·007375 gives the quantity of total alkaloids contained in 5 Gms. of bark. To determine the amount of pelletierine and isopelletierine present in these alkaloids, the solution, after the titration of the total alkaloids, is treated with just sufficient $\frac{1}{20}$ normal H_2SO_4 solution to render it faintly acid, and then with 2 Gm. of $NaHCO_3$; the mixture is thoroughly agitated, set aside for thirty minutes, when 90 Gm. of the ethereal layer are removed and again titrated with $\frac{1}{20}$ normal acid. The number of C.c. required is divided, 0·9, and the quotient obtained deducted from the number of C.c.'s used for the titration of the total alkaloids, the difference multiplied by 0 00705 gives the quantity of pelletierine and isopelletierine in 5 Gm. of bark. In ordinary practice the determination of the total alkaloids is sufficient.—*Journ. de Pharm. d'Anvers*, 55, 154, after *Oest. Zeit. für Pharm.*

Modification of Liebig's Process for Determining Prussic Acid.—Lextriet recommends the use of C4B blue as an indicator of the alkalinity of the solution to be titrated with silver nitrate in Liebig's process for determining HCN. This colour is perfectly neutral to hydrocyanic acid and the alkaline cyanides, but gives a red tint in the resence of caustic alkalis.—*Journ. de Pharm.* [6], 9, 323.

SELECTED PRACTICAL FORMULÆ.

Ointment Gelatins.

M. Pelagatti recommends ointment gelatins for the treatment of skin diseases, prepared as follows:—White zinc gelatin, 30; glycerin, 20; water, 50; pure lanoline, 48; zinc oxide, 20. The lanoline is mixed warm with the gelatin dissolved in water, and poured into moulds. When cool, the ointment gelatin is easily taken out of the moulds and stored in boxes, or in paraffin paper; it does not become hard. If needful, as much as 40 per cent. of metallic mercury can be incorporated with the basis by first triturating 16 parts of mercury with 8 parts of lanoline; the same process is followed with resorcin, salicylic acid, and litharge. Before use, the preparation is dissolved on the water bath, painted thinly on the affected skin, and well dusted over with lycopodium; in five minutes the application will be quite dry.—*Pharm. Central.*, 40, 76, after *Monatsh. f. prakt. Dermat.*

Purified Coal Tar.

Coal tar is purified for pharmaceutical purposes by being dissolved in three parts of acetone or benzene, and filtered. The solvent is distilled off, leaving about 80 per cent. of purified tar. The purified preparation is a thick fluid in the cold, less dense when warm, having the peculiar tarry odour and is of a brownish black colour. It mixes readily with vaseline, lanoline, etc.—*Pharm. Centralh.*, 39, 933.

A Complex Laxative.

The following recipe is a fine example of the polypharmacy which still prevails to a considerable extent in French medicine. Its author, Bardet, states that it gives excellent results as a laxative in cases of chronic constipation. It is composed of:—Cassia pulp, 60; tamarind pulp, 60; mannite, 80; hydrated magnesia, 70; sodium phosphate, 60; powdered senna, 40; sulphur, 20; powdered jalap, 20; resin of scammony, 10; leptandrin, one-half part; baptisin, one-fifth part; euonymin, 2; podophyllin, 5; amorphous quassin, 2; extract of *Rhamnus catharticus*, 8; extract of *Rhamnus frangula*, 2; alcoholic extract of cascara, 20; extract of nux vomica, one-fifth part; aqueous extract of belladonna, one-fifth part. Mix and mass; divide into cachets or boluses of 1 Gm. each. The dose is 3 to 4 Gm.—*Bull. gen. de Therap.*, 68, 426.

Syrup. Calcii et Guaiacoli Chlorohypophosph.

(1) Calcium phosphate, 60; water, 120; hydrochloric acid, 70. (2) Balsam tolu, 15; alcohol, 75; water, 75. (3) Guaiacol, 10; glycerin, 150; simple syrup, 90; arrack, 30; Malaga wine, 60. The three solutions are mixed, the mixture set aside for five to six days and filtered.—*Oest. Zeit. für Pharm.* 53, 210.

To Whiten the Hands.

Lanoline, 30; glycerin, 20; borax, 10; eucalyptol, 2; essential oil of almonds, 1. *The Quart. Therap. Rev.* recommends a mixture of these ingredients to be rubbed on the hands, which are then covered with gloves during the night.—*Deutsch. Am. Apoth. Ztg.*, 19, 157.

Preparations for Chilblains.

(1) For broken chilblains: Zinc sozoiodolate, 1; vaseline, 10; m. f. ungt. (2) Resorcin, ichthyol, tannic acid, of each, 2; distilled water, 10. D.S.: To be shaken up before use and rubbed into the affected parts. For frost bites: Pine needles are boiled for two to three hours, the decoction strained, and the frozen limbs bathed in it three times per diem. The bath should be luke warm and last ten to fifteen minutes.—*Deutsch. Am. Apoth. Ztg.*, 19, 157.

A Pick-Me-Up.

Valerian, 6; cardamoms, 2; coriander, 20; cinnamon, 6; orris root, 1; are coarsely powdered and boiled with water, 300. The decoction is strained, and the residue digested for two days with alcohol, 300. The tincture is filtered, and mixed with the first decoction. Coca leaves, 30; green tea, 6, are infused for thirty minutes with hot water, 100, strained, and the residue digested for twenty-four hours with alcohol, 100. The infusion and tincture are mixed and finally both mixtures are united and filtered.—*Deutsch. Amer. Apoth. Zeit.* 19, 157, after *Nat. Drugg.*

NEW REMEDIES.

Calcium Santonate.—This preparation is a white tasteless powder, insoluble in water. It is obtained by saturating santonin with milk of lime and drying the product. In consequence of its insolubility and slow absorption, it is recommended by Bombelon as a substitute for santonin as an anthelmintic.—*Oest. Zeitschr. für Pharm.*, 53, 215, after *Apoth. Ztg.*

Ferrichthol.—Under this name an almost odourless and tasteless combination of iron with sulphichthiolic acid has been introduced as a remedy for anæmia and chlorosis. It is prescribed in tablets containing 10 Cgm. each.—*Journ. de Pharm. d'Anvers*, 55, 147, after *Oest. Zeitschr. für Pharm.*

Wintergreen Oil in Chorea.—By means of the local application of wintergreen oil, F. Luigi has cured several cases of chorea. The oil, mixed with an equal quantity of vaseline, was applied locally with gentle friction to the affected parts, which were afterwards enveloped with impermeable dressing. The application was repeated daily for fifteen days.—*Bull. Comm.*, 27, 132.

Chloroform Water to Obviate the Secondary Effects of Chloroform Narcosis.—Weber states that by treating the patient for as long as possible before operation with daily doses of chloroform water, a complete immunity may be obtained from the distressing and often dangerous secondary symptoms, such as nausea and excitement, which follow chloroform narcosis. So marked is the benefit derived, that he advocates the treatment in all cases when this anæsthetic is to be used in surgical operations. In order to mask the taste of the chloroform, to which some patients have a great repugnance, he advises the employment of the following mixture:—Chloroform water, 200 Gm.; oil of peppermint, oil of anise, of each 4 drops. Mix, set aside for twelve hours, and filter.—*Bull. de Therap.*, 137, 488.

Napelline as a Remedy in Morphinomania.—In a communication to the Société de Therapeutique de Paris, Rodet states that the "napelline" of H. Duquesnel is a most useful remedy in the treatment of morphinomania. A two per cent. solution in sterilised water is employed, in the form of a subcutaneous injection, the dose being 3 to 5 C.c., equivalent to from 6 to 10 Cgm. of the alkaloid. [It should be borne in mind that this so-called "napelline" has been shown by Dunstan and Harrison (*P.J.* [3], 23, 625) to be a mixture of amorphous aconite alkaloids, and is distinct from the base isoaconitine, $C_{33}H_{45}NO_{12}$, isolated by them and named napelline. The "napelline" of Duquesnel is a mixture of this base with aconine.]—*Bull. Gen. de Therap.*, 137, 451.

Phenosal and Pyrosal.—*Phenosal* or para-phenetidine aceto-salicylic acid is a white crystalline powder, sparingly soluble in water and in alcohol, melting at 182° C. *Pyrosal*—antipyrine aceto salicylate, $C_9H_8O_5{\cdot}C_{11}H_{12}N_2O$—is also a crystalline powder, and is sparingly soluble in water. It melts at 146-150° C. Both pyrosal and phenosal have antipyretic and antineuralgic action. They have given good results in articular rheumatism, cystitis, sciatica, and migraine. The dose is 50 Cgm. twice to six times per diem.—*Merck's Report*, 1898, 127.

Pyrantine.—Pyrantine or para-ethoxyphenyl-succinimide was obtained by Piutti in 1898 in the form of brilliant prisms, melting at 155° C., sparingly soluble in water, but soluble in alcohol and in acetic acid. Gioffredi finds that, in small doses, pyrantine is without effect upon the heart or respiration of the larger animals. Larger doses cause a slowing down of both, and materially lessen the blood pressure. Small non-toxic doses cause a lowering of the temperature. The therapeutic action of pyrantine has not yet been fully worked out.—*Nouv. Rem.*, 15, 153.

Uvæ Ursi Salol Pills.—Oscar Werler prescribes the following pills in diseases of the bladder and urinary organs. Extracti uvæ ursi sicci, saloli, āā 5.0 m. f pilulæ No. 30. Sprinkle with pulv. aromat.; 1 to 3 pills three times per diem, after meals. The dry extract of uva ursi is obtained by evaporating the fluid extract on the water-bath. 5 Gm. of dry extract are obtained from 15 Gm. of the fluid preparation. The action of these pills is disinfectant, astringent, and tonic.—*Pharm. Centralh.* 40, 164.

The Therapeutic Value of Iodvasogen.—T. Floras reports on 144 cases treated with iodvasogen in which favourable results were obtained with the remedy in stomatitis and gingivitis, the diseased parts being rapidly healed. The action of the remedy was equally favourable in various cases, both acute and chronic, of retro-nasal and pharyngeal catarrhs. In vomiting of pregnancy the author recommends doses of 5 to 7 drops of iodvasogen in milk three times per diem. The compound is without action in phthisis and whooping cough, but chronic bronchial catarrhs are favourably influenced, especially where there is increased secretion. The treatment is supplemented with external applications of the remedy on the chest and back. Rapid cure is effected on chronic pleuritis and in pleuritic pains generally. Favourable results followed the internal administration of the remedy in scrofulous affections of children and in chronic rheumatism and synovitis.—*Wien Klin. Rundschau*, 13, 178.

Fluorphenetol-Difluordiphenyl and Fluor-Rheumin.—Fluor-rheumin is a name given to an ointment containing the above in the proportion of 1:15. It is used for rheumatic affections, and is composed of fluorphenetol, 1 Gm.; difluordiphenyl, 1 Gm.; anhydrous wool fat, 85 Gm.; vaseline ointment, 10 Gm.—*Merck's Report*, 1898, 71.

Lactose.—In addition to its well known diuretic action, milk sugar is reported by G. Klein to possess the valuable property of accelerating parturition. Twenty to twenty-five Gm. of lactose are dissolved in half a pint of milk, and, if necessary, a similar dose is repeated after an interval of one or one and a half hours. As a diuretic in heart disease, G. See orders 100 Gm. dissolved in 2 litres of water, which must form the exclusive drink of the patient.—*Merck's Report*, 1898, 96.

Zinc Stearate in Burns.—In treating burns, B. Werner first bathes the wounds in 2 to 5 per cent. carbolic acid solution, which is then washed off with physiological salt solution, and the wound well dusted with a mixture of zinc stearate, 5, and acetanilide, 1. Lister's protective and wet sublimate gauze are used as bandages.—*Merck's Report*, 1898, 154.

Pure Theobromine.—Brissemoret recommends the use of trisodium phosphate for dissolving theobromine. By means of this salt 2 per cent. aqueous solutions may be obtained, which has the advantage over diuretine that it does not irritate the mucous membrane. For use the following formula is recommended:—Pure theobromine, 1 Gm.; trisodium phosphate, 4·5 Gm.; dried egg albumin, 0 5 Gm.; distilled water, *q.s.* to 80 Gm. To be taken three to four times per diem in warm milk.—*Merck's Report*, 1898, 146.

PROCEEDINGS UNDER THE PHARMACY ACT.

Pharmaceutical Society *v.* Boundary Chemical Co., Ltd.

At Liverpool Police Court, on Wednesday, before Mr. W. J. Stewart, stipendiary magistrate, the Boundary Chemical Company, Ltd., carrying on business at the Railway Arches, Luton Street, Liverpool, was charged, at the instance of the Pharmaceutical Society of Great Britain, with having, on May 29, "unlawfully sold a poison which is in the first part of Schedule A of the Pharmacy Act, 1868, to wit, arsenic, to one Harry Moon, he being a person unknown to the seller thereof, and not being introduced by some person known to the seller."

Mr. C. E. Nield conducted the prosecution, and Mr. J. H. Glover appeared for the defendants.

Mr. Glover said the defendants pleaded guilty. The thing was done in ignorance, but, of course, that was not a good defence. The defendants had never been summoned before, and they would take care the offence was not repeated.

Mr. Nield thought the Court should hear the analyst's report, as the offence was a very serious one. According to that report, the tin sold by the defendants on the occasion in question contained 1 lb. 14 ozs. of a powder consisting chiefly of arsenic and soda, the arsenic being present in the proportion of 61·5 per cent. The total amount of arsenic in the tin was, therefore, 1 lb. 2½ ozs., a quantity sufficient to kill over 4000 adult persons.

The Stipendary imposed a fine of £1, and also ordered the defendants to pay £4 4s. costs.

THE STUDENTS' COLUMNS.

ZOOLOGICAL NOTES FOR PHARMACISTS.—XVI.

Glands Forming Materia Medica (Continued).

Liver.—A two-lobed, highly vascular body, situated towards the right side, immediately below the diaphragm, consists of small masses of cells or "lobules," intersected by minute blood-vessels and bile passages. It secretes "bile," which is collected finally into special hepatic ducts and so poured into the intestine, where it assists the digestive and assimilative process, or stored up temporarily into a special receptacle—the gall bladder. The liver also secretes glycogen or animal starch, and is the seat of urea formation. Bile as found in the gall bladder is somewhat more concentrated than that flowing direct from the cells into the intestine.

Pancreas.—A branching mass of tubules whose main duct opens into the anterior portion of the intestine. Secretes a special fluid containing four ferments, which act on starch, proteids, fat, and milk respectively. In the lower forms the liver takes on the double duty of a liver and a pancreas.

Sebaceous Glands.—Small sacs lying beneath the epidermis having ducts which open close to the surface into the hair pits or follicles. Secrete a fatty substance which acts as a lubricating material for the hairs. In animals where the hairs are extremely numerous and close set, as the sheep, this secretion, "wool fat," is abundant.

Odour-secreting Glands.—Found in many animals, their secretion being in some cases a source of attraction, as in the musk-deer, and in others a source of repulsion, as in the skunk. In the musk-deer and beaver these glands occur on the inner surface of special sacs placed in the region of the preputial opening. Moschus possesses one sac, and in the male animal only; Castor, both male and female, carries two. In the latter case the whole sac is used, in the former the secretion only should be employed.

EXPLANATORY NOTES ON THE B.P., 1898.

Phosphorus.—For the detection of arsenic occurring as an impurity in phosphorus the Pharmacopœia directs the phosphorus to be boiled with nitric acid, and "the resulting solution should yield no characteristic reaction with the tests for arsenium." The phosphorus is thereby converted into phosphoric acid, and any arsenic present will also be oxidised to arsenic acid. In applying the official (see B.P. Appendix III., p. 418) or other tests for arsenic the student must carefully bear in mind the conditions under which he is working. For instance, the solution to be tested contains some undecomposed nitric acid, in addition to the phosphoric acid. If, now, sulphuretted hydrogen be passed through the solution the nitric acid present will react with the sulphuretted hydrogen and produce a yellowish precipitate of sulphur, which might be mistaken for arsenic sulphide. Before applying the stannous chloride test it would be advisable to evaporate the solution to a small bulk to remove the excess of nitric acid. This evaporated product, after redilution, should give no precipitate with sulphuretted hydrogen, but it should be remembered that arsenic in the condition of arsenic acid must be reduced to arsenious acid before a precipitate of arsenious sulphide is obtained. This reduction is accomplished by the sulphuretted hydrogen itself, but may be more quickly produced by the addition of sulphurous acid. Compare these notes with the information to be found in your text-book of analytical chemistry. In applying the special tests for arsenates the similarity of phosphates and arsenates must be remembered. With nitric acid and ammonium molybdate a yellow precipitate is produced by both. Ammonio-magnesium phosphate and the corresponding arsenate are also indistinguishable in appearance and are produced under similar conditions. The colour of the silver salts is, however, very different, but a trace of arsenate of silver would hardly be detected by this means in presence of a large excess of phosphate of silver, which would also be precipitated at the same time.

FLORAL CALENDAR FOR JULY.

Alismaceæ.—*Butomus umbellatus, Alisma plantago, Actinocarpus damasonium.*

Araceæ.—*Acorus calamus* (*P.J.* [3], **7**, 1060).

Aristolochiaceæ.—*Aristolochia clematitis* (*P.J.* [3], **7**, 1060).

Asclepiadaceæ.—*Asclepias syriaca.* B.G. *A. vincetoxicum.* B.G.

Boraginaceæ.—*Borago officinalis* (*P.J.* [3], **8**, 63). *Echium vulgare, E. violaceum, Lithospermum purpuro-cæruleum, Mertensia maritima, Symphytum officinale.*

Cactaceæ.—*Anhalonium Williamsi.* B.G.

Chenopodiaceæ.—*Chenopodium olidum.*

Valerianaceæ.—*Valeriana officinalis.*

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences

LONDON: SATURDAY, JULY 1, 1899.

A DEGREE FOR PHARMACISTS.

THE question of granting a university degree to pharmacists has once more been raised, this time in connection with the establishment of the proposed university for Birmingham. The text of a circular which has been sent to all registered chemists in the Midlands—with the object of interesting them in the subject—was published in the *Pharmaceutical Journal* a fortnight ago. In that document is briefly outlined a scheme of pharmaceutical education for which, we understand, Mr. JOHN BARCLAY is more or less responsible, and in which Professor HILLHOUSE, of Mason College, is greatly interested. The scheme involves a voluntary curriculum extending over six to nine months, the classes to be attended during the day, and the aim is to provide for Birmingham an institution similar to the School of Pharmacy at Bloomsbury Square. If such a scheme could be carried into effect, it is believed that the Senate of the University of Birmingham which it is proposed to call into existence would not be disinclined to entertain a suggestion for granting a degree to pharmacists, after examination in chemistry, botany, and materia medica, the title of the proposed degree being that of Bachelor of Science. So far as the general outline of the scheme is concerned, it accords closely with one which has been under consideration by the authorities of the Victoria University for some time past, and to which allusion was made in this Journal more than twelve months ago. But, in that case, we believe it has been stipulated that an additional subject should be taken by candidates for the degree, the scientific subjects included in the pharmaceutical syllabus—chemistry, botany, and materia medica—counting as two only in the degree examination. In connection with the reconstituted University of London, something may also be done in the matter of granting a degree to pharmacists, but the first step in that direction would probably be the affiliation of the School of Pharmacy with the University, and recognition of the courses of instruction at that institution as qualifying *pro tanto* for admission to the degree examination.

But in the case of each of the three universities referred to, it is probable that the utmost concession obtainable at the outset will be the acceptance of evidence of certain courses of instruction having been taken at recognised institutions, as entitling candidates for the degree of Bachelor of Science to submit themselves for examination in those subjects at the degree examination. There will be no question, at first, of granting a degree in pharmacy, and if ever there should be, it is exceedingly doubtful if the passing of the Pharmaceutical Society's examinations will be taken into consideration, by being allowed to reckon *pro tanto*, unless and until the passing of those examinations is preceded by a definite curriculum similar to that which is now compulsory in the case of candidates for medical registration. If candidates for the Pharmaceutical Society's qualifying examination were compelled to produce evidence of having been registered as students for three or more years, and of having, in addition, attended courses of day lectures and laboratory instruction in all the subjects of the examination, during nine months or more, there might be something to be said in favour of asking universities to grant degrees in pharmacy and to accept the subjects of the qualifying examination *pro tanto*. As things are, however, anything of the kind is quite out of the question, for no British university could be expected to devote serious consideration to such a suggestion. The degrees of British universities are, fortunately, not granted except for sufficient reason, even those of the existing University of London requiring an expenditure of time and energy which is far in excess of that necessary in the case of the pharmaceutical qualification. If, therefore, a degree in pharmacy is to be of any real value, and on a par with existing university degrees, it must not be granted except the recipient has proved his fitness in an equal degree with those upon whom other degrees are conferred, and that he cannot at present do by simply passing the examinations conducted by the Pharmaceutical Society.

On the other hand, a formal protest must be entered against any attempt to establish other qualifications in pharmacy than that which is obtained by passing the examination conducted by the Pharmaceutical Society, under the control of the Privy Council. It must be borne in mind that, when statutory authority for registering all chemists and druggists was granted in 1868, provision was immediately made by the Pharmaceutical Society for examining candidates from any part of Great Britain. The capacity of the Society to perform the work of examination has never yet been overtaxed and no conceivable extension of the work is likely to find the statutory examining body in any but a fit condition to cope with it. Whatever courses of instruction may be established, therefore, and however provincial enterprise may supplement the work of the Pharmaceutical Society in so far as the provision of educational facilities is concerned, legal qualification of the chemist and druggist must continue to be based upon the results of the Society's Minor examination. It may possibly be urged that the two examination centres are equally remote and inconveniently situated for students residing in certain parts of the country, but if that difficulty should ever prove of such importance as to require the adoption of special measures to meet it, the obvious remedy would be multiplication of the Society's examination centres rather than delegation of its statutory duties to other bodies. It may be taken for granted, therefore, that examinations conducted by university authorities can no more replace those conducted by the Pharmaceutical Society than the latter can be accepted as qualifying for a university degree. If ever a degree in pharmacy should be conferred by any properly constituted body in Great Britain, it must be supplementary to the legal qualification, and it ought not to be granted except the conditions fulfilled by the recipient are fully as onerous as those which are associated with the acquirement of the ordinary degrees now granted. At the very least a candidate for such a degree should have attained the same standard of general education as a bachelor of arts or science, have passed the Major examination and also a special degree examination in some scientific subject—such as general biology or zoology—which is not included in the subjects pharmacists are at present required to study. That is the least which can justify the conferment of a degree worth receiving.

ANNOTATIONS.

CARBOLIC ACID appears at last to be in a fair way to become a scheduled poison in Great Britain, Sir J. Leng, the member of Parliament for Dundee—who, we understood, was prompted by Mr. William Cummings, chemist and druggist, Dundee—having obtained from the Secretary of State for the Home Department what may be regarded as a satisfactory answer to his question of which notice was given last week. Sir John asked whether the attention of the Home Secretary had been called to the large number of painful deaths by poisoning from carbolic acid, and whether he was aware that coroners had repeatedly urged that carbolic acid should only be sold as a scheduled poison, whilst the Pharmaceutical Society had, in accordance with Section 2 of the Pharmacy Act of 1868, applied to the Privy Council to add it to the list of poisons controlled by that Act, but without effect. He further asked whether carbolic acid had been scheduled as a poison in Ireland, and could only be sold there by qualified persons, and if he could explain why the Privy Council had refused to schedule carbolic acid in Great Britain, also whether it was proposed to deal with the subject in any other way? Sir M. W. Ridley, in reply, said he was aware that a considerable number of deaths yearly are due to carbolic acid poisoning, and that it has frequently been suggested that the sale of carbolic acid should be placed under restrictions such as apply to poisons named in the Schedule to the Pharmacy Act of 1868. Some years ago, he continued, the Pharmaceutical Society did apply for the insertion of carbolic acid in that Schedule, but it was considered that the gain to the public would not be commensurate with the inconvenience arising from the proposed restrictions on the sale of the article. The Irish Government had scheduled carbolic acid, but that was done without consulting the Privy Council in this country. Continuing, the Home Secretary said that the objections to scheduling carbolic acid in Great Britain had now been lessened by the fact that regulations for the keeping, dispensing, and selling of poisons within the meaning of the Pharmacy Act of 1868 have recently been prescribed by the Pharmaceutical Society; and the Privy Council is prepared to consider whether carbolic acid can advantageously be dealt with in some way, though no action can be taken except upon a resolution of the Pharmaceutical Society. Such a resolution will, we understand, be again formally passed at the meeting of the Council on Wednesday next.

THE SALE OF BENZENE is the subject of an inquiry by a correspondent (see p. 23) who has been visited by an inspector under the Petroleum Acts. The London County Council, under the authority of which the inspector acts, is only putting in force the provisions of the Petroleum Acts, which provide that no petroleum that gives off an inflammable vapour at a temperature of less than 73° F. shall be kept on unlicensed premises—either for private use or for sale—unless it is kept "in separate glass, earthenware, or metal vessels, each of which contains not more than a pint, and is securely stopped." It is also provided that the aggregate amount kept, "supposing the whole contents of the vessels to be in bulk," must not exceed three gallons. We have always understood this to imply that benzene or benzoline must be purchased in closed bottles containing not more than a pint each, and that those bottles must not be opened by the retailer but sold as received into stock. The object of the exemption in Section 7 of the Petroleum Act, quoted above, was to enable chemists and others to keep and sell bottles of light petroleum, without the necessity of obtaining a licence, and it is obvious that the intention of the Legislature would be defeated if it were allowed to retail the spirit in small quantities or to purchase it in bulk and bottle it on unlicensed premises. We understand that correspondence is now in progress between the Pharmaceutical Society and the proper licensing authorities under the Petroleum Act with a view to securing for chemists and druggists reasonable concessions in respect to the storage, bottling, and retailing of benzene. The London County Council, it may be stated, is not desirous of harassing chemists and druggists in any way, but it must make regulations stringent enough to prevent the possibility of a pint bottle of spirit being partially emptied and then left about unstoppered. The result of the present negotiations will be published in the *Pharmaceutical Journal* in due course. With regard to the question of labelling, Section 6 of the Petroleum Act, 1871, provides that where petroleum (*i.e.*, benzene, etc.) is sold or exposed for sale, the vessel containing it shall have a label in conspicuous characters, stating the description of the petroleum, with the words "highly inflammable" and the name and address of the vendor.

IN CONNECTION WITH THE PLYMOUTH CONFERENCE, we are again asked to impress upon our readers the necessity of securing accommodation at once if they intend being present at the meeting. It is pointed out in the Pink Circular that though the Royal Hotel, Plymouth, has been selected as the nominal headquarters, only a very limited number of rooms have been secured there. In addition, as two other associations will be holding conferences at Plymouth the same week as the B.P.C., the other hotels in the town will be unusually full. Accordingly, pharmacists who intend visiting Plymouth during the last week of this month should write at once to the Hon. Local Secretary—Mr. J. Davy Turney, 15, Leigham Terrace, Plymouth—specifying what accommodation they require. Another point to which prominence is given in the Pink Circular has reference to the issue of tickets for the luncheons, excursions, etc. In order to make the local arrangements as complete as possible and so insure the comfort of visitors, it has been definitely decided that no applications for tickets can be entertained after Monday, July 17. The prices of the books of tickets are as usual, *i.e.*, ten shillings and sixpence each. No. 1 book will admit to the sessions of Conference and also cover the cost of luncheons at the Corn Exchange on the Tuesday and Wednesday (July 25 and 26), a steamer trip along the Cornish coast to Looe on Tuesday, afternoon teas on Tuesday and Wednesday, and the smoking and drawing-room concerts on the Wednesday evening. On production of this book of tickets also, admission may be obtained to the Aquarium of the Marine Biological Association. The No. 2 book of tickets covers the steamer fares on Thursday, July 27, the visit to Mount Edgcumbe, access to the promenade pier, luncheon in the pier pavilion, and afternoon tea on board the steamer. The restriction of the time during which the tickets may be obtained is an innovation but, at the same time, it is very necessary, and it is satisfactory to learn that it is intended to adhere strictly to the time limit mentioned. Whoever may apply, no tickets will be obtainable after Monday, July 17.

A HANDBOOK TO PLYMOUTH is in course of preparation, on the lines of similar books published in connection with the meetings at Oxford, Bournemouth, and Liverpool, and copies will be presented by the local executive committee to all who attend the Conference. There will be a descriptive and historical account of Plymouth, notes on the flora and geology of the district, hints for cyclists and photographers, lists of places of interest in the vicinity, and much useful information regarding trains, trams, mails, etc. A map of the Three Towns—Plymouth, Devonport, and

Stonehouse—and a number of attractive illustrations will also add to the utility of the work and to its interest as a souvenir. The title of the book, 'Plymouth Revisited,' recalls the fact that it is twenty-two years since the Conference visited Plymouth. The late Professor Redwood was President on that occasion, and the Vice Presidents were Messrs. T. H. Hills, R. Reynolds, A. P. Balkwill, and J. Williams. This second visit to the historic town will doubtless, as suggested in the Pink Circular, revive many old and pleasant associations, in addition to still further strengthening, especially in the West of England, the interest felt by pharmacists in the aims and objects of the Conference. From the days of "Good Queen Bess" to the present, it is pointed out, Plymouth may be said to have grown steadily in importance. To-day it is one of the chief ports in the United Kingdom, though war rather than commerce is the object of most of the vessels which resort there. The town yields to none in the variety and beauty of its surrounding scenery, and the sight of its magnificent harbour—bordered on the western side by the wooded heights of Mount Edgcumbe, and on the east by the equally imposing cliffs of Staddon and Mount Batten—will come as a revelation to many whose acquaintance with picturesque seaports is limited. By the way, the local press is already going astray in its remarks on the approaching meeting, the *Western Mercury* having published a reference to the "forthcoming meeting of the Pharmaceutical Society at Plymouth." Such a slip, however, is excusable, having regard to the inappropriateness of the word "Conference" as the designation of a permanent association.

The Dispensing Grocer Suggestion has not called forth an alarming number of expressions of opinion from the vendors of sugar and spices. One such person informs his none too eager fellows, in the columns of the *Grocer*, that about eight or ten years ago he added a drug department to his business and employed a "qualified chemist," but after a time he found that the profits on the poisons which the "qualified chemist" alone could sell "were not enough to pay the extra salary, although he helped in the grocery department." The "qualified chemist," therefore, received his marching orders and, since he left, the grocer has carried on his drug department with the assistance of his wife, "who makes all ointments, etc.," but he has sold only those goods which do not need to be handled by a qualified chemist. As to results, this enterprising grocer has not found his profits appreciably increased by this addition to his business. He pathetically remarks, however, that if he had not added the drug department his returns might have been less. Continuing, he states that he and his wife can put up an ordinary prescription which is "plainly written," but such do not present themselves once a month. In conclusion, he makes the naïve confession that "it requires some time to master the ordinary work of the department, and also some reading up," but "it is all right if you have a qualified friend to whom you can go with any difficulties and get help with formulas, etc." This is interesting, but far from creditable to the "qualified friend." Incidentally, it might be asked, what is the qualification of a friend?

Another Contribution to the Discussion is, appropriately enough, signed "Saponis." That individual has never before heard of a "dispensing grocer," and seems curious to know what he dispenses with. He also proffers much really useful advice to giddy plunging grocers who may be disposed to sample the seemingly inexhaustible stores of wealth in the pharmaceutical Klondike, and reach the frozen pass of bankruptcy in the attempt. As he sagely remarks, "Medicine is not like jam; people do not swallow it unless they are absolutely obliged. The demand is only small, and surely the source of supply is already large enough." He also suggests that it would be much better if the discoverer of this supposed source of wealth would advise other grocers to stick to their own legitimate trade in which they have been brought up, and not dabble with a business of which they have, generally speaking, only a crude knowledge, or attempt to take away the bread out of the mouth of the chemist, who has spent so much time and money in studying his business. But perhaps, he surmises, the latter sentiment is of very little importance in these days of "every man for himself." If that be so, perhaps the very best thing the avaricious and grasping grocer can do is to proceed forthwith to burn his fingers by attempting to rival the poor chemist in maintaining a professional status on a labourer's income, and being content to slave from early morning till late at night in the vain hope that a grateful (?) public will hasten to spend enough on physic to pay for the gas, etc., consumed. The British public is a safe client to depend upon if one can afford to appear independent of it, and perhaps also if it is self-evident that one's capacity to perform certain duties is unexceptionable. But Heaven help the grocer who invests much capital in a drug department and then seeks to persuade the British public that he is competent to dispense medicines!

The Explosion from a Chloroform Still which occurred at the chemical works of Messrs. Duncan, Flockart, and Co., Edinburgh, on January 13 last, has been reported on by the Board of Trade, which recently held an inquiry into the matter. It appears that the bolts by which the bottom of the still was attached to the cylindrical portion gave way. The upper portion was lifted from the bottom in a slanting direction, and, striking a wall, fell back again in an upright position. There was a great rush of steam from the broken steam pipes, but the pressure dropped to zero within a couple of minutes. The explosion seems to have been caused by the accumulation of vapour, until a pressure was reached that the still was unable to withstand, but how such accumulation arose is not clear from the evidence of those in attendance at the time. No one was injured by the explosion. In commenting on the matter, Mr. A. N. Peacock, of the Board of Trade Surveyors' Offices, Leith, states that it is not usual to fit stills of this description with safety-valves; but, as they are liable to be subjected to internal pressure if condensation be stopped, or if the vapour pipe becomes choked, he thinks it is very desirable that efficient arrangements should be provided to prevent accumulation of pressure. Mr. Peter Samson, Engineer Surveyor-in-Chief, also thinks it should be impressed upon users of this and similar apparatus that the omission of such fittings as safety-valves or alarms involves considerable risk to those employed near to them, as explosions which are attended with serious loss of life not infrequently occur from vessels of this description, working under somewhat similar conditions, notwithstanding that in all probability they are looked after by intelligent attendants.

The Wellcome Club and Institute.—At the annual excursion of the employés of Burroughs, Wellcome and Co. last year Mr. Wellcome mentioned that he was making arrangements to carry out an idea he had long cherished of establishing a club, with pleasure grounds, etc., for the use of those engaged in the firm's works. That liberal project has now been accomplished, and a fine old manor house adjacent to the works, as well as a former mill and other buildings, handsomely fitted up for the purpose. This year's annual excursion was made the occasion for the opening, which took place last Saturday, and, in addition to the staff and employés of the firm, a large number of visitors were present at the ceremony (see page 12*b*).

AUSTRALIAN INDIGENOUS VEGETABLE DRUGS.*

BY J. H. MAIDEN,

Government Botanist and Director of the Botanic Gardens, Sydney.

PART I (*Concluded*).

MYRTACEÆ.

Eucalyptus.

The medicinal properties of this extensive Australian genus are to be attributed mainly, and perhaps entirely, to its essential oils and kinos, and in my introductory remarks to this paper I have stated that I will defer reference to these, as a matter of convenience.

I have a very large number of bibliographical references in regard to the genus and I am preparing them for publication, as in their collected form I feel sure they would be valuable for workers and inquirers, as a really useful digest of Eucalyptus Materia Medica and Therapeutics can scarcely be compressed within the limits of a 'Gazette' article.

Eugenia jambolana, Lam.

A vinegar prepared from the juice of the ripe fruit is an agreeable stomachic and carminative; it is also used as a diuretic in India. The bark is a useful astringent. The expressed juice of the leaves enters into Indian medicine in various ways. The seeds are said to be a powerful remedy in diabetes, but their true value has not yet been assigned. New South Wales and Queensland.

Leptospermum.

The leaves and young shoots of all species of *Leptospermum* are at least of the same service to the urinary organs and against gravel as those of the European *Uva ursi* (Dr. Lauterer, 'Proc. R.S., Qd.,' 10, 101).

Melaleuca leucadendron, Linn.—"Broad-leaved Tea-tree," or "Native Cajeput."

The young leaves are bruised in water and drunk for headaches and colds, and general sickness; the bark is also used for bedding, etc. (E. Palmer.)

Western Australia, New South Wales to Northern Australia.

Melaleuca uncinata, R.Br.—A "Tea tree."

According to Mr. J. G. O. Tepper ('Proc. R.S., S.A.,' 3, 174), the leaves of this plant, if chewed, are very useful in alleviating and curing ordinary catarrh. This observation is well worth repeating, especially as this particular species is widely distributed, and as there is no reason to suppose that this property is confined to this species.

Western and South Australia, Victoria, New South Wales, and Queensland.

MELASTOMACEÆ.

Melastoma malabathricum, Linn.

The leaves are used in India in cases of diarrhœa and dysentery. (F. M. Bailey.)

From New South Wales to Northern Australia.

LYTHRARIEÆ.

Ammannia indica, Lam.—Perhaps introduced.

The whole plant has a strong aromatic smell. The leaves are acrid, and are commonly used by the natives of India to raise blisters in rheumatic pains, fevers, etc. The fresh leaves bruised perform their office effectually in half an hour. (F. M. Bailey.)

Queensland and North and South Australia.

ONAGREÆ.

Epilobium tetragonum, Linn.

The Rev. Dr. Woolls mentions that this small swamp plant is used in rustic medicine in certain urinary disorders.

All the colonies.

* From the *Agricultural Gazette of New South Wales.*

CUCURBITACEÆ.

Bryonia laciniosa, Linn. (Syn. *Bryonopsis laciniosa*, Naud.)

I invite my readers to peruse an article entitled, "A Fatal Case of Poisoning by the Fruits of a Native Climbing Plant, *Bryonia laciniosa*, Linn.," in the 'Gazette' for July, 1896. These fruits caused the death of a four-year old girl at Lismore. The article in question contains some notes on the poisonous properties of *B. dioica* of Europe. The genus contains bryonin, which is a very bitter amorphous glucoside, yielding sugar and bryonetin. See Sohn, p. 114.

New South Wales to Northern Australia.

Cucumis trigonus, Roxb.

This is an aboriginal food (see "Foods"), but I am unaware of its use in the colonies as a medicine.

"The fruit is of the size and shape of a small egg, and marked with green and yellow streaks, like colocynth. It is very bitter, and at the feast of the Diwali, or New Year of the Hindus, is brought to market for sale. The Hindus of Bombay have a custom at this season of breaking the fruit under the foot, and then touching the tongue and forehead with it, with the idea that having tasted bitter of their own accord, they may hope for preservation from misfortune during the year. It is not eaten, but is used medicinally in the same way that *Citrullus amarus* is used in Sind." (Dymock, 'Materia Medica of Western India.') See also 'Pharm. Indica,' part 3, p. 65.

A bitter principle, melonemetin, and a glucoside, prophetin, have been found in some species of *Cucumis*. See Sohn, p. 46.

New South Wales, Queensland, Northern and Western Australia.

Lagenaria vulgaris, Seringe.—"Bottle Gourd."

This plant, so plentiful along the tropical coast of Queensland, is said to be a dangerous poison. It is said that some sailors were killed by drinking beer that had been standing for some time in a bottle formed of one of these fruits. (F. M. Bailey.)

According to Capt. P. P. King ('Narrative of a Survey,' etc., 1, 203) each native of the Endeavour River had one of these gourds, in which he carried water.

See also 'Pharm. Indica,' part 3, p. 67.

Queensland.

Luffa ægyptiaca, Mill., var. *peramara*, Bailey, in 3rd 'Suppt. Qd. Flora.'

Upon tasting the fruit there is experienced an intensely bitter sensation, which in a few minutes disappears, but leaves a distressing acridity in the throat, which is not at its worst until several hours afterwards. An extract is very poisonous, and contains two principles, a bitter substance and a saponin. Dr. T. L. Bancroft ('Proc. Linn. Soc., N.S.W.' [2], 4, 1062). It is used on the Mitchell River to poison fish when green, according to Mr. E. Palmer.

Northern Queensland.

FICOIDEÆ.

Mesembryanthemum æquilaterale, Haw.—"Pig's Face."

Many species, and especially *M. acinaciforme*, Linn., from which this species scarcely differs, are used in South Africa. There the expressed juice of the succulent leaves taken internally checks dysentery, and acts as a mild diuretic, while it is also, for its antiseptic property, used as an excellent gargle in malignant sore throat, violent salivation, and aphthæ, or in the form of a lotion in burns and scalds. (Bailey, in 'Syn. Qd. Flora.')

Near the coast in all the colonies.

UMBELLIFERÆ.

Hydrocotyle asiatica, Linn.

In anæsthetic leprosy good results have followed the use of this

herb, but it possesses no claim to the character of a specific attributed to it by some. It has been found more useful in secondary or constitutional syphilis, especially in those cases where the skin and subjacent cellular tissue are principally affected. In non-specific ulcerations, and in skin diseases, it is of value, both as an internal and as a local remedy. ('Pharm. of India.')

Credited locally as valuable when applied to wounds or sores in the form of a salve or poultice. (G. M. McKeown, Wollongbar.) See 'Agric. Gazette' for May, 1894, p. 306.

Lepine ('Journ. Pharm.' [3], 23, 47) has found in this plant a yellow, oily, neutral, bitter principle, to which he has given the name of vellarin.

In all the colonies.

Trachymene incisa, Benth.—"Wild Parsnip."

In the 'Gazette' for October, 1894, is an article on this plant, which had been accused of poisoning stock. In that article, and also 'Gazette' for January, 1897, p. 14, I suggest an examination of the Australian species of *Trachymene* (*Didiscus* of some authors).

In all the colonies.

Panax.

The most celebrated remedy of the Chinese is ginseng, the root of *Panax ginseng*, which is purchased at prices which seem extraordinary to our ears, especially when it is considered that it contains no active principle of importance. Not that, by the way, considering the faith our own people put in secret remedies and quack medicines, we can afford to smile at the Chinese in the matter. The Americans also have a species of ginseng (*P. quinquefolium*), and the root of this plant is exported in large quantities to China. It is also systematically cultivated to supply the demand. Between 1883 and 1893 the trade in American ginseng amounted to between 600,000 and 1,000,000 dollars annually. The species of ginseng used are small plants, usually below 30 inches in height. We have several species of *Panax* in the Coast district larger than these (though whether the size of the species affects the quality of the ginseng I do not know). But I do think the matter is worthy of attention by residents of the Coast districts in which species of *Panax* abundantly grow, and if selected roots are sent to me I will engage to procure the opinion of Chinese merchants upon them. A second edition of an admirable brochure on American ginseng has recently been published by the Department of Agriculture of the United States.*

Garrigues ('Ann. Chem. Pharm.,' 90, 231) has found a bitter principle, to which he has given the name of panaquilon, in American ginseng, and at the outset it should be looked for in our Australian species of *Panax*.

LORANTHACEÆ.

Loranthus quandang, Lindl—"A Mistletoe."

The leaves are bruised in water and drunk for fevers by Queensland aborigines.

In all the colonies except Tasmania.

RUBIACEÆ.

Morinda citrifolia, Linn.—"Indian Mulberry."

The Cochin-Chinese place this amongst their medicinal plants, believing the fruit to be deobstruent and emmenagogue. In Bombay the leaves are used as a healing application to wounds and ulcers, and are administered internally as a tonic and febrifuge. (Dymock.)

Psychotria.

In Pereira's 'Materia Medica and Therapeutics' it is stated that the roots of *P. emetica*, Mutis, form the striated ipecacuanha of commerce. He states that it contains emetia, and that in its medicinal qualities it resembles the true ipecacuanha, but it is less powerful. We have several species of *Psychotria* in Queensland, of which two also occur in New South Wales, *P. loniceroides*, Sieb., being specially abundant. It is desirable that it be ascertained whether the roots of any of these plants contain the active principle of ipecacuanha.

Sarcocephalus cordatus, Miq.

It has a bitter bark, long known to bushmen, and used by them occasionally in the form of an infusion for ague, in default of quinine, but with no good results, as far as I could ascertain. Extract of the bark, which is very bitter, had apparently no effect on frogs. Tincture of the bark is somewhat fluorescent; I used it medicinally in cases where simple bitters were indicated; it appeared to be as useful as calumba. Some commercial use, such as a bitter for beer, might be made of this bark, which could be obtained in any quantity; when dry it is extremely light, and is apparently free from tannin. It is physiologically almost inert (Dr. T. L. Bancroft, 'Pharm. of Some Queensland Plants,' 1889, p. 2).

Mr. N. Holtze points out that the wood is also very bitter, and would make excellent "bitter-cups."

Queensland and Northern Australia.

COMPOSITÆ.

Walz ('N. Jahrb. Pharm.,' 13, 176) has found a bitter principle, called by him "crepin," in *Crepis fœtida*. It might be looked for in our *Crepis japonica*.

Cymbonotus lawsonianus, Gaud.

In the southern parts of New South Wales the country people prepare a salve, used for wounds, etc., by extracting the medicinal properties (if it possesses any) of this plant by means of melted lard. Alternate layers of lard and leaves are made, the mass is allowed to cool slowly, and afterwards the lard is run out and is ready for use. Some country folk are loud in their praises of its quick healing effects. Mr. Bäuerlen tells me they copied this use of the plant from the Chinese. Recently I have received it from New England, where also it is believed to contain healing properties. Although this humble plant is found in all the colonies, it does not extend to China, so the Chinese probably first used it in an empirical manner.

All the colonies.

Elephantopus scaber, Linn.

The leaves of this plant are used in Travancore, boiled and mixed with rice, for pains in the stomach, and swellings in the body. ('Treasury of Botany.')

Queensland and Northern Australia.

Gnaphalium luteo-album, Linn.—Native name, "Kai-kai."

Used medicinally for general sickness, as a drink, by Queensland natives. (E. Palmer.)

In all the colonies.

Myriogyne minuta, Less. Syn. *Centipeda orbicularis*, Lour.; *C. cunninghamii*, F. v. M.—"Sneezeweed."

The following letter from the Rev. Dr. Woolls (then of Richmond) appeared in the 'Sydney Morning Herald' on Christmas Day, 1886:—

"Some weeks since, the Rev. S. G. Fielding, of Wellington, called my attention to a weed (known to botanists as *Myriogyne minuta*), which he stated had been used with success in case of blight. Being anxious to test the efficacy of the remedy, and to ascertain whether any bad effects would arise from its application, I placed some of it in the hands of Dr. Jockel, of this town, who has furnished me with the following remarks:—'I have much pleasure in testifying to the efficacy, in cases of ophthalmia, of the plant which you so kindly sent me. A case came under my notice

* 'American Ginseng: Its Commercial History, Protection, and Cultivation.' G. V. Nash and M. G. Kains. Bulletin No. 16. Division of Botany.

a few days ago of a drover who was suffering from a severe form of purulent ophthalmia, contracted up the country. I had an infusion of the plant according to directions, and the first local application seemed to have almost a magical effect. The man expressed himself as relieved at once of the intense smarting which he had previously suffered. He had got on so well that in two days he was able to start back up country again, and could hardly express his gratitude for the very great relief afforded.—Louis C. Jockel.'

"I find, from a communication of Baron Mueller, that for some time past he has had an idea that *Myriogyne* might be utilised for medicinal purposes, and that he had actually submitted it to Dr. Springthorp, an eminent physician in Melbourne, for the purpose of experiment. The Baron, however, was not aware of its efficacy in simple ophthalmic inflammation, and he regarded the discovery as interesting. I mention this as a matter of justice to Dr. Jockel, who, I believe, is the first medical man in Australia who has proved the value of *Myriogyne* in a case of ophthalmia. This weed, growing as it does on the banks of rivers and creeks, and in moist places, is common to all the Australian colonies and Tasmania, and it may be regarded as almost co-extensive with the disease it is designed to relieve. It is described in the 'Flora Australiensis,' 3, p. 553, and figured amongst Baron Mueller's plants of Victoria. In the document relating to the Intercolonial Exhibition, 1866-67, it is noticed as remarkable for its sternutatory properties, and recommended for the manufacture of snuff; and I find that Endlicher, in alluding to the species of the genus of *Myriogyne*, characterises them as *herbæ ramosissimæ acres sternutatoriæ* ('Genera Plantarum,' p. 440)"

I find this use of the plant as a cure for sandy blight is fairly well known in the Colony; how long it has been known I cannot say. It was packed in tins by one enterprising firm and sold as "Magic Ophthalmia Cure," with what business results I do not know. It can be said of this remedy that if its effects are not beneficial in any particular case, they can scarcely be injurious.

The Rev. Mr. Hartmann says (Brough Smyth's 'Aborigines of Victoria,' 2, 173) that this plant is used as medicine by the aborigines of Lake Hindmarsh, but he does not say for what complaint.

It is also found in India, Madagascar, and Japan. The natives of India consider it a hot and dry medicine, useful in paralysis, pains in joints, and special diseases; also as a vermifuge. ('Cyclop. of India.')

In all the colonies.

Pterocaulon glandulosus, Benth. and Hook., f.

Used for medicine in fevers by Queensland natives. (E. Palmer.)

Queensland and Northern Australia.

Senecio.

An extract is prepared from the plant and roots of the European *Senecio vulgaris* (common groundsel), which is used medicinally in some ailments peculiar to women. See Dalché and Heim ('Nouv. Remèdes,' 1896, pp. 409 and 697), 'Therap. Monatshefte,' 1897, p. 275; also Merck's 'Ann. Report,' 1897, p. 65.

Our native species of *Senecio* are numerous and widely diffused; here is a suggested line of research for some of our medical practitioners.

Vernonia.

See 'Pharm. Indica' (part 3), 241 and 243.

Heckel and Schlagdenhauffen have found an amorphous white glucoside (called by them vernonia) in *V. nigritiana*, from West Africa. See Sohn, p. 103. It might be looked for in our Australian species of this genus.

FORMULÆ, METHODS, AND REACTIONS.

KNOWN BY THE NAMES OF THEIR AUTHORS.

(Supplementary List).*

Kolisch (Kreatinin).—The precipitant consists of mercuric chloride, 30; sodium acetate, 1; in absolute alcohol, 125 Gm.; to which 3 drops of acetic acid are added.

Kopp (Nitric Acid) is a solution of diphenylamine sulphate; it is prepared by the addition of a little concentrated sulphuric acid to a few crystals of diphenylamine and then a little water; finally the solution is diluted with more concentrated sulphuric acid; 0·55 Gm. of the reagent are put on a watch glass, and a drop of the fluid to be examined is allowed to fall in the middle, the presence of nitric acid is indicated by the appearance of a blue circle; numerous other bodies, such as sulphurous acid, hypochlorites, ferrous salts, give a similar colour. Diphenylamine sulphate solution is also known as Pollet's reagent.

Kossel (Hypoxanthine).—The solution to be examined is treated with zinc and hydrochloric acid, then made alkaline; the presence of hypoxanthine is indicated by a ruby red colour, changing to brown.

Krasser (Albumin).—Alcoholic solution of alloxan gives a bright red colour with albumin.

Kubli (Carbon Dioxide Test for Quinine).—Quinine is precipitated from a saturated solution by means of sodium carbonate. The precipitate is dissolved on the addition of sodium bicarbonate. Carbonic acid gas is then introduced, and quinine carbonate precipitated. Carefully conducted, the result gives an indication of the purity of the quinine salt under examination.

Kubli (Water Test for Quinine).—This test is based on the solubility of hydrated quinine, obtained by precipitating the alkaloid with soda and observing the amount of water necessary to dissolve the alkaloid thus liberated. The associated cinchona alkaloids are less soluble in water than quinine, consequently in their presence a larger amount of that solvent is required to produce a solution.

Kuehne (Stain for Typhoid and Cholera Bacillus).—A cold saturated solution of methylene blue is mixed with one per cent. solution of ammonium carbonate. Preparations are immersed in the stain for five or ten minutes, then well washed and placed in 1 per cent. solution of hydrochloric acid.

Kunz-Krause (Glycotannoids). — Those glucosidal tannins which are derivatives of oxycinnamic acids are rapidly decomposed in the cold after a few days with the formation of a considerable amount of prussic acid, on being treated with Liebemann's reagent. (A solution of potassium nitrate, 6 Gm., in concentrated sulphuric acid, 100 Gm.)

Lagrange (Glucose). — This is a modification of Fehling's solution, containing neutral copper tartrate (? acetate), 10 Gm., and sodium hydrate, 40 (? 400) Gm., dissolved in water, 500 C.c. It gives a red precipitate with glucose.

Laillier (Olive Oil).—Characteristic colour reactions are produced on shaking 1 volume of aqueous chromic acid solution (1 in 4) with 4 volumes of oil. Or, the simple chromic acid solution may be replaced by a mixture of chromic acid, 9, water, 30, and nitric acid (s. g. 1·185), 80.

Landerer (Strychnine).—A violet colour is produced on heating gently with iodic acid or an iodate and sulphuric acid.

Landott (Paraffin in Beeswax).—Strong sulphuric acid attacks beeswax at once, but only very slowly affects paraffin.

Lang (Taurine).—Taurine gives a white precipitate when a solution is mixed with freshly precipitated mercuric oxide.

* After Wilder, Schneider, Altschul, etc. Continued from last vol., p. 553.

Langbeck (Indicator).—Nitrophenol is colourless in very dilute acid and neutral solutions, but alkalies turn it yellow.

Laronde (Iodine).—On treatment with petroleum and nitric acid, the former is coloured violet by the iodine.

Lasaulx (Iron).—Particles of metallic iron separated from a powdered substance with a magnet, and treated with tungstic acid solution, are seen under the microscope to have blue margins. Organic matter must be absent, as well as zinc and copper.

Lassaigne (Flour).—Mineral substances in flour are detected by shaking with chloroform and examining the sediment.

Lassaigne (Gum Arabic).—A transparent, gelatinous, yellow precipitate is thrown down on adding solution of ferric sulphate.

Lassaigne (Iodine).—(1) Solution of palladium nitrate or chloride gives a brown or blackish colour. (2) On treatment with chlorine water, iodine colours starch paper blue.

Lauth (Paratoluidine).—On adding nitric acid to a solution of paratoluidine in sulphuric acid, the colour changes from blue to violet, then to red and brown.

Lauth (Sulphuretted Hydrogen).—Paraphenylene-diamine in slightly acid solutions gives, on the addition of ferric chloride, a violet colour in the presence of sulphuretted hydrogen. If a few grains of para-amido-dimethylaniline sulphate are substituted for the paraphenylene-diamine a reaction due to methylene blue is it obtained. (Caro Fischer's reaction.)

Lea, Carey (Hyposulphites).—See Carey Lea.

Lebbin (Formaldehyde).—Solutions containing formaldehyde are heated to boiling for thirty seconds, with a solution of resorcine in sodium hydrate. Formaldehyde gives a reddish tint, but the presence of albuminoids interferes with the reaction; chloroform produces a similar colour.

Leers (Quinine).—A green colour is produced on shaking quinine in fine powder with ether, then adding chlorine water and ammonia.

Leewenthal-Lenssen (Hydrochloric Acid).—In the presence of a protochloride, free hydrochloric acid gives off chlorine on treatment with lead peroxide.

Leffmann (Urine).—Drinking water containing urine is coloured brown with silver nitrate solution.

Lefort (Morphine).—A yellow to yellowish-brown colour is produced on adding iodic acid solution and then ammonia.

Lefort (Strychnine).—A violet colour is produced with sulphuric acid and potassium bichromate.

Legal (Acetone).—The red colour produced on adding sodium nitroprusside solution turns green on adding potash.

Lenz (Alkaloids).—Certain alkaloids give characteristic colour reactions when heated to redness with caustic potash, containing so much water that it is solid at ordinary temperature, but melts when heated on the water bath. Quinine and quinidine give a green coloration. Cinchonine and cinchonidine a greenish blue, cocaine a greenish yellow.

Leonhardi (Alcohol in Essential Oils).—Fuchsine dissolves in alcohol, but not in the pure oils.

Lepage (Alkaloids).—A white or yellowish precipitate is thrown down by a solution of cadmium iodide, 10, and potassium iodide, 20, in water, 60 to 80.

Lepage (Potassium Iodide).—Test the purity of potassium iodide by dissolving in 30 per cent. alcohol and examining the residue, if any.

Lepel (Magnesium Salts).—The violet colour of a solution of alkaninin in a mixture of alcohol, 2, and ether, 1, is changed to blue.

Letheby (Aniline).—1. A blue to purple colour with sulphuric acid and lead or manganese peroxide. 2. A blue to purple colour with sulphuric acid and potassium ferricyanide. 3. A bronze-blue to pink colour on adding diluted sulphuric acid, placing two drops on platinum foil and passing a current from a Grove's battery.

Letheby (Arsenic).—Cause the evolution of arseniuretted hydrogen and pass it into silver nitrate solution, which is coloured brown to black.

Leube (Quinine).—A red colour is produced with chlorine water, potassium ferrocyanide and ammonia.

Leuchs (Water in Essential Oils).—On shaking with petroleum spirit, milkiness will be produced.

Lex (Ammonia).—A green colour is produced on adding phenol and a few drops of solution of chlorinated lime, and changes to blue on warming.

Lidoff (Textile Fabrics).—Silk is readily soluble in powdered oxalic acid (on melting). Cellulose is less soluble and wool fibre insoluble.

Lieben (Alcohol).—Iodoform is produced on adding a crystal of iodine and just sufficient potash to make a clear solution.

Liebermann (Albuminoids).—When treated with fuming hydrochloric acid, albuminoids gives a bluish-violet colour.

Liebermann (Phenol)—Is a solution of potassium nitrite in concentrated sulphuric acid.

Liebermann (Sulphurous Acid in Wine).—(1) Reduce to sulphuretted hydrogen with sodium amalgam and hydrochloric acid; (2) distil and shake the distillate with a few drops of iodic acid solution and a little chloroform. The latter is coloured violet.

Liebermann (Textile Fabrics).—The fibres are dyed for half an hour in fuchsin solution, then washed out to a slight yellow colour with caustic soda solution, and subsequently washed with water. Silk is coloured dark red, wool light red, flax pink, while cotton remains colourless.

Liebig (Aldehyde).—A mirror is formed on adding ammoniacal solution of silver nitrate.

Liebig (Coniine).—A purplish-red to blue colour is produced on passing dry chlorine gas over coniine.

Liebig (Determination of Cyanides).—Titrate in a slightly alkaline solution with decinormal silver nitrate solution until a permanent opalescent precipitate occurs. 1 C.c. of decinormal silver nitrate = 0·0054 Gm. of hydrocyanic acid.

Lightfoot (Tarry Matter in Acetic Acid).—On neutralising with sodium or potassium carbonate and adding a few drops of potassium permanganate solution, the pink colour is discharged in a few minutes.

Lindo (Elaterin).—A crimson to scarlet colour is produced on adding 1 or 2 drops of phenol and then 2 or 3 drops of sulphuric acid.

Lindo (Glucose).—A yellow colour which changes to an intense blue is produced on adding a solution in soda or potash of the yellow substance obtained by the action of nitric acid on brucine.

Lindo (Morphine).—An emerald green colour is produced with ammonio-cupric sulphate solution, prepared by dissolving copper sulphate, 1, in water, 10, and adding sufficient ammonia to make a clear solution.

Lindo (Nitric Acid).—A deep-brown to red colour is produced on adding 8 or 10 drops of phenol mixed with 30 drops of a cooled mixture of sulphuric acid, 2, and water, 1.

Lindo (Phenol).—See Lindo's test for nitric acid.

Lindo (Santonin).—On dissolving in sulphuric acid, without heating, and adding a very dilute solution of ferric chloride in

small successive quantities, a red to purple or violet colour appears after agitating.

Lipowitz (OLIVE OIL).—The purity of the oil is estimated by noting the colour, degree of emulsification, etc., on rubbing it with one-eighth its weight of chlorinated lime.

Lloyd (WATER IN SPT. ÆTH. NIT.).—Milkiness is produced on shaking with chloroform or (? and) castor oil.

Loeffler (FLAGELLA STAIN).—Gallic acid solution 1 in 4, 10 C.c. cold saturated of ferrous sulphate, 5 C.c., and alcoholic fuchsine solution, 1 C.c. Fischer's modification of this consists of tannin solution 1 in 10, 20 C.c.; ferrous sulphate solution 1 in 2, 4 C.c.; and alcoholic solution of fuchsin, 1 C.c. The sections are macerated in this in the warm, washed in water, then stained with concentrated aqueous solution of fuchsin.

Loewe (GLUCOSE).—(1) Dissolve by the aid of heat hydrated copper oxide, 15·305 Gm. (= crystallised copper sulphate, 40 Gm.) in glycerin, 30 Gm., sodium hydroxide solution (s. g. 1·34), 80 C.c., and water, 160 C.c. Dilute the solution to 1155 C.c., and 10 C.c. will then = 0·05 Gm. of anhydrous glucose. (2) To a solution of copper sulphate, 16 Gm., in water, 64 Gm., add gradually (so as to avoid heating) sodium hydroxide solution, 80 C.c., and glycerin, 6 to 8 Gm. (3) Hydrated copper oxide, 6; glycerin, 6 to 8; water, 50; sodium hydroxide solution, 56.

Longi (NITRIC ACID).—An aqueous solution of paratoluidine sulphate gives with a solution containing nitric acid on the addition of an equal volume of concentrated sulphuric acid, a red zone, which later changes to yellow. In the presence of chlorates, bromates, iodates, chromates and permanganates, a blue colour is produced. Nitrous acid gives a yellow reaction afterwards changing into red.

Loubian (INDICAN) is a modification of Hammarsten's reaction, in which hydrogen peroxide is substituted for calcium hypochlorite to convert indican into indigo. Two C.c. of urine are mixed with an equal volume of chloroform and 1 C.c. of 5 to 10 p. c. solution of hydrogen peroxide. Concentrated hydrochloric acid, 2 C.c., are then added, and the mixture warmed and well shaken; the presence of indican is shown by the deep blue colour of the chloroform layer.

Luck (CARBON BISULPHIDE IN MUSTARD OIL).—Distil the oil in a water-bath and add to the distillate alcoholic potash solution, a slight excess of acetic acid, and copper sulphate solution. A lemon-yellow precipitate indicates the presence of carbon bisulphide.

Luck (INDICATOR).—Phenolphthalein solution is colourless with acids, but becomes purplish-red with alkalies.

Ludwig (MERCURY).—Organic substances suspected to contain mercury should be mixed with zinc dust or finely-divided copper and the mercury distilled off.

Luff (URIC ACID IN BLOOD).—Fresh blood is allowed to flow direct into its own volume of rectified spirit, with which it is thoroughly agitated; the mixture is then evaporated on the water-bath until the mass can be reduced to a coarse powder, which is dried in the water-oven and afterwards finely powdered. The admixture of the blood with the spirit precipitates the albuminous matters in a granular form, so that when dried the blood can be reduced with ease to a fine powder. One part of the dried blood is taken as being equal to five parts of liquid blood. For the extraction and estimation of uric acid in blood from 50 to 100 Gm. of the powdered blood should, if possible, be taken. The extraction is effected by adding 100 Gm. of the powdered blood to 1 litre of boiling distilled water, and allowing the mixture to boil for half-an-hour, during which time it is frequently agitated. It is then filtered, first through glass-wool and afterwards through filter-paper, and evaporated down to 50 C.c.; this liquid is filtered, allowed to cool, and then submitted to the Gowland Hopkins process for the determination of uric acid. See the *Journal of Pathology and Bacteriology*, 1893, 1., p. 451.

Lunge (BICARBONATES IN CARBONATES).—To a weighed quantity of solid bicarbonate add an excess of semi-normal ammonia, followed by excess of baric chloride. The whole is made up to a known volume and a definite portion filtered through a dry filter. This is then titrated with normal acid. The alkalinity indicated represents the amount of carbon dioxide existing as bicarbonate in the quantity of liquid taken.

Lunge (INDICATORS).—(1) Tropæolin or methyl-orange is changed from yellow to crimson by mineral acids, but it is indifferent to carbon dioxide and sulphuretted hydrogen. (2) Phenacetolin, obtained by heating for several hours 1 equivalent each of carbolic, sulphuric, and glacial acetic acids, is turned from brown to red by alkalies.

Lux (INDICATOR).—The colourless alcoholic solution of flavescin, an extract from half-charred oak-wood, is turned yellow by alkalies.

REVIEWS AND NOTICES OF BOOKS.

KING'S AMERICAN DISPENSATORY. By HARVEY WICKS FELTER, M.D., and JOHN URI LLOYD, Phr.M., Ph.D. Eighteenth edition, third revision, in two volumes. Vol. I. Pp. 950. Price $4.50. Cincinnati: The Ohio Valley Company. (London: Potter and Clarke.)

No more convincing proof can be required of the high estimation in which King's 'American Dispensatory' is held than the fact that it has now reached the third revision of the eighteenth edition. Indeed, it may be doubted whether the term "revision" is correctly applied to the task that Dr. Felter and Dr. Lloyd have performed, since the latter remarks in the Preface that the "pharmacy and chemistry of the book could not be revised but must be re-written."

A work of this nature must, as Dr. Felter remarks, be largely a compilation. A dispensatory is not intended to voice the author's opinion and experience only, but, whilst alluding to the principal investigations of the past, to clearly show to what point the work has been carried, to reflect, that is, the present state of our knowledge of each subject dealt with in the work.

The labour of revising the first volume of the dispensatory may be gauged partly by the size of the volume, which includes over 900 pages of closely-printed matter, and partly by the variety of subjects dealt with. These include the botany, chemistry, pharmacognosy, pharmacy, physiology, and therapeutics of the drugs considered. From the preface the reader learns that Dr. Lloyd is responsible for pharmacy and chemistry, whilst Dr. Felter has revised the botany, botanical history, and botanical descriptions in addition to the entire medical section.

The revision of the chemical section of the work has, on the whole, been fairly well accomplished. The description of each preparation includes its formula, synonyms, history and source, preparation, description and tests, action, medical usage and dosage, specific indications and uses. The United States Pharmacopœia, the National Formulary, and the British Pharmacopœia are largely quoted, and it is unfortunate that the new edition of the last-named work was not published sufficiently early to be available. There are, however, many statements that exhibit an inaccuracy in the facts that should certainly be corrected in a subsequent revision. Thus, hydrocyanic acid is said to be found "in the seeds, barks, leaves, and flowers (of the suborders Amygdaleæ and Pomeæ) existing uncombined largely in the fluid portions of the plant. It is this acid which gives to

almonds and to peach seeds and leaves their pleasant and characteristic flavour." It may well be doubted, too, whether the process for preparing hydrochloride of cocaine, which was contained in the British Pharmacopœia, is ever used, and amongst the tests for its purity one would have expected to find Maclagan's, which is now generally used.

The pharmacy of the work has also been revised in a commendable manner, although this section bears evidence of having been done under a pressure not consistent with the production of work of the highest class. The article on "emulsions," for example, consists practically of a reprint of the corresponding article and formulæ of the National Formulary, and in such a work as the Dispensatory might well have been extended so as to enter somewhat more into detail, and to consider the subject at rather more length. This objection applies less to the article on extracts, although here, too, quotations from the United States Pharmacopœia and National Formulary figure largely.

The medical section, which is by far the largest, appears to have been very carefully done, the action and uses of the drugs being detailed at great length. The review of this portion of the Dispensatory must, however, be left in the hands of a competent medical authority.

The part of the work that appears to be least satisfactory is the pharmacognosy, which shows evidence of having received very unequal attention. The article on ergot, for example, extending over eleven pages, presents a lucid and concise but at the same time comprehensive review of the subject, including the researches of Jacoby in 1895 and 1897. The details of the process of assay and the results of the assays that have been made by Keller, Beckurts, and others, which are both interesting and important, might perhaps have been with advantage added. With this article that on belladonna, which is quoted largely from Dr. F. B. Filmer, compares very unfavourably; in the latter there are inaccuracies in the statements, and a looseness of expression that reflects little credit on their author. Stramonium leaves are said to be distinguished by the hairs, which are shorter, with a many-celled apex, by the numerous cells containing a large single crystal of calcium oxalate, and the lamina which does not taper into a petiole, all of which statements are incorrect, whereas the odour, venation, and outline, all of which are distinctive characters, are not mentioned. As examples of an unhappy diction, not confined, unfortunately, to the article under consideration, the following may be cited:—"Scopolia is a rhizome and resembles the genus Atropa in containing peculiar crystal-like contents, but they are less prominent. . . . Belladonna scopolia is also a rhizome, and, like Japanese belladonna, may be distinguished from true belladonna, which is a root. Where a preparation claims to represent the Pharmacopœia, which explicitly calls for true belladonna, this drug should not be used." (!) Nor is the following description of the transverse section of belladonna to be commended either for accuracy or clearness:—"At the periphery of the fundamental tissue of the pith are yellowish vascular bundles scattered apparently indiscriminately. These finally disappear beyond the cambium." The illustrations also in this section should have been referred to their true source (Professor Vogl's 'Anatomical Atlas') and not credited to Dr. Filmer. Considering also the attention that has lately been paid to the assay of potent drugs and to the large amount of work that has been done in this drug in particular, one might well have expected something more than the apparently casual statement that 0·82 per cent. of alkaloid has been found in the root. A similar neglect is conspicuous in the article on hemlock, in which the valuable investigations of Wright and Farr, that must have been easy of access, have been totally ignored, and the only statement as to the percentage of alkaloid present is that Wertheimer (1856) found 0·2 per cent. in the fresh seeds. The recent investigations on balsam of Peru, balsam of tolu, asafetida, ammoniacum, etc., also remain unnoticed.

It would seem that the labour of revising so comprehensive a work as the Dispensatory has made a demand upon the time of the revisers greater than could be complied with, and the question remains whether, in the event of another revision being required that labour should not be undertaken by a larger number of experts, in order that all sections of the work may receive sufficient critical revision.

PHARMACEUTICAL SOCIETY.

SCHOOL OF PHARMACY EXAMINATIONS.

SESSION 1898-99.—ELEMENTARY COURSE.

PRACTICAL CHEMISTRY.

PROFESSOR J. NORMAN COLLIE.

Friday, June 23—From 11 a.m. to 1 p.m.

1. The chloride of sodium in box A is supposed to be impure; detect the impurity.
2. The solution given you contains two substances. Find out what they are.

PRACTICAL CHEMISTRY.

PROFESSOR J. NORMAN COLLIE.

Friday, June 23—From 2 p.m. to 5 p.m.

The solution of sodium carbonate you are given was made in the following manner:

25 grammes of a solution of sodium carbonate of specific gravity 1·11 (at 15° C. was diluted to one litre.

1. Calculate its strength in grammes per litre.
2. Determine the strength of the oxalic acid solution that you are supplied with.
3. Determine also the strength of the permanganate of potassium solution that you are supplied with.

Data.—Na=23 C=12 O=16 K=39 Mn=55.

Amount of sodium carbonate in a solution of known specific gravity (at 15° C).

Sp. Gr.	per cent. Na_2CO_3
1·100	contains 9·43.
1·108	contains 10·19.
1·116	contains 10·95.

CHEMISTRY.

PROFESSOR J. NORMAN COLLIE.

Saturday, June 24—From 10 a.m. to 1 p.m.

1. How would you prepare pure calomel from metallic mercury, pure sodium chloride from sea salt, chloral hydrate from alcohol; and what are the usual impurities in commercial iodide of potassium, subnitrate of bismuth, and oxalic acid?
2. Compare the points of similarity and difference in the simpler compounds of sulphur and chromium.
3. Give examples explaining the terms: Allotropy, Isomorphism, Molecule, Diffusion of Gases, and Dialysis.
4. Why is it that the molecular weight of any gas is twice the density of that gas (compared with hydrogen)?
5. Describe in detail the method you would employ to obtain a specimen of pure alcohol from grape sugar.
6. Calculate the pressure of the atmosphere in lbs. per square inch at the bottom of a mine where the mercury stands at 40 inches.
7. Describe Nicholson's Hydrometer, and explain with the help of a numerical example how it may be used to determine the specific gravity of a liquid.

MATERIA MEDICA.

PROFESSOR HENRY G. GREENISH.

Monday, June 26—From 10 a.m. to 1 p.m.

1. From your experience in identifying leaves indicate the characters to which particular attention should be paid in examining and describing leaves. Illustrate your answer by instances taken from official leaves.
2. What is myrrh? How is it obtained, and what are its chief constituents? Give the botanical and geographical source. By what means would you seek to distinguish the genuine drug from any other that might be substituted for it?
3. Write a short account of musk.

4. (*a*) Compare alder buckthorn bark with cascara sagrada, both as regards their physical characters and chemical constituents.
(*b*) Compare similarly Vera Cruz jalap with Tampico jalap.

PHARMACY.

PROFESSOR GREENISH.

Monday, June 26—From 2 to 5 p.m.

1. Suggest a process for the preparation of a liquid extract from each of the following drugs:—
(*a*) Rhizome of *Agropyron repens*,
(*b*) Leaf of *Piper angustifolium*,
(*c*) Guarana.
In each case give the reasons upon which your suggestion is based.

2 (*a*) Describe the processes of ordinary, fractional, and destructive distillations, alluding particularly to the differences between them.

(*b*) What is the most suitable temperature for drying fresh henbane leaves? Adduce evidence in support of your answer.

3. The following is a basis suitable for making the official lamellæ:—

Transparent Gelatin	180 grains.
Glycerin	15 minims.
Distilled Water	2 ounces.

Describe exactly how you would proceed to make 100 lamellæ of cocaine hydrochloride, each of which shall weigh about 1/20th gr. and contain 1/75th gr. of cocaine hydrochloride.

4. Describe the official processes for making
(*a*) Unguentum Zinci Oleatis,
(*b*) Extractum Pareiræ Liquidum,
(*c*) Tinctura Pruni Virginianæ.
Explain the various steps in each process.

NORTH BRITISH BRANCH.

A meeting of the Executive of the North British Branch was held in the Society's House, 36, York Place, Edinburgh, on Friday, June 23, at 11.30 a.m., Mr. J. LAIDLAW EWING in the chair. Messrs. Boa, Bowman, Burley, Cowie, Currie, Ewing, Fisher, Gilmour, Henry, Kerr, McAdam, McLaren, Russell, Strachan, and Tocher were also present.

ELECTION OF CHAIRMAN.

Mr. MCADAM moved that Mr. Peter Boa, Edinburgh, be elected Chairman for the ensuing year, and the motion having been seconded by Mr. BOWMAN, and unanimously agreed to,

Mr. BOA took the chair. He said he felt very much honoured by the confidence they had shown in him. While he highly appreciated this mark of confidence, he must also say the position was not one he at all coveted. He should very much have liked if an arrangement could have been made for placing Mr. Currie in the chair, but that appeared to be impracticable. He hoped they would be able to carry on the business with efficiency and good fellowship among themselves.

Mr. CURRIE, Vice-Chairman, said he desired at this stage to propose a very special vote of thanks to the retiring Chairman, Mr. Ewing. During the eight years he had been their Chairman, the work had gone on very smoothly, and a great deal of work had been done. It was due to his untiring efforts and the able way in which he represented their case in London that they had been enabled successfully to complete the commodious and well-equipped premises they now occupied in Edinburgh. In all the other work of the branch Mr. Ewing had shown great devotion and had spent a great deal of time, and for these services he deserved the best thanks of every member of the Executive. He would express the confident hope that so long as he occupied a seat on the Executive he would place his services and his experience at the disposal of the Society.

Mr. EWING thanked Mr. Currie very heartily for the kind way in which he had spoken of him, and the Executive for the hearty reception they had given to his suggestion. Eight years was a long time to be in such a position as he had occupied, and he began to feel that a change should take place. He could only say that during these years he had had great pleasure in the work, and it was chiefly owing to the support he had received from past and present members of the Executive that he had been able to accomplish anything. A good deal had been done to the Society's House, and he had pleasure in handing it over to his successor in excellent condition. He would have very great pleasure at all times in doing his best in the interests of the Pharmaceutical Society and the Executive. He could not have done so much if it had not been for the support he received from the Assistant-Secretary, Mr. Hill. He had been at all times willing to give him that aid which his great knowledge of pharmaceutical affairs in Scotland enabled him to do, and he placed them at his service, and he found them invaluable.

ELECTION OF VICE-CHAIRMAN.

Mr. MCLAREN moved that Mr. Robert McAdam, Glasgow, be elected Vice-Chairman for the ensuing year. They had a large constituency in Glasgow, and Mr. Currie, who was near Mr. McAdam, would doubtless give the assistance of his experience in carrying on the work.

Mr. CURRIE, in seconding the motion, said that during the four years he had held office as Vice-Chairman he had seen a good deal of the internal working of the Executive, and it had always been very delightful to him. He would vacate the vice-chair with great pleasure in favour of Mr. McAdam.

Mr. MCADAM accepted, and, having taken the vice-chair, said he could not promise to do the social part of the work so successfully as Mr. Currie had done.

Mr. KERR, Dundee, moved a vote of thanks to Mr. Currie for the able manner in which he had performed the duties of Vice-Chairman. The motion was seconded by Mr. C. F. HENRY, and cordially agreed to, after which Mr. CURRIE expressed his thanks.

WELCOME TO NEW MEMBERS.

The CHAIRMAN then formally welcomed the new members of Executive—Messrs. Burley and Cowie, Edinburgh; Gilmour, Dunfermline; and Tocher, Dumfries—who thanked the Executive for the welcome accorded to them.

APPOINTMENT OF COMMITTEES.

The CHAIRMAN intimated that the next business was the appointment of the General Purposes Committee.

Mr. RUSSELL here raised a question on a point of procedure. He asked who was responsible for the billet of the meeting, and having been informed that it was the retiring Chairman, he pointed out that the Chairman's position terminated at the expiry of the year.

The ASSISTANT-SECRETARY, however, said the Chairman of the Executive held office till his successor was appointed, and

Mr. EWING said the Assistant-Secretary could himself call an Executive meeting at any time that might be desired.

Mr. RUSSELL asked if it was the Council which was to conduct the affairs of the Executive or was the Executive to conduct its own affairs? He quite saw that the Assistant-Secretary acted as such to the Council and the Council provided them with his services, but it must be the Executive which determined the manner in which its business was conducted.

After some discussion,

Mr. GILMOUR moved that the Chairman, Vice-Chairman, and resident members of the Executive be appointed a General Purposes Committee to attend to any business arising between meetings of Executive or remitted to them by the Executive.

Mr. FISHER having seconded the motion, Mr. RUSSELL said, in order to raise his point, he would move as an amendment that they do not appoint this Committee. It had always been determined beforehand that the business of the Executive should be conducted in a particular manner, and that, he thought, was going behind the Executive.

The amendment, however, was not seconded, and the motion was declared carried.

Mr. FISHER next moved, and Mr. MCLAREN seconded, that Mr. Currie be appointed a member of the Committee for the nomination of examiners in room of Mr. Kermath, resigned.

Mr. GILMOUR moved, and Mr. BURLEY seconded, that Mr. Ewing be appointed a member of the Committee.

It was then unanimously decided that the Chairman and Vice-Chairman, and Messrs. Bowman, Currie, Ewing, Kerr, Storrar, and Strachan be appointed a Committee for the nomination of Examiners and to consider any names that may be submitted to them, and to report to a meeting of Executive to be held prior to the meeting of the Council in November. It was also decided to continue to hold evening meetings of the Society in Edinburgh on the third Wednesday of each month from November to April inclusive, and it was remitted to the General Purposes Committee to arrange for an opening address and to take charge of the other meetings.

The Chairman, Vice-Chairman, and Messrs. Burley, Cowie, Currie, Johnston, and McLaren were appointed delegates to attend the Plymouth meeting of the British Pharmaceutical Conference in July.

LETTERS TO THE EDITOR.

NOTICE TO CORRESPONDENTS.—All Communications for the 'Pharmaceutical Journal' must be Addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received, if specially arranged for, as late as Thursday morning. Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C., and Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

The Sale of Benzene.

Sir,—I have recently been paid a visit by one of the inspectors under the Petroleum Acts. He gave me to understand that in future I must not retail benzene for cleaning purposes in small quantities, only in bottles which I must obtain from my wholesale house. Since then I have been informed it is compulsory that the bottles, in addition to the name and address of the bottlers being upon them, must also have my name and address affixed as the seller. Can you tell me if this is correct?

East Dulwich, June 24, 1899. F. W. Sandy.

*** The subject of this letter is commented on at page 14.—[Ed. *P.J.*].

What is a Profession?

Sir,—When one considers the interpretation of the words "profession" and "trade," it should not present any real difficulty to differentiate between the two. If a profession is something better and beyond mere trade, and the business calling of a pharmacist is held to be beyond a trade, the inference to be drawn is that pharmacy is professional, since its work is of a technical and professional nature. A youth bent on a pharmaceutical career must spend three years compounding medicines, but he has not done then; in fact, he has done very little indeed towards his training. He must find money and brains for a college training, and after fagging hard for some months, and I may say some years (in some cases), he must present himself for his Minor, and when he has done this and qualified, must it not appear more than a grievance to know that, after all his expenditure and study, his social status is equivalent to that of a grocer or a draper? That the calling of a pharmacist is a profession no one can deny. The pharmacist is guilty of conduct of a retrograde nature, and I may say of such a nature calculated to lower his standing and also to deprive him of that respect and sympathy due to him from the general public. As one passes through the back streets in large manufacturing towns one sees in the windows of little shopkeepers bottles labelled "sweet nitre," tincture of rhubarb, Epsom salts, syrup of squills, etc., and a host of medicaments. Who is to blame for this? Does this kind of thing tend to improve the social standing of the true pharmacist? These little shopkeepers would not undertake the sale of these drugs (being ignorant of their composition), but the "wholesale druggist" assures them of the profit attending these drugs, and this is an inducement to sell. Now, Sir, the majority of people reason that if these little shops sell drugs, and the bigger shops sell drugs, both are chemists. I have read articles in the Journal to the effect that all drugs should be sold by the pharmacist. If the "wholesale druggist" would confine the sale of drugs to the pharmacist, then the latter would not be bracketed socially with ordinary tradesmen. The medical profession is spoken of as a sister profession—so it should be, but the existing feeling between the two is no proof. Is it not well known that the majority of the members of the medical profession treat the pharmacist much the same as they do grocers? The Pharmaceutical Society has helped the Medical Council in the matter of company trading, and it is only natural that the latter body should work side by side with the Pharmaceutical Council in helping to raise their status as a professional body, instead of which they "decline respectfully," fearing rebuff. In face of all these grievances, why do not the members of the Pharmaceutical Society demand what is just and legal independently? They are a strong body, and as professional men they should enjoy the privilege their qualification gives them, and distinguish between the individual who practises pharmacy and the drysalter who is the tradesman pure and simple.

Sheffield, June 20, 1899. B. Ellis.

The National Photographic and Allied Trades' Exhibition, 1900.

Sir,—Will you kindly permit me to announce through the columns of your valuable Journal that the second Trade Exhibition of Photographic and Scientific Apparatus and Sundries will be held early next year. The Portman Rooms, Baker Street, London, W., have again been secured, and the exhibition will open on Friday, April 27, and close Saturday, May 5. Arrangements have been made for increased space, and some thirty or more stalls, in addition to the spaces occupied last year, will be available for exhibits. The entertainments, lectures, and musical arrangements, which proved so attractive on the last occasion, will be repeated, and special attention is being given to this department in order to make the exhibition, if possible, even more attractive to the outside public. The magnificent suite of rooms are specially adapted to a display of technical apparatus, and the Portman Rooms are easily accessible from all points of the Metropolis. Any suggestions from your readers will be much appreciated and, if practicable, will probably be adopted. Most of the firms who exhibited last year have already intimated their intention to again take space, and several firms have also expressed a desire to be represented. The prospectuses and application forms for space will be issued shortly, and space will be allotted strictly in rotation as applications are received, the only exception being that former exhibitors will have first refusal of the spaces previously occupied by them. I trust that an early announcement of these dates will prevent clashing with any other exhibition, and that exhibitors will thus be free from the inconvenience of having two displays to attend to at the same time. It is of the utmost importance that intending exhibitors should reply to the prospectus immediately upon receipt of same, in order to avoid disappointment.

15, Harp Alley, Farringdon Street, London, E.C., June 21, 1899. Arthur C. Brookes, *Secretary.*

Chemists and the Southport Election.

Sir,—You have several times alluded to the action of the chemists of the Southport Parliamentary division in the recent bye-election, and though you commend them for their activity, you believe they were wrong in selecting and recommending one particular candidate when both replied favourably to the questions put by the deputation. I think it desirable that the circumstances should be briefly explained for the information of those who may soon have an opportunity to press the questions involved in prospective legislation on the practice of pharmacy upon their would-be representatives. In the first instance it was decided to strenuously oppose one of the Lord Chancellor's Bills and to endeavour to amend the other as we wished, and to do our utmost to secure the return of the candidate who would best represent our interests in Parliament. The unsuccessful candidate replied to our questions favourably, provided "the selling of poisons by unqualified persons would be prevented and the status of chemists be raised," but though the difference between "selling" and "keeping open shop for the sale of" poisons had been explained to him, he appeared to evade the point. This, taken in conjunction with the drift of his questions and the general tenor of his remarks at the interview, impressed every single member of the deputation with the belief that his sympathies were not wholly with us. Sir George Pilkington, on the other hand, was perfectly familar with the subject, and outspokenly pledged himself in most definite terms, not only to do his best to fulfil our wishes, but to keep a watchful eye on legislation affecting the interests of pharmacy. He objected to the assumption of titles belonging to individuals by unqualified com-

panies, and to any legislation which would tend to crush cut the individual chemist and bolster up company monopoly. These being the circumstances, I maintain the Southport chemists were right. The decision arrived at by the deputation was unanimcus; not one of the twelve dissented. On the general question as to whether or not it is wise to select a candidate, I am convinced it should be done unless both candidates are so nearly equal in their attitude that there is no room for choice. I fail to see the advantage to be obtained from interviewing the candidates in the heat of a contested election unless we endeavour to obtain definite pledges, and to do that we must be prepared to give or withhold our votes. Nor need we fear disfavour from the new member if he happens to be the man we opposed. It is certain that the votes of a hundred or more constituents who have the courage of their opinions and will give effect to them on the polling day will be valued more than those of men who appear to be wanting in backbone, and it will not be forgotten that those votes may be useful in another election.

Liverpool, June 26, 1899. JOHN SMITH.

The Question of Title.

Sir,—It is interesting to read Mr. W. J. Rawling's letters which have been published in the Journal. He appears to be possessed of light and common sense on the one hand, but to show darkness and ignorance on the other. The former is readily seen in his statement of the case; the latter in his remarks on the constitution of the Council and on the members of the Society. Have not the whole affairs of the Society for the past seventeen years been practically over-ruled by the President and Secretary? Has not the presidential chair been filled for the same period by men who contravene the spirit and letter of the 1868 Pharmacy Act? What, and how many, members of the Council at the present day are violating the spirit and letter of the Pharmacy Act? How stupidly blind the members of the Society are to place on the Council men whose first interest is in the wholesale trade, who belong to "limited" drug businesses, who carry on business under dead men's names, are in league with outside proprietors, nostrum-mongers, and grocers' associations! Would it not be absurd in the extreme to expect these men to go against their personal interests? Can retail pharmacists expect any petition for a remedy of their grievances to receive from that Council any other reply than *Non possumus*? Let the Council be constituted of retail pharmacists. Is not a man out of place on that Council who is a member of a wholesale drug house or a member of a limited liability drug company with outside capital, or one who carries on business under an unregistered name? Should not such persons resign their seats on the Council forthwith and be struck off the Register of members for conduct derogatory to and subversive of the best interests of the Society? What is required in the present day is a Cromwellian President, and a Council of good men and true, who will go straight for our legal rights on the points of justice and equity. The whole evil of unqualified company pharmacy arises out of the action of the Secretary of the Board of Trade granting certificates to unqualified persons to carry on company pharmacy in contravention of the 1868 Act, made and provided for public safety. If the Secretary of the Board of Trade is not bound by the provisions of the Pharmacy Act, 1868, neither is any other person. If seven or more unqualified persons can get a certificate for pharmacy, why not anything else, any other Act notwithstanding? If so, then the Secretary of the Board of Trade is above any Act of Parliament and those who make the Acts.

Sheffield, June 24, 1899. G. ELLINOR.

Detection of Methyl Alcohol.

Sir,—During the preparation of some liquor calcis saccharatus, a bottle was used which had contained methylated spirit, but which had been washed until it smelt quite clean. On the addition, however, of the lime, sugar and water, the odour of the methyl became very apparent. On trying this with some methylated spirit, the odour of which had been sweetened by shaking up with animal charcoal, the same effect was produced on the addition of the liquor calcis saccharatus. This seems to me to be a useful means of detecting the methyl in preparations containing it. The above operation was carried out in the laboratory of Mr. F. H. Allcock, of Birmingham, and it is at his suggestion that I venture to send this letter to you.

Lichfield, Staffs, June 26, 1899. FRANK OAKLEY.

Unqualified Opinion.

"A DOWN-TRODDEN CHEMIST" (191/38) replies to the letter of "Qualified" (see *P.J.*, June 17), but no good purpose can be served by publishing anonymous letters which introduce personalities.

Chemists and Dentists.

"J. T. S." (191/30) has a grievance against certain persons who, he alleges, "do all kinds of dental work under the cover of the title 'chemist,'" and suggests that the Council of the Pharmaceutical Society should take action against them under Section 26 of the Pharmacy Act, 1868. As it happens, however, the Privy Council alone is competent to put that Section in force.

The Company Trading Question.

"ASSISTANT, M.P.S." (192/2) sends a letter on this subject, in which he makes a charge that would require, at least, to be authenticated by the publication of his name.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Botanical (E. P.—30/26)—Buckbean or bogbean, *Menyanthes trifoliata* (Gentianaceæ).

Prescription (T. G. W.—30/34).—East Indian oil is intended, *Ostindien* being the German for East Indies.

Water Softener (B. & Co.—30/24).—Mix slaked lime, 1, and dried sodium carbonate, 2, both in fine powder.

Terebene (L. O —30/27).—You will find articles on the subject in the *Pharmaceutical Journal* [3], **16**, 611; **17**, 124, 274, 275.

Gray's Supplement (E. B.—30/30).—You might dispose of it if you advertised it in the *P. J.* "Exchange." We cannot say what price the book would command.

Veterinary Surgeon (A K. M. L.—30/28).—We have no information on the subject, and would suggest that you should apply to someone in the profession.

Sale of Non-Alcoholic Drinks (T. G. W.—30/33).—Unless you have a refreshment house licence you must not sell non-alcoholic drinks after 10 o'clock at night or before 5 o'clock in the morning. It is also illegal to sell refreshments of any kind during prohibited hours, *i.e.*, the hours during which licensed public-houses must be closed.

Lead Intensifier (E. C.—30/19).—Your trouble with the lead intensifier, as modified by Hirschfeldt (see last volume, p 492*e*), may be due to the use of common tap water or, more probably, your negative was not sufficiently washed free from hypo. Making the solution slightly acid with nitric acid ought to prevent the deposit. Thanks for your expressions of appreciation.

Manufacture of Indiarubber (J. E. M.—30/7).—The crude caoutchouc, as imported, is first cleansed by being cut into small pieces, washed with water, and then dried. The purified product is next ground or kneaded with water by special machinery, during which process a heat is evolved, both rubber and water becoming very hot. The kneaded mass is then ground dry in another machine, with a little lime, when it finally assumes the brown ductile appearance as met with in "stationers' rubber."

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

COLOURING MATTERS OF DYER'S BROOM AND HEATHER.

A. G. Perkin and F. G. Newbury find that *Genista tinctoria* contains two colouring matters, the first identical with the luteolin of weld (*Reseda luteola*), and the second, a new colouring matter, *genistein*. The latter has a composition corresponding to the formula $C_{14}H_{10}O_5$, colourless needles, and yields an acetyl derivative, $C_{14}H_7O_5(C_2H_3O)_3$, m.p. 197—201°, and a tetrabromo-compound, $C_{14}H_6Br_4O_5$, colourless needles melting above 290°. On decomposition with alkali, it gives phloroglucinol and an acid of the formula $C_8H_8O_3$, m.p. 147—149°; this, with fused alkali, forms parahydroxybenzoic acid, and appears to be *parahydroxyphenylacetic acid*. *Genistein dimethylether*, colourless leaflets, m.p. 137—139°, is insoluble in alkaline solutions, but forms a *monacetyl derivative* of the formula $C_{14}H_7O_3(OCH_3)_2.Ac$, fine needles, m.p. 202—204°. A second product of the methylation, formed in minute quantity, melts at 187—189°, and appears to be isomeric with the above ether. In dyeing property, genistein closely resembles apigenin and vitexin, and to it the constitution of a *trihydroxyphenylketocumaran*, $(OH)_2.C_6H_2\langle{}^{\cdot O\cdot}_{CO}\rangle CH.C_6H_4(OH)$, has been provisionally assigned. The colouring matter of heather, *Calluna vulgaris*, is quercetin, and there is also present a catechol-tannin in small quantity.—*Proc. Chem. Soc.*, **15**, 179.

COLOURING MATTERS OF COTTON FLOWERS AND KAMALA.

A. G. Perkin also finds that the flowers of the cotton plant, *Gossypium herbaceum*, contain as glucoside a new colouring matter, *gossypetin*, $C_{16}H_{12}O_8$, soluble in alkalis with an orange-red colour, becoming green on oxidation. The *hexacetyl* compound, $C_{16}H_6O_8Ac_6$, colourless needles, m.p. 212—216°; the *sulphate*, $C_{16}H_{12}O_8,H_2SO_4$, the *hydriodide*, $C_{16}H_{12}O_8,HI$, orange-red needles, and the *monopotassium* salt, $C_{16}H_{11}O_8,K$, a crystalline powder, have been prepared. Gossypetin contains no methoxyl groups, and on fusion with alkali yields phloroglucinol and protocatechuic acid. It is probably a member of the flavone group of colouring matters. Gossypetin is similar to, but not identical with, thujetin, which is present in *Thuja occidentalis*. In a note on rottlerine, the same investigator states that the decomposition products of rottlerine, $C_{33}H_{30}O_9$, a colouring matter of kamala, *Mallotus phillipinensis*, previously described (*P.J.* [3], **24**, 159; *Trans. Chem. Soc.*, **67**, 230), are with fused alkali acetic and benzoic acids, and with nitric acid *o*- and *p*-nitro-cinnamic acids. It is now found that fused alkali at 220—240° yields also phloroglucinol.—*Proc. Chem. Soc.*, **15**, 161.

THE MACLAGAN TEST.

In reference to the statement by Dr. Fr. Günther that a salt of pure cocaine does not answer to the Maclagan test, and that the formation of a crystalline precipitate in that test is due to the presence of another base melting at 111° C., Messrs. Boehringer and Son point out that it amounts to saying that all cocaine which answers the test is impure and contains the other base to which Günther refers. They have therefore endeavoured in various ways to obtain evidence of the existence of that base in a large quantity of coca leaves operated upon especially for that purpose. One portion of the crude basis obtained was treated so as to ascertain the presence of an ethyl-alcohol residue, with a negative result. Another portion was converted into hydrochloride by partial neutralisation and re-crystallised in fractions, as directed by Günther, while the mother liquors of cocaine hydrochloride were also subjected to the same treatment. The only instance in which any evidence was obtained of a base having a higher melting point than cocaine was in the mother liquor of cocaine hydrochloride which yielded a very small quantity of base, melting at 104° to 106° C. Examination of the mother liquors obtained in the synthetic preparation of cocaine and of ordinary commercial cocaine salts, as well as chemically pure cocaine prepared from benzoylecgonine and pure methyl alcohol, gave similar results. No base melting at 111° C. could be obtained, and the extremely small quantity (0·00006 per cent.) of the base melting at 104° to 106° C. was quite insufficient to account for the crystalline precipitate in Maclagan's test, for in place of obtaining 20 kilo. in ten weeks, Messrs. Boehringer estimate that they would not obtain a kilo. in the course of a year, and they therefore conclude that the objections made to the Maclagan test are quite destitute of foundation.—*Pharm. Centralh.*, **40**, 393.

CHANGES IN CELLS OF DROSERA TENTACLES.

Miss Lily H. Huie has continued her observations on the changes produced in the tentacles of *Drosera* by feeding them with various food-materials. She finds that very characteristic alterations are obtained both in the colour reaction and in the morphology of the cell. In five seconds white of egg causes both the cytoplasm and the nuclear plasm to become more eosinophil, while pure amphopeptone increases their susceptibility to blue stains. White of egg quickly causes great impoverishment of the cytoplasm and nucleoplasm, while the first effects of pure peptone are to increase the bulk and density of these ingredients of the cell. They both give rise to an enormous increase in the chromatin element of the nucleus. While the cytoplasm is the constituent of the cell that is most rapidly and most constantly affected by external stimuli, the nucleus is the seat of metabolic activity, and the state of the nuclear organs indicates whether or not the food-supply was of service to the metabolism of the plant.—*Quart. Journ. Micros. Science*, **42**, 203.

PHYSIOLOGY OF GRAFTING.

M. L. Daniel distinguishes two stages in the anatomical processes which take place in grafting herbaceous or woody plants—the preliminary and the definitive stages. The former stage extends up to the moment when the functions of the outer and inner generating layers, interrupted by the operation of grafting, are resumed. The definitive stage may again be divided into two periods—the formation of the cellular tissues which fill up the vacancies caused by the wound, and the differentiation of the vessels and sieve-tubes in the healing tissues produced by the activity of the inner generating layer, and the formation of bark and phelloderm.—*Bonnier's Rev. Gén. de Bot.*, **11**, 78.

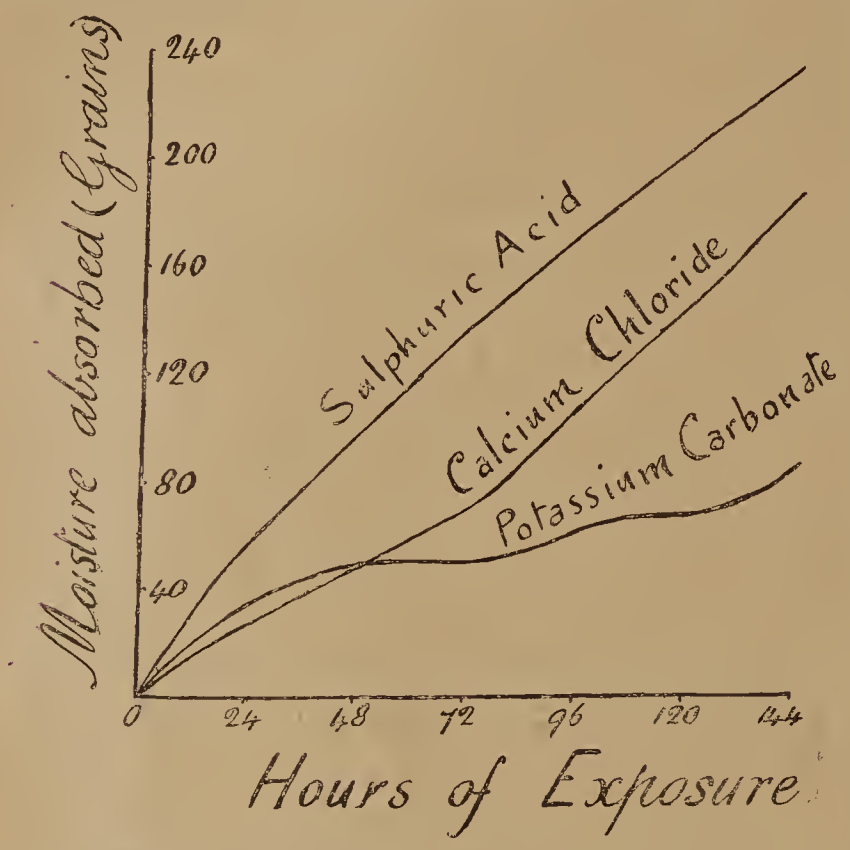
BIOLOGY OF POLLEN.

Further evidence is adduced by Herr B. Lidforss in favour of his view that moisture is not necessarily destructive to the germinating power of pollen-grains. The power of resistance of pollen-grains to moisture is much influenced by the surrounding conditions, and is greatly increased in moist air. The connection between the exposure of the pollen and its power of resisting moisture is illustrated in a large number of cases. As a general rule, those pollen-grains which are unable to resist moisture germinate very rapidly. The pollen-grains of anemophilous plants are, as a general rule, characterised by their comparatively small size. The proportion in them of starch is usually smaller, that of nitrogenous substances larger, than in the pollen of entomophilous plants.—*Pringsheim's Jahrbucher*, **33**, 232.

A NOTE ON DESICCATING AGENTS.

BY W. ELBORNE, M.A.

The relative behaviour of three substances (sulphuric acid, sp. gr. 1·843, fused calcium chloride, and dry potassium carbonate) commonly used in desiccators as drying agents—that is, substances used for absorbing aqueous vapour from the superincumbent air—is illustrated by the following curves. Equal weights of the respective substances were simultaneously exposed under similar conditions to the action of the atmosphere of the laboratory, and their respective increase in weight (regarded as being due to absorption of moisture) frequently ascertained. The horizontal numbers (abscissæ) indicate in hours the duration of exposure, the ordinates, or vertical numbers, the increase of weight in grains. Of the three, sulphuric acid is the most efficient agent.



Quantity of substance taken (in grains).	Approximate weights per 24 hours during exposure.					
Sulphuric Acid 258	315	356	397	432	464	494
Calcium Chloride 258	285	307	331	368	406	448
Potassium Carbonate 258	293	308	310	322	328	345

A NOTE ON THE PHARMACOPŒIA TEST FOR ADEPS LANÆ.

BY W. ELBORNE, M.A.

Operating upon one of the best brands of Adeps Lanæ on the market, the melting point was found to be 38°C (uncorr.), specific gravity compared with water at the same temperature 0·913 at 45°C. 50C.c. of the melted wool-fat poured into 100C.c. of ether sp. gr. 0·720, and the mixture heated to boiling yielded a clear solution; on setting aside in a tall glass cylinder to cool, at 15°C. it became very turbid, and after the lapse of four hours the sediment occupied half the total volume, the supernatant liquid being clear and bright. The official test says, "readily soluble in ether." . . . "10 grammes. dissolved in 25C.c. of ether, etc."—heat is required to effect a clear solution. Wool-fat is certainly very soluble in chloroform—"the solution in chloroform poured gently over the surface of sulphuric acid acquires a purple red colour"; in this form the test is not very striking, but, when performed in a different way, an additional phenomenon occurs constituting a delicate and characteristic reaction for Adeps Lanæ, either alone or mixed with other ointment bases. The procedure is as follows:—To the solution in chloroform contained in a test-tube gently and slowly add an equal volume of sulphuric acid; within two or three minutes the latter (the lower acid layer) assumes a beautiful green fluorescence by reflected light, in intensity proportional to the wool-fat present; the chloroformic layer assumes a blood-red colour by transmitted light, best seen at the junction of the liquids. This green fluorescence is due to the cholesterin of the wool-fat, and, in fact, is a known characteristic reaction of cholesterin itself (in chloroformic solution).

Adeps Lanæ, worked into a paste with sulphuric acid, assumed a very dark red colour; the mass subsequently kneaded in running water until free from acidity "appeared" not to have suffered at all by the treatment, yielding a yellowish-white product sensibly indistinguishable from Adeps Lanæ Hydrosus. 50C.c. of melted wool-fat poured into 500C.c. of light petroleum (b.p. 60°C.) and the mixture warmed to 20°C. afforded a clear solution; on cooling to 15°C. it became cloudy, and ultimately afforded an abundant sediment. Dried wool (direct from the fleece) exhausted with such hot light petroleum, yielded 31 per cent. of fat.

THE VALUE OF CONCENTRATED FOODS.

In the second Baillie lecture, delivered at St. George's Hospital by Dr. W. Howship Dickinson on the 18th ult., the subject of "Concentrated Foods" was dealt with by the lecturer in the following terms:—"I might make a short chapter like that 'Concerning Snakes in Iceland,' and say that there are no such things. For 'human nature's daily food' are required certain weights of nitrogen, carbon, oxygen, and hydrogen which are ultimate forms of matter and not capable of concentration or further reduction to essential principles. An ox cannot be got into a teacup by any other process than by leaving the greater part of the animal outside. The stomach of the average man demands every twenty-four hours twenty-one grammes of nitrogen, or about three-quarters of an ounce; 307 grammes of carbon, or about eleven ounces; twelve grammes of hydrogen, not quite half an ounce; besides sulphur and salts. This is required to make up for the waste—to restore what leaves his body in various shapes. Three-quarters of a pound of carbon cannot be got into less than three-quarters of a pound. The nutritive effect cannot be separated from the bulk. The man must have his pound of flesh. He has to find fuel and to replace waste—charcoal to burn and nitrogen for repairs. If he does not get the necessary poundage he will dwindle, peak, and pine. His account of profit and loss must be adjusted according to weight. A drachm of Liebig's extract cannot supply more than a drachm. Quality cannot supply the place of quantity. The chief nourishers of life's feast are not creatin and creatinin, but albumin, myosin. fat, gluten, starch, and sugar. None of these are capable of being administered otherwise than in their natural bodies and corporeal bulk. A sick person who is presented with Valentine's food in teaspoonfuls when he should have milk in pints has as much right to complain as I should have if I were to ask for a steak in the luncheon-room and be put off with a minute quantity of Liebig out of the shop. I might object that whatever the virtues of the Liebig it was not filling at the price. But we cannot reckon concentrated extracts as entirely useless, though they are not, properly speaking, food. They contain little or no albumin—some little, some none—no fat, and of the vegetable carbohydrates none. They contain salts and extractives which may be accessories to food, but are not food itself. Perhaps they may be regarded as complementary or supplementary to the essentials of food, and may in special circumstances have special use. I have long been in the habit of using them to help to make up for the loss by suppuration, and so prevent or re-

tard the consequent lardacity. So far as pus carries off the salts meat extracts cannot fail to supply the means of replacing them. These extras are, of course, only to be employed as superadditions to a diet abundant in other respects, not as substitutes for any part of it. They cannot take the place of nutriment in bulk. Beside their power of supplying salts and extractives which under special circumstances may be wanting it is supposed that they have some stimulant action. But the utility of concentrated foods has been greatly exaggerated in practice; they are additions to the essential diet, not substitutes for it. It is possible that a pennyworth of milk may be worth more to the patient than a shillingsworth of Liebig's extract."—*Lancet.*

AUSTRALIAN INDIGENOUS VEGETABLE DRUGS.*

BY. J. H. MAIDEN,

Government Botanist and Director of the Botanic Gardens, Sydney.
(Corresponding Member of the Pharmaceutical Society of Great Britain.)

PART II.

CORNACEÆ.

Marlea vitiensis, Benth.

"Preparations of this plant apparently kill frogs by bringing the heart to a standstill in diastole. Motor nerves and muscles are unaffected if death takes place rapidly, but if delayed they are found in a state of paralysis. This paralysis is due, in part at any rate, to stasis of blood circulation, for the heart beats very feebly from an early period of the poisoning. Vomiting is a remarkable symptom.

"Frogs, when poisoned with this substance, become less irritable to a stimulus of any kind. The active principle is an alkaloid, easy of preparation. It is insoluble in chloroform, ether, benzine, and turpentine, slightly soluble in water and in aqueous alcohol. So far I have not been successful in getting it or any of its salts in a crystalline form. It appears not to be emetine, although it probably belongs to the group of poisons of which emetine is the type." (Dr. T. L. Bancroft, *Proc. Linn. Soc., N.S.W.* [2], iv, 1062.)

Queensland.

GOODENIACEÆ.

Goodenia spp.

A species of Goodenia is supposed to be used by the native gins to cause their young children to sleep while on long journeys, but it is not clear which is used, or how it is administered. (Bailey.) Many plants of this Natural Order contain a tonic bitter which does not seem to have been critically examined. Perhaps in the possession of this bitter principle affinity to the Gentianeæ is indicated, as suggested by Mueller many years ago.

Dr. Thomas Bancroft informs me that this genus is physiologically inert, or practically so.

Throughout the Colonies.

CAMPANULACEÆ.

Lobelia purpurascens, R. Br.

I have a note in the *Agricultural Gazette* for July, 1894, p. 473, on this plant as a reputed antidote for snakebite, to which reference may be made. I asked for scientific evidence in this matter, but have received none.

All the Colonies except Western Australia and Tasmania.

EPACRIDEÆ.

Astroloma sp., near *dilatata.*

Dense shrub, 2 ft. 3 in. high, at King George's Sound, Western Australia. Called "Native Sarsaparilla," having much the taste of that plant. The decoction, which is thick and black, and of a sweet taste, acts powerfully on the urinary organs. Various other medicinal properties are attributed to the plant, but they require confirmation. (Oldfield.)

Western Australia.

* From the *Agricultural Gazette of New South Wales.*

PLUMBAGINEÆ.

Plumbago zeylanica, Linn.

In India, a tincture of the root-bark has been employed as an antiperiodic. Dr. Oswald states that he has employed it in the treatment of intermittents with good effect. It acts as a powerful sudorific. (*Pharm. of India*) It is a common medicine for dyspepsia in India. It is also frequently used as a poultice for abscesses, etc.

New South Wales to Northern Australia.

MYRSINEÆ.

Ægiceras majus, Gærtn.

The River Mangrove. The bark has an extremely nauseating, acrid taste due to saponin, which is present in large amount. (T. L. Bancroft.)

New South Wales to Northern Australia (coast only).

SAPOTACEÆ.

Achras laurifolia, F.v.M. (Syn. *Sideroxylon richardi*, F.v.M.)

This bark has a remarkably sweet taste, but is at the same time astringent. Dr. J. Bancroft suggests that lozenges made of an extract of it might prove useful in throat diseases. Following is a proximate analysis by Mr. Staiger:—

Extract (containing glycyrrhizin)	30.0
Tannin	12.0
A substance intermediate between indiarubber and gutta-percha	0.25
Woody fibre	50.0
Moisture	7.75

New South Wales and Queensland.

Achras sapota, Linn. (Sapodilla Plum) and *Argania sideroxylon*, Rœm. and Schult (Argan tree) both belong to this Natural Order. From the latter S. Cotton (*J. Pharm.* (v.) 18, 298) has separated a glucoside, arganin, apparently identical with Michaud's sapotin from the same plant. From the kernels of the former an alkaloid, sapotine, has been separated by Bernon. (*See* Sohn. 1.)

JASMINEÆ.

Chionanthus picrophloia, F.v.M. (Syn. *Mayepea picrophloia*, F.v.M.)

The intensely bitter bark of this tree may be administered in intermittent fevers.

Queensland.

APOCYNEÆ.

Alstonia constricta, F.v.M. "Fever Bark"; "Bitter Bark."

This yellowish-brown, often thick and deeply-fissured bark, is intensely bitter, and possesses valuable febrifugal and tonic properties. It is regularly quoted in London drug lists. A decoction is sometimes sold in the colonies as "bitters." Mr. Christy states that it is used by some English brewers of pale ale for export, as it produces neither headaches nor other ill effect of hops. I have heard of its use by foreign brewers. It tastes remarkably like cinchona bark, and seems to partake somewhat of the properties of both quinine and strychnine. This drug is undoubtedly worthy of careful experiments by medical men. (See *A. scholaris.*)

From a pamphlet prepared by Dr. Joseph Bancroft, of Brisbane, for the Colonial and Indian Exhibition, 1886, I cull the following particulars in regard to his observations. He obtained the bark from near Dalby, Queensland, some time after 1868. "It gives out to water and alcohol a yellowish principle, intensely bitter, and not easily made to assume any crystalline form. When the tincture is poured into water, the mixture becomes fluorescent, and excepting a slight yellowness, is not easily distinguished either by colour or taste from a solution of quinine. Its utility as a general tonic is established beyond all doubt. Indeed, if any powers are left, a debilitated stomach will respond to Alstonia. Alstonia has been used in the earlier stages of typhoid fever with considerable success. No unfavourable symptoms are produced by it, but patients complain of a bitter taste in the mouth, remarking that they consider themselves bilious. After fifteen years' experience of the use of Alstonia,

the writer is of opinion that there is no better or more generally useful tonic. The tincture made with 3 oz. of the bark to a pint of proof spirit is the form generally used, the dose being from five to ten drops. The powder in grain doses, made up with extract of liquorice, forms a convenient tonic pill. An alcoholic extract made by Mr. Staiger is a much more powerful remedy, but experiments are wanting to determine its special utility."

This action of *Alstonia* bark is described in a letter from Dr. A. W. Bixby to the *Therapeutic Gazette* (Detroit, U.S.A.), December, 1880, p. 369, as follows:—*Alstonia constricta* (F.v.M.), has a wide range of application and action as a medicine. Its action resembles in many respects the combined action of quinine and nux vomica. It is an antiperiodic of the highest type, giving better satisfaction, to my mind, than quinine or cinchonidine. It is a cerebro-spinal stimulant and tonic; acts positively upon the great sympathetic nerve centres, and consequently increases positively and permanently the vital forces of the entire system. I prepare the system for its use by the administration of the proper sedative; then *Alstonia* seldom fails. Where quinine fails in chronic cases, *Alstonia* often effects a speedy cure." He further states:—"In typhoid, synochal, and puerperal fevers, where an antiseptic and nerve tonic is demanded, it answers well. I used it in the treatment of about seventy-five such cases last fall, and with the happiest results. In recent colds or coryza it is an excellent remedy.

"At the beginning of an attack of this annoying trouble two grain doses of the powder every two hours gives prompt relief. The whole system is soon reinvigorated; the secretions and excretions, which have been more or less suppressed, are re-established, and the patient is all right and feels well." He concludes:—"I believe it will become a favourite with all who test it."

I have heard that the bark of *A. constricta* has been used as a remedy for worms in sheep with splendid results.

The bark contains, according to C. Palm, *Kopp u. Will Jahresb.*, 1863 ("Rinde eines australischen, der Familie der Apocyneen angehörenden Baumes"). Wolff, *Aschen Analysen*, i., 128.—A neutral resinous bitter principle, called by him *alstonin*, similar to *cailcedrin* and *tulucunin*, a volatile oil, smelling like camphor, an iron-greening tannin, gum, resin, fat, wax, protein substance, oxalic acid, and citric acid. The ash amounted to 6.06 per cent. of the bark, and an analysis of it is quoted in Watts' *Dict.*, vi., 1st suppt., 101.

Mueller and Rummel, in Wittstein's *Organic Constituents of Plants*, gives the following account of *Alstonin*, the alkaloid of the bark of *Alstonia constricta*:—"*Alstonin* differs from *ditamine* chiefly by its behaviour towards concentrated acids, and by its fluorescence, which has not been recorded of the other alkaloid."

The correctness of the above results has been disputed by Hesse, who expressed the opinion that the supposed alkaloid was a mixture of *chlorogenine* and *porphyrine*. (*Ber.* 1878, p. 2175.)

In June, 1879, Oberlin and Schlagdenhauffen* announced the isolation of two alkaloids from this bark, a crystallisable and an amorphous one. They found the bark to be soluble in ether to the extent of 1.038 per cent., and to this ethereal extract their attention was confined. In *Pharm. Journ.* [3], ix., 1059, is an abstract of their paper, and an account is given not only of the method of preparing these alkaloids, but also of their physical and chemical properties. The crystalline alkaloid occurring in silky tufts of brilliant, colourless, isolated, or stellate crystals, is styled *alstonine*†, while an amorphous nitrogenous residue, possessing alkaloid properties, obtained by spontaneous evaporation from the mother liquor, which yielded *alstonine*, is provisionally termed *alstonicine*.

In 1881 an exhaustive research on this bark was contributed by Hesse to the *Annalen der Chemie*, ccv., 360, of which a careful abstract appears in the *Pharm. Journ.* [3], xi., 775. Palm's *alstonin* (notwithstanding the alleged absence of nitrogen) was shown by Hesse to consist essentially of an alkaloid which he had obtained from the bark, and called *chlorogenine*; but as Palm's name had priority, Hesse called the alkaloid *alstonine*; but unfortunate confusion has arisen in Mueller and Rummel and Oberlin and Schlagdenhauffen (*vide supra*) also having given so descriptive a name to substances of different composition. The abstract above referred to gives a very lucid account of the overlapping of various researches, and shows how the different products obtained by different observers may be reconciled. After this necessary preliminary statement, Hesse gives a full account of the preparation and properties of the alkaloids found by him. They are:—

1. *Alstonine* (synonymous with *chlorogenine*, and probably identical with Palm's *alstonin*). It is a brown, amorphous mass, which can be rubbed to a brownish-yellow powder. Merck (*Bulletin*, i., 5) speaks of this alkaloid as forming white, lustrous, silk-like crystals, easily soluble in ether, chloroform, or alcohol. It is nearly insoluble in cold water, somewhat soluble in hot water, to which it imparts an intensely bitter taste. It is an antiperiodic, antiseptic, and stimulant, thus uniting the properties of quinine and strychnine. It is employed in typhoid and lacteal fevers.

2. *Porphyrine*, a white powder found in very small quantity.

3. *Porphyrosine*, the examination of which is not yet complete.

4. *Alstonidine*, consisting of colourless, concentrically grouped needles.

Hesse believes that this list by no means completely enumerates the alkaloids obtainable from this interesting bark.

Hesse has since worked at the bark, and it is to him that we mainly owe our accurate knowledge of its constituents and derivatives. It is one of the very few Australian barks which have, up to the present, been exhaustively examined. For a list of his researches on the subject see p. 21 of my "Bibliography of Australian Economic Botany." (1892.)

There is also a paper in *Annalen der Chemie*, ccv., 360—371, abstracted in *Year-book of Pharmacy*, 1881, p. 172.

There are a few references in more recent medical and pharmaceutical literature.

The list of substances obtained from Alstonia barks (including *A. scholaris*) are enumerated by Sohn at pp. 7 and 108, and comprise the alkaloids Alstonine, Ditamine, Echitamine, Echitenine, Porphyrine, and Alstonidine; also the non-alkaloidal, non-glucosidal Echitin, the wax-like Echicerin, and the aromatic body Echiretin.

New South Wales and Queensland.

Alstonia scholaris, R.Br. "Devil Tree" of India; "Dita Bark."

The powerfully bitter bark of this tree is used by the natives of India in bowel complaints. (*Treasury of Botany.*) It has proved a valuable remedy in chronic diarrhœa and the advanced stages of dysentery. It has also been found effectual in restoring the tone of the stomach and of the system generally in debility after fevers and other exhausting diseases. (*Pharm. of India.*) It is officinal in the Pharmacopœia of India as an astringent tonic, anthelmintic, and antiperiodic. It is held in the highest repute in the Philippine Islands. For further information see Dymock (*Materia Medica of Western India*). Most writers who refer to it at all speak of it in terms of high praise.

See also Jobst (J.) and Hesse (O.) "Ueber die Ditarinde, *Annalen der Chemie*, clxxviii., 49; *Journ. Chem. Soc.*, xxix., 276; *Pharm. Journ.* [3], vi., 142; Watts' *Dict.*, viii. (1), 688." A later research by Hesse, "Ueber die Alkaloide der Ditarinde," will be found in *Annalen der Chemie*, cciv., 144; *Pharm. Journ.* [3], xi., 331. These two papers contain a full account of the chemistry of the bark.

Northern Queensland.

(To be continued.)

* *Journal de Pharmacie et de Chimie.*

† Probably Hesse's *porphyrine*.

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, JULY 5, 1899.

Present:

Mr. W. Martindale, President.

Mr. G. T. W. Newsholme, Vice-President.

Messrs. Allen, Atkins, Corder, Cross, Glyn-Jones, Grose, Harrington, Harrison, Hills, Savory, Storrar, Symes, Warren, and Young.

The minutes of the last Council meeting were read and confirmed.

The Inaugural Address.

The President announced that Prof. Leech, of Manchester, had kindly consented to deliver the inaugural address on October 2 next. Prof. Leech was the representative of the Victoria University on the General Medical Council, and one of the honorary members of the Society. He had taken great interest in the subject of the revision of the Pharmacopœia. They would have an excellent address from Prof. Leech, which he trusted the students would appreciate.

The President said he had received letters from Mr. Bateson and Mr. Park regretting their inability to be present. The latter said he was very much occupied with the arrangements for the forthcoming Conference, and expressed the hope that as many members of the Council as could make it convenient would attend the meeting.

Election of Members.

The following persons having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Alexander, John; Aberdeen
Bentley, Joseph; Barrow-on-Humber
Blakemore, John Bowen; Smethwick
Bright, William Henry; Bath
Cowley, Harry James; London
Davies, Philip Percival; Southsea
Drackley, Thomas; Market Bosworth
Dye, Charles Page; Marlow
Freeland, James; Dunoon
Goodwin, James; Atherstoue
Hall, Alfred William; Herne Hill
Harries, John Davies; Milford Haven
Heaton, Wallace Evans; Leyburn
Henderson, Andrew W.; Aberdeen
Hindmarch, Thomas Forster; Lytham
Howorth, Henry Cook; Hong Kong
Jenuings, Henry G. H.; Birmingham
Johnstone, William S. L.; Coventry
Jones, Stephen; Cardiff
Kaye, Alexander; Perth
Kershaw, James; Bradford
Milner, Jonah; Greenwich
Murray, Robert; Rhynie
Stavert, Walter; Selkirk
Taylor, John; Rochdale
Vernon, Walter; North Ormesby
Walker, George; Penang
Walter, William; Southampton
White, Herbert; Rock Ferry
Whitton, Andrew C.; Pietermaritzburg
Wildgoose, John G.; Nottingham

Election of Student-Associates.

The following persons having passed the First Examination, and tendered their subscriptions for the current year were elected "Student-Associates" of the Society:—

Cammell, Horace Watson; Hull
Chesworth, Colin Percy; Levenshulme
Daunt, Mary; Nottingham
Grout, Harry Fred.; London
Marsland, Alfred; Ashton-under-Lyne
Sampson, John William, Heckington
Thomson, Alexander; Aberfeldy
Venn, John Archibald; Devonport
Weiss, Richard; London
Whitehouse, Alexander; Nottingham

Restorations to Membership.

Several persons were restored to their former status in the Society.

The North British Branch Executive.

The Secretary read a letter received from the Assistant-Secretary in Scotland, reporting the election, on June 16, of the members of the Executive for the ensuing year. The names have already been published (see *P. J.*, June 24, p. 581).

Finance Committee.

The Secretary read the report of this Committee, which recommended various accounts for payment.

The President, in moving the adoption of the report and recommendations, remarked that the fees received for examinations were larger than usual and left the Society with a fair amount of cash in hand. The number of candidates entered for the examinations now going on in London and Edinburgh was altogether 663, which was, he believed, far in excess of any number recorded.

The motion was at once agreed to.

Benevolent Fund Committee.

The Vice-President moved the adoption of the report of this Committee, which included the recommendation of grants amounting to £65 in the following cases:—

A registered chemist and druggist (55), who has had one previous grant. He is a hopeless invalid, and dependent upon a sister who is in poor circumstances. (Edinburgh.)

The widow of an associate (49), who has had three previous grants. She is in ill health, and has no one to look to for assistance. (Towyn.)

A registered chemist and druggist (71), and occasional subscriber to the Fund. Has had five previous grants, and is now past work. (Liverpool.)

A registered chemist and druggist (43), who had a grant last year. He is suffering from spinal sclerosis, and is quite an invalid He has two children dependent. (Crayford.)

Widow of a member and subscriber (66), has had three previous grants. She has an invalid step-daughter dependent on her. (Motherwell.)

A former associate (44), who has had four previous grants, and requires assistance owing to having been without employment for some time past. (London.)

The Vice-President said there was nothing unusual to refer to, excepting that on this occasion there were two applications from North of the Tweed, both of which cases were relieved. This was unusual, and it was sometimes said that Scotland did not always get as much money as it ought, but he might say that whenever the Committee had a case from Scotland, it was always dealt with in the same liberal spirit as a case from anywhere else. The resolution was carried.

The Vice-President then moved that the name of Mr. S. R. Atkins be added to the Committee. Mr. Atkins had taken the very greatest interest in the work of the Benevolent Fund Committee, and if he were to remain off the list of members it would be a distinct loss to that Committee.

Mr. Cross seconded the motion.

The President, in putting the resolution, said they all knew the great interest which Mr. Atkins had taken in the Benevolent Fund. Mr. Atkins was known throughout the country as a representative pharmacist, and as one who took much interest in ascertaining the details of the necessitous condition of the candidates, and it would be a great loss to the Committee if he were not a member of it.

The resolution was carried.

Mr. Atkins, in thanking the Council for his election, said he had taken great interest in the work of the Benevolent Fund Committee, and should regret to be out of touch with it.

Library, Museum, School and House Committee.

The President moved the adoption of the report of this Committee, which stated that the Librarian had presented his usual report, including the following particulars regarding attendance:—

Attendance.	Total.	Highest.	Lowest.	Average.
May	400	24	7	15

Circulation of Books.	Total.	Town.	Country.	Carriage paid.
May	159	84	75	16s. 7½d.

Several donations to the Library and Museum had been

received (see *Ph. J.*, June 17, page 559), and the Committee had directed that the usual letters of thanks be sent to the respective donors.

Library.—The Committee recommended that the undermentioned Books be purchased:—

For the Library (London)—

De Tabley, Flora of Cheshire.
Solereder, Systematische Anatomie der Dicotyledonen.
Greenish, Materia Medica.
Whitla, Pharmacy, 7th Edition.

For the Library (Edinburgh)—

Greenish, Materia Medica.
Whitla, Pharmacy, 7th Edition.

Museum.—The Curator's report had also been received, and included the following particulars:—

Attendance.	Total.	Highest.	Lowest.	Average.
May	756	44	20	29

The Salters' Fellowship.—A communication had been received from the Clerk to the Salters' Company stating that the Court of Assistants preferred to leave the selection of a candidate for this Fellowship in the hands of the Research Committee, and an advertisement had, therefore, been inserted in the *Pharmaceutical Journal*, inviting applications.

Gibraltar Pharmacy Ordinance.—The Committee had considered the communication from the Colonial Office on this subject, and the Secretary was instructed to reply that in the opinion of the Council the Pharmacy Ordinance of 1898 should stand without amendment, but if this were thought impracticable, an amendment bringing it into line with the English law might be recommended, and a draft of an amendment for this purpose was submitted.

School Prospectus. — At an adjourned meeting of the Committee on July 4, a proof of the revised School Prospectus was submitted and approved, and an application from the Bell scholars, asking permission to continue their studies next session was acceded to under certain conditions.

The PRESIDENT said the report and recommendations did not call for any special comment. The applications for the Salters' Fellowship would be considered at the next meeting of the Council.

The motion was unanimously agreed to.

Correspondence.

The PRESIDENT reported the receipt of the following communications:—

A letter from Mr. T. Bowen, Bolton, suggesting an amendment for insertion in the Companies Bill now before the House of Lords—"that the word person include a Company."

A letter and resolution from the North-East Lancashire Chemists' Association, in support of the policy of the Council in respect to the question of company trading.

A letter and resolution from the Western Chemists' Association in support of the policy of the Council with regard to Sections 2 and 3 of the Companies Bill.

A letter from the Edinburgh District Chemists' Trade Association, with a resolution embodying suggestions for a new Pharmacy Bill. These have already been published.

A memorial by chemists in the Aberdeen district urging the Council to secure an amendment of the law for the purpose of effectually stopping the practice of pharmacy by companies.

The PRESIDENT moved that all the communications be referred to the Law and Parliamentary Committee for consideration.

This was at once agreed to.

Meeting of the Conference at Plymouth.

The PRESIDENT moved that the following members of the Council be appointed delegates to attend the meeting of the Pharmaceutical Conference at Plymouth;—The President Vice-President, Messrs. Atkins, Cross, Glyn-Jones, Grose, Harrington, Hills, Park, Warren, and Dr. Symes, and that the Secretary be also instructed to attend.

Dr. Symes said he hoped there would be a good attendance at the Conference. He knew that the Local Committee was doing its utmost to provide for the carrying out of the business of the Conference, and also for the pleasure of those who attended. The President of the Conference and the Hon. Secretaries were most anxious to do their utmost to make the Conference a thorough success.

The resolution was carried.

Appointment of School Staff.

The PRESIDENT proposed that the following gentlemen be appointed on the School Staff:—

Botany—Professor J. R. Green.
Chemistry—Professor J. Collie.
Materia Medica and Pharmacy—Professor H. G. Greenish.
Assistant Lecturer in Chemistry—Dr. A. Lapworth.

The resolution was carried.

General Purposes Committee.

The report of this Committee included reports on the prize examinations.

Professor GREEN had reported that the work done in the botany class was, on the whole, very satisfactory.

Professor NORMAN COLLIE'S report simply gave the results of the class examinations.

Professor GREENISH had reported that forty-five students, a number above that of last year, had attended the materia medica class, and their conduct had been satisfactory. The same number had attended the pharmacy lectures, and the work had been well maintained.

In accordance with the above reports, the Committee recommended that the following awards be made:—

Botany.

Bronze Medal	Sara Annesley.
Certificate of Honour	Horace Finnemore. Percy B. Gray.

Chemistry.

Bronze Medal	Thomas W. Maddison.
Certificate of Honour	John F. S nook. George A. Taylor.

Practical Chemistry.

Bronze Medal	Thomas W. Maddison.
Certificates of Honour	Cyril H. Baker. William T. Ransom.

Materia Medica.

Bronze Medal	Horace Finnemore.
Certificates of Honour	Percy B. Gray. Newell E. Melbourn.

Pharmacy.

Silver Medal.....	Thomas W. Maddison.

The PRESIDENT moved the adoption of the above portion of the report, which was at once carried.

The Sale of Carbolid Acid.

The report of the General Purposes Committee also stated that a recommendation from the Watch Committee that carbolic acid should be added to the Poison Schedule had been considered, and it was recommended that the Council should formally resolve that the following articles ought to be deemed poisons within the meaning of the Pharmacy Act, 1868:—Carbolic acid in crystals, commercial carbolic acid and other liquids containing more than 3 per cent. of phenols.

The PRESIDENT moved, in accordance with the above recommendation, that the above-named articles be formally declared poisons within the meaning of the Pharmacy Act, 1868, and placed in

Part 2 of Schedule A. They were all aware that a question was recently asked in the House of Commons, by Sir John Leng, why carbolic acid was not scheduled as a poison, although it was so scheduled in Ireland. The Home Secretary replied that the Pharmaceutical Society had applied to the Privy Council no the subject, but had not done so recently. The fact was that the Council had twice passed resolutions, and four times made application to the Privy Council asking that carbolic acid might be placed in Schedule A, Part 2, viz., in February, 1882; February, 1886; October, 1888; and February, 1891; and his predecessor in the chair, when in communication with the Privy Council, had reminded that body of the matter. It was quite evident therefore, that the charge of neglect could not be laid at the door of the Pharmaceutical Council, but that it was owing to the opinion of the Privy Council that it was not desirable to restriot the sale of carbolic acid, as the advantage would not be commensurate with the inconvenience of interfering with the free sale of carbolic acid as a disinfectant. Nevertheless, the deaths from this substance increased from 94 in 1891 to 258 in 1895, though in 1897, which was the last year of which there were complete records, there was a slight decrease. Now that regulations had been passed with regard to the keeping and dispensing of poisons, there appeared to be a likelihood of a resolution being received by the Privy Council more favourably. Mr. Bateson, who had always taken a great interest in this question, had written him a letter in which he spoke of carbolic acid as the "demon poison," a term which he thought was quite justified, for it had caused more deaths within recent years than any other poison, or than the whole series of opiates taken as a group. On the day following the question in Parliament a letter was received from a London Coroner, Dr. Danford Thomas, enclosing a rider added by a jury to a verdict of "suicide while of unsound mind." It was to the effect that the attention of the Pharmaceutical Council should be called to the fact that carbolic acid is not in the schedule of poisons, and suggesting that an application be made to the Privy Council on the subject. They also drew attention to the fact that the poison was procured n an ordinary bottle from an oil shop without label of any kind. That was further evidence of the necessity for placing restrictions on the sale of such substances, and those who knew anything of the corrosive nature of the acid and the painful death which it caused would agree that it ought to be sold only under proper restrictions, and by persons who were aware of its nature. He had seen Sir John Leng both before and after he put his question, and his opinion was that there was now an opportunity of approaching the Privy Council with more hope of success. The Committee had carefully considered the matter, especially the definition of carbolic acid which should be adopted, the most dangerous substances which contained the dangerous homologues, and a series of bodies which had not been examined chemically. It was necessary that the restriction should be wide enough to include these poisonous bodies, but it would not include the disinfecting powders which were largely sold; and which it was hardly wise to restrict the sale of. The restriction would also include carbolic acid lotion, the 1 in 20 strength, which was largely used as an antiseptic lotion, and was a dangerous poison which acted quickly on the heart. It was intended to go for the registration of carbolic acid alone, and not to hamper the matter by the addition of other poisons which might be advisedly added, but which would be reserved for a future occasion. It was necessary that the application should be made at once while the subject was still in the minds of the Privy Council and the public.

Mr. Atkins seconded the resolution. It ought to be very clearly understood by chemists and the public that it was not the fault of the Society that carbolic acid had not been added to the schedule years ago. Some eighteen or twenty years ago he was one of those who went to the Privy Council to urge on Lord Carneford the introduction of carbolic acid into the schedule; but that noble Lord seemed to think it would be in restraint of trade. The Society had again and again approached the Privy Council on the subject, and it was within their cognisance that not only the President's predecessor but his predecessor had taken every opportunity of urging the necessity of the inclusion of carbolic acid in the schedule in the interests of the public safety. It ought to have been done years ago; but it had been now forced upon the public conscience by the fact that the poisoning by carbolic acid exceeded that by all other poisons put together.

Mr. Harrison said it was impossible that there could be any difference of opinion at that table as to the advisability of including carbolic acid in the Schedule. He suggested that when the communication was sent to the Privy Council a letter ought to be sent showing that their attention had been called to the matter by the recent reply made by the Home Secretary in the House of Commons. On the last occasion that a request was made to the Privy Council for the inclusion of carbolic acid, the answer given by them was that it would be undesirable in the interests of public health that there should be any restriction placed on the facility of obtaining carbolic acid in remote country districts where no chemists could be found. Now that the Home Secretary had clearly indicated in his reply to the House of Commons that there had been some neglect on the part of the Pharmaceutical Society in making application, they would do well to at once approach the Privy Council, and stating that they do so in consequence of what had been stated in the House of Commons. They wished to make it clear to the public at large that the failure to include carbolic acid in the schedule had not been on account of want of activity on the part of the Council, but was due solely and entirely to the refusal of the Privy Council.

Dr. Symes wished on the part of the Council to repudiate any suggestion of neglect on their part. He had himself moved a resolution on a former occasion, and the Council were unanimous on the subject. At that time not a week, and scarcely a day, passed but there was a death in Liverpool and district from carbolic acid. It became so serious that he had approached the sanitary authorities on the subject. Coroners all over the country had sent recommendations, and yet for some extraordinary reason the Privy Council had persistently refused to acknowledge the desirability of adding carbolic acid to the schedule. It was supposed by those who did not understand the Act that putting carbolic acid in the Poison Schedule would prevent local sanitary authorities distributing carbolic acid gratis to the poor in their districts, though in his opinion it would certainly be a good thing if they distributed it much more carefully. He hoped that the next time the Council met they would have the satisfaction of knowing that this very dangerous poison had been added to the schedule.

Mr. Hills said as reference had been made to his predecessor and himself he should like to corroborate the statement that they had maintained a certain amount of relationship with the Privy Council on this matter, and he was glad to think that there was a possibility now of carbolic acid in its most dangerous form being added to the schedule of poisons. He could not altogether agree with Mr. Harrison; he thought the most dignified way would be to send the resolution as the previous ones had been sent. The Privy Council would know perfectly well why they were acting at the present moment, and were well aware what had taken place in Parliament during the last few days. This question of adding carbolic acid had been under the consideration of the General Purposes Committee, who also considered the desirability of adding other dangerous articles; but he was very glad that the Committee had come unanimously to the conclusion that at the present moment carbolic acid should be deemed to be a poison within the meaning

of the Act. The objections hitherto raised by the Privy Council had been to a certain extent removed. If the resolution were confirmed by the Privy Council carbolic acid in a more or less innocuous form might still be supplied in remote country districts where there was no registered chemist. He wished it to be distinctly understood that he had evidence that up to very recently the Privy Council held the same opinion as they had held for a great many years—viz., that it was not desirable that carbolic acid should be deemed a poison. He quite realised that during the last few months the society had taken a very important step fn passing poison regulations, and that might, in the opinion of the Privy Council, make it more advisable that carbolic acid should be deemed a poison.

The resolution was carried.

Dispensing by Unqualified Persons.

The SECRETARY then read a further paragraph from the report of the General Purposes Committee referring to dispensing by unqualified persons. After considerable discussion the Committee agreed to defer the further consideration of the matter until after the report of the General Medical Council thereon shall have been made public.

The PRESIDENT said this matter was discussed for a long time, with the result which had been read. The General Medical Council had appointed a Committee to investigate and report upon a matter which concerned medical men more than pharmaceutists, because in the Apothecaries Act, 1815, there was a compounder's clause which made it penal for anybody to dispense or compound medicines for an apothecary without holding the assistants' qualification of the Apothecaries' Society. Anything concerning dispensing of medicines concerned pharmaceutists, but the Committee thought it best to wait and see what the General Medical Council had to say on the matter. It must also be remembered that chemists had to train apprentices themselves, and he feared a *tu quoque* argument might be applied, and in the interest of the public they thought it would be better to wait. If nothing came from the General Medical Council it might be necessary for some steps to be taken in the interests of public safety. Sir Walter Scott said: "Should he mix hellebore who doth not know how many grains to the mixture go?" They wanted to see that it was done by some one who possessed the proper qualification, and took care that the dose was not too great.

Mr. GLYN-JONES having intimated a desire to raise the question of taking some immediate action,

The Council went into committee for a short time to settle the form in which the question should be raised.

On resuming, the PRESIDENT moved that the question of dispensing medicines by unqualified persons be deferred until after the report of the Medical Council on the subject.

Mr. ATKINS seconded the motion.

Mr. GLYN-JONES then moved, as an amendment: "That a communication be sent to the General Medical Council respectfully requesting that their Committee appointed to consider the question of the dispensing of medicines in surgeries should hear this Council, either by deputation or letter, before arriving at a definite conclusion." In doing this he was, perhaps, taking an unusual course, but it was not unprecedented, as was shown by the recent action of Sir Richard Thorne at the General Medical Council with regard to the report of the Committee appointed to consider the Midwives Bill. Deferring this matter until after the report of the General Medical Council was a most serious step, and to his mind amounted to relinquishing their right to consider any question concerning the dispensing of medicines. The Committee of the General Medical Council was, to all intents and purposes, a Government Committee, and after the report had been presented it would be practically too late to make suggestions which ought to have been made before. He certainly thought that if they passed this resolution they deprived themselves of the right to approach the General Medical Council on the subject afterwards. They knew the matter was under consideration, and, what was equally as serious, the General Medical Council knew that that Council had the matter under consideration, and any step taken that day would be with the cognizance of the General Medical Council. The resolution practically gave them a free hand, and relinquished any claim of the Pharmaceutical Society to consideration; according to the old proverb, it would be too late to shut the stable door after the horse was gone. He was sorry to hear the President refer to two arguments which might be used against them. In the first place, he said there was a certificate which qualified a man to act as dispenser to a certain branch of the medical profession. An apothecary was a man who held an L.S.A. certificate, and an apothecaries' assistants' certificate was only a qualification to act as assistant to an apothecary, not to a L.R.C.P. The whole conditions of medicine and pharmacy had changed since 1815. At that time it was quite reasonable that a qualification of that kind should be given to an apothecary's assistant, because then the apothecary was the chemist and dispenser, and was in a position to train his pupils; but he did not admit that such a certificate was sufficient to-day to qualify a man to dispense for medical men in general. The other argument, the *tu quoque*, was one which ought not to be considered for a moment. This was a question above all feeling as between medical men and chemists; it was a question of the public safety, and if the General Medical Council were to sanction the practice of employing unqualified men, which had been proved to be dangerous, he did not think they would stoop to use the argument—keep your own house in order before you speak to us. But there was not much force in the argument anyhow. He did not believe there was much dispensing carried on in chemists' shops except by qualified men or under the direct supervision of a qualified man. The Society insisted that there should be a qualified man in every shop; but did the Medical Council insist that there should be a qualified dispenser in every surgery? It was one thing to employ a man who was not qualified to dispense under the supervision of the pharmaceutist, and another thing for a medical man, who might be away for six hours at a time, to leave medicines to be dispensed by a surgery boy. Only last week there was a report of an accident to a dispenser himself, who turned out to be the surgery lad. He failed to see anything, however, in the *tu quoque* argument, and even if there were he did not believe the General Medical Council would stoop to make use of it. Now was the time to take action, if at all and he submitted that if the Council had come to the conclusion that it could not interfere in any way with medical dispensing, it would be much fairer to chemists and druggists generally to say so straight out. The Council was holding out certain hopes which he did not think it was justified in doing unless it was prepared to take some action. Were they true to the principles of the founders of the Society in simply sitting still and taking no action when the matter had been brought so prominently to their attention? Would Jacob Bell or William Allen have allowed such a thing to go on quietly without putting in some claim to be considered? After quoting a passage from a petition in connection with the Bill of 1851, cited in the 'Progress of Pharmacy,' p. 208, Mr. Glyn-Jones went on to say that the course now proposed was not progressive, but retrogressive. Again, was it fair to the annual meeting to simply lie by and do nothing? A resolution was brought forward, of which due notice was given, for approaching the General Medical Council, and an amendment was moved that the whole question be referred to the Council, which was carried, but he doubted if it would

have been carried if the mover of it had stated that the Council did not intend to do anything until the General Medical Council had reported. The amendment was carried by fifty-six votes to forty-eight, and if he deducted the fifteen members of the Council who voted for the amendment there was a majority of independent members in favour of his resolution. If, then, the Council did not act something in the spirit of the evident feeling of the unofficial members of the Society, he should submit that it was open to the charge, at any rate, of over-riding the wishes of the members. Another point, which was a somewhat delicate one, was this: he owed his seat on the Council to the fact that a great number of the members believed that this was the proper course to take. He made it a prominent plank in his platform, and he was the only one out of six new candidates who was returned.

The PRESIDENT said Mr. Glyn-Jones's resolution was rejected, not carried. The members of the Council had as much right to vote as any other member.

Mr. GLYN-JONES said he was referring to the evident feeling of the independent members of the Society.

The PRESIDENT said all the members were independent.

Mr. GLYN-JONES said he would use the word "unofficial" apart from the vote of the Council.

Mr. ALLEN said the members of the Council knew most about the matter.

Mr. GLYN-JONES said his point was that the unofficial members had shown in several ways that they were anxious for something to be done on the lines of his amendment. He would ask his colleagues to consider the position of the rank and file of the trade; 80 or 90 per cent. of the members hardly saw a prescription a week. It was not a question merely of trade interest; he put it on the higher ground of the public safety, the question which underlay the whole of the Pharmaceutical Act. But having gone to the trouble and expense of training and qualification, if anything could be done to prevent people who had not gone to the trouble and expense of doing their work, it should be done. It had been said that the members of the Council did not suffer very much from lack of dispensing, and there was a great deal of truth in it. They were generally men fortunate enough to own the best business in their district, and they did not feel as strongly as some others the pressure of the question whether they were qualified to dispense medicines and sell poisons, or simply to sell poisons. In fact, many men spent fifteen months in study and went to almost as much expense as was necessary to enter the medical profession, simply to qualify them to sell Battle's Vermin Killer, or a penny-worth of red precipitate. That was the position of a great many men, through no fault of their own, but simply because other persons who had had no training were allowed to dispense medicines. He felt that if nothing were done now, it would be a colossal error, from which he wished to dissociate himself, and an error which would be irretrievable. If the view was that the General Medical Council was at all likely to tell them to mind their own business, he thought that would be much more probable if they waited until the report of the Committee had been presented, than if they made a representation at once. What risk did they run? He listened on the previous evening very carefully to the arguments of men of greater experience than himself, and perhaps more wisdom, but he failed to gather one argument against approaching the General Medical Council respectfully, and asking to be heard. The cheap dispensary, which was as dangerous to the public as it was inimical to the interests of the medical profession and of pharmaceutists, could not be conducted if the men who ran it had to keep qualified men. There were hundreds of such places in London, where human beings were treated with less consideration—both as regarded diagnosis and dispensing—than pet animals. He protested against that kind of thing going on, without raising a finger, or asking to be heard before the General Medical Council came to any conclusion.

Mr. YOUNG seconded the amendment in order that the question might be discussed. He did not agree with all that Mr. Glyn-Jones had said, but rather shared the view that it would be injudicious to do anything which might savour of an interference with the rights and privileges of such an ancient body as the Society of Apothecaries.

Dr. SYMES said that they would all agree with Mr. Glyn-Jones that it was undesirable that medical men should employ unqualified assistants, but the present time was inopportune for taking action. He thought the Medical Council were in earnest, and the best way would be to first hear what they had to say. No doubt they would look at it from a medical point of view, but still with an open mind. He did not wish to vote against the desirability of taking an interest in the question, but only against doing it now at what he thought an inopportune moment.

Mr. CROSS said the question was largely one of administration. The Pharmaceutical Council had to administer the laws affecting pharmacy, whereas the Medical Council had to administer the law as far as the practice of medicine was concerned, and he declined to assume that the General Medical Council was not as keenly alive as they were to the necessity of the extremist cautions in the preparation of medicine. To that responsible body the question had been referred by the Government, and he thought it was not opportune for the Council, when the General Medical Council had gone so far as to appoint a committee to go into the matter, to interfere with its proceedings. It would be unwarrantable on their part to offer advice at the present moment, or to sue for a hearing, and it would be unworthy of the position which they held as administrators of their own affairs. Why should they accentuate their ability to dispense medicines; all the world knew that, and no one better than the General Medical Council. It had been said that a feeling of irritation might exist at the subject ever being raised at all by the medical profession, but he could not believe that that would be so.

MR. STORRAR said they were all indebted to Mr. Glyn-Jones for bringing forward the arguments he had brought forward, and even for his amendment, which gave them an opportunity in open council of stating their opinions on a very important question. Although he was in sympathy with Mr. Glyn-Jones's objects, he could not agree with many of his arguments. In the first place, the Council were in no way in the position of delegates; they were sent there by their constituents to use their own judgment, and to act on their own responsibility. With reference to what Mr. Glyn-Jones had said about the result of the elections to the Council, he would point out that the old Council would returned with but one exception. They were there for the purpose of carrying out an Act of Parliament, and the constitutional way to interfere in this question was to prosecute unqualified dispensers whenever they had the power to do. They should, if possible, get into touch with the Medical Council on the question. He thought, perhaps, the decision come to by the General Purposes Committee was a little too strict, and that the Watch Committee should have power to approach the Medical Council if they saw fit even before a report was presented. He should suggest that something be added to the General Purposes Committee's report to that effect.

The PRESIDENT said there was a distinct resolution and an amendment to that resolution before them.

Mr. HILLS said the state of pharmacy in this country would never be satisfactory until the prescribing of medicines and the dispensing of medicines were in different hands. It was thought that the dispensing of medicines, whether in private or open surgeries, or in chemists' shops, should only be carried out by those who held the Pharmaceutical Society's qualification, unless they

were actually carried out by a man holding a medical qualification. He regretted that public departments did recognise other qualifications, which made the matter more difficult to deal with. He could not agree with Mr. Glyn-Jones that the General Medical Council was at all on a par with any Special Committee of the House of Commons. There were many reasons, which it would be impolitic to bring forward, which did influence the General Purposes Committee in coming to the resolution it had after hearing the views which Mr. Glyn-Jones had expressed with considerable ability.

Mr. ATKINS said he admired the compactness and cogency with which Mr. Glyn-Jones presented his case, and his intense earnestness; but he could not altogether agree with him. He thought it would be impolitic, certainly at that moment, to address the General Medical Council, and he was afraid that some gentlemen took rather too much for granted their rights as to dispensing. He agreed with Mr. Hills that the ideal was that one class of persons should prescribe, and another class should dispense; but they, as a Society, had only a record of some fifty years, while the medical profession had existed for centuries. When the question came to be argued before the Committee of the General Medical Council they would find very complex interests involved. He could not but think that if medical men could see their way they would be glad to get rid of dispensing; but he could not support the amendment that they should claim to be heard at once.

The PRESIDENT said it was not proposed to shelve the question, but merely to await the report of the Medical Council. They had to move with caution. In his opinion it would have a better effect if, rather than adopting a defiant tone, they were to use the "oily feather." They had not the sole right to dispense medicines, for apothecaries had the right long before. He thought the dispensing of medicines would come into their hands if they waited. From his experience of the younger race of medical men they were not going in so much for preparing their own medicines as their fathers did before them.

The amendment was then put and lost.

Mr. STORRAR said he thought that the Council should not be tied up quite so hard and fast as it would be by the resolution, and suggested as an amendment that the Watch Committee be instructed to keep in view the action of the Medical Council Committee, and be authorised to act if it were thought advisable.

Mr. ALLEN said the Watch Committee had power already to act in any case of emergency.

Mr. GLYN-JONES said he understood the resolution would forbid anything being done until after the report of the committee of the General Medical Council. He should be glad to second Mr. Storrar's amendment.

Mr. STORRAR did not see how the Watch Committee could act if the resolution were carried.

Mr. CROSS said the Watch Committee could only act on some further information.

Mr. SYMES submitted that Mr. Storrar's suggested amendment was out of order, not being an amendment at all, but in reality negativing the effect of the resolution.

After some further discussion, including a statement by the PRESIDENT that the Watch Committee could take action at any time if necessary. Mr. STORRAR said if that were understood he would withdraw his amendment. The original resolution was then put and carried.

Legal Business.

The Council then went into Committee to hear and consider the report of the General Purposes Committee dealing with legal matters. On resuming, the report and recommendations were unanimously adopted, and a special resolution was passed authorising the Registrar to take proceedings against the persons named therein.

STROPHANTHUS KOMBE.

BY E. M. HOLMES, F.L.S.

Curator of the Museums of the Pharmaceutical Society.

The difficulty of obtaining pure seed of *Strophanthus kombe*, agreeing with the description and colour test given in the British Pharmacopœia, has long been known. (*See Pharm. Journal* [3], **23**, pp. 868, 927.) The seeds entering commerce have sometimes come from East Africa, sometimes from the west of that Continent, and in either case have frequently consisted of a mixture of the seeds of different species; or, if pure, of the non-official species. This, indeed, was so much the case that even some of the seeds supplied to Professor T. R. Fraser, F.R.S., for his experiments consisted of mixed seed, similar in appearance, but some giving the red and others the green reaction with sulphuric acid. The original *Strophanthus kombe*, Oliver, is a native of East Africa, and has never to my knowledge been found on the West Coast, therefore, any *Strophanthus* seed imported from the West Coast is not in the least degree likely to be the genuine drug. For the last ten years I have been endeavouring to obtain the flowers and fruits, together with the leaves, of the genuine *Strophanthus kombe*, and in the course of my inquiries I have learned that what I formerly suspected is true, viz., that the best *Kombe* seed obtainable in commerce has hitherto consisted of the seeds of at least two, and probably three, species mixed, the seeds from different districts being bulked together. Through the kindness of Mr. F. M. Moir, of the African Lakes Corporation, Limited, 45, Renfrew Street, Glasgow, and Professor G. F. Scott-Elliot, M.A. (corresponding member of the Society, and well known as an African traveller), I have been able to obtain specimens of the plants from which the seeds are stated to be obtained. These consist of *S. emini*, *S. kombe*, *and S. courmonti*. The seeds have also been received separately in pods, not mixed as in commerce. Of these, I have pointed out to Mr. F. M. Moir the variety that complies with the British Pharmacopœia tests, and asked him, if possible, to secure its being sent into commerce in pods and with some distinguishing mark—such as a definite brand, that would enable chemists to obtain a uniform seed agreeing with the official tests in the Pharmacopœia, since there is little doubt that the somewhat uncertain action of the tincture met with in commerce is largely due to the unequal character and different kinds of the seeds that arrive in commerce. In reply, he states:—

"We have written fully to our friends in Africa on the subject, and are asking them to ship only the genuine quality, and under the mark 'Mandala Brand.' All packages of this genuine *Strophanthus* will be marked A.L.C.L. 'Mandala Brand,' London, and the seed will be sent in pods."

As it is obviously impossible to test separately every seed in a mixture of seeds and thus separate them, whilst it is comparatively easy to test one seed out of each pod, the plan of sending the seed in pods will render it now possible to get a pure and uniform drug.

GONOROL.—This is a preparation which is being recommended for urethritis and gonorrhœa. It consists solely of the alcoholic constituents of sandal wood oil. The esters (3-4 per cent.) are split up into gonorol and the respective acids, these and the remaining non-alcoholic portions (about 10 per cent.) are removed. These latter consist principally of sesquiterpenes and other aromatic bodies. The preparation is a colourless, syrupy oil, of very feeble musty odour and taste. It has the following characters:—Specific gravity at 15° C. 0·976; boiling point constant at 286-288° C.; specific rotation in 100m. tube —18°; Köttstorffer saponification number 12·4; Hubl's iodine, number 104·5. Gonorol is soluble in 3·5 parts of 70 per cent. alcohol at 20°6C., while ordinary sandal oil is only soluble in 5 parts of alcohol, 70 per cent. The purity of the preparation is evidenced by the high proportion of "santalol," which amounts to 96·5 per cent. on acetylisation.—*Wien Klin. Woch.*, **52**, 11.

LONDON: SATURDAY, JULY 8, 1899.

THE COUNCIL MEETING.

The ordinary routine business of the Council last Wednesday was not marked by any feature of special interest. After the minutes of the previous meeting had been read, the President announced that Professor Leech had consented to deliver the inaugural address at the opening of the Society's School in October.

The additions to the Society comprised thirty-three members and ten student-associates, besides a considerable number of persons who were restored to their status in connection with the Society.

The report of the Finance Committee showed that the receipts from candidates for qualification had given a fair amount of cash in hand.

On the recommendation of the Benevolent Fund Committee six grants, amounting to sixty-five pounds, were ordered to be paid. Mr. S. R. Atkins was added to the Committee on the motion of the Vice-President.

The report of the Library Committee stated that the Court of Assistants of the Salters' Company desire to leave the selection of a Fellow in the hands of the Research Committee, and that in reply to the inquiry of the Colonial Office respecting the Gibraltar Pharmacy Ordinance, the Council has expressed the opinion that it should, if requisite, be brought into line with the British law.

The receipt of various communications was mentioned by the President; they all related either to the Companies Bill or other proposed pharmaceutical legislation, and expressed approval of the action taken by the Council. On the motion of the President delegates to the Pharmaceutical Conference at Plymouth were appointed.

The members of the Society's School staff were re-appointed. (See page 30.)

The report of the General Purposes Committee contained a statement of the awards of prizes to candidates successful in the recent examination, one of the number being a lady student in the Society's School. (See page 30.)

An exceptionally interesting detail was the recommendation that in view of a recent expression of opinion by the Home Secretary the Council should, in accordance with the provision of Section 2 of the Pharmacy Act, 1868, again formally pass a special resolution that carbolic acid ought to be added to the schedule of poisons within the meaning of that Act. The President, in moving the adoption of this recommendation, referred to the terms of the answer given by Sir Matthew White Ridley to the question asked by Sir John Leng as affording indication of a change in the position of the Privy Council in regard to this matter. He also pointed out that, in addition to recent references to the subject by his predecessor, when in communication with the Privy Council Department, the Council had, since 1882, on two previous occasions, passed special resolutions that carbolic acid should be added to the Poison Schedule, and had also made four applications to the Privy Council on the same subject without success. Hence, he argued that the neglect to carry out, in regard to carbolic acid, the provision of the Act could not be charged to the Pharmaceutical Society or its Council, but that it has been a consequence of the opinion that was held by the Privy Council Department as to the undesirability of restricting the sale of carbolic acid in the public interest, and thus causing inconvenience incommensurate with any advantage to be gained. But the increase in the number of deaths caused by carbolic acid since 1891 has been very considerable, and by the adoption of regulations as to the storing of poisons other objections to the addition of carbolic acid to the Poison Schedule had now been removed so far that it is likely the resolution of the Council would be received by the Privy Council with greater favour.

Mr. Atkins, in seconding the motion, which was subsequently carried, remarked that both chemists and the public should very clearly understand that it was by no fault of the Society that carbolic acid had not been added to the Poison Schedule many years ago. As a member of the deputation to the Privy Council, he could remember that Lord Carlingford's objection to scheduling carbolic acid seemed to be due to the belief that it would cause "restraint of trade," and a similar idea had defeated all subsequent attempts made by the Council in the discharge of its statutory duty, and in the interest of public safety. Now that the necessity has been forced upon the public conscience by the established fact that poisonings by carbolic acid are more numerous than those caused by all other poisons put together, adequate provisions might be effected.

Mr. Harrison suggested that in communicating with the Privy Council particular mention should be made of the circumstance that the Council's attention had, on this occasion, been drawn to the matter of carbolic acid by the remarks of the Home Secretary in replying to Sir John Leng, and that any previous failure was entirely due to the Privy Council. He recalled the fact that when the last request was made for adding carbolic acid to the Poison Schedule the answer given by the Privy Council Department was that any restriction of the facility for

obtaining that article in remote country districts would be prejudicial to the interests of public health. He thought that should be made clear, because the reply of the HOME SECRETARY to Sir JOHN LENG'S question very clearly indicated that there had been some neglect on the part of the Pharmaceutical Society in not making a renewed application to the Privy Council, whereas that neglect was solely referable to the Privy Council.

Dr. SYMES also repudiated the suggestion of neglect on the part of the Council. At one time there had been a death almost daily in Liverpool and the district, and he had moved the sanitary authorities on the subject. Coroners all over the country had made urgent recommendations, but the Privy Council Department had persistently refused to sanction the addition of carbolic acid to the Poison Schedule.

Mr. HILLS corroborated the statement that the question as to carbolic acid had been kept before the Privy Council by himself and his predecessor, and expressed his satisfaction that there was now a prospect of the most dangerous form of that article being suitably dealt with. In reference to Mr. HARRISON'S suggestion, he thought that the Privy Council Department would be sufficiently aware, from what had taken place in Parliament, why the Council was acting at the present time. The recommendation now made would leave the more innocuous forms of carbolic acid preparations without interference, and thus the objection raised on the ground of their use as disinfectants had been removed. He wished it to be distinctly understood that the change of opinion at the Privy Council Office was quite recent, and he thought the very important step taken by the Society in regard to poison regulations might have induced the opinion that the addition of carbolic acid to the Poison Schedule was now advisable.

The Council finally passed a resolution adopting the recommendation of the General Purposes Committee, that carbolic acid in crystals, commercial carbolic acid, and liquids containing more than three per cent. of phenols should be added to the Poison Schedule.

Another portion of the report of the General Purposes Committee related to the subject of dispensing by persons having no pharmaceutical qualification, the Committee recommending that further consideration of that matter should be deferred until after the General Medical Council's report upon it had been published.

The PRESIDENT remarked that the matter, referred to a Committee by the General Medical Council, concerned medical men more than pharmacists, and therefore it was thought best to see what the Committee of the General Medical Council would say in regard to it, and he moved that the recommendation of the General Purposes Committee be adopted. That was seconded by Mr. ATKINS, and Mr. GLYN-JONES then moved as an amendment that the General Medical Council should be requested to hear the Society's Council either by deputation or letter before arriving at a definite conclusion, remarking that he took that unusual but not unprecedented course because he thought that by deferring action the Council might be to some extent relinquishing its right to consider any question relating to the dispensing of medicine. Regarding the General Medical Council as a Government Committee, he held that it would be practically too late to offer suggestions when its report had been presented. In regard to the assistants' qualification under the Apothecaries Act, 1815, he held that it was only a qualification for assisting a licentiate of the Society of Apothecaries, and not a licentiate of a College of Physicians. Since that time the conditions of the practice of medicine and of pharmacy have been entirely changed, and the chemist now occupied the position then held by the apothecary. The employment of unqualified dispensers by medical men was, he contended, very different from the dispensing by an unqualified person under the supervision of a legally qualified chemist, and if the Council could not interfere in any way with the medical dispensing, it would be fairer to chemists to say so at once. He thought the Council would not be true to the principles of the Society's founders if it did not take action in regard to a matter that had so prominently been brought under its notice, and give effect to the evident feeling and desire of members of the Society. He held that inaction at the present moment would be a colossal error, from which he wished to dissociate himself.

Mr. J. RYMER YOUNG seconded the amendment, mainly in order that the question might be discussed.

Dr. SYMES agreed that it was undesirable medical men should employ unqualified dispensers, but he also thought it would be inopportune for the Council to take action now.

Mr. CROSS could not assume that the General Medical Council was not as keenly alive to the necessity of caution in the dispensing of medicine as the Council of the Society, and as no one knew better than the General Medical Council chemists' ability to dispense, it was unnecessary for them to accentuate that capacity.

Mr. STORRAR expressed satisfaction at the opportunity afforded for discussing the subject in open Council, but, while sympathising with Mr. GLYN-JONES'S object, he did not agree with some of his arguments, and suggested that some addition to the recommendation of the General Purposes Committee might meet the case.

Mr. HILLS called attention to the fact that the state of pharmacy in this country would never be satisfactory until the prescribing and dispensing of medicines were separated. He regretted also that other qualifications than that of the Pharmaceutical Society were recognised by public departments.

Mr. ATKINS thought the assumed rights of chemists as to dispensing were too much taken for granted, and that very complex interests were involved, though many medical men would no doubt be glad to be relieved of dispensing.

The PRESIDENT remarked that there was no intention of shelving the subject, but only to wait until the report of the General Medical Council's Committee appeared. He thought dispensing would in time come into the hands of chemists, and that the younger medical men would promote that change.

Mr. GLYN-JONES'S amendment was then put, but not carried, and some conversation ensued as to the powers of the Watch Committee, after which the original motion to adopt the recommendation of the General Purposes Committee was carried.

After consideration of the legal portion of the report, a special resolution was passed authorising the Registrar to take proceedings in various cases of alleged infringement of the Pharmacy Acts.

ANNOTATIONS.

The Plymouth Programme of the British Pharmaceutical Conference is printed in full at page 39, and attention is again directed to the necessity of applying to the Hon. Local Secretary—Mr. J. Davy Turney—for tickets by Monday, July 17, at latest. This rule is a new one, but it is meant to be enforced, and much trouble and regret may be saved if all who think of attending the meeting at Plymouth will decide promptly, and intimate the fact if they are going. Similar remarks may fitly be addressed to members who propose to contribute papers on this occasion. It is not desired to have a long list of papers, and those sent in should be in the hands of the Hon. Gen. Secretaries, 17, Bloomsbury Square, London, not later than Friday, July 14. The titles of the papers should be intimated earlier, if possible, and authors are requested to note that all applications for copies or abstracts of their papers must be referred to the Hon. Gen. Secretaries, who will deal with them in due course. To delay sending in papers, in order that abstracts may be prepared, or for any other purpose simply causes unnecessary trouble to the Secretaries, and may prevent the papers being put into type sufficiently promptly to enable the authors to check the printed proofs properly. Proofs will be sent for revision and correction to every person whose paper is received by the Hon. Gen. Secretaries within the time specified, but no such undertaking can be given in respect of papers which arrive at a later period.

Mr. A. C. Wootton, who has for many years past been editor of the *Chemist and Druggist*, has recently retired from that position and, as will be gathered from a letter in this week's Journal (see page 44), a project is on foot to recognise his services to the drug trade, in some form or other, and to that end it is proposed to hold a meeting at Anderton's Hotel, Fleet-street, London, on Monday next. Mr. Wootton's long career as a journalist has been an eminently successful one from a business point of view, and he is to be congratulated upon the fact that his retirement takes place at a time when he is fully capable of participating in all the pleasures of life. The persistent tone of antagonism towards the Pharmaceutical Society adopted in the organ which Mr. Wootton has so ably conducted during more than a quarter of a century has probably conduced largely to its commercial success, but at the same time it has been beneficial to the Society and, during the past two years or more, has gone far to increase its membership, and encourage the improvement of its organisation. That which is threatened tends to survive beyond the normal period of existence, and in proportion as the Pharmaceutical Society has been the subject of perverse opposition—and been attacked by misleading mistatements of facts—so has it thrived and become more firmly established than ever. Not the least, therefore, of Mr. Wootton's claims to the gratitude of the craft is that of having helped to weld more firmly the bonds of union, which are better exemplified in the Pharmaceutical Society than in any similar organisation. On his retirement, he will doubtless continue to be a member of that body, and as such he will have the hearty good wishes of all his fellow members who are able to weigh his labours impartially and judge his aims aright.

Sir William Henry Flower, whose death occurred on Saturday last, was born at Stratford-on-Avon on November 30, 1831. After a course of study at University College, London, he entered the Army and served in the Crimea with the 63rd Regiment as assistant-surgeon, receiving the medal with clasps for Alma, Inkerman, Balaclava, and Sevastopol, and the Turkish medal. On his return to this country he became Assistant-Surgeon and Demonstrator in Anatomy at the Middlesex Hospital, and a year or so later he was appointed to the curatorship of the Hunterian Museum of the Royal College of Surgeons. In 1869 he was chosen Hunterian Professor of Comparative Anatomy and Physiology, and fifteen years later he succeeded Owen as Director of the Natural History Museum at South Kensington, a position which he resigned only last year, in consequence of failing health. As the *Times* points out Sir William Flower will probably be remembered rather in connection with his work on the classificatory side of science than as the author of any brilliant discovery or striking generalisation. Yet he made substantial contributions to natural science, the Royal Society's catalogue of scientific papers giving eighty-nine entries under his name, and though many of the papers deal with abstruse points which can only be appreciated by the specialist, taken altogether they represent a solid addition to scientific knowledge. He had considerable talent for the patient and minute collation of facts, and in articles such as that on the Mammalia in the last edition of the 'Encyclopædia Britannica' he showed himself a master of compressed and accurate statement. Many of the smaller articles on zoological subjects in the 'Encyclopædia' also came from his pen, and he was the author of several books of acknowledged merit including 'An Introduction to the Osteology of the Mammalia,' 'Diagrams of the Nerves of the Human Body,' 'Fashion in Deformity,' and 'The Horse; a Study in Natural History.' His last publication was a volume of collected essays on museums and their administration. He was much and justly esteemed by scientific men all over the world, and numerous honours fell to his lot. In 1864 he was elected a Fellow of the Royal Society, which awarded him a Royal medal in 1882. He was President of the British Association in 1889, having previously acted as President of the biological section in 1878, and of the department of anthropology in 1881. In 1879 he became President of the Zoological Society, and from 1883 to 1885 he served as President of the Anthropological Institute. He also presided over the anatomy section of the International Medical Congress which met in London in 1881. Oxford and Cambridge both conferred honorary degrees upon him, and the Institute of France made him one of its corresponding members. He received the honour of C.B. in 1887, and of K.C.B. in 1892.

Difficulty in Obtaining Temporary Aid during the holiday season is referred to by a correspondent in the *Lancet* as a probable consequence of the agitation against the employment of unqualified assistants that is likely to be experienced by medical men, and will have to be provided against in the future. As regards the dispensing of their medicines, he suggests that the medical men of a given locality should unite together and open a chemist's shop for themselves, with a qualified manager to carry out that part of their work. It may, however, be pointed out that in most instances a more convenient method might well be adopted by making an arrangement with local chemists, since there are now few places where the services of a duly qualified person are not available for the purpose of dispensing, and such an arrangement as that referred to recently by several writers in the medical journals would be desirable in other respects.

The Qualification of Public Analysts is a matter of grave importance to the public, and the action of the Irish Local Government Board in raising the question of the fitness of candidates for the post of public analyst is, therefore, to be commended. Quite recently it was reported that the Board had cancelled the appointment as analyst to an Irish Union of a practising analytical chemist of forty years' standing, on the ground that he had not the requisite qualification. What that qualification is may best be gathered from a letter recently received from the Local Government Board, by the Athlone Board of Guardians. In that it is stated that, in appointing an analyst for the Athlone Union, it is

desirable to endeavour to obtain the services of an analyst who, in addition to being a Fellow of the Institute of Chemistry, has had considerable experience in the analysis of drugs, and either possesses or is connected with a fully-equipped laboratory. This appears to be almost too common-sense a view for a Government department to take, but it is none the less one to be encouraged. Practical experience in performing work of the same character as the analyst may expect to be called upon to do in his official capacity is of much greater importance than membership of any number of societies, even though—as in the case of the Institute of Chemistry—entrance cannot now be obtained unless the would-be member is properly qualified. And it is especially to be desired that public analysts should have a much more practical acquaintance with the analysis of drugs than is now usually the case.

THE DENTAL BOARD OF VICTORIA has framed regulations under the Dental Act, 1898, and forwarded them for the approval of the Governor in Council. Under those regulations, candidates for registration as dentists and for the diploma of Licentiate of Dental Surgery of Victoria must produce evidence of having passed a preliminary examination, served an apprenticeship, and pursued a course of professional study. The preliminary examination will be in English, German, French, Latin, arithmetic, algebra, geometry, history, and geography, and candidates must pass in four of those subjects, including Latin. The apprenticeship must extend over a period of not less than three years, and be served with a registered Victorian dentist. The course of professional study must extend over four years, the subjects of study being chemistry, anatomy, dental mechanics and metallurgy, materia medica and therapeutics, physiology and histology, general surgery and pathology, dissections, medicine, dental anatomy and oral surgery, dental surgery, pathology and bacteriology. Four examinations must also be passed before the Board.

THE SPALDING POISONING CASE has ended, as anticipated, with a verdict of "Guilty" against the accused man Bell, who was sentenced to death in due course. Mr. Justice Lawrance, who tried the case, commented, when summing up, on the large quantity of poison supplied to Bell, and pointed out, according to a local newspaper report, that "this had been done in face of an Act of Parliament regulating the sale of poisons." Apparently, therefore, the judge was of opinion that the requirements of the Act had not been properly fulfilled. The seller of the poison, who recently wrote to the Journal (see last volume, p. 512*c*), protesting against the statement that he had acknowledged supplying poisons to a person who was neither known to him nor introduced by some person known to him, gave evidence at the trial which appears fully to confirm the view that he did supply the poisons under such improper conditions. According to the local newspaper report, A. H. Molson, Manager of the Spalding Branch of Dr. Talbot's Herbal Remedies Company, Limited, stated that prisoner came to him on Saturday, April 22, and asked for two ounces of laudanum and one ounce of "white mercury" for poisoning rats. "He had been a customer before—at least, witness thought so, as his face seemed familiar . . . He (prisoner) signed his name and address in the sales of poisons book, as 'Edward Bell, of Holbeach Hurn,' and gave the name of Mr. Clayton as a person who knew him." On a subsequent occasion Bell returned, and "asked to be supplied with arsenic, but not having any, strychnine was supplied instead . . . also a further ounce of mercury." In cross-examination, the same witness said "he believed prisoner had been in his shop four or five times previously; his face was familiar, but he did not know his name. He knew Mr. Clayton, his employer, very well by name, but did not know him personally." In effect, therefore, Molson appears to have acknowledged that he neither knew the man who purchased he poisons, nor the person whose name was given as a reference, and there was no suggestion of the purchaser having been introduced by a person known to the seller. Under those circumstances, therefore, the requirements of the Act certainly appear to have been ignored by the seller

---

TWO OTHER NOTABLE POISONING CASES have also been concluded this week. In one, Mary Ann Ansell was found guilty of having caused the death of her sister, who was an inmate of Leavesden Asylum, near Watford, by administering phosphorus paste in a cake, sent by post. The second case was that of a girl of fifteen, who was charged with administering atropine to the members of her employer's family, in a rice pudding. The defence, however, was that the whole affair was the result of an accident. The bottle containing the atropine solution was alleged to have acquired a flavour of almonds, and the prisoner stated that she added some of the contents to the pudding in the belief that she was adding almond flavour. In the result the judge (Mr. Justice Mathew) advised the jury not to convict the prisoner of an attempt to murder, and she was acquitted.

A GIFT OF POISON is supposed by some registered chemists to be exempt from the restrictions imposed by Section 17 of the Pharmacy Act, 1868, but it is far from certain that such is absolutely the case, and in any event the onus of proving that no consideration had been received might place any chemist who had been freely distributing poison in an extremely awkward position. At an inquest held in the City Coroner's Court, Liverpool, last week, there was a case of the kind referred to, the deceased—a man of seventy-four—being shown to have died as the result of taking prussic acid which had been given to him by a chemist's assistant. The latter, who is a duly registered person, said he had known the deceased as a customer for about ten years and gave him the two drachms of prussic acid to poison "an old dog." As no sale was effected no entry was made in the poison book, witness considering that an entry was only required when an actual sale was effected. The Coroner, however, said it was essential that every precaution should be taken by chemists supplying deadly poisons, and he expressed extreme surprise that prussic acid should have been given to the deceased upon merely saying that he wished to poison a dog. It was no palliation, he said, that the transaction was a mere gift and that the Act of Parliament did not apply, and the jury also expressed disapproval of the chemist's conduct.

THE PREVENTION OF CORRUPTION BILL which is in charge of Lord Russell of Killowen, has now been amended on report. Its object, as briefly stated in the memorandum prefacing the Bill, is an effort to check, by making them criminal, a large number of inequitable and illegal secret payments, "all of which are dishonest and tend to shake confidence between man and man and to discourage honest trade and enterprise." Sections 1 and 2 make the gift, offer, receipt, and solicitation of any corrupt payments' offences. But "corrupt payments" are not defined by the Bill, though certain transactions are declared to be corrupt. The reason given for this is that corruption "is so protean that to define it is almost impossible. For this reason the courts have always declined to define fraud." However, Sections 3 to 8 contain declarations that certain transactions are corrupt unless the contrary be shown. Subsequent sections deal with gifts to an agent and to an agent's wife or child, also to cases where prejudiced advice is given because a secret commission has been received or is expected. The practice of giving falsified invoices is also aimed at, as well as the formation of clubs to afford an indemnity against fines. In the event of the Bill becoming law, it is proposed that it shall not come into operation until January 1, 1900, in order that its provisions may become widely known before they are enforceable.

BRITISH PHARMACEUTICAL CONFERENCE.

Plymouth Meeting, 1899.

PRESIDENT: MR. J. C. C. PAYNE, L.P.S.I., J.P.

The thirty-sixth annual meeting of the British Pharmaceutical Conference will be held in the Western Law Courts, Plymouth, on Tuesday and Wednesday, July 25 and 26, and the arrangements already made include the following:—

Monday, July 24.—The President's reception at the Assembly Rooms, Royal Hotel, at 8 p.m. Scientific exhibits, vocal and instrumental music, light refreshments, etc.

Tuesday, July 25.—Opening meeting of the Conference in the Western Law Courts, at 10 a.m. 10 a.m., welcome by the Right Worshipful the Mayor of Plymouth, Alderman J. Pethick, Esq., J.P. Address by the President of the Conference, followed by the reading and discussion of Papers. Adjournment for Luncheon, at 1 p.m, at the Corn Exchange. Reading of Papers resumed at 2 p.m. until 4 p.m. 4.30 Steamer Trip along the Cornish Coast to Looe; Afternoon Tea on board.

Wednesday, July 26.—Sessions of Conference and Luncheon will be arranged as on the previous day. Afternoon Tea, 4.30, at the Assembly Rooms. At 8 p.m. there will be a Smoking Concert, a Ladies' Drawing-room Concert; and at 10.30 to 12, Dancing.

Thursday, July 27.—At 9.30 a.m. the members and their friends leave the Promenade Pier by Steamer for Mount Edgcumbe, to visit, by kind permission of the Earl of Mount Edgcumbe, his Park and Gardens. The beauty of these stately grounds defies description, they have a world-wide reputation. From the higher paths a complete panorama of the Town, the Harbour, and the surrounding country can be seen. At 12.45 a.m. the Steamer will leave Cremyll Beach for the Pier. At 1 p.m. Luncheon will be served in the Pavilion. At 2.30 p.m. Steamer will leave for trip around the Sound, through the Hamoaze and up the River Tamar to Morwellham. Afternoon Tea will be served on board. Steamer returning about 9 a.m. to the Promenade Pier.

Friday, July 28.—Arrangements will be made for the members and their friends to visit the Dockyards and places of interest in the neighbourhood.

Handbook.—A specially written and illustrated handbook to Plymouth and neighbourhood is in course of preparation, and copies will be presented to the members and their friends who attend the annual meeting.

Tickets.—No. 1 Book of Tickets, 10s. 6d. each, will admit to Conference; Luncheons at the Corn Exchange on Tuesday and Wednesday; Steamer Trip to Looe; Afternoon Teas on Tuesday and Wednesday; Smoking Concert and Ladies' Drawing-room Concert. By kind permission of the director of the M.B.L., admission to the Aquarium of the Marine Biological Association may be obtained on exhibition of Book No. 1. No. 2. Book of Tickets, 10s. 6d., Steamer Fares; Promenade Pier Ticket; Luncheon in the Pavilion; Afternoon Tea on Steamer, etc. Owing to local arrangements that have been made, and in order to insure the comfort of our visitors, applications for tickets cannot be entertained after Monday, July 17.

Hotels.—The Royal Hotel, Plymouth, has been selected as the nominal headquarters, but only a very limited accommodation has been obtained there. The Local Committee wish to emphasise a fact already made known to most of the members through the official press that, owing to two other Conferences meeting at Plymouth the same week as the British Pharmaceutical Conference the hotels will be unusually full. If members who propose visiting Plymouth will kindly write at once to the Hon. Local Secretary, Mr. J. Davy Turney, 15, Leigham Terrace, Plymouth, specifying what accommodation they require, and allowing him under the circumstances to use his own discretion, much valuable time will be saved and possibly inconvenience avoided.

Local Committee.—The following are the members of the Plymouth Local Committee:—Messrs. C. J. Park (Chairman), Plymouth; J. Allen, Plymouth; N. Andrews, Plymouth; W. H. Austin, Devonport; J. Harvey Bailey, Plymouth; A. P. Balkwill, Plymouth; J. Barge, Plymouth; E. P. Blamey, Plymouth; J. Blamey, Plymouth; Geo. Breeze, Plymouth; A. D. Breeze, Plymouth; J. Kinton Bond, Plymouth; J. Cocks, Stonehouse; H. J. Dalgleish, Exeter; H. D. Davey, Devonport; R. D. Doble, Tavistock; F. Downing, Launceston; E. L. Foster, Plymouth; G. H. Green, Plymouth; H. P. Hearder, Plymouth; Freeman W. Hunt, Plymouth; G. E. Jackson, Crediton; Martin K. Johnson, Devonport; H. Keen, Penzance; P. A. Kelly, St. Budeaux; N. F. Lakeman, Modbury; J. A. Lamble, Devonport; J. Hinton Lake, Exeter; J. Luxton, Exeter; F. Maitland, Stonehouse; J. Maurice, Plymouth; J. G. Netting, Plymouth; J. Poad, Looe; F. H. Ralph, Plymouth; R. F. Roper, Plymouth; J. Rees, Looe; J. W. B. Swainson, Devonport; S. B. Turney, Plymouth; J. Davy Turney (Hon. Local Secretary), Plymouth; W. Condy U'Ren, Plymouth; C. Wakeham, Helston; C. T. Weary, Devonport; J. M. White. Devonport; W. Wise, Launceston; E. T. Wood, Stonehouse; W, Woods, Plymouth; W. H. Woods, Plymouth.

Ladies' Committee.—A Committee of Ladies has also been formed to ensure the comfort of the lady visitors.

PHARMACEUTICAL SOCIETY.

MAJOR EXAMINATION QUESTIONS.

PHYSICS.

Monday, July 3, 1899.—*From* 10 *a.m. to* 1 *p.m.*

1. What do you understand by the satement that the specific heat of mercury is 0.032? State the use that has been made of the specific heats of the elements in determining or confirming their atomic weights, and show how the number given above is actually applied for this purpose in the case of mercury.

2. What is meant by the term "refractive index"? How would you measure the refractive index of a glass prism?

3. Describe the construction of Bunsen's ice calorimeter and explain the method of carrying out experiments with it.

4. Make a drawing of and describe fully the principles of the action of some form of stereoscope.

5. Instance three of the most notable cases with which you are acquainted of the influence of light in promoting chemical changes, and give in each case an account of the chemistry of the changes concerned.

6. Describe in detail the construction of some form of primary battery, an explain the chemical changes taking place during its action.

7. What method might be adopted with a view to determining the temperature of liquid hydrogen at its boiling point? Explain the principle of the method you mention.

8. What is meant by "coefficient of linear expansion"? Explain how temperature affects the rate of a pendulum clock.

CHEMISTRY.

Monday, July 3, 1899.—*From* 2 *p.m to* 5 *p.m.*

Only six questions are to be attempted and, of these, at least two must be taken from Part II.

PART I.

1. Explain fully why the molecular weight of a substance is equal to twice its vapour density.

2. 0.1700 gram. of an organic substance gave on combustion 13.4 Cc. of dry nitrogen measured at 15° C. and 735 Mm. pressure. Calculate the percentage of nitrogen, and, assuming the presence of only one atom of this element in the molecule of the compound, what is the molecular weight of the latter?

3. Potassium cyanide is frequently used in qualitative and quantitative analysis; state the more important cases in which it is thus employed, and explain its action in each.

4. What occurs when each of the following substances is separately heated with concentrated potash:—Phosphorus, Silicon, Silica, Aluminium, Alumina, Potassium permanganate, Magnesium chloride?

5. Describe the physical and chemical properties of bismuth and give the names, formulæ, and methods of preparation of any two important compounds of this metal.

6. How could you demonstrate the presence of combined sulphur in dilute sulphuric acid?

PART II.

7. State shortly and clearly what you understand by isomerism. Illustrate your answer by instancing two sets of isomeric substances chosen from paraffin derivatives and two sets chosen from benzene derivatives.

8. Describe fully any single method for preparing lactic acid in quantity. What is obtained by heating lactic acid (*a*) alone, (*b*) with fuming hydriodic acid, (*c*) with hydrobromic acid?

9. State fully the nature of the chemical changes that take place in the ordinary process of the manufacture of ether.

10. To what class of substances is the term "terpene" usually applied? Describe the properties of any two compounds of this class and mention the sources from which they are usually obtained.

MATERIA MEDICA (A).

Tuesday, July 4, *from* 10 *a.m. to* 11 *a.m.*

1. Name the commercial varieties of sarsaparilla root with the botanical and geographical sources from which they are derived. What are the chief points of difference between them?

2. What are the chief constituents of the following drugs, and what steps would you take to ascertain whether given samples of each were of good quality, viz., pellitory, jalap, calumba, ipecacuanha, ginger, and rhatany?

MATERICA MEDICA (B).

Tuesday, July 4, *from* 2 *p.m. to* 3 *p.m.*

1. Name the chief commercial varieties of ipecacuanha root with their botanical and geographical sources. How would you determine the value of a given sample for pharmaceutical use?

2. What are the chief constituents of the following drugs, and what steps would you take to ascertain whether given samples of each were of good quality:—podophyllum, rhubarb, linseed, stramonium leaves, valerian root, henbane leaves?

BOTANY (A).

Tuesday, July 4, *from* 11 *a.m. to* 1 *p.m.*

1. Write a short essay on climbing plants. Give illustrative examples and explain in each case by what means the plant climbs. What advantage does a plant gain from a climbing habit?

2. Give a comparative account of the structure of the sexual generation in a liverwort and in a fern.

3. Give an account of the influence of light on the growth of (*a*) the shoot, (*b*) the root.

BOTANY (B).

Tuesday, July 4, *from* 3 *p.m. to* 5 *p.m.*

1. Give a general account of the structural modifications met with in terrestrial plants growing on the sea-coast of Britain.

2. Describe carefully the changes which an ovule undergoes in becoming a seed.

3. Describe briefly the structure of the reproductive organs of an Ascomycetous fungus (*e.g.*, *Eurotium*) and trace succinctly its life history.

PRACTICAL MATERIA MEDICA (A).

Tuesday, July 4, *from* 2 *p.m. to* 3.30 *p.m.*

1. Prepare and leave for inspection slides showing the histological characteristics of the henbane leaf provided. Draw and describe your preparations, pointing out any important features presented by them.

2. Report upon the sample of powdered henbane leaf.

PRACTICAL MATERIA MEDICA (B).

Tuesday, July 4, *from* 9.30 *a.m. to* 11 *a.m.*

1. Prepare and leave for inspection slides showing the histological characteristics of the stramonium leaf provided. Draw and describe your preparations, pointing out any important features presented by them.

2. Report upon the sample of powdered stramonium leaf.

PRACTICAL BOTANY (A).

Tuesday, July 4, *from* 3.30 *p.m. to* 5 *p.m.*

1. Prepare and mount one transverse section of A. Identify the organ. Draw the preparation and give explanatory references on your drawing.

2. Describe B carefully and point out the functions of its various parts.

3. Refer C to its natural order, giving your reasons for so doing. Describe the flower and draw its floral diagram and give its floral formula.

PRACTICAL BOTANY (B).

Tuesday, July 4, *from* 11 *a.m. to* 12.30 *p.m.*

1. Prepare and mount one transverse section of A. Identify the organ. Draw the preparation and give explanatory references on your drawing.

2. Describe B carefully and point out the functions of its various parts.

3. Refer C to its natural order, giving your reasons for so doing. Describe the flower and draw its floral diagram and give its floral formula.

EUGENOFORM.—Sodium eugenol-carbinol occurs in broad, colourless crystalline foliaceous crystals, melting at 160° C., which are readily soluble in water, with difficulty in alcohol, and insoluble in ether. When taken internally, it readily liberates formaldehyde. Vogel recommends eugenoform for the disinfection of the stomach and intestines in cholera, typhoid, and other infectious diseases. Eugenoform is equal to phenol in its action, and may be taken in much larger doses. A single dose, morning and evening, consists of 0·5 to 1·0 gramme, and this may be doubled in a few days.—*Pharm. Centr.*, **40**, 135.

PHARMACY IN AUSTRALASIA.

(*From our Melbourne Correspondent.*)

PUBLIC attention has been drawn in Victoria to the urgent necessity of an amendment of the existing Poisons Law by the recent death, from cyanide of potassium, of a young married woman named Bentley, at South Melbourne. Under the law, as it stands at present, there is practically no restriction upon the sale of cyanide of potassium, which is exempted under the head of photographic materials, and may be obtained from any protographer without any record being made of the sale, while protographers are not even compelled to keep the poison locked up. Under the circumstances it is not surprising that the detectives found it impossible to discover how the woman became possessed of the poison, and on the suggestion of the coroner, who described this as a "terribly dangerous" state of things for the community, the jury added to their verdict of death from poison, self-administered, the following rider: "We are of opinion that further restrictions should be placed upon the sale of cyanide of potassium."

As a matter of fact, the Amending Act introduced by the Government last year did, as was pointed out in these notes, provide that the sale of poisonous substances used by photographers should be subjected to certain provisions for labelling the bottles, etc., and keeping a record of the sales; and, so far as it went, was calculated to greatly minimise the present "terribly dangerous" state of things. The Pharmacy Board, supported by the craft, strongly urged that the Bill did not go far enough; that, in fact, no poisons legislation could be said to afford any substantial security to the public, whether from crime or accident, which permitted of the general and indiscriminate distribution of such common means of suicide and murder as "Rough on Rats," "Battle's Vermin Killer," and other cheap and deadly poisonous mixtures; and that the sale of all patent and proprietary medicines containing poisons should also be placed under effective restrictions. Unhappily the Government could not be induced to undertake this larger "contract," and the measure was quietly dropped. It now remains to be seen whether, in view of the coroner's remarks, and the jury's rider, in the case referred to, to which the Chief Secretary's attention has been drawn by the Pharmacy Board, the Government will not feel compelled to tackle the subject in a more liberal spirit during the coming session.

MR. GEORGE SWIFT, a well-known and greatly esteemed member of the craft in Melbourne, died very suddenly on May 12, from rupture of the heart. Commencing his pharmaceutical career as an apprentice in Leicester (England), Mr. Swift was for some time in the employment of the well-known firm of Allen and Hanbury, Plough Court, London. On his arrival in Victoria, in 1864, he accepted an engagement with Messrs. H. Francis and Co., Bourke Street, Melbourne, of which firm (as Francis and Swift) he subsequently was for some years a partner, and after several other experiences finally established himself about five years ago in Collins Street. Mr. Swift was for some time a member of the Council of the Pharmaceutical Society of Australasia, and from May, 1887, until January, 1896, a member of the Pharmacy Board of Victoria. The funeral was attended by representatives of the Pharmacy Board, the Pharmaceutical Council, and a large number of the pharmaceutical and medical professions, as well as a numerous contingent of private friends, by all of whom his death will be sincerely mourned.

ANOTHER case of sudden death occurred recently at Adelaide, S.A., where Mr. Lenthall, for many years with Messrs. F. H. Faulding and Co., was taken ill while on his way to business, and died shortly after his removal to the hospital. It appears that Mr. Lenthall had been ailing slightly for a few days previously, and that his medical attendant feared typhoid. His loss is greatly regretted by his fellow employés and his employers, who closed their establishment for the funeral.

THAT Australian pharmacists—at least those of New South Wales—feel considerably chagrined by the non-recognition of their certificates by the authorities in Great Britain is demonstrated in a somewhat forcible manner by the record of the proceedings at the May meeting of the Pharmacy Board of the colony mentioned. At the meeting referred to, Mr. W. M. L. Wilson, holder of the Minor Certificate of Great Britain, applied to know if after serving three years in the colony he could present himself for the qualifying

examination, adding that he had attended a course of lectures (as required by the N.S.W. Pharmacy Act) at Bloomsbury Square, London. The following discussion on the subject then ensued :—

> The Registrar intimated that Mr. Wilson was now serving as an apprentice with Mr. Pattinson, of Sydney, but could not say when he was indentured.
> Mr. Bellemey: Unless he served twelve months of his time prior to the passing of our Act, he will have to pass the Preliminary examination, and then complete his full term of apprenticeship, besides attending a course of recognised lectures.
> The Registrar: He produces his certificate of the Minor examination of Great Britain.
> Mr. Hallam: If he has passed that Examination we ought to admit him.
> The President: Does he produce his English Preliminary examination Certificate?
> The Registrar: No.
> Mr. Butcher: Having passed the Minor examination, it goes without saying that he must have passed the Preliminary examination.
> Mr. Brothwood: The question is, whether or not we are going to recognise the Minor certificate of Great Britain.
> The President: This is the first case of the kind we have had before us.
> Mr. Brothwood: If we recognise the minor certificate of Great Britain we must register him. We don't even recognise the Major certificate of Great Britain.
> Mr. Bellemey: Just so. The Act was drafted so that we might have the power of forcing the recognition of our certificate of qualification in Great Britain. He moved "That the application be not entertained."
> The Registrar said, in reply to a question, that Mr. Wilson had been in this colony for about two years.
> Members: Then he ought to know the Pharmacy Act.
> Mr. Jones seconded the motion, which was carried *nem. con.*

Later on in the proceedings at the same meeting an even more deliberate challenge was launched at the claims of British pharmacists for recognition by the mother colony. The case was that of one Frederick Thornley, of Dulwich Hill, who wrote asking for registration on the grounds that he held the Major certificate of Great Britain, and had been dispensing at the Cootamundra Hospital. According to a statement made by the Registrar, it appeared that the applicant came to New South Wales about the year 1884; but this is how his claim was treated :—

> Mr. Bellemey We have power under the Act not to entertain the application. Until our certificate is recognised in Great Britain, theirs ought not to be recognised here.
> Mr. Brothwood expressed similar views, and the application was refused.

Whether it is or not that the new Registered Pharmacists' Society of N.S.W. threatens to make things "hum" in Sydney, the fact remains that the Pharmacy Board of New South Wales has all at once become aware of the fact that it has been permitting the Council of the Pharmaceutical Society to ursurp one of its most important functions—that of the control of the preliminary examinations. The matter was brought before the May meeting of the Board by Mr. Bellemey, who, in moving—

> That the Pharmacy Board make arrangements with Mr. Lloyd, the Preliminary Examiner, or some other suitable person, to carry out, as soon as possible, the preliminary examinations as provided for in the Pharmacy Act, sec. 11, sub-sec. 1, pointed out that the Board had not complied with the section in the Pharmacy Act which provided for the appointment of examiners. The examinations had been carried on by the Pharmaceutical Society, and the certificates from that body had been recognised by the Board just as if the examinations had been sanctioned by the Board. The preliminary examiner should be some person appointed by the Pharmacy Board, and that step had not been taken. The result was that the fees from the candidates, which properly belonged to the Board, went into the coffers of the Pharmaceutical Society.

Now that the Board has awoke to its rights and responsibilities, it is understood that it is its intention to arrange for a considerably reduced scale of fees. Apart from this, however, it appears that owing to its previous laxity all the Preliminary examination certificates issued since the passing of the Act would have been quite worthless but for the words in a sub-section, "or acknowledged by the Board."

Meanwhile, leaving the Society to look after itself, the new Registered Pharmacists' Society of N.S.W. seems to be making good headway. Its application for registration under the Companies Act (under the section "not for profit") is under Government departmental favourable consideration; and the success of a series of "Winter" lectures to be given under its auspices is fully guaranteed by the promises and expressed sympathy of such men as Professor Anderson Stuart, Professor Pollock, Professor Liversidge and Mr. J. H. Maiden (Director of the Botanical Gardens).

At the April meeting of the Council of the Pharmaceutical Society of New South Wales, Mr. J. C. Hallam (who has recently been appointed a member of the Pharmacy Board), was elected to fill the seat rendered vacant by the recent death of Mr. H. W. Sadler; and Mr. Sydney Mears to occupy that vacated by Mr. W. G. Jones (resigned). As Mr. Hallam has had previous "official" experience, and Mr. Mears is a man of marked personality, the Council has reason to congratulate itself on these accessions to its strength.

It seems sad to say, but it is undoubtedly a fact, that no great enthusiasm is being expressed in Australia anent the proposed Indian and Colonial Addendum to the British Pharmacopœia, 1898. In Victoria the latest communications on the subject have been referred by the Pharmacy Board and the Pharmaceutical Society of Australasia to the Lectorial Board for a "report"; while in South Australia the Pharmacy Board resolved "that the letter be replied to, intimating that in the Board's opinion the addendum, as suggested, would not appreciably affect dispensing in this colony, and that in the case of at least one drug, the present officinal definition was more satisfactory."

EXTRACTS FROM CONSULAR REPORTS.

The Jordan Almond Business during the year 1898, according to Consul Finn, in a recent report on the trade and commerce of the Consular district of Malaga, was very unsatisfactory to shippers and importers abroad, as, owing to false reports about the scarcity of the crops, they submitted to high prices at the beginning of the season, and these prices were further forced up by pressing wants to fulfil early engagements. The demand could not support these high figures, consequently fruit, which growers had refused 50 pesetas for in September, in the spring of this year could be had for 27½ pesetas. The prospect for this season's crop is said to be most satisfactory.

The Import of Foreign Opium into Amoy (China) fell about 600 piculs in quantity and £31,000 in value, the figures being 3,800 piculs for 1898, and 4,400 piculs for 1897, and £298,000 and £329,000 respectively. The decrease was in the Persian article, Indian opium showing an actual increase of 400 piculs. Native opium advanced some 200 piculs on the figures for the previous year, it being imported from Kiangsu, Ssuchuan, and the greater part (some 80 per cent.) from Yünnan.

The Total Production of Chinese Opium is very considerable and appears to be on the increase. The fact is that the cultivation of the poppy pays better than corn-growing, and will stand heavy taxation better than most industries, for its chief competitor, Indian opium, is burdened with a heavy duty, and the opium smoker will make any sacrifice to satisfy his craving. There are no statistics of the local crop in the district round about Amoy, but its value, according to Acting-Consul Little, is estimated at over 2,500,000 dols.

The Consumption of Morphine in the Amoy district last year increased by some 2,000 ounces, and appears to find considerable favour with the Chinese, for the import has risen in three or four years to over 11,000 ounces. The greater portion of it is taken in the form of pills, but hypodermic injection is also common; it is frequently sold, too, as a cure for the opium habit. The retail price is said to be about 3 dols. per ounce.

A Source of Riches, consisting of large tracts of forest with abundance of rubber trees, is said to exist in the unexplored interior of the State of Bahia (Brazil), but unfortunately, owing to the difficulties of transport through a country without roads, and to the fact that the forests are inhabited by different tribes of Indians, some of whom are cannibals, it is said to be unavailable. The quantity of rubber produced in the State during 1898, however, increased materially, the high prices realised inducing collectors to procced farther afield for supplies.

Coffee Tablets.—A few weeks ago the preparation of wine in tablets was reported from France, then followed a rumour that in Germany the national beverage, beer, had been compressed into a convenient form for carrying in the vest pocket, and now comes a report from Rio de Janeiro that a process has been invented and patented for preparing coffee in tablets by a system of compression. It is argued that not only will there be less expense in exporting coffee in that form, but that the consumer will be more certain of receiving the pure unadulterated article.

REVIEWS AND NOTICES OF BOOKS.

A Short History of the Progress of Scientific Chemistry in Our Own Times. By William A. Tilden, D.Sc., F.R.S., etc. Pp. x. + 273. Price 5s. London: Longmans, Green, and Co. 1899.

Professor Tilden has written a concise account of the progress made in chemical science in our own times, and in so interesting a manner that the student is enabled clearly to understand how the system of scientific chemistry has gradually advanced to its present position. This short history, in fact, forms a worthy sequel to Thomson's 'History of Chemistry,' which deals with the science from the earliest times to 1831. Dr. Tilden starts from 1837, when Liebig, the founder of organic chemistry, was at the height of his fame, and was attracting students from England—and indeed from all parts of Europe—to the famous laboratory at Giessen to study the new organic chemistry. At that period Berzelius's views on the composition of salts and acids—that the base was electro-positive and the acid radicle electro-negative—were still predominant. Liebig and Wöhler had established the theory of compound radicles in organic chemistry—from which Frankland was led to the investigation resulting in the discovery of ethyl—and Dumas that of substitution, which eventually upset the Berzelian theory of electro-chemistry. Chemical science in this country was sufficiently satisfied by the Royal Societies of England and Edinburgh being the only important societies to receive communications relating to chemical investigations, for it was not until 1841 that the Chemical Society and the Pharmaceutical Society were considered necessary and came into existence. The number of papers on chemical subjects then and now gives evidence of the progress made in our own times. The important discoveries in chemistry are all distinctly set out by the author, such as Joule's determination of the mechanical equivalent of heat and its relation to thermo-chemistry; Kirchhoff and Bunsen's discoveries in spectrum analysis, and the important results obtained in spectroscopy; the application of the laws of Avogadro and Petit and Dulong as a means of determining atomic weights; the critical point; Frankland's doctrine of atomicity; the periodic law; Pasteur's work; stereo-chemistry; ionic dissociation; liquefaction of gases. It is also pointed out how synthetic chemistry applied to carbon compounds has been developed since urea was synthesised by Wöhler and acetic acid by Kolbe. There is also a chronological table of important events in chemical science. In a retrospect of sixty years it is, of course, difficult in some cases to rightly assign the claims for originality, but it can truly be said that no fault can be found with the impartial judgments expressed by the author. For instance, no one has now a right to dispute Newlands' claim as the discoverer of the periodic law, although, as Dr. Tilden neatly puts it, "the Chemical Society in 1866 were disposed to laugh at Newlands and his law. Twenty-one years later the Royal Society awarded him the Davy medal for his discovery." All students of chemistry should read this book.

The Soluble Ferments and Fermentation. By J. Reynolds Green, Sc.D., F.R.S. Pp. i.-xiii., 1 to 480. Price, 12s. Cambridge: Messrs. C. J. Clay and Sons. 1899.

As the author points out in the preface to this book, the various problems connected with the phenomena of fermentation have received attention during the past ten years from so many investigators in different countries, and are now occupying the minds of so many people, that a synopsis of what is known on the subject had become a pressing need. That need Professor Green has set himself to satisfy, and the result is the addition of this handsome volume to the excellent series of Cambridge Natural Science Manuals.

The contents of the volume are arranged in twenty-four chapters, the first of which is naturally devoted to a consideration of the nature of fermentation and its relation to enzymes. Early views of fermentation are summarised; the work of Becher, Leuwenhoek, Lavoisier, and other workers is briefly referred to; and a concise account is given of the discovery and classification of enzymes. Fermentation is provisionally defined in this chapter as "the decomposition of complex organic material into substances of simpler composition by the agency either of protoplasm itself or of a secretion prepared by it." The fundamental difference between organised and unorganised ferments or enzymes is shown to be a difference of differentiation of the organisms in which they are produced, and the study of fermentation resolves itself very largely into an investigation of the destructive or decomposing power of protoplasm, exerted either directly or by means of secreted enzymes.

The activity of enzymes is greatly dependent upon temperature, ceasing at temperatures approaching the freezing point of water but increasing gradually as the temperature rises, the maximum being attained between 30° and 50° C., above which it gradually diminishes, and finally disappears. It is pointed out that "it is generally held that enzymes do not themselves enter into the reactions which they set up, but provoke those changes without undergoing any alteration. Further, they are not destroyed by their own activity, the energy with which they work not apparently proceeding from any decomposition of their substance." Certain recently observed facts, however, throw a certain amount of doubt on the accuracy of those generally accepted statements, and those points are discussed by the author in a subsequent chapter.

For convenience of discussion, the enzymes have been classified according to the materials on which they work. Thus, in one group, are placed those which transform insoluble carbohydrates into soluble sugar, including the various forms of diastase, which attack starch and its allies; inulase, which decomposes inulin; and cytase, which hydrolyses cellulose. A second group includes enzymes—invertase, glucase, etc.—which transform sugars of the biose type into simpler sugars, generally hexoses. Emulsin, myrosin, and other bodies decompose glucosides; pepsin and trypsin decompose insoluble proteids; the clotting enzymes—rennet, thrombase and pectase—produce jelly-like substances from various soluble bodies; lipase decomposes oils or fats; the oxidases, including laccase and tyrosinase, assist in the oxidation of various substances, and there are many other enzymes which appear to occupy isolated positions, such as urease, which forms ammonium carbonate from urea, and zymase, the alcohol-producing enzyme discovere by Buchner.

Vegetable diastase in its different forms is dealt with in chapter two, and animal diastase in chapter three, after which the conditions of the action of diastase are considered. Subsequent chapters are devoted to accounts of the occurrence, characters, etc., of inulase; cytase and other cellulose-dissolving enzymes; sugar-splitting, glucoside-splitting and proteolytic enzymes; fat-splitting, and clotting enzymes. Ammoniacal fermentation, oxidases, alcoholic fermentation, the fermentative power of protoplasm, and the secretion, constitution, and mode of action of enzymes are next treated at length, the last chapter being a careful summary of the various theories of fermentation. A bibliography and index complete the work, which is in every way an admirable one and as important an addition to scientific literature as has of late been presented to the world. Being in itself an extended critical review of all that is known on the subject of which it treats, the book hardly lends itself to criticism, and this all too-imperfect notice must be concluded with a strong recommendation to everyone who is in any way interested in the subject of fermentation to add a copy of Professor Green's excellent work to those which he is in the habit of consulting regularly.

PROCEEDINGS UNDER THE PHARMACY ACT, 1868.

Case under Section 17.

Selling Laudanum Without a Label.

At the Leigh (Lancashire) Police-court on Wednesday last, before Dr. A. J. Lowe and Mr. F. Burton, William Warden, landlord of the Cross Keys beer house, Culcheth, near Leigh, who is also a grocer and "patent medicine" vendor, was charged with selling a bottle containing laudauum without putting a label thereon.

Mr. T. R. Dootson appeared for the prosecution, but defendant was not represented.

Mr. Dootson said he appeared on behalf of Superintendent Higgiubotham, and the proceedings were taken under Section 17 of the Pharmacy Act of 1868, which stated that "it shall be unlawful to sell any poison, either by wholesale or by retail, unless the box, bottle, vessel, wrapper, or cover, in which such poison is contained be distinctly labelled with the name of the article and the word 'poison,' and with the name and address of the seller of the poison." The allegation in the case was that Mr. Wardeu on June 9, sold some laudanum to Florence Drinkhall, a girl, aged seven years. The girl was sent by her mother to buy some Godfrey's cordial for the baby, which was ill; but, instead of asking for that cordial, she asked for and was supplied with a pennyworth of laudanum, which was put into a small bottle that she brought with her. No label was on the bottle when it was brought to the shop and none was put on there. The girl returned home, gave the bottle to her mother, who gave a portion of the contents to her baby, which died. At the coroner's inquest a verdict of "Death from misadventure" was returned. Of course, for anyone to sell poison in that way was a serious offence, especially if the purchaser was a young girl.

Betsy Drinkhall, wife of Septimus Drinkhall, of Culcheth, and her daughter Florence, gave evidence bearing out this statement.

Police-constable Leeming said defendant in reply to his question said he had sold the laudanum to the girl.

Defendant, in reply to Dr. Lowe, said he thought the laudanum was for toothache. He was never told it was for a four-weeks'-old baby. He had never sold laudanum before, although he held a "patent medicine" licence, and the laudanum in question was taken out of a bottle which was used by his grown-up daughter, who died some months ago. He did not sell the laudanum to the child, he gave her a few drops. He was afterwards informed there had been a penny found on the counter. He had been a policeman twenty years, and only retired to take up his present shop, and he was very sorry matters had turned out as they had. He was positive that nothing was said to him about the laudanum being for the baby.

Mr. Buxton said the Bench considered the case serious, and defendant would be fined £2, and costs.

Tannoform and Tannoform Dusting Powder.—Tannoform is a methyl ditannin, obtained by the condensation of tannin with formaldehyde. It forms a voluminous, reddish-white, odourless and tasteless powder, which decomposes at 230° C. Tannoform has proved, after several years' trial, to be one of the best local applications for wounds, diabetic gangrene, and various forms of chronic and acute eczema. It also has a marked effect in checking excessive perspiration, so much so that it may be regarded as a specific for hyperhydrous and bromhydrosis. The perspiration is not checked altogether, but regulated. The evil odour and irritation of the skin following excessive perspiration are entirely avoided, without any unpleasant consequences. Frank recommends the compulsory use of tannoform by all military authorities, and reports brilliant successes in over one hundred cases of footsores. Inflamed and frequently lacerated feet are restored to a normal condition in a very short time by the simple use of tannoform dusting powder, a mixture of tannoform, 1 part, with French chalk, 2 parts. In very bad cases tannoform itself is rubbed on the soles and between the toes. For eczema a 10 per cent. tannoform ointment is the best application. Tannoform is equally beneficial in counteracting chafing. For tourists, cyclists, sportsmen, and athletes tannoform in fine powder put up in dusting bags forms an excellent remedy.—*Schweiz. Woch.*, **37**, 66.

LETTERS TO THE EDITOR.

NOTICE TO CORRESPONDENTS.—All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received, if specially arranged for, as late as Thursday morning. Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C., and Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

The Question of Title.

Sir,—After an experience of twenty-eight years (sixteen qualified), I must respectfully deny the soft impeachment of "darkness and ignorance" ascribed to me by your correspondent, G. Ellinor. I frankly admit the truth of all he asserts, but have yet to learn that a thousand wrongs will make one right, and to show that I have not been in ignorance of these facts, I may tell him that for these reasons I have refrained from voting for candidates for election to the Council of late years, and have only once during fifteen years' connection with the Society voted and regretted the step I took then. If your correspondent could refer to former correspondence of mine to your columns he would see similar facts to those he has called attention pointed out by me in one article especially, styled "Trade Morality." Instead of Pharmacy Law Amendment, I would suggest in a series of articles I have prepared: 1st, The reformation of the Society and its Council; 2nd, The method of apprenticing young men to the profession of pharmacy, instead of the system now in vogue; 3rd, The licensing of assistants and of businesses to ensure the safe custody and legislative control of every place in which pharmacy is carried on, so that no one should evade the Act by keeping open branch shops except under the care and control of a duly qualified licensed and registered assistant. The fact is also patent to anyone that thinks that the Poisons Act has been nullified until recently by the sale of such poisons under cover of the patent medicine stamp, the hapless seller was prosecuted; but what did the Society do to the manufacturer before the Collis Browne's chlorodyne test case was made? I am afraid it is rather late in the day to stop company pharmacy, but it behoves every one like myself who is trading upon his own capital for his own profit that he should not be handicapped by the capitalist company unless each director and shareholder has a right by qualification under the Pharmacy Act, 31 and and 32, Vic., cap. 121, and to that end licence and coutrol should be demanded by every individual member, who could, if he wished, become a member of a legally qualified company. If the Society had had any grit at the time of the test case of the London Provincial Supply Association, and had an able barrister to have pointed out that this was the way to get a qualified company, the dictum would not have been given that "it was not possible for a company to pass the examinations for qualifying." Such rot as that to emanate from such wiseacres as Law Lords shows clearly that by spending the money we could get a different construction put upon that judgment now, as Law Lords following in the march of progress see things differently to what they did eighteen or twenty years ago.

Torquay, June 30, 1899. Wm. Jno. Rawling.

The Sale of Benzene.

Sir,—I am obliged for your comment on the above in this week's Journal, and am also pleased to hear that the Society is in correspondence with the licensing authorities under the Petroleum Act. It certainly appears to be an unwarrantable interference with the trade. I frequently have customers ask for a small quantity of benzene to take out a spot of grease, perhaps about the size of a shilling, on their coat or dress. They are not disposed to purchase a bottle; consequently I am obliged to tell them that the County Council, with its usual officiousness in small matters, will not allow the liquid to be sold in any other way. It is very certain that if a chemist is not fit to be trusted with a pint of benzene, which is about the most that a great many of us will keep in stock, he is certainly not fit to dispense poisons. I have been in shops where benzene was kept on the shelf in an ordinary gilt-labelled bottle, and the proprietors never had or even thought of a mishap. Doubtless technically it would be considered dangerous, yet what is possible is not very often probable. It is very easily understood that precautions are absolutely necessary where large quantities of an inflammable spirit are stored; on the other hand, there is no rule without an exception, and this appears to be one of them.

East Dulwich, July 1, 1899. T. W. SANDY.

Sir,—I have a 10-gallon retail licence for the sale of benzene, benzoline, etc. The plan I adopt may be useful to other chemists. I have a small outbuilding at the foot of the yard about 12 feet from the main building. The insurance company endorse my policy that only two gallons may be kept and retailed straight away to the customer; they allow this without making any extra charge. The outbuilding is, of course, uninsured. As an extra precaution I never allow the article to be sold after the gases are lighted.

Bishopwearmouth, June 30, 1899. ALFRED D. PURSE.

The Retirement of Mr. Wootton.

Sir,—It has been announced that Mr. A. C. Wootton retired from the editorship of the "Chemist and Druggist" on the 30th of last month. We, the undersigned, feel that a large number of his trade friends desire to express their esteem and respect for him, and also to make some public acknowledgment of the services which he has rendered to the trade during the thirty-two years he has occupied the position he is now relinquishing. We beg to invite those desirous of participating in this matter to attend a private meeting to be held on Monday next, July 10, at 3 p.m., at Anderton's Hotel, Fleet Street, London, E.C., to decide upon the necessary arrangements.

(Signed)

ALBERT COOPER	DAVID HOWARD
W. EDWARDS, JUN.	F. HARWOOD LESCHER
F. W. FLETCHER	J. MORGAN RICHARDS
W. S. GLYN-JONES	SAMUEL ROBERTS
ALFRED S. GUBB, M.D.	JOHN THOMPSON
CORNELIUS HANBURY	THOMAS TYRER
ARTHUR B. HILL	CHARLES UMNEY
	HENRY S. WELLCOME

157, *Queen Victoria Street,*
London, E.C., July 4, 1899.

Liquor Ferri Perchlor. Fort., P.B.

Sir,—A comparison between the last two British Pharmacopœias will show a great difference in the amount of Fe_2O_3 which should be contained in this liquor, although in both editions the mode of production and the specific gravity are identical. In that of 1885 it is stated that one fluid drachm should contain 15 to 16 grains, *i.e.*, 5 C.c. should contain from 1.369 to 1.476 grammes; whereas in that of 1898 5 C.c. should contain 1.6 grammes, there being a difference of .124 grammes per 5 C.c. The results of a few experiments seem to show that the 1885 edition is the more correct, as it was found impossible to obtain a liquor of sp. gr. 1.42 to contain 1.6 grammes Fe_2O_3 per 5 C.c. A sample of the liquor was carefully made, using the quantities mentioned in and following every detail as laid down by the P.B. On making the solution up to the required volume (17½ fluid ounces) the sp. gr. was 1.476, and in order to obtain a sp. gr. of 1.42 as stated—it was necessary to add about 2 ozs. more water. 5 C.c. of this 1.42 liquor gave 1.368 grammes Fe_2O_3, corresponding with the quantity required by the 1885 edition. Thinking that an excess of free acid might account for the discrepancy, a portion of the liquor was carefully evaporated to expel all the free acid, and the thick liquid was diluted with pure water to a sp. gr. of 1.42. On testing 5 C.c. of this gave 1.436 grammes Fe_2O_3, a result still agreeing with the 1885 edition. It will be of interest if some of your numerous readers will give their experience in this matter.

Poplar, E., July 4, 1899. FREDK. J. ALLEN,

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Remuneration of Witnesses (A. H. B.—31/3).—Witnesses subpœnaed on the part of the Crown are allowed travelling and other expenses according to a fixed scale of allowance. You should claim as a professional man and can ascertain the proper amount to claim by referring to the scale at the Court.

Benzene and Benzoline (F. P. B.—192/40).—For the purposes of the Petroleum Acts, the term "petroleum" includes "any rock oil, Rangoon oil, Burmah oil, oil made from petroleum, coal, schist, shale, peat, or other bituminous substance, and any products of petroleum, or any of the above-mentioned oils." The legal definition of the term "petroleum" is such of the above liquids as, when tested in a specified manner, give off an inflammable vapour "at a temperature of less than seventy-three degrees of Fahrenheit's thermometer."

Storm Glass (F. R.—31/8).—Have you tried the formula published in the *Pharmaceutical Journal* for May 27 last, at page 502?

Combined Toning and Fixing Bath (J. E. B.—31/9).—A suitable formula was given at page 23 of our photographic supplement, published April 15 last.

Hand Camera (R. H. R.—31/11).—Everything depends upon the price you care to pay. For a beginner Edwards' half-guinea hand camera commends itself, and, of the more expensive forms, any of those specially referred to in the "Notes on Novelties" in our photographic supplement of April 15 last, may be depended upon to give satisfaction.

Explanatory Notes on the B.P. (G. B.—31/1).—Yes, it is hoped so.

Diseases of Children (J. R. S.—31/3).—McCaw's 'Aids to the Diagnosis and Treatment of Diseases of Children' (Baillière, 3s. 6d.) appears to meet the requirements you mention.

Botanical (W. H. J.—31/4).—The plant is *Colchicum autumnale*. The only way of getting rid of it would be to plough the field deeply and repeatedly.

Chloroform in Mixtures (W. W.—31/5).—(1) A "poison" label seems rather out of place on a mixture containing only one drachm of spirit of chloroform in six or eight ounces. (2) Part 2 of the Poisons Schedule specifies chloroform only, but the sale of a preparation containing chloroform might conceivably be held to be a sale of chloroform itself.

Headache Powders (W. W.—31/6).—Caffeine citrate is probably less harmful in its effects than the other preparations you name, but half the quantity you mention would be a safer dose for repeated use.

Purified Petroleum (J. B. M.—31/7).—You can now obtain it of any firm of wholesale druggists.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

THE GENUS NAJAS.

Dr. A. B. Rendle recently read a paper before the Linnean Society, entitled "A Systematic Revision of the Genus *Najas*." This is a primitive genus of Monocotyledons containing about thirty known species, which are generally distributed in both Old and New Worlds, and consist of submerged herbs, often of great delicacy, growing in mud in resh or brackish water. The slender stem branches more or less profusely, and the laxity or density of branching determines the habit, which shows considerable variation. The leaves are in pairs at each node; one member of the pair is slightly older than the other, and in its axil arises a branch. The flowers, which are extremely simple, arise by the dichotomy of a branch-rudiment; the lower half forming a male or female flower, the upper the lateral branch, at the base of which the flower seems in the adult plant to stand. There is a difference of opinion as to the value of the parts of the flower, Dr. Rendle's view being that the male consists of a single anther (of axial origin) surrounded by a sac-like perianth, which is enveloped in a bottle-shaped spathe, absent only in *N. graminea*. The female consists generally of a naked ovary, terminated by 2 or 3 stigmas, and enclosing a single anatropous ovule; in a few species it is enveloped by a spathe like that of the male. The seed has a hard testa, the detailed structure of which affords useful specific characters. Others are also furnished by the shape of the leaf-sheath and the form of the marginal spines.

NATALOIN AND HOMONATALOIN.

In the course of his researches on aloins, A. Leger finds that besides nataloin, Natal aloes contains another aloin, homonataloin, which differs from the former in having a CH_2 group less. The aloes were first treated with acetone to remove the resins, the insoluble residue, consisting mainly of aloins, was dissolved and crystallised from methylic alcohol. By fractional crystallation from this solvent while boiling the homonataloin was obtained in crystalline crusts, while the more soluble nataloin separated in pale yellow scales. Both aloins were anhydrous. To nataloin the author attributes the formula $C_{16}H_{18}O_7$, and homonataloin he represents as $C_{15}H_{16}O_7$. The following reactions, which are common to both these aloins, distinguish them from barbaloin. A little manganese dioxide or potassium dichromate, added to a sulphuric acid solution of the aloins, develops a bright green colour. A fragment of ammonium persulphate added to a solution of the aloin in caustic soda slowly develops a violet colour, which dyes silk, but is not fixed by cotton.—*Comp. rend.*, **128**, 1401.

GLUCOSIDES OF IVY.

Houdas find that there are several glucosides in ivy, one of which, hederin, $C_{64}H_{104}O_{19}$, he describes in detail. It crystallises from alcohol (90 per cent.) in fine long radiating needles which lose 6.2 per cent. of their weight on prolonged exposure to 130° C. and melt at 248° C. It is insoluble in water and in chloroform, aud very sparingly soluble in ether. It is soluble in alcohol and in acetone, the alcoholic solution is dextro-rotatory. When boiled with dilute sulphuric acid for 12 hours it is converted into hederidin—$C_{26}H_{40}O_4$, and two sugars —hederose, $C_6H_{12}O_6$, and rhamnose, $C_6H_{12}O_5$. *Hederidin* crystallises from boiling alcohol in brilliant rhomboidal crystals, which are insoluble in water, ether, benzene, and chloroform. It melts at 324° C., and sublimes at a higher temperature without decomposing. The sugar, hederose, crystallises from alcohol in radiating needles before the rhamnose separates out. It melts at 155° C.; its solutions are strongly dextrogyre. The rhamnose is obtained after the hederose has crystallised out, in oblique rhomboidal prisms, which melt at 93° C., and is slightly dextrogyre.—*Comp. rend.*, **128**, 1,463.

ACETIC EXTRACT OF CINCHONA.

Dr. E. R. Squibb reports that 10 per cent. acetic acid is a good menstruum for the exhaustion of cinchona bark. The U.S.P. menstruum (800 C.c. alcohol, 91 p.c.; 200 C.c. glycerin, 95 p.c.) was found to be a better one for rapid exhaustion, but the percolates were so loaded with useless and objectionable organic matters, from which the acetic acid percolates were comparatively free, that the advantage was transferred to the acetic acid side. The stronger percolates from the alcohol and glycerin menstruum were almost syrupy in consistence so black as to be almost opaque and very astringent, whilst they threw down an unmanageable precipitate of nearly insoluble cincho-tannates on dilution or admixture with other preparations or any ordinary diluents. The acetic acid stronger percolates were nearly free from those disadvantages, and far more manageable pharmaceutically as well as therapeutically. The acid menstruum besides costing very much less than the alcohol and glycerin, is much easier to manage during percolation and in the standardising process, since evaporation does not injure the percolates. The proportion of free acid contained in an acetic extract of cinchona was found to be from 10 to 11 per cent., the least quantity being present where there had been most evaporation. Ten per cent. of acid fully suffices to secure the stability and permanency of the extract under all ordinary conditions. When the extract is mixed with 3 or 4 times its volume of water, the mixture has the appearance of coffee with milk; in that condition the taste of free acid is very slight, and not disagreeable, and it is concluded that the acid fluid extract is in every way a better preparation than an alcoholic one.—*Am. Journ. Pharm.*, **71**, 305.

ASSAY OF CINCHONA.

Dr. E. R. Squibb finds that, in assaying cinchona, he can easily and completely exhaust the bark in No. 9 powder with 10 per cent. acetic acid. The apparatus he employs is a modification on a small scale of his syphon percolator and, by its aid, 10 Gm. of the powdered bark can be completely exhausted in 36 hours, the percolate then measuring 180 to 200 C.c. This percolate is evaporated to such a condition that it is capable of being stirred when hot, but a soft solid when cold. Its weight is usually equivalent to 35-38 per cent. of the cinchona taken, and it retains a small amount of acetic acid. The extract is dissolved in a mixture of ammonia and alcohol, more ammonia added to ensure all the alkaloids being set free, and separation effected by shaking out with chloroform. The alkaloids are then taken up with decinormal sulphuric acid, precipitated with decinormal potassium hydroxide, and again taken up with ether. Finally, the varnish-like residue left on evaporating the ethereal solution is weighed in order to get to approximate percentage of alkaloids, after which the alkaloids are converted into acid salts and titrated. Dr. Squibb divides the alkaloids of cinchona into three groups: (1) The quinine group, with a molecular weight of about 0·324; (2) The cinchonine group, with a molecular weight of about 0·294: (3) The remaining alkaloids, with a molecular weight of about 0·312. For pharmaceutical purposes, he thinks no cinchona bark should contain less than 5 per cent. of total alkaloids, of which at least half should belong to the quinine group, and one-fourth each to the other two groups. That proportion being arbitrarily assumed, a combining weight of 0.314 is obtained and adopted as the factor for total alkaloids in the assay process.—*Am. Journ. Pharm.*, **71**, 312.

WOMEN AS PHARMACISTS.

BY ONE OF THEM.

Fifty years ago the possibility of a woman becoming a qualified pharmacist would have been regarded as a very wild dream indeed, and anyone daring to predict such a thing would have met with ridicule. The contrast between then and now is nowhere more striking than in the field of woman's work—old ideals are abandoned, or greatly modified; woman's life is altogether freer, less artificial and restricted; educational advantages have enabled her to develop all her faculties; and it is proved by experience that women are capable of becoming successful doctors, pharmacists, dentists, and even lawyers. Few will question the statement that the "higher education" is a gain, not only to the particular women concerned, but also to society in general, for benefit to the members of any community must be a benefit to the community itself. The broader mental horizon and wider interests introduced by a more liberal education must make the person enjoying those advantages a more enlightened and useful member of society; and scientific studies, requiring great accuracy and careful observation, are perhaps particularly desirable for women, as tending to correct the somewhat vague or exaggerated methods of thought and expression which often prevail when the course of education has been less liberal.

Throughout the civilised world the desirability of better education and wider opportunities for women has during recent years attracted a great deal of attention. In America women have even greater facilities for entering the learned professions than they have here; while on the Continent, even in Germany—so conservative with regard to its women—the subject is receiving careful consideration, and the doors of the universities are being opened to women students.

WOMEN STUDENTS AT THE SCHOOL OF PHARMACY.

It is a matter of great interest to turn to the records of the discussions by the Council of the Pharmaceutical Society on the subject of women as students in the Society's School and as chemists. The report of the Council meeting held September 4, 1872, states that "the Secretary read a letter from a lady asking if ladies were admitted to the lectures of the School of Pharmacy and to the laboratory. He stated that some years ago Miss (now Dr.) Garrett applied for admission to the lectures, and the professors seeing no objection, she paid the fees and attended the course. On the matter being brought to the attention of the Council, however, some members thought such a proceeding was irregular, and a resolution was passed prohibiting the admission of ladies to the lectures in future. He did not know whether the present Council would be inclined to reconsider the matter." At the next meeting Mr. Hampson brought forward a resolution "That ladies be admitted to attend the lectures and the laboratory of the Pharmaceutical Society." It was remarked that the adverse resolution passed in 1862 was not recorded in any of the transactions, and that in view of the social and educational changes that had since taken place the present Council could not be expected to endorse a decision of their predecessors, "which was, in fact, most arbitrary, unjust, and impolitic." By the Pharmacy Act, 1868, women were admitted to the examinations, and could become legally qualified to practise pharmacy, and therefore it would be contrary to the spirit of the Act to exclude women from the instruction necessary to enable them to pass the examination. Mr. Hampson's motion was seconded by Mr. W. S. Brown, who thought no possible harm could result from its adoption. Other members said they would support the resolution if it were confined to attendance at lectures, and it was finally decided that women should be admitted to attend as students the lecture classes of the Pharmaceutical Society.

The subject again came before the Council on December 4, 1872, when Mr. Hampson moved "That lady students should be eligible to compete for the Sessional Prizes and Certificates, and for all prizes and scholarships given for proficiency by the Society." He urged that it would be most unfair to debar them from the chance of equal participation in the results of study. Another member objected to including the Bell Scholarship, which involved laboratory instruction, to which women were not admissible according to the previous decision of the Council. Attention was also called to the fact that the "Prize of Books" and the "Pereira Medal" could only be given to associates or registered students of the Society; ladies who were permitted to attend the lectures on botany and chemistry were not associates, and consequently were not entitled to compete for these prizes. An amendment proposing that ladies should be entitled to receive certificates of attendance at the lectures, and suggesting that special prizes might be offered to be competed for by lady students was brought forward by Mr. Bottle, but Mr. Hampson contended that lady students did not want special prizes, but opportunity to compete with male students under precisely similar circumstances. The law permitted women to become chemists and druggists, and therefore the Council ought to grant them the same privileges as male students. After further discussion, opinion being very much divided, it was resolved to defer consideration of the matter for a time. It was again brought forward on January 11, 1873, in a motion "That all persons attending the professors' morning lectures be eligible to compete for the prizes and certificates given at the end of the session." Mr. Hampson urged that lady students, having paid their fees, ought to be entitled to the full privilege of students. Mr. W. S. Brown supported that view. Even those who objected to the admission of women to the privileges of the Society agreed that inasmuch as they had been admitted to the lectures, they were entitled, under the bye-laws, to compete for the prizes. One member urged that "a school of pharmacy was not a place for ladies at all," while another went so far as to say that "there was some excuse for ladies seeking a medical education, but there was none for their desiring to become chemists and druggists." On putting the question to the vote, seven voted for and nine against it, and the motion was therefore lost.

WOMEN AS STUDENTS OF THE SOCIETY.

The next discussion on this subject arose in consequence of three women having passed the Preliminary examination and presented themselves for election as "Students of the Society." Their election was moved and seconded. An amendment was moved to the effect that the three ladies in question "be not elected apprentices or students of the Society." Discussion waxed warm on the subject, one member asserting that "as the admission of ladies as apprentices would lead to their attending the evening meeting, and ultimately, perhaps, to their appearance at the Council table, he thought it would be best to oppose and check at the very outset what he considered a move in the wrong direction"; while another held that "if ladies had the moral courage to undergo an examination and obtain the qualification which was granted irrespective of sex, they ought to be allowed to go through the whole curriculum, and be encouraged in so doing." After much discussion the Council deferred the further consideration of the question.

At the annual meeting in 1873 there was a lengthy discussion on the desirability of admitting women to the Society, when the following resolution was brought forward by Mr. Hampson:—"That inasmuch as the examiners of the Pharmaceutical Society are empowered by law to test the qualifications of persons—*female as well as male*—before the State permits them to be registered as persons fitted to 'keep open shop' to practise pharmacy, and as all persons having passed the Major and Minor examinations are eligible for admission into the Society, as members and associates, that they may exercise control and direction over the working of the Pharmaceutical Society, and have the benefit of its associative influence and protection, this meeting is of opinion that it is contrary to the plain intention of the statutes to refuse admission to female persons, who, having conformed to the legal tests of the examiners and the regulations of the Society, may desire to become connected with the

Pharmaceutical Society in the capacity of apprentices, or students, or associates, or members." It was urged that qualification constitutes eligibility, and that the question was simply one of justice and common fairness, the exclusion of women being not in accordance with "the great principle of English fair-play." One member said he did not believe that a dozen women would present themselves in forty years, "but whatever the number might be they must be above the average character or they would not pass the examinations, and he did not see why they should be kept out in the cold." Another thought that "the question as to the desirability of women entering the business was a question for the women to decide for themselves; having passed the requisite examinations it was simply a matter of justice to admit them to membership." Finally, after much discussion, an amendment proposing to adjourn the question *sine die* was carried.

In July, 1874, two ladies having applied for permission to work in the Society's laboratory, the question of granting such permission was discussed. It was urged that as ladies were admitted to the lectures and to the examination they could not consistently be refused laboratory instruction. That view was opposed by the argument that admission to the laboratory was an entirely different thing to admission to the lecture-room; that it had been decided ladies should not be admitted as members of the Society, and "when the question came before the general meeting opinion was overwhelmingly against it, and even against encouraging them to enter the trade at all"; and it was then decided not to agree to the reception of lady students in the laboratory.

Nothing further was done in connection with the subject until January, 1876, when, at the Council meeting, the name of the first woman who passed the Major examination was included in the list of proposed pharmaceutical chemist members. The Vice-President (Mr. Bottle) drew attention to that circumstance, and referred to the decision of the former meeting when the subject was discussed. Mr. Hampson then urged that the Council was constantly regretting that Major students did not enter the Society, and that it was not consistent to refuse admission to this applicant. Mr. W. S. Brown supported that view, remarking that he did not think it probable that so many ladies would have sufficient energy and perseverance to pass the Major examination as to occasion any danger of the male members' votes being swamped, but the Council decided by a majority of one not to elect the lady a member of the Society. The question was again raised in July, when Mr. Hampson said he felt something very much akin to a sense of shame in finding it necessary to rediscuss the question. He believed the lady in question had as much right to membership as any man at the board. She was eligible according to Act of Parliament, having passed the highest examination that the Society imposed on the candidates. He considered that in refusing her election the Council would be acting illegally, and that probably a mandamus from the Court of Queen's Bench would be the result. He referred to a passage bearing on the point in the report of a conference held in 1867 between the Pharmaceutical Society and the United Society of Chemists and Druggists. Mr. Sandford was then President, and in speaking of the word "eligibility" he quoted the opinion of the solicitor that if a man were "eligible" under the Act of Parliament the Council was bound to elect him and to proceed according to the spirit of the Act. But in spite of this strong statement of the case the prevailing opinion was against the admission of the lady, and she was not elected to membership. The same result was arrived at in October, 1877, when the question was again discussed.

Women and the Society's Associateship.

The names of two ladies who had passed the Minor and applied to be elected as associates of the Society were submitted to the Council on November 7, 1877. During the somewhat lengthy discussion that took place it was urged that the Council, though not legally bound to elect women, was yet bound in equity to do so, and by refusing "would only show the world that it did not keep pace with the nineteenth century." There was some division of opinion as to whether it would be necessary to appeal to an annual general meeting for the vote of May, 1873, to be rescinded, and in accordance with the suggestion of the President the question of admitting women to all the privileges of the Pharmaceutical Society (membership or associateship) was referred to the next annual meeting of the Society. At that meeting, held May 15, 1878, considerable time was given to its discussion, and it was decided by a majority of two (fifty-nine against fifty-seven) "That in the opinion of this meeting it is not considered either necessary or desirable that ladies should be admitted as members, associates, apprentices, or students of this Society." At the adjourned meeting on May 17, however, it was found that there had been some mistake about the numbers, fifty-nine having voted *against* and fifty-seven *for* the above-quoted resolution, instead of *vice-versâ*. At the next Council meeting Mr. Hampson pointed out that at the annual general meeting there was a majority of two in favour of the principle that women should be admitted into the Society, and moved that Miss Isabella Clarke, who had applied for membership, should be elected. The voting on this occasion was equal, and the chairman's casting vote was given against her election. The question of the two ladies applying for associateship was then considered, and decided in the negative.

At the annual general meeting held May 21, 1879, a motion was brought forward by Mr. Wade, "That all persons duly qualified (irrespective of sex), being eligible for admission into the Society in accordance with the bye-laws, women should not be excluded from participation in the privileges of the Society." There was again a long discussion, which ended in an amendment being carried by a majority of three, and to the effect that inasmuch as registration under the Pharmacy Act secured all trading rights to persons so registered, and membership of the Pharmaceutical Society in no way increased those rights, membership was unnecessary so far as females themselves were concerned, and that it was undesirable on the part of the Society to introduce so complete a change in its constitution as would be involved by the admission of women as members, associates, apprentices, or students of this Society.

But the long-drawn-out opposition was nearly at an end. The question which had been the subject of so many discussions, and had engaged the attention of the Council at intervals for so many years, was finally settled at the Council meeting of October 1, 1879. The two ladies—pharmaceutical chemists—having again applied for membership, Mr. Hampson moved their election. He urged that "if the members of the Council refused to admit eligible persons to membership of the Society because of their private convictions or sentimental views, they were over-riding the Act of Parliament and neglecting their duties as a Council. It would be as reasonable to ask what church they attended as to inquire as to the sex of eligible persons who applied for admission, and he hoped the matter would now be settled by carrying out the Act in its entirety." Nearly all present declared their intention of voting in favour of the motion, one gentleman remarking that he did so "with a view of bringing about a peaceful termination to a question which had formed a bone of contention for some years; a prolonged agitation would be infinitely worse than admitting even a dozen women into the Society." The motion was then put and carried, the President being the only dissentient.

From that time forward, then (the right to work in the laboratory having been previously granted), all the privileges of connection with the Pharmaceutical Society were as open to women as to men. There is a possibility, though no great probability, of women being elected to the Council—a possibility which was spoken of with horror at one of the meetings when the question of admitting women to membership was being discussed! So far, only a comparatively small number of women have passed the Minor examination, and still fewer the Major; but it may be claimed with modest pride that no woman has ever given cause for the Council to regret its decision.

(*To be continued*).

STARCH AND ITS FORMATION.*

BY LEOPOLD D'E. LENFESTEY.

In the field of botany starch is of especial interest as being the first visible product of assimilation, and apparently the starting point from which are produced all those wonderful substances which are formed in the course of the constructive and destructive metabolism of plant life. Physiologists are intimately concerned with a substance which constitutes so important an article of food; the wonderful way in which the kinetic energy of the sun's rays is transformed into the potential energy of the starch granule, to which—I believe I am correct in saying—may be traced the greater part of the energy of the animal and vegetable kingdoms, provides food for reflection to physicists; phyto-chemists find much ground for research in investigating the means by which the complex molecule of starch is synthesised from the simple molecules of carbonic acid gas and water, and the complicated metamorphoses which it subsequently undergoes in the plant; and pure chemists will not find this subject devoid of interest if only for the humiliating fact that although the ultimate composition of starch is common knowledge, yet the constitution of the starch molecule is a problem yet unsolved.

THE ORIGIN OF STARCH.

All green plants can, under favourable circumstances (i.e., when supplied with air and light of sufficient intensity) produce starch. The substance which gives to the plant its green colour is that also which is instrumental in producing starch. The exact nature of this green substance, chlorophyll, is not known; it is a proteid substance containing the elements N, O, H and C which, according to Gautier, who analysed the green crystals obtained by the evaporation of an alcoholic extract of green leaves, are combined together in ratios expressed by the formula $C_{19}H_{22}N_2O_3$. By means of the spectroscope it may be shown that the spectrum of light which has passed through a solution of chlorophyll contains seven dark bands. The position of these bands is as follows:—A broad dark band in the red between the Fraunhofer lines B and C, a second almost as well marked in the orange between C and D, a third less easily visible at the junction of the yellow and green, a fourth more distinct near the line E, and three wide bands in the blue and violet, which except when using only a small thickness of the chlorophyll solution coalesce so as to completely obliterate that part of the spectrum. These absorption bands have a very great significance, for they show us that the rays of light whose wave lengths correspond to the positions of these bands in the spectrum have been arrested in their passage through the solution of chlorophyll, and as by the Principle of Conservation of Energy, energy cannot be destroyed, it follows that chlorophyll has the power of absorbing the energy of certain of the sun's rays, and transforming it into a form the plant can make use of in the exercise of that vital force which is necessary for producing starch from carbonic acid gas and water.

By a method devised by Sachs it is easy to demonstrate that it is light which supplies the energy operative in the production of starch. To a portion of any leaf of convenient dimensions is attached a band of tinfoil. After a few days the leaf is cut off, killed by immersion in boiling water, placed in alcohol to remove the chlorophyll, and then treated with a weak solution of iodine. Iodine is a very sensitive reagent for starch, which it colours a deep indigo blue. It is then readily seen that that part which has not been interfered with is coloured a deep blue, due to the formation of iodide of starch, whilst that portion which has been shaded from the tinfoil remains colourless. The function of chlorophyll, then, in the plant is clearly to obtain the necessary energy for the synthesis of starch, and wherever the formation of starch occurs, *de novo*, chlorophyll is intimately associated with it. It is, perhaps, this fact that has led some observers to regard chlorophyll as a substance intermediate between carbon dioxide and starch, and to suppose that starch is formed by a direct conversion of chlorophyll into it, a supposition, however, which is not borne out by circumstantial evidence.

* Paper read before the Birkbeck Science Society

CHLOROPHYLL AND ITS FUNCTIONS.

Chlorophyll is present in the green parts of plants, usually in specialised portions of protoplasm termed chlorophyll corpuscles, but in the Conjugatæ amongst Algæ it takes the form of spiral bands arranged about the cell, and in many unicellular plants it is diffused throughout the general protoplasm.

Not only is chlorophyll essential for the production of starch, but it is the chlorophyll containing protoplasm wherein this process occurs. If a green plant, from the chlorophyll corpuscles of which all starch has been removed, is placed in a confined volume of air and exposed to strong sunlight, very important observations may be made. First, the volume of air remains unchanged; secondly, the carbonic acid gas constituent disappears, and simultaneously starch makes its appearance in the chlorophyll corpuscle; and lastly, the gas which fills the space previously occupied by carbon dioxide is oxygen. Wherever starch is formed in the green parts of plants, these three factors are invariably corelated. For every volume of carbon dioxide which disappears, an equal volume of oxygen appears, and starch is the resultant product. This fact may be expressed by the equation—

$$6CO_2 + 5H_2O = C_6H_{10}O_5 + 6O_2,$$

but it must not be for a moment supposed that the change which actually occurs is so simple as the equation might appear to indicate. From the complexity of the starch molecule one cannot for a moment imagine it to be produced by a simple condensation of carbon dioxide with water, but although it is the first recognisable product, intermediary products are unquestionably formed. Much labour has been spent in the endeavour to ascertain what are these temporary products, which because of their evanescent nature it is very difficult to trace, and at the present time we are quite ignorant of the changes which occur. But although we are unable to demonstrate the gradual evolution of starch, yet from a knowledge of the chemical changes which can be effected in molecules by suitable treatment, we can at least outline a possible process which has the semblance of probability.

HOW STARCH IS PRODUCED.

When a coal or wood fire is burning the carbon of the fuel combines with the oxygen of the air and forms carbon dioxide, a colourless gas which is present ordinarily in the air to the extent of 4 parts in 10,000. In the operation of breathing we inhale oxygen, and the food we have taken into our bodies is burnt up by combination with this oxygen and again carbon dioxide is formed. In this chemical change a great deal of energy is given out in the form of heat, which in the former case may be utilised for driving machinery, and in the latter case is made use of in our bodies in such a way as to enable us to perform the varied avocations of daily life. The carbon dioxide produced in these operations the plant makes use of and from it reconstructs both food and fuel, and thus the cycle of changes is completed. But energy, although it can be transformed, cannot be created, and the whole of the energy which is produced by the combustion of these plant products has been stored up in them by the plant. This energy, as we have seen, the plant obtains from the sun. It is thus evident that the plant makes use of a very great deal of energy, and we will therefore not be surprised if we subsequently learn that it has produced substances less stable than carbon dioxide, the formation of which has necessitated the absorption of a great deal of energy.

When a coke fire is burning one not infrequently sees a lambent blue flame playing on the top. This flame is produced by burning carbon monoxide which has been formed from carbon dioxide by

the loss of one half of its oxygen, the energy for this transmutation being obtained from the heat of the fire. Now, we have already observed that when the plant uses up carbon dioxide it gives up oxygen, and aware of the great energy the plant has at its disposal, it is not difficult to admit that this process may also take place in the plant, and that carbon monoxide is the first step towards the formation of starch.

There is every reason to suppose that the next stage consists in the mutual reaction between the carbon monoxide thus produced and the water present in the plant, resulting in the formation of a gaseous substance, "formaldehyde," and a further liberation of oxygen. I know of nothing that can be adduced as evidence why this also should not take place in the plant, and admitted it does so, it accounts exactly for the observation that the volume of oxygen liberated is equal to that of the carbon dioxide absorbed—

$$\left.\begin{array}{rrcrcrl} (2\text{ mols.}) & 2CO_2 & = & 2CO & + & O_2 & (1\text{ mol.}) \\ 2CO & + & 2H_2O & = & 2CH_2O & + & O_2 \quad (1\text{ mol.}) \end{array}\right\}$$

In addition to this evidence, the probability of formaldehyde being one of the earlier products receives weighty support from the researches of Bokorny. He found that when the alga *Spirogyra majuscula* was placed in a culture solution containing 0.1 per cent. K_2HPO_4 and 0.1 per cent. methylal (which is readily resolved into methyl alcohol and formaldehyde

$$H{\cdot}CH\begin{cases} O.CH_3 \\ O.CH_3 \end{cases} + H_2O = H{\cdot}CHO + 2CH_3.OH)$$

or 0.1 per cent. of sodium hydroxymethyl sulphonate (which is broken up into sodium sulphite and formaldehyde

$$CH_2{\cdot}\begin{cases} ONa \\ SO_3Na \end{cases} = H.CHO + Na_2SO_3)$$

and exposed to light it contained, at the end of five days, very considerable quantities of starch.

Aldehydes have the property of readily undergoing polymerisation; they may do so spontaneously or only on the addition of a small quantity of certain mineral substances. Formaldehyde is no exception, and when its aqueous solution is treated with some weak alkali, such as potash, it is converted into "formose," a member of the sugar group. This is what probably takes place in the plant, and it may be that this is why potassium is so essential to the plant. It has been shown by Nobbe, in a series of water cultures, that little or no starch is produced in the absence of potassium, but that on the addition of salts of this metal, starch immediately made its appearance. From a sugar the plant can readily produce starch; the one is being constantly transformed into the other, as a sugar starch is conveyed to the different parts of the plant, and from such is deposited as reserve starch.

This I think the most probable explanation of the production of starch—although there are many others. Erlenmeyer does not admit of the formation of formaldehyde with carbon monoxide as the intermediate product, but supposes that formic acid and hydrogen peroxide are first produced, which together react to form formaldehyde and oxygen in accordance with the equations

$$\left.\begin{array}{rrcrcrcrl} (1\text{ mol.}) & CO_2 & + & 2H_2O & = & H.COOH & + & H_2O_2 & \\ & H.COOH & + & H_2O_2 & = & H.CHO & + & H_2O + O_2 & (1\text{ mol.}) \end{array}\right\}$$

I have already alluded to the theory that chlorophyll itself is directly converted into starch; another is that it is the protoplasm which undergoes this change. Just as molecules of protoplasm are converted into molecules of cellulose in the formation of cell walls, so it is supposed molecules of starch are formed; but this supposition would appear to be negatived by the fact that although in the fungi the protoplasm produces cellulose as in green plants, yet no starch whatever is formed.

We have assumed that the absorption bands in the chlorophyll spectrum indicate that the energy obtained by the absorption of these rays is directly concerned in the synthesis of starch, and this assumption is shown to be correct by the experiments of Engelmann, to which I will hereafter allude. Pringsheim is responsible for the view that those rays are not so active, but are even prejudicial to the synthetic processes, and that it is those rays which are transmitted which are concerned in the formation of starch, the chlorophyll acting as a kind of filter. The function of the energy of the absorbed rays is, in his opinion, to promote respiration and destructive metabolism, and thus make the constructive processes possible. The combustion of highly carbonised material in the plant, as elsewhere, will be an exothermic reaction, and it seems to me that little energy will be required to effect this change. Moreover, there is no evidence to show that light has any influence whatever on destructive metabolism. Still, certain of these theories, being more or less based on well-established facts, have something by which to commend them. Although there is not sufficient evidence to give any the pre-eminence, it is possible the light of future research will withdraw the veil which at present obscures this wonderful process, and declare in favour of one of them.

Conditions of Starch Formation.

We have seen that the conditions absolutely necessary for starch formation are that the plant shall have access to carbon dioxide and light of sufficient intensity. Although the percentage of carbonic acid gas in the air is very small, yet the constant motion of the air, and the usually relatively large assimilating area of the plant, ensure a sufficiency to meet all requirements. The formation of starch has been shown by Godlewski to be dependent on the amount of carbon dioxide in the atmosphere, reaching a maximum when this gas is present to the extent of 5 to 10 per cent. A too large quantity of carbon dioxide will suffice to stop altogether the formation of starch. Similarly, starch is produced much more rapidly, and in larger quantity, in bright sunlight than in diffused light, and it may be well to notice that the plant has a special mechanism whereby to adapt itself to external conditions in a manner as favourable to itself as possible. In diffused light the chlorophyll granules take up a position (termed Epistrophe) in which they lie along the free walls of the cells parallel to the assimilating surface presenting their broad surfaces to the incident light; but if the light becomes too intense they take up an "end on" position (termed Apostrophe) along the lateral walls of the cells. All the rays which together constitute white light do not exhibit to the same extent the capacity for producing starch. Rays of wave length less than $\frac{40}{100000}$mm. are not concerned in the production of starch. Those with greater wave length than $\frac{40}{100000}$mm. and less than $\frac{62}{100000}$mm. comprise the active part of the spectrum, the maximum effect being produced by rays of wave length $\frac{59}{100000}$mm. Engelmann has taken advantage of the fact that oxygen is liberated as carbon dioxide is decomposed, to devise a most ingenious method for determining the relative activity of different parts of the spectrum. For this purpose he made use of a microspectroscope, a small alga, and a certain bacterium (*B. termo*) which is highly sensitive to oxygen and only exhibits its movements in presence of this gas. By varying the width of the slit he was able to determine the relative intensities of light necessary to bring about the evolution of oxygen, and the consequent movement of the bacteria in different parts of the spectrum. The activity at any part will be inversely as the intensity, *i.e.*, as the width of the slit. His results show—and it is not surprising—that the rays most active are those occupying parts of the spectrum, which, when the light passes through a solution of chlorophyll, exhibit absorption bands.

The value of bright illumination is illustrated by the observations of Kraus. He showed that within five minutes after exposure to bright sunlight starch made its appearance in the chlorophyll corpuscules of Spirogyra, and within two hours in diffuse daylight, and within two hours and six hours respectively in the case of Funaria.

How the Starch Granules Grow.

The first visible indication of starch in the chlorophyll corpuscles is the appearance of minute specks; as fresh starch is formed about them they grow in size, and if assimilation is proceeding very rapidly they soon fill up the entire corpuscle, and by their mutual compression assume an irregular polygonal shape. These granules are very soon dissolved and carried away to those parts of the plant requiring them, it is not these which are characteristic of the plant producing them. There are deeper in the tissues of the plant—in tubers, roots, rhizomes, etc.—specialised portions of protoplasm, corpuscles not green, which from the carbohydrates presented to them can elaborate starch. These corpuscles have been variously termed "starch-producing corpuscles," leucoplasts (from the fact that they contain leucophyll and on exposure to light become green), and by Schimper, who first discovered and described them, "amyloplasts." In these the granules are formed more gradually and attain a larger size, and in their markings, form, and size are fairly constant for the plant in which they are produced. If the granule is formed quite within the substance of the corpuscle, the deposition of the new material takes place regularly on all sides of it and concentric granules result; but if, on the other hand, the granules originate immediately beneath the surface, subsequent growth causes them to protrude through the corpuscle, and being nourished unequally, excentric granules are eventually produced.

The possible ways in which a starch grain, once formed, may increase in bulk are either by apposition or by intussusception. Here, again, there is much difference of opinion. From the fact that granules are more watery from without inwards, the external portion being a relatively dense layer and the hilum correspondingly watery, Naegeli has arrived at the conclusion that the starch granules grow by the intercalation of new particles between those already existent. He ascribes the stratification to alternating layers containing more or less water, and argues that if the apposition theory were correct, then the external youngest layers should contain the most water. In opposition to this view, and in favour of the apposition theory, Schimper has shown that occasionally a grain which has lost its form on account of partial dissolution, is to be found with fresh starch deposited about it in regular layers, the irregular outline of the old granule being visible inside. Schimper agrees with Naegeli as regards the alternation of layers containing more and less water, and accounts for it by supposing that each apposed layer becomes differentiated into three by the tensions of the grain, a middle watery layer, with a dense layer on each side of it. Strasburger does not believe in the alternation of layers, but that the external layers, like those of a cell wall, are more dense than those within, and that the older layers gradually absorb water. The result of such absorption is that the layers stretch those external to them, producing positive tension. This is the opposite condition of things to that existent in the cell wall, the force in that case being one of compression or negative tension. The study of the optical properties of the granules appears to confirm Strasburger's conclusions, for, as Von Mohl has pointed out, the interference colours of starch grains are complementary to those of cell walls, the former being optically positive and the latter negative.

The Characteristics of Starch Granules.

The fully-formed starch granules possess certain characteristics such as shape, size, and nature of the markings and hilum by which they may be distinguished from one another, and referred to the plant producing them. As starch enters very largely into the adulteration of food and drugs, and as no chemical tests are possible to discriminate between the various kinds, the microscopic study of the above characteristics is very important. The granules may be ovate in shape, as in the potato and arrowroot; round, as in wheat and barley; truncated, at one end, as in sago and cassava; reniform, as in the pea and bean; or polygonal, as in rice and maize. The hilum may be circular, linear or stellate, and its size and position are also important factors in identifying the grains. According to these distinguishing features, the various starches readily fall into five groups, and have been so classified as follows:—

Group I.—The Potato Group includes such oval or ovate starches as give a play of colour when examined by polarised light and with a selenite plate. The rings and hilum are clearly visible.

Group II.—The Leguminous Group comprises such round or oval starches as give little or no colour with polarised light. The hilum is well marked and cracked or stellate, whilst the rings are all but invisible.

Grou III.—The Wheat Group contains such starches as have both hilum and rings invisible in the majority of the granules.

Group IV.—The Sago Group contains such very characteristic starches as are truncated at one end.

Group V.—The Rice Group comprises those starches all the granules of which are polygonal in form.

The members of these groups are detected by structural peculiarities and by the size of the granules. The sizes of the granules of different starches are very variable. They may be of any size between the immeasurably small granules of the "cactus" and the comparatively very large granules of Tous-les-mois starch. I append a list of some of the commoner starches which may be interesting:—

	Mm.		Mm.		Mm.
Canna	·175	Lentils	·067	Tapioca	·028
Maranta	·140	Peas	·063	Barley	·025
Potato	·140	Wheat	·050	Rice	·022
Sago	·070	Maize	·045	Beetroot (seeds)	·044

Unfortunately the size of the granules of any particular starch is by no means a constant quantity. In potato starch one finds granules of pretty well all sizes within a certain range, and in wheat the granules are of two sizes, large and small; still, by practice and by combining the dimensions with the morphological characteristics of the granules, one is generally able to spot a starch fairly accurately.

(*To be continued*).

NOTE ON MISTURA OLEI RICINI, B.P.

BY W. A. GREGSON.

The new method of emulsifying castor oil adopted in the 1898 Pharmacopœia appears to beginners in pharmacy to possess some difficulties, which, however, are less in number and degree than those of the formula of the addendum of 1890. My object in writing this note is to offer to your readers a plan which I have found simple, speedy, and effectual. The official process recommends the use of mucilage, but this is not as a rule available in many pharmacies in the fresh condition. Operating on one quarter of the B.P. quantity, the suggestion is to put 75 grains of powdered acacia in a dry mortar; add now all at once 6 fluid drachms of castor oil, then add 3 fluid drachms of water, and mix them intimately; having made them perfectly homogeneous, add the aqueous fluids in one fluid drachm or more quantities according to the skill of the operator, care being taken to maintain uniformity. Prepared in this way, and kept under observation for some time, it compares favourably with the official process.

AUSTRALIAN INDIGENOUS VEGETABLE DRUGS.*

BY J. H. MAIDEN,

Government Botanist and Director of the Botanic Gardens, Sydney.
(Corresponding Member of the Pharmaceutical Society of Great Britain.)

APOCYNEÆ *(continued).*

Alyxia buxifolia, R.Br.

Letters patent, No. 866, dated August 15, 1888, were granted in New South Wales, "for the discovery of the medicinal properties and virtues of *Alyxia buxifolia,* and the production therefrom of Austral Marine Bitters and other distilments and compounds of the said *Alyxia buxifolia.*" An "extract" of this plant, presumably of the bark, was sold as a patent medicine for a short time, and wonderful were the virtues claimed for it on the prospectus. I do not doubt that these claims are every bit as valid as those of quack or patent medicines in general.

Coast of all the Colonies except Queensland.

Carissa ovata, R.Br., var. *stolonifera,* Bail.

Dr. T. L. Bancróft communicated a paper (*Proc. Roy. Soc. N.S.W.*, xxviii., 44) on the pharmacology of the bark of this plant. "An alcoholic extract of the bark was made, and solutions in water of this when injected into frogs rapidly killed them. The muscles were pale and paralysed, and the heart stopped in systole. Applied to the exposed hearts of frogs, pithed or under the influence of curare, it slowed and finally brought them to a standstill in systole. It was then seen that the substance resembled closely in its action *Strophanthin* and *Ouabin,* glucosides from allied genera of Apocyneæ."

At Dr. Bancroft's request I took the matter up, and, in conjunction with Mr. H. G. Smith, published a paper on the chemistry of the bark in the *Pro. Aust. Assoc. Adv. Science* (Brisbane), vi., 278. No alkaloid was found, but a glucoside, to which the name *Carissin* was given, which approaches *Strophanthin* in certain respects. The reaction and method of isolation are described in the paper referred to.

Queensland.

Cerbera odollam, Linn. (Syn. *C. manghas, Bot. Mag.*)

This tree is also a native of Malabar, and while the fleshy drupe, according to Lindley, is innocuous, the nut in the interior is narcotic, and even poisonous. The bark is purgative; the unripe fruit, moreover, is dangerous, and is said to be used by the natives of Travancore to destroy dogs; the teeth of the unfortunate animals being, as is reported, loosened so as to fall out after masticating it. (*Treasury of Botany.*)

Waring (*Pharm. of India*) deprecates the use of the milky juice, and leaves of this plant as emetics and purgatives, on the ground that they are dangerous, and that there are numbers of safe and efficient drugs for these purposes.

In Java the leaves are used as a substitute for senna. (Drury.)

The sap, leaves, and bark of this plant have no toxicological action, but the seed-kernel contains, in addition to a non-poisonous fatty oil, the compound *cerberin,* which has a poisonous action on the heart. Breshoff (*Ber.* xxiii., 3537; *Journ. Chem. Soc.*, lx., 337, where a chemical account of *cerberin* is given). See also Sohn, p. 26, for notes on the bodies found in *Cerbera.*

Queensland and North Australia.

Ochrosia moorei, F.v.M.

Timber yellow, and both timber and bark intensely bitter. They are worthy of chemical investigation and comparison with *Alstonia.*

Coastal New South Wales and Queensland.

Tabernæmontana orientalis, R. Br. "Bitter Bark."

This small tree has an intensely bitter bark, and a decoction of it is sometimes sold as "bitters."

Dr. Thomas Bancroft, of Brisbane, informs me that the bark is physiologically inert, or practically so.

New South Wales to Northern Australia.

T. sphærocarpa, Bl., also contains an alkaloid and a wax-like compound, which is free from nitrogen and melts at 185°. Greshoff (*Ber.* xxiii., 3537; *Journ. Chem. Soc.*, lx., 337).

For a list of the Apocyneæ worked at by Greshoff, see Sohn, p. 10.

ASCLEPIADEÆ.

Sarcostemma australe, R. Br.

The juice is used by the Port Darwin (Northern Territory of South Australia) natives as a remedy in small-pox. (*Proc. R.S., S.A.*, v., 9.) In the interior districts of New South Wales its milky juice is used by white men as an application to wounds.

"The caustic plant is really very valuable, and will cure warts and corns very quickly." (Mrs. Kennedy, of Wonnaminta, in a letter to me.)

An amorphous yellow, bitter glucoside, called Asclepiadin, has been found in several genera of Asclepiadaceæ. For an abstract, see Sohn, p. 13.

All the Colonies except Victoria and Tasmania.

TYLOPHORA.

A crystalline, alkaline, emetic alkaloid, named Tylophorine, has been isolated by D. Hooper from the root of the East Indian *Tylophora asthmatica* (see Sohn, p. 99). It should be looked for in our numerous species of the same genus.

LOGANIACEÆ.

Strychnos psilosperma, F.v.M., and *S. lucida,* R. Br.

I am indebted to my friend, Mr. F. M. Bailey, for his kindness in placing in my hands specimens of the two native species of Strychnos, viz., *Strychnos psilosperma* and *S. lucida.* All parts of *S. psilosperma* are bitter, but not so bitter as strychnine. I was unable to kill frogs with this plant. *S. lucida* is, on the other hand, extremely bitter. So intensely and persistently bitter is this plant, that one would imagine that it was very rich in strychnine. I was astonished, however, to find that I could not tetanise frogs with it. It was not even poisonous to them. The frogs used (*Hyla cærulea*) are very susceptible to strychnine. I had only one fruit and several leaves—too small a quantity to attempt any chemical analysis."

(Dr. T. L. Bancroft, *Trans. Intercol. Med. Congress,* 1888.)

Rennie and Goyder, *Proc. R.S. Vict.*, iv. (new series), 29, have a "Note on the Alkaloids and *Strychnos psilosperma.*" A quantitative separation revealed the presence of both strychnine and brucine, the former apparently in considerable excess, but the quantity available was too small for quantitative determination.

Queensland.

GENTIANEÆ.

Erythræa australis, R.Br. "Native Centaury."

This plant is useful as a tonic medicine in indigestion, liver complaints, diarrhœa, and dysentery. The whole plant is used, and is pleasantly bitter. It is common enough in grass-land, and appears to be increasing in popularity as a domestic remedy; in fact, it is the one native plant remedy known to a great many people, and to my personal knowledge it is used in all parts of New South Wales.

For a note on its use as a Western Australian remedy in eczema se *Chem. and Drugg. Aust.*, May, 1894, p. 112.

It contains a glucoside known as erythrocentaurin; see Sohn, p. 52.

All the Colonies.

Sebæa ovata, R.Br.

This neat little annual herb can be utilised for its bitter tonic principle. It and *Erythræa australis* may be used indiscriminately.

Throughout the Colonies.

BORAGINEÆ.

Cordia myxa, Linn. The "Sebesten Plum" of India.

This plant is also a native of India, and has succulent, mucilaginous, and emollient fruits. From their mucilaginous qualities, combined with some astringency, they have been employed as pectoral

From the *Agricultural Gazette of New South Wales* (continued from page 28).

medicines under the name of *Sebestens*. The bark is a mild tonic, and is used in India as gargles. (*Treasury of Botany.*) The bark is much used as a mild tonic in Java. (Drury.)

Queensland.

Heliotropium ovalifolium, Forsk. Native name, "Kai-kai."

"Used medicinally for general sickness, as a drink." (E. Palmer.)

A poisonous alkaloid, heliotropine, has been found in the European *H. europcum*, L., and in the closely allied *Cynoglossum vulgare*.

South Australia and Queensland to North Australia.

Trichodesma zeylanicum, R.Br. (Syn. *Pollichia zeylanica*, F.v.M.)

In India this, with other species, is considered diuretic, and one of the cures for the bites of snakes. (Bailey.)

All the Colonies except Victoria and Tasmania.

CONVOLVALACEÆ.

Evolvulus alsinoides, Linn. (Syn. *E. linifolius*, Linn).

The stalk, leaves and roots are a reputed remedy in dysentery and fever. (Ainslie.) This plant is not endemic in Australia.

All the Colonies except Victoria and Tasmania.

Ipomœa Pes-caprœ, Roth.

The boiled leaves are used externally as an anodyne in cases of colic, and in decoction in rheumatism; the juice is given as a diuretic in dropsy, and at the same time the bruised leaves are applied to the dropsical part. (Dymock, *Materia Medica of Western India.*)

Western Australia, New South Wales, and Northern Australia.

SOLANEÆ.

Anthocercis littorea, Endl.

For notes on a case of poisoning by this plant in Western Australia see *Chem. and Drugg. of Australasia*, xiii., 200 (July, 1898). The symptoms were those of poisoning by belladonna. See also *Prod. Gazette and Settlers' Record of W.A.*, v., 397. (May, 1898.)

Western Australia.

Anthocercis viscosa, R.Br.

A yellow oily liquid alkaloid (anthocercine), "heavier than water, with agreeable odour and alkaline reaction," has been found in this plant. See Sohn, p. 9.

Western Australia.

Duboisia myoporoides, R.Br. "Corkwood."

I have illustrated this plant, and given so full an account of it, and of the chemical and therapeutical researches in regard to its leaves, in the *Agricultural Gazette* for November, 1893, p. 845, that it is quite unnecessary to go over the same ground again. At the same time, it will be a convenience to inquirers and investigators to give the following references additional to or more ample than those given in my paper.

Attention is also invited to a paper by Gordon Sharp, "On our present knowledge of the Mydriatic Group," in *Pharm. Journ.* of Aug. 14, 1897, p. 161.

GREGORY, J.

'Pituri and Tobacco.' Brisbane, 1879. 8vo. Chiefly on Duboisia, Pituri, and *Anthocercis tasmanica*.

LADENBURG, A.

"The Mydriatic Alkaloids," *Chem. Zeitung*, 1881. No. 9. *Year-Book of Pharm.*, 1881. 20.

"Ueber Pseudhyoscyamin. Ein neue Alkaloid aus *Duboisia myoporoides*."

Bericht, 1892, p. 11. *Pharm. Journ.* [3], xxiii., 606.

MERCK, E.

"A new alkaloid, contained in *Duboisia myoporoides*, R.Br., together with hyoscyamine and hyoscine."

Arch. Pharm., 231, 117. *Journ. Chem. Soc.*, lxiv., 491.

There is also a useful paper on "Duboisine and its use in the Colonies" in *Pharm. Journ. of Australasia*, May, 1891. Dr. Finselbach makes the statement that the leaves of *D. myoporoides* contain rather less alkaloid during the flowering period than later, and recommends them to be collected in November or December.

New South Wales and Queensland.

Solanum aviculare, Forst.

Dr. Joseph Bancroft says an extract of the leaves of this plant does not dilate the pupil, but is poisonous. Dr. T. L. Bancroft points out that the taste of the leaves is extremely like that of tobacco; and, as the result of some experiments, he believes them to contain nicotine.

All the Colonies except Western Australia.

Solanum verbascifolium, Ait.

A large shrub, often twenty feet high, with a bitter bark. An extract of the bark is only slightly poisonous to frogs. An alkaloid can be prepared in a pure state from this plant in the following manner:—Pulverise the bark, exhaust by boiling aqueous alcohol, distil off the alcohol, dissolve the extract in water, filter, precipitate with carbonate of soda. It seems to be insoluble in ether and chloroform, but very soluble in alcohol. It is not mydriatic. In these particulars it agrees with solanine. (Dr. T. L. Bancroft, *Proc. Linn. Soc., N.S.W.* [2], iv., 1063.) This alkaloid is also found in the fruit. *See* Wittstein's *Organic Constituents of Plants*, trans. Mueller, p. 204.

New South Wales and Queensland.

SCROPHULARINEÆ.

Gratiola pedunculata, R.Br., and *G. peruviana*, Linn.

"Brooklime."

A decoction of these plants is used by country people in Australia for liver complaints with (many say) good results. They enter into domestic medicine for some complaint or other in various parts of the Colonies. The latter plant is not endemic in Australia.

Dr. Thomas Bancroft, of Brisbane, informs me that this genus is physiologically inert, or practically so. Nevertheless, the closely-allied *G. officinalis*, of Europe, contains a bitter, poisonous glucoside, known as Gratiolin, and an amorphous or crystalline glucoside (a red or yellow powder) known as Gratiosolin. See Sohn, p. 55; also notes in the *Agricultural Gazette* for August, 1894, p. 595, and for January, 1897, p. 16.

All the Colonies except Tasmania (*G. pedunculata*); all the Colonies (*G. peruviana*).

Herpestis monniera, H.B. et. K. (Syn. *Bramia indica*, Lam.).

This small creeping plant is common to the tropical portions of both hemispheres. It is regarded by the Hindoos as a powerful diuretic and aperient, and the juice of the leaves, conjoined with petroleum, is used in India as a local application in rheumatism. "Whatever benefit is derived from this formula is doubtless due to the petroleum." (*Pharm. of India.*)

New South Wales and Northern Australia.

Scoparia dulcis, Linn.

This plant is a native of every part of the world within the tropics. In India it is used in infusion in ague. (*Cyclop. of India.*)

Queensland and Northern Australia.

ACANTHACEÆ.

Justicia procumbens, Linn.

In South India the juice of the leaves squeezed into the eyes is a remedy in ophthalmia. (Drury.)

All the Colonies except Tasmania and Victoria.

(To be continued.)

THE MANUFACTURE OF TARTARIC ACID.*

A NEW COMMERCIAL METHOD.

BY DR. G. SCARLATA.

Tartaric acid occupies one of the most important places among chemical products. It is found in abundance in the form of acid tartrate of potassium and neutral tartrate of lime, in the raw tartar from casks, in wine lees, and in grape skins, which, by the way, constitute the only raw materials used for its extraction.

It is curious to note that, at the present time, the extraction of tartaric acid is almost entirely carried on in England, the United States, and Germany, the wine-producing countries possessing only a few factories of little importance, limited to the treatment of raw material produced on the spot, though more often —in fact nearly always—the stocks are allowed to accumulate, and are then shipped to some foreign factory.

The method of extraction at present used in most factories is very old, viz., that of Scheele. Only very slight modifications have been introduced into this method, while nearly every other chemical industry has undergone radical changes; one fact is certain, that there has been no improvement made in the manufacture of tartaric acid.

I have been attracted to this remunerative industry with the hope of devising a plan by which the English and German methods can be efficiently combined. I have therefore sought principally for an economical method which would not require too much capital to establish in the first place.

The results I have obtained in the laboratory lead me to hope that I have attained the desired result. I leave to practical experience the task of justifying my opinions.

The first part of Scheele's process consists in obtaining tartrate of calcium. This can be done by different methods, but they are all long and delicate. The methods of Scheurer-Kestner, of Gladysz, of Dietrich, and of Schutzner, all require a considerable amount of time and fuel; the same can be said of the second part of the process, which consists of decomposing the tartrate of calcium with sulphuric acid. This operation yields no useful by-product, and does not allow of the recovery of any of the materials first used.

These drawbacks do not exist in the new method which I propose to use, since by its means we are enabled to extract the tartaric acid directly from the raw product, and to recover the materials used in the operation.

This method, broadly speaking, is based on the decomposition of the tartrates by fluosilicic acid. In the raw product the tartaric acid exists both as acid tartrate of potassium and as tartrate of calcium. These salts are decomposed by fluosilicic acid, with the formation of tartaric acid and of the corresponding fluosilicates.

$$2C_4H_5O_6K + H_2SiFl_6 = 2C_4H_6O_6 + K_2SiFl_6$$
$$C_4H_4O_6Ca + H_2SiFl_6 = C_4H_6O_6 + CaSiFl_6$$

Tartaric acid and fluosilicate of calcium are both soluble and remain in the clear solution, while the fluosilicate of potassium is to a great extent precipitated; its solubility is only 1 part in 825 parts of water. By evaporating the clear solution the last portions of the fluosilicate of potassium are precipitated very rapidly. There now remains only the fluosilicate of calcium to be eliminated, of which the quantity present is first determined by analysis. The calculated quantity of sulphuric acid is then added, plus a little excess, as tartaric acid crystallises much better in solutions made slightly acid with sulphuric acid. After concentration to help the deposit of sulphate of lime, the organic matter, and the last traces of fluosilicate of potassium, the clear solution is decanted and allowed to crystallise.

We thus obtain fluosilicate of potash as principal by-product; it is found mixed with silica for reasons which will be shown later on, and constitutes an excellent material for the preparation of fluosilicic acid; in fact, by treating it with sulphuric acid, we obtain sulphate of potassium, hydrofluoric acid, and fluoride of silicon, according to the equation—

$$K_2SiFl_6 + H_2SO_4 = SiFl_4 + 2HFl + K_2SO_4.$$

But hydrofluoric acid in the presence of silica gives fluoride of silicon and water:—

$$4HFl + SiO_2 = SiFl_4 + 2H_2O.$$

So that the whole of the fluorine from the fluosilicate of potassium is brought to the state fluoride of silicon, which, by reacting on water, gives fluosilicic acid and silica according to to the equation—

$$3SiFl_4 + 4H_2O = 2H_2SiFl_4 + Si(OH)_4.$$

As can be seen, the recovery of the fluosilicic acid is complete by a simple treatment with sulphuric acid.

Preparation of Tartaric Acid.

I am not able to describe in detail the apparatus necessary for the manufacture of tartaric acid, but will confine myself to the description of the experiments made with the ordinary apparatus found in the laboratory.

The tartar I used contained by analysis:—

Total tartaric acid ..	..	62.56 per cent.
Tartrate of potassium	..	67.16 ,,
Tartrate of calcium..	..	11.25 ,,

I operated on 10 kilogrammes of well broken-up material, placed in a wooden vat furnished with a stirrer. To these 10 kilogrammes of raw material I added the quantity of fluosilicic acid theoretically necessary to set all the tartaric acid at liberty—that is to say, 58 kilogrammes of a solution at 60 per cent. After agitating for an hour, the mixture was transferred to a filter-press, and the clear solution was led into a wooden vat lined with lead and heated by a current of steam passing through a spiral tube. The evaporation was continued until fluosilicate of potassium commenced to be deposited. The contents of the vat were then left alone for some hours, after which the clear solution was decanted into another vat furnished with a stirrer. The lime was estimated on a sample of the solution, by adding an excess of oxalate of ammonia and titrating the excess of oxalic acid by permanganate of potash. The total quantity of solution contained 209 Gms. of lime. To eliminate this the solution was treated with the theoretical quantity of sulphuric acid—that is 512 Gms. H_2SO_4 diluted to 1 litre, then transferred to the filter-press.

The solution of tartaric acid thus obtained was coloured a deep reddish brown; after decolorising by animal black, it was evaporated and crystallised, care being taken to remove the sulphate of lime which is again precipitated at the commencement of the evaporation.

The purity of the crystals of tartaric acid thus obtained was determined by titrating with potash and comparing it with a chemically pure sample of the same acid. It is evident that, in this kind of test, equality of results indicates equality of purity. The results obtained were as follows:—

Tartaric acid at 100 per cent.	Tartaric acid from the experiment.
I. 35·0 C.c. of solution of KOH.	I. 34.5 C.c. of solution of KOH.
II. 41.0 ,, ,, ,,	II. 40.5 ,, ,, ,,
III. 33.0 ,, ,, ,,	III. 32.5 ,, ,, ,,
IV. 36.0 ,, ,, ,,	IV. 35.5 ,, ,, ,,

These figures show that the tartaric acid obtained by the fluosilicic acid process titrated 98.57 per cent. of purity; it may therefore be considered as commercially pure.

Preparation of the Fluosilicic Acid.

Description of the Apparatus.—This consists of a cast-iron pot fitted with a mechanical stirrer, in which the raw material obtained

* From the *Moniteur Scientifique* [4], **13**, 360, through the *Chemical News*.

as a by-product from the above reaction is placed. The calculated quantity of concentrated sulphuric acid is added, the cover is luted on, and the whole heated and stirred continuously. The cover has two tubes passing through it; the first—which is for passing a current of air through at the end of the operation—is kept closed by means of a tap during the first phase of the operation; the second—which is much larger—is for the purpose of passing the fluoride of silicon into a vessel filled with water. The water necessary for the decomposition of the fluoride of silicon is added, the quantity is estimated approximately by the quantity of fluosilicate of potash present, so that the solution of fluosilicic acid can be prepared of practically any desired strength. The fluoride of silicon on entering the vessel, comes in contact with the water, which decomposes it into fluosilicic acid and gelatinous silica.

As a secondary product of this preparation, we obtain sulphate of potassium, which, mixed with the residues from the first operation, forms excellent manure. In any case its intrinsic value will always cover a part of the expense of the process.

As can be seen, this method has the double advantage of being very rapid, and of returning in a useful form all the materials originally used.

SELECTED PRACTICAL FORMULÆ.

Linimentum Capsici Compositum.

V. Fassati advocates the inclusion of the following formula in the new Austrian Pharmacopœia:—Capsicum fruits, 500, are moistened with dilute tragacanth mucilage, dried gently and ground to a coarse powder. This is mixed with alcohol, 125, and ether, 125, macerated in a closed vessel, then percolated with alcohol until 1250 of percolate have been obtained. Camphor, 500, is dissolved in the percolate and the following ingredients added. Solution of ammonia, sp.g. 0.91, 25; thyme oil, 10; lavender oil, 10.—*Pharm. Centralh.*, **40**, 132; after *Oest. Zeit. für Pharm.*

Dika's Zinc Gelatin Bandage.

The bandage is composed of zinc oxide, white gelatin, of each 20, glycerin and distilled water, of each 80 Gm.—*Oest Zeit. für Pharm.*, **53**, 85.

Elixir of Pancreatin.

Pure pancreatin, 10; white Malaga wine, 500; simple syrup, 400 alcohol (80 per cent.), 90.– *Rev. Med. Pharm.*, **6**, 74.

Elixir of Peptone.

Peptone, 50; Frontignan wine, 500; simple syrup, 350; alcohol (80 per cent.), 100.—*Rev. Med. Pharm.*, **6**, 74.

Sulphur Paste for Acne.

Sublimed sulphur, alcohol (90 per cent.), water, of each 20; mucilage of acacia, 6. Mix. To be applied night and morning to the affected parts. If it causes irritation, a paste of boric acid containing from 1 to 50 per cent. of sulphur may be substituted for it.—*Rev. Med. Pharm.*, **6**, 74.

Solid Brilliantine.

Olive or castor oil, 30; spermaceti, 8; melted together and perfumed with bergamont oil, 5; lemon oil, 2.5; rose geranium oil, 0.5.—*Deutsch. Amer. Apoth. Ztg.*, **19**, 157, after *Seifen Fabrik.*

Menthol Opodeldoc.

Soft soap, 20 grs.; camphor, 8 grs.; menthol, 2 grs.; distilled water, 2 grs.; arnica tincture, q.s. to produce 1 fl. oz.—*Deutsch. Am. Apoth. Ztg.*, **19** (12), 157, after *Pharm. Era.*

THE SALE OF BENZENE AND BENZOLINE.

The following correspondence has passed between the Secretary of the Pharmaceutical Society and the Public Control Department of the London County Council:—

Pharmaceutical Society of Great Britain,
17, Bloomsbury Square, London, W.C.
June 27, 1899.

Dear Sir,

My attention has recently been directed by several members of this Society to the difficulties placed by officers of the County Council in the way of the storage and use of petroleum by chemists.

The regulations do not appear to allow of bottles being opened and the contents used, although a chemist may, under Section 7 of the Petroleum Act, stock a certain quantity of spirit in bottles so long as they are securely stoppered.

The British Pharmacopœia directs the employment of petroleum in certain pharmaceutical processes, and it is not possible for a chemist to carry on his business without using it from time to time, but the statutory permission to keep a small quantity of petroleum is rendered valueless by the proviso that the bottles must not be opened for use.

Cannot an exemption be made in favour of chemists so that bottles of petroleum may be opened for filling smaller bottles for sale, or for use in carrying on their business?

I am, yours faithfully,
(Signed) Richard Bremridge,
Secretary and Registrar.

A. Spencer, Esq.,
Public Control Department,
London County Council.

Public Control Department,
6, Waterloo Place, S.W.
July 8, 1899.

PETROLEUM ACTS, 1871-1881.

Dear Sir,

The Council has had under consideration your letter of the 27th ultimo, on behalf of the Pharmaceutical Society of Great Britain, pointing out difficulties experienced by chemists in connection with the keeping of petroleum spirit under these Acts, and asking whether an exemption could not be made, so that bottles of petroleum may be opened for filling smaller bottles for sale or for use by chemists in carrying on their business.

I am to point out that although the exemption provided by section 7 of the Act of 1871 only extends to petroleum spirit when in vessels securely stopped, the Council has not insisted on a licence where spirit is removed from such vessels for use in pharmaceutical or other processes.

What you now propose is virtually to extend the exemption clause to the repacking of spirit into smaller vessels, and although the Council has no legal power to give sanction to such a practice, it is prepared to meet the wishes of the Society to the extent of not requiring licences in such cases. To give effect to this the Council has issued the following instruction on the subject:—

"Persons keeping petroleum spirit in the County of London will not be required to obtain a licence, provided

(*a*) "That the total quantity kept does not exceed three gallons.

(*b*) "That the spirit is kept in securely stopped vessels, each of which contains not more than one pint.

(*c*) "That not more than one of such vessels is opened upon the premises at one time, whether for use or for rebottling for sale."

I enclose copy of print to be issued for the information of chemists.

I am, dear Sir,
Yours faithfully,
(Signed) Alfred Spencer,
Chief Officer.

Richard Bremridge, Esq.,
Secretary and Registrar,
Pharmaceutical Society of Great Britain,
17, Bloomsbury Square, W.C.

The following printed instruction on the subject has been issued by the Public Control Department of the London County Council:—

PETROLEUM ACTS, 1871—1881.

Exemption for Small Quantities of Petroleum Spirit.

The Pharmaceutical Society of Great Britain has submitted to the Council representations as to the difficulties experienced by chemists and druggists in connection with the keeping of petroleum spirit in pursuance of the provisions of these Acts, which require that such spirit should be kept under licence, except where it is kept in small quantities in securely stopped bottles of not more than a pint. Although this exemption does not extend to bottles when opened, the Council has not insisted on a licence for small quantities of spirit used in pharmaceutical or other processes.

The Pharmaceutical Society now urges that the Council should recognise the practice of filling small bottles (such as 2 oz., 4 oz., and 8 oz.) on unlicensed premises, and consequent upon the representations of the Society, the Council has issued the following instruction, viz.:—

Persons keeping petroleum spirit in the County of London will not be required to obtain a licence, provided,

(*a*) That the total quantity kept does not exceed three gallons.

(*b*) That the spirit is kept in securely stopped vessels, each of which contains not more than one pint.

(*c*) That not more than one of such vessels is opened upon the premises at one time, whether for use or for re-bottling for sale.

Alfred Spencer,
Chief Officer,
Public Control Department
London County Council.

6, Waterloo Place, S.W.,
June 30, 1899.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.
Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, JULY 15, 1899.

REGULATIONS RELATING TO THE STORAGE AND SALE OF "PETROLEUM."

THE term "petroleum" has a statutory definition which includes the volatile petroleum spirit of the British Pharmacopœia, as well as the coal tar product known as benzene, in regard to the keeping of which some difficulty has arisen, as pointed out two weeks ago by Mr. SANDY (see page 23). As already stated in the Journal a communication has been officially addressed to the London County Council on this subject by Mr. BREMRIDGE, calling attention to the difficulties placed in the way of the storage and use of "petroleum" by chemists. Under Section 7 of the Petroleum Act (1871) a chemist may, apparently, stock a certain quantity of material, coming within the statutory definition, without obtaining a licence from the local authority, so long as it is kept in bottles that are securely stoppered; but the regulations made for carrying out the provisions of the Act did not appear to allow of a bottle being opened, for occasional use of the contents, in cases where the British Pharmacopœia directs the use of benzene in certain pharmaceutical operations. A representation to that effect has now been considered by the County Council, and Mr. SPENCER, of the Public Control Department, has written to say that, notwithstanding the limited provision of the 7th section of the Act, the Council has not insisted on chemists taking out a licence where spirit is removed from a securely stoppered pint bottle for use in pharmaceutical or other operations, and that, although the Council has no legal power to extend the exemption clause of the Act to the case of repacking spirit into smaller vessels, as suggested by the Pharmaceutical Society, an instruction calculated to meet the case has been issued to the effect that persons keeping "petroleum" spirit in the County of London will not be required to obtain a licence, provided the total quantity kept does not exceed three gallons, that the spirit is kept in securely stoppered vessels, each containing no more than one pint, and that not more than one such vessel is opened on the premises at one time, whether for use or for re-bottling for sale. A print of this official instruction has been prepared for the information of chemists, the terms of which will be found, together with the correspondence, on the subject, at page 54.

The provisions of Section 6 of the Act of 1871, in regard to the labelling and sale of "petroleum" are that where any "petroleum," to which the Act applies, is sold or exposed for sale, the vessel containing it shall have attached a label stating in conspicuous characters the description of petroleum, together with the words "highly inflammable," and the name and address of the owner or vendor. This requirement is somewhat less than that indicated by the inspector to whom Mr. SANDY refers in his letter (see page 23). The name and address of the sender of "petroleum" appears to be required only in the case of a vessel being sent or conveyed, and presumably that requirement would be fulfilled in the case of "petroleum" sold from a chemist's stock by the use of a label with the name and address of the seller, whether he was the actual bottler of the petroleum or not, since the new instruction issued by the London County Council distinctly recognises that chemists may not only apply the contents of a pint bottle for occasional use, but also for re-bottling for sale, if they desire to do so, in preference to the more convenient plan of purchasing small bottles ready for sale. In the latter case it is the name and address of the chemist selling, or having the bottles in stock for sale, that must appear on the labels. The other provisions of the 6th section of the Act seem to apply more especially to "petroleum" in transit, or when kept on licensed premises, and in larger quantities than can be kept by a chemist who is not required to take out a licence.

In any case the concession now made by the London County Council to meet the wishes of the Pharmaceutical Society is an important one, as it virtually removes the difficulty to which the Secretary drew attention, and to which the letter of Mr. SANDY referred. In other districts it may be anticipated that similar instructions will be given to the inspectors under the Petroleum Acts whenever the circumstances are properly represented to the local authorities empowered to grant licences, who would presumably have power also to regulate the conditions under which "petroleum" might be kept or sold, in accordance with the exemptions provided for by the 7th section of the Act. For such purpose applications should be made to local authorities by the Society's local secretaries, with a reference to the action taken respectively by the Secretary of the Society and the London County Council. But a remark in Mr. SANDY'S second letter (see p. 44) as to the sale of small quantities, suggests the necessity of pointing out that the sale of "petroleum" either in the form of benzene or the light petroleum spirit commonly called "benzine," in small quantities, is not provided for by the Act otherwise than that the bottle in which it is kept for sale shall not contain more than one pint each. Hence it is to be inferred that the sale of an ounce from the pint stock bottle would, strictly speaking, be contrary to the provisions of the Act. Any small quantity sold over the counter by a person having no licence must, therefore, be supplied in accordance with the terms of the Act in a glass, earthen, or metal vessel, securely stopped. The case mentioned by Mr. PURSE is different, as he holds a licence, and has, in consequence, greater freedom of action.

AWARD OF THE HANBURY MEDAL.

The tenth Hanbury Medal is, we are officially informed, to be presented to Albert Ladenburg, Ph.D., Hon. M.D., formerly Professor of Chemistry and Director of Chemical Laboratories in the University of Kiel, and now of Breslau. It will be remembered that the Hanbury Memorial Fund was raised to establish a memorial to the late Daniel Hanbury, and that it has since been customary to award a gold medal biennially for high excellence in the prosecution or promotion of original investigations in the chemistry and natural history of drugs—Daniel Hanbury's especial subjects of study. The adjudicators are the Presidents for the time being of the Linnean, Chemical, and Pharmaceutical Societies, the President of the British Pharmaceutical Conference, and a pharmaceutical chemist nominated by the last-named two Presidents. On the present occasion, therefore, the adjudicators are Dr. Günther, Dr. T. E. Thorpe, Mr. William Martindale, Mr. J. C. C. Payne, and Mr. Francis Ransom, and they have unanimously decided that Professor Ladenburg is the most fitting person to receive the medal to be awarded this year. He has specially devoted himself, as a chemist, to the synthesis of organic bodies, and has studied more particularly the constitution and synthesis of alkaloids—atropine, homatropine, and coniine being among the more important of the numerous substances which he has succeeded in forming synthetically. His first paper on a scientific subject was published in 1868, and the Royal Society's Catalogue of scientific papers includes a list of seventy-seven records of investigations conducted by him independently, in addition to numerous others published in conjunction with other investigators. It is usual to present the medal formally at the inaugural sessional meeting of the Pharmaceutical Society in October, and it is expected that Professor Ladenburg will be in England to receive the medal in person on October 2 next. Former recipients of the medal have been Friedrich August Flückiger (1881), John Eliot Howard (1883), Georg Dragendorff (1885), William Dymock (1887), Gustave Planchon (1889), Julius Oswald Hesse (1891), Johann Michael Maisch (1893), August E. Vogl (1895), and John Elishee De Vrij (1897).

CLUB PRACTICE AND EXPENSIVE DRUGS.

Some time ago the *Hospital* pointed out the very serious position in which club surgeons, and other medical men who accept contracts for the supply of "attendance and medicine" at very low rates, might find themselves in consequence of the high price of antitoxin, and it now reverts to the subject. It appears that an ingenuous person is in great trouble because, having recommended a certain expensive proprietary medicine to a club patient, on condition that the patient should pay for it, the "lodge" immediately demanded that the doctor should supply the medicine at his own cost, he having contracted to supply "proper and sufficient medicine." This, it is suggested, is a case exactly analogous to that of the antitoxin. The medical man evidently thought that the drug was an appropriate one to give, yet he "could not himself afford to supply it under the club contract." But then he should not have accepted the contract at such a low rate.

ANNOTATIONS.

The Plymouth Local Committee of the British Pharmaceutical Conference is now engaged in completing the arrangements for the proceedings which commence on Monday week, and for the last time attention is directed to the fact that no applications for books of tickets can be entertained after Monday next, July 17. The tickets already applied for are now being issued, and it is hoped that all will be sent out within the next few days. Full particulars regarding the arrangements, so far as they were then settled, were published in last week's Journal, at page 39, as well as in the pink circular recently issued to members of the B.P.C.; but further details are now available. Special reference must first be made to the fact that the Mayor of Plymouth, Alderman J. Pethick, J.P., has announced his intention of inviting the members of the Conference and their friends attending the meeting, to a garden party at his country residence, Donn House, Yelverton, on Friday afternoon, July 28. All who have applied for books of tickets, and those who apply up to Monday next will receive an official invitation to the garden party in due course. The books of tickets, it may be noted, will also secure free admittance to the Devon and Cornwall Exhibition of Oil Paintings and Water Colour Drawings, now being held at Plymouth, as well as to the Promenade Pier, on Thursday, July 27, the day of the steamer trip, and to Devonport Dockyard, on Friday, July 28. The time of the visitors to Plymouth will thus be fully occupied from Monday, July 24, to the following Friday inclusive. Another point to which reference must be made is the fact that the Great Western, Midland, and London and South-Western Railway Companies have undertaken to issue return tickets to those attending the meeting at Plymouth on payment of a single fare and a quarter, on condition that each person for whom a ticket is required is able to produce a certificate signed by Mr. W. A. H. Naylor, the senior hon. secretary of the Conference. Applications for the necessary certificates must be addressed to Mr. Naylor, at 38, Southwark Street, London, S.E., and in each case a stamped addressed envelope must be enclosed. The railway tickets will, we understand, be available from Saturday, July 22, to Saturday, July 29.

Makers of Methylated Spirits are, according to a notice just issued by the Commissioners of Inland Revenue, to be informed in future, as precisely as possible, what kind of wood naphtha will be accepted as suitable for methylating purposes, as well as the nature of the objections to any samples which may be rejected. All wood naphtha submitted for approval must consist entirely of substances derived from the destructive distillation of wood. It must also be so impure as to make nine times its volume of spirit of wine sufficiently nauseous to be rendered incapable of being used as a beverage, or of being mixed with potable spirits of any kind without rendering them unfit for human consumption. Not more than 30 C.c. of the wood naphtha must be required to decolorise a solution containing 0·5 Gm. of bromine; it must also be neutral or only slightly alkaline to litmus, and require at least 5 C.c. of decinormal acid to neutralise 25 C.c. of the spirit when methyl orange is used as the indicator. No wood naphtha will be approved which contains (*a*) less than 72 per cent. by volume of methyl alcohol; (*b*) more than 12 Gm. per 100 C.c. of acetone, aldehydes, and higher ketones, determined as "acetone" by the formation of iodoform according to Messinger's method; (*c*) more than 3 Gm. per 100 C.c. of esters, determined as methyl acetate by hydrolysis. Details are given respecting the indications which wood naphtha, suitable for methylating purposes, should give, and it is stated that particulars of the methods and apparatus used in applying the tests will be supplied on application to the Principal of the Government Laboratory, Clement's Inn Passage, London, W.C.

In Referring to the Spalding Poisoning Case last week, it was stated that Mr. Justice Lawrance's remarks, in summing up, appeared to indicate that he was of opinion that the requirements of the Pharmacy Act had not been properly fulfilled by the seller of the poisons, a fuller report of the case now available makes that inference a certainty. According to the *Lincolnshire, Boston, and Spalding Free Press*, the Judge said it was found that the prisoner had paid three visits to the place where the poisons were sold, and on each occasion had been supplied with poison, "although poisons should not be sold to an unknown person unless he were introduced by someone." It was clear, the Judge continued, "notwithstanding what the chemist said, that he did not know the prisoner; his own evidence showed that, and yet he did not hesitate to sell him poison enough to poison a whole parish."

A Chemists' and Druggists' Indemnity Scheme, to which attention is directed by the Ocean Accident and Guarantee Corporation, Limited, appears well worthy of consideration, though the risks incurred by chemists and druggists in the dispensing and sale of medicines are far from being so serious as might be imagined from a perusal of the prospectus. In fact, it is no exaggeration to say that the properly trained chemist and druggist, who personally supervises all that is done in his establishment or delegates his duties only to duly qualified persons, may safely disregard the possibility of error. At the same time, it is well to know that it is now possible to assure against mishaps in the pharmacy, the Ocean Accident and Guarantee Corporation being prepared to indemnify chemists against any liability they may incur through a momentary lapse of attention on the part of a dispenser, or mistakes on the part of packers, countermen, and others in their employment. The terms are five shillings per cent. upon the amount of indemnity, with half-a-crown for each assistant, and in the form of proposal the chemist is expected to state the address or addresses at which his business is carried on; whether it is wholesale or retail, or both; how long it has been established; the number of persons engaged in dispensing and selling drugs, and whether they are all registered chemists; also the number of persons, other than the above, who are engaged in compounding, filling, and despatching drugs. Further particulars may be obtained on application to the head offices of the Corporation, Moorgate Street, London, E.C.

The Council of the Royal College of Surgeons, at an extraordinary meeting held on Monday, July 3, received a report from the Laboratories Committee on the work on diphtheria done for the Metropolitan Asylums Board, Bacteriological Department. Since March 10 last, 1,100 doses of antitoxin, each containing 2,000 units, and 4,425 doses, each containing 4,000 units, for the treatment of diphtheria in the hospitals of the Metropolitan Asylums Board have been supplied, and all the demands fully met. During this period 19,900,000 units have been supplied. During the same period five doses of 4,000 units each have been supplied to medical officers of health according to instructions received from the Metropolitan Asylums Board. Under the grant from the Goldsmiths' Company, 459 doses of antitoxin, containing 1,134,000 units, have been supplied to the general and children's hospitals in or near London.

The National Revenue from Medicine Stamps was the subject of a question in the House of Commons, on Monday, when Sir John Leng asked the Chancellor of the Exchequer if he could state the amount of revenue derived from the sale of medicine stamps in Scotland for the years ended March 31, 1898, and 1899, respectively. In reply, Sir Michael Hicks-Beach said the stamp revenue derived from the sale of patent medicine stamps in Scotland was in 1897-8, £2,127; and in 1898-9, £2,142. "Patent" medicine vend Excise licences were also taken out to the value of £643 in 1897-8, and £667 in 1898-9.

The Direct Way of Obtaining Things is not always the only way, and an indirect method of procuring postage stamps suggested in last week's *Truth* possesses a merit which is entirely its own. The Post Office, it appears, has what our lively contemporary styles "an idiotic rule" which precludes the public from buying postage stamps at offices which are restricted to telegraphic business. The rule was ingeniously circumvented the other day by a gentleman who had written a letter in a train and went to a telegraph office at a station *en route* for the purpose of obtaining stamps. The clerk in charge having declined to sell them, the traveller asked for a telegraph form, and wrote the following message:—"Postmaster-General, London,—Your clerk says I cannot purchase two stamps at this office. Rats." Claiming the right to affix the stamps himself, in accordance with another Post Office rule, he took the stamps which the clerk handed over, put them in his pocket, tore up the telegraph form, and departed in triumph. According to *Truth*, a man who could thus make red-tape look ridiculous deserves to be regarded as a public benefactor.

The Hybridisation of Flowers was the subject to consider which an international conference on hybridisation has been held at the gardens of the Royal Horticultural Society, Chiswick, and the conference was opened by Dr. Maxwell Masters, who spoke of the history of the artificial hybridisation of plants, and said that if we were to advance it must be by means of judicious experiments, carefully and scientifically carried out. Nine-tenths of the flowers now exhibited at shows, he pointed out, are the results of the gardener's art, not natural productions. Very few new plants, in the old sense of the term—orchids excepted—are now shown. At the early part of the eighteenth century a fierce discussion went on as to whether there was sex in plants. Some argued from Aristotle, but others went to Nature, and the thing was proved. The first person to form an artificial hybrid purposely was Thomas Fairchild, and the hybrid which he produced, a cross between the sweet william and the carnation pink, is still cultivated. But progress was slow in the direction of crossing plants till the time of Linnæus, who was struck by the same phenomenon as Fairchild. There was, however, a prejudice against the new method, the hybridists being accused of contravening the laws of Providence. Dean Herbert, however, saw in the Pyrenees a narcissus growing between two narcissi of similar character, and found that it was a hybrid. He produced a similar hybrid, and asked why he was to be blamed for doing what Nature had done; and so that particular prejudice was knocked on the head. Still, to so great an extent was religious prejudice carried that nurserymen were afraid of exhibiting plants as hybrids, and so they introduced plants which they had reared in their own nurseries as having come from the Cape and other places. Another prejudice existed in the minds of some botanists who found their little systems upset by the proceedings of the hybridists; but it was better to uphold the interests of science and truth than to uphold the interests of petty systems. There was a time when a "species" was considered a sort of sacrosanct thing, but the researches of Darwin and others had altered all that. No one can say what a species is. There is nothing but individual opinion on the subject. To say that there is a definite line of demarcation between species, genera, or varieties is absurd—there is no such line. Some botanists say they would not call crossing between varieties hybridisation, as that word should be kept to denote crossing between species; but until they define what a species is, Dr. Masters thinks they had better use the word in its widest sense, and not quibble about trifles.

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

An Introduction to Dermatology, by Norman Walker, M.D. (Bristol: John Wright and Co. Pp. 247. Price 8*s.* 6*d.* net), is a reproduction of lectures which the author has delivered to students for several years. All the more common diseases of the skin are fully described, and rare ones less completely. In each case the description of the disease is followed by particulars of the treatment recommended. The book, which is exceedingly well produced, includes twenty-nine plates, mostly coloured, and there are thirty-four illustrations in the text.

The Matriculation Directory for June, 1899 (London: University Correspondence College, Red Lion Square, W.C. Pp. 140. Price 1*s.* net), gives the usual particulars regarding courses of instruction for the examinations of the University of London, and more detailed information about the books to be read by candidates for the matriculation examination.

Living Pictures, by H. V. Hopwood (London: Offices of the *Optician*, Fleet Street, E.C. Pp. 275. Price 2*s.* 6*d.* net), is a guide to the voluminous and scattered literature of the subject of which it treats. The persistence of vision and illusion of motion are first discussed, after which the author proceeds to deal with chromo-photography, and the practical development of the living picture, of present day cameras and projection apparatus, the production and treatment of films, etc., etc. The book is a most useful one and probably the most complete on the subject.

'Our Baby,' by Mrs. Langton Hewer (Bristol: John Wright and Co. Sixth Edition. Pp. 154. Price 1*s.* 6*d.*) is a most useful guide for mothers and nurses, as the fact that, whilst originally published in 1891, it has now reached its sixth edition should go far to prove. In this new edition a few points of minor importance have been omitted, and the rest of the book has been carefully revised, the subject of infant feeding being amplified so as to include more details regarding the practical management of those babies which it is necessary to rear by artificial means.

'Hydrophobia and Serotherapy,' by Dr. A. Lutaud (London Anti-Vivisection Society. Pp. 24. Price 6*d.*), is a pamphlet which has been published with the object of proving that the Pasteurian method as applied to rabies is useless and dangerous, and that the inoculation of animals and human beings with serums of various kinds constitutes an error and a danger. Serotherapy is asserted to have been without influence in the cure of diphtheria, Koch's remedy for tuberculosis is said to have produced no results beyond hastening death in many cases, and in tetanus and other diseases the alleged good effects of serotherapy are steadily denied.

The Slide Lending Department established by C. Baker, 244 High Holborn, London, W.C., is now in full working order, and the list of slides ready for sending out can be obtained on application. According to this novel scheme, prepayment of one guinea secures the loan of 240 mounted specimens for examination under the microscope, the slides being supplied in twelve deliveries of twenty each, and postage paid both ways. There are twelve series from which the slides may be selected, each containing a number of sets. The subjects of the twelve classes are (1) diatoms, (2) foraminifera, etc., (3) botanical, (4) physiological, (5) pathological, (6) zoological, (7) bacteria, (8) entomological, (9) polariscope, (10) rock sections, (11) marine, (12) general (assorted). Subscribers can choose the class of specimen they wish to secure, and they can have the delivery of the twelve sets spread over twelve months or less, as desired.

BRITISH PHARMACEUTICAL CONFERENCE.

PLYMOUTH MEETING, 1899.

Papers to be Read.

1. "The Assay of Preparations containing Pilocarpine, and the Characters of Pilocarpine Nitrate and Hydrochloride," by H. A. D. Jowett, D.Sc.
2. "Three Natural Rubber Substitutes," by David Hooper, F.C.S., F.L.S.
3. "Notes on Terebene, B.P.," by Lewis Ough, F.L.C., F.C.S.
4. "Note on the Assay of the Official Liquid Extract, Wine, and Vinegar of Ipecacuanha," by E. H. Farr, F.C.S., and R. Wright, F.C.S.
5. "The Composition of Commercial Araroba," by Edwin Dowzard, F.C.S.
6. "*Delphinium Staphisagria*," by E. M. Holmes, F.L.S.
7. "The Alkaloidal Strength of Commercial Samples of the Official Preparations of Jaborandi," by R. Wright, F.C.S., and E.H. Farr., F.C.S.
8. "Glucose Determination; Fehling and Picric Methods Compared," by R. H. Parker, Ph. C., F.C.S.
9. "Notes on the Results of the Examination of Various Terpeneless Oils of Lemon in the Market," by T. H. Williams Idris, J.P., F.C.S.
10. "A Note on Carbon Disulphide," by W. Elborne, M.A.
11. "Note on Syrup of Balsam of Tolu," by E. H. Farr, F.C.S., and R. Wright, F.C.S.
12. "Almond and Other Kernel Oils." by John C. Umney, F.C.S., and R. S. Swinton.
13. "The Assay of Belladonna Plaster," by H. J. Henderson, F.C.S.
14. "Oil of Cardamons," by E. J. Parry, B.Sc., F.I.C., F.C.S.
15. "Further Note upon Ferrum Redactum," B.P., 1898, by E. Saville Peck, B.A. (Cantab.)
16. "Johore Ipecacuanha," by John C. Umney, F.C.S., and R. S. Swinton.
17. "The Bone Caves of Devon," by Hansford Worth.
18. "A Weight Burette," by E. Saville Peck, B.A. (Cantab).
19. "Analytical Notes on the B.P. Lozenges," by Frederick Davis.
20. "Note on Liquor Bismuthi et Ammon. Citratis," by Frank R. Dudderidge, Ph.C.
21. "The Liberation of Carbonic Anhydride from Bicarbonates upon Heating," by C. S. Dyer.
22. "A Method for Determining the Acidity of Beers, Stouts, and Other Highly-coloured Liquids," by L. Guy Radcliffe.
23. "The Assay of the Liquid Extract and Wine of Ipecacuanha of the B.P.," by W. A. H. Naylor and John J. Bryant.
24. "Note on the Strength of the Blaud's Pill Capsules of Commerce," by C. E. Stuart, B.Sc.

Note.—The Hon. Secretary (Mr. W. A. H. Naylor, 38, Southwark Street, London, S.E.) requests that all manuscripts of papers may be sent to him without delay, in order that the papers may be formally approved for presentation to the Conference, and put in type. Proofs will then be supplied for the authors to correct and to read from at Plymouth.

Soluble Tannin Albumin.—This new tannin albumin compound promises, according to Hummer, to prove a useful substitute for tannin, being quite free from the irritating astringent properties of that body. It occurs as a yellowish-white, odourless and tasteless powder, which is insoluble in water and dilute acids. Tannin is, therefore, only liberated in the intestines, and so does not affect the stomach. The method of preparation is as follows:—Tannin, 5, is dissolved in hot distilled water. When cool a solution of egg albumin, 10, is added, with energetic stirring. The mixture is stirred until of a uniform doughy consistence, and heated on the water-bath above 70° C. The yellow-white rubber-like substance is separated from the water, washed and dried until hard, brittle, and transparent. It is then powdered and again dried. It is prescribed in the same way as tannin.—*Oest. Zeit. für Pharm.*, **53**, 86.

PHARMACEUTICAL SOCIETY.

DONATIONS TO THE LIBRARY AND MUSEUM.

At a meeting of the Library, Museum, School, and House Committee on Wednesday, July 12, the Librarian and Curator presented the following reports of donations:—

To the Library (London).

University of Glasgow:—Roll of Graduates, 1727—1897; Calendar, 1899.
University of Edinburgh:—Calendar, 1899.
University of London:—Calendar, 1899.
Editor of *Chemist and Druggist*, London:—Proctor's Pharmaceutical Testing. Second edition, 1899.
Mr. W. E. Crow:—The Laws of Metals, by J. Pettus, 1683.
Mr. F. M. Bailey, Brisbane:—Contributions to the Flora of Queensland, etc. Four pamphlets.
Deutscher Apother-Verein, per Herr Froelich, Vorsitzende, Berlin:—*Apotheker Zeitung*, 1899, to be continued.

To the Museum.

Mr. S. A. Owen, Ceylon:—Specimen of Fresh Bael Fruit; photograph of the Papaw Tree.
Mr. F. B. Filmer, New Jersey:—Photographs illustrating the collection of the cotton harvest.

To the Herbarium.

Dr. D. Prain, F.L.S., Royal Botanic Gardens, Calcutta:—Specimens of the Coca Plants cultivated in India.
Mr. J. Dunning, Ventnor:—Specimens of *Melampyrum arvense* and *Rubia peregrina*.

FIRST EXAMINATION QUESTIONS.

First Paper.

July 11, 1899, *from* 11 *a.m. to* 12.30 *p.m.*

LATIN.

1. FOR ALL CANDIDATES. Translate into Latin:—

1. I will answer neither you nor your friend.
2. Ambassadors were sent to the king on the next day.
3. Does not experience teach us very many things?
4. This man must be avoided by me.
5. The army, which had been raised by the king, arrived in Gaul.

2. Translate into English *either* A (Caesar) *or* B (Virgil).

A.—CAESAR.

1. Post ejus mortem nihilo minus Helvetii id, quod constituerant, facere conantur, ut e finibus suis exeant. Ubi jam se ad eam rem peratos esse arbitrati sunt, oppida sua omnia, numero ad duodecim, vicos ad quadringentos, reliqua privata aedificia incendunt, frumentum omne, praeterquam quod secum portaturi erant, comburunt, ut, domum reditionis spe sublata, paratiores ad omnia pericula subeunda essent: trium mensium molita cibaria sibi quemque domo efferre jubent.

2. Ei legationi Ariovistus respondit: Si quid ipsi a Caesare opus esset, sese ad eum venturum fuisse; si quid ille se velit, illum ad se venire oportere. Praeterea se neque sine exercitu in eas partes Galliae venire audere, quas Caesar possideret; neque exercitum sine magno commeatu atque emolimento in unum locum contrahere posse: sibi autem mirum videri, quid in sua Gallia, quam bello vicisset, aut Caesari, aut omnino populo Romano negotii esset.

GRAMMATICAL QUESTIONS.

(For those only who take Caesar.)

1. Give the gender, genitive singular, and the English of *agmen, annus, cornu, citio, initium, mens, opus, res.*

2. Give the principal parts of all the verbs in Passage 1.

3. Write in Latin:—13, 47, 96, 200, 16*th*, 19*th*, 87*th*, *one-fourth*, *three times a day*.

4. Explain the following terms, and give *one* example of each:—*deponent verb, anomalous verb, ablative absolute.*

B.—VIRGIL.

1. Talia flammato secum dea corde volutans,
Nimborum in patriam, loca feta furentibus austris,
Aeoliam venit. Hic vasto rex Aeolus antro
Luctantes ventos, tempestatesque sonoras
Imperio premit, ac vinclis et carcere frenat.
Illi indignantes, magno cum murmure montis,
Circum claustra fremunt: celsa sedet Aeolus arce,
Sceptra tenens, mollitque animos, et temperat iras.

2. Namque videbat, uti bellantes Pergama circum
Hac fugerent Graii, premeret Trojana juventus:
Hac Phryges; instaret curru cristatus Achilles.
Nec procul hinc Rhesi niveis tentoria velis
Agnoscit lacrimans: primo quae prodita somno,
Tydides multa vastabat caede cruentus;
Ardentesque avertit equos in castra, priusquam,
Pabula gustassent Trojae, Xanthumque bibissent.

GRAMMATICAL QUESTIONS.

(For those only who take Virgil.)

1. Give the gender, genitive singular, and the English of *cithara, complexus, cor, equus, fragor, officium, ops, sedile.*

2. Give the principal parts of all the verbs in Passage 2.

3. Write in Latin:—13, 47, 96, 200, 16*th*, 19*th*, 87*th*, *one-fourth*, *three times a day*.

4. Explain the following terms, and give *one* example of each:—*deponent verb, anomalous verb, ablative absolute.*

Second Paper.

Tuesday, July 11, 1899, *from* 12.30 *p.m. to* 2 *p.m.*

ARITHMETIC.

(*The working of these questions, as well as the answers, must be written out in full.*)

1. How many allotments, each 16 sq. po. 4 sq. yd., can be made out of a field 16 ac. 21 sq. po. $4\frac{3}{4}$ sq. yd.?

2. If 6 cwt. 2 qr. 2 lb. cost £9 3s. 4d., what will 4 cwt. 2 qr. 7 lb. cost at the same rate.

3. The difference between two numbers is $2\frac{5}{12}$, and the smaller of them is $\frac{54\frac{2}{5}}{\frac{1}{5} \text{ of } 8\frac{2}{3}}$. What is the larger number?

4. Find the value of

2.86805 of $\dot{3}$ shillings + 8.$\dot{3}$ of 4 shillings − 1.8 of 5 shillings.

5. A man sells 60 articles at a profit of 2s. 6d. each. What additional number must he sell at a profit of 3s. 4d. each so as to realise an average profit of 3s. 1d. on each article sold?

6. What sum must be invested in $2\frac{3}{4}$ per cent. Consols at $96\frac{1}{4}$ in order to derive an income of £166 13s. 4d.? [*Neglect brokerage.*]

The following question must be attempted by every candidate:—

7. A farmer's corn-land yields at the rate of 60 hectolitres per hectare. How many bushels is this per acre?

Third Paper.

July 11, 1899, *from* 3 *p.m. to* 4.30 *p.m.*

ENGLISH.

1. Analyse:—

"The long-remember'd beggar was his guest,
Whose beard descending swept his aged breast;
The ruin'd spendthrift now no longer proud,
Claim'd kindred there, and had his claims allow'd."

2. Parse fully:—

"Who can direct when all pretend to know?"

3. Correct the following sentences, giving your reasons:—

(i.) This is the man whom you said was guilty.
(ii.) This house has been furnished by a cousin of the owner's.
(iii.) I cannot run so fast as him.

4. In the following passage, supply the necessary capital letters, and put in the stops and the inverted commas where necessary:—are the officers gone i asked and oh how my hopes hung upon the answer they are said he looking somewhat disconcerted why do you ask i wish you had kept them i answered solemnly enough although my heart at that same moment leaped with exultation master i must not conceal from you the truth the servants on this estate are in a dangerous condition and mutiny has long been brewing

The following question must be attempted by every candidate:—

5. Give, briefly, the outline of one of Shakespeare's plays, *or* of one of Scott's prose works, *or* the history of some scientific discovery.

BELL SCHOLARSHIPS EXAMINATION QUESTIONS.

First Paper.

Tuesday, July 11, 1899, *from* 11 *a.m. to* 2 *p.m.*

LATIN.

1. Translate into English:

"Adsit laetitiae Bacchus dator, et bona Juno:
Et vos, O coetum Tyrii, celebrate faventes."
Dixit, et in mensam laticum libavit honorem;
Primaque, libato, summo tenus attigit ore.
Tum Bitiae dedit increpitans: ille impiger hausit
Spumantem pateram, et pleno se proluit auro:
Post alii proceres. Cithara crinitus Iopas
Personat aurata, docuit quae maximus Atlas.
Hic canit errantem Lunam Solisque labores;
Unde hominum genus et pecudes; unde imber et ignes;
Arcturum pluviasque Hyades geminosque Triones:
Quid tantum Oceano properent se tingere soles
Hyberni, vel quae tardis mora noctibus obstet.
Ingeminant plausu Tyrii, Troësque sequuntur.
Necnon et vario noctem sermone trahebat
Infelix Dido, longumque bibebat amorem;
Multa super Priamo rogitans, super Hectore multa;
Nunc, quibus Aurorae venisset filius armis;
Nunc, quales Diomedis equi; nunc, quantus Achilles.

2. Translate into English:—

(*a*) Medicamina, quae in pharmacopoeiam non sunt recepta, attamen passim a medicis praescribi et hinc in pharmacopoliis praesto esse solent, optimae indolis nec inquinata nec corrupta sint oportet.

(*b*) Quantum id quod destillaveris acidi hydrocyanici contineat ratio infra descripta examina; deinde dilue tanta quantitate aquae quanta sufficiat ut mille partes unam acidi contineant.

(*c*) Macera per quadraginta octo horas. Quo tempore elapso, collige liquorem defluentem in lagena noti ponderis donec quantitas liquidi pondus octoginta quinque grammatum attigerit. Liquorem collectam in balneo aquae destillando a spiritu vini libera, residuum ad extractum tenue evaporando redige.

3. Parse fully:—"Cithara crinitus Iopas personat aurata, docuit quae maximus Atlas."

4. Translate into Latin:—

(*a*) "If," said the philosopher, in answer to the question of his brave young son—"if in our great calamities we had been spared by the conquering Romans, we should have pitied them now."

(*b*) The general made answer as follows:—"The enemy that you have been so long seeking is now only two miles distant; prepare then to conquer or to die. I will send spies to bring me word of their numbers and the position of their camp; this done I must entrust the rest to you."

ENGLISH.

1. Parse fully:—

"I could myself
Take up a brace o' the best of them."

2. Write a short Essay on *one* of the following subjects:—

(*a*) Our Colonies.
(*b*) "The noblest vengeance is to forgive."
(*c*) "Si vis pacem, para bellum."

ARITHMETIC.

1. The carpeting of a room, twice as long as it is wide, at 5s. per sq. yd., cost £6 2s. 6d.; and the painting of the walls, at 9d. per sq. yd., cost £2 17s. 9d. How high are the walls?

2. Simplify $\frac{2\cdot\dot{4}\dot{6}-2\cdot\dot{3}\dot{0}}{\cdot\dot{3}+\cdot1\dot{2}\dot{7}} + \frac{4\frac{1}{3}}{19}$

3. A solution contains 15 Gm. of salt to one litre of water. How many ounces must be added to 1 gallon of it, in order that 1 quart of the solution may contain $2\frac{1}{2}$ ounces?

FRENCH.

1. Translate into English:—

George, appelé dans un âge avancé à gouverner un peuple dont il n'entendait point la langue et chez qui tout lui était étranger, se regardait comme l'électeur de Hanovre plutôt que comme le roi d'Angleterre; toute son ambition était d'agrandir ses Etats d'Allemagne: il repassait presque tous les ans la mer pour revoir des sujets dont il était adoré. Au reste, il se plaisait plus à vivre en homme qu'en maître; la pompe de la royauté était pour lui un fardeau pesant; il vivait avec un petit nombre d'anciens courtisans qu'il admettait à sa familiarité; ce n'était pas le roi d'Europe qui eût le plus d'éclat, mais il était un des plus sages, et le seul qui connût sur le trône les douceurs de la vie privée et de l'amitié.

2. Translate into French:—

I have read somewhere that the vizier of the Caliph Mostady, having gained a complete victory over the Greeks, and made their Emperor prisoner, asked the latter what treatment he expected at the hands of his conqueror. "If you wage war like a king," nobly replied the Emperor, "send me back to my country; if you are a disguised merchant, sell me; if you are a butcher, kill me."

GERMAN.

1. Translate into English:—

Philipp II. hoffte die holländischen Provinzen wieder zu erobern, wenn sie ihres Hauptes, des Prinzen Wilhelm von Oranien, beraubt würden. Er hatte deshalb einen hohen Preis darauf gesetzt, wenn jemand ihm denselben lebendig oder todt ausliefern würde. Der erste, der den Versuch machte, war ein Franzose. Er begab sich nach Antwerpen, wo der Prinz sich aufhielt, überreichte ihm eine Bittschrift, und während er sie las, schoss er eine Pistole auf ihn ab. Der Schuss verwundete den Prinzen zwar gefährlich, aber nicht tödtlich. Noch andere Versuche, den Prinzen zu ermorden, wurden gemacht. Endlich übernahm es ein Franzose, Balthasar Gérard. Er trat in den Dienst des Prinzen und zeigte solchen Eifer für die reformirte Religion, dass der Prinz ihn sogar zu einem geheimen Geschäft gebrauchte. Für Geld, das ihm derselbe geschenkt hatte, kaufte et Pistolen, die er jede mit drei Kugeln lud. Am 10. Juli 1584 stellte er sich an die Thür des fürstlichen Speisesaals, während der Prinz zu Tische sass, und schoss nach ihm, als er nach der Mahlzeit heraustrat, so geschickt, dass er niederfiel und gleich darauf starb.

2. Translate into German:—

Then said Æneas to Anchises: "Sit on my shoulders, dear father; I will carry thee. The little Ascanius shall go with me, and my wife shall follow me. And ye servants of my house, listen to me: There is a Temple of Ceres, and an old tree, not far from the gate of the city. Go to that place, and I shall find you there." As he spoke he put a cloak upon his shoulders, and the old man sat thereon.

Second Paper.

Tuesday, July 11, 1899, *from* 3 *p.m. to* 5 *p.m.*

CHEMISTRY.

1. How is nitric acid prepared? Write equations showing the action of strong nitric acid upon (*a*) metallic copper, (*b*) ferrous sulphate.

2. Describe two experiments by which the composition of water may be demonstrated.

PHARMACY.

1. Describe Percolation and Repercolation. Give Pharmacopœial examples of the application of each. How would you recover the alcohol left in tincture marcs?

2. How is Tincture of Opium B.P. 1898 prepared? Suppose you had two samples of opium, one containing 13 per cent. and one only 9 per cent. of morphine—In what proportion must they be mixed to enable the powder to be used for the official preparations?

BOTANY.

1. On what parts of the plant are stomata most abundant. What is their function?

2. Give a short account of the germination of an ordinary bean.

MANCHESTER PHARMACEUTICAL ASSOCIATION SCHOLARSHIPS EXAMINATION QUESTIONS.

First Paper.

Tuesday, July 11, 1899, *from* 11 *a.m. to* 2 *p.m.*

The tests in Latin, English, Arithmetic, French and German, set at this examination, were the same as those for the Bell Scholarships Examination, but the following was given as an alternative Latin paper:—

LATIN.

1. Translate into English:—

Quamobrem placuit ei, ut ad Ariovistum legatos mitteret, qui ab eo postularent, uti aliquem locum medium utriusque colloquio diceret, velle sese de republica et summis utriusque rebus cum eo agere. Ei legationi Ariovistus respondit: Si quid ipsi a Caesare opus esset, sese ad eum venturum fuisse; si quid ille se velit, illum ad se venire oportere. Praeterea se neque sine exercitu in eas partes Galliae venire audere, quas Caesar possideret; neque exercitum sine magno commeatu atque emolimento in unum locum contrahere posse: sibi autem mirum videri, quid in sua Gallia, quam bello vicisset, aut Caesari, aut omnino populo Romano negotii esset.

2. Parse fully:—"Velle sese de republica et summis utriusque rebus cum eo agere."

Second Paper.

Tuesday, July 11, 1899, *from* 3 *p.m. to* 5 *p.m.*

CHEMISTRY.

1. What is an oxidising agent? Give example with equation.

2. Describe two tests by which arsenic may be detected in aqueou solution.

PHARMACY.

1. What do you understand by a "percentage solution"?

How many grains of mercuric chloride are required for 1 gallon of solution 1 in 2000? Show working.

2. Describe a method by which half a pint of cod-liver oil emulsion (50 per cent.) may be prepared.

BOTANY.

1. Illustrate by means of diagrams the following terms:—Perfoliate, connate, reniform, serrate. Describe in botanical language the leaf of the horse-chestnut.

2. Enumerate briefly the distinguishing characteristics of monocotyledons and dicotyledons.

PHARMACEUTICAL SOCIETY OF IRELAND.

The monthly meeting of the Council was held on Wednesday, the 5th instant, at the Society's House, 67, Lower Mount Street, Dublin, at three o'clock, the President, Mr. R. J. Downes, in the chair. The other members of the Council who attended were the Vice-President, Mr. Beggs, and Messrs. Michie, Grindley (Treasurer), W. F. Wells, junior, Bernard, and Dr. Walsh.

Miscellaneous Correspondence.

A letter from the Clerk of Sligo Poor Law Union intimated that the Guardians had unanimously adopted the Council's resolution in reference to company pharmacy. A letter from the Registrar of the Royal College of Surgeons of Ireland stated that the Council of that body did not feel at liberty to take any steps that might interfere with the passing of the Companies (Medical Profession) Bill.

A letter from the Royal College of Veterinary Surgeons, 10, Red Lion Square, W.C., acknowledged the receipt of the Council's resolution with reference to the Companies (Medical Profession) Bill, and stated that it would be placed before the President and Council of that College at their next meeting.

A letter from the Royal Veterinary College, Camden Town, acknowledging the receipt of a copy of the same resolution, stated that that College was solely an educational institution, and could not exercise any influence in the matter; but that the resolution had been forwarded to the College of Veterinary Surgens, Red Lion Square.

A letter from the New Veterinary College, Edinburgh, stated that the best assistance of that body would be given to obtain the inclusion of pharmacists and druggists in the Companies (Medical Profession) Bill; and the writer, Mr. Owen Williams, Vice-President, requested to have pointed out in what way he could be of service, mentioning that a meeting of the Council of the College would be held in London in about ten days.

The Registrar (Mr. Ferrall) stated that he had replied, thanking Mr. Williams, and sending him all the information in his possession.

A letter from the Secretaries of the Royal University of Ireland (Sir J. Creed Meredith and Dr. McGrath) stated, in reply to an inquiry from the Council, that certificates of having compounded medicines under a pharmaceutical chemist were no longer accepted by that University; and accompanying the letter was a pamphlet containing the following regulation of the University on the subject:—"Practical Pharmacy. A three months' course, with lectures on at least two days in the week given, in a recognised school in a properly equipped laboratory, by a duly appointed lecturer in pharmacy. (This course may be attended before, at the same time, or after that in materia medica, but must be attended in the third year.)"

Mr. Wells: I think we should approach the Royal University on the subject. It is monstrous that they will not accept our certificate.

The President: They think their requirement is sufficient for a medical man whose business is to prescribe.

Mr. Wells: Yet we shall be told by-and-bye that these men are competent to open and keep shops. I can produce a gentleman who went to one of those places and can testify that they get no practical work. A young lady who had taken out a course at one of those schools came to me to learn pharmacy, and she did not know the graduations on a measure. That is the way they teach pharmacy in those classes. We should memorialise the Senate of the University, saying that our men are qualified to teach pharmacy; that hitherto they have accepted our certificates; and that now they have cut down their own requirement to a mere class attendance.

Mr. Bernard: To make it easier for the students.

It was decided that the President should write to the Senate of the University on the subject.

The Qualifications of Public Analysts.

A letter dated June 27, from the Assistant Secretary of the Local Government Board, stated, in reply to a previous letter from the Council, that the Board had had under consideration the qualifications which candidates for the position of public analyst should possess, and they regretted that they could not see their way to recognise the certificates of the Pharmaceutical Society of Ireland as being sufficient evidence of analytical skill in the examination of drugs for the purposes of the Boards regulations under the Local Government (Ireland) Act, 1898.

Mr. Wells: They will not accept any man unless he is a Fellow of the Institute of Chemistry. They want a man who can test the purity of drugs; but being a Fellow of the Institute of Chemistry affords no guarantee that the man had been in the habit of analysing drugs. Lately, a gentleman who was giving evidence before a Court as to the adulteration of an article, was obliged to admit that he had never analysed the thing at all. A man might be a splendid chemist and yet not know anything about drugs.

The President: The question is as to ability to analyse drugs in connection with drug contracts. I hold that our examination fulfils entirely their original requirement, that the person has had experience in the examination of drugs, and that he is competent to form an opinion as to their quality. They say they will not sanction the appointment of any person who shall be unable to satisfy them that he has had considerable experience in the analysis of drugs. Our licentiates have had "considerable experience in the handling of drugs," and we know that the analysis of drugs is a thing that must grow under everybody's hand. They require a "diploma obtained in pharmacy, materia medica, and volumetric estimation, obtained from a recognised examining body." These are all subjects in our examination. In one of yesterday's papers it is stated that "The Local Government Board require the Board of Guardians to appoint chemists of repute to analyse the drugs supplied to the workhouses and dispensaries. The qualifications of the analyst must be as follow:—He must be a public analyst"—how does he get his diploma or certificate that he is such but by election?—"already appointed or a Fellow of the Institute of Chemistry, have a well-appointed laboratory, and experience in the analysis of drugs." Unless our qualified men should go over to London and pass an examination there they will not be accepted; we are the only body in Ireland that can grant a certificate such as they require. Mr. Barklie, of the Working Men's Institute, Belfast, is not a Fellow of the Institute of Chemisty. He is a Fellow of the Chemical Society, which is not an examining body; and that title is practically no qualification—it is only a courtesy. We have, I repeat, an examination which fulfils all the Board's requirements; outside of that, our licentiates have experience in the examination of drugs; and, therefore, if our licentiate applying for the office has a "well-appointed laboratory," he should be eligible. I consider that the Local Government Board has no right to pass our licentiates over, and I think we should press this matter.

Mr. Bernard: The wholesale trade in Ireland laugh at the Government analysts.

Mr. Wells: When the Local Government Board wanted information as to what were fair prices for drugs they went to the wholesale houses instead of coming to us.

The President: The following appears in a newspaper report of the proceedings of the Lisburn Guardians:—"The clerk read a letter from the Local Government Board stating that before they can sanction the appointment of Mr. Robert Barklie to the position of analyst of drugs for the union they must be satisfied that he has had considerable experience in the analysis of drugs and has after examination obtained a diploma in pharmacy, materia medica, and volumetric examination of drugs from a recognised examining body." I am informed that Mr. Barklie does not possess these qualifications, yet his appointment has been ratified.

Mr. Michie remarked that he did not think the Local Government Board would object to a pharmaceutical chemist. But the Society did not certify that their licentiate was an analytical chemist. In England a pharmaceutical chemist was not appointed to a position of the kind unless he was acquainted with analytical chemistry. There was nothing to prevent the licentiates of the Society from getting qualified in that respect.

Mr. Wells said he disagreed with Mr. Michie. A great many of the analysts in England had passed no legal examination whatever. Perhaps many of the Society's licentiates were not well up in the work in question; but a great many others from their training and study were well able to test and report on the purity of drugs.

Mr. Bernard: The point we have to impress on the Local Government Board is the necessity of having a practical pharmaceutical chemist who has passed an examination such as ours, in addition to having whatever other qualifications they may require.

Dr. Walsh: We should point out to them that ours is the only examination that embraces the three subjects which they mention.

Mr. Bernard: We should bring home to them that their analyst should be a trained pharmacist with the necessary qualification in chemistry; but a chemist who has been only trained as such should not be allowed in. You might as well appoint a chemist to be a tea-taster.

On the motion of Mr. WELLS, seconded by the VICE-PRESIDENT, it was resolved to ask the Local Government Board to receive a deputation on the subject.

DONATIONS OFFERED AND RECEIVED.

A letter was read from Mr. Forbes Watson, the Society's Examiner in Chemistry, in which he said: "In order to encourage independent practical work and reading among the junior members of the Society, I am willing to give two prizes, to take the form of medals, or their value (say, five guineas each), in books, instruments or money. I suggest that one prize be given for the best preparation of a chemical substance, preferentially organic, and that the other be given for the best essay on a subject to be set by me. I think that all students, assistants, or members who have not been qualified for more than five years on December 31 next, should be eligible for the competition."

The VICE-PRESIDENT: Well, I think we should be very much obliged to Mr. Forbes Watson for his kind and generous offer, but I think it would be premature for us to accept it, for this reason, that we might not have the pleasure and profit of Mr. Watson's help for more than a year; and then who would follow it up? Would the medals have to be dropped after he went, or would the Society be prepared to give them each year for the same work?

Dr. WALSH: I think that as long as he wishes to give the medals we should take them.

The PRESIDENT: The matter was referred to the School Committee.

Later on a report of the School Committee was read, which stated that they highly appreciated Mr. Watson's offer, but that they considered that at present it would not be advisable to accept it.

Donations were received from the Smithsonian Institution of pamphlets, entitled "The Revival of Alchemy," "An Undiscovered Gas," "Fluorine," "Recent Progress in Physiology," and "Mescal: A New Artificial Paradise," and from the Editor of the *Chemist and Druggist* of a copy of a new edition of Proctor's 'Pharmaceutical Testing.'

On the motion of Mr. GRINDLEY, and seconded by Mr. WELLS, thanks were voted to the donors.

HONORARY MEMBERSHIP OF THE SOCIETY.

The PRESIDENT moved the following resolution pursuant to notice:—"The Council may elect to honorary membership persons of eminence in pharmacology and its kindred subjects. Such honorary members shall have the privileges of members, but shall not be licentiates of the Society, nor shall they exceed the number of twenty at any time, nor shall more than three be elected in any one year." He thought the Society might very well have the power which he proposed. Other societies possessed it. They could in this way compliment men of scientific distinction. He did not know whether this resolution, if passed, would be sanctioned by the Privy Council or not; and it would not be contrary to their Acts of Parliament, for at present the original members of the Society were honorary members. He would, however, formally propose the resolution and leave the Council to deal with it as they thought proper.

The VICE-PRESIDENT: We need not elect anyone if we do not like.

The PRESIDENT: I had a letter to-day from Professor Tichborne, who has been unable to attend this meeting, in which he says he thinks ten honorary members would be sufficient.

Mr. WELLS: Have you power under your Acts of Parliament to elect honorary members?

The PRESIDENT: The approval of the Privy Council has been given to regulations not altogether within our Acts. There is nothing repugnant to them in this proposal.

Mr. MICHIE: I do not think it would be any harm to have honorary members.

Mr. WELLS: What privileges would you confer on them?

The VICE-PRESIDENT: They should have power to vote.

Mr. MICHIE: No; I would not give them the power to vote.

The PRESIDENT: I will postpone the resolution to another day if you wish. There is no hurry about it. It is not seconded.

The VICE-PRESIDENT: I second it with pleasure, to see what comes of it.

Mr. BERNARD moved an amendment that the discussion of the subject be adjourned to the next meeting.

Mr. MICHIE seconded the amendment, which was agreed to.

On the motion of Mr. GRINDLEY, seconded by Mr. WELLS, Mr. John Morrison Torrens, of Youghal, was elected a member of the Society.

Mr. Robert J. Savage, of Dublin, and Mr. H. A. Patterson were nominated for membership.

Other business having been disposed of, the Council adjourned.

NEW REMEDIES.

ANOTHER NEW ANTYPYRETIC.—Diacetphenetidide consists of colourless crystals melting at 53·5 to 54° C. It is an acetylised phenacetine, which Bistrzycki and Ulffers credit with physiological and therapeutic action similar to phenacetine, differing only slightly quantitatively. The compound is not likely to be much used in medicine, since it is not very stable, easily liberating acetic acid under the influence of atmospheric moisture.—*Pharm. Cent.*, **40**, 123.

PHENOSAL (Salicyl-acetic-acid-para-phenetidine) is a white crystalline powder, sparingly soluble in water, ether or alcohol, more readily in hot alcohol. It melts at 182° C. It is introduced as a remedy for articular rheumatism, cystitis, and sciatica. The dose is half a gramme.—*Merck's Report*, 1898, 127.

AMMONIUM FLUORIDE AS A GASTRIC ANTISEPTIC.—Ammonium fluoride occurs in colourless crystals which are soluble in water. Baudoin and Robin recommend the salt as a non-irritating remedy for abnormal fermentative action in the gastro-intestinal canal. The remedy is well tolerated and quickly suppresses butyric, lactic, and acetic fermentation. It may be dispensed in the form of of a solution, thus: ammonium fluoride 1, distilled water 300. One tablespoonful after each meal. When only a little food is taken the dose should be limited to a teaspoonful. It may also be administered in a pilular form, thus: Ammonium fluoride 3 Gm., sodium chloride 3 Gm., powdered acacia 4 Gm., water 5 drops; mass and divide into sixty pills. One to be taken after each meal. The antiseptic properties of ammonium fluoride are useful for cleaning Soxhlet milk bottles. After washing with warm soda solution, the flasks may be rinsed with 1 per mille ammonium fluoride solution and subsequently with water.—*Merck's Report*, 1898, 31.

KUMMERFELD'S SOLUTION FOR ACNE ROSACEA.—Precipitated sulphur 1 to 3 drms., powdered camphor 5 grs., powdered tragacanth 10 grs., lime water, 1 fl. oz., rose water, 1 fl. oz. Apply at night after washing.—*Therap. Gaz.* **22**, 238.

TOLUIDINE BLUE AS AN OPTICAL DISINFECTANT.—Toluidine blue is the double chloride of zinc and dimethyl-toluthionine. It is a black powder soluble in water and alcohol, the solution being of a fine blue colour. Toluidine blue is said by Veasey and Schweinitz to be a powerful poison to organisms of low development. In ophthalmic practice it may be employed in a similar manner to methylene blue for infectious conjunctivitis and inflammatory affections. Dilutions of 1 per mille are sufficient to arrest the formation of pus, without exciting any irritation on the tissues. Before application, the eye should be well bathed with physiological salt solution. Stains on the skin may be removed with water. Toluidine blue may also be used as a substitute for fluoresceine for detecting the seat and extent of corneal lesions, since it does not affect the normal cornea. The injured parts are revealed by the deep blue staining.—*Merck's Report*, 1899, 45.

TREATMENT OF CARBUNCLES.—Rosenbaum *(New York Med. Journ.)* claims that the following method of treatment affords a rapid, painless, and complete cure for carbuncles. A pad of eight layers of gauze, somewhat larger than the inflamed surface, is soaked in Thiersch's solution, composed of salicylic acid 30 grs., boric acid 210 grs., distilled water 32 fl. ozs. This is covered with 10 per cent. ichthyol ointment, and held in place by a rubber protective, cotton wool, or a bandage. This dressing is left in place for two days, when the cores will be found to have separated from their walls, and can be painlessly removed at the next dressing.—*Therap. Gaz.* **22**, 273.

ALCOHOL IN EXTERNAL PHENOL POISONING.—A. M. Phelps states that pure alcohol entirely prevents the escharotic action of phenol upon the tissues. If after the application of phenol or its solutions to wound cavities, these are thoroughly washed out with alcohol, no caustic effect is observed. So marked is the action that it is suggested that the immediate and free administration of alcohol may prove a possible antidote in those cases where phenol has been swallowed by accident, or with suicidal intent.—*Therap. Gaz.*, **22**, 255.

LETTERS TO THE EDITOR.

NOTICE TO CORRESPONDENTS.—All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received, if specially arranged for, as late as Thursday morning. Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C., and Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

Liquor Ferri Perchlor. Fort. B.P.

Sir,—Mr. F. A. Allen's letter to you on this subject, in last week's issue, refers to discrepancies in the official formula for liq. ferri perchlor. fort., which have doubtless been noticed by others when verifying the strength of this preparation, and Mr. Allen has done good service in drawing attention publicly to the matter. He shows by careful practical experiment that the B.P. figures are not concordant, a fact which is further demonstrated on looking closely into the formula and calculating the amount of iron that can theoretically be taken up by the quantity of hydrochloric acid allowed for its solution. 12½ fl. oz. acid. hydrochlor. B.P. contain 4.609 oz. wt. hydrogen chloride; and as 72.38 parts by wt. of hydrogen chloride combine with 55.6 parts by wt. of metallic iron, the 12½ fl. oz. acid. hydrochlor. will dissolve 3.54 oz. of the 4 oz. of iron taken. Having removed excess of iron, oxidised, evaporated, etc., the final product is 17½ fl. oz., containing the 3.54 oz. iron dissolved. ∴ 17½ fl. oz. contain 3.54 oz. iron. 5 fl. oz. contain 1.011 oz. iron. 5 Gm. contain 1.011 Gm. Fe, or 1.44 Gm. Fe_2O_3, which is the maximum quantity of Fe_2O_3 which 5 C.c. of the B.P. liquor can theoretically yield. The question arises as to which figure should be taken as a guide in making the liquor—the specific gravity, the volume of the product, or the residue on ignition. The context apparently decides this, for it is therein stated that 100 C.c. of the liq. ferri perchlor. fort. contain 22.5 Gm. of iron, equivalent to 32.14 Gm. Fe_2O_3, which gives the official figure 1.6 Gm. as the yield from 5 C.c. of the liq. ferri perchlor. fort.

London, July 11, 1899. F. C. J. Bird.

The Employment of Unqualified Dispensers.

Sir,—I think that a much larger section of the members than the Council seem to appreciate are watching with interest their action with reference to the employment of unqualified dispensers in surgeries, etc. There is no doubt that Mr. Glyn-Jones in bringing this matter forward at the earliest possible time has simply fulfilled his trust, and has voiced the wishes of a large number of members; and it is extremely doubtful if the attempt to prevent him from doing so was wise on the part of the majority of the Council. The members of Council appear to have come to the conclusion that their re-election implies entire satisfaction with their policy. From personal knowledge of some of the new members I believe something must be put down to a courteous appreciation on the part of the new electorate of their having provided them with the full dignity and voting power of the Society. But this democratic policy must necessarily be followed in dealing with all questions of vital interest to the members, and any attempt to suppress a representative when expressing some at least of the members' views savours a little of casting the boomerang. If the opinion expressed by our worthy President (whose election to that position every provincial chemist should welcome as an acknowledgement of work done most beneficial to them) is that of London chemists generally, dispensing by surgeons cannot be as general there as in some other districts. In this district the younger medical men do their own dispensing until able to employ, when lately it has come to be the rule to take a compounder from one of the services, who is drawn from the ranks, and having undergone a short term of training is sent out as a competent dispenser. It would certainly appear probably, with the existing anxiety on the part of the officials to find employment for discharged soldiers, etc., that an opening of this sort will not be neglected, but rather that the supply will be fully equal to any demand from the surgeons throughout the country and, being cheap labour, will not lessen the tendency for surgeons to do their dispensing and ignore any claims chemists may have. The alternative to this on the part of the younger medical men is to have an arrangement with a chemist. In some cases the chemist sends the medicine out for them without his name appearing (of course the legality of this is doubtful where the medicine contains poisonous preparations), and the profit derived is only small and not remunerative to the average chemist. The question the Council of the Society has to consider is—are these conditions favourable to the production of a better class of pharmacists? If not, it is most important that, when the whole question is before Parliament and before the Medical Council, the claims of chemists to the legitimate work for which they have been trained should be pressed as hard as possible; work which they are able to do much better and with greater safety to the public than medical men. To stand by and see a class of men drawn from the ranks of the Army and Navy, who, after a perfunctory training, are given our work to do whilst the pharmacist has to cast about him for any or every means to eke out a living, is tantamount to an acknowledgment of a very weak case. A section of the medical profession has been prevented from continuing the employment of unqualified medical assistants; the work done by their unqualified dispensers in their absence would seem equally bad for the public. Certain it is that if the trained compounder has come amongst us to stay and becomes numerically strong—backed by the services who have trained him—the Council will find, perhaps too late, that he is too strong for them.

Plymouth, July 11, 1899. Robert F. Roper.

A Warning.

Sir,—I wish to give warning to my brother pharmacists. A new prescription was to-day presented by a lady to be dispensed for one dozen powders, each containing four grains of morphine hydrochlorate, to be used for hypodermic injections. It was perfectly in order, and was, moreover, marked "Not to be renewed." I was about to make it up when a neighbour brought in a similar prescription for the same lady, asking what I should do about dispensing it. We decided to retain the prescriptions and not to dispense them. The lady called again in due course, and I informed her that there was an irregularity in the prescription, and that I should not dispense it. She told me that the doctor resided in Paris, and I got her to write down his address. From a comparison of the writings I have no doubt that the prescriptions were written by herself, and this points out to us the danger we incur when dealing with morphino-maniacs. Sooner or later an overdose will be taken and then will arise the question, "By what authority did you supply this poison?" A verdict of death from an overdose of morphine will follow, accompanied by a censure upon the unfortunate chemist for not taking precautions to ascertain that the prescription was written by a qualified medical man. Our task would be much easier if prescribers were compelled to write their names and addresses in full, and to add their qualifications.

London, July 5, 1899. W. Murton Holmes.

The Conference at Plymouth.

Sir,—In view of the approaching Pharmaceutical Conference in Plymouth, will you permit me to announce through the medium of your valuable Journal that the pharmacists of this club have approached its Committee with the view of granting the privilege

of honorary membership to those attending the Conference during their visit to the neighbourhood? I am pleased to say that this has been cordially granted, and on behalf of the Committee I shall be happy to extend a hearty welcome to all who choose to avail themselves of the advantages the club offers.

Plymouth, July 11, 1899. ALBERT WEBB, *Secretary*, Plymouth and Western Counties Liberal Club.

Medicine Stamp Duty in Scotland.

Sir,—Thanks to Sir John Leng, M.P., we now know how much is contributed to the Revenue from the sale of medicine stamps in Scotland. Out of the total revenue from these stamps of over £260,000, Scotland yields a little over £2,000. With this knowledge chemists in Scotland will, I hope, take steps to get relieved from the antiquated Medicine Stamp Laws which are so rich in intricacies, anomalies, and exceptions. At present we are muzzled, harassed, and spied upon in a way which I am sure no other body of educated men would tolerate. And this we suffer, not that the public health may be protected, but that the Government may obtain a paltry £2,000. We are not permitted to mention on the labels the uses of the common pills, powders, tinctures, lozenges, liniments, and ointments suitable for everyday domestic use, and the consequence is that the public are far more familiar with, and use more freely, the much-advertised medicines sold under cover of the Government medicine stamp. Then we hold a strong position in demanding to be placed on an equality with Ireland, for the Medicine Stamp Acts do not extend to Ireland, and I have not heard that chemists in Ireland suffer from the evils which, we are told by certain timorous chemists, would fall upon us were we placed on an equality with Ireland in this respect. If chemists in Scotland are at all unanimous in wishing to be rid of these laws, I do not believe that the trifling amount they produce would form a serious obstacle in the way.

Dundee, July 11, 1899. WILLIAM CUMMINGS.

The Company Trading Question.

Sir,—In my previous letters discussing the company pharmacy question I endeavoured to show the futility of asking for—(1) A monopoly in the sale of drugs; and (2) The abolition of unqualified companies. The reason for (1) is that it would interfere with the principles of Free Trade, and for (2) *non possumus*. The important questions yet to be solved are: 1. What do we want? 2. What is the most we can get? "Chemists ought to be included with doctors and dentists in the medical proposals of the Companies' Amendments Bill" is the favourite cry of some. "Compromise is not to be thought of," say they. Let us see what this policy of no compromise will do for us. "Companies" would be prohibited from dispensing and selling poisons. Titles would be protected. Such reforms would be worth striving for if they could be obtained. But suppose that these reforms were obtained—would they be absolute? The inevitable coach and four could still be driven through the Act of Parliament. Private arrangements between stores and chemists have existed before and would be instituted again. No Act of Parliament could touch such arrangements. Besides we might wait for twenty years before reform of the nature of prohibition could be obtained, by which time the "companies" would have acquired vested rights, and then the question of compensation would have to be considered! It may not be easy for us to yield to compromise, but we must not be led away by the dream of the optimist. I say that the unqualified companies should not have been allowed to carry on the drug business even by means of registered men. But they have been doing it and mean to continue to do it. The mischief's done! They have built their house and interdict has not been granted. We are now called upon as practical men to face a question which offers peculiar facilities at the present time for settlement. If *chemists* perceived clearly that it is hopeless to endeavour to veto the "companies" the course to be adopted would be made clear, and all would readily fall into line in a demand that their house should be regulated. We have two choices. Mending and ending. Ending is impracticable; impossible. Therefore mending is our only course. Indications are not wanting that this policy is gaining ground. The Western Association of London has discussed such a policy. The Edinburgh Trade Association has adopted it. You have yourself, sir, hinted that "Some practicable compromise between the society's views and those of the Lord Chancellor" might be arrived at. Discussion is needed.

Edinburgh, July 3, 1899. W. S. GLASS.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Supply of Drugs by Medical Man (R. T.—31/18).—Send the particulars to the Secretary of the Medical Defence Union, 4, Trafalgar Square, London, and to the Secretary of the Pharmaceutical Society, as they can deal with the case—on the medical and pharmaceutical sides respectively—if there be any illegality.

Photographic Outfit (J. B.—31/14).—You will find Fallowfield's "Celerity Camera Set," ½-plate, 70s., excellent value. Similar outfits, at the same price, are Butcher's "No. 4"; Perken, Son and Rayment's "Optimus"; Woolley's "No. 3 Victoria"; and Barclay's "Diamond Favourite." See the *Pharmaceutical Journal* Photographic Supplement of April 5 last for particulars of the above and other outfits.

Grasses (T. J.—31/19).—(1) *Festuca elatior*; (2 and 3) *F. pratensis*; (4) *F. duriuscula*; (5) *Bromus asper*; (6) *Brachypodium sylvaticum*.

Alginic Acid (S. H. P.—31/16).—You will find the particulars you require in the *Pharmaceutical Journal*, [3] **13**, 1019 and 1037; **16**, 1005, [4] **7**, 199. Write to the British Chemical Company, Limited, 149, St. Vincent Street, Glasgow, for samples and further particulars.

Ingredient in Prescription (R.F.—31/19).—It is difficult without seeing the prescription to say what can be meant, but probably diluted nitro-hydrochloric acid is intended. To some extent the dose ordered should serve as a guide.

What is a Wholesale Quantity? (R. R.—31/20).—The question of quantity does not affect the matter. It is equally a sale by retail if any quantity of a scheduled poison—great or small—be sold to a consumer, either by a wholesale or a retail dealer. The exemption in Section 16 of the Pharmacy Act, 1868, applies only to the business of "wholesale dealers in supplying poisons in the ordinary course of wholesale dealing," and the ordinary course of wholesale dealing is selling to a middleman or a retailer, not to a consumer. Send the price list to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, London.

Acacia Emulsion of Cod Liver Oil (J. W.—31/17).—Cod liver oil, 6 fl. ozs.; powdered gum acacia, 1½ ozs.; saccharin elixir, 40 mins.; oil of bitter orange, 5 mins.; oil of cinnamon, 4 mins.; cherry laurel water, 3 fl. ozs.; spirit of chloroform, 3 fl. drachms. Put the acacia in a perfectly dry mortar with the cod liver oil, mix it intimately, then add in one lot the cherry laurel water. Mix thoroughly until a perfect emulsion is formed, then add the rest of the water gradually, well mixing after each addition. Finally add the essential oils dissolved in the spirit of chloroform and saccharin elixir.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

HEROÏN. Professor Harnack, writing from the Pharmacological Institute of Halle University, expresses a highly unfavourable opinion of the diacetyl derivative of morphine, which has been introduced into use under the name of heroïn, and recommended as preferable to morphine as a medicinal agent. After recalling the fact that the physiological action of morphine and its derivatives was fully investigated in 1890 by Dott and Stockman, and that the general result arrived at in regard to esteroid acidyl derivatives, was that several of them, and especially diacetyl morphine, acted very powerfully on the respiration of rabbits and frogs, also affecting the heart, and were consequently more poisonous than morphine. But nothwithstanding the knowledge of this fact Dreser suggested the use of diacetyl morphine as a specially appropriate substitute for morphine and codeine in the treatment of coughs, and Harnack considers that in doing so he overlooked two important facts: First, that in no department of pharmacology are the results of experiments with animal life less to be relied upon as applicable to the human subject than in the case of narcotics; secondly, that some organic bases by substitution of acid residues give rise to products which are more toxic than the originals, and that this is especially the case in acetylation. In agreement with Dott and Stockman as to the greater influence of diacetyl morphine on the respiration as compared with morphine and the greater depression of the heart's action, Harnack condemns the use of heroïn even in minute doses, and declares that it is more properly to be placed on a level with arsenic and veratrine as a poison than adopted as a substitute for morphine.—*Münch. Med. Wochensch.*

TINCTURE OF FAT-FREE DIGITALIS. J. W. England shows that the effects of a tincture made from digitalis leaves freed from fat by treatment with purified petroleum spirit for forty-eight hours are, on the whole, superior to those of the ordinary tincture. The fat-free tincture is described as being of a deep reddish-brown, almost black, colour, of most unpleasant odour, and of pure bitter taste. It does not become turbid on admixture with water. The primary effects of the fat-free tincture, when administered to patients, were manifested in 15 minutes, and the maximum was attained in 45 minutes, as against 30 and 60 minutes respectively with the ordinary tincture. In both cases the duration of effect was the same—30 minutes, though the pulse reduction was slightly greater with the fat-free tincture. The most striking difference, however, was the much greater rapidity of absorption and action of the fat-free tincture, showing a more speedy assimilation.—*Am. Journ. Pharm.*, **71**, 332.

DECOLORISED TINCTURE OF IODINE. F. A. Sieker, some time ago, published the following formula for decolorised tincture of iodine:—Sodium iodide, 48·9 Gm.; ammonium iodide, 47·3 Gm.; ammonia water (10 per cent.), 10·0 C.c.; water, 155·0 C.c.; alcohol, a sufficient quantity to make 1,000 C.c. He now suggests that distilled water should invariably be used in making the preparation, whilst the alcohol should be redistilled or treated as follows:—To 1,000 C.c. of alcohol add 0·5 to 1·0 Gm. of potassium permanganate in coarse powder; strain the liquid when it is of a dark purple colour, and, after standing a few hours, filter. Unless the filtrate is clear and colourless refiltration will be necessary. The tincture prepared with alcohol so purified and with distilled water is said to be colourless and to keep well.—*Pharm. Review*, **17**, 306.

WOOD TAR CREOSOTE. L. F. Kebler finds that commercial creosote is almost entirely devoid of guaiacol, the percentage varying from 0 to 16. He is also of opinion that no creosote ever contained so much as 60 per cent. of guaiacol, thus bearing out the results of the work of Béhal and Choay, who found that the fraction obtained by distilling crude wood tar creosote between 200° and 210° C. contained at most only about 25 per cent. of guaiacol. Kebler suggests that the B.P. boiling point range (200° to 220° C.) should be adopted in the U.S.P.—*Am. Journ. Pharm.*, **71**, 356.

SYRUP OF RHUBARB. F. W. Haussmann suggests the following process for making a syrup of rhubarb which he regards as an improvement on the B.P. and U.S.P. preparations:—Mix 4 C.c. of spirit of cinnamon, U.S.P., with 100 C.c. of fluid extract of rhubarb, U.S.P., and add 375 C.c. of water in which 10 Gm. of potassium carbonate has previously been dissolved. Allow the mixture to stand for two hours, with occasional agitation, then filter and pass sufficient water through the filter to bring the volume of liquid to 475 C.c. In this dissolve 750 Gm. of sugar by agitation, without heat, and strain; finally, add sufficient water to make 1,000 C.c. of the finished syrup.—*Am. Journ. Pharm.*, **71**, 267.

ELIXIR OF TERPIN HYDRATE. F. A. Sieker prepares an elixir of terpin hydrate by dissolving 17.5 Gm. of the hydrate in 400 C.c. of alcohol, with the application of gentle heat if necessary, and then adding 400 C.c. of glycerin and enough distilled water to make 1,000 C.c. The terpin hydrate is said to remain in solution indefinitely at the ordinary temperature, and although some of it crystallises out on exposure to a low temperature, it will redissolve on warming gently in a water-bath.—*Pharm. Review*, **17**, 307.

HORN-DESTROYING FUNGUS. According to H. Marshall Ward, there are half-a-dozen species of fungi of the genus *Onygena*, remarkable for their growth on feathers, hair, horns and hoofs of cattle. A cow's horn, thoroughly infested with the mycelium of one species, *O. equina* (Willd.), yielded material for the investigation. The fungus has been cultivated, and its life-history, structure, and development fully investigated. It is an ascomycete, and the ascospores require digesting in gastric juice. Hence, in nature, they have to pass through the stomach of the animal. By using artificial gastric juice, and employing glue and other products of hydrolysis of horn, the details of germination and growth into mycelia were traced step by step under the microscope and fully described. It is evident that as the spores of *Onygena* pass through the body of an animal an extract of the dung affords a suitable food medium to re-start the growth on horn. Probably the cattle lick the *Onygena* spores from their own or each other's hides, hoofs, horns, etc., and this may explain why the fungus is so rarely observed on the living animal.—*Proc. Roy. Soc.*, **65**, 158.

TUBERONE. From the concentrated extract of tuberose "pommade" A. Verley has isolated a fraction boiling at 167° C. at 15 Mm. pressure, which corresponds to the formula $C_{13}H_{20}O$, and to which the name tuberone has been given. It possesses in a marked degree the odour of tuberose, resembling somewhat that of coumarin, but being much softer and more persistent. It is a liquid, the density of which is 0.970 at 8° C. From its behaviour with phenylhydrazine and with acetic anhydride, it is evidently a ketone, and since it yields formaldehyde when oxidised with chromic acid, probably contains a terminal CH_2 group. The molecule probably comprises two closed chains with one double linkage of which a tentative graphic formula is given.—*Bulletin de la Soc. Chim. de Paris*, **21**, 306.

THE CHROMIC ACID TEST FOR COCAINE.

BY DR. GEORGE L. SCHAEFER.

Since the publication of my proposed new test for cocaine several articles have appeared in criticism thereof which call for some reply. A. J. Cownley[1] objects on the ground that the test is too delicate, and that only a "synthetic" cocaine would stand it.

P. W. Squire[2] states that the test "produces a turbidity in solutions of the best commercial samples of cocaine hydrochlorate." Further than this he does not go, but in a note appended to his communication the editor states that the "value of the chromate test is questionable." The most satisfactory reply to these critics is the statement that the finest commercial brands of cocaine hydrochloride satisfactorily answer the chromic acid test.

E. Merck,[3] in criticising the tests, states that the strength of the hydrochloric acid will affect the results obtained. In applying the test he found that a solution of cocaine to which he had added 5 C.c. of 10 per cent. hydrochloric acid yielded negative results, and that upon increasing the amount of acid by using 5 C.c. 12½ per cent. hydrochloric acid, a turbidity was produced; thus, in the first case, showing the cocaine to be pure, and, in the second case, indicating impurities. This is in accord with my own observations, and the difference in the results is due to the fact that the sample of cocaine employed contained only very minute traces of amorphous alkaloids; the chromates of these latter bodies being far less soluble in the solution containing the higher percentage of hydrochloric acid. The turbidity will therefore be produced more rapidly and more distinctly than in the solution containing the weaker acid. An acid of 10 per cent. strength was decided upon, as it is sufficient to indicate such very small traces of amorphous impurities that only the very best brands of cocaine in the market will stand this test, and it, together with the permanganate test, guarantees a purity of product which cannot be obtained when McLagan's test is taken as the standard. If the reaction is carried out with a stronger acid it is necessary to do so side by side with a specimen of chemically pure cocaine, as at a low temperature cocaine chromate causes a turbidity in the more acid solution.

Merck further claims that the results are influenced by the age of the chromic acid solution. My own experience has failed to prove that such is the case. In a recent series of experiments with a number of samples of cocaine, using the same solution of chromic acid for fourteen consecutive days, and always applying the test side by side with a freshly prepared chromic acid solution, at no time was there noticed any difference in the results obtained.

In applying the test it is important that the temperature of the cocaine solution be maintained at 15° C., the chromates of both pure cocaine and the amorphous alkaloids being influenced by rise and fall of temperature, heat increasing and cold diminishing their solubility. The test produces no turbidity when the acid is added to a solution of a pure specimen of cocaine, the temperature being 15° C. If, however, the solution be subjected to a considerably lower temperature it becomes turbid, and if it be preserved at this reduced temperature for several hours, a crystalline deposit will be found, consisting of long needle-shaped crystals of cocaine chromate. A solution of impure cocaine rendered turbid by the reagent at 15° C., and exposed to a lower temperature remains turbid for several hours, then slowly deposits a yellowish-brown amorphous sediment. These reactions are characteristic, and serve to distinguish between cocaine and the amorphous alkaloids, especially isatropyl-cocaine. If a stronger acid is used the alkaloids will separate out quicker.

In order to show the superiority of the chromate test over McLagan's test, I prepared a series of specimens of cocaine of different degrees of purity. These, as well as the various brands of cocaine in the market, I subjected to McLagan's and the chromate test. As a result I found specimens, which gave negative results with McLagan's test, to be impure by the chromate test, and those specimens which reacted with McLagan's test yielded a decided turbidity upon the addition of even less than 5 C.c. of the 10 per cent. hydrochloric acid.

1 "Note on a New Test for Cocaine," *Pharmaceutical Journal*. April 15, 1899.

2 "The New Test for Cocaine," *Chemist and Druggist*, April 22, 1899.

"Cocaine Tests," *Pharmaceutische Zeitung*, No. 42, 1899.

NOTE BY A. J. COWNLEY.

It cannot be said that Dr. Schaefer has advanced any further facts to contradict the views already expressed in the Journal. There is no doubt that for commercial purposes Maclagan's test is to be preferred to the chromic acid test for ascertaining the purity of cocaine hydrochloride, and this opinion is corroborated by Dr. Schaefer's own statement that specimens of cocaine hydrochloride which gave negative results—that is, were condemned by Maclagan's test—were also shown to be impure by the chromate test. Such a result was naturally to be expected. The further statement that "specimens of cocaine hydrochloride, which reacted with Maclagan's test, yielded a decided turbidity upon the addition of even less than 5 C.c. of the 10 per cent. hydrochloric acid," requires further explanation in consequence of the influence of free hydrochloric acid in causing precipitation, as E. Merck has already pointed out (*P.J.*, 62., 523), and at present the results mentioned by Schaefer only go to show, as already stated in the Journal (*P.J.*, 62., 336), that probably the only salt that would pass the chromic acid test would be one prepared from synthetic cocaine.

WOMEN AS PHARMACISTS.

BY ONE OF THEM.

(Concluded from page 47.)

PHARMACY AS A PROFESSION FOR WOMEN.

The consideration of the means of becoming a qualified pharmacist may be prefaced by the remark that no woman should take up pharmacy as a profession without being prepared for real hard work; not only do the examinations involve a good deal of close study, but a dispenser's life can never be a very easy one. Long hours of standing, the strain of a continual pressure of work requiring the utmost attention, and the heavy responsibility that such work involves, have to be faced. On the other hand, the work is most interesting, needing skill and care, and paying for all the pains and attention devoted to it. By far the greater number of qualified women are engaged as dispensers in hospitals, infirmaries, and dispensaries; only a very small proportion take advantage of being legally qualified to "keep open shop," which requires not only business ability, but some years of practical experience in the commercial side of a chemist's business, and command of capital. The course of training open to women does not, as a rule, present opportunities for acquiring a knowledge of business, and to this question of training we will now turn.

THE FIRST STEP.

When a youth chooses to follow the calling of pharmacy, the first step is an apprenticeship to a qualified chemist for three, four, or five years, according to arrangement. When the candidate for admission to the ranks of chemists and druggists of the opposite sex rather different arrangements are usually made, as there are not many chemists up to the present who will take female apprentices.

At the same time, no one is eligible for the qualifying examination until he or she can produce a certified declaration as to having been for three years registered and employed as an apprentice or student, or otherwise practically engaged in the translation and dispensing of prescriptions. This condition is generally fulfilled by going as "pupil" to some one actively engaged in dispensing, and qualified to teach it. There are a few hospitals in London where the dispensers take pupils, who thus not only get teaching in dispensing, but also the necessary practical acquaintance with the work of a hospital dispenser. The term of pupilage in a hospital is usually six months or longer, the pupil attending half-days only, and the fee is from £7 7s. to £10 10s. There are also in London two qualified women, who have well-fitted private dispensaries, and take pupils, teaching them not only dispensing, but all the subjects required for the Minor examination. The teaching is individual, and the term of pupilage is as arranged.

The Preliminary Examination.

Before commencing any course of work at dispensing, either as apprentice or pupil, it is desirable to pass the Pharmaceutical Society's Preliminary examination, or one of the examinations accepted as its equivalent. It is not essential to pass it before the term of pupilage is commenced, but it is advisable to do so, because then the student's time is free to be devoted to more strictly technical subjects. Also, the fact of having passed it renders the pupil eligible to be elected an apprentice or student (now student-associate) of the Pharmaceutical Society, which carries with it certain advantages, and prepares the way for future membership.

Part Time Work.

After about a year's work under a capable teacher it is sometimes possible to obtain a post as assistant dispenser for part time. The amount of time taken up by a "part time" post varies very much. At some hospitals or dispensaries such an assistant is required two or three afternoons per week, while at others attendance may be required every morning, or every afternoon, and sometimes the evening is the time chosen. An unqualified assistant is paid from £20 to £35 per annum, according to hours, and apart from the satisfaction of earning a small salary during the period of study, it is an advantage to be in constant touch with actual hospital work. At the same time, it must not be forgotten that it involves a considerable strain to be simultaneously studying for an examination and holding a dispensing post.

Preparation for the Minor Examination.

It may be taken as an established fact that it is false economy to endeavour to prepare for the Minor examination without attending a course of lectures and laboratory work in a satisfactory school of pharmacy. This course of instruction will occupy the student's whole time for nearly a year before the examination; or, if it is considered desirable to be filling a small post as dispenser or assistant during the whole period of study, the course of work in a "school" may be divided into two parts, so that during the first session of attendance chemistry and botany, for instance, may be the subjects taken; while during the second, materia medica and pharmacy (which includes dispensing, the making of B.P. preparations, and prescription reading) will be the subjects of study. Perhaps to those who have given little attention to the subject it may seem that after "learning dispensing" in a hospital there is no need to study the same subject in a school; but those who have had any experience know very well that such a subject cannot be mastered without careful study, as well as experience in practical work. There are a thousand things that cannot be gone into at all in the rush of hospital work, and that have to be accepted in faith for the time being, until a fuller knowledge is reached. There is not time in the busy life of a hospital dispenser to explain everything that presents a difficulty to the pupil; and, indeed, there are many things the explanation of which is impossible until a certain amount of technical knowledge has been acquired. When the study of chemistry and the other subjects required is taken up, many of these mysteries explain themselves, and it is very delightful to find as one's studies go on that old difficulties vanish, and satisfying reasons present themselves for much that practical work had rendered familiar to the hand and eye, but not to the mind. To be a really efficient dispenser, and capable of standing alone, it is necessary to have a thorough knowledge of the nature and general chemical relations of all the substances likely to be dealt with, and of their behaviour towards each other under various conditions; and it will be easily imagined that all this cannot be mastered without the expenditure of considerable time and pains. All the energy expended on it is, however, thoroughly well spent, for an intelligent understanding and grasp of the subject not only makes the dispenser more efficient and reliable, but makes the work itself far more interesting. And when it is remembered what responsibilities lie in the dispenser's hands, the necessity for a thorough training and complete fitness for the work cannot be too strongly insisted on. In the field of pharmacy, perhaps more than anywhere else, "a little knowledge is a dangerous thing."

The Approximate Cost of Training.

Let us now consider what is the approximate cost of training, and what are the prospects when the qualification has been obtained. Of course, it makes a good deal of difference in the expense whether a girl is able to live at home during her three years of preparation, or whether there are items of board and lodging to be considered. In the following estimate the moderate amount of 18s. per week is reckoned for such expenses, and no allowance is made for holidays and such matters as dress, which can be regulated according to individual requirements:—

	£ s. d.	£ s. d.
Preliminary examination	2 2 0	
Fee at Hospital	10 10 0	
Books	5 0 0	
Apparatus, etc.	2 10 0	
Fees at School of Pharmacy	30 0 0	
Fee for Minor examination	5 5 0	
Three Years' Subscription to Pharmaceutical Society (as Student)	1 11 6	
Living Expenses (for three years, at 18s. per week)	140 0 0	
	196 18 6	
From that amount may in some cases be deducted:—		
Earned during second year	20 0 0	
Earned during third year	30 0 0	
	50 0 0	
		196 18 6
		50 0 0
Making a total of		146 18 6

or, in round numbers, £150 for the three years' training. The figures are necessarily only approximate, and the total is, if anything, too low rather than too high, as it is, of course, not at all certain that the student will have the opportunity of earning £50, even if she is capable of doing so. Then again, unless she resides near to the school of pharmacy chosen, there will be an extra item of cost in the fares to and fro; and if from any reason it is desirable to attend any course of lectures or other work more than once, additional fees will render the total expense greater. This, however, ought not to be necessary if proper attention is paid to the work in the first instance.

The Question of Qualification.

The Pharmaceutical Society's qualification is the only one recognised by the law; at the same time, it is often desirable, if seeking a small post as assistant dispenser before the termination of the required "three years," to have some means of proving that one

has some fitness for such a post. For this purpose the "Assistant's" certificate of the Society of Apothecaries is often useful, and the examination can be passed without difficulty by anyone who has had a year's teaching in a hospital, and who has devoted the spare time during that year to the study of chemistry, materia medica, and prescription reading.

The Minor examination having been passed, and the candidate registered as a "chemist and druggist," there is still another examination to be faced if the rank of "pharmaceutical chemist" is desired. This is the Pharmaceutical Society's Major examination, the subjects required being chemistry and physics, botany, and materia medica. The work of preparation will occupy about six months, and the fees for lectures and laboratory work will amount to about twenty pounds. The fee for the examination is three guineas. This will, of course, make the total cost of training greater, and will extend the time. Probably all, or at any rate most, of the posts open to women can be satisfactorily filled by a person with the Minor qualification alone; and the work done for the Major, though of great value for its own sake, will seldom, if ever, be required in actual practice. Still, in the case of several candidates applying for one post, naturally anyone who had passed the higher examination would stand the best chance of being chosen, provided that her experience of hospital work, etc., was equal to that of the others.

How to Gain Experience.

The question of experience is, of course, an important point; and it is often a good plan, when one is first qualified, to get posts as *locum tenens* in two or three places, if possible, before applying for any permanent appointment. In this way experience in the working of various institutions is acquired, many valuable hints may be picked up, and much that is useful afterwards may be learned by anyone who is on the alert to make the most of such opportunities.

The salaries paid to qualified women as dispensers vary a good deal, because the hours and conditions of the work vary. There are half-day appointments, the salaries varying from £40 to £60 per annum; whole day appointments, salaries from £80 to £120; and resident appointments, salaries from £30 to £60. In some small hospitals the dispenser is required to discharge the duties of secretary in addition to those of her own particular province, and thus the post is more remunerative than if the few hours' dispensing were alone considered in the salary. Doctors sometimes employ women to do their dispensing. These posts are sometimes resident and sometimes daily, and the salaries vary a good deal. The dispenser is generally required to keep the books and to assist in sending out the accounts.

There are a number of small hospitals all over the country where women are employed as dispensers; in provident and charitable dispensaries, too, a number of women are at work. There are also in London several appointments under the Local Government Board that are at present filled by women. These appointments are open to both men and women, and thus differ from some of the hospital posts, where a "lady dispenser" is advertised for. Occasionally, too, the services of qualified women are required in the warehouses of wholesale and manufacturing chemists, and quite recently an advertisement appeared for a "lady assistant" in a retail dispensing business.

It is evident, therefore, that there is a distinct demand for women as dispensers, and it is also apparent that the necessary qualification for such appointments requires not only the expenditure of time and money, but good abilities, and a large amount of patience and perseverance. The salaries paid for such work cannot be considered excessive, seldom, if ever, being above £120 per annum, though sometimes there is an addition to the salary in the shape of pupils' fees. No woman should take up pharmacy as a means of livelihood who has not a genuine love of the work for its own sake, and who is not prepared to do her full share of the world's hard work.

AUSTRALIAN INDIGENOUS VEGETABLE DRUGS.*

BY J. H. MAIDEN,

Government Botanist and Director of the Botanic Gardens, Sydney.

(Corresponding Member of the Pharmaceutical Society of Great Britain.)

MYOPORINÆ.

Eremophila maculata, F.v.M.

The aborigines in the Hungerford district, N.S.W., use the leaves as a blister when suffering from a cold.

All the Colonies except Tasmania.

VERBENACEÆ.

Callicarpa longifolia, Lam.

Bailey suggests the use of the bark as an Australian substitute for the betel leaf. (*Eighth Botany Bulletin.*)

Queensland.

Clerodendron inerme, R.Br.

Used to heal spear-wounds in New Guinea. (Bailey, 1*st Supp.*, p. 43.) See also *Pharmacographia Indica*, v., 76.

New South Wales to Northern Australia.

Verbena officinalis, Linn.

I have received this plant from the north-west of New South Wales as a remedy employed by the blacks in venereal complaints.

All the Colonies except Western Australia.

LABIATÆ.

Mentha gracilis, R.Br. "Native Pennyroyal."

I have been informed that this plant and *M. satureoides* are used in New South Wales as a substitute for the pennyroyal of Europe. Either infusion or decoction is used. It should, however, be borne in mind that these two species are much more acrid than the European species of *Mentha* commonly used for a similar purpose, and, therefore, greater care should be exercised in their use. Both herbs are also strewn about floors and beds for the purpose of keeping away insects, and they are very efficient in driving away fleas and bugs.

All the Colonies except Western Australia and Queensland.

Mentha satureioides, R.Br.

See *M. gracilis*.

All the Colonies.

Moschosma polystachya, Benth.

Used as a medicine by mixing in water, for fevers, etc. (E. Palmer.)

New South Wales to Northern Australia.

Ocimum sanctum, Linn.

This plant is much cultivated in India and Ceylon, and is frequently used in medicine in the latter country. (*Treasury of Botany.*) Stimulant, diaphoretic, and expectorant virtues are assigned to it by the natives. (*Pharm. of India.*)

The leaves are crushed up in water in a kooliman, and drunk for fevers and sickness by Queensland natives. (E. Palmer.)

Queensland and Northern Australia.

Plectranthus congestus, R.Br. Native name on Mitchell, "Kai-kai."

Leaves and branches crushed in water, and drunk for internal complaints. (E. Palmer.)

Queensland.

Prostanthera rotundifolia, R.Br.

An application has been made to the Patents Office, Sydney, to patent the use of an infusion of this plant for medicinal purposes.

All the Colonies except Western Australia and Queensland.

PHYTOLACCEÆ.

Codonocarpus cotinifolius, F.v.M. "Quinine Tree"; "Medicine Tree" of the interior; called also "Horse-radish Tree," owing to the taste of the leaves.

* From the *Agricultural Gazette of New South Wales* (Continued from page 52).

This bark contains a peculiar bitter, and perhaps possesses medicinal properties. The taste is, however, quite distinct from quinine. Its leaves resemble horse-radish or turnips in taste. The bark is smooth, and when quite fresh of a pinkish colour. In describing an allied species (*C. australis*), Hooker (*Bot. Miscell.*, i., 245) says: "While dissecting the flowers and fruit, they were found to diffuse a most powerful smell, resembling that of ether."

All the Colonies except Tasmania and Queensland.

POLYGONACEÆ.

Muehlenbeckia adpressa, Meissn.

The stems have been used as a substitute for sarsaparilla.

All the Colonies except Queensland.

AMARANTACEÆ.

Achyranthes aspera, Linn.

Found also in all the tropical and sub-tropical regions of the old world. The herb is administered in India in cases of dropsy. The seeds are given in hydrophobia, and in cases of snake-bites, as well as in ophthalmia and cutaneous diseases. The flowering-spikes, rubbed with a little sugar, are made into pills, and given internally to people bitten by mad dogs. The leaves, taken fresh and reduced to a pulp, are considered a good remedy when applied externally to the bites of scorpions. The ashes of the plant yield a considerable quantity of potash, which is used in washing clothes. The flowering-spike has the reputation in India (Oude) of being a safeguard against scorpions, which it is believed to paralyse. (Drury.)

South Australia, New South Wales, Queensland, and Northern Australia.

Alternanthera triandra, Lam.

Mr. P. Corbet, Mount Browne, sends this plant with the information that the Chinamen of the district use this plant, to use their own language, "to cure sore hand—sore anything."

All the Colonies.

MONIMIACEÆ.

Atherosperma moschata, Labill. "Victorian Sassafras" (see Doryphora).

The bark contains an agreeable bitter, of much repute as a tonic amongst sawyers. It is called "Native Sassafras," from the odour of its bark, due to an essential oil closely resembling true sassafras in odour. Bosisto likens the smell of the inner bark to new ale, and says that a decoction from this part of the tree is a good substitute for yeast in raising bread. It is diaphoretic and diuretic in asthma and other pulmonary affections, but it is known more especially for its sedative action on the heart, and it has been successfully used in some forms of heart disease.

It is prepared of the strength of 4 oz. of the bark to 20 oz. of rectified spirit, and is given in doses of thirty to sixty drops, usually on a lump of sugar.

The first reference to the medicinal properties of this bark I can trace is a letter by Mueller, dated April 5, 1855, in Hooker's *Journ. of Botany*, vii., 240, in which, "on behalf of Dr. Greeves, M.L.C.," he draws attention to it as a remedy in bronchitis, and suggests that it be examined chemically and medicinally.

Chemical examination was finally undertaken by Zeyer, who published his results in Kopp u. Will, *Jahresb.*, 1861; see also Wolff's *Aschen-Analysen*, i., 128, and Watts' *Dict.*, vi., Suppt., 231. Following are the principal results of this research:—

Zeyer found in it volatile oil, fixed oil, wax, albumin, gum, sugar starch, butyric acid, an aromatic resin, iron-greening tannic acid, and an alkaloid which he designated *atherospermine*. The lead-compound of the tannic acid was obtained by precipitating the clarified aqueous decoctions of the bark with lead acetate, digesting the well-washed precipitate with acetic acid, and exactly saturating the filtrate with ammonia. The greyish-yellow precipitate thus formed gave by analysis, after drying, numbers corresponding to ing to the formula, $C_2H_{32}O_5$.

When the bark, after being boiled with water and treated with dilute sulphuric acid, is exhausted with weak soda ley, the aromatic resin passes into solution, and may be separated by precipitation with hydrochloric acid and purified by treatment with alcohol and water. It is brown-red, has a faint aromatic odour, tastes distinctly like nutmeg and sassafras, melts at 114°, dissolves easily in alcohol and in alkaline hydrates and carbonates, but with difficulty in ether and turpentine oil. The analysis of the resin gave numbers according to the formola, $C_2H_{32}O_5$.

The ash, amounting to 3.64 per cent. of the air-dried bark, and 4·06 per cent. of the bark dried at 100°, has also been analysed by Zeyer.

Atherospermine.—The solution filtered from the impure lead precipitate, already said to have been obtained by N. Zeyer, yields, on addition of ammonia, a precipitate which, after washing and drying, digestion with alcohol, evaporation of the brown solution, mixing of the remaining mass with hydrochloric acid, and precipitation with ammonia, yields crude *atherospermine*; and by agitating this substance with carbon bisulphide, dissolving the mass left after evaporating off the carbon bisulphide in hydrochloric acid, and again precipitating with ammonia, the *atherospermine* is obtained in the pure state.*

Atherospermine forms a white, somewhat greyish, light, highly electric powder, inodorous, and having a pure bitter taste. It turns yellowish when exposed to sunshine, melts at 128°, and at a higher temperature emits an empyreumatic odour, takes fire, and burns away without residue; when slowly heated it gives off an odour of putrid meat, and afterwards of herrings (*propylamine?*). It is nearly insoluble in water, dissolves with difficulty in ether, more easily in alcohol, the solution having a distinct alkaline reaction; is soluble also in chloroform, oil of turpentine, and other volatile oils. When dissolved in dilute acids, it neutralises them with formation of varnish-like salts. In contact with iodic acid and a little water, it liberates iodine with brown colour. The neutral solution of the alkaloid is hydrochloric acid; is precipitated white by alkalies and alkaline carbonates, yellow by picric acid, yellowish-white by tannic acid, dirty-yellow by phosphomolybdic acid, pale yellow by platinic chloride; it likewise precipitates with iodide, ferrocyanide and sulphocyanide of potassium, auric chloride, etc.

There is a letter on the subject in the *Australian Medical Journal* for October, 1861, and a letter by Dr. Greeves will be found in the *Lancet*, i., 134 (1862).

Years after, some notes on the bark were published in Mueller and Rummel's edition of Wittstein's *Organic Constituents of Plants*. See also Sohn, p. 14.

Attention was early given to the essential oil, to whose presence the medicinal properties (if any) of the bark are due.

The oil obtained by aqueous distillation from the bark is thin, unctious, pale yellow when fresh, but becomes yellowish-brown with age. (That obtained from the leaves is a distinct essential oil, is of a greenish colour, and resembles oil of mace. It requires further examination. Bosisto.) It resembles in odour ordinary sassafras oil, with an admixture of oil of caraways. The taste is aromatic, bitter, and prickly to the tongue. Sp. gr. 1·04. Boils at 230° to 245°. (*Report of the London Exhibition of* 1862.)

100 lb. of the bark yielded, in one case, 18 oz. 6 dr. of the oil.

In large quantities it must be regarded as a dangerous poison. Rubbed externally upon the skin it does not, like myrtaceous oils, act as a rubefacient or irritant. It is said to have a lowering effect on the heart; but it has been, however, given in certain circumstances in doses of one or two drops.

* The bark, which had been boiled with water for the preparation of the tannic acid, still retained a portion of the alkaloid, which was extracted therefrom by digestion with dilute sulphuric acid.

OIL of *Atherosperma moschata.*

Specific Gravity at 15·5 deg. C.	Refractive Index.				Rotation.
	Temp.	A	D	H	
1·0425	degrees. 14	1·5172	1·5274	1·5628	degrees. +7

These determinations were made by Dr. Gladstone. The rotary power was determined for a column of liquid ten inches long. (Watts' *Dict.*)

Finally, R. Stockman read a paper "On the action of the volatile oil of *Atherosperma moschatum*, Labill." See *Pharm. Journ.* [3], xxiii., 512 (December 24, 1892). Dr. Stockman's conclusion is:—"It seems, therefore, certain that neither the volatile oil nor any other constituent of the bark of *Atherosperma moschatum* is particularly active or poisonous, and, further, that the volatile oil has a close resemblance in physiological action to other volatile oils. Regarding its use as a diaphoretic, expectorant, and alterative, there is little doubt that it is simply similar to the many other essential oils or plants containing them which are used in medicine for similar purposes."

Dr. Stockman is an eminent man in research of this character, and his decision must be accepted as final, and so the short list of supposed Australian medicinal plants must be still further reduced.

Tasmania, Victoria, and Southern New South Wales.

Piptocalyx moorei, Oliv.

An account of this plant is given in the *Agric. Gazette* for August, 1894, p. 545. The leaves were exported to Europe to be used as a substitute for hops, and perhaps for other purposes. Mr. R. T. Baker and I published a note and an illustration of this plant in *Proc. Linn. Soc., N.S.W.* [2], x., 514 (1896).

New South Wales.

Daphnandra micrantha, Benth. "Light Yellow-wood"; "Satin-wood."

The bark of this tree is bitter, and is in repute as a tonic amongst sawyers. Dr. T. L. Bancroft has quite recently drawn attention to the properties of this bark, which are similar to those of *D. repandula* (q.v.).

New South Wales and Queensland.

Daphnandra repandula, F.v.M.

The bark of this tree has a transient bitter taste, and when first removed from the tree it has a yellow colour on the inner surface, which changes to a metallic black on exposure to the air, but this disappears again as it dries. Infusions of the bark are of a yellow colour, and remain free from microscopic organisms when kept. The extract of the bark is very poisonous, one grain being a fatal dose for a frog, and ten for warm-blooded animals. The alkaloids contained in the bark are colourless when pure and crystalline. The active one is easily separated from the others, being soluble in water. Its poisonous action is chiefly due to its action on the heart. To some extent it is antagonistic to strychnia. The poison powerfully affects fish, molluscs, and infusoria. When applied topically to voluntary or involuntary muscles, it paralyses them rapidly. It also retards the development of septic organisms, and will deodorise putrid meat. It will kill some water plants. (Dr. T. L. Bancroft, *Proc. R.S. N.S.W.*, 1888, p. 69.) The subject is continued, and the physiological action more thoroughly treated, in a paper by the same author in *Proc. R.S. Queensland*, 1887. Later on Dr. Bancroft reports:—"The genus Daphnandra, of the order Monimiaceæ, is very interesting, as possessing several alkaloids of a stable and crystalline nature. In their physiological action they resemble somewhat the Digitalis group.

(To be continued.)

STARCH AND ITS FORMATION.*

BY LEOPOLD D'E. LENFESTEY.

(Concluded from page 50).

THE ABSORPTION OF WATER BY STARCH.

Starch exhibits in a high degree the property of imbibition—*i.e.*, of swelling up by absorption of waterunder suitable conditions—a property common to organisedstructures. As the absorption of water proceeds the markings gradually disappear and the granule loses its contour; eventually the granule bursts, and the contents emerging the swelling progresses more rapidly, so that the space the swollen granule now occupies is very many times the original volume. This goes on till all the water enters into combination with the starch and a homogenous paste is produced. This is notably the case with potato starch, arrowroot, rice, and other starches; but with others again, of which wheat may be taken as a type, I find the swelling of the granules is very gradual and it is very difficult to burst them possibly due to the presence of a small quantity of gluten.

The temperature at which this process takes place, spoken of as the point of tumefaction, varies an appreciable number of degrees with different starches, and this is made use of in conjunction with the microscopic characters to identify starches. As such it is a valuable adjunct to the analyst, but its value in this respect is, in my opinion, exaggerated. To begin with, the point at which the individual granules of the same starch begin to swell embraces a comparatively wide range of temperature, and these overlap with different starches. Secondly, previous treatment of the granules markedly affects their tumefying points; thus, if potato starch, which begins to tumefy at 57° C. (according to my observations) be kept for some time at, say 55° C., no granules will swell at that temperature, but, on the contrary, they appear to become inured against heat, so that they no longer begin to tumefy at 57° C., but at some temperature higher. I have carefully determined the tumefying point of potato starch, which I have prepared myself and commercial samples, and although my results with each are constant, they do not tally with one another. I can only suppose that this must be due to one drying at a higher temperature than the other in the process of manufacture. Further, with some starches it is very difficult to say just when the granules begin to swell, and two observers would probably not agree when this takes place, so that if the tumefying points are to be used for identifying starches, then these points must be determined by every individual who makes use of this method for identifying starches, and I am of opinion that it takes longer to obtain sufficient skill to apply this determination with satisfactory results than it does to familiarise oneself with the minute microscopic characteristics. Again, as the arrowroot obtained from Natal differs from that obtained from Bermuda and St. Vincent in its tumefying point, so also may be the case with other starches, and to see if this is the case with potato starch, I have had sent me potatoes from Australia and elsewhere, and am at the present time preparing starches from these for the determination of their tumefaction points.

To illustrate these remarks I give here the figures determined by W. H. Symons for various common starches:—

Order of Size.	Starch.	A Few Swollen.	Majority Swollen.	All Swollen.
2	Potato	55° C.	60° C.	65° C.
7	Cassava	58° C.	63° C.	68° C.
4	Natal	58° C.	65° C.	70° C.
5	Wheat	60° C.	65° C.	70° C.
1	Tous-les-mois	65° C.	68° C.	72° C.
4	Bermuda	62° C.	69° C.	73° C.
3	Sago	64° C.	68° C.	74° C.
6	Maize	65° C.	70° C.	77° C.
8	Oat	65° C.	70° C.	77° C.
4	St. Vincent	66° C.	73° C.	77° C.
9	Rice	70° C.	75° C.	80° C.

* Paper read before the Birkbeck Science Society

The tumefaction of starches is also brought about by alkalies (though not by ammonia), and Symons has devised a method for identifying starches by this means. The tumefaction is effected by solutions of different percentage strength.

The most delicate and characteristic reagent for starch is a solution of iodine. This colours the granules a deep blue colour, due to the formation of a compound or compounds of the starch with iodine. The test is best applied by adding the iodine to a thin starch paste produced by adding a considerable quantity of hot water to the starch and cooling. The colour disappears on boiling, but reappears as the temperature falls.

Chemical Composition of Starch.

Starch is made up of two closely allied carbohydrates, "granulose," which constitutes the major part of the granules, and is coloured blue by iodine and "starch cellulose," which forms the framework of the granules. It is easy to affect a separation, either by the prolonged action of diluted sulphuric acid, by the action of saliva for a short time at a temperature of (35-55)° C., or by means of diastase. In each case the granulose goes into solution, and the starch cellulose remains behind, still presenting the structure of the granule. If to this iodine is added, it will be found that no longer is a blue colour produced, but a copper red. This starch cellulose is soluble in an ammoniacal solution of copper.

Unbroken starch granules yield to no solvent, but if broken by attrition, heat or alkalis, the granulose is gradually dissolved by water, and when boiled the starch cellulose also is almost entirely dissolved, that which remains being readily soluble in dilute alkalis.

Under certain treatment starch undergoes a most remarkable and peculiar change whereby it is rendered soluble. According to Wroblewski, this modification is best prepared by macerating rice starch with a 1 per cent. solution of potassium hydrate, and then heating it with excess of this alkali for thirty minutes on a water bath. The product is filtered, acidified with acetic acid, and precipitated by alcohol. Thus prepared it is a snow-white amorphous substance, readily soluble in water, it slowly reduces Fehling's solution and gives a pure blue colour with iodine.

Action of Enzymes on Starch.

When enzymes (or unorganised ferments) are allowed to act upon starch, the starch molecule is broken up into others of less complexity, and soluble products are eventually produced. When diastase is added to starch paste, total liquefaction is brought about in a very short time. At this stage iodine gives the characteristic blue reaction, indicating the presence of soluble starch. On the continued action of the ferment, the iodine no longer gives a blue colour, but the reddish-brown, characteristic of erythrodextrin. Eventually achroodextrin is produced, and iodine ceases to give a colour reaction. Simultaneously with the above changes maltose is formed and in increasing quantities as the reaction proceeds, also intermediate products, termed amyloins, which are molecular aggregates of dextrose and the amylin group.

Diastase, being the ferment contained in malted barley, it will be seen how valuable is malt extract for aiding the digestion of starchy foods.

Similar is the action of the ferments present in the body, the ptyalin of the saliva, the pancreatin of the pancreatic fluid, and the animal diastase of intestinal mucus. In the case, however, of these animal ferments, the maltose produced is further hydrolysed into dextrose.

A great deal of work has been done on the hydrolysis of starch by diastase and acids, in the endeavour to elucidate the molecular constitution of starch. From the nature of the products formed, it is evident that the molecule is very highly complex, and Brown and Morris have shown that in the case of soluble starch, the molecular weight cannot be less than 32,400, corresponding to a formula $5(C_{12}H_{20}O_{10})_{20}$.

Hydrolysis of Starch by Acids.

With dilute acids, Johnson gives, for the expression of the hydrolytic action, the following equations:—

$$(C_{12}H_{20}O_{10})_n + 2(H_2O)_m = \begin{matrix}(C_{12}H_{20}O_{10})_{n-m} \\ (C_6H_{12}O_6)_m\end{matrix} + C_6H_{12}O_6)_m$$

$$\begin{matrix}(C_{12}H_{20}O_{10})_{n-m} \\ (C_6H_{12}O_6)_m\end{matrix} + (C_6H_{12}O_6)_m + 2(H_2O)_{n-m} = 2(C_6H_{12}O_6)_n$$

This differs from the hydrolysis effected by diastase, in that glucose is produced and gluco-amylins, the amyloins that would be formed by diastase being converted at the moment of their formation into dextrose and gluco-amylins. Johnson is of opinion (*q. v. Ch. Soc. J.*, 1898) that the molecule of starch is probably formed by the condensation of a large number of molecules of dextrose. In the first place, two molecules of dextrose condense to form maltose, and then a large number of maltose molecules further condense to form starch. As a result of his extensive investigation, he represents figuratively in what he calls a "starch $\sigma\chi\eta\mu\alpha$," the probable nature of the starch molecule.

Johnson thus explains this $\sigma\chi\eta\mu\alpha$. Each amylin group (between the large brackets) is composed of two maltose molecules (separated by the dotted lines) each of the latter being composed of two dextrose molecules. To show the points where the dextrose molecules condense to maltose and the latter to amylin groups the H_2O molecules are enclosed in brackets. As is seen the two dextrose molecules condense in a secondary group HC.$\overline{\text{OH H}}$O.CH, whilst the maltose molecules condense in the primary group $H_2C.O\overline{\text{H HO}}.CH_2$, the former becoming HC.O—CH and the latter $H_2C.O—CH_2$. The two aldehyde groups of the original dextrose molecules condense in the amylin group as is shown above. This explains the non-reducing character of starch. According to this $\sigma\chi\eta\mu\alpha$, the molecular weight of starch can be any multiple of $(C_6H_{10}O_5)_4$.

The Uses of Starch.

The uses of starch are many. It is employed largely for laundry purposes, for the sizing and stiffening of cloth, as an adhesive agent, and for the manufacture of dextrin or British gum, it also enters largely into the composition of toilet powders, and is extensively employed for the sophistication of foods and drugs, but above all its chief use to man lies in its great value as an article of food, its function in this respect being to supply heat and energy. The number of edible starches is legion, they are obtained all over the world from an infinite variety of sources; it is impossible to allude to them here other than to mention that any interested will find in a paper read by P. L. Simmonds before the Society of Arts a full and interesting account of them. This paper is printed in the *Pharmaceutical Journal* for the year 1873.

Source of Starch.	Time required for digestion when boiled in hours.	Grains per pound of C and N.		Thermal effect of 10 grains in the body. 10 grains produces sufficient heat.	
		C	N	To raise x lbs. of water 1° F	Equiv. to lifting x lbs. 1 ft. high.
Oats		2,768	140	x = 10·1	x = 7,800
Wheat { Flour	3½-4	2,656	120	9·87	7,623
Wheat { Bread		1,968	92	5·52	4,263
Rice	1	39%	1%	9·66	7,454
Pea	2½	2,683	252	9·57	7,487
Arrowroot	1¾	2,555	—	10·06	7,766
Potato				2 6	1,977
Carrot				1·36	1,031
Barley	2	2,500	68		
Rye		2,660	86		
Maize	3-3½	2,800	121-6		
Sago	1¾	2,555	1-75		
Tapioca	(identical with arrowroot).				
Macaroni	Contains 73·8% of starch and 11·1 % albuminoids.				
Semolina*	12-15% gluten —very nutritious.				

* Obtained from finest and hardest Wheat—Spain, Odessa, and South Italy.

The value of a starch as a complete article of food lies largely in the combination with it of nitrogenous material as gluten. The cereal starches and leguminous meals, pea meal, etc., for this reason constitute particularly valuable food-stuffs and artificial starchy foods, such as macaroni, which contain albuminous matter obtained from white of egg, are highly nutritious, and are largely used in Italy. In the accompanying table are shown some data of common everyday starchy foods which may be interesting.

EXTRACTS FROM CONSULAR REPORTS.

COD-FISH WERE FATTER last year than in some of the previous years, consequently the produce of cod-liver oil in Norway was larger than was expected in proportion to the quantity of cod-fish caught—viz., 40,000,000, against 61,000,000 in the previous year. The exportation of cod-liver oil amounted to 43,000 barrels, against 49,000 barrels in 1897. The price of steam refined medicinal oil at Bergen was 72 kr. (£4) per barrel at the opening of the season, but at the end of the year the quotation was 57 kr. (£3 3s.).

A CALCIUM-CARBIDE FACTORY, to be established at Flekkefiord, is also reported as under the consideration of a Norwegian company. The factory is to be built and connected to a waterfall of 6,000 horse-power. Vice-Consul Franklin, commenting on the fact of so many new factories being erected in Norway, remarks that the rate at which companies have been formed to open different kinds of new industries is simply astonishing, and goes to prove the general prosperity of the communities all round.

IN ADDITION TO RUBBER, which is the chief article of export from Iquitos (Peru), the district is said to yield sarsaparilla, vanilla, cocoa, copaiba, and various gums. None of these, however, are regular articles of trade owing to the expense and scarcity of labour, although there can be little doubt that they and many other natural products of the country might with improved labour be cultivated successfully. The products of the district are stated to be practically unknown, and will require much time for development.

EXPERIMENTS ARE NOW BEING MADE, according to Vice-Consul Venn in his report on the trade and commerce of Pisco (Peru), in the cultivation of the castor-oil bean, and so far they tend to show that this cultivation will yield much better returns than cotton. The cost of cultivation of the castor-oil bean is said to be very much less than that of cotton. The shrubs commence to yield beans in about ten months from the seeds being planted, and can be constantly cropped the year round for five or six years. This is a great advantage over cotton, for the haste with which cotton has to be harvested once the pods open, and the consequent enormous competition for labour, form one of the most serious drawbacks to its cultivation.

THE MINERAL BATHS OF YURA (Peru), some 28 kiloms. from Arequipa, are now the scene of a new industry in the country, viz., the bottling of the ferruginous and sulphurous waters that abound there for home consumption and export. It is claimed for these waters that they are equal in quality to any of the German article, and quite a demand is said to have sprung up for them. A soap factory has also been established in the district and is reported to be doing moderately well.

OF COCA LEAVES, 617,100lb, value approximately £15,427, were exported from Cuzco last year, the average price during the year being 6 soles 25c. per drum of 25lb in Cuzco. The shipments went principally to Hamburg. There appears to have been a considerable falling off in the quantity of coca leaves exported during the last few years, for in 1897 658,700lb were shipped and in 1896 as much as 937,800lb.

SELECTED PRACTICAL FORMULÆ.

OINTMENT FOR SCABIES.

Leistikow recommends the following ointment for scabies:—Beta-naphthol, 77 grs.; precip. sulphur, 150 grs.; storax, powd. pyrethrum, of each 7 drms.; lard, 3 ozs. This ointment rubbed in once a day for three days in succession, during which the patient should wear flannel next the skin.

FLOOR WAX.

Hard paraffin, 3710 Gm.; powdered boric acid, 450 Gm.; lavender oil, 4 Gm.; neroli oil, 20 drops. The paraffin is melted and the other components are carefully added.—*Pharm. Ztg.*, **44**, 135.

INFLUENZA REMEDIES.

(1) For abatement of the fever; lactophenine, 75 centigrammes Send ten such powders. One powder in a wafer or in hot lemonade three times per diem; or lactophenine 50 centigrammes. D.S. One powder every two to three hours. (2) For influenza neuralgia: Lactophenine, 65 centigrammes; quinine hydrobromide, 20 centigrammes. M.f. pulv. One such powder in a wafer or hot lemonade three times a day. Or lactophenine, 3 Gm.; quinine hydrobromide, 1 Gm.; cacao butter, 10 Gm.; mass and divide into five suppositories. One such suppository to be used three times per diem. In the convalescent stage: Ferratin, 30 centigrammes; quinine hydrochloride, 20 centigrammes. To make a powder. One powder to be taken a quarter of an hour after meals three times per diem.—*Pharm. Ztg.*, **44**, 134.

FOR PERSPIRING HANDS.

Borax, salicylic acid, aa 75; boric acid, 25; glycerin, 25; dilute alcohol, 50. This mixture to be rubbed in three times per diem.—*Pharm. Ztg.*, **44**, 134.

TOOTHACHE REMEDIES.

(1) Ol. cajeputi, ol. caryophyll., aa 1.0; chloroform, 2.0. (2) Camphor, chloral hydrat., aa 8.0; spir. menth. pip., 120.0. (3) Ol. caryophyll., tinct. cannab. ind. chloroform p. æqual. (4) Ol. menth. pip., spirit ætheris, tinc. opii, p. æqual. (5) Menthol, 8; ether, 100; ol. caryophyll., 60; extr. aconiti fluid, 4. (6) Ol. eucalypti, 4; mastich, 8; camphor, 45; morphine (alkaloid), 5.5; chloroform, 75; alcohol q.s. ad 150.—*Pharm. Ztg.*, **44**, 135.

SOAP DENTIFRICE.

Powdered hard soap, 20; glycerin q.s. to dissolve with heat. Rub down sufficient carmine and eosine with a little powdered soap, to produce a rose tint, add salicylic acid, 50 centigrammes; oil of star anise, 1 Gm. When cool, a pasty mass will be obtained, which may be put up in suitable pots.—*Bullet. Com.*, **27**, 179.

COURT PLASTER.

Pieces of fine silk (marceline) are stretched on a frame similar to that used in embroidery, which is adjusted until the surface of the material is drawn quite firm and tight. The wrong side of the silk is then coated, by means of a soft brush, with a mixture of white gelatin, 50 Gms. in warm water, 400 Gms. When dry, three or four more coats are laid on of a mixture of fine isinglass, 1 kilo; in warm water, 3.5 kilos alcohol (90 per cent.), 2 kilos; sugar, 100 Gms.; glycerin, 100 Gms.; salicylic acid, 5 Gms. Each coat of the application must be quite dry before the next is laid on while tepid. The silk is finally coated on the other side with a mixture of tincture of benzoin, 1 part, and alcohol (90 per cent.) 3 parts. When quite dry the silk is cut up into suitable squares, and put up for sale in the customary envelopes.—*Pharm. Ztg.*, **44** 15, 127.

PHARMACEUTICAL SOCIETY.

EXAMINATIONS IN LONDON.

July, 1899.

MAJOR EXAMINATION.

Candidates examined	32
„ failed	15
„ passed	17

Bennett, Charles Thomas

Scott, Thomas; Glasgow
Shapley, James Bernard; Torquay
Sharp, Henry William; Sherborne
Stoneman, John Edey; Dawlish
West, Francis Paynter; Liskeard
Whaley, Francis Thomas B.; Kingston
Wood, Harold; Clapton
Wray, Sydney Edward; Grimsby
Wreathall, Robert D.; Hull

DENTAL NOTES.

A VOLUMINOUS AND INSTRUCTIVE CATALOGUE has been issued by the Dental Manufacturing Company, Lexington Street, W. Besides being profusely illustrated with all the newest dental instruments and appliances, it contains annotations upon the recent alterations in the British Pharmacopœia, local anæsthesia, some new and unofficial remedies used in dental surgery, microscopical reagents and preparations for histological and bacteriological work; also formulæ of some proprietary lotions and mouth washes. The useful information it contains makes a work of reference. The illustrations are excellent throughout, and the index is well arranged. Our readers will do well to procure a copy.

TO PREVENT TEETH CRACKING WHEN SOLDERING.—Before a tooth is backed, the holes in the metal backing should be countersunk on both sides. This allows for any irregularity of mineral around the pins of the tooth, which would prevent the metal backing if not countersunk, fitting quite flush, and consequently much endanger the tooth during the process of riveting. The pins should only be riveted sufficiently to secure the backing and prevent the tooth shifting. If riveted too tightly, the tooth will invariably crack under fire, owing to expansion of the metal. Whenever possible bend the pins in preference to riveting.

IN TAKING PLASTER OF PARIS IMPRESSIONS, let the patient thoroughly rinse out the mouth with a little milk immediately before the tray is inserted.

AFTER ZINC DIES ARE CAST they should be thoroughly annealed before use in an oven until they are too hot to be held in the hand. This makes them very much tougher and stronger than unannealed dies.—*Ash's Circular.*

ZINC OXIDE AND EUGENOL are recommended in *Items* for making a filling quite equal to the best cement. The eugenol should be made to take up as much zinc oxide as possible without becoming crumbly. It is valuable for covering the floor of deep cavities previous to filling, and as a covering for dressings, or where a non-irritating thermol protector and antiseptic filling is required.

LIQUID DENTIFRICE.—A preparation which has a considerable reputation in France as a liquid dentifrice is stated to be composed of alcohol (96 per cent.), 1,000; Mitcham peppermint oil. 30; aniseed oil, 5; oil of *Acorus calamus*, 0·5. Finely powdered cochineal and cream of tartar, of each 5, are used to tint the solution. The mixed ingredients are set aside for 14 days before filtering.—*Brit. Jour. Dent. Science.*

THE STUDENTS' COLUMNS.

ZOOLOGICAL NOTES FOR PHARMACISTS.—XVII.

Distribution.

The distribution of animals is studied from two points of view—horizontally—in which case the surface of the earth is divided into certain regions, each having a more or less characteristic fauna—or vertically—where they are grouped according to the vertical position of their habitat from sea bottom to mountain top. In the first case the position and limit of these zoo-geographical regions can only be satisfactorily determined by a study of such forms as are prevented from dispersal by various disabilities, such as inhabitants of fresh water incapable of existence in any other medium, and terrestrial forms which can neither fly nor swim, nor are small enough to be carried away by winds, and so have no natural means of migration from their original place. In such a determination the comparatively shallow seas and straits which have been formed within geological time, such as between England and Europe, Spain and N. Africa, and Papua and Australia, are of no account compared with lofty mountain ranges as the Himalaya, and vast uninhabitable deserts as Sahara, which have been impassable barriers during the history of the animal kingdom.

In the vertical arrangement we have marine, freshwater, aerial, terrestrial, and alpine fauna. The marine fauna are divided into littoral or shore animals, pelagic forms, or such as appear in the open sea at or near the surface, and deep sea animals, occurring at vast depths. The mass of floating organisms is again spoken of collectively as the "plankton," whilst such as freely move of their own accord constitute the "nekton," and those that remain fixed or creeping on the bottom of the sea form the "benthos." The following is a rough indication of the range and habitat of the more interesting groups that have been mentioned:—

Protozoa.—Very widely distributed, chiefly in fresh water. Mycetozoa are terrestrial, and Foraminifera and Radiolaria are exclusively marine.

Porifera.—All marine, with the exception of one family which occurs in fresh water, appear in all seas and at all depths, the deep-sea forms being of the non-calcareous siliceous type.

Hirudinea.—Mostly freshwater inhabitants. A few are marine, and several species of land leeches infest tropical forests in all parts of the world.

Cephalopoda.—All marine, some littoral, many pelagic, and most abundant in warm seas.

Pisces.—The subdivisions and orders of this large class are so widely distributed over the world both in sea and fresh water that it is almost impossible to define the limit of any group higher than a family or genus. The Ganoid fishes, which include the sturgeons, inhabit fresh water except in one or two cases, and are confined to rivers of the Northern Hemisphere. The various species of Gadus, with the exception of one deep-sea form, frequent the shore in temperate regions, as do most other fishes used as human food. Gadus is common round the north temperate shores of Newfoundland, Norway and the British Islands.

Aves may be terrestrial or aerial in their habit. The large majority are aerial, and include all such as are able to spend any length of time on the wing. Terrestrial birds are either entirely or almost flightless such as the ostrich and its allies and the Gallinæ, which order includes poultry and game. Many Gallinæ, as the domestic fowl, are natives of E. Asia and the E. Indian Archipelago.

Mammalia.—Cetaceans are marine with few exceptions, the Balœnidæ are usually sought for in cold regions, but Physeter is found in temperate and warm seas. Australia and Polynesia appear to have no native ungulates. The ox belongs to the old world with the exception of one North American species, the bison. The sheep, more or less Alpine in its native habit, belongs originally to W. Asia, America has one species and Africa one. Deer are pretty widely distributed and are frequently Alpine in habit. Moschus is a native of the Himalaya and mountains of S.E. Asia. The true swine are confined to the old world, whilst rodents are most widely distributed, Castor being a native of Europe and North America.

EXPLANATORY NOTES ON THE B.P. 1898.

Pilulæ.—The official formulæ for pill masses have been subjected to considerable alteration so far as their excipients are concerned. In numerous instances the new syrupus glucosi has replaced the confection of roses, syrup, glycerin, and treacle in the various 1885 B.P. formulæ. Owing to the *slightly* hygroscopic nature of glucose, pill masses made with syrup of glucose are not so apt to get hard and unworkable as those made with simple syrup or confection of roses; on the other hand they are not so sticky as those made with glycerin and treacle. Moreover pills cut from masses containing much glycerin usually remain too soft, and have a tendency to "sweat" and stick together. Probably, therefore, the substitution of glucose for the other excipients will prove to be advantageous in most cases. It should always be remembered that the official formulæ are constructed for the most part to yield masses from which portions may be cut and rolled as required. Apart from the changes in excipient, the following are the chief alterations in composition to be noted:—

PILULA ALOES ET MYRRHÆ.—The saffron is omitted on economic grounds, since it is not now credited with possessing any useful pharmacological action.

PILULA FERRI.—Exsiccated ferrous sulphate and sodium carbonate are employed in place of crystallised ferrous sulphate and potassium carbonate (which contains about 16 per cent. of water). The exclusion of the water of crystallisation contained in the two latter salts enables one to effect the reaction between the iron salt and the alkaline carbonate in the presence of a relatively considerable quantity of syrup and glycerin, which protect the ferrous carbonate, owing to the well-known property possessed by syrup and glycerin of retarding the oxidation of ferrous to ferric compounds. If the hydrous salts were employed under these conditions, the mass produced would be so soft and aqueous that an undue proportion of gum acacia and tragacanth would be required to produce a plastic pill mass. In making pilula ferri according to the new formula, care should be taken to see that the salts employed are really free from water, since a very small quantity of water so introduced will produce a paste instead of a pill mass.

PILULA PHOSPHORI.—The phosphorus in place of being incorporated in a melted condition with balsam of tolu and yellow wax is to be added in the form of a carbon bisulphide solution to a mixture of lard and white wax. The alteration in strength should be carefully noted, the present formula being approximately twice as strong as that of the B.P., 1885.

The omissions comprise three pill masses: pilula conii composita, which has practically fallen into disuse; pilula ferri carbonatis, which is replaced by pilula ferri, and pilula ferri iodidi. The last mentioned is acknowledged to be an unsatisfactory form in which to administer ferrous iodide.

The only addition to the official formulæ is pilula quininæ sulphatis. The formula adopted may be regarded as deciding the question which has often been debated—whether the addition of tartaric acid in making quinine pills was admissible or not. Tartaric acid undoubtedly enables a much smaller pill to be produced from a given weight of quinine than can be obtained by the use of ordinary plastic excipients alone, such as syrup, glycerin of tragacanth, etc.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.
Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, JULY 22, 1899.

WHAT DIRECTION IS PHARMACEUTICAL LEGISLATION TO BE ATTEMPTED?

SINCE the publication of the suggestions submitted to the LORD CHANCELLOR as expressing the views of the Pharmaceutical Society's Council in regard to amendment of the Pharmacy Act, 1868, there has been abundant evidence of the interest taken in this subject by chemists throughout the country. At most of the more important provincial centres the details of the suggestions have been discussed at meetings of the respective local associations, and resolutions have been passed which invariably express sympathy with the general principle embodied in the suggestions put forward by the Council as the mouthpiece of registered chemists throughout the country as well as members of the Pharmaceutical Society. As stated by the late President, Mr. WALTER HILLS, when moving the adoption of the report of the Law and Parliamentary Committee last February, the suggestions then made really involve a reversion to the principle, underlying the Pharmacy Act, 1868, that the keeper of a chemist's shop should be legally qualified as that Act provides, and they propose a remedy for the departure from that principle which has resulted from a defect in the Act; they also propose legislative extension of that principle to the compounding and dispensing of medicines, by which the object of pharmacy law would be more completely attained, in the public interest, and the business of the chemist would acquire a more professional character, in conformity with the practice of other countries. In that respect the Council's suggestions have received unanimous approval, as shown by the resolutions passed in regard to them, first by the Dewsbury Association and subsequently by other Associations, as well as by the remarks of the honorary secretary of the North East Lancashire Chemists' Association, who has on various occasions given particularly emphatic expression to the view that the qualification demanded by the State in connection with a chemist's business confers on qualified persons exclusive right to use the title of chemist in that connection. But in other respects approval of the suggestions has been in several instances more or less qualified by considerations relating to various subordinate details, such as interference with the exemption now provided for the continuance of a deceased chemist's business by executors and for the benefit of the widow; the practicability of the proposed restriction of the sale of medicines, and questions as to the practical teaching of dispensing to apprentices. Objections raised on these grounds have been to some extent the result of "misconception"; but in relation to what is known as the widows' clause of the Pharmacy Act they appear to have been of such a nature as to raise the question whether the chemist's business is to be regarded only as a branch of trade or as having a distinctive professional character.

Having regard to the various published expressions of opinion relating to amendment of the Pharmacy Act, the question just referred to appears to be the point on which there is a distinct diversity in the views held by chemists as to what is desirable in their own interest. While the advocates of endeavouring to acquire professional status, in accordance with the ideal of the Pharmaceutical Society, recognise that any kind of exemption from the necessity for qualification of the proprietor of a business would be inconsistent with the claim for exclusive privilege of qualified persons, others—regarding the matter from a trade point of view—are unwilling to sacrifice the advantages sometimes attaching to the opportunity afforded, under the existing law, for carrying on a business after the death of the qualified proprietor. Whether these two different views can be reconciled in any practical manner by chemists among themselves remains to be seen; but, in the absence of any definite proposal having that object, attention may be drawn to the circumstance that when the subject of pharmaceutical legislation has been hitherto considered from the public point of view, apart from the interests of chemists themselves, the tendency has always been to regard their business as a trade and to favour the view that qualification of the proprietor of a chemist's business is by no means essential, but that, in the public interest, every requirement would be satisfied by the personal qualification of the individuals engaged in carrying out the operations connected with a chemist's business. That was certainly the view taken by the House of Lords, in preference to the one contended for by the Pharmaceutical Society which has always sought to make personal qualification of the proprietor or proprietors of a pharmaceutical business the prime necessity for the proper conduct of that business, as well as for the control, superintendence, and teaching of assistants and apprentices. It is probably the more popular view of the matter which has induced the LORD CHANCELLOR to propose an amendment of the Pharmacy Act that would, as he thinks, sufficiently remove the present anomaly, resulting from judicial construction of the Act, which has enabled companies to assume the title and carry on the business of a chemist without even necessarily employing qualified assistants.

In addition to the difficulty already referred to, as surrounding amendment of pharmacy law, and arising from old standing internal differences of opinion, there is another serious difficulty which has been created from without through the exercise of the chemist's business by unqualified persons incorporated under the Companies Acts, and, therefore, outside the scope of the Pharmacy Act,

1868, according to judicial construction of it. On that point also there is important difference of opinion among chemists. On the one hand, some have argued that since the House of Lords' construction of the Pharmacy Act, 1868, has proved so subversive of the obvious public purpose of the Act, and so prejudicial to the just claims of qualified persons, there is—from a common-sense point of view—ample opportunity afforded for seeking amended legislation to remedy the defects of the Act. But with many others, disinclination to accept the other consequences of such an amendment has prevailed to such an extent as to prove an insuperable obstacle. Meanwhile, companies constituted of unqualified persons have obtained a footing, and on that account are disposed to claim that they have thus acquired a vested interest which entitles them even to act in direct opposition to the spirit of the provisions of the Pharmacy Act. That such a position should be taken by the companies referred to is more intelligible than the objection made, on that account, by chemists to the Council's suggestions. But the fact must be recognised that this particular objection to the Council's suggestions has recently met with increased support from chemists, and has even found some expression in the Council without calling forth, in either case, any countervailing manifestation of preference for taking a line of action that would dispute the claim made by companies of unqualified persons. Under all these conflicting conditions the prospect of obtaining practically unanimous support from all registered persons seems to be at least as remote as that of securing the equally indispensable support from the Government, and in the absence of these two factors, so essential to success, the outlook of pharmaceutical legislation is at present far from being encouraging.

"PLYMOUTH RE-VISITED."

JUST as we go to press, an advance copy has been received of a handbook bearing the above title, which has been specially prepared by the Plymouth Local Committee for presentation to the members of the British Pharmaceutical Conference who attend the meeting next week. The contents of the book include a detailed programme of the coming week's proceedings, a well-written and most interesting article on Plymouth and its history, by Mr. HANSFORD WORTH; a brief sketch of the geology of Plymouth, by the same capable writer; a practical guide to the flora of Plymouth, by Messrs. E. M. HOLMES and O. A. READE; photographic notes by Mr. J. DAVY TURNEY, the untiring Local Secretary of the Conference; cycling notes by Mr. W. H. WOODS; and some useful information compiled for the use of visitors by Mr. A. D. BREEZE. The illustrations include portraits of Mr. J. C. C. PAYNE, J.P., President of the Conference, and of the members of the Local Executive Committee, in addition to a number of superbly printed photographs by Messrs. HEATH AND CO. It would be impossible to speak too highly of the manner in which the work of printing has been performed by Mr. J. H. KEYS, of Plymouth, who is evidently a perfect master of his art. In conclusion, we must congratulate the Plymouth Local Committee on the brilliant realisation of an excellent idea, and also the members of the Conference who are to be the fortunate recipients of such a beautiful souvenir of Plymouth and its surroundings.

ANNOTATIONS.

THE QUALIFICATIONS WHICH ENTITLE an individual to practise as a doctor or a dentist should, in the opinion of *Truth*, be defined by law, and practice without those qualifications should be made a punishable offence. Everything short of that is held to be "mere tinkering." That view as to desirable regulation of medical practice is heartily echoed by the *British Medical Journal* as a "sentiment" affording reasonable hope that public opinion may be brought to perceive that such an amendment of the medical acts is necessary for the public weal, and the expression of opinion by *Truth* is valued because the general tendency of that paper is not in the direction of advocating any form of restrictive legislation unless there be strong and good cause shown for it. The further opinion expressed by *Truth* in regard to the Lord Chancellor's proposed legislation affecting the practice of pharmacy may for the same reason be regarded as affording pharmacists some ground for hoping that their qualifications will also meet with recognition from the public and the Legislature similar to that thought desirable in the case of medical practitioners.

THE MEDICAL AID ASSOCIATION DIFFICULTY is referred to in this week's issue of *Truth*, where it is stated that the only possible objection to the arrangement by which subscribers to "a sort of club" are entitled to medical attendance in return for their subscriptions, rests on trade union grounds. It is presumed that the view of those doctors who object to the practice is that it enables the members to obtain medical advice at lower rates than they would have to pay as individual patients consulting a doctor on their own account. The doctor, therefore, who thus contracts for his professional services is to be treated as a "blackleg" and struck off the Register. As a matter of principle, it appears to *Truth* that if the professional union—the General Medical Council—thus attempted to restrict the liberty of the doctors to make general contracts for medical attendance, it would very considerably strain its statutory powers; and it is questioned whether Parliament, had it ever seen the matter in this light, would have given to a professional organisation powers capable of being used for such a purpose. But, however that may be, the proposed interference with the Medical Aid Associations is thought likely to prove in practice extremely unjustifiable and ill-advised. "The members of those Associations are poor people, who in the ordinary way could not afford to employ such a doctor. The result, of a professional boycott of such associations would simply mean, therefore, that the members would go to the nearest hospital, where they would obtain advice gratis." Again, it is asked, how does a contract on the part of a doctor made with a body of patients collectively differ in principle from the contracts which are frequently made by doctors with patients individually? Suppose, for instance, that a private individual compounds with his medical attendant, as many people do, on the terms that he is to have the doctor's services for himself and household, whenever required, for a payment of fifty pounds a year. It may happen that there are one or two bad illnesses in the house, or a serious epidemic which affects the whole family, with the result that at he end of the year the payment to the doctor per visit works out at about one-half what he would have charged had he been paid by the job, instead of by contract. How, asks *Truth*, does this differ from the case of the club? In conclusion, it is pertinently remarked that if the medical profession are wise they will be very careful how they stir up the many ticklish questions connected with professional attendance by contract.

THE PLYMOUTH CONFERENCE ARRANGEMENTS are now complete and no more tickets can be issued for the meeting next week. Of course, any member of the B.P.C. is entitled to attend the

Sessions of Conference, but unless he has previously procured tickets from the Hon. Local Secretary, he will be unable to take part in any of the festivities arranged for by the local Committee. With respect to the garden party at Down Park, Yelverton, invitations to which are being sent by the Mayor and Mayoress of Plymouth to everyone who has applied for books of tickets, it is suggested that brakes should be engaged to convey the visitors from Plymouth. The distance is about ten miles, and Yelverton can be reached by train if preferred, but if brakes were engaged, the party would drive round Roborough Down—the southern edge of Dartmoor—and after attending the garden party the drive would be continued to Burrator, where the wonderful new reservoir is to be seen, over the dam to Sheepstor, and then over the moor to Plympton, arriving at Plymouth again about 8.30 p.m. The fare for this drive would be about 4s. per head, and those who would like to drive rather than go to Yelverton by train must communicate at once with Mr. C. J. Park, 23, Mutley Plain, Plymouth. The general travelling arrangements were referred to at length last week, but it may not be amiss to state that any member of the Conference can secure tickets for Plymouth for himself and friends at a single fare and a quarter each for the double journey, from any station on the Great Western, Midland, and London and South-Western systems. A certificate signed by Mr. W. A. H. Naylor must be forthcoming for each person for whom a ticket is required, and will be supplied by him on receipt of a stamped addressed envelope at 38, Southwark Street, London, S.E. The special tickets will be issued from July 22 to July 28, and will be available for return up to and including Saturday, July 29. The London and South-Western Railway Company also intimates that, during the sitting of the Conference, return tickets at the single-journey fare (minimum 1s. 6d.) will be issued to members upon production of their cards of membership, or letters of invitation to the meeting, from Plymouth station to any station within a radius of fifty miles. The tickets will be available for the return jouney on the day of issue or the following day.

The Apotheker Verein of Germany holds its annual meeting this year at Danzig, commencing on August 21 and lasting until the 26th. This meeting corresponds to the annual meeting of the Pharmaceutical Society, and the sittings are chiefly occupied with the discussion of political matters affecting the interests of German pharmacists as well as the administrative affairs of the Association, for which purpose the numerous local branches of the Verein are represented at the annual meeting by delegates, who alone are entitled to give a vote in the decision of any question brought before the meeting for consideration.

The Federation of Local Pharmaceutical Associations is announced to hold its annual meeting at Plymouth, on Wednesday, July 26, when the usual reports will be received, officers elected, and resolutions proposed by delegates from affiliated associations. Mr. J. Smith, of Liverpool, will propose that nominations of Local Secretaries of the Pharmaceutical Society should proceed from local associations and their committees, and that the Society's Local Secretaries should be appointed by the associations to represent them on the Federation, also that a closer co-operation between local associations and the Society's local secretaries should be aimed at. Mr. C. J. Park, of Plymouth, will propose that each association shall have the right to appoint one delegate for each twenty-five members. The Burnley and District Chemists' Association desires the appointment of an organising secretary, but that modest requirement is quite overshadowed by the suggestions of the North-East Lancashire Chemists' Association. In the first place, that body is of opinion that it is the urgent business of the Federation to bring about early and full discussion of the policy of the Council of the Pharmaceutical Society, "with a view to eliminating fallacious ideas (*sic*), and uniting the country upon definite lines." There is to be the "earliest possible" settlement of the question of chemists' titles, and a "large" extension of Part II. of the Poison Schedule. But, over and above all this, the Lancashire contingent is to propose a brand new constitution for the Federation. All the affiliated associations are to be arranged in sectional groups — North Eastern, North Western, Midland, Southern, and Scottish — and the representatives of all the associations in a group are to meet at a convenient centre whenever occasion requires. This reads somewhat like a parody of Mr. G. T. W. Newsholme's suggestions for the improvement of local organisation. Again, the representatives of each section are to constitute the Executive Committee of the Federation, which may be called together at any time during the year if requests to that effect be received by the Secretary from the representatives of three sections. The Secretary is also to make further attempts to secure the adhesion of all associations not yet affiliated with the Federation, and to do various other things which honorary secretaries have so far, and not unreasonably under the circumstances, found it difficult to spare time to do. In fact, what looks remarkably like a revolution of the Federation is threatened, and after that has been effected other marvels in the world of pharmacy may doubtless be anticipated.

The Sale of Proprietary Articles was the subject of a paper read by Alderman Ireland, J.P., of Dublin, at the meeting of the Federation of Grocers' Associations last week, in which he urged that the time has come when owing to the extent that proprietary articles are being forced on the retail trader by every conceivable method—it should be considered how best their introduction can be stopped and a system devised whereby each trader shall purchase every article from the manufacturer and sell it as his own, on its own merits, with his own name attached and not that of another. In view of the extension of the pernicious system of cutting prices adopted by so many dealers in proprietary articles, and the difficulty of maintaining a standard price, the discouragement of the sale of proprietary articles of all kinds—by every fair and legitimate means—was strongly advocated. Otherwise it becomes a question whether the necessity of learning a business will continue to exist, as it would appear to be only necessary to employ assistants who are capable of handing over packages received from the manufacturers, the result being that the trader is simply living and working for the manufacturer. It was recommended that every trader, if he be a judge of his business, and one who has commenced at the bottom rung of the ladder, should buy an article on its merits, and put his own name on it. Though a little time may elapse before his customers will appreciate the article, yet if it be the right article and that which he states it is, they will soon find him and it out, and he will very soon make a name and reputation for himself rather than for another. It was contended that the retailer who best caters for his customers and the public is one who knows his business best. But to vend proprietary articles no knowledge is required, and those people who have the least knowledge of the business they are engaged in are the persons who do the most cutting.

Anæsthesia Extraordinary ought to have been the heading of a paragraph which recently appeared in the *Daily Telegraph*, a medical student at St. Thomas's Hospital having sent the following contribution to the history of anæsthetics: A pet tortoise, owned by a lady in South London, was badly worried by the house-dog, so the owner decided to have the maimed reptile put out of existence. A friend, a medical student, undertook to achieve the business of killing with a minimum of pain, so he placed the thing in a box along with a duster saturated with chloroform. "The next

morning it was found that the dog, which had apparently jumped on the box with the idea of again mauling his victim, had been overcome by the fumes of the substance escaping out of a hole in the receptacle, and was lying dead, while the tortoise, which had been doomed to destruction, was alive and comparatively brisk in its movements, and looked as though it had considerably benefited by the chloroform." Now, it so happens that it is extremely difficult to kill dogs by means of chloroform, and the account of the manner of this particular dog's death is distinctly lacking in the sense of reality. Indeed, on the whole, it is not unreasonable to assume that the medical student, after the manner of his kind, was simply attempting to gauge the credulity of the *Daily Telegraph*.

THE HANDLING AND SALE OF POISONS require great care and discrimination on the part of the pharmacist, as the *Pharmaceutical Era* points out in a recent issue, and so far as the British pharmacist is concerned that care and discrimination are displayed almost invariably. He usually takes precautions far in excess of what the law calls for, and, as a result, accidents caused by poisons which have been sold by a registered chemist are of the extremist rarity. The common sense and knowledge of human nature possessed and used by him are considerable; he knows the legal requirements governing the sale of poisons, how poisonous substances should be labelled, and, more often than not, the probable disposition of the poison by the customer. Not only does he carry out the provisions enumerated by the law; in addition he imposes upon himself others, dictated by common sense and business foresight—labelling every poisonous substance he sells, calling the attention of the customer to the dangerous nature of the substance bought, ascertaining definitely whether it is the substance wanted, and advising the customer not to keep it along with harmless household medicines. But, assuming that all or most of the above-mentioned precautions are taken by registered chemists in Great Britain, their attention may nevertheless be directed profitably to the *Era's* suggestion that it is within the power of the pharmacist to instruct the public, through his customers, of the necessity of reading carefully the directions placed upon every package or bottle of medicine before any of it is administered or used in any way. "Not only should the directions placed upon the usual domestic remedies be understood, but those placed upon proprietary medicines as well. Great good may come from instruction of this character, and it is the duty of every manufacturer of any remedy to place upon it in language that cannot be misunderstood, full directions and instructions for administration and use. These remarks are emphasised by the many fatal accidents which have resulted within the past year from too careless administration of proprietary headache powders and other remedies. Let the pharmacist disseminate information of this character, whenever and wherever possible. Such a course costs him nothing, and it may be the means of saving a human life."

A DIPLOMA AS A PRE-REQUISITE TO EXAMINATION is regarded as a necessity of the times by many American pharmacists, but a discussion upon the subject at the latest annual meeting of the New York State Pharmaceutical Association ended in a majority voting adversely to the proposal. It should be explained that the possession of a diploma in pharmacy does not, of necessity, imply the right to practise pharmacy in the United States. A student may go through a three years' curriculum at one of the leading colleges, and gain a so-called degree in pharmacy, but he must yet present himself for examination before the State Board of Pharmacy before he can obtain a licence to practise. And, it may be remarked parenthetically, considering that candidates are at liberty to present themselves for examination before State Boards without being required to show proof of having undergone any course of training or study, the conduct of those who take a two or three years' course at a college is worthy of all praise. According to the *Pharmaceutical Era* the sentiment in favour of insisting upon the production of a college diploma prior to examination for the licence to practise pharmacy is fast growing, and though the objectors urge that the colleges do not give the right sort and amount of education, when it is demanded of them they will be forced to provide it or go out of business. The diploma, it is pointed out, is not to be considered evidence of all that is desired, it is merely to be a pre-requisite to examination by the Board of Pharmacy. It does not take from the Board any of its powers, but gives the Board the additional power of insisting upon an additional acquirement, to guard more stringently against the registration of imperfectly qualified men. Such a regulation would soon eliminate the inferior colleges, as their graduates could not pass the examination by the Board, and there would quickly be established among the reputable colleges that uniformity of standard, the lack of which has long been their weak point. The diploma requirement would not cause hardship to anyone. "No rights will be taken away from any now in business, while to those yet to enter the profession it guarantees protection against incompetents and nincompoops, and, what is better still, it insists that they, themselves, shall secure a sound, systematic and thorough education. Some think this a hardship, it is really a blessing. Two or three years at a college costs no more in money or labour than several years in a store performing the multitudinous duties of 'the boy' and the unregistered clerk." By requiring a young man to be properly equipped for the profession he would not be abused or injured in the least, but rather receive a favour and benefit for which he would ever after be deeply grateful.

THE PROPOSAL OF THE CHEMIST to do all in his power to prevent the syndicate druggist from trading as a pharmaceutical chemist, even though he employs properly qualified assistants, will, according to Mr. A. J. Giles, Secretary of the Federation of Grocers' Associations, who writes to the *Grocer*, have no chance of becoming law for the present unless the chemists can induce Lord Dudley to alter his Companies Bill. But, he thinks, although there seems no likelihood of a new Statute dealing with the question, the syndicate druggists have put themselves into a strong position of defence, with a "war chest" that will enable them to resist the attack vigorously. It will be well also, he says, for the ordinary retail distributor to watch carefully the action of the Pharmaceutical Society, "whose every move is directed towards an extension of that monopoly which is injurious to the public interests as well as to the trader." It is, of course, needless to say that the injurious "monopoly" is not defined by Mr. Giles, who, like most other writers who take his prejudiced view of the matter, is fond of writing vaguely when he has no case. He contents himself with asserting that the basis of the claim for this "extension of monopoly" (*sic*) is the safety of the public, and that the weakness of the claim is to be seen in the frequent reports of cases in which poison has been carelessly sold in chemists shops with sad results. Again, it is hardly necessary to state that Mr. Giles does not quote a single instance in support of his utterly erroneous statement. He merely strings words together recklessly, and incoherently asserts that "the chemists want to keep the selling of all pharmaceutical preparations in their own hands, they most unhesitatingly go into the grocery trade, and invade the doctor's realm by prescribing as well as dispensing, and the result in both cases can hardly be said to be perfectly satisfactory to the public." Having travelled so far over his uncertain ground, Mr. Giles clumsily retreats, but as he does so he throws a quasi-Parthian shot by stating that there is every reason for the retail grocer to support the syndicate druggist in the action which he is taking to resist the granting of "further powers of monopoly" to the chemist.

PLYMOUTH REVISITED.

After the lapse of twenty-two years, it is not unreasonable to assume that only a comparatively small number of those who are actively engaged in the practice of pharmacy retain very vivid impressions of the place where the members of the British Pharmaceutical Conference assembled in 1877, when the late Professor Redwood presided and a most successful meeting was held. For the benefit of the newer generation of pharmacists, therefore, the following brief notes are published on the eve of the 1899 meeting at Plymouth.

The town is situated in the extreme south-west of Devonshire, and as far as surrounding natural beauties are concerned, it cannot be equalled in England. The beautiful river Tamar separates it from Cornwall on the west; it is bounded by the Plym on the east; Plymouth Sound forms a superb frontage to the south, and on the northern side the tors of Southern Dartmoor constitute an appropriate and picturesque background.

As a centre for holiday makers, Plymouth is unsurpassed, excursions innumerable offering themselves alike to pedestrians, cyclists, and those who prefer to travel by coach, steamer or railway. The rivers Tamar, Tavy, Plym, Lynher and Yealm are available for oarsmen; steamer excursions to Looe and Fowey, Torquay, Dartmouth, etc., enable visitors to gain a fair impression of the Devon and Cornwall coasts; Dartmoor offers much more variety in the form of walks and climbs than can be found in most other districts; and anglers, antiquarians, botanists and geologists can find unstinted employment and recreation on every hand.

Plymouth may be conveniently reached by sea, road, or rail, and intending visitors who have not yet decided whether to travel by steamer, cycle, or railway would do well to consult the pages of Ward, Lock and Co.'s illustrated guide to Plymouth (price 1s.), which contains a useful plan of the Three Towns—Plymouth, Stonehouse, and Devonport, and a map of South Devon, in addition to a mass of information of the most varied character.

The Three Towns, considered as a whole, constitute the capital of the West Country, and owing to their situation partake in great measure of the characteristics of both Devonshire and Cornwall. At the same time Plymouth, Stonehouse, and Devonport are three distinct entities, each having its own local governing body. Plymouth proper lies to the east, where the commercial harbour is found; Devonport, to the west, is the site of Britain's greatest naval arsenal; and Stonehouse—sandwiched in between the other two, with no further outlet for expansion—is the connecting link which virtually makes the three towns one, with a population approaching two hundred thousand.

Two hamlets named Sutton appear to have existed originally where Plymouth and Devonport now stand, and Sutton-super-Plymouth, as Plymouth was formerly named, took rank as a leading seaport at a fairly early period in the history of England. In the year 1287 it was the port of rendezvous for the fleet of more than three hundred ships, which took part in the expedition to Guienne. The following year Plymouth sent its first deputies to Parliament, and from that time onward the town has been prominent in many ways. The defeat of the Spanish Armada was an event that very closely interested the inhabitants of the seaport where the English fleet lay waiting for the foe whose world-wide power it was to destroy utterly. The captains of the fleet—Drake, Hawkins, Raleigh, Frobisher, Grenville, Howard, and many others—were whiling away the time with a game of bowls on the "Hoe," when a comrade brought the news that the Spanish vessels had been seen, and is not the story familiar to everyone how Drake insisted upon finishing the game, observing that there was time enough to do that before thrashing the Spaniards? The Civil War found Plymouth on the side of the Parliament, and it resisted sieges and blockades for four long years. It is also famous for the fact that the passengers of the "Mayflower" last touched English ground ther in 1620, a record on the Barbican bearing witness to the event. But it is needless to deal further with the history of the town in these pages, as it receives full consideration at the hands of an expert in the handbook prepared by the Local Committee at Plymouth for presentation to all who attend the meeting next week.

Arriving in Plymouth at the Great Western Railway terminus, it is but a few minutes' walk to the Hoe, one of the most famous and attractive promenades in England, and, not without reason, described as the most breezy and pleasant open space in South Devon. The Hoe Park slopes upwards from the town towards the asphalted plateau, with its winding paths and artistically laid out flower beds, the Spanish Armada Memorial, and a statue of Sir Francis Drake. On the seaward side of the Hoe are grassy slopes intersected by winding paths and steps leading to the carriage way, which skirts the waters of Plymouth Sound. The promenade pier here provides a convenient landing place, and also serves as a pleasant lounge. The pavilion at the end of the pier is one of the favourite resorts of visitors, and will be a familiar spot to British pharmacists before many days have passed. Bathing accommodation is provided close by and can be indulged in by ladies at any time of the day. The Citadel, a fortification erected by Charles II. to overawe the town, and the Royal Marine Biological Laboratory, are also near the Hoe, and both will be found well worth a visit of inspection. To the east of the Laboratory is Sutton Pool, the ancient harbour of Plymouth, a creek of the Cattewater where the English fleet lay in wait for the Armada. The Barbican adjoining, where the fish market will be found, is the oldest portion of ancient Plymouth and the point from which the town radiated. The inscription commemorating the sailing of the "Mayflower" will be found there as well as many curious examples of old-time architecture.

Of the buildings in the town, it must suffice to refer to those with which the members of the Conference and their friends will become chiefly acquainted. In the first place, there is the Royal Hotel, the headquarters of the Conference. The Hotel is quite near to the Hoe, and the Assembly Rooms there will be open all day whilst the meetings continue. The meetings are to be held in the Western Law Courts, which are close at hand, as is also the Corn Exchange, where the luncheons will be served. The exact relative position of these and other buildings of special interest can be ascertained readily by reference to the plan printed in the pink circular and reproduced on a smaller scale in the special handbook which has been prepared. The Guildhall and Municipal Buildings are well worth a visit, and St. Andrew's Church (the mother church of the district) possesses many points of interest. It is said to be one of the finest parish churches in the kingdom and a thoroughly typical example, with its long nave and aisles and waggon roof, of the characteristic Devonshire church architecture of the Perpendicular period. The Athenæum is the home of the Plymouth Institution and of the Devon and Cornwall Natural History Society.

A capital system of trams enables visitors to get about Plymouth with ease, and Stonehouse and Devonport are quickly reached by this means. Keyham Yard, at Devonport, is the most extensive place in the world for the repair and fitting out of war steamers. Government buildings occupy the foreshore of the Hamoaze, as the estuary of the Tamar, used as a great naval anchorage, is named. The Royal Albert Bridge, one of Brunel's greatest triumphs, crosses the Tamar at a height of a hundred feet above high water, and touches the Cornish bank at Saltash. Down stream are to be seen miles of warships of various types, from old-fashioned three-deckers to the speediest torpedo boats and destroyers. The victualling yard is at Devil's Point, opposite which are the beautiful wooded heights of Mount Edgcumbe. The Royal Naval Hospital is at Stonehouse. But space will not permit even of a mere enumera-

tion of all the places of interest in and about the Three Towns The local Committee's handbook must be referred to for fuller information, whilst the illustrated guide already mentioned may be profitably consulted for descriptions of short walks around Plymouth; excursions by river and sea; longer excursions by rail, road, or moorland track; and short excursions into Cornwall. It is enough to say that—given even moderately fair weather—the most critical taste should find satisfaction in the capital of the West Country and its surroundings, and that pharmacists who may decide to spend a holiday in the district are certain to come away contented with the results of their visit.

FORMULÆ, METHODS, AND REACTIONS,

KNOWN BY THE NAMES OF THEIR AUTHORS.

(Supplementary List.)*

McClellan Forney (Alcohol and Turpentine in Essential Oils).—Mix 5 drops of the oil with 1 drop of iodine pentabromide. See *Am. Journ. Pharm.* for 1882, p. 546.

Mack (Strychnine).—With sulphuric acid and manganese dioxide, strychnine gives a dark blue colour, which changes to violet, pink, and yellow.

MacMunn (Indican).—This is a modification of Hammarsten's reaction, in which the urine is treated with hydrochloric acid and a few drops of nitric acid instead of with chlorinated lime solution.

MacWilliam (Albumin).—A concentrated aqueous solution of salicyl-sulphonic acid gives a white precipitate with albumin. The precipitate dissolves, on heating, in the presence of albumoses or peptones, and separates out again on cooling.

Magnier de la Source (Uric Acid).—Triturate the sediment from urine with water, add a few drops of bromine water, and evaporate. If uric acid be present the residue is brick-red; on dissolving it in potassium hydroxide solution a blue colour results, but with ammonia the solution is purple.

Maier (Iodine).—A blue colour is produced on adding a very dilute solution of potassium iodide to a solution of an iodide mixed with starch paste and sulphuric acid.

Maier (Turpentine in Essential Oils).—Note the optical behaviour of the oils in a polarising apparatus. See *Am. Journ. Pharm.*, **37**, 338.

Maisch (Croton Oil).—Oils suspected to contain croton oil are treated with alcoholic potash solution, water and hydrochloric acid are added to the separated alkaline layer, and the oil which separates is applied to the skin. A peculiar eruption is the result if croton oil be present.

Maisch (Essential Oils).—Note the appearance (1) on letting 1 drop of bromine fall upon 5 drops of oil in a watch-glass, (2) on adding 5 drops of ethereal solution of bromine (ether 5, bromine 1) to 5 drops of oil. See 'Proc. Am. Pharm. Assoc.,' for 1859, p. 338.

Maisch (Nitrobenzol in Almond Oil).—(1) On shaking 2 or 3 C.c. of the oil with half its weight of fused potassium hydroxide a reddish-yellow colour is produced which quickly changes to green; on adding water a green layer separates and turns red within twenty-four hours. (2) Dissolve 1 part of the oil in 12 of alcohol, add 9 of potassium hydroxide (? solution) and evaporate to about 14. If the oil be pure the residue is brownish red, contains no crystals, and dissolves in water; with nitrobenzol it is crystalline and insoluble in water.

Maisch (Quinine).—A voluminous crystalline but jelly-like precipitate is thrown down on adding a concentrated solution of an alkaline acetate to a solution of quinine sulphate.

Maisch (Turmeric in Rhubarb).—When rhubarb powder containing turmeric is shaken for one or two minutes with absolute alcohol and the liquid filtered off, the yellow filtrate is turned brown with concentrated solution of borax and the colour becomes only a little lighter on adding hydrochloric acid. In the case of pure rhubarb, the acid at once changes the colour to light yellow.

Malerba (Acetone).—Fluids containing acetone, such as urine, are coloured red by demethyl-paraphenylene-diamine solution. The spectrum of the red solution is similar to that of oxyhæmoglobin.

Man (Microscopical Fixing Solution).—Mercuric chloride 12, sodium chloride, 0·75; picric acid, 1; tannin, 1; in water, 1,000. Another formula is tannin, 1; picric acid, 1; and saturated solution of mercuric chloride in 0·75 per cent. salt solution, 200.

Mandel (Precipitant for Proteids).—A 5 per cent. solution of chromic acid forms a delicate reagent for albuminoids; a turbidity results with a dilution of one part of albumin in 50,000 parts of water. If the solution is first acidulated with acetic or citric acid, the precipitate subsides very rapidly. A 10 per cent. solution of chromic acid may be used instead of nitric acid for Heller's zone reaction for albumin.

Mandelin (Strychnine).—A little strychnine is mixed in a watch glass with a few drops of a 1 per cent. solution of sodium vanadate in concentrated sulphuric acid. On the appearance of a dark colour, the glass is tilted to allow the fluid to run off, and the residue develops a beautiful blue colour, which changes to vermillion and reddish yellow. On the addition of a little alkali a permanent pink to purple colour is obtained.

Mangin (Cellulose).—(1) The microscopical section is first macerated in a solution of iodine, 0·5; potassium iodide, 1·5; water, 100, and sulphuric acid (2 volumes of concentrated acid to 1 of water) is then added. Cellulose is indicated by a blue colour. The section may be treated directly with one of the following solutions:—(1) Zinc chloride, 20; iodine, 1·3; potassium iodide, 6·5; water, 10·5; or (2) with saturated calcium chloride solution, 10; potassium iodide, 0·5; iodine, 0·1; or (3) with concentrated phosphoric acid, 25; potassium iodide, 0·5, and a few crystals of iodine. (2) Another reagent is a solution of free iodine in iodic acid; the section is dipped in water or alcohol, and then dried, a few drops of the reagent are added, and the preparation washed in water. Cellulose is thus coloured black.

Marchand (Cinchona Alkaloids).—Note the effects of nascent oxygen from lead peroxide and sulphuric acid.—See *Am. Journ. Pharm.*, **16**, 198; **30**, 244.

Marchand (Iodine).—A rose to violet colour with dry starch, excess of hydrochloric acid and potassium bichromate.

Marchand (Olive Oil).—Note the colour reactions with sulphuric acid.

Marchand (Organic Matter in Water).—The presence of suspended organic matter is revealed on placing the water in a flask surrounded by back paper, in which two rectangular apertures are cut so as to be opposite, and passing a beam of light through the water.

Marchand (Strychnine).—On triturating strychnine with sulphuric acid containing 1 per cent. of nitric acid, and adding lead peroxide, a blue colour is produced, which changes to violet, green, and yellow.

Marme (Alkaloids).—Verven modifies this by dissolving potassium iodide, 10; cadmium iodide, 5; in distilled water, 100; five parts of the alkaloidal solution slightly acidulated are added to the reagent.

Marquis (Morphine).—The reagent consists of a mixture of 10 C.c. of sulphuric acid and 10 drops of concentrated oxymethylsulphonic acid solution.

Marsh (Indicator).—An infusion of dahlia petals, containing ½ fl. oz. sulphuric acid and 2 grs. mercuric chloride to the pint, is neutralised with ammonia. Alkalies turn the infusion green, and acids change the colour to red.

* After Wilder, Schneider, Altschul, and others. Continued from page 20, a

Martin (Nitric Acid).—A solution of diphenylamine in sulphuric acid and water gives a blue to black colour when a liquid containing nitric acid is added drop by drop.

Maschke (Glucose in Urine).—Dissolve crystallised sodium tungstate 30, in 30 p. c. acetic acid 75, and water 120. A black deposit is formed on adding to urine containing glucose one-third its volume of the above solution, filtering if necessary, adding half the volume of concentrated soda solution and a small fragment of basic bismuth nitrate, then boiling.

Maschke (Indicator).—An alcoholic solution of hæmatoxylin is changed from brownish-yellow to purplish red by alkalies.

Maschke (Molybdenum).—A blue colour is produced on placing 2 drops of sulphuric acid upon platinum foil, dusting upon the liquid a little of the powdered substance containing molybdenum, heating till vapours begin to escape, then cooling and breathing upon the foil.

Maschke (Nitrous Acid in Water).—The bluish colour produced on adding 6 to 10 drops of diluted acetic acid, followed by 1 or 2 drops of blue molybdic acid solution, disappears within an hour if nitrous acid be present.

Masset (Biliary Matter).—A grass-green colour is produced on adding 2 or 3 drops of sulphuric acid and a crystal of potassium nitrite to 2 C.c. of urine containing biliary matter.

Massie (Fixed Oils).—Note the change of colour on adding 5 Gm. of nitric acid to 10 of oil, and stirring with a glass rod for two minutes. Then add 1 Gm. of mercury, stir a few times during three or four minutes, and note the colour reactions.

Mayençon-Bergeret (Arsenic).—On exposing mercuric chloride paper to arseniuretted hydrogen, it is coloured lemon-yellow to light brown.

Mazzara (Glucose).—A green precipitate is thrown down on heating the liquid with nickel chloride in presence of a little potassium hydroxide.

Mehu (Albumin).—In applying this test (see *P. J.* [4 , **5**, 211), add 1 C.c. of the reagent (Phenol 1, acetic acid 1, 90 p. c. alcohol 2) to 10 C.c. of the liquid, after adding 5 C.c. of crude nitric acid ; then shake well and allow to deposit. The acid may be advantageously replaced by 5 C.c. of saturated sodium sulphate solution. A flocculent precipitate is thrown down.

Mein (Absinthiin).—Dissolves in sulphuric acid with a brownish colour, which soon turns greenish blue and becomes dark blue on adding water.

Meldola (Nitrous Acid).—A solution of 0·5 Gm. of para-amido benzolazodimethyl aniline in 1 litre of diluted hydrochloric acid. A few drops of the reagent added to the fluid to be examined, followed by a few drops of hydrochloric acid and subsequently by ammonia, develops a blue colour in the presence of nitrites; the reagent keeps well for an indefinite period, contrasting in this respect favourably with the phenylenediamine solution of Griess.

Mene (Phenol).—Bromine water gives a yellowish-white precipitate with carbolic acid.

Merck (Opium).—Treat with potash solution and shake with ether, then dip a strip of filter paper into the ethereal solution, moisten it with hydrochloric acid and expose to the vapour of boiling water. The paper should then turn red.

Merget (Mercury).—Alternative methods to those previously described (see *P.J.* [4], **5**, 211) are (1) to expose a strip of filtering paper moistened with ammoniacal silver nitrate solution and dried, to mercury vapour, which produces a black stain ; (2) to dip a copper wire in the liquid containing mercury, dry with filter paper and wrap up in tissue paper which has been moistened with ammoniacal silver nitrate solution. The mercury produces a black stain in this case also.

Merkel (Fixing Solution).—Chromic acid solution 0·025 per cent. 1 part, platinum chloride solution 0·25 per cent. 1 part. The solution takes a long time to act, but the preparations stain well.

Mermet (Carbonic Oxide).—The following solutions must be freshly prepared :—Solution A. : Silver nitrate 2 or 2-3 Gm. dissolved in water 1,000 C.c. Solution B. : A few drops of nitric acid free from chloride are added to a litre of boiling water. Then permanganate solution is added until a permanent red colour is obtained. In this 1 Gm. of permanganate is dissolved ; the reagent is prepared by mixing 20 C.c. of solution with 1 C.c. of solution B, and 1 C.c. of pure nitric acid, diluting with distilled water to 50 C.c. The reagent is decolourised by carbonic oxide also by sulphuretted hydrogen.

Mermet (Sulphocarbonates).—A currant-red colour is produced on adding an ammoniacal solution of nickel sulphate or chloride, which has been diluted with water until almost colourless.

Merz (Fixed Oils.)—On mixing an adulterated oil with an equal volume of pure oil and shaking gently the mixture appears streaky.

Merz (Phosphoric Acid).—If a drop of liquid containing free phosphoric acid, or a little of the dry substance mixed with sulphuric acid, is placed in the loop of a platinum wire and held close to the lower part of a hydrogen flame, the latter is coloured green.

Merz (Turpentine in Essential Oils).—These oils become milky if pure, on shaking with an equal volume of poppy-seed oil, but they remain clear if turpentine be present.

Mialhe (Cruciferous Oils).—On saponifying the oils of cruciferous plants with potash solution and filtering the filtrate is coloured black on adding silver nitrate.

Michailow (Proteids).—The substance in solution is mixed with ferrous sulphate, then poured upon concentrated sulphuric acid. On the addition of very little nitric acid the familiar reddish brown zone develops to a blood red colour in the presence of proteids.

Miller (Indicator).—Tropæolin, or methyl-orange, is changed from yellow to crimson by mineral acids, but it is indifferent to carbon dioxide and to sulphuretted hydrogen.

Miquel (Culture Solution).—Peptone, 20 ; sodium chloride, 5 ; wood ash, 0·1 ; in water, 1,000.

Moddermann (Ammonia).—A very dilute solution of copper sulphate becomes turbid on adding ammonia.

Moer Van de (Cytisine).—A 0.5 per cent. solution of ferric chloride and 0·05 per cent. solution of hydrogen peroxide gives first a red, then a blue colour with solution of cytisine.

Moerner (Acetone).—If urine containing acetone be heated with a little of potassium iodide solution and excess of ferric chloride intensely irritating vapours are given off.

Mohler (Tartaric Acid).—If a little solid tartaric acid or a tartrate be heated with a few drops of a solution of resorcin 1 in concentrated sulphuric acid 100, until sulphuric acid vapours develop, the fluid becomes of a fine wine red colour: the smallest trace of tartaric acid is sufficient.

Mohr (Antimonous Acid).—The acid, or any of its compounds, is dissolved in an aqueous solution of tartaric acid, the excess of acid neutralised with sodic carbonate, then a cold saturated solution of sodium bicarbonate is added in the proportion of 10 C.c. to each 0·1 Gm. of Sb_2O_3. The clear solution is titrated with N/10 iodine with starch indicator. The titration must be conducted immediately the solution of bicarbonate has been added, 1 C.c. N/10 iodine = 0·006 Gm. of antimony.

Mohr (Chlorides).—This is the familiar volumetric process with decinormal silver nitrate, using potassic chromate as an indicator.

Mohr's (Solution).—The potassium permanganate solution generally used in volumetric analysis.

Mohr (Free Mineral Acids).—(1) Add a few drops of potassium sulphocyanide solution to a light yellow solution of ferric acetate, free from alkaline acetates. Traces of mineral acid turn the mixture blood red, but the colour disappears on adding an excess of sodium acetate. See also P. J. [4] **5**, 212 ; (2) potassium iodide starch paste, with a light-yellow solution of ferric acetate, is turned red by traces of mineral acid ; (3) on adding cane sugar to a

solution containing sulphuric acid, and evaporating to dryness on a water-bath, a blackened residue is left.

Mohr (NITRO GLYCERIN).—A purple to dark-green colour is produced on extracting with ether or chloroform, mixing with a few drops of aniline, evaporating, and adding a few drops of sulphuric acid.

Mohr (POTASSIUM SALTS).—A saturated solution of potassium and sodium acid tartrates precipitates potassium salts from neutral solutions.

Molher's (REAGENT).—See Gayon's reagent.

Molisch (WOOD PULP).—To a 20 per cent. solution of thymol in absolute alcohol, water is added until no more thymol separates. The solution is set aside for some hours with an excess of potassium chlorate, and then filtered. Paper made with wood pulp moistened with this solution gives a bright blue colour on the addition of a drop of concentrated hydrochloric acid.

Morgan (MERCURY).—A silvery stain appears on placing 2 drops of the liquid on a piece of bright copper, and adding strong potassium iodide solution.

Morrell (LINSEED OIL).—Pure oil is coloured sea-green to greenish yellow on mixing 10 parts by weight with 3 of crude nitric acid and allowing to stand for a time. Adulterated oil assumes a light yellow colour.

Morson (CREOSOTE : PHENOL).—Creosote is insoluble in glycerin ; phenol is soluble.

Morton (ARSENIC).—The solution is placed in an apparatus similar to Doebereiner's lamp and an electric current passes through to decompose the water, thus replacing the zinc and sulphuric acid.

Muller (CAUSTIC SODA IN CARBONATE).—In the presence of caustic soda potassium permanganate solution turns green.

Muir (BISMUTH).—A brownish-black precipitate is thrown down on heating with a solution of stannous chloride, 1, and tartaric acid, 3, in a sufficiency of potassium hydroxide solution.

Mylius (GALLIC ACID),—In this modification of Pettenkofer's reaction, one drop of furfurol solution and 1 C.c. of concentrated sulphuric acid are added to each cubic centimetre of the alcoholic solution of gallic acid, cooling if necessary. The resulting red colouration is permanent for some time changing gradually to violet. Compare Udransky's modification of Pettenkofer's reaction.

ANALYTICAL NOTES.

SODIUM HYPOPHOSPHITE IN KJELDAHL'S NITROGEN PROCESS.

When mercury is employed to aid the oxidation of nitrogenous matter in Kjeldahl's process, sodium sulphide is generally used to remove the metal. Maquenne and Roux find that sodium hypophosphite is preferable for the purpose, since it effectually reduces the mercury salts, and obviates the formation of insoluble sulphur compounds, which are difficult to decompose with alkali, or of volatile sulphur compounds which may distil over with the ammonia, vitiating the results. They employ a gramme of hypophosphite, which is added to the sulphuric acid solution after dilution. The mixture is warmed to 60° to 70° C., to complete the reduction, and cooled before the addition of the alkali. The results obtained are a trifle higher than those from experiments conducted with sulphide, and accord better with those obtained with the soda lime method.—*Bull. de la Soc. Chim. de Paris*, **21**, 312.

DETECTION OF FORMALDEHYDE IN MILK BY PHLOROGLUCIN.

According to Jorissen's test, 0.1 Gm. of phloroglucin is dissolved in water 100 C.c., and 1 to 2 C.c. of this solution are added to 8 to 10 C.c. of the milk to be tested, together with a few drops of a solution of caustic potash or soda. A red colour is developed in the presence of formaldehyde. L. Vanino finds that strong solutions of formaldehyde, from 10 to 30 per cent., give no reaction whatever, or only a feeble one. A 3 per cent. solution, however, gives a raspberry colour, while the most distinct reaction is obtained with a dilution below 0.5 per cent. ; 0.00004 per cent. of formaldehyde gives a distinct reaction, but this appears to be the limit.—*Phar. Centr.*, **40**, 101.

SOCIETY OF CHEMICAL INDUSTRY.

The annual meeting of this Society was held at Newcastle-on-Tyne, as briefly reported last week. About two hundred delegates from all parts of the kingdom attended. The business part of the gathering began at the Durham College of Science, and the Annual General Meeting was afterwards held in the Chemical College's Theatre. Mr. GEORGE BEILBY (Edinburgh), President, was in the chair, and the company comprised Mr. John Pattinson, Newcastle; Professor Bedson, Newcastle; Mr. G. F. France, Newcastle; Mr. F. S. Newall (Chairman of the Newcastle Section) ; Professor G. G. Henderson, Glasgow ; Dr. C. A. Kohn, Liverpool ; Mr. Thomas Tyrer, London ; Mr. D. Howard, London ; Dr. G. Schack Sommers, Liverpool ; Mr. B. Redwood, London ; Mr. B. E. R. Newlands, London ; Mr. C. G. Cresswell (General Secretary ; and Mr. Samuel Hall (Hon. Treasurer). The Mayor of Newcastle (Councillor Geo. Harkus) attended for the purpose of welcoming the delegates.

After the usual formal business, the General Secretary, Mr. C. G. Cresswell, handed in the following list of the new Council . for the ensuing year's Society :—President, Professor C. F. Chandler, M.D., Ph.D. (of New York). Vice-Presisidents: George Beilby, R. Forbes Carpenter, Professor F. Clowes, D.Sc., George E. Davis, John Heron, David Howard, Dr. C. A. Kohn, Ivan Levinstein, B. E. R. Newlands, Dr. E. Schunk, F.R.S., Wm. Thorp, B.Sc., R. C. Woodcock. Ordinary members of the Council : Sir John Evans, K.C.B., F.R.S., Sir David Gamble, Bart., C.B., W. Winwood Gossage, E. Grant Hooper, Dr. Rudolph Messel, J. M. C. Paton, John Pattinson, Dr. Fred B. Power, Sir Robert Pullar, Walter F. Reid, Dr. Wm. S. Squire, E. C. C. Stanford ; Hon. Treasurer, Samuel Hall ; Hon. Foreign Secretary, Dr. Ludwig Mond, F.R.S. ; General Secretary, Charles G. Cresswell.

The PRESIDENT then announced that Professor Chandler, of New York, the President-elect, had not been able to cross the Atlantic to attend this year's meeting. He had, however, written a letter which would be submitted by the General Secretary. The annual report then followed. From it it is learned that the members now on the register number 3,304, as compared with 3,185 at the previous annual meeting.

Mr. SAMUEL HALL, Hon. Treasurer, presented his statement, and replying to questions, said that the collective index would cost about £1,280. This was for about 2,500 copies. The original subscribers would get copies for 5s. each, although such actually cost 10s. each.

Mr. BOVERTON REDWOOD (chairman of the London section) proposed London as the next place of meeting, seeing that they would be near the Paris Exhibition, which is to be held next year.

Mr. B. E. R NEWLANDS, London, seconded, when the proposal was carried unanimously.

The PRESIDENT afterwards amid applause delivered his address, the chief topics treated on being "The Coal Supply and Smoke Nuisance," Remedial Appliances," "Effects of New Processes on the Markets," "Production and Distribution of Fuel Gas," "Domestic Heating" ; and to cover all points a conference is suggested. On the coal supply, the rapid exhaustion of British coalfields, the President said, makes it absolutely desirable to go into the subject of dealing with the reckless waste that is daily going on in the running to waste of the smoke and gases in the ordinary burning of fuel in common fire grates. In place of seeing crude coal thrown into furnaces and tossed on fire grates, causing the masses to daily inhale finely divided carbon and other deleterious matter, it would be better by processes of distillation to secure all bye-products without impairing any loss whatever in the necessary heat for manufacturing and domestic purposes. For metallurgical and chemical works of all kinds, fuel gas is the most suitable, being smokeless and more easily under control. He thought the time was not far distant, when centres for the production and distribution of fuel gas would be established in all industrial districts to the general benefit and health of surrounding places. Coming to the question of thirty-five million tons of raw coal annually burned for domestic purposes, much attention is being given to the ultimate position of ordinary fuel gas for cooking, heating, ventilation and other uses. As a means of bringing all of the different interests concerned into line, it was suggested that the Society might arrange for the holding of a conference on the subject of fuel and smoke, at which the leading technical societies, as well as the industries concerned, should be fully represented. The President was cordially thanked for his

very able address. Later on in the afternoon (Wednesday) the visitors were invited to a garden party by the Mayor, at Leazes Park, where upwards of 2,000 citizens took part. In the evening a conversazione was held at the Hancock Museum, Barras Bridge, where perhaps is to be found the finest and rarest collection of stuffed birds in any part of the world, to say nothing of pre-historic fauna, found in the coal measures of the district. The subsequent days were spent in visits to local places of interest, as may be seen from the list appended :—

River Excursion. The steamer "Siren," from Newcastle to the Sea; visit to the Works of the Wallsend Slipway and Engineering Company, Limited: demonstration with the Hon. Chas. A. Parsons' boat, the "Turbinia," off the mouth of the river. Visit to Messrs. C. S. Swan and Hunter's Shipbuilding Yard, Whitburn Colliery. Descent of Whitburn Pit. Inspection of the limestone quarries on the coast. Durham Coke and Bye-Products Company, Lanchester. Simon-Carve Coke Ovens and plant for recovery of bye-products. Elswick Ordnance Works. The Aerated Water Works of the Newcastle Breweries, Limited. Messrs. Locke, Blackett and Co. Dutch process of white lead manufacture. Redheugh Works of The Newcastle and Gateshead Gas Co. Mechanical charging of retorts and sulphur recovery in the Claus kiln. Northumberland County Council's Experimental Farm, Cockle Park, near Morpeth. Elswick Ordnance Works. Messrs. Maling's Ford Potteries. Messrs. The United Alkali Company's Allhusen Works. The Chance Sulphur Recovery Process. Messrs. Palmer's Shipbuilding and Iron Company, Limited, Jarrow.

NEW REMEDIES.

Betaine for Tetanus.—Betaine hydrochloride forms colourless monoclinic crystals, soluble in water. Roger and Josué claim to have discovered that betaine neutralises the toxin of tetanus, but it remains to be proved if this property is capable of application in practical medicine.—*Merck's Report*, 1898, 41.

Orthoform in Toothache.—Hildbrandt (*Med. Press*) states that orthoform immediately and completely relieves the severe pain due to pulpitis in a decayed tooth. A plug of cotton wool saturated with an alcoholic solution of orthoform is introduced into the cavity. As the remedy is free from toxic properties it may be safely applied by the patient without danger.—*Therap. Gaz.* **22**, 270.

For Stomatitis in Children.—In Germany a mixture of borax 4, tincture of myrrh 8, and syrup of mulberries 6 is much used.—*Pediatrics*, **7**, 66.

For Fissures of the Hands.—Mix menthol 1 black, salol 1, olive oil 1, and make up with lanolin to 200.—*Pediatrics*, **7**, 366.

Ointment for Acne Rosacea.—Precipitated sulphur 60 to 240 grains, salicylic acid 10 to 30 grains, oil of sweet almonds 1fl.drm., lanolin 1 oz. Rub to a perfectly smooth ointment. Apply at night after washing.—*Therap. Gaz.* **22**, 238.

Lactic Acid in Irritant Skin Diseases.—Du Castel finds lactic acid to be an excellent means of allaying the intense itching of many skin diseases such as urticaria, prurigo, and other similar affections; the remedy is particularly successful with juvenile patients. It is given in the form of drops, from six to twenty, in sweetened water, according to the age of the patient. With adults as much as 1·5 to 2 Gms. per diem may be given; with moderate doses no ill effects are observed even after prolonged use. The good effects in allaying the irritating itching were very marked in all those cases where digestive derangement exists.—*L'Union Pharm.*, **40**, 199.

Menthophenol.—This is a mixture of menthol 3 and phenol 1, which forms a transparent aromatic fluid. It is analgesic and antiseptic in action; in dilute solution, such as fifteen drops to a tumblerful of water, it forms an excellent gargle; in stronger solution it may be used as an antiseptic dressing, while the hot 3 to 5 per cent. solution in warm water may be used as an analgesic in minor operations.—*Rev. Med. Pharm.*, **6**, 131.

LETTERS TO THE EDITOR.

NOTICE TO CORRESPONDENTS.—All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received, if specially arranged for, as late as Thursday morning. Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C., and Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

Liquor Ferri Perchlor. Fort. B.P.

Sir,—I think if Mr. Bird will revise his calculations regarding liquor ferri perchlor. fort. B.P. he will find he has made a mistake at the outset in saying that 12½ fl. oz. acid. hydrochlor. only contains 4·609 oz. weight HCl, with a specific gravity of 1·160. 12½ fl. oz. acid. hydrochlor. weighs 14·5 oz., and so contains 5·1 oz. HCl. 5·1 oz. HCl will dissolve 3·917 oz. Fe., so that at the finish of operation 17½ fl. oz. of liquor will contain 3·917 oz. Fe. Therefore, 5 fl. oz. will contain 1·119 oz. Fe., equivalent to 1·68 oz. Fe_2O_3. Thus the B.P. is theoretically correct in stating that 5 C.c. should give 1·6 gramme Fe_2O_3.

Rothbury, July 15, 1899. G. H. Athey.

Mr. F. C. J. Bird writes to correct two slight errors in his letter published last week. In the first line the name "F. A. Allen" should be "F. J. Allen," and in line eighteen "5 Gm." should be "5 C.c."

The Company Trading Question.

Sir,—Mr. Glass asks qualified chemists various questions and also supplies the answers, a very convenient but not a convincing method of argument. He tells us that we can never have a monopoly in the sale of drugs because it would interfere with the principles of free trade; really he ought to know that this is not a question of free trade at all. It does not alter the fact at all that McCrae tells him so. Mr. McCrae may not know. Indeed, I believe he does not understand what he is talking about. I believe he would go further than Jesse Boot; he would employ doctors and lawyers, which shows us what he knows. I understand he obtained a considerable number of votes by supporting some rather extreme trades union business—so we see that with him the workman has rights, but the chemist, the doctor, and the lawyer have none. Let Mr. McCrae begin with the lawyers! It is our duty in interviewing these people to be in a position to combat preconceived impressions; and to give them sound argument. Again, Mr. Glass asks "What is the most we can get?" (he is not modest when he proceeds to answer that question). Really now, how can we tell him? Surely it depends upon our leaders, our organisation, and ourselves; but to go with cap in hand without even proof of being a deserving mendicant—well, it is not creditable to "Auld Reekie." Mr. Glass should really think this matter over again; for if, as he says, the Council's suggestions embody what he considers just, what is the sense of asking for anything else?

Blackburn, July 15, 1899. R. Lord Gifford.

The Present Position of Registered Chemists.

Sir,—It seems more than ever important that qualified chemists should know where they are, and where they are likely to get to.

In approaching the remedying of our grievances, people entitled to hearing appear to go in one or other of three lines of thought and argument; these may be classified as follows:—(1) The Council's suggestions, are generally allowed to indicate what pharmacists oughtto strive for. To bring these, taken literally, into effect would necessitate legislation, apparently hopeless and impracticable, but efforts can be based upon these suggestions. Why can we not for example consider they would be met by first settling the question of title and everything involved by that, and afterwards insist upon a natural exten ion of Part 2 of the Schedule. (2) We have the line of thought the Edinburgh chemists seem to pursue, viz., the recognition and registration of unqualified people and companies. That this line is possible for qualified chemists to take simply astounds us; we could not have thought it possible. (3) We have the line of thought which thinks from a trader's point of view, and would grasp every opportunity for trade advantage, *e.g.*, doctor's dispensing is attacked on the ground of resulting advantage to chemists. There can be much said for this policy, but I will endeavour to show it is mischievous and fallacious. Is interference with dispensing practicable? How would an outsider (say the Lord Chancellor) view our intervention? Naturally as a body without a curriculum, presuming to regulate the affairs of another body which has a five years' curriculum. The thing is absurd. The sensible procedure would seem to be, to realise our weakness as a body relatively to the medical profession, and begin by making them our friends. How would that advantage us? We will deal with facts. Doctors now commonly send patients to stores to get medicines and prescriptions made up, in the idea that they are saving patients money, and giving at the same time an illustration of the doctor's solicitude on the patient's behalf. The practical result of this is disastrous to the chemist, because it confirms in the strongest manner the general impression of the public, that stores are cheap and "just as good." Now this is mere thoughtlessness on the part of the medical profession, and it is not difficult to get a better understanding with them. Chemists should look at this matter broad-mindedly, because it follows inevitably, that with doctors insisting, in their everyday work, upon the necessity of a qualification, more grist and status will be brought to chemists than in any other way. This is a broad view, a practical view, and, we have strong reason for saying, a true view. The only solution of the "Dispensing by Doctors" question will be found in rationalising the practice of Pharmacy. To us, who pose as common-sense people, it appears the wisest course would be the adoption of the Council's policy as the base of operation, and acting upon it; at the same time there is no reason for ignoring trade advantages, as practical people, whenever they can be acquired. It is incompatible, however, with the Council's position to have any cognisance of trade interests. Its duty is to administer the Pharmacy Acts, to see that chemists are adequately qualified, to conserve the rights and extend the privileges of those who qualify; well, then, our legitimate objects are to assert the right of the chemist to the exclusive use of his legally acquired title, and also to claim that the time has arrived for fulfilling the manifest intention of the Pharmacy Act of 1868, viz., additions to the Poison Schedule. We submit that the Council might with all advantage immediately cause agitation throughout the country on the question of titles. I do not think there is any doubt that if this were done at once, insisted upon and persisted in on every and any occasion and with all people, practical results would soon follow. Let this be done and let us show that it is no pretence but business, and the first result will be entire unanimity amongst qualified chemists, hearty support from the medical, and all other professions, and indeed all disinterested thought. I believe that with the Council's initiative and earnest interest this landmark, this Magna Charta could be established. Let us ask with one voice for the one right we undoubtedly were intended to acquire in the examination room and nothing can resist us. We have already delayed too long; but now our enemy is the intensely smart business men, who are honeycombing the country with the title of "chemist," evidently the tradesman's idea of obtaining a vested interest. Events are moving quickly, and we are not awaking. There are those of our own body who meekly say these parasites have already acquired our rights. It will be to the everlasting disgrace of the present race of chemists if it allows its title to be quietly filched. And it will prove to history that in Bloomsbury Square chemists lost their manhood and became fitted only for slaves.

Blackburn, July 15, 1899. R. L. GIFFORD.

Presentation to Mr. Henry Wootton, B.Sc.

Sir,—A presentation is being made to Mr. Wootton, late of the Westminster College of Pharmacy, and as it is desired to let as many old students as possible know the date and time, I shall be obliged if you will kindly permit me to announce in this week's issue of the Journal that the presentation will take place at a smoking concert to be held at the "Swan" Hotel, Clapham Road (opposite Stockwell electric station) on Monday, July 31, at 8.30 p.m. It is hoped that as many as possible will attend.

Southwark, S.E., July 19, 1899. A. ROBERTS.

The Proposed Testimonial to Mr. A. C. Wootton.

Sir,—At a meeting of the Committee, appointed on July 10, to arrange for a complimentary dinner to Mr. A. C. Wootton, in acknowledgment of his services to the drug trade while Editor of the *Chemist and Druggist*, it was decided that the dinner should be given in the first week of October. It had also been decided at the meeting on July 10 that Mr. Wootton's portrait should be presented to him, but, in consequence of the strongly expressed wish of Mr. Wootton, the Committee has abandoned this, and has decided to compile an album of signed portraits of the subscribers to the dinner, for presentation to Mr. Wootton. A Sub-Committee, consisting of Messrs. John Thompson (Chairman), Henry S. Wellcome, Albert Cooper, J. Morgan Richards, F. W. Fletcher, W. S. Glyn-Jones, and W. Edwards, jun., was appointed to carry out the arrangements. Mr. W. Edwards, jun., 157, Queen Victoria Street, E.C., and Mr. W. S. Glyn-Jones, 2, Stonecutter Street, E.C., are acting as Secretaries. May we request that all inquiries regarding the dinner should be addressed to us,

W. EDWARDS, JUNR., } *Hon.*
W. S. GLYN-JONES, } *Secretaries.*

London, July 19, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Botanical (F. G.—31/15).—It is a specimen of *Plantago lanceolata*, with the bracts developed into small leaves.

Botanical (T. K.—31/12).—(1) In too imperfect a condition for identification (2) *Cochlearia armoracia*; (3) *Beta maritima*; (4) Probably *Ranunculus sceleratus*, but the leaves are too imperfect to permit of identification.

Preparation of B.P. Lamellæ (B. J. K.—31/23).—The basis may be prepared (*vide* Lucas's 'Practical Pharmacy') by soaking 180 grains of transparent gelatin in a mixture of 15 minims of glycerin and 2 ozs. of distilled water. When the gelatin is softened apply heat until solution is affected and strain through muslin. The medicament in solution is added to the liquefied basis, and the medicated mass spread on plate glass which has been thinly coated with white beeswax and heated to about 38° C. A thick writing paper shape with an opening 4 ins. square should be pasted evenly over the waxed glass prior to heating it, and the mass should be spread evenly so as to occupy the space exactly. Afterwards dry the gelatin film at a temperature not exceeding 38° C. for fourteen days. Then detach from the glass and cut out discs having a diameter of ½in. by means of a shoemaker's eyelet-hole punch. To 80 grains of basis, add, for atropine lamellæ, 20 minims of solution of atropine sulphate; for cocaine lamellæ, add 20 grains of cocaine hydrochloride dissolved in 20 minims of distilled water; for homatropine lamellæ, add 10 grains of homatropine hydrobromide dissolved in 20 minims of distilled water; for physostigmine lamellæ, add 1 grain of physostigmine sulphate dissolved in 20 minims of water.

THE ASSAY OF THE OFFICIAL LIQUID EXTRACT, WINE AND VINEGAR, OF IPECACUANHA.*

BY E. H. FARR, F.C.S., AND R. WRIGHT, F.C.S.
Pharmaceutical Chemists.

The process for the determination of the alkaloids in liquid extract of ipecacuanha is undoubtedly the most unsatisfactory of all the official assay processes, and has been subjected to severe and well-merited criticism and unqualified condemnation by Wilson.† It possesses every fault possible to such a process, without a single compensating advantage. It would indeed be impossible to imagine a method of assay more complicated, more wasteful of material or more tedious in operation. And when to this is added the fact proved by Wilson and fully confirmed by our own experiments that a considerable amount of alkaloid is lost in the lead precipitate, together with the further fact, now pointed out for the first time, that the residue finally weighed and reckoned as "total alkaloids" contains from 12 to 20 per cent. of foreign matter, it will be agreed that the process can only be adequately characterised by a phrase not to be found in any pharmaceutical vocabulary.

The alternative process proposed by Wilson is in several respects a great improvement upon the official one, and has received commendatory notice from Moss, who states that "it yields the alkaloids in a purer condition, with greater accuracy and expedition." ‡

The practical testing of both processes, together with a critical examination of the entire subject of ipecacuanha assay has, however, convinced us that it yet remains for practical pharmacists and laboratory experts to devise a process of assay for the galenical preparations of the drug which shall combine the requisites of economy, simplicity, and accuracy, with rapidity of working.

The object of this note is to place on record the results of experiments which it is hoped may contribute somewhat towards the attainment of this end.

Before doing so, it may be well to allude a little more in detail to what we consider to be the faults and drawbacks of the two processes above mentioned.

(*a*) One fault common to both is that the quantity of material used in each determination is far greater than is either necessary or desirable.

The official monograph for the preparation of the liquid extract (which is satisfactory to this extent, that it yields an active and stable preparation, free from an unduly large proportion of inert matter) provides for the production of about 800 C.c. of finished product, 20 C.c. of which is forthwith directed to be employed in the assay process.

The process is equally wasteful in chloroform, 75 C.c. of which is used for the extraction of about 0.4 Gm. (six grains) of alkaloids. This objection is emphasised when it is considered that for an assay process like this, only so much material need be taken as is calculated to contain from 0.02 to 0.05 Gm. alkaloids. For the assay of the liquid extract of ipecacuanha 1 or 2 C.c. is ample in the hands of an expert, and in no circumstances should more than 5 C.c. be employed.

When a much greater quantity is taken, the amount of resinous matter present renders it almost impossible to shake out the alkaloids without resorting to a special method for the prior removal of the resinous extractive. It is in the carrying out of this part of the official process that the principal loss of alkaloid occurs.

(*b*) There is a further loss involved in the undue dilution of the liquid. This objection applies in a lesser degree to Wilson's process, where distinct traces of alkaloid are left both in the mother liquor and also in the ether-chloroform washings. Wilson claims that if his modification is carefully worked, the precautionary treatment of these washings with acidulated water is unnecessary. This statement is not borne out by our experience, for in performing the operation one of us has recovered as much as 0.002 Gm., and in one case 0.005 Gm. weighed alkaloid.

In a third determination the wash-water thus employed was added to the mother liquor from which the alkaloids had been removed. To the mixed liquids alcohol was added in quantity sufficient to re-dissolve separated matter, the liquid rendered slightly acid with diluted sulphuric acid and then placed on a water-bath and evaporated to small bulk. An excess of ammonia was then added, and the alkaloids shaken out with chloroform. In this experiment 0.009 Gm. almost pure alkaloid was recovered.

(*c*) In both processes the mistake is made of regarding the weighed product as pure, or approximately pure, alkaloid. According to Wilson's own showing, however, this could not possibly be the case, seeing that the results obtained by weighing were invariably much higher than those indicated by titration.

In his note on the subject he does hint at the possible presence of some impurity, but accounts for the great discrepancy between the gravimetric and volumetric results by supposing the presence of a third alkaloid having a much higher molecular weight than those of the principal alkaloids.* It is true that Paul and Cownley,† in their classic research on the chemistry of ipecacuanha, recorded the discovery of a third alkaloid having a higher molecular weight than those of emetine and cephaeline, but the amount found by them (0·04 per cent. of the total in one specimen of the root and 2 per cent. in another specimen) is quite insufficient to affect the results at all seriously. And a subsequent consideration of the chemistry of the ipecacuanha alkaloids by Hesse‡ serves to confirm our opinion, founded upon a number of experiments, that for volumetric determinations, an equivalent calculated from the molecular weights of emetine and cephaeline gives perfectly accurate and reliable results.

The method employed in order to establish the fact that the alkaloidal residues obtained by the official and Wilson's processes contained other than alkaloidal matter was as follows:—

The crude alkaloids from 5 C.c. of liquid extract were dried in an air oven at a temperature below 80° C., till of constant weight, and the weight noted. The residue was then dissolved in water containing 1 per cent. of sulphuric acid, and the alkaloids precipitated by the addition of an excess of solution of iodine with potassium, iodide, the precipitate filtered off, washed with weak iodine water, and allowed to drain. The alkaloidal hydriodides were then washed through a hole pierced in the bottom of the filter into a bottle and decomposed by the addition of an excess of sodium thiosulphate. The solution was filtered into a separator, the filter washed with a little water and the filtrate and washings bulked. A slight excess of ammonia was then added, and the alkaloids shaken out with chloroform. The chloroformic solutions were bulked and evaporated and the alkaloidal residue dried and weighed. It was then dissolved in a little alcohol a calculated excess of HCl/10, with some distilled water added and the liquid titrated back with NaHO/20; cochineal being used as indicator.

In order to render the test perfectly conclusive, each determination was performed in duplicate; in the first, the impure alkaloid was titrated, and in the second, the alkaloid from an equal volume of liquid extract, purified by the method above-mentioned, was similarly treated.

The following results were obtained:—

	By Weight.	By Titration.
Experiment 1.—Impure Alkaloid	0·097	0·070
„ Purified ditto	0·072	0·070
Experiment 2.—Impure Alkaloid	0·098	0·086
„ Purified ditto	0·087	0·036

The proper equivalent based upon the mean of the molecular weights of emetine and cephaeline is 0.023939 Gm., or practically 0.024 Gm. for each cubic centimetre of HCl/10.

For the purpose of our experiments several ipecacuanha percolates and fluid extracts were used.

The following assay processes were employed:—

1. The official process.
2. Wilson's alternative process.*
3. Our proposed process.
4. A modification of No. 3 for rapid working.

The details of No. 3 are as follow:—

Five C.c. of the fluid extract is placed in a small porcelain dish, 10 drops of diluted sulphuric acid B.P. added, with 5 C.c. of water, and the mixture evaporated over a water-bath until the volume of liquid is reduced to about 3 C.c. This is run into a separator, the dish carefully rinsed with 10 drops of water, and then with 15 C.c. of chloroform, the whole being transferred to the separator. An excess of ammonia is added, and the mixture well shaken, and allowed to stand until the chloroform has separated. This is run off, and the agitation and separation repeated with two successive quantities of 5 C.c. of chloroform. The chloroformic solutions are bulked, and the alkaloids extracted by shaking with three successive quantities of 10 C.c. 1 per cent. sulphuric acid. The acid alkaloidal solutions are drawn off in turn and mixed. The alkaloids are finally recovered from this solution by repeating the treatment with ammonia and chloroform. The solution of the alkaloids in chloroform is then evaporated in a tared dish over a water-bath until all chloroform has been removed. The weight is taken, and the alkaloidal residue titrated with HCl/10 and NaHO/20 as previously described.

4. Two C.c. of the fluid extract is acidified and evaporated, and the alkaloids extracted with chloroform as described under No. 3. The chloroformic solution of the alkaloids is evaporated to dryness and the residue titrated at once.

The following results were obtained:—

	No. 1.		No. 2.		No. 3.		No. 4.	
	Weight.	Titration.	Weight.	Titration.	Weight.	Titration.	Weight.	Titration.

F. & W. ,,	2·20	2·02	1·90	1·78	2·04	1·82	2·06	1·73
Quick ,,		1·97		1·74		1·80		1·72

No. 4 is proposed as a rapid process for employment in laboratories where economy of time is an object. The whole process can be performed in half an hour, and the results are practically accurate. It should be noted that in this case the solution for titration is opalescent, owing to the presence of traces of fat and resin. It is, therefore, necessary, in order to obtain accurate results, to dilute the solution largely with distilled water, and to observe the end of the reaction with corresponding care.

In practised hands it will present no great difficulty.

In working by the official process the amount of alkaloid in the lead precipitate was determined in each case. The results merely confirm those obtained by Wilson, and are, therefore, not recorded. In working process No. 3, should there be any sign of emulsification, separation of the chloroform may be induced by standing the containing vessel in hot water.

The improvements claimed for the method of assay now proposed over the official method and that of Wilson are as follows:—

1. The bulk of the liquid is kept as small as possible, thus rendering the separation of the chloroform easier and more complete.

2. The partial purification of the alkaloids by shaking out with acidulated water before the final extraction.

3. The substitution of a volumetric for a gravimetric standard. We have clearly proved that the alkaloids obtained from the liquid extract by means of solvents contain a large and variable amount of impurity. This can be separated, and the alkaloids obtained by precipitation as periodides in a practically pure condition. The process is, however, a somewhat tedious one, and seeing that the alkaloids can readily be determined by titration of the crude residue we have no hesitation whatever in recommending the substitution of an alkaloidal standard depending upon titration alone for the present one.

The titration itself presents no difficulty whatever, as the end of the reaction is clearly marked and is very sharp and precise.

For the determination of the alkaloidal value of the wine and vinegar we recommend the following modification:—

Fifty C.c. of the sample is placed in a porcelain dish, 10 drops of diluted sulphuric acid added, and the liquid evaporated to about 5 C.c. It is then transferred to a separator, the dish rinsed with a few drops of water and 10 C.c. of chloroform, and the alkaloids separated and determined exactly as described in the process recommended for the fluid extract.

Several commercial samples of the wine were determined by this method with the results shown in the following table:—

Sample.	Alkaloid obtained. By Weight.	Alkaloid obtained. By Titration.	Percentage in Wine.
No. 1.	0·031	0·031	0·062
No. 2.	0·022	0·022	0·044
No. 3.	0·042	0·040	0·080
No. 4.	0·012	0·012	0·024
No. 5.	0·040	0·036	0·072
No. 6.	0·022	0·021	0·042
Average.	0·028	0·027	0·054

The alkaloids from the wine were almost colourless, and the titration results show that they are yielded in an almost perfectly pure condition. This is evidently attributable to the fact that the impurity present in the crude alkaloids from the liquid extract, and which is most probably of a resinous nature, is thrown down and filtered out in the process of conversion into the wine.

The vinegar was not examined, but as it is prepared by simple dilution of the fluid extract, it is evident that the process employed for the wine is equally applicable to this preparation.

FLY PAPERS.—*Sticky Paste.*—(1) A mixture of resin, 150; linseed oil, 50; honey, 18. (2) Colza oil, 70; resin, 30. (3) Resin, 600; linsced oil, 380; yellow wax, 20, melt and strain. (4) Resin, 10; crude turpentine, 5; rape oil, 5; honey, 1. (5) Boil linseed oil in an iron vessel in the open until it catches fire. Let it burn until a drop taken out of the pot is stringy, then add yellow wax to attract the flies. Sesame oil, 5; resin 11. Melt together. *Non-Poisonous Fly Paper.*—(1) Quassia decoction (1:10), 1·25, are mixed with brown sugar, 6; ground pepper, 3, and exposed on plates with blotting paper. (2) Ground pepper, 1; brown sugar, 1; are mixed with milk, 15, and the mixture exposed on plates with or without bibulous paper. (3) Quassia wood, 75, are boiled with water, 200, until evaporated to one-half, strained and mixed with cobalt chloride, 5; tartar emetic, 1; tincture of long pepper (1:3 dilute alcohol), 40; blotting paper saturated with the solution is exposed on plates. (4) Potassium bichromate, 5; sugar, 15; essential oil of pepper, 1, are mixed with water, 60, and alcohol, 10, added. Unsized paper is saturated with this solution, and then dried. *Sticky Fly Paper.*—A mixture of resin, 600; poppy seed oil 300; honey, 100, is spread on parchment. *Dusting Powder for Flies.*—Powdered orris root, 4; powdered starch, 15; cucalyptol, 1, are mixed and put up in a tin with a perforated lid. Powdered long pepper, 5; powdered quassia, 1; powdered sugar, 10, are mixed and moistened with dilute alcohol, 4. The mixture is dried and again powdered.—*Pharm. Ztg.*, **44**, 349.

THE ASSAY OF THE LIQUID EXTRACT AND WINE OF IPECACUANHA OF THE B.P., 1898.*

BY W. A. H. NAYLOR, F.I.C., AND JOHN J. BRYANT.

The process directed for the assay of the liquid extract of ipecacuanha of the British Pharmacopœia, 1898, has caused widespread dissatisfaction among practical pharmacists. It is tedious, complex, prodigal of time and wasteful of alkaloidal product.

For some months past our attention has been devoted to remedying these defects, and numerous experiments have been conducted with the object of devising a process that would possess the essential qualities of accuracy, speed and facility of manipulation.

Wilson's statement that the Pharmacopœia process is inaccurate is amply confirmed by the figures in the following tables from five separate determinations of the same liquid extract.

TABLE I.—PHARMACOPŒIA METHOD, SHOWING LOSS.

Lead Ppt.		Result in grammes per 100 C.c. liquid ext.	Loss (by difference) between the mean of two results by Wilson's process.†
Washing Water used for washing only.	Time, in hours, taken up in washing.		
½ litre	5	1·94	0·25
1 litre	10	2·00	0·19
1½ litres	13	2·030	0·16
2 litres	16	2·065	0·125
2½ litres	20	2·105	0·085

Another serious objection to the Pharmacopœia process is the extraction of the alkaloid from such a large volume of liquor as results from the combined washings of the lead precipitate and the excess of lead as sulphate produced by decomposition with the diluted acid. The loss of alkaloids entailed may be minimised either by shaking out the washings in small portions at a time or by previously evaporating them to a small bulk, the tendency in either case being to make the process more lengthy and tedious.

Wilson‡ has published a process which is a great improvement on the official one, inasmuch as it is more accurate, and provided the liquid extract operated upon is not of an exceptionally resinous nature it may be assayed by it in much less time. The solvent he employs in the early part of the process extracts matter that would otherwise be finally weighed as alkaloid, while a large portion of the resinous constituents remain in the acidified liquor in a precipitated and insoluble state. The presence of this insoluble matter renders subsequent separations under certain conditions both difficult and tedious. In two or three samples of liquid extract to such an extent has the insoluble matter interfered that, after making the liquid alkaline with ammonia and shaking up vigorously with the chloroform ether, the solvent showed little tendency to separate after several hours and even days, although the separator was immersed in hot water. The important point to note is that the separations are comparatively speedy or prolonged according as the resinous constituents vary.

Of the methods we have tried the following deserve notice:—

1. *The Lime Process.*—To 5 Gm. of slaked lime in a basin add 5 C.c. of liquid extract, care being taken to prevent the latter from coming into direct contact with the containing vessel. The measure is rinsed with alcohol and the rinsings added to the lime mixture, and the whole dried over a water-bath. The dry residue is next exhausted in a Soxhlet by boiling ether. The ethereal solution is extracted with ½ per cent. sulphuric acid, and the latter with ammonia and chloroform. The residue from the chloroformic extractions was dried and weighed.

Our only object in including Glenard's process is to point out the exact cause of the low results yielded by it. The explanation is rendered possible by the elaborate researches of Paul and Cownley on ipecacuanha. Small quantities of the alkaloids, emetine, and cephaeline in a pure condition were treated alone and separately by the lime process exactly as with the liquid extract, the alkaloid being first dissolved in alcohol. The results here tabulated clearly show that the loss of alkaloid is due to the action of the lime on the cephaeline, the emetine being uninfluenced by the treatment.

TABLE II.—LIME PROCESS WITH PURE ALKALOIDS.

Alkaloid.	Amount taken.	Amount returned.	Per cent. returned.	Per cent. loss.
Emetine	0·100	0·098	98	2
Cephaeline	0·074	0·060	81·09	18·91

We note Paul and Cownley in their researches make the statement that "Glenard's extraction by means of lime and ether and recrystallisation of the hydrochloride are precisely the conditions most favourable for eliminating cephacline, and insuring the production of pure emetine. (*P. J.* [3], **25**, 115.)

2. *Kieselguhr Process.*—To 5 Gm. of kieselguhr, freed from every trace of lime, placed in a porcelain basin, add 5 C.c. of the liquid extract, and dry the mixture over the water-bath. The dry powder, after transference to a Soxhlet, is then treated throughout by Ransom's* ammoniated chloroform process. The chief drawbacks to this method are the time and care required for its exact performance.

3. *Process.*—To 5 C.c. of the liquid extract, placed in a porcelain basin, add 2 drops of diluted sulphuric acid, and heat over the water, bath gently to drive off the spirit. The acid solution is then transferred to a separator, together with the small portions of water used for washing the basin, ammonia is added in excess, followed by 10 C.c. of chloroform and agitated. The agitation and separation with chloroform is twice repeated. The chloroformic solutions are mixed and extracted with 10 C.c. of ½ per cent. sulphuric acid thrice repeated. The separated acid solutions are united, rendered alkaline with ammonia, and extracted with three successive 10 C.c.'s of chloroform. The chloroformic solutions are evaporated and the residue dried, weighed, and titrated with N/10 HCl. Although the process is not open to the charge of inaccuracy it has the one serious defect of consuming much time, owing to the great difficulty with which the separations take place, even when the separator is immersed in hot water. After giving this process a fair trial and experimenting further we decided to abandon it and to adopt the following:—

4. *Process.*—Place 10 C.c. of liquid extract in a basin over a warm water-bath until the alcohol is dissipated. The solution is transferred to a 50 C.c. flask, and the basin is washed with small portions at a time of a mixture of 2 C.c. of diluted sulphuric acid and 30 C.c. of water. The solution is filtered and water passed through the filter until the volume measures 50 C.c. Of the filtrate 25 C.c., representing 5 C.c. of liquid extract, are transferred to a separator, together with the small portions of water used for washing the measure, and the solution is shaken up with 10 C.c. of chloroform. After removal of the separated chloroform the solution is agitated with another 10 C.c. of chloroform, which after separation is also withdrawn. The solution is then made alkaline with ammonia and extracted successively with 3 × 10 C.c. of chloroform. The chloroform solutions are mixed, evaporated, and the residue weighed and titrated with N/10 HCl.

The accuracy of this process is shown in the appended table, which gives strictly comparable results on the same sample of liquid extract. An additional recommendation is the rapidity with which the assay can be made. Its distinctive feature is the removal of the resinous substances by a rapid and simple method without loss of alkaloid, thereby making possible the quick separation of the chloroformic solutions.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

† Which is 2·19 grammes per 100 C.c.

* 'Year-Book of Pharm.,' 1887, p. 450.

TABLE III.—COMPARATIVE RESULTS.

Process.	Amount of liquid extract taken in C.c.'s.	Weight of alkaloid obtained.	C.c.'s of N/10 HCl absorbed.	Yield of alkaloid by titration.	Amount of impurity.	Alkaloid in Gms. per 100 C.c. liquid extract by weighing.	Alkaloid in Gms. per 100 C.c. liquid extract by titration.
B.P. 1898....	20	0·402	14·0	0·3374	0·0646	2·010	1·687
Wilson's....	20	0·400	13·5	0·32535	0·07465	2·000	1·62675
Lime	5	0·088	2·8	0·06748	0·02052	1·760	1·3496
Kieselguhr .	5	0·106	4·0	0·0964	0·0096	2·120	1·928
No. 3.....	5	0·114	4·2	0·10122	0·01278	2·28	2·0244
No. 4.....	5	0·110	4·1	0·09881	0 01119	2·20	1·9782

In the above examinations the separations in most cases were troublesome, owing to the nature of the liquid extract being very resinous.

The calculations are made upon the basis that 1 C.c. of N/10 HCl is equivalent to 0·0241 Gm. of mixed alkaloids, titration being conducted as given in the B.P., 1898, page 104, under belladonna assay.

As alkaloidal residues differ in their degrees of purity, we are of opinion that their amount should not be determined by gravimetric processes, but that their titration should be insisted on.

In the following table the results given are obtained from six samples of liquid extract by the foregoing processes, titrations excepted, and by the processes respectively of Wilson and the Pharmacopœia.

TABLE IV.—ASSAYS OF LIQUID EXTRACT.*

No. of sample.	B.P. 1898 process.	Wilson's process.	Lime process.	Process No. 3.	Process No. 4.
1 (*a*)	1·94	2·25	1·28	—	—
(*b*)	2·0	2·13	1·38	—	—

(*b*)	1·935	2·104	1·612	2·397	2·349

For the assay of the wine the following adaptation of the previous process is recommended. 100 C.c. is evaporated over the water-bath to 10 C.c., a little kieselguhr stirred in, the mixture transferred to a beaker and the basin washed with the mixture of 2 C.c. of dilute sulphuric acid, and 30 C.c. of water. The solution is then filtered and water passed through the filter until the volume measures 50 C.c. Of this filtrate 25 C.c. is taken, which, represents 50 C.c. of the wine, and the remaining operations are conducted as detailed in process No. 4.

The appended table shows the results yielded by three samples of wine.

TABLE V.—VINUM IPECACUANHÆ, B.P. '98, ASSAYED BY PROCESS 4.

MISCIBLE LIQUID EXTRACT OF IPECACUANHA.*

BY F. C. J. BIRD.

The liquid extract of ipecacuanha of the present Pharmacopœia is, undoubtedly, a great improvement on the dried acetic extract official in the last edition of that work. The new preparation possesses the advantages of standard strength, good keeping properties, and fine aroma of the root, but these good qualities are accompanied by the minor defect, from a pharmaceutical point of view, of precipitation when diluted with weak alcoholic or aqueous liquids.

The cause of this precipitation is usually attributed to the presence of resinous substances in the liquid extract, although the view has been advanced that the turbidity is partly due to the decomposition product of a peculiar pectin compound. There have been no published statements as to the nature of the deposit which in the official formula for the wine is directed to be filtered out, but if the wine be not free from astringent matter the sediment will certainly contain a little alkaloid. A liquid extract not forming a precipitate on dilution would, therefore, not only save filtration, but what is often of greater importance, avoid the 48 hours' delay incidental to the preparation of vinum ipecacuanhæ by the present B.P. formula.

The constituents of ipecacuanha root, isolated and identified by various observers, are the following :—Emetine, cephaeline, and a third alkaloid (unnamed), ipecacuanhic acid, volatile oil, fat, resin, and sugar, all of which are probably contained in the official liquid extract. There are also present in the root pectin, waxy bodies, dextrin, mucilage, albuminous substances, starch (in large proportion), and colouring matter. Other principles of doubtful existence have also been described.

The resins of ipecacuanha have never been credited with either emetic, diaphoretic, or expectorant effects, and their entire or partial removal can hardly affect the medicinal action of any preparation of the drug, at least as far as those particular properties are concerned.

When an equal volume of water is added to liquid extract of ipecacuanha and the mixture allowed to stand the filtered liquid will generally be found to form a perfectly bright solution when diluted with detannated sherry wine, and the following process for rendering the official liquid extract "miscible" is based on this fact.

Liquid extract of ipecacuanha B.P.....	1,000 C.c.
Distilled water	1,000 C.c.

Mix, and allow to stand in a cool place for twenty-four hours. Filter and wash the residue on the filter paper with a little distilled water until colourless, keeping the washings separate. Acidify the filtrate with acetic acid, *q.s.*, to a very faint acid reaction. Distil by the heat of a water bath until the distillate (as shown by volume and sp. gr.) contains 400 C.c. absolute alcohol. This will generally measure about 520 C.c. Reserve this portion of the distillate, and continue the distillation to recover remaining alcohol. Evaporate the residue on the water bath to about 420 C.c. Allow to cool, and pour off the bright liquid from any slight deposit of oily or resinous matter adherent to the dish. Add this to the reserved distillate. Rinse the dish with the washings obtained in the first part of the process. Filter if necessary, and evaporate sufficiently to make the total volume of the preparation equal 1,000 C.c.

The finished product of the above formula gives a bright mixture with detannated wine, yields from 2 to 2·25 per cent. alkaloid by the B.P. method of assay, and compares favourably in point of aroma with the original preparation, nearly the whole of the odorous principles coming over with the reserved distillate. On determining the alkaloid in a sample of miscible extract there was found to have been no appreciable loss in the process. Similarly a glycerole of ipecacuahna may be prepared as follows :—

Liquid extract of ipecacuanha.....	1,000 C.c.
Distilled water	1,000 C.c.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

Mix as before, allow to stand, filter and wash the residue, evaporating the washings separately. Acidify the filtrate with acetic acid to a very faint acid reaction, distil off the alcohol, and evaporate on a water bath (adding the evaporated washings toward the end)

To	500 C.c.
Add Glycerin	500 C.c.

This also forms a clear solution with detannated wine, syrups or aqueous liquids. It contains the B.P. proportion of alkaloid, and for many obvious purposes furnishes a convenient preparation of ipecacuanha.

An alternative process for the direct preparation of miscible liquid extract of ipecacuanha was also tried, and found to work well. It is as follows:—

Ipecacuanha root in No. 120 powder	2,250 Gms.
Calcium hydroxide	225 Gms.
Alcohol (90 per cent.)	a sufficiency.

Pack the powdered ipecacuanha root lightly but uniformly in a conical percolator, add successive portions of 400 C.c. of the alcohol at intervals of twelve hours until the liquid begins to drop from the percolator; close the lower orifice, and set aside for twenty-four hours. Then percolate slowly until 700 C.c. have been collected. Continue the process as detailed in the Pharmacopœia. Recover the alcohol from the remaining percolates, evaporate on a water bath to a soft extract, dissolve in the reserved portion and assay by B.P. method. Finally dilute with alcohol (90 per cent.) to a volume that shall contain 5 Gms. of the alkaloids in 100 C.c.

Take of liquid extract of ipecacuanha (5 per cent.)	900 C.c.
Distilled water	100 C.c.

Mix, set aside for twenty-four hours in a cool place and filter. Wash the filter with sufficient distilled water to produce 2,000 C.c.

Ipecacuanha, when percolated with rectified spirit, can be used in the very finest powder, complete extraction of the alkaloids when coarse powder is employed being very tedious. By pouring the menstruum directly on the drug in a dry state, without previous moistening, as recommended above, and using the ipecacuanha in very fine powder, an intensely strong reserve percolate collects in the receiver. Even an alcohol as dilute as 20 per cent. will successfully percolate ipecacuanha in No. 120 powder provided the drug be first uniformly mixed with an equal weight of dry sand. The 5 per cent. liquid extract can also be made by repercolation, but the process just described is preferable.

The statement has frequently been made that alcohol of about 90 per cent. is the best solvent for extracting ipecacuanha; but very little published information exists on the value for this purpose of alcohol of other strengths. The only experimental investigation to determine the point appears to have been made by Mr. J. C. Umney some seven or eight years ago. He, however, worked with crushed root and an ammoniacal menstruum, somewhat different conditions to those obtaining in the case of a very finely powdered root and a purely alcoholic menstrum. It is easy to imagine that dilute alcohol, acting on a comparatively large mass of tissue, such as would be presented by crushed root, would extract the alkaloid from the cells at the surface with facility, but by the swelling of the water-soluble constituents its action on the cells in the interior of the mass of tissue would be impeded and the alkaloid would be imperfectly dissolved out by a limited volume of solvent. Under altered conditions different results may be expected, and the few experiments tabulated below apparently show that other strengths of alcohol are, with the drug in very fine powder, equally as effective as rectified spirit. Strong tinctures were prepared by macerating 1 part of ipecacuanha in No. 120 powder in 3 parts of alcoholic menstruum for three days, with frequent agitation. Equal portions of each were then filtered off, and the alkaloid strength determined by titration.

	No. 1 90% alcohol	No. 2 70% alcohol	No. 3 60% alcohol	No. 4 45% alcohol	No. 5 20% alcohol
Colour of tincture	Brown	Full brown darker than (1)	Deep brown, most intense colour	Brown between 2 and 3	Pale brown
Per cent. alkaloid	0·5	0·6	0·62	0·6	0·34

Of these tinctures, Nos. 1 and 2 gave a copious turbidity on dilution with detannated sherry. The 60 per cent. tincture showed but a moderate opalescence, and the 45 per cent. formed an almost bright mixture. It seemed probable, therefore, that an alcoholic menstruum of from 40 to 30 per cent. strength, if it could be made to extract the whole of the alkaloid and did not dissolve out an objectionable proportion of the water-soluble bodies of the root, might by simple percolation furnish a liquid extract miscible with wine. Experiments were, therefore, commenced in this direction, but I regret that the results were not sufficiently advanced to bring before this meeting of the Conference.

JOHORE IPECACUANHA.*

BY JOHN C. UMNEY AND RALPH S. SWINTON.

The recent importation of a quantity of ipecacuanha from Johore (Straits Settlements) is, at the moment when the drug is so scarce and of such high market value, of considerable importance. The root is with little doubt derived from *Psychotria ipecacuanha*, the species that yields the Rio or Brazilian root. In characters the root differs but little from that imported from Brazil, but in the particular shipment upon which these notes are based, the root was practically free from stem and the anulations more prominent.

In general appearance, however, there is but little difference as compared with a sample of bold picked Brazilian ipecacuanha root.

Microscopic examination of the powder of cultivated ipecacuanha imported from Singapore has already been made by Greenish (*Pharm. Journal* [3] **25**, 688), who reported that it is identical in physical character, in structure and in the size of the starch grains with the Brazilian root, and is practically indistinguishable from it

In the present instance microscopic examination of the powder. showed absolutely no differences as compared with powdered Rio root, free as far as possible from stem.

The *Chemist and Druggist* (May 26, 1888) states that a sample imported from Johore contained 1·4 per cent. of emetine, whilst Ransom examined a sample of the root cultivated in India and reported (*Pharm. Journal* [3] **18**, 400) that it contained 1·7 per cent. of emetine.

The chemical researches of Paul and Cownley on the ipecacuanha alkaloids and the physiological experiments of Dr. Wild, have made it possible on the one hand and necessary on the other to push the investigation further and ascertain whether the alkaloids contained in the root are the same as in the Brazilian variety, and in what relative proportions, if more than emetine only, they exist.

It will be remembered that the ratio of emetine and cephaeline in the Brazilian and Carthagena varieties is approximately as under (disregarding the small proportions of the third alkaloid) :—

	Emetine.	Cephaeline.
Brazilian	75	25
Carthagena	45	55

The processes detailed by Paul and Cownley (*Pharm. Journal* [4], **2**, 321) have been followed, which consist in extracting the total alkaloids with amyl alcohol and determining the proportions of cephaeline and emetine by taking advantage of the solubility of the former in soda solution.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

The proportion of total alkaloids was found to be 1·7 per cent., but some little difficulty was experienced in arriving at concordant results in the determination of the relative proportions of emetine and cephaeline.

The following are the mean of three experiments :—

		Percentage proportion.
Emetine	1·24 per cent.	72·94
Cephaeline	0·39 ,, ,,	22·94
3rd alkaloid or other alkaloids	0·07 ,, ,,	4·12
	1·70	100·00

These results point to the conclusion that the ipecacuanha root is, so far as the relative proportion of alkaloids are concerned, practically identical with the Brazilian, except that in the experiments that we have made there appears to exist a larger proportion of the third alkaloid, which may or may not be identical with that contained in the Rio ipecacuanha, which, in our experience, varies somewhat.

Without, of course, deciding upon the relative value of this Johore root upon one shipment only, as compared with the Brazilian, it appears to differ from it in containing a lower proportion of total alkaloids than the average Brazilian roots unmixed with stems.

Time has not permitted the extended examination of the other constituents of the root, but we have noted that the extractive yielded by the Johore root is not so great as that yielded by the Brazilian, and that the precipitate yielded by basic lead acetate solution in the extractive freed from alcohol, is very much greater in the case of the Rio root than the Johore.

These results may, of course, point to some difference in the value of the root for dysentery and allied purposes where its action may not be dependent upon the alkaloids that it contains.

So far as our observations go, however, there appears to be no reason why this root, which corresponds most closely with the official Brazilian variety, should not be used in medicine for standard preparations of ipecacuanha, unless of course it be proved that the third alkaloid, or other alkaloids, differ from that contained in the Brazilian root in character and have powerful physiological action.

THE ALKALOIDAL STRENGTH OF COMMERCIAL SAMPLES OF THE OFFICIAL PREPARATIONS OF JABORANDI.*

BY E. H. FARR, F.C.S., AND R. WRIGHT, F.C.S.

Pharmaceutical Chemists.

For several years past we have had great difficulty in preparing standard preparations of jaborandi from commercial samples of the leaves, and it occurred to us that an investigation into the strength of the tincture and liquid extract as found in pharmacy would not only serve to show whether such an experience was common to pharmacists generally, but might also yield results possessing some degree of interest to the members of this Conference. For the purpose of the inquiry twelve samples of each of the official preparations were obtained from various sources, and the results embodied in this note may be taken to represent the average strength of the preparations as found in pharmacy at the present time.

The process employed for the determination of the alkaloids was the one devised by us in connection with our previous work on the tincture of this drug.†

The details are as follows :—

Fifty C.c. of the tincture (or ten of the fluid extract) is acidified with dilute sulphuric acid and evaporated over a water-bath to a syrupy consistence, 30 C.c. of 90 per cent. alcohol added, and the mixture well stirred and allowed to stand for an hour. The liquid portion is then separated by decantation or filtration, the mucilaginous deposit dissolved in a little acidulated water, and the treatment with alcohol repeated. The dish and filter are rinsed with a little alcohol, the filtrates and rinsings bulked and evaporated over a water-bath, water being added from time to time until all alcohol has been removed. The residual liquor is transferred to a separator, the dish rinsed with a few drops of water, and the rinsings run into the separator. The liquor in the separator is rendered alkaline with ammonia, and the alkaloids shaken out with two successive 15 C.c. of chloroform. In order to obtain them in a pure condition, they are withdrawn from the chloroformic solution by shaking with acidulated water, 25 C.c. of distilled water being mixed with 2 C.c. semi-normal sulphuric acid, and the mixture used in three portions. The mixed acid alkaloidal solutions are then rendered alkaline, and the alkaloids shaken out with chloroform as before. The chloroform is removed by evaporation over a water-bath and the alkaloids dried and weighed.

The gravimetric results were in each case checked by titration, the alkaloids being dissolved in a little alcohol, a calculated excess of HCl/10 with some distilled water added, and the solution brought back with NaHO/20. Cochineal was used as the indicator. The results of the analyses are shown on the accompanying table.

Table showing the amount of alkaloids, in grammes, from 100 C.c. of the tincture and liquid extract of jaborandi.

No.	Tincture.	Liquid Extract.
1	0·025	0·240
2	0·032	0·090
3	0·024	0·190
4	0·050	0·210
5	0·084	0·090
6	0·020	0·160
7	0·022	0·120
8	0·012	0·090
9	0·044	0·190
10	0·064	0·030
11	0·040	0·170
12	0·018	0·210
Average	0·036	0·150

Before proceeding to indicate the principal conclusion to be drawn from these results, it will be well to consider for a moment the question as to what ought to be the approximate alkaloidal standard for a tincture and fluid extract, having in view the doses given in the British Pharmacopœia. Our calculations are based upon the average dose of the salts of pilocarpine, which may be taken at from $\frac{1}{20}$ to $\frac{1}{2}$ grain (0·0032 to 0·032 Gm.).

For a tincture having a fixed dose of from $\frac{1}{2}$ to 1 fluid drachm (1·8 to 3·6 C.c.) the alkaloidal standard should be about 0·15 per cent. (0·15 Gm. in 100 C.c.).

By a similar method of calculation the liquid extract should contain roughly from 0·8 to 1 per cent. alkaloids.

Looking at the question from this standpoint it is evident that the galenical preparations of the drug found in retail pharmacies at the present time are very deficient in strength, only containing about one-fifth the proportion of active constituents which, judging from the official doses, they are supposed to contain.

For this condition of things we do not think that pharmacists can be held altogether responsible. In the year 1891, in connection with our work on the pharmacy of jaborandi, we prepared a series of eleven tinctures, by the official process, from samples of the leaves then obtainable through the regular sources of supply. Two of these yielded practically 0·150 per cent. of alkaloids; eight gave over 0·1 per cent., and the average for the whole series was 0·105 per cent. At the present time, according to our personal experience, it is practically impossible to obtain a sample of the drug which will give a 1 in 5 tincture having an alkaloidal content of 0·15 per cent.

* Read before the British Pharmaceutical Conference, at Plymouth, July, 1899.

† *Pharm Journ.*, [3], **22**, 3.

What is the explanation of this state of affairs? The most feasible one seems to be that for some reason or other the true jaborandi leaves (or at any rate leaves of the best quality) are being withdrawn from the drug markets, and so prevented from coming into the hands of pharmacists at all. It may be that manufacturers of pilocarpine salts buy up all samples of leaves rich in alkaloids, for, as all of us know to our cost, the present price of these salts is quite prohibitive. *Pari passu* with this dearth of the genuine article, quite a number of substitutes have been thrown upon the drug markets. Some of these have been described and figured by Holmes,* Greenish† and others, and Paul and Cownley‡ have shown that nearly all are valueless as substitutes for the original drug.

The consideration of this subject leads to the pertinent question, are the official leaves obtainable, and if so, where are they to be had?

This is a question of great practical importance, because, should the reply be in the negative, we shall have the curious picture of an official drug which cannot be obtained from wholesale druggists, and of official preparations sometimes prescribed by medical practitioners, which are not to be found in the pharmacies of this country.

It is a question which may very appropriately be propounded at a Conference like this, and one to which our drug-brokers and pharmacologists ought, and doubtless will, be able to furnish a reply.

THE ASSAY OF PREPARATIONS CONTAINING PILOCARPINE AND THE CHARACTERS OF PILOCARPINE NITRATE AND HYDROCHLORIDE.§

BY H. A. D. JOWETT, D.SC.

Our knowledge of the alkaloids of jaborandi is in a very unsatisfactory condition, especially that relating to the assay of preparations containing pilocarpine and to the characters of the two salts used in medicine, viz., the nitrate and hydrochloride.

As regards the assay, it is possible to determine the amount of total alkaloid contained in the leaves or their preparations with a fair degree of accuracy. This information, however, is of little value, for it gives us no indication of the amount of pilocarpine contained in the total alkaloid, and it must be assumed that on the pilocarpine alone depends the therapeutic value of the preparation.

The nitrate and hydrochloride are somewhat largely used in medicine, but the official characters of these salts as given in the various Pharmacopœias are very unsatisfactory and hardly serve to identify the alkaloid, much less to determine its purity. The only salt of pilocarpine officially recognised by the B.P. is the nitrate, of which the following description is given :—

"A white crystalline powder, soluble in 8 to 9 parts of cold water, slightly soluble in cold, freely soluble in hot alcohol (90 per cent.)."

In commerce the salt generally occurs in distinct crystals and can always be obtained in this form. A little more definite information should be given as to its solubility, the factors above mentioned for water being incorrect. The test for identity which is given can hardly be considered distinctive, and depends on the oxidation of the base by chromic acid and the appearance of the green colour of chrome alum. The only other proof of identity required is furnished by a physiological test which could hardly be carried out by the analytical chemist or pharmacist.

The purity is determined by the absence of a residue after ignition Whilst this test would preclude any inorganic impurity, it would afford no discrimination between pilocarpine and a mixture of the other alkaloids of jaborandi, and indeed the alkaloid might be accidentally or intentionally mixed with an organic impurity and still meet the Pharmacopœia requirements.

* *Pharm. Journ.*, [4], **1**, 520.
† *Pharm. Journ.*, [3], **24**, 381.
‡ *Pharm. Journ.*, [4], **3**, 1.
§ Read before the British Pharmaceutical Conference at P mouth, July, 1899.

The characters and tests for the hydrochloride, which is official in the U.S.P. and German Pharmacopœia, are better than those given for the nitrate in the B.P., but still leave room for improvement. The hydrochloride is described as consisting of "white deliquescent crystals, easily soluble in water and alcohol, sparingly soluble in ether or chloroform." As this salt is exceedingly soluble in the two former solvents, the general statement is sufficient.

The melting point is given as 197° in the U.S.P., and the usual reactions for alkaloid and the inorganic acidulous radical are required as proof of identity. The freedom from inorganic impurity is ensured by the ignition test.

The chromic acid colour reaction is given in the U.S.P., but not in the German Pharmacopœia, but both give a test which distinguishes this from most other alkaloids, including most of the associated alkaloids of jaborandi.

This test is the non-formation of a precipitate on the addition of ammonia to an aqueous solution of the salt. A solution of sodium hydrate gives a precipitate only with a concentrated solution of the alkaloidal salt.

Allen ('Organic Analysis,' **3**, pt. iii., p. 37) states that the alkaloid gives no reaction with picric acid, but I have found that a yellow precipitate of the picrate is thrown down, which dissolves on warming, then separates out in needles on cooling.

Paul and Cownley (*Ph. J.*, **57**, pp. 1, 437) have made some important observations with regard to the pilocarpine nitrate and hydrochloride of commerce. They found that commercial specimens of pilocarpine nitrate were far from pure, three samples examined melting at 141·7°, 150·5°, and 167·2° respectively; further, the crystallised nitrate obtained by them from different kinds of jaborandi leaves melted at different temperatures, viz., from 151·5°–162·7°, but no proof was adduced that these were the melting points of pure chemical substances. According to these chemists, a salt described as "pure pilocarpine nitrate" melted at 141·7°, and when recrystallised from alcohol in different fractions gave no considerable alteration in the melting point. They have also examined samples of pilocarpine hydrochloride on the market and found indications of the presence of more than one alkaloid. They remark that a possible explanation given, viz., that the impurity present was jaborine, requires more definite proof.

Petit and Polonowsky* have examined the salts of pilocarpine and give the following constants :—

Pilocarpine nitrate	Prisms soluble in 7 parts of water at 18°, in 146 parts alcohol (95 p.c.) at 18°. Melting point 177°-178° $[\alpha]_D = + 82{\cdot}2°$.
Pilocarpine hydrochloride	Anhydrous prisms, soluble in 0·4 parts of water, in 10 parts alcohol. Melting point 200°. $[\alpha]_D = + 91°$.

They also state that commercial specimens examined contained an impurity, stated to be pilocarpidine, to as large an extent as 50 per cent.

These results, however, relate to chemically pure products, and it is not always advisable to insist on this degree of purity for chemicals required for medicinal use, owing to the extra expense incurred not being commensurate with the corresponding therapeutic advantage.

These results, therefore, required confirmation and also investigation as to the ease with which such impurities are removed, and the effect of small amounts of such impurity on the physical constants of the pure salt. The question has also been raised as to the identity of the alkaloid pilocarpine, when obtained from different species of jaborandi leaves, the results of Paul and Cownley being insufficient to answer this question.

In the present communication I give a method for determining the amount of pilocarpine in the total alkaloid, then proof of the identity of pilocarpine from different sources, and finally the characters and tests for pilocarpine nitrate and hydrochloride.

* *Journ. de Pharmacie* [6], **5**, 370, 430, 475, and [6], **6**, 8.

ASSAY OF PREPARATIONS CONTAINING PILOCARPINE.

Several methods are available for extracting the total alkaloid from jaborandi or its preparations, and any of these may be used to obtain the mixture of amorphous bases.

The varnish obtained is dissolved in a small quantity of a saturated alcoholic solution of pilocarpine nitrate, and to this solution is added a strong alcoholic solution of nitric acid (freshly prepared) until the solution is faintly acid, and it is then set aside to crystallise, after the addition of a small crystal of pilocarpine nitrate. It is then allowed to stand for two hours without concentration, stirred vigorously, and any crystals which have separated are filtered off, drained by the filter pump, washed with the saturated alcoholic solution of pilocarpine nitrate, dried and weighed. If no crystals separate the total alkaloid contains not more than traces of pilocarpine.

From the weight of crystalline nitrate thus obtained, the percentage of bases in the total alkaloid yielding crystalline nitrate can be calculated.

It is sufficient in most cases to assume this to be pilocarpine, but if a very accurate determination be required the melting point and specific rotation of the nitrates should be determined, and from these data can be calculated the amount of pilocarpine present. My experience, however, is that it is quite sufficient to take the melting point, and as this is generally above 170°, the calculation can be made on the assumption that the crystalline nitrates consist entirely of pilocarpine. Assuming the other impurity to be pilocarpidine, and the constants given for that salt by Petit and Polonowsky to be correct, the percentage of pilocarpine present could be determined from the specific rotation of the mixed nitrates by the following formula :—

$$p = \frac{100}{43{\cdot}7 \times}\ (x - 38{\cdot}5)$$

When p = percentage of pilocarpine present in mixture, x = specific rotatory power of salt examined.

Good results will be obtained by this method of assay if as much as 0·5 Gm. of total alkaloid be taken.

The melting point will also serve as an indication of the proportion of pilocarpine present, if above 174° it may be calculated as pure pilocarpine, if from 167° – 174° from 80 – 90 p.c. pilocarpine

If the product melts below 167° it should be recrystallised from a small quantity of hot absolute alcohol and the weight taken of the crystalline nitrate thus obtained, and proceeded with as above. Whilst not claiming that this method gives results comparable in accuracy either with the methods for inorganic or organic analysis, or even those for determining the amount of total alkaloid, yet I do claim that it is more important to know, within limits of even 5 per cent., the amount of pilocarpine in the total alkaloid than to be able to determine the latter factor with greater accuracy, since this figure gives us absolutely no information as to the amount of pilocarpine present, whilst the method described does so within the limits of experimental error above indicated.

CHARACTERS OF PILOCARPINE NITRATE AND HYDROCHLORIDE.

In order to be certain of the identity of pilocarpine nitrate from various sources, I prepared the salt from two varieties of jaborandi leaves, viz., the true jaborandi and the small leaved variety, Maranham jaborandi, and I also purified some pilocarpine nitrate purchased from two manufacturers. I found that, contrary to the statements of Paul and Cownley, and Petit and Polonowsky, the nitrate is easily purified by repeated recrystallisation from strong alcohol, and this method was used to purify the salts.

The proof of the identity of the pilocarpine nitrate prepared from these different sources and of its chemical purity was furnished by the fact that the salt, after several recrystallisations from different solvents and when obtained in different fractions, underwent no change in the melting point or specific rotatory power, and that the physical constants of the purified salt from every source were identical. The physical constants of the pure salt were :—

	Jowett.	Petit and Polonowsky.
Melting Point	178°	177 – 178°
$[a]_D$ +	82·9°	+ 82·2°
Solubility in water	1 in 6·4 (at 20°).....	1 in 7 (at 18°).

A further proof of the identity of pilocarpine nitrate as obtained from different sources is furnished by the agreement of the factors obtained by me and those given by Petit and Polonowsky.

I am unable to understand why a sample of pilocarpine nitrate, melting point 141·7°, when recrystallised from alcohol in different fractions should give no alteration in the melting point, as I obtained the following results with a commercial specimen melting at 168°, and I have never met with a preparation with a lower melting point than 167°.

Melting points of pilocarpine nitrate after recrystallisation from alcohol :—

Melting point of original salt	=	168°	
After first recrystallisation	=	175°	
„ second „	=	176°	
„ third „	=	176°	
„ fourth „	=	178°	and $[a]_D$ = + 82·34°

The specimen referred to by Paul and Cownley must have been very impure.

I am able to confirm the observations of other chemists that the pilocarpine nitrate of commerce is impure. Two specimens were examined by me from different manufacturers, and both yielded by recrystallisation about 85 p.c. of pure pilocarpine nitrate.

The examination of these specimens gives the following results :—

A. Melting point 167° . $[a]_D$ = + 77·88°
B. Melting point 168° . $[a]_D$ = + 79·08°

The impurity consisted of a crystalline nitrate of much lower melting point and specific rotatory power. This would appear to be possibly pilocarpidine nitrate, but I am not in a position at present to state whether this is the case.

Pilocarpine hydrochloride was prepared in the usual way through the base from pure pilocarpine nitrate, and then purified by repeated recrystallisation till the melting point and specific rotary power were unchanged by further treatment.

The pure salt had the following physical constants :—

	Jowett.	Petit and Polonowsky.
Melting point = 204	— 205	200°
$[a]_D$	+ 91·74°	+ 91°

I attribute the higher figures obtained by me to the greater purity of the salt examined as though made from pure pilocarpine nitrate, it melted at 202°, but after recrystallisation at 204-205°.

The hydrochloride described by Paul and Cownley as melting at 192°-196° must have been impure, but there is no reason to suppose that this impurity was different from that found in the nitrate, and stated to be pilocarpidine, as I have found that the nitrate of low melting point obtained from commercial pilocarpine nitrate yields a hydrochloride melting below 200°; this would be a likely impurity. Having thus determined the physical constants of the pure substances I am able to suggest characters and tests for these salts. With regard to their purity I should not recommend that absolute purity be required, as the removal of the last traces of the other alkaloid requires an amount of recrystallisation out of proportion to the amount of impurity originally present. A nitrate melting at 175°-176° would not contain more than 1 per cent. of impurity, but would require three or more recrystallisations to be completely purified.

I would therefore suggest the following characters and tests :—

Pilocarpine Nitrate.—White distinct crystals, permanent in the air. Soluble in 6 to 7 parts of water at ordinary temperatures, and in 146 parts of cold alcohol (95 per cent.), and fairly soluble in boiling alcohol; almost insoluble in ether or chloroform.

When heated in a capillary tube the salt melts at 176° to 178°. The specific rotatory power in aqueous solution should be + 81° to

+ 83°. On ignition the salt yields no residue (absence of inorganic impurity). A concentrated aqueous solution gives no precipitate on the addition of ammonia water or aqueous solutions of sodium or potassium hydrate (distinction from most other alkaloids). Affords the characteristic tests for nitrate.

Pilocarpine Hydrochloride.—White crystals, deliquescent in damp air. Soluble in less than its own weight of water, and in 10 parts of absolute alcohol; almost insoluble in ether or chloroform.

When the salt, dried at 100°, is heated in a capillary tube, it melts at 200° to 204.

The specific rotatory power in aqueous solution should be + 90° to + 92°. On ignition the salt yields no residue (absence of inorganic impurity). A concentrated aqueous solution gives no precipitate on the addition of ammonia water, and only a few oily drops, on the addition of aqueous solution of sodium or potassium hydrate, which quickly redissolve (distinction from most other alkaloids). Affords the characteristic tests for chlorides.

These characters and tests would ensure such a product as would seem suitable for medicinal use; but if it be thought desirable that the chemically pure salts should be used, then the constants given for these salts must be used.

DELPHINIUM STAPHISAGRIA, L.*

BY E. M. HOLMES, F.L.S.,

Curator of the Museums of the Pharmaceutical Society.

Having been accustomed to grow *Delphinium staphisagria* in my garden from seedlings obtained by exchange from various botanic gardens, and knowing by experience that it is almost impossible to raise the plant from the commercial seed employed in pharmacy, I had, until lately, naturally supposed that the plant grown in botanic gardens was correctly named. It was only when I received seeds of *Delphinium staphisagria* from a continental botanic garden that I noticed that they were much smaller than, and had not the greyish tint characteristic of, those sold by druggists. When they were sown they produced the plant already well known to me by its pale lilac flower, a spur nearly as long as the calyx, pubescent stems, and a rigid habit different to other garden larkspurs. Judging from their larger size and greyish colour that stavesacre seeds could not be produced by this plant, I obtained last year, through the good offices of Messrs. Potter and Clarke, some fresh seed of the commercial kind, but on sowing them only two germinated. These, however, showed by their very hairy stem and leafstalks and the shape of the leaves that the plant was different to that which I had previously cultivated under the name of *Delphinium staphisagria*. Unfortunately the seedlings died during last winter, and I therefore, through the kindness of the same firm, obtained last April some living plants from the district where the seed is grown. One of these, forwarded to Kew Gardens, and another to the Botanic Gardens at Cambridge, flowered in June. The flowers were of a bright blue colour, with oval, obtuse sepals, and a very short spur, not exceeding two lines long. The stem and petioles, as in the two seedlings I had raised, were densely covered with spreading, long, soft hairs, intermixed with shorter glandular hairs. On comparing the plant with the specimens of *D. staphisagria* in the National Herbaria at Kew and South Kensington, I found that this plant was undoubtedly the *Delphinium staphisagria* of Linnæus, if the herbarium specimens were correctly named. To make sure of this, I compared it with Linnæus' own specimen in his herbarium, in the possession of the Linnean Society at Burlington House, with which I found it to correspond perfectly. There can, therefore, be no doubt that the plant at present in cultivation in botanic gardens in this country is not *Delphinium staphisagria*. A comparison of it with published figures of *Delphinium staphisagria* reveals the fact that in books, as well as in botanic gardens, two species have been confused under this name. The plant with pale lilac flowers evidently agrees with the figure given in Woodville's 'Medical Botany,' tab. 154, which is quoted by De Candolle ('Prodromus' i., p. 56) as being *Delphinium pictum*, Willd. To this species, therefore, the ordinary garden plant must be referred. By De Candolle, three species are separated from the rest of the genus *Delphinium* as a distinct section, characterised by the ventricose follicles, large seeds, short spur, and biennial habit. These are named *D. pictum*, Willd., *D. requienii*, D.C., and *D. staphisagria*, L. They are distinguished as follows:

D. requienii.—Spur usually as long as the calyx, petioles pilose.

D. pictum.—Spur scarcely shorter than the calyx, petioles pubescent.

D. staphisagria.—Spur very short, petioles pilose. One of the distinctive characters given by De Candolle under D. Requienii, viz., bratclets inserted on the middle of the pedicels, does not seem to be a constant feature, and the character that the length of the pedicels is "scarcely longer than that of the flower" in *D. pictum*, "twice as long" in *D. staphisagria*, does not appear to be dependable, the length of the pedicels varying from the base to the apex of the raceme in both species. No clue is given by this author to the colour of the flower nor to the shape of the petals or sepals. Nevertheless, the two plants *Delphinium pictum* and *D. staphisagria* are very distinct in possessing the following features:—

D. staphisagria.—Stem with long, soft spreading hairs intermixed with glandular hairs. Flowers bright blue with broadly elliptical sepals; spur very short, or almost obsolete; half hardy, growing best in shade; follicles ventricose, 10Mm. diam., 20 Mm. long, with long styles; seeds large, 1-5.

D. pictum—Stem pubescent, with shorter hairs. Flowers pale lilac with narrowly elliptical sepals; spur nearly equalling calyx in length; hardy, growing well in sunlight; follicles 5-6 Mm. diam., 15 mm. long, with shorter style; seeds smaller, 1-12.

In the latest monograph by Huth (Engler 'Botanischer Jahrbucher,' 1895, p. 481), *Delphinium pictum* is made a variety of *D. requienii*. This plant is, however, so rare in our national herbaria that it is difficult to point its distinctive features. In such specimens as I have seen the 5-7 linear segments of the upper leaves are very different from the 3, usually oblong, lanceolate segments of the upper leaves in *D. staphisagria*. The spur is as long as the calyx and the follicles are less ventricose.

The best illustrations of the three species that I have been able to find are as follow:—

Delphinium staphisagria (Linn. Sp. 750), T.F.L., Nees von Esenbeck, 'Pl. Med.,' tab. 394 (1832).

Delphinium pictum (Willd. Enum. 574), Woodville 'Medical Botany,' tab. 154 (1752).

Delphinium requienii (D.C., 'Fl Franc.' 5, p. 642), Delessert 'Icones Selectæ,' tab. 63 (1820).

In Nees' figure the sepals are rather more pointed than in the living plant, but as the illustration was drawn from a dried plant lent for the purpose by Professor Reichenbach, this may account for the inexactness of their shape. In every other respect it is an admirable representation of the plant. In a footnote, Nees von Esenbeck remarks that *D. staphisagria* is often confounded with *D. pictum*, a nearly allied species occurring abundantly in gardens, whilst *D. staphisagria* is rarely cultivated, and that *D. pictum* is distinguished by its less hairy stem, much shorter flower stalks, pale flowers, longer spur, and smaller seeds. The cultivation of the wrong species, under the name of *Delphinium staphisagria*, was also noticed in 1834 by Professor Wenderoth, who published an article on the subject in the *Pharmaceutische Centralblatt* of that date, in which he states that the seeds of *Delphinium pictum*, Willd., or *D. requienii*, D.C., were received from botanical gardens under the name of *D. staphisagria*, L., and remarked that the seeds were black instead of greyish brown, and barely half the size of stavesacre seeds. He, therefore, tried to grow the plant from the

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

commercial seeds, and after numerous fruitless efforts at last succeeded. The plant he obtained he considered to be new (and gave an illustration of the plant in 1835 in the same journal, sup. 1, p. 76), and named it *Delphinium officinale*, which he described as follows:—

D. villosum et villosi-glandulifcrum, caulc simpliusculo; foliis urceolato-palmatis, 5-7 *lobis, lobis inciso-dentatis, laciniisve integerrimis, acuminatis, pedunculis bracteolas, floresque longe superantibus.*

There is nothing in this description to indicate that Wenderoth's plant is distinct from *D. staphisagria*, Linn.* But he apparently founds his idea upon Sibthorp's figure in the 'Flora Græca,' since he says that the *D. staphisagria* has violet flowers tinged with yellowish green, almost as in *D. pictum*, only more vivid, larger in all dimensions, the filaments bent outwards in a semi-circle, and the anthers brown. The concave leaves and the more divided root leaves he considers characteristic of his *D. officinale*. But the flowers of Linnæus' specimen of *D. officinale* are blue, and the leaves are more or less concave in *D. pictum*, as well as in *D. staphisagria*, and the anthers are also brown in the latter before dehiscence. Professor Wenderoth therefore offers no characters for *D. officinale* that are not found in the *D. staphisagria* of Linnæus.

It seems probable that the confusion of ideas which has existed during the last two centuries concerning the stavesacre plant is largely due to the fact that the true plant is not hardy in our climate, whilst *D. pictum* appears to bc so. The following data will show how imperfectly the true plant was distinguished.

In 1578, J. Camerarius, in his 'Epitome de Plantis Matthioli,' p. 947, figures the plant with a short spur and a lower leaf quite correctly, with seven divisions, but in 1633, Gerard, in his 'Herbal,' figures it with a long spur, although he seems to have known the true plant, since he remarks, "It is with difficulty preserved in our cold countries, albeit in some mild winters I have kept it covered with a litle Ferne to defend it from injury of the March winde, which doth more harme unto plants that come forth of hot countries than doth the greatest frosts."

In 1737, Blackwell, in 'Herbarium Blackwellianum,' tab. 265, figured the flower correctly, but the fruit and seeds incorrectly.

In 1752, Woodvillc figured *D. pictum* under the name of *D. staphisagria*.

In 1806-1840, Sibthorp, in the 'Flora Græca' gives what is apparently a Grecian form of *D. staphisagria*, differing from the Linnean plant in the flowers being of a pinkish purple, tinged and striped with green (not pure blue), although agreeing in the short spur, and ventricose, but not ovate follicles. The figure in Stephenson and Churchill's 'Medical Plants,' 1837, **2**, No. 55, is copied from Sibthorp's work.

In 1830-1832, Reichenbach, in his 'Flora Germanica,' **4**, pl. 69, No. 4674, gives a good figure of the plant but no lower leaves.

In 1875-1880, Bentley and Trimen ('Med. Plants,' **1**, pl. 4) figured a plant obtained from the Apothecaries' Garden, at Chelsea, which appears to have been *D. pictum*, but which the artist has apparently modified in his drawing by adding the hairy character taken from specimens of true *D. staphisagria* in the Herbarium of the British Museum, where the drawings were made. Dr. Trimen's remark that the seeds in each follicle are 1—12 also indicates that the plant was not *D. staphisagria*.

In 1898 Koehler ('Med. Pflanz.,' **3**, 67) gave a figure of *D. staphisagria* with a short spur to the flower, but apparently taken from a genuine dried specimen, or possibly from Reichenbach's figure modified by a fresh specimen of *D. pictum*, since the colour of the flower is given as a greyish blue, or deep violet with a greenish apex, and the stem as pubescent, not villous. The petals also are represented as less oval and the follicles less ventricose than in the true plant. But the only figure hitherto published, which is worthy of reference in any future Pharmacopœia is that by Nees von Esenbeck, and this should replace the very composite and incorrect figure given in Bentley and Trimen's 'Medicinal Plants.'

The most recent and full description of the plant is given by Huth in his 'Monographie der Gattung "Delphinium"' published in Engler's *Jahrb.*, 1895, p. 481, etc. The chief distinctive features mentioned by Huth, in addition to those already referred to, are the greater height of *D. staphisagria*, 30-100 Cm. (*D. requienii*, 30-50 Cm.), the sepals "cœruleis virenti-vittatis rarum pallidis vel albis," the ventricose carpels 10 Mm. diam., 20 Mm. long, and the seeds 1-4, large, 5 Mm. in diameter, and of *D. requienii*, the bluish colour of the flowers. This author makes *D. pictum* a variety of *D. requienii*, with variegated leaves, and enumerates a second variety named "muscodorum" with more slender stem leaves and carpels, and a musky odour.

The true *D. staphisagria* extends from Tencriffe around both the northern and southern coasts of the Mediterranean to Asia Minor, according to specimens in the British National Herbaria in London from those regions. It is quite possible, therefore, that varieties having blossoms of different tints may occur. The evidence obtainable goes to show that the form of the plant from which the seed of commerce is obtained has clear blue flowers. The exact country from which the seeds are imported I have been unable to learn with certainty, but believe them to come from the Adriatic *via* Trieste. Camerarius speaks of the plant as growing wild at Crepanum in Illyria, but it is probably cultivated also.

* See also *Botanische Zeitung*, 1853, pp. 155-157.

ON THREE NATURAL RUBBER SUBSTITUTES.*

BY DAVID HOOPER, F.C.S., F.L.S.

There is a growing demand in Europe for indiarubber and guttapercha, principally on account of the needs of tyre manufacturers on the one hand, and those of electrical apparatus makers on the other. The produce of rubber-bearing districts is being drawn upon to an unprecedented extent, and the prices of the crude article are maintained sufficiently high to encourage enterprise among collectors and traders; any information with regard to new sources of supply readily arouses an interest, and inquiries by experts are at once established to compare samples with those of recognised origin.

The three elastic gums which form the subject of this paper were collected for the Department of Economic Products to the Government of India, and specimens of two of them were handed to me for examination by Dr. George Watt, C.I.E., the Official Reporter of the Department. The products are all peculiar to India, and allusion has been made to them at various times in departmental records and public journals, but, so far as I can ascertain, no adequate analyses appear to have been made, either of the natural exudations or of the coagulated rubbers.

The first substance of this kind which might be described is that obtained from the stem of the Banian (*Ficus bengalensis*), a tree with peculiar aërial roots growing from its branches, which is frequently met with in the plains. The sister tree, *Ficus elastica*, affords the indiarubber of Assam and Burma, and I am not aware that any other species besides this one is used for producing commercial rubber, notwithstanding the large number of plants belonging to this genus, which are indigenous in India and Malaya. Watts' 'Dictionary of Chemistry' records an instance of the gum from *F. Vogellii* yielding 33 per cent. of rubber, but on account of this small proportion it was considered of too low a quality to be of use to the trade. The sample of Banian tree gum was sent under the suspicion that it was used for the purpose of mixing with Assam rubber, and an opinion was asked as to whether such an admixture would be regarded as an adulteration. No very large quantity of it could be collected at the time of year when such juices are yielded,

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

and this, of course, would be a serious drawback in the event of a demand arising for the gum.

The rubber had a dirty white appearance, a sourish odour, and a tough consistence. It sank in water. In testing it with various solvents, it was found to dissolve without previously swelling in ether, chloroform, or carbon bisulphide. This property distinguishes it at once from the rubbers of *Ficus elastica* and *Hevea brasiliensis*. Another character was the perceptible loss it experienced when boiled with alcohol. In conducting a proximate analysis of the crude rubber, an estimation was made for moisture and ash in one portion of the cake, and another portion was boiled with alcohol (90 per cent.) to remove resinous matters. A soluble crystalline substance was extracted by means of boiling distilled water. The following results were obtained:—

Water	4·06
Resins	65·24
Caoutchouc	19·82
Aqueous extract	3·64
Ash	2·06
Dross, etc., undetermined	5·18
	100·00

The resins consisted of alban and fluavil in nearly equal proportions; the former occurred in white crystals melting at 175° C. and the latter was amorphous and yellow and softened at 50°. The purified caoutchouc was brownish in colour and possessed very feebly elastic properties. The large proportion of resins present in the gum is a damaging feature, and the analysis is not calculated to attract the attention of manufacturers of rubber goods to the secretion.

The second article which has been tried as a substitute for india-rubber, or rather of gutta-percha, is obtained from two common wild plants, *Calotropis gigantea* and *C. procera*, known in the vernacular as *Madar*. The milky juice or latex of these species of *Calotropis* have long been known to yield a form of gutta-percha. Dr. Riddell, of the Nizam's Army, pointed out this fact in 1852. In 1853 a small quantity of the separated gutta was examined by Professor T. Redwood, who found it to possess many properties in common with gutta-percha of commerce. Sir Richard Shakespeare, the Resident of Gwalior, subsequently caused the electrical properties of the gum to be tested, and the result showed that it was a bad insulator. Col. Pitcher, of Lucknow, also reported that it was unsuited for cable-making purposes, as it was a good conductor of electricity.

Dr. C. J. H. Warden, of Calcutta, made a very complete examination of the madar plant in 1885, and obtained from the bark a white crystalline resin madar-alban, a yellow resin madar-fluavil, black and bitter resins, besides a considerable proportion of caoutchouc. Dr. Warden tabulated the results of his analysis according to the percentages of proximate principles found in the bark. By calculation we are able to obtain the proportion which the various resinous principles bear to each other:—

Madar-alban	12·66
Madar-fluavil	48·86
Black acid resin	19·72
Caoutchouc	16·92
Yellow bitter resin	1·84
	100·00

The amount of caoutchouc is exceptionally low, and judging from the composition of analogous gums, Calotropis gutta would doubtless be condemned by the trade.

Confirmation of the above was sought by analysing, last March, a sample of the milky juice freshly obtained from the plants growing in Bengal. The latex was milky-white in colour, and had a strong nauseous odour, and a specific gravity of 1·0416 at 15° C. The liquor was miscible with water, but was coagulated on boiling, and precipitated with rectified spirit and solutions of ferric chloride and mercuric chloride. It yielded 18 per cent. of solid matter after boiling and washing the juice. The freshly separated and washed gutta was white, tough, and feebly ductile in the cold. A small portion was dried and boiled repeatedly with alcohol (90 per cent.) until nothing further was dissolved. The solvent removed 62 per cent. of resins consisting of madar-alban and madar-fluavil, and 25·54 per cent. of insoluble gum was left. This purified gum was soft, light brown in colour, and slightly elastic in the cold.

I have recently been informed that the Director-General of Telegraphs, Cairo, has experimented with Calotropis juice, and he found that it contained 40 per cent. of pure gutta. On testing this substance he found that the molecular arrangements were not the same as those of good gutta-percha, and he was not aware of any suitable process for improving its physical properties. There is no doubt that the resins which are intimately associated with caoutchouc play an important physiological part in its formation, and when the constitution of these bodies are more thoroughly studied, it is hoped that what are at present looked upon as bye-products will eventually, by chemical methods, be converted into useful compounds with highly elastic properties.

The third substance which I am about to describe as a rubber substitute is the coagulum of the milky juice of *Excœcaria agallocha*, Linn. This tree inhabits the tidal forests of India and Burma, and the sap which exudes from the bark when it is cut is said to be poisonous, hence the name "Blinding Tree" which is sometimes applied to it. The juice is certainly very acrid, and causes intense pain to the woodcutters who by accident happen to get some of it into their eyes. The name "Arbor Excœcans" given to the tree by Rumphius, is attributed to this cause. The Conservator of Forests, Southern Circle, Madras, states that a tree supposed to be this species is known in Travancore as the "Tiger's Milk Tree," as the juice is said to blister the skin. The Dictionary of Economic Products' says that the juice "remains fluid when preserved in a bottle, but it hardens when exposed to the air into a black caoutchouc-like substance."

During a tour made last October in the district of the Sunderbans, Bengal, I was able to collect a small supply of the milky juice. The *Excœcaria agallocha* in this district is called *Gengwa*, and the tree is largely cut for fuel, and sold to merchants in Calcutta. The tree is genuinely dreaded by the woodcutters on account of the irritating nature of the juice, but as this flows freely at certain times of the year, and is known to yield a kind of rubber, I was asked by the officer of the Forest Department to particularly ascertain its value in this respect.

The latex was a milk-white liquid, having an acid reaction and an odour of sour milk. It remained in a closed bottle for several weeks without separating or changing in colour. It mixed freely with water, but coagulated below the boiling point, and was also precipitated when spirit was added. The specific gravity at 15° C. was 1·0718. The following is an analysis of the latex:—

Water	61·94
Resin (fluavil)	28·85
Sol. in water	1·76
Albumin soluble	3·40
„ insoluble	4·05
	100·00

The resin, which was soluble in alcohol, ether, chloroform and bisulphide of carbon, was a clear, amber-coloured body, softening at 45° C., and fluid at 55°; it was unaffected by caustic soda solution and the diluted mineral acids. The resin gave off the odour of caoutchouc when burning, and produced a smoky flame peculiar to hydrocarbons. These characters are those of fluavil, but in this case it was unaccompanied by any substance related to caoutchouc or the white crystalline alban.

The soluble albumin coagulated like the white of egg when boiled with water; the insoluble albuminous matter remained after extract-

ing the gently evaporated juice successively with carbon bisulphide, alcohol, and distilled water. The acrid principle was removed with the fluavil-like resin.

An analysis has recently been published* of the milky juice of the *Excœcaria dallachyana*, Benth. a native of Australia. The examination was made by Mr. J. C. Brünnich on a sample of the juice which had a strong smell and a slight acid reaction; it was somewhat decomposed, and had a specific gravity at 15° of 1·0578. The report certified to the following composition:—

Water	61·65
Caoutchouc sol. in naphtha	19·61
Resins sol. in ether	0·58
Tannin sol. in alcohol	5·52
Pot. salts and org. acids, sol. in water	4·07
Albuminoids insol. in water	6·54
Undetermined and loss	2·03
	100·00

The centesimal composition of this juice has certain points of resemblance with that from the Indian species, but it is evidently not adapted for commercial purposes with its irritating properties and alcohol-soluble resins.

Although the three rubber-like substances may have no industrial future, I believe a useful purpose has been served in drawing attention to them in this paper, and giving what information we possess in order that inquiries for more suitable substitutes might be made in other directions.

THE LIBERATION OF CO_2 FROM SODIUM BICARBONATE BY HEAT.†

BY C. S. DYER.

The investigation of the above subject was taken on account of the absence of information in the text books, its importance in certain branches of pharmacy, and the somewhat misleading statements which have recently been published.

During my inquiry last year on the granular preparations, the question arose as to whether sodium bicarbonate decomposed in itself during the heat of granulation to any extent, and to test this point a small quantity was heated in an air bath for ten minutes at a temperature of 100°-105° C. and then weighed. The loss was about 2 per cent. This was assumed to be largely moisture, and the practical stability of the salt under those conditions was taken for granted without further experiment.

Since that date a paper by Mr. Cowie was read at Edinburgh, where he stated and maintained that bicarbonates decompose at a temperature of between 50° and 60° C. This surprising assertion naturally called for the clearing up of the matter.

Three processes were adopted, and the examination of the salt was carried out for comparatively short periods and at moderate temperatures only.

First Method.—There is the plain heating of the salt in an air bath and noting the loss in weight.

Second Method.—The volumetric method: that is, connect a tube containing the weighed salt with a nitrometer filled with mercury; heat the tube in a sulphuric acid bath and measure the gas evolved at various temperatures.

Third Method.—Heat the weighed salt in a U-tube immersed in a water bath; connect with potash bulbs and calcium chloride tubes; pass dried air through all and weigh separately the CO_2 and H_2O evolved, and check result by weighing the decomposing salt.

The apparatus is similar to that used for carbon combustions, substituting the U-tube for the combustion tube and furnace.

The results of the first and simplest method are as follow:—

$NaHCO_3$, 10 Gm., heated for ten minutes at 100° C., lost 0·77 per cent.; $NaHCO_3$, 10 Gm., heated for ten minutes at 100°-108° C., lost 0·93 per cent. additional; $NaHCO_3$, 10 Gm., heated for ten minutes at 105°-110° C., lost 1·27 per cent. additional; or, total loss, 3·17 per cent. 100° C. was the lowest temperature tried by this method.

So after heating for thirty minutes at temperatures 100°-110°, only 3.17 per cent. loss occurred. This simply bears out my last year's experiment, but does not carry much information.

The second method: 0·488 Gm. contained in a tube connected with a Lunge nitrometer filled with mercury was heated for periods of ten minutes successively at various temperatures with an interval between each to allow the gas to cool and be measured. Here are the results:—The 0·448 $NaHCO_3$ can evolve 65 C.c. of CO_2.

Centigrade temperature.		Time exposed.	Quantity of CO_2 evolved.
60°	Cooling interval between each.	10 minutes.	*Nil.*
80°		" "	*Nil.*
90°		" "	0·6 C.c.
100°		" "	1· C.c.
120°		" "	2· C.c.

After this the heat was continuously raised without cooling intervals to 178° C., fifteen minutes being the time so used.

130°	No interval	15 minutes aggregate.	9 C.c.	These of course are too high, as the amount of CO_2 evolved was read while the gas was hot.
135°			10 C.c.	
140°			14 C.c.	
150°			20 C.c.	
155°			25 C.c.	
160°			32 C.c.	
178°			50 C.c.	This after cooling declined to 33 C.c.

So the loss of CO_2 by weight up to 120° was 0·86 per cent. out of a possible 25 per cent. This is very slight, owing to the absence of air circulation. The loss at the high temperature at the end of experiment was only 15 per cent. of CO_2, or a little more than half the possible loss if the whole of the salt was converted into normal carbonate.

The third method: As previously described the weighed salt was successively heated for ten minutes at different temperatures, then removed from source of heat, and air was still passed through the apparatus for three minutes to wash out all traces of H_2O and CO_2.

The mean of a number of experiments is tabulated below; the quantity of salt used is calculated to 1 Gm.

No. of Experiment.	Temp.° Centigrade.	CO_2	H_2O.	Per cent. Loss in Weight of CO_2.	
				Each Experiment.	Aggregate.
1	50°—60°	0·0005	0·001	0·0015	
2	70°	0·001	0·003	0·004	0·0055
3	80°	0·001	0·004	0·005	0·0105
4	90°	0·007	0·005	0·012	0·0225
5	100°	0·012	0·006	0·018	0·0405
6	105°	0·021	0·009	0·030	0·0705
7	110°	0·040	0·016	0·056	0·1265

To comment on this table it appears that the liberation of CO_2 is practically *nil* at 60° C., and under then at 70° to 80° chiefly H_2O comes off, and, after the gas is set free, in regular increase as the heat rises.

Now a loss by heat alone is possible to the extent of 36·9 per cent. as expressed by the equation—

$$2NaHCO_3 = H_2O + CO_2 + Na_2CO_3$$

Examine the above table at 105°. When the salt has been heated for an aggregate period of one hour, only 7 per cent. by weight is lost, scarcely one-fifth of the total possible amount under these rather severe conditions.

As regards Mr. Cowie's experiments I have no doubt that they were perfectly accurate, but finding traces of CO_2 by a delicate test on exposing a bicarbonate to a temperature of about 55° C., is, in my opinion, not sufficient ground for declaring that the salt decomposes at that temperature to any practical extent, and probably the traces of CO_2 merely came over with the smal amount of moisture usually present. At temperatures below 100° dry sodium bicarbonate decomposes slowly; below 60° scarcely a all, and above 120° decidedly rapidly.

* *Queensland Agricultural Journal*, October, 1893, p. 285.

† Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

THE DETERMINATION OF DIABETIC GLUCOSE. PICRIC AND FEHLING METHODS COMPARED.*

BY R. H. PARKER, F.C.S.

Of the many available methods for the quantitative determination of diabetic glucose, the picric and Fehling tests offer most advantages to the busy pharmacist, particularly to such as cannot conveniently set apart counter space for the exclusive use of special apparatus.

The picric method is rapid, and with close attention to manipulative detail, constant results are easily obtained. The necessity however, of removing creatinine and other "interfering substances" in order to deal with small percentages of sugar, involves the expenditure of too much time for clinical purposes.

The Fehling method, when dealing with high percentages, is perfect, but if the sugar falls below 2 per cent, the cuprous oxide usually refuses to subside, so that rapid reading is impossible. Gerrard's "cyano-cupric" and Pavy's "ammonio-cupric" modifications dispose of this difficulty, but are less convenient, and for very small percentages their precision is marred by the colour reactions of normal constituents.

Noting the beautiful precision with which the Fehling test invariably reacts when dealing with high percentages, it occurred to me that the same result might be realised with specimens under two per cent. by adding a known quantity of glucose before determination. This proved eminently satisfactory, an aqueous solution of commercial glucose of known strength (from 6 to 8 per cent.) being used for the purpose; but as diabetic glucose reacts with Fehling's solution much more sharply than commercial glucose, even better results attend the use of a diabetic urine of similar sugar strength, preserved with 1 per cent. of formalin. On adding this to an equal volume of a sample giving the "non-subsiding" yellow cuprous oxide the mixture may be determined immediately, the Cu_2O then coming down as a dense, rapidly subsiding red precipitate.

Having observed occasional discrepancies between the Fehling and picric determinations, I have for a considerable period assayed samples by both methods, and in the following table the results are recorded arranged in sequence according to the amount of sugar indicated by Fehling. The Fehling's solution was taken as equivalent to 0·5 per cent. of glucose, and the value of the picric standard colour was fixed by the results obtained with the high percentage urines, and found to equal 0·059 per cent. Taking this as unity I have usually recorded the "picric indication" by a numeral indicating multiples of this unit.

TABLE I.

Fehling and Picric results compared.

Sample.	Glucose found, Fehling Method.	Glucose found, Picric Method.	Ratio of Results, F. to P.	Sp. Grav. of Sample.
	Per Cent.	Per Cent.		
1	0·2	0·33	1 : 1·65	1·021
2	0·36	0·55	1 : 1·53	1·027

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

It will be seen from this table that the determinations are always in close agreement when the sugar is over 1 per cent.; below this the divergence is considerable, increasing as the sugar diminishes and being usually intensified by increase of specific gravity. Evidently the "interfering substances" have a much more intense reducing power upon picric acid than upon Fehling's solution, and the discrepant results are simply conditioned by the quantitative position which the sugar holds in the total solids.

Further questions arise: (1) Is there a natural limit to the possible percentage of "interfering substances"? (2) How can "interfering substances" be most readily distinguished from glucose? On this quest I have studied the behaviour of the two tests as applied to non-diabetic samples on the one hand, and to diabetic samples, having a sugar indication below 0·5 per cent., on the other. In every case the sample was first treated with 25 per cent. of liquor potassæ and filtered (to remove phosphates, etc.). The picric results are recorded in terms of the dilution required to equal the colour standard (unity being equivalent to 0·059 per cent. glucose). The Fehling results record the behaviour of 1·25 volume of alkalised urine dropped slowly into one volume of boiling Fehling's solution, noting any change in colour, and the lapse of time after which opacity (if any) occurs.

Table 2 comprises all diabetic samples of low sugar percentage, while in Table 3 are collected all non-diabetic samples showing high picric indication.

Op. = opaque.

Tr. = translucent, opaque by reflected, bright by transmitted light.

N. D. = next day.

TABLE 2.

Diabetic samples with low Picric indication.

	Sp. Gravity.	Picric Indication 1 = 0·059 Glucose.	Behaviour with Fehling's Solution.
1	1·017	1·5	No opacity; N.D. upper portion more blue than lower.
2	1·011	1·8	No opacity; N.D. bottom third opaque.
3	1·018	2	No opacity; N.D. bottom half translucent green.
4	1·018	2·5	No opacity; N.D. no opacity, upper portion more blue.
5	1·025	3	No opacity; N.D. no opacity, upper portion more blue.
6	1·025	3	Brilliant green, no opacity.
7	1·016	3	No opacity; N.D. trace ochre ppt. and bottom 10th Tr.
8	1·024	4	Brilliant green, no opacity.
9	1·020	4	Tr. in 1 hour, Op. in 3 hours.
10	1·020	4	Do. do.
11	1·015	4	Op. in 30 seconds.
12	1·027	5	Tr. in 2 hours.
13	1·025	5	Op. in 1 minute.
14	1·018	5	Tr. in 2 minutes, Op. in 5 minutes.
15	1·022	5	Op. in 30 seconds.
16	1·021	5·5	Op. in 1 minute.
17	1·024	6	Op. in 2 minutes.
18	1·019	6	Op. at completion of ebullition.
19	1·026	8	Op. in 20 seconds.
20	1·025	8	Brilliant green, Op. in 30 seconds.
21	1·018	8	Op. before completion of ebullition Half strength = Op. at end of boiling Quarter strength = Op. in 1½ minute.

The difference between these two tables is very marked; in diabetic samples (Table 2) the peculiar translucency or opacity appears sooner or later in almost every case, even with a picric indication as low as 1·8. On the other hand, in non-diabetic samples (Table 3) no opacity whatever occurs. Moreover, it may be noted in Table 3 that a picric indication of 6 (equal to 0·35 per

cent. glucose) appears to be the highest limit for the occurrence of "interfering substances."

Table 3.

Non-diabetic samples with high Picric indication.

	Sp. Grav.	Picric Indication 1=·059 Glucose.	Behaviour with Fehling's Solution.
1	1·026	3	Brilliant, slightly green, no opacity.
2	1·025	4	Brilliant green, no opacity.
3	1·028	4	Do. do.
4	1·030	4·5	Brilliant olive green, no opacity.
5	1·025	4·5	Brilliant green, no opacity.
6	1·031	5	Scarcely altered.
7	1·024	6	Brilliant olive green, no opacity.
8	1·015	6	Very dark green, no opacity.
9	1·028	6	Do. do.
10	1·029	6	Brilliant green; N.D. bottom fourth Tr. (patient overfed and gouty).
11	1·025	7·5	Brilliant greenish brown, N.D. very slightly Tr. (dark brown sample; much salol derivatives).

Attention was next directed to the possibility of utilising the first appearance of opacity as a fixed point for quantitative observation of minute traces of glucose. In every case the sample was mixed with one-fourth its volume of liquor potassæ, filtered, and 1·25 volume of filtrate dropped slowly into one volume of boiling Fehling's solution. It was found (1) that highly saccharine urine diluted with water never gives opacity with Fehling's solution, the Cu_2O being always produced as a dense red precipitate; even 0·05 per cent. can readily be detected by the spot of red precipitate at the bottom of the test tube; and (2) that highly succharine urine, diluted with normal urine, gives a dense red precipitate down to 2 per cent. Below this the precipitate subsides less rapidly; below 1·5 per cent. the yellow ochre opacity appears during ebullition, and the Cu_2O is practically non-subsiding. At 0·4 per cent. the opacity still appears before ebullition is completed; at 0·3 per cent., just at the end of ebullition; at about 0·2 per cent. the solution remains unaltered blue during ebullition, but about a minute afterwards it changes rapidly to deep transparent green, then translucent, and finally opaque; at 0·1 per cent. the opacity appears five or ten minutes after ebullition; and at 0·05 per cent. no observable change takes place for some hours.

The first appearance of opacity is somewhat deferred by the normal constituents of urine; the following series of comparative experiments will illustrate this. A highly saccharine urine (containing 8·8 per cent. glucose) was diluted with normal urine to contain 0·5 per cent., this was further diluted to lower percentages (A) with water, and (B) with normal urine; the behaviour of each with Fehling's solution was then noted:—

0·4 per cent. { A. Opaque before end of boiling. B. Do. do.
0·3 per cent. { A. Opaque before end of boiling. B. Opaque just at end of boiling.
0·2 per cent. { A. Opaque just at end of boiling. B. Unaltered for two minutes, then translucent green for several hours.
0·1 per cent. { A. Opaque after twenty seconds. B. Unaltered for six minutes, then translucent green for several hours.
0·05 per cent. { A. Brilliant blue, no opacity, red deposit visible in a few minutes. B. Brilliant blue, no opacity, no deposit.

Conclusions.

1. The production of opacity in Fehling's solution by alkalised urine is characteristic of glucose.

2. "Interfering substances" do not produce this opacity, and rarely occur in greater quantity than a picric indication of 0·35 per cent. glucose.

3. When the picric indication falls below 0·4 per cent. the actual amount of glucose present (if any) may be approximately ascertained by noting the point at which opacity appears, diluting, if necessary, until the Fehling remains unaltered during ebullition and becomes opaque about a minute later. This dilution will be approximately 0·2 per cent.; a further halving of the strength should leave Fehling unaltered blue for five or ten minutes.

4. Samples of urine giving the non-subsiding yellow cuprous oxide may be rapidly assayed with Fehling's solution, if previously mixed with an equal volume of glucose solution of known strength (6 or 8 per cent.).

THE SALIENT FEATURES OF THE FLORA OF DEVONSHIRE.*

by G. Claridge Druce, M.A., F.L.S.

On two or three occasions I have been permitted by the generosity of your long-suffering Honorary Secretaries to intervene for a few moments between your truly pharmaceutical subjects and to give a slight sketch of the botany of the district which in our itinerations we are from time to time visiting. At Oxford I dealt with the physiography and botany of the Thames Valley, and showed that the scenery was influenced by the character of the strata through which the river cuts its way. And though that county exhibited no grand rocky cliffs, nor was there any mountainous chain to be encountered, yet in the rather obscure escarpments and in the rich and fertile meadows through which the full-fed river winds slowly through an almost endless plain, diversified occasionally with chalk hills richly clad with beech woods, the flora was large and possessed some plants of great interest and rarity. At Glasgow, as those who had the misfortune to be present may perhaps remember, I treated for a few moments on the special plants to be found native in Scotland, and I contrasted the flora of England with that country, and showed that between sixty and seventy Scottish species are not found south of the Border; and at that meeting I was enabled to state that I had been able to add another species to the group, namely, *Carex helvola*, which I gathered on Ben Lawers, where I have subsequently found that it was gathered as long ago as 1794 by Robert Brown, and a specimen of it labelled *C. cinerea* exists in the British Museum Herbarium.

At Belfast last year I discussed the peculiarities of the Irish flora, and pointed out that whereas 800 British species found the Irish Channel too wide a barrier to cross, on the contrary, twenty-three species are recorded for Ireland which are not found in either England or Scotland. I am afraid I have created another Irish grievance, but I have confidence in your President enough to believe he will save me from any untimely end if I once again cross to those hospitable shores. The truth is that after our pleasant meeting at Belfast I investigated the marsh about Mullaghmore Lough in Central Armagh, from whence a new species of sedge (*Carex rhynchophysa*) had been recently recorded, but which was not known to occur in Great Britain, the species being, in fact, limited to Finland, Russia, and Northern Europe. The discovery, therefore, of a sedge with this range of distribution in Ireland, but unknown in Scotland, was of peculiar interest to the phyto-geographer. However, my rather protracted search, and subsequent examination of authentic Irish specimens of the sedge called *C. rhynchophysa*, led me to believe that a mistake of identification† has occurred, and that although the Mullaghmore sedge is of considerable interest it is not *C. rhynchophysa*, but a peculiar form of *Carex rostrata* (a sedge having a wide range of distribution and variation in the United Kingdom) called var. *latifolia* by Ascherson. Perhaps the President will take my discovery of *Gentiana baltica* and *Callitriche obtusangula* in Co. Down as some amends for taking away one of the species recorded for Ireland, but not from Great Britain. This year I must plead an apology for addressing you, as I am comparatively a stranger to this lovely district, but whenever I have visited it I have been delighted with its scenery, its flora, and with other amenities which I must not waste your time by detailing. Few places are surrounded by such attractive country as the three towns, and I am quite sure everyone who goes with us up the Tamar will have but one opinion as to the rare

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

† See *Journ. Linn. Soc.*, p. 276 (1899).

beauty of Devon. The geology of the district is entirely different from that of the district of Oxford or Belfast; and, in fact, we have hard igneous rocks, granite and shales, slates, and crystalline limestone beds, which account for the bold and almost mountainous character of the scenery. Indeed, on Dartmoor, within twelve miles of Plymouth, we have hills attaining to 1,700 feet in altitude. I need say very little about the flora of the neighbourhood of Plymouth, since one of the very best local floras ever compiled is that which was written by my late friend, Mr. T. Archer Briggs. It is only to be hoped that a flora of the whole of the large county of Devon may be ere long issued on similar lines, although it will be a difficult task to accomplish. I have prepared a table showing roughly how the flora of Plymouth and Devonshire compares in numbers with that of Oxfordshire, Ireland, and the United Kingdom. But the difference is much greater than the figures would lead us to suppose. The county of Devon possesses over 100 species which are not native in Ireland, nearly 140 which are not native in Scotland, and nearly 180 which are absent from Oxfordshire. In the latter case this large number is made up to a considerable extent of maritime species, Oxfordshire being entirely inland. But we may state that probably the flora of Devonshire is not less in numbers than the flora of the whole of Ireland. I will not weary you with a detailed account of the rarieties of the county, but I may draw your attention to some of the more interesting. First among them is a small Iridaceous plant which occurs on the sands at Dawlish; but nowhere else on the British mainland, namely, *Trichonema columnæ* or *Romulea columnæ*, which has a wide range on the Mediterranean coasts. Another rarity confined to Devon and Cornwall is *Hypericum undulatum* (which may eventually be found in Ireland) and *H. linearifolium*, which is also confined to the Peninsula and one locality in Carnarvonshire. *Geranium versicolor* or *striatum* is quite naturalised about Plymouth. Two species of *Lotus*, namely, *angustissimus* and *hispidus*, which are limited to the southern coast of England, are not unfrequent about this town. Six Rosaceous plants of interest occur, namely, *Rosa micrantha* var. *Briggsii*, *Pyrus latifolia*, and a small fruited pear, *P. Cordata*, which has a wide range in the east of Europe and Western Asia. The three remaining species are Brambles, one of them being a very striking species first found in the neighbourhood of Llanberis, namely, *Rubus longithyrsiger*. The order *Umbelliferæ* affords two interesting species, namely, *Eryngium campestre*, which occurs close to the Hoe, and another, a woodland species, *Physospermum commutatum*, was for a long time thought to be a species endemic to the Peninsula, and called *P. cornubiense*, but is now considered to be identical with the Continental form named *commutatum*. *Valerianella eriocarpa* has been found as an introduced plant, as has a pretty Toad flax named *Linaria supina*, which is common on the Cattedown Quarries, to which it is supposed to have been introduced with ballast. The graceful little *Sibthorpia* is found in damp, shady places, while the handsome Labiate *Melittis melissophyllum* is found in many woods, and is interesting to us as containing coumarin. A curious Dock, *Rumex rupestris*, is not unfrequent by the coast. *Poa bulbosa*, a small, bulbous grass, occurs on the Hoe, but its headquarters in Britain are on the eastern coast. Another local grass *Glyceria Borreri* is found in muddy salt marshes. In addition to these, but outside the twelve-mile radius, are the White Rock rose, only known from Somerset and Devon; *Bupleurum aristatum*, a small Umbelliferous plant found near Torquay; *Lobelia urens*, restricted to Devon and Cornwall; *Senecio squalidus*, found near Bideford; *Ononis reclinata*, known with certainty only from Devonshire, where it is found in the eastern part of the county; *Aster linosyris*, a late flowering composite; *Scirpus holoschoenus*, only known from Devon and Somerset; a very rare fern, *Asplenium septentrionale*, two rare species of *Euphorbia*, namely, *E. peplis* and *E. hiberna* and *polycarpon* are also found. It will, therefore be seen from this brief enumeration how rich in rare species is this lovely county. And it is quite certain that systematic exploration of its large area would materially add to the numbers. I may add one sentence to congratulate the Conference on the presence of Mr E. M. Holmes, who has done so much in exploring the flora of this district, and whose algœological researches have done so much to enrich the knowledge of the marine flora of Great Britain. I may also add that on our excursion we shall see a variety of *Melampyrum pratense*, which I named some years ago as var. *hians*. near the Weir Head, and two years ago on the Cattedown Quarries I met with an interesting species of *Lepidium perfoliatum* which has a curious heterophyllous condition of foliage. On that occasion I also added, contemporaneously with my friend the Rev. E. S. Marshall, a new species of *Euphrasia* to Britain in finding *E. occidentalis* on the Devon coast. It had previously been known only from the Isle of Ushant.

ANALYTICAL NOTES ON THE B.P. LOZENGES.*

BY FREDERICK DAVIS.

It was my privilege to place before the members of the Conference of 1891, a report upon the medicated lozenges of the B.P., and the state of commercial qualities of the B.P. lozenges at that time being considered somewhat unsatisfactory, not only respecting the quantity of active ingredient contained in each lozenge, but in the quality and quantity of the excipient or bases used, Professor Attfield, in his report upon the British Pharmacopœia to the General Medical Council, mentioned my report, and suggested that at an interval further experiments should be conducted. These analyses were carried out by myself at intervals of about two years, but until the advent of the 1898 British Pharmacopœia no material improvement in the medicated commercial lozenges appears to have taken place; but it is now a pleasure to be able to report upon the satisfactory state of the commercial qualities of the B.P. lozenges taken as a whole. There is no doubt that the definite statement in the current British Pharmacopœia that each lozenge shall contain a definite weight of active ingredient, and that this definite weight shall be intermingled with a basis of specific composition, tends to greater accuracy.

The lozenges of the leading manufacturers vary in size and shape, but this does not now appear to influence the quantity of active ingredient present.

I append a table showing the quantity of active ingredient analytically found in each lozenge expressed as decimal of a grain, from six samples respectively.

It will be observed the quantity of active ingredient is very nearly that which the B.P. directs, and taking into consideration experimental error, the constants are good excepting in the lozenges of sodium bicarbonate and sulphur, and in these cases there appears to be a laxity in making which should not exist.

In the reduced iron lozenge the determination was calculated upon 75 per cent. basis of metallic purity.

In the rhatany and cocaine lozenge the cocaine hydrochloride only was determined, and similarly the morphine hydrochloride in the morphine and ipecac. lozenges.

No examination of the basis has been made in any case.

Sample.	Benzoic Acid.	Carbolic Acid.	Tannic Acid.	Bismuth.	Catechu.	Eucalyptus.	Reduced Iron.	Guaiacum.	Ipecac.	Krameria.	Krameria and Cocaine.	Morphine.	Morph. and Ipecac.	Potassium Chlorate.	Santonin.	Sodium Bicarbonate.	Sulphur.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

HYDROGEN PEROXIDE.*

BY CHAS. T. TYRER.

I have endeavoured in the following paper to give some idea of the rate of decomposition and the protective value of various agents for solutions of hydrogen peroxide:—

(1) Hydrogen peroxide, 10 vol., containing 0·5 per cent. of free sulphuric acid was taken, bottled in pint stoppered bottles, Winchester quarts stoppered, champagnes corked, soda-water bottles corked, half-gallon stone bottles screw stoppered, and placed in diffused light and at ordinary temperature and atmospheric conditions. The volume of each was taken every month for six months; after that, as it seemed probable that the loss was accelerated by taking out the 1 C.c. from each, necessary for examination, they were allowed to remain until ten months had elapsed. The following are the results:—

Time.	Pints.	Wr. Quarts.	Champagnes.	Soda Water Bottles.	½-Gallon Stone, Screw Stoppered.
1 month	9·8	9·0	10·0	9·6	10·0
2 months	9·0	8·4	9·2	8·9	9·6
3 ,,	8·7	8·1	8·7	8·5	8·8
4 ,,	7·9	7·8	8·5	8·2	8·6
5 ,,	7·3	7·3	8·1	7·6	8·0
6 ,,	6·5	7·0	7·6	7·1	7·9
10 ,,	3·5	4·8	5·0	4·9	5·3

(2) Hydrogen peroxide solutions of 12, 15, 20 and 30 vols. were taken and bottled in champagne qts. leaving spaces of 2 inches between the cork and the top of the solution. They were protected with glycerin, sulphuric acid, hydrochloric acid, boroglyceride, alcohol, acid phosphoric, and under identical conditions with No. 1 experiment.

The following table gives the results:—

Protected with	Initial Volume. 12	15	20	30	
1% Glycerin	8·9	11·7	15·3	17·0	Loss in 6 months.
1% Sulphuric acid	8·1	11·5	15·0	cork blown out	
1% Hydrochloric acid	7·6	Burst	13·2	14·3	
1% Boroglyceride	8·8	11·6	15·0	16·4	
1% Alcohol	8·6	11·6	15·2	16·0	
1% Acid Phosphoric, 1,500	9·2	12·2	16·8	17·3	

As hydrochloric acid appeared to be the worst protective agent, experiments were made with this alone—the 10 vol. solution was protected with 1 per cent. of hydrochloric acid bottled (*a*) champagne qts. corked and wired; (*b*) Winchester qts. stoppered. The volumes were taken every month for six months, with the following results:—

	Champagne.	W. Qts.
1 month	9·1	8·8
2 months	8·6	8·2
3 ,,	7·8	7·2
4 ,,	7·1	6·3
5 ,,	6·7	6·0
6 ,,	6·3	5·8

1 W. qt. of 12 vols. acid phosphoric protection, exposed to full sunlight during the hot weather at an average temperature of 73 for three weeks, lost 4·3 vols.

1 W. qt. of 20 vol. burst in thirteen days, exposed to full sunlight.

1 W. qt. of 90 vol. lost 27 vols. during three winter months, in diffused light.

In order to ascertain the effect of different coloured quarts, three W. qts., amber, blue, and green, of 12 vol., were taken. After six winter months, in diffused light, the amber qt. gave 7·4 vols., the blue qt. 6·9 vols., and the green qt. 6·6 vols.

Regarding carriage, the above experiments were not subjected to shaking or vibration.

Ten vol. hydrogen peroxide solution, phosphoric acid protection, in champagnes and W. qts. were packed in straw in a hamper and subjected to daily journeys from Stratford to the City for thirty days in June weather. At the end of this time the volumes had decreased to:—

Champagnes.	W. Qts.
(a) 7·3 Cork pressed well into wire.	(a) Burst after 13th journey.
(b) 7·0 ditto	(b) 6·9

12 vol. hydrogen peroxide solution, phosphoric acid protection, from London to Liverpool and back, nine days in all, out of two dozen W. qts. two burst, and the volume averaged 11·1.

Twenty volume, sulphuric acid protection, steamer London to Newcastle and back, three weeks in all, 6 × ½ gallon stone bottles, screw stoppered, one burst; remainder averaged 17·3 vols.

London to New Zealand, 20 vol. solution, three dozen champagnes, corked and wired, alcohol protection, none broken, several corks forced well into wire, one cork broke the wire and came out, the average vol., 13·4.

Regarding breakage. In ten years, during which many thousands of gallons have been despatched, there is no record of champagne qts. or soda-water bottles breaking; next in order come beer bottles with patent screw stopper, which rarely break. Stone bottles with patent screw stoppers frequently break; when they do break the fracture shows that it is owing to some defect in making the bottle. Corbyn qts., about 1 per cent. break, and W. qts. about 2 per cent. break. Carboys, about 1 per cent. when subjected to railway journeys.

As regards pressure from the gas evolved, many people order champagne bottles and other containers to be half full only. This is a mistake, there is less pressure developed if the space between the cork and the liquor is about two inches (incidentally I may say that this coincides with results of some experiments made with regard to ether in drums, much more pressure was generated when the drum was three parts full, than when only a space of one inch was left, the drum being placed in hot water). Dr. Squibb, of Brooklyn, N.Y., in 1894 made experiments as to the rate and extent of pressure of gas evolved from hydrogen peroxide in a bottle at ordinary temperature, but he did not carry them out to the point of bursting. From his figures he calculated that a 10·5 vol. solution which after a time had lost 5·7 vols., gave a pressure of 96 lbs. to the square inch. On repeating these experiments on W. qts. fitted with a pressure gauge and surrounded with gauze in a stove at a temperature of 125° F., the following were the results:

Hydrogen peroxide 20 vol., phosphoric acid protection, after six hours the pressure indicated 35 lbs. to the square inch; after fourteen hours, 42 lbs. to the square inch, and burst between four and five hours later.

Peroxide 20 vols., after twelve hours' pressure indicated 43 lbs. to the square inch, and burst between two and three hours later.

Peroxide 12 vols., after eight hours gave pressure of 35 lbs. to the square inch, and burst between nine and ten hours later.

Peroxide 12 vols., burst after six hours.

Several other experiments were attempted, but owing to the inequality in strength of the bottles no concordant results were obtained. A soda-water bottle corked and well wired, and hung upside down in the laboratory during the winter months, had exerted such pressure on the cork that the wire had cut halfway through it, and the liquor was entirely forced out in sixty-two days. It is preferable to cork bottles than to stopper them, as the pressure is released by escape of gas through the pores of the corks. Bottles should never be laid on their side when corked, as the action on the cork hastens decomposition. Care should be taken in the selection of bottles for storing hydrogen peroxide, any angular inequality hastens decomposition, as do the small rough patches of iron oxide frequently found on stone bottles.

It may not be generally known that by careful evaporation hydrogen peroxide can be highly concentrated to 50 to 100 or more vols.;

*Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

for greater vols. it must be concentrated *in vacuo*, but if during evaporation the slightest speck of dust or dirt comes in contact with the solution, the evolution of gas is rapid and in some cases almost explosive. The clear oily residue left in the retort on evaporation *in vacuo* of pure hydrogen peroxide (presumably absolute hydrogen peroxide) if rubbed with a glass rod will probably explode violently, indeed loss of life from this cause occurred a year or two ago abroad.

Hydrogen peroxide can also be concentrated by freezing, the ice crystals containing very little hydrogen peroxide.

During the past two years the use of hydrogen peroxide solution as an oxidising agent in analysis has greatly increased, and for this purpose practically pure solution is required for oxidising SO_2 to SO_3 and peroxidising thiosulphides sulphide and sulphites and in the analysis of gas liquors. This solution however, is too unstable for ordinary pharmaceutical use. It should contain none of the ordinary protective agents and should show only the faintest traces of chlorides, fluorides, sulphates, and phosphates.

The best method of keeping in a laboratory is to store in a receiver having a tap at the base, the solution being protected by a layer of petroleum carefully poured on the surface. The extended use of hydrogen peroxide in dentistry, and in medicine for diseased surfaces, throat complaints, ear diseases, and its recent application in cholera has well warranted its inclusion in the B.P. It has also been used in India for snake bites with excellent results, and in the gold mining districts it is kept in a 2 per cent. solution for subcutaneous injcetion in cyanide poisoning. One test, however, should be included in the Pharmacopœia, a test for fluoric acid which is not infrequently found in commercial samples. In bleaching, various acids and combinations of acids are used for various purposes. The solutions for bleaching hair, silk, ivory, bones, etc., all have their different modes of manufacture, therefore in ordering hydrogen peroxide "Medicinal" or "B.P." should be specified.

Of all the modes of protection, acid phosphoric seems to be the best as well as medicinally least harmful.

It may be of interest to compare a paper of Dr. Squibb in 'Ephemeris,' 1894, with this paper, which will show the differences of decomposition of hydrogen peroxide under different climatic conditions.

In conclusion I have to acknowledge the valuable assistance of Mr. A. Wertheimer in preparing these notes.

LIQUOR BISMUTHI ET AMMONII CITRATIS.*

BY FRANK R. DUDDERIDGE,
Pharmaceutical Chemist.

In a previous note on this preparation, read before the Newcastle-upon-Tyne and District Chemists' Association on March 8th last, drew attention to the impossibility of obtaining a satisfactory preparation if the B.P. directions are strictly followed, owing to the precipitated bismuth citrate (?) not being completely soluble in the liquor ammoniæ; also to the fact that the quantity of potassium carbonate ordered is inadequate to neutralise the free nitric acid, 236 grains being required for one pint of liquor and only 175 grains directed to be used, with the result that the nitric acid renders the washings acid, and retains a certain amount of bismuth in solution, thus rendering the preparation deficient in strength. Mr. T. E. Wilson, my assistant at that time, obtained a soluble precipitate by omitting to dilute the nitric acid solution to opalescence as directed in the B.P. and adding to it the potassium carbonate and citrate dissolved in a little water.

This process has been followed since with varying results, sometimes the whole of the precipitate being readily soluble, at other times more or less remaining undissolved, but always much more passed into solution by this method than by following the official process. As I consider this state of things unsatisfactory, and tending to lead the retail pharmacist to depend for his supply upon the wholesaler, instead of preparing it himself—a result also of many other of the changes in the 1898 B.P. which will help to increase the number of inefficiently taught apprentices — I have endeavoured to devise a process which will be at once satisfactory and uniform, without departing to any great extent from the official directions, and I think I have succeeded. First of all, the fact that Mr. Wilson's method always gave a much more readily soluble precipitate than the B.P. process, led me to suspect that the quantity of water present when the two solutions are mixed is a most important item; in fact, I doubt if when to the acid solution of bismuth—diluted to slight opalescence as ordered—the solution of potassium carbonate and citrate in a "little"—no directions for any definite quantity being given—in a "little" water is added, whether the resulting precipitate is not to a great extent not citrate but an oxysalt, in all probability oxynitrate of bismuth, hence its insolubility. Therefore the method I adopt with satisfactory results differs from the B.P. only in these respects:—(1) The solution of bismuth oxynitrate in equal volumes of nitric acid and distilled water is *not* diluted to opalescence, it is not diluted at all; (2) the order of mixing is reversed, the potassium salts not being added to the bismuth, but the bismuth poured carefully into the solution of the potassium salts, which is kept well stirred all the time; (3) I dissolve the potassium salts in a definite quantity of water, two fluid ounces for an imperial pint of product, or 100 C.c. for a litre. This forms a thick magma, to which I add another two ounces or 100 C.c. of water, heat to the boiling point, throw on to a filter and wash with hot water until free from nitrate contamination, when it is easily soluble in liq. ammoniæ. I also find that if the quantity of potassium carbonate be increased by one third, *i.e.*, 240 grains or 27 grammes being used in place of 175 grains or 20 grammes, the washings are practically neutral, and very little if any loss of bismuth results. With these slight modifications the B.P. process may be easily and speedily performed in any pharmacy. Another point worth attention is that the B.P. does not use heat in effecting the solution of the bismuth oxynitrate, and my experience is that the heat produced in mixing equal volumes of nitric acid and water is quite sufficient to effect solution if a little agitation be used. Too great heat appears to retard instead of aiding solution. Mr. W. G. Stratton, in his paper, read before the Glasgow Conference, drew attention to the fact that many commercial samples of liq. bismuth contained an excess of ammonium citrate, causing considerable difference in the appearance of mixtures containing it in combination with an alkaline bicarbonate, those dispensed with a strictly B.P. liquor depositing, whilst those which were dispensed from a liquor containing such excess remaining clear. Whilst deprecating an unwarranted departure from the official process I would venture to remind those who take in hand the revision of the Pharmacopœia that both Schacht's preparation and the liquor of the 1867 Pharmacopœia contained such excess, and to suggest that in the next issue a reversion be made to these lines, which may easily be done after dissolving the precipitated citrate in the liq. ammoniæ by adding either 8 fl. oz. or 400 C.c. of liquor ammonii citratis and diluting to one pint or one litre of finished product as the case may be. Such a preparation would contain the double salt:—Bi $C_6H_5O_7$, $(NH_4)_3$ $C_6H_5O_7$, the formula of that contained in the present liquor, according to Attfield, being $(NH_3)_3$ Bi $C_6H_5O_7$. The fungoid growth which so frequently develops, may be prevented by the presence of alcohol, which Mr. Stratton found to be present in several of the samples he examined.

* Read before the British Pharmaceutical Conference, at Plymouth, July, 1899.

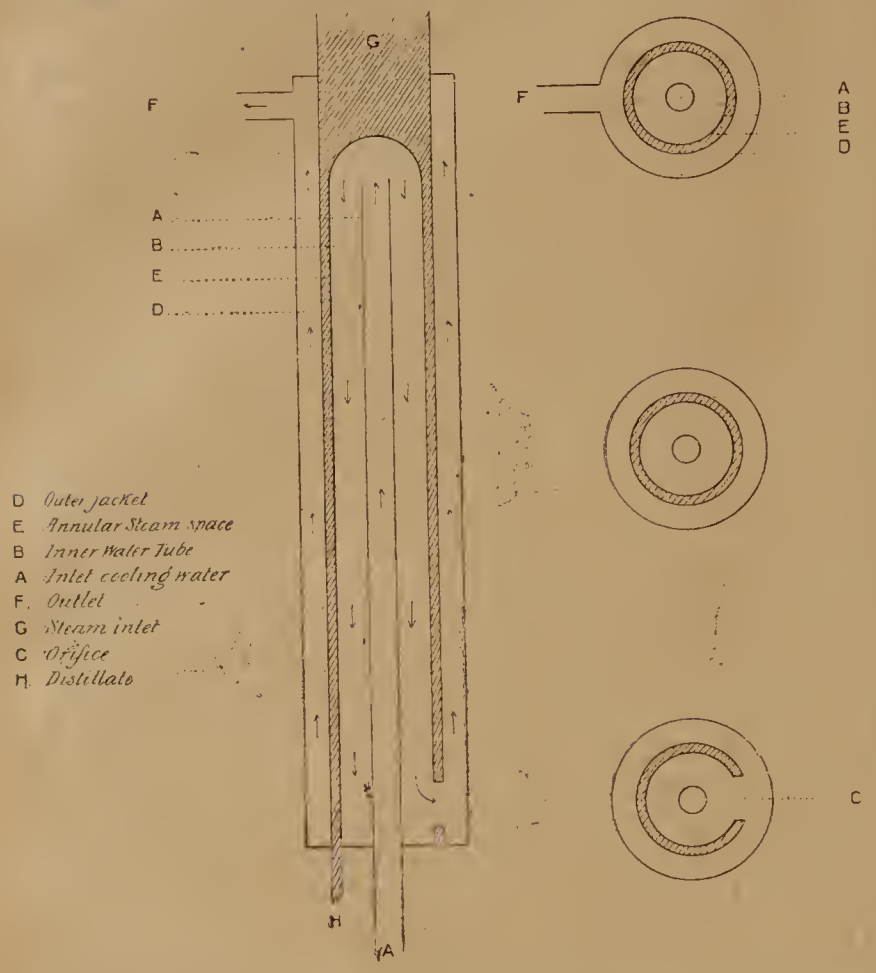
* The above experiments were carried out in the laboratories of Messrs. Thomas Tyrer and Company, Limited, Stirling Chemical Works, Strotford, London, E.

A NEW CONDENSER.*

BY E. W. LUCAS.

This condenser practically consists of an *annular* steam space, the inner and outer sides of which are contiguous to cooling surfaces, This distinguishes it from forms of condenser where the steam space is *columnar or cylindrical* and contiguous to only one cooling surface.

Reference to Diagram I. shows that the cooling water first ascends



a comparatively narrow tube A, and projects against the underside of the dome. The concave end returns the water down a second and wider tube, B, through an orifice in the steam space, C, to the outer tube or jacket, D, which it completely traverses before escaping at the outlet, F.

If the course indicated by the arrows is followed, it will be evident that the cooling water exerts double duty. In the first place, owing to the manner of its projection against the underside of the dome, it brings all the successive units of cold water into direct contact with the successive units of steam that are delivered against the opposite side, the steam and cooling water only being separated by thin metal of high conductivity. In the second place, the water in its downward course cools the innerside, and, in its upward course, the outerside of the annular steam space.

The steam enters at G, and at once impinges on the cold dome, where it loses most of its heat and practically condenses. The condensate is then pushed down the annular space by more steam from above, until it finally escapes at H.

Too much importance cannot be attached to the part played by the dome, as it brings the steam and cooling water into the most intimate contact. Besides, owing to the convex shape, the condensed water is brushed aside as soon as formed, leaving the metal surface clean and in a good condition for transmitting heat. In other forms of condenser, a film of condensate remains spread over the cooling surface, which, owing to its comparatively poor conductivity, materially impairs the efficiency.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899

The following tests on the distillation of water were made with a copper condenser having a condensing area of 100 sq. inches. Its extreme length was 15 inches, and diameter 2 inches.

	1	2	3
Cooling water, gallons per hour	220	220	220
,, ,, temperature at inlet	58° F.	58° F.	58° F.
,, ,, ,, ,, outlet	98° F.	101° F.	104° F.
Condensate, gallons per hour	7·30	9·00	10·20
,, temperature	130° F.	170° F.	197° F.
Steam pressure in lbs. per sq. inch	15 lbs.	20 lbs.	25 lbs.
Duration of experiment	1 hour	1 hour	1 hour

Comparative Experiments between the Patent Condenser (100 sq. inches) and a Worm Condenser of Equal Area.

	Patent Condenser.	Worm Condenser.
Cooling water, gallons per hour	90	90
,, ,, temperature at inlet	52° F.	52° F.
,, ,, ,, ,, outlet	130° F.	98° F.
Condensate, gallons per hour	7·50	3·5
,, temperature	176° F.	164° F.
Steam pressure in lbs. per sq. inch	12 lbs.	12 lbs.
Duration of experiment	1 hour	1 hour

This comparison was made under precisely similar conditions as regards steam supply and inlet and outlet of cooling water.

After the test had proceeded for an hour the cooling water was increased to 250 gallons per hour, the steam pressure at the same time being gradually raised. At 25 lbs. to the sq. inch the patent condenser supplied over 10½ gallons per hour of distilled water. The worm condenser, on the other hand, could not condense more than 4 gallons per hour, and when the pressure was increased to 15 lbs. per sq. inch, steam blew through uncondensed, although the temperatures of both distillate and cooling water were still a long way below 212° F.

That this double form of condenser possesses great efficiency is exemplified by the following simple experiment:—

Steam was generated in a 2 gallon boiler over a powerful gas stove, and sent into both the worm and patent condensers through ½-inch pipes at atmosperic pressure. Cooling water was supplied to each condenser under equal conditions. When the steam was turned on both condensers condensed at an equal rate, but after a few minutes the worm condenser fell behind, although an equal amount of steam was offered to it. After half an hour or so the worm practically ceased distilling, because the patent condenser drew away the steam as quickly as it was generated.

This result is caused by the capillary bore of the annular steam space ($\frac{1}{16}$ inch). The steam as it entered was immediately condensed on the dome, and trickling down drove the air before it, a perfect ring of water being formed. This cut off all communication with the outer air, a partial vacuum being produced in the upper part of the condenser, which, by reducing the pressure, increased the rate of distillation.

In the worm condenser no such partial vacuum can be formed, as air circulates through the whole length of the coil, while if the bore is narrowed so that the condensed water will drive all the air before it, the rate of condensation is sensibly diminished.

In all the tests this condenser has been tried against the worm type of condenser. There are, it is true, other types, but they differ in form only from the worm, as in each, the steam is allowed to enter as a solid cylinder or column. Consequently, if the pressure is increased the steam is only partially condensed, the inner core issuing as live steam. This is not because the supply of cooling water is deficient, but because the full duty is not exacted, only the periphery of the cylinder of steam being condensed, the central core not being reached.

In the double condenser the steam is met by, practically, a solid cylinder of cold water directly it enters the condenser; this con-

denses its core at the outset, while the periphery is condensed in the narrow annular space. The condensing capacity of this pattern is then only measured by the amount of cold water it is possible to force through the inlet and outlet pipes.

Briefly it may be said that this condenser possesses at least double the efficiency of any other form of condenser; its construction is simple and admits the use of a brush for cleansing purposes.

Several forms of double condenser have been recently placed before the public, but as the author had the pattern described in use two years ago he believes he may claim priority. Another point worthy of note is the fact that the cooling water is used under pressure.

EXAMINATION OF THE TERPENELESS OILS OF LEMON AND ORANGE IN THE MARKET.*

BY T. H. WILLIAMS IDRIS, J.P., F.C.S.

In response to the request of the honorary secretaries, and to a suggestion in the circular on "Subjects for Papers," I have pleasure in offering a few notes on the examination of the terpeneless oils of lemon and orange in the market.

As a large user of lemon preparations I have had these substances under observation in the laboratory of my firm for the last few years, but the present notes refer only to recent examinations of products now on the market.

These oils appear under several names, and are stated to have a flavouring equivalent of some thirty times that of good oil of lemon. The coppers of ordinary lemon oil as imported often have attached to them a certificate of analysis guaranteeing the contents to contain 7 per cent. of citral, but too much reliance should not be put on the many statements concerning essential oil of lemon made by interested persons, especially as to percentage of citral, which may possibly apply to a mixture of lemon terpene and lemon grass citral. Such a mixture, though containing no genuine lemon oil, would be certified as pure if the rotation, gravity, and amount absorbed by sodium bisulphite solution were the only tests to which the oil was subjected, but the terpeneless oil produced from such a sample would, of course, be easily recognised as lemon grass citral.

Variations are naturally to be expected in the quality of the most carefully prepared terpeneless oils, not only on account of the fact that skill and care are necessary for their successful manufacture, but also on account of the variable nature of the original oils from which they are produced.

Such variations naturally make it the more difficult to fix any definite standard for the manufactured products, but it must be admitted that a "terpeneless" oil implies:—(*a*) That the product is free from terpenes; (*b*) that it is manufactured solely from the oil bearing its name.

How far commercial samples (which vary in price from, say 60s. to 120s. per lb.) correspond with these requirements will be seen.

For the purpose of comparison, I have used samples manufactured from the purest oil of lemons obtainable in my own laboratory. Many of these were examined and the results of two typical samples are here given:—

(1)

Specific gravity at 15·5°	0·8966
Optical rotation 100 Mm. tube	−8° 53′
Absorbed by solution of $NaHSO_3$	62 per cent.
Not absorbed „ „	38 per cent.

Practically none distilled over under 220° at ordinary pressure, and the oil was soluble in all proportions in 90 per cent. alcohol and in 20 to 30 volumes of 70 per cent. alcohol.

(2)

Specific gravity at 15·5°	0·8963
Optical rotation 100 Mm. tube	−7°
Absorbed by solution of $NaHSO_3$	61 per cent.
Not absorbed „ „	39 per cent.
Solubility and distillation same as No. 1.	

No terepenes could be identified in either, and only very small quantities could possibly have been present.

Thirteen commercial samples of terpeneless lemon oil were obtained through ordinary business sources, and the following results were obtained from them:—

No.	Sp. gravity at 15·5°	Rotation 100 Mm. Tube.	Absorbed by Na HSO3	Not absorbed.	Solubility in 70 per cent. alcohol.	Solubility in 90 per cent. alcohol.
			Per cent.	Per cent.		
1	·8956	− 7°12′	67	33	1 in 9	In all proportions.
2	·8963	− 7°21′	42	58	1 in 20	„ 1 in 4
3	·8712	+41°21′	8·	92	Very insoluble.	„ „
4	·8966	−11° 5′	6	94	„ „	In all proportions.
5	·8943	− 1°41′	76	24	1 in 3	1 in 3
6	·8836	+10°58′	30	70	Very insoluble.	In all proportions.
7	·9036	− 6°20′	51	49	1 in 2	Very insoluble.
8	·8698	+42° 6′	15	85	Very insoluble.	„ „
9	·8707	+38°21′	14	86	„ „	Soluble in all proportions.
10	·8966	+ 2° 8′	70	30	1 in 40	„ „ „
11	·8925	− 7°15′	61	39	1 in 15	„ „ „
12	·8956	0°	66	34	1 in 6	„ „ „
13	·8955	0°	67	33	1 in 7	„ „ „

These results show such great differences that it is almost incredible that the products should have the same name.

Dealing with the samples *seriatim*, the following remarks may be made:—

Samples Nos. 1, 2, and 11 are, in my opinion, all genuine samples of terpeneless lemon oil. Their odour was fine and purely lemon and no traces of terpenes could be detected either by distillation or by examination of the residue not absorbed by sodium bisulphite. These three samples were all made by the same firm and obtained through different channels.

Samples Nos. 3, 6, 8 and 9 were merely ordinary oil of lemon to which a little citral had been added, or from which a portion of the terpenes had been removed. The low specific gravity, high rotation, and insolubility indictate this, and in addition in each case considerable quantities of terpenes of the specific gravity ·855 to ·865 and optical rotation of over +50° were separated.

No. 7 was sold as a synthetic oil, which, of course, is an absurd name for this product. It had a marked verbena odour.

No. 4. contained very little citral and had a very poor lemon odour. I am unable to understand its composition.

Nos. 5, 12, and 13 had distinct verbena odours, and a lemon grass citral had clearly entered into their composition.

No. 10 had a fine lemon odour and I have been able to ascertain beyond doubt that it is a genuine product; but a little of the terpene has been left in the oil, which should have been concentrated a little further.

The great difference in the value of these products is apparent, and users of terpeneless oils should be careful in their purchases, as so-called "terpeneless" and "concentrated" lemon oils are offered at absurd prices.

I have also examined several samples of commercial terpeneless orange oil. These have the following characteristics:—

No.	Specific Gravity.	Rotation.
1.	0·890	+17°
2.	0·894	+12°8′
3.	0·878	+33°4′
4.	0·884	+24°40′

I have not compared these samples with any of my own make, bu the lowest specific gravity and high optical rotation of the last two samples indicate the presence of a considerable quantity of terpene.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899

TEREBENE, B.P. *

BY LEWIS OUGH, F.C.S., F.L.S.
Pharmaceutical Chemist.

In attempting to answer the query in the Blue List, "To what extent do commercial specimens of terebene correspond with the characters and tests of the 1898 Pharmacopœia?" I must apologise for taking up a subject that has previously been investigated by such able workers as Lascelles Scott and J. Hodgkin, and reported upon at the Pharmaceutical Conference at Birmingham, but as this article is now included in the Pharmacopœia it may be that an examination of a series of commercial specimens will not be devoid of interest, especially as several English makers assert that it is practically impossible to obtain an article that will agree in all particulars with the official requirements.

As is well known, terebene is produced by repeatedly treating turpentine with sulphuric acid, until after washing and neutralising with lime or soda and distilling with water an optically inactive liquid is obtained.

One may note in passing that the requirements of the British Pharmacopœia and those of the United States are not quite identical, as will be noticed by the following:—

British Pharmacopœia.	United States Pharmacœpia.
1. A mixture of dipentene and other hydrocarbons.	1. A mixture consisting chiefly of pinene, and containing a small proportion of terpinene and dipentene.
2. Colourless.	2. Colourless or slightly yellowish.
3. Specific gravity 0·862 to 866.	3. Specific gravity 0·862.
4. Boils between 312° F. and 356° F., not more than 15 per cent. distilling below 329° F.	4. Distils between 312° F. and 320° F.
5. Does not rotate the plane of polarised light.	5. Should not have more than a very slight action on polarised light.

A more recent investigation by Power and Kleber in a research undertaken for the U.S.P. Committee states that the specific gravity of terebene is ·855, and the boiling point 338° F. to 365° F. (170° C. to 185° C.) That it "resembles oil of turpentine in its chemical properties" is not correct. Upon the basis of their investigations the following amended text was drawn up by Power and this will doubtless be adopted in the forthcoming edition.

Terebene, an optical inactive liquid, obtained by the action of concentrated sulphuric acid on oil of turpentine and subsequent rectification with steam. It consists chiefly of the hydrocarbons ipentene and terpinene with some cymol and camphene.

Terebene should be kept in well stoppered bottles, in a cool place protected from light.

A colourless thin liquid having an agreeable thyme-like odour and an aromatic taste.

Specific gravity 0·855 at 59° F. (15° C.)

On exposure to light and air terebene gradually becomes resinified and acquires a yellowish colour and an acid reaction.

Terebene should possess its characteristic odour, should not redden moistened blue litmus paper (absence of acids) and should be completely inactive toward polarised light (absence of unaltered oil of turpentine).

If about 10 C.c. of terebene be evaporated in a capsule on a water-bath, not more than a very slight residue should be left (absence of more than traces of resinous matters).

Source of Samples.—With the exception of two, which were of German origin, all the specimens examined were obtained from English manufacturers of the highest reputation, and in some instances the makers have kindly furnished me with a few remarks concerning the article.

The makers of No. 1 say: "We regret that we have no terebene that will answer all the requirements of the Pharmacopœia, neither do we think such an article is procurable on the market. The sample sent approaches as near as possible to the characters and tests of the B.P., 1898."

Sample No. 3 was about five months old when tested, and "was made by the action of 5 per cent., *by weight*, of sulphuric acid on the turpentine."

The manufacturers of No. 4 remark: "We do not polymerise terebene to the extent of its being optically inactive. The demand for the B.P. article with us is comparatively small, and we do not make it."

With regard to Nos. 5 and 6 I am informed: "This article varies so much that it is almost impossible to say that any one sample is typical of our manufacture. Both samples were made in exactly the same way from American turpentine, one of which (No. 5) is nearly B.P., the other (No. 6) being different in several particulars. The variation appears to be caused by some unexplained effect of age on the turpentine from which the terebene is made, and we are still endeavouring to find a key to the problem."

Sample No. 7 was labelled "B.P., 1898," and No. 8 "optically inactive."

The last sample of the series (No. 12) "was obtained by acting on the turpentine with 5 per cent of sulphuric acid *by volume*," and had only been made two days when examined.

TABLE I.

Sample.	Specific Gravity.	Origin.	Colour.	Action on Litmus.
No. 1..	0·868	English	Slightly yellow ..	Neutral
,, 2..	0·866	,,	Distinctly yellow	,,
,, 3..	0·876	,,	Colourless	,,
,, 4..	0·864	,,	Distinctly yellow	,,
,, 5..	0·858	,,	Slightly yellow ..	,,
,, 6..	0·869	,,	Slightly coloured	Slightly acid
,, 7..	0·865	German	Distinctly yellow	Neutral
,, 8..	0·866	,,	Slightly coloured	Slightly alkaline
,, 9..	0·862	English	,, ,,	Neutral
,, 10..	0·863	,,	,, ,,	,,
,, 11..	0·864	,,	,, ,,	,,
,, 12..	0·861	,,	Colourless	Slightly alkaline

The specific gravities were taken at 60° F. by means of the balance, and it will be noticed that samples 2, 4, 7, 8, 9, 10, and 11 are in this particular within the limits of the official requirements.

TABLE II.

Sample.	Boiling Between.	Amount Distilling Below 329° F.	Percentage of Residue.	Watts' Colour Test.
No. 1.....	320° and 360° F.	12 per cent.	1·3	7 minutes
,, 2.....	300° and 340° F.	62·5 ,,	1·6	9 ,,
,, 3.....	314° and 344° F.	25 ,,	1·9	50 ,,
,, 4.....	318° and 348° F.	62 ,,	2·3	4 ,,
,, 5.....	329° and 356° F.	one	1·9	14 ,,
,, 6.....	316° and 364° F.	45 er cent.	1·0	6 ,,
,, 7.....	326° and 346° F.	4 ,,	1·3	4 ,,
,, 8.....	321° and 344° F.	20 ,,	1·3	8 ,,
,, 9.....	325° and 361° F.	15 ,,	1·2	6 ,,
,, 10.....	300° and 340° F.	62 ,,	0·5	5 ,,
,, 11.....	326° and 362° F.	9 ,,	0·8	8 ,,
,, 12.....	315° and 353° F.	75 ,,	0·3	3 hours

From the above figures it will be seen that only five samples (Nos. 1, 5, 7, 9, 11) can be looked upon as fulfilling the tests with regard to the boiling limits and the amounts distilling below 329° F. With regard to the residues, Nos. 7 and 10 are of a dark brown colour, the remainder being of a light amber tint.

Colour test.—Watts (1892) gives the following test for the freshness of this article:—"Fifteen minims of terebene are introduced into a stoppered bottle containing a cooled mixture of 2½ grs. of iodide of potassium, with 8 grs. of compound powder of tragacanth and one ounce of boiling water. Old terebene will colour the liquid blue within an hour, whilst the fresh article will cause no change within twenty-four hours."

This test has been applied to the series of samples, and the results are given in the above table, but a distinctly blue colour was obtained in three hours with the sample (No. 12) which was only

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899

two days old, and the specimen that had been made five months (No. 3) yielded the same result within fifty minutes. The remainder ranged from four to fourteen minutes, so I think it will be readily granted that this test cannot with any degree of certainty be relied upon.

Table III.

Sample.	Solubility in Alcohol 90%.	Solubility in Pure Æther ·720	Solubility in Methylated Æther ·717.	Optical Rotation.
No. 1	1 in 5·5	1 in 10	1 in 2·5	1·0″–
„ 2	1 „ 5	1 „ 10	1 „ 2·5	4·30″+
„ 3	1 „ 5	1 „ 10	1 „ 2·5	5·45″+
„ 4	1 „ 5·5	1 „ 10·5	1 „ 1·5	1·30″+
„ 5	1 „ 5	1 „ 10	1 „ 1·5	Inactive
„ 6	1 „ 4·75	1 „ 11	1 „ 1·6	1·0″–
„ 7	1 „ 5	1 „ 10	1 „ 2·	0·45″+
„ 8	1 „ 4·75	1 „ 11	1 „ 1·4	Inactive
„ 9	1 „ 4·9	1 „ 16·6	1 „ 5	Inactive
„ 10	1 „ 5	1 „ 13	1 „ 2·3	4·0″+
„ 11	1 „ 5	1 „ 20	1 „ 1·6	0·25″+
„ 12	1 „ 6	1 „ 16·6	1 „ 2·5	3·30″+

Solubility.—According to Squire's 'Companion' terebene is stated to be soluble 1 in 6½ of alcohol (90 per cent.) and 1 in 3¾ of æther.

Optical rotation.—Tested in the ordinary way by the polarimeter with a column of the liquid, one decimetre in length, the above varied results were obtained, three samples only (No. 5, 8, 9) being optically inactive, the others ranging from 1·0″— to 5·45″+

Sample No. 6 is peculiar in this respect, for as previously stated the makers of this specimen informed me it was made from American turpentine, therefore I am quite at a loss to understand why it should have a levogyrate action on polarised light.

From the results obtained from these experiments it appears that commercial terebene is most varied in its composition, only one sample of the series (No. 9) being in strict accordance with the Pharmacopœial requirements.

OIL OF CARDAMOMS.*

BY E. J. PARRY, B.SC., F.I.C.

The chemistry of oil of cardamoms is in a very hazy condition owing to the fact that those who have reported on the subject rarely state what they mean by "cardamoms." The most recent figures for the oil are those given by Schimmel in the *Report* for April, 1897, where it is stated that oil of cardamoms (Ceylon), has a sp. gr. 0·895 to 0·910, and an optical rotation of + 12° to + 13°. Oil of Malabar cardamoms is described in the *Report* for October, 1897, as being much higher in price, and therefore unable to compete with the commercial oil. The seeds are described as being difficult to obtain, and the oil as having a sp. gr. 0·943, and an optical rotation of + 34° 52′. Haensel in his 1896 report, in commenting upon a cardamom dultivated in the Cameroon country, contrasts the physical properties of the oil from it with that of Malabar cardamoms thus:—

	Malabar.		Cameroon.
Sp. gr. at 15° C.	0·9338	.....	0·9071
Op. rot. in 100mm	+26·0	.....	—23·5
Refract. no. at 25° C.	54·1	.....	62·5
Index ref. at 25° C.	1·4612	.....	1·4675
Iodine no.	123·7	.....	152·1

"One volume of Malabar cardamom oil," he adds, "is not quite soluble in 45 volumes of 60 per cent. alcohol, and one volume of Cameroon cardamom oil is not quite clearly soluble in 250 volumes of 60 per cent. alcohol."

These expressions of opinion serve to show that distillers take the oil of Malabar cardamoms as their standard, but it is not unchari-

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899

table to suppose that the more abundant and, on the whole, cheaper Mysore variety is used for distillation purposes. Anyway, my experience with the commercial oil did not fit in with either of these records, and I wished to satisfy myself as to the relative differences, if any, between oil distilled from Malabar cardamoms and that from Mysores. I, of course, refer to these varieties as cultivated in Ceylon, which almost exclusively come to Europe, the only direct imports from India being a portion of Malabar and a fair amount of Mangalore cardamoms, which are used, I am informed, as a spice for special purposes.

Ceylon-Malabar cardamoms and Ceylon-Mysore cardamoms come into the market as the whole fruit, but large quantities of the seed freed from the pericarps are also imported and sold. Whether the latter are bought by distillers or not is a question which did not come within the present inquiry, which had solely for its object determination of the properties of the two oils, and identity was best ensured by purchasing the entire fruit. These were obtained from London drug-brokers who were able to positively guarantee the same. The seeds were distilled for me by Messrs. Evans, Sons and Co., of Liverpool, whose courtesy I have to acknowledge.

The Ceylon-Malabar seeds yielded 1·3 per cent. of oil, and the Ceylon-Mysores 2·6 per cent. Both were bright yellow liquids, whose odours were scarcely distinguishable. The sp. grs. and optical rotations were as follows:—

——	Sp. Gr. at 15·5°	Optical Rotation at 16° (100mm. Tube)
Oil of Malabar cardamoms	0·9418	+40° 41′
Oil of Mysore cardamoms	0·9418	+46° 39′

These figures are in fair agreement with those given for Malabar oil, but in no way resemble those quoted by Schimmel for Ceylon oil, which I do not at all understand.

The oils were soluble with a slight opacity in 40 to 45 volumes of 60 per cent. alcohol, agreeing with Haensel's oil, which, however has a much lower rotation.

I find little difference between the two oils. On distillation at ordinary pressure the oil, which is very rich in esters, in both cases decomposes partially, and a considerable quantity of free acid distils over. According to Weber (*Annalen*, 238, 89), formic and acetic acids are found in the distillate. Acetic acid is undoubtedly the chief acid constituent of the esters, but I am unable to confirm the presence of formic acid. If it is present, it is only in faint traces. On distillation under reduced pressure the earlier fractions (the boiling-point rises gradually until 50 per cent. has distilled over) contain cineol, but only to the extent of 5 to 10 per cent. of the oil. This figure is the result of an approximate estimation by means of phosphoric acid. The carlier fractions also contained one or more terpenes, amongst which I identified limonene. Weber states that terpinine is also present, but I was unable to identify this hydrocarbon, nor could Schimmel find it in Malabar oil; and as it easily forms a well-defined nitrite when present, it cannot exist in an appreciable quantity. A small quantity of terpineol is present in both oils, and is easily identified by its phenyl-urethane. Schimmel states that it is an optically active modification, but I had not enough oil to examine this. The terpineol comes over with the fraction obtained at 160°-170° C. at 18mm. The nature of the alcoholic constituent of the greater part of the esters requires further elucidation.

From the economic point of view it will be seen that Ceylon-Mysore cardamoms are preferable to the Ceylon-Malabars for distillation purposes, as they give the larger yield.

ALMOND AND OTHER KERNEL OILS.*

BY JOHN C. UMNEY AND RALPH S. SWINTON.

The new British Pharmacopœia in its characters and tests for expressed almond oil gives the following test as indicating the absence of peach kernel and other fixed oils:—"If two cubic centimetres of the oil be well shaken with one cubic centimetre of fuming nitric acid and one cubic centimetre of water, a whitish, not brownish-red, mixture should be formed, which, after standing for six hours at about 50° F. (10° C.), should separate into a solid white mass and a nearly colourless liquid."

This is practically the same test as given in the United States Pharmacopœia for the presence of peach and apricot kernel and other fixed oils. The United States Pharmacopœia also includes another test for the oil, which is practically that of the German Pharmacopœia, and is based on the researches of C. W. Peters (*Archiv der Pharm.*, 26, 1888, 857), depending upon the fluidity at 15° C. and solubility in alcohol of the separated fatty acids.

As this test is valueless for the purpose of distinguishing the presence of peach and apricot oils in almond oil, and as the recognition of such admixture is the purport of this note, we do not refer to it except to note that in our hands the test does not give very satisfactory or definite results, and that the detection of cotton seed (one of the most likely adulterants) may be carried out with far greater certainty by the application of Halphen's reaction. This reaction is obtained by heating in a boiling sodium chloride solution equal parts of the oil, amyl alcohol and carbon disulphide, the latter containing 1 per cent. of sulphur. In the presence of less than 5 per cent. of cotton seed oil an orange to red colour is developed.

The question has arisen lately as to whether the British Pharmacopœia test alone is a satisfactory distinguishing one or not. It should be stated first of all that the oil sold by some as a second grade of almond oil under the name of "Oleum Amygdalæ Persic," or oleum amygdalæ exot., is derived, according to their relative market value, from either apricot or peach kernels.

At the present time the former are considerably cheaper, and the oil met with in commerce under the names we have mentioned is almost without exception that of apricot kernel.

The characters of oils of apricot and peach kernels were examined by Maben (*Pharmaceutical Journal* [3], **16**, 797), who, amongst other things, reported upon the difference in behaviour of the oils to the nitric acid test as compared with true almond oil.

In a subsequent letter in the *Pharmaceutical Journal* (same volume, page 976) he refers to the fact that the specimens which he examined were very inferior to those pressed in this country, and he refers to the difference in reactions shown on cursory comparison of pure oils from those upon which he had previously reported.

A few experiments have been made, therefore, to ascertain whether the pure oils of apricot and peach kernels are identical, or, rather, behave similarly, when the Pharmacopœial test is applied. The oils have been obtained by expression and by extraction with ether from both varieties of kernels. In specific gravity they are practically indistinguishable, and there is no apparent difference in the point at which they become viscid on cooling. They show, however, certain marked differences on the application of the Pharmacopæial nitric acid test referred to.

In the case of peach kernel oil the colour produced is almost white, with the slightest trace of darkening, but no brown colour, separating on standing from four to six hours to a very pale yellow solid mass and nearly colourless liquid. The apricot kernel oil, however, darkens considerably and separates into a brownish solid mass, in almost the same time, and a yellowish brown liquid.

The application of the test to oil pressed from almonds only shows the very palest yellow coloration and separation of the solid mass practically indistinguishable from that afforded by the oil of peach kernels.

It would appear, therefore, that the wording of the British Pharmacopæia test as it stands is not strictly accurate, although the non-compliance with it indicates admixture with apricot kernel oil at any rate.

THE COMPOSITION OF COMMERCIAL ARAROBA.*

BY EDWIN DOWZARD, F.C.S.

In the 1885 B.P., araroba is synonymous with chrysarobin, this is, of course, erroneous, as araroba is a mixture of chrysarobin, fragments of wood, etc.; this error has been corrected in the 1898 B.P. The official description is now as follows:—

Araroba.—A substance found in cavities in the trunk of *Andira araroba*, Aguiar, freed as much as possible from fragments of wood. dried and powdered.

Test.—It should yield to hot chloroform not less than 50 per cent. of chrysarobin. This is yet another of the many pharmacopœial inconsistencies which have been pointed out; in some cases the B.P. tests are so stringent that it is almost impossible to obtain articles which will satisfy them, in other cases, such as the present, the B.P. tests will admit an adulterated article.

The worst sample of araroba which I have yet examined contained about 8 per cent. of sand and 20 per cent. of twigs, when dried and powdered it yielded 51.8 per cent. of chrysarobin, and yet this is practically 2 per cent. above the B.P. limit; therefore, in this case, a sample which had been adulterated to the extent of about 28 per cent. was well within the B.P. requirements.

Araroba, containing from 65 to 75 per cent. of chrysarobin is easily obtainable, and it would be advisable to make the former figure the minimum limit.

As imported, araroba contains a large proportion of water (usually from 14 to 30 per cent.). I have been informed that water is added, not as an adulteration, but for hygienic reasons, the powder being of a very irritating nature; but when the amount rises to 25 or 30 per cent. it must be considered an adulteration, 15 per cent. of water is quite sufficient to prevent dust from rising.

The following table gives the results obtained in the examination of nine samples of commercial araroba:—

	No.		No		No. 3		No. 4		No. 5		No. 6		No. 7		No. 8		No. 9	
	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample	Sample as recd.	Dried sample

† Consists principally of coarse sand.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

It is almost impossible to powder this substance, because of the large proportion of water present. The following is a short description of the method I am in the habit of using :—

The sample is spread out, and a fair average taken (weight about 25 Gm.), the weight is determined before and after drying at 100° C. (the percentage of water being calculated from the loss). The dry sample is ground in a small drug mill, and the chrysarobin and ash determined in the resulting powder, the woody fibre, etc., is found by difference. The percentage of water being known it is an easy matter to calculate the composition of the original sample.

Pure dry araroba contains from 70 to 85 per cent. chrysarobin, and 0.3 to 3 per cent. of ash.

SYRUP OF BALSAM OF TOLU.*

BY E. H. FARR, F.C.S., AND R. WRIGHT, F.C.S.,
Pharmaceutical Chemists.

For some time past it has been our intention to take up the question of the best method of making this syrup, as we have had considerable doubt as to whether the process now official is the best available.

That there is something defective in the pharmacopœial method would seem to be indicated by two facts, which everyone who has made this preparation must have noticed, viz., the amount of volatile matter driven off in the process of boiling the balsam with water, and the subsequent copious separation of crystals which takes place.

The aromatic and acid principles represent the characteristic properties of the balsam, and hence the object should be to introduce into the syrup as large a proportion of these substances as may be possible, having regard to the elegance of the product.

The first point of our enquiry was to ascertain, as far as possible, the precise relation which the official syrup bears to the balsam, and in this direction we had no published work available for reference. After looking up the literature bearing on the chemistry of balsam of tolu, we concluded that it would be necessary to work partly on scientific and partly on empirical lines, the prime object of our work being the production of an improved syrup.

In this connection it was considered that the amount of volatile flavouring matter could be sufficiently estimated by the taste of the product, there being no means of making a scientific quantitative determination of the traces present in the syrup. With reference to the acid constituents too, it was thought that the precise proportion, if any, of benzoic acid which might accompany the cinnamic acid had no particular practical bearing on the result, though no doubt of interest, from a strictly scientific standpoint.

Two samples of balsam were procured, one old, brittle and easily pulverisable, the other new and of the consistence of a firm extract, and it was on these that the experiments detailed in this note were conducted.

In the first place the samples were subjected to the official carbon bisulphide test, the amount of free acid removed by that solvent being determined, in addition to the saponification equivalent.

The results obtained were as follows :—

	Hard Balsam.	Soft Balsam.
Total Residue Soluble in CS_2 per 100 Gm. of Balsam	20·5	32·8
Saponification equivalent	19·536	20·12
Free Acid	9·62	11·24

The benzyl cinnamate (cinnamein) was determined by dissolving 10 grammes of the balsam in 30 cubic centimetres of 10 per cent. aqueous solution of potash, and shaking the resulting solution with ether. The ethereal solution was washed with further portions of weak alkali until nearly colourless, when it remained as a jelly-like mass. On adding carbon bisulphide and shaking separation ensued, and the clear liquid was decanted from the insoluble residue and evaporated until all the ether and carbon bisulphide were expelled. The residue was then weighed, in each case, and saponified with alcoholic potash in known slight excess, the solution being afterwards titrated back with decinormal acid (1 C.c. normal KOH = 0·238 cinnamein) the results obtained being :—

	Total weight of residue from 100 Gm.	Cinnamein, by saponification, from 100 Gm.
Hard Resin	4·35	4·28
Soft Resin	8·55	8·04

For volatile constituents 500 Gm. of soft resin were distilled with water. The first portions of the distillate contained a very fragrant volatile oil lighter than water, consisting chiefly, if not entirely, of tolene. After separation of this body the water was returned to the retort, and distillation continued.

In the middle fraction of the distillate a further portion of the fragrant principle was seen, together with a denser product, drops of which collected at the bottom of the receiver, and, finally, the whole of the last volatile products were denser than water, but did not separate very freely, it was, therefore, considered advisable to extract these two portions with ether, and distil off the latter, leaving the volatile oil. This having been done, the products of distillation proved to consist of :—

(*a*) A very fragrant volatile body lighter than water, 1·4 per cent.

(*b*) A slightly fragrant mixture of *a*, with a substance heavier than water, and congealing in cold weather, 0·7 per cent.

The contents of the retort were next boiled with sodium carbonate and water, the resulting solution filtered and treated with excess of sulphuric acid, the quantity used being sufficient to combine with the whole of the sodium originally taken. The solution was evaporated to a pasty consistence, treated with 90 per cent. alcohol, and then filtered. The cinnamic acid was recovered from the alcohol by evaporation, twice recrystallised from boiling alcohol, after which it was crystallised from water. The final product amounted to 40 Gm., being 8 per cent. of the balsam operated upon. It melted at 131° C. (M. P. of cinnamic acid 133° C.), and ·265 Gm. required 17·8 C.c. N/10 soda to neutralise (= ·2634 Gm. cinnamic acid) these results indicating that the amount of benzoic acid present, if any, must be extremely small.

The constituents soluble in water, under different conditions of temperature, were next considered, the solutions being obtained by boiling with water, as in making the B. P. syrup ; but the filtration being conducted under different conditions such as might occur in actual practice.

No. 1	filtered at	25° C.	contained	·337 Gm.	cinnamic acid in	100 C.c.
No. 2	,,	20° C.	,,	·260 Gm.	,, ,,	,,
No. 3	after standing all night at	5° C.	,,	·148 Gm.	,, ,,	,,

These experiments indicate that the official syrup of tolu is liable to vary considerably, according to the time of the year when it happens to be made, and, further, the desirability of filtering the liquid as soon as it reaches a given temperature, and immediately converting it into syrup.

A number of syrups were next made from the two samples of balsam by each of the following processes, and the resulting products titrated. The flavour was judged by diluting with water and tasting the mixture.

The syrups were prepared as follows:—

1. By the U.S.P. process.

Dissolve 10 of balsam in 50 of alcohol by the aid of heat, and pour on a mixture of precipitated calcium phosphate 50, with sugar

* Read before the British Pharmaceutical Conference, at Plymouth, July, 1899.

120. Triturate well, then set aside until the alcohol has evaporated. Next add 500 of water, by degrees, triturating well, filter bright; to the filtrate, heated to 140° F. (60° C.) add the remainder of the sugar, dissolve by agitation. Cool, strain, and make up with water to 1,000 fluid parts.

2. By the B.P. process.

3. 1¼ of balsam dissolved in 1¼ of spirit was poured into simple syrup 34, well shaken, and, after a time, filtered. This form is given in Squires' 'Companion,' and is similar to the Edinburgh Pharmacopœia syrup, which was made by shaking 1 oz. of tincture of tolu with 2 lbs. of warm syrup.

4. 5 of balsam dissolved in 5 of alcohol was poured on 125 of sugar and well titurated in a mortar with water 240 until the sugar was all dissolved. The solution was next filtered bright, and 300 of sugar dissolved in it by the aid of gentle heat. When cold the product was strained and made up to 500 with water.

5. 5 of balsam dissolved in 5 of alcohol was poured into 240 of water heated to about 60° C., and the bottle containing the mixture well shaken, then set aside until cold, when the solution was filtered through powdered talc and converted into syrup, 500.

6. Take 4 of balsam and dissolve in 12 of alcohol 90 per cent., then add to 26 of water, previously heated to 70° C., and placed in a bottle; shake vigorously, then set aside for twenty-four hours; filter bright. Mix the filtrate with 7 times its volume of simple syrup.

Of the foregoing, the U.S.P. process is somewhat complicated and seems to defeat its special object, for the product has scarcely more flavour, and is considerably less acid than the B.P. syrup.

The B.P. form affords an elegant preparation, containing a good proportion of acid constituents, but, as might be expected, deficient in flavour. In this process the use of about one-fourth part of the balsam used might produce as good a preparation.

No. 3. This yields a syrup superior to any of the others in flavour, but the filtration is very tedious and the finished product by no means bright.

No. 4. This syrup is fairly aromatic but, like the U.S.P. products, somewhat deficient in acid bodies. Cold water even in presence of sugar is evidently not a good solvent of the acid.

5. The amount of spirit used is insufficient to produce the desired effect.

No. 6. The flavour of the preparation made by this process is excellent and it contains a high proportion of acid constituents. We consider that it might with advantage replace the form now official. If desired the solution may be kept, and diluted with syrup as required, but, being a saturated solution it is liable to deposit crystals in cold weather. These, however, dissolve on placing the bottle in a warm place.

TABLE COMPARING THE DIFFERENT SYRUPS.

THE STRENGTH OF CAPSULES OF BLAUD'S PILL OF COMMERCE.*

BY C. E. STUART, B.SC.

The enormous amount of labour and brains that have been bestowed upon the details of the formula for Blaud's pill of carbonate of iron, culminating in the production of an official formula, have practically exhausted the field of the chemistry and pharmacy of the subject. Capsules of Blaud's pill, however, that is, capsules containing the equivalent of one or more Blaud's pills, being of more recent introduction, have still a sphere of interest attaching to them, and are still—as my figures given below will show—somewhat of a problem to the pharmacist.

It is a comparatively easy matter to make a large capsule containing three grains of ferrous carbonate, which is the strength most in demand; but to make a small capsule of the same strength requires much care in the preparation of a concentrated soft mass with which to fill the capsule shell.

I have had occasion at intervals during the past year to examine a number of samples of Blaud's pill capsules of various makes, as a rule freshly prepared, and the results obtained seem to me of sufficient interest to justify me in laying them before the Conference as a contribution to the thirty-fifth subject specified in the Blue List.

Mr. Merson's note in *Pharmaceutical Journal*, Nov. 24, 1888 gave the percentage of ferrous carbonate in various capsule masses. From the point of view of prescriber and patient, however, the actual amount of the salt in each capsule is more important, seeing that no definite size or weight of capsule is authorised.

I have, therefore, in the following table given the amount of ferrous carbonate found in an average of from three to eight capsules, and in some cases the average weights of the contents of the capsules, so that percentage of carbonate in the mass may be calculated if desired.

In each case the iron salt was found to be rendered semi-fluid by admixture with an oily body—liquid paraffin in some cases, probably so in all.

The contents of the capsules fall according to their method of manufacture in the three classes A, B, C. Each number represents a separate make or batch of capsules.

A.—*Capsules containing Saccharated Ferrous Carbonate.*

No.	Average Ferrous Carbonate in each in grains.	Average weight of contents in grains.	Remarks.
1.	0·07	—	Total Iron calculated as $FeCO_3$ ·46 grains.
2.	0·92	4·01	—

B.—*Capsules containing Ferrous Carbonate badly washed, and excess of alkaline carbonate.*

3.	0·46	—	—
4.	0·89	—	—
5.	2·59	—	—
6.	0·50	8·0	Strong effervesence with acid.
6a.	0·45	8·0	as 6, after six weeks.
7.	0·70	4·77	—

C.—*Capsules containing well-washed Ferrous Carbonate.*

8.	3·36	6·2	—
9.	3·83	6·6	—

It will be seen that Nos. 8 and 9 show that the problem of a small and active Blaud's pill capsule is not an insoluble one. The remaining numbers reveal the fact that the required standard is not always attained. In No. 1 it is evident that the maker had a very curious notion of what the theoretical iron contents of a

* Read before the British Pharmaceutical Conference, at Plymouth, July, 1899

Blaud's pill capsule should be, for the total iron calculated as ferrous carbonate in each capsule is only 0·46 grn., and the actual amount of ferrous salt is practically *nil*.

No. 2 was labelled simply Blaud's pill capsules; all the others were stated to contain the equivalent of three Blaud's pills.

The method of determination was to weigh the capsules, cut them open under ether, squeeze out the contents, and remove and weigh the rapidly dried shells, giving contents by difference.

A little dilute sulphuric acid (or phosphoric acid with those containing sugar) was then poured into the dish, and the oily mass rapidly disintegrated and dissolved. Standard bichromate solution was run in without removing the ether and the estimation conducted in the usual way.

FURTHER NOTE UPON FERRUM REDACTUM, B.P., 1898.*

BY E. SAVILLE PECK, B.A.

During the discussion which followed the reading of my paper upon Ferrum Redactum at the last Conference, the question arose as to whether I had compared my results of the determination of Ferrum Redactum with the methods of the British and United States Pharmacopœia with the "iodine method." In this paper I have endeavoured to answer this inquiry.

This "iodine method," devised by E. Schmidt, is given in the 'Year-Book of Pharmacy' for 1898, and consists in the separation of the metallic iron from the oxides by means of iodine and the subsequent estimation of the excess of the iodine by titration. "0·4 gramme of the finely powdered sample is treated in a 100 C.c. flask with 10 C.c. of water and then slowly with 2 to 2·5 grammes of powdered pure (and dry) iodine, the latter being added gradually from a weighed tube. When the action is completed any iodine adhering to the neck of the flask is washed down with water, 1 gramme of potassium iodine is added, and after the iodine is all dissolved the liquid is diluted with water to exactly 100 C.c. It is then shaken and allowed to settle, and the excess of iodine is now titrated in 50 C.c. of the clear liquid by means of decinormal solution of sodium hyposulphite. After deducting the total excess of iodine from the entire quantity originally taken, the difference represents the amount of iodine used up in the formation of ferrous iodide, from which the percentage of metallic iron in the sample is readily calculated.

In working the above method the Ferrum Redactum was powdered and passed through a 60 sieve. The iodine was resublimed and powdered, and weighed by difference from a stoppered tube.

The decinormal solution of sodium thiosulphate was standardised by decinormal iodine which had been previously standardised by arsenious anhydride. Notwithstanding all these precautions it seemed impossible to obtain concordant results, as the following. Table A will show:—

TABLE A.

	Ferrum Redactum taken.	Iodine taken.	Iodine Used.	Fe Found.	Percent. of Iron.
P. 1	0·2775	0·685	0·4143	0·1152	41·51
„ 2	0·3690	0·9745	0·7303	0·1613	43·60
„ 3	0·3080	0·9250	0·5353	0·1181	38·34

These results appeared not only unsatisfactory because of their want of uniformity, but also from the low percentage yielded from a sample which I had reason to believe was a good one.

It then occurred to me to use much less water, in fact, in the following examples, in Table B, as little as 0·5 to 1 C.c. was used. It was then found that the action of the iodine upon the iron was "*immediate and complete*," but not sufficiently violent to cause any appreciable loss of iodine from volatilisation—a stoppered 100 C.c. flask being used in each case.

The following Table B shows that concordant results can be obtained much higher in percentage than those in Table A, although the same sample (P) was used in both cases.

TABLE B.

	Ferrum Redactum taken.	Iodine taken.	Iodine Used.	Fe Found.	Percent. Fe.
P. 4	0·2825	1·281	1·049	0·2316	82·01
„ 5	0·3425	1·429	1·260	0·2782	81·24
„ 6	0·270	1·313	1·003	0·2216	82·09
Q. 1	0·4965	1·089	0·8777	0·1938	39·03

„ 3	1·25	2·787	2·320	0·5122	40·98

The two samples P and Q were then estimated by the copper sulphate method (B.P., 1898), with the modifications suggested in my last paper.

The results are given in Table C.

TABLE C.

Determination by Copper Sulphate Method.

Sample.	Ferrum Redactum taken.	Fe Found.	Percentage Fe.
P. 7	0·5095	0·4250	83·42

„ 5	52·58	38·62	40·67
„ 6	52·88	38·90	40·98

From the above comparison (Table E) it will be seen that the mercuric chloride and iodine methods give almost similar results in both samples, although the two samples differ widely in per-

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899

centage of pure iron. From this fact we may fairly infer that one corroborates the other.

It will also be noticed, as I pointed out last year, that the copper sulphate method invariably gives a higher reading than the mercuric chloride method, the average difference varying in different samples. It also appears that the lower the percentage of pure iron in the sample the greater the difference in the results of the two methods.

Again, although it seems comparatively easy by adopting various precautions, and conducting each determination under like conditions, to obtain concordant results by the copper sulphate methods, it does not necessarily follow that those results give the accurate percentage of the sample.

From these data it appears obvious that the copper sulphate method is not satisfactory, and that either one of the other two methods is to be preferred. From practical experience I am fully convinced that the "mercuric chloride" method is the most satisfactory.

I have to thank Mr. R. Foster Moore, of Christ's College, for his kind assistance.

THE ASSAY OF BELLADONNA PLASTERS, B.P., 1898.*

BY H. J. HENDERSON,

Pharmaceutical Chemist.

The assay of belladonna plasters presents some considerable difficulty, owing to their complex composition. In this paper I shall concern myself only with those plasters which have been prepared strictly in accordance with the formula of the British Pharmacopœia. I hope to be able at some future time to publish a satisfactory method of assay which shall be applicable to those plasters which have a rubber base, but my work on these is at present incomplete. A process of assay to be of practical utility to a busy pharmacist must not be a complicated one, yet it must yield results which are not merely approximations to the truth. For this reason I have been at considerable pains to prove the purity of the alkaloidal residues. One great point in favour of the process I have devised is the absence of that tendency to form intractable emulsions when shaken with chloroform in alkaline solution. In the case of the liquid extract of nux vomica, the formation of these emulsions mars the beauty of what would otherwise be a very elegant and rapid process. The separation of the extract of belladonna from the other constituents of the plaster is the chief difficulty to be overcome, for this once done, the shaking out of the alkaloid with an immiscible solvent, on the lines laid down in the B. P. for the assaying of the liquid extract, is all that is necessary for the completion of the assay. To attain this object, many trial experiments were made with various solvents, such as ether, carbon bisulphide, chloroform, petroleum ether, etc., and it was found that ether was most suitable for the purpose. Ether does not dissolve the plaster entirely, which was not to be expected, but it causes it to disintegrate in a finely divided condition, forming a dirty-looking emulsion, which when agitated with a mixture of glacial acetic acid and water in certain proportions, separates sharply into two clear layers, the lower acid solution containing the belladonna extract and acetate of lead, whilst the supernatant ether contains the decomposition products of the other constituents of the plaster.

Two shakings only are necessary, as it was found upon experiment that no alkaloid was present in the acid liquor from a third shaking. The details of the process are as follow:—Weigh 5 Gms. of the plaster, and introduce it into a stoppered glass separator, with 25 C.c. of ether, allow the plaster to disintegrate. When the contents of the separator present the appearance of an emulsion, add 5 C.c. of a mixture of glacial acetic acid and water (3 parts of the former to 2 parts of the latter), shake for thirty seconds, and set aside until the acid liquor has completely separated. Draw off the lower layer into a small beaker, and again agitate the ether solution with 5 C.c. of the dilute acetic acid of the B.P. and draw off as before. To the united acid liquors in the beaker add dilute sulphuric acid in slight excess, stir well, and allow the sulphate of lead to subside. Filter the solution through a small filter into a separator, transferring the whole of the sulphate of lead on to the filter by means of a glass rod tipped with rubber, allow to drain. Remove the funnel from the separator, and wash the lead precipitate with distilled water until a drop of the filtrate gives no precipitate with Mayer's reagent. Concentrate the washings to a small bulk and add them to the contents of the separator.

It will be found to be advantageous to use a filter pump in washing the lead precipitate, but it is not essential. The separator now contains the extract of belladonna, freed from the other constituents of the plaster. Add excess of solution of ammonia and 10 C.c. of chloroform, shake well for thirty seconds, and draw off the chloroform into another separator. Repeat this treatment with two more successive portions of chloroform of 5 C.c. each. Mix the chloroformic solutions of the alkaloids, and shake out the alkaloids with three successive portions of dilute hydrochloric acid, using 5 C.c. for each shaking. To the mixed acid solutions, in a separator, add excess of solution of ammonia and 10 C.c. of chloroform, shake well, and draw off the chloroform into a weighed dish, repeat the shaking with two successive portions of chloroform, using 5 C.c. for each, draw off as before, and allow the chloroformic solutions to evaporate spontaneously. Dry the residue in the air oven at a temperature not exceeding 93° C. until the weight is constant, and weigh. The residues obtained were beautifully white and crystalline. Applying the process to a plaster, prepared by myself, from a liquid extract of belladonna which I assayed for the purpose. The plaster therefore contained exactly 0·5 per cent. of alkaloid. To prove the purity of the alkaloidal residues, advantage was taken of a process devised by Professor Dunstan and Mr. Francis Ransom (*Ph. J.* [3], **14**, 623). In this process the residues are dissolved in dilute hydrochloric acid, strong solution of iodine is added, and the green periodides, which are precipitated, collected on a small filter, rapidly washed with solution of iodine, and decomposed with solution of thiosulphate of sodium, ammonia is added to the filtrate, and the alkaloids shaken out with chloroform in the usual manner. After drying, the weight of the residue should not appreciably differ from the original weight of the residue operated upon, within the limits of experimental error. Other residues were checked by dissolving them in N/10 solution of hydrochloric acid, afterwards titrating back with N/100 solution of soda, using cochineal as indicator. The weight of plaster taken in each case was 5 Gms., the theoretical quantity of alkaloid obtainable being 0·0250 Gm.

Weight of Residue Obtained.	Weight of Pure Alkaloid Indicated by Dunstan and Ransom's Periodide Method.
α 0·0235	0·0225
β 0·0230	0·0221
γ 0·0233	0·0225

Weight of Residue Obtained.	Weight of Pure Alkaloid Indicated by Volumetric Method.
δ 0·0240	0·0243
ϵ 0·0230	0·0229
ζ 0·0230	0·0231

It will be noticed that in two of the volumetric determinations a plus error appears, yet the figures appear to justify the conclusion that the residues are practically pure. The experiments necessary for this paper were carried out in the laboratory of Messrs. W. Ransom and Son, of Hitchin.

*Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

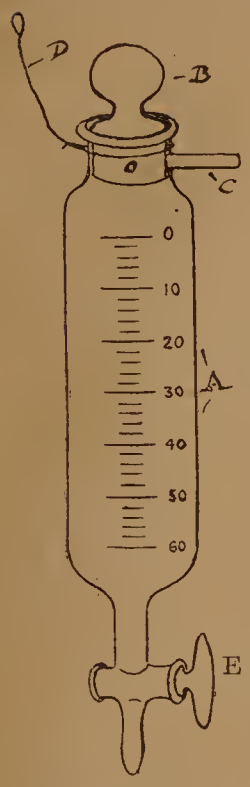
A WEIGHT BURETTE.*

BY E. SAVILLE PECK.

A weight burette, as its name implies, is simply a burette which can be weighed before and after titration, giving the weight of solution used instead of its volume.

An illustration of one of these is given. They were made from the directions of Mr. C. T. Heycock, M.A., F.R.S., to whom they occurred upon reading the work of Stas upon the 'Laws of Chemical Proportions.' They have been used in the Sidney College Laboratory, Cambridge, when determinations of great accuracy have been required.

By referring to the diagram it will be seen that they consist of—



A, an ordinary glass cylinder of about 70 C.c. capacity, very roughly divided into c.c.'s These divisions are not absolutely necessary, but they will be found useful in the case of a second titration of the same solution.

B, a hollow stopper with a small perforation opposite C, which is a glass tube used to admit the air when drawing out the solution without taking out the stopper.

E, an ordinary glass stop-cock.

D, a wire loop for hanging the burette upon the hook above the balance pan.

A standard weight solution is make by taking a flask, carefully drying and weighing it, the standard substance being introduced into this from a stoppered weighing tube, water added to approximate volume desired and solution effected.

The whole is then weighed. The weight of dry flask being known the weight of the solution is found.

The strength of this sulution is then x grammes of standard substance in x grammes of the solution, which, therefore, becomes the standard solution.

This standard solution is placed in one of these burettes and another filled with the solution to be estimated.

Both are carefully weighed, a certain quantity from one, say 10-15 Gm., is run into a suitable vessel, in which the titration can be made and again weighed. The titration is then carried out and the weight of second burette found. It is seen that a definite weight of the solution of unknown strength requires a definite weight of standard solution which in its turn contains a definite weight of standard substance.

From these data the strength of the unknown solution is obtained. It is essential when weighing both the empty flask and burettes that each is approximately counterpoised by a similar vessel upon the opposite scale-pan, so that the same amount of air is displaced on both sides, and thus corrections for variations of temperature and pressure are avoided.

As in ordinary volumetric work different substances will require slightly different manipulation; for instance, it will frequently be found convenient to weigh sufficient only of the standard substance for each titration.

The advantages of this method of using weight burettes are:—

(1) Changes of temperature during the experiment, and differences of temperature of the two solutions exert no influence upon the result.

(2) The errors arising from inaccurate calibration of the ordinary burette are entirely eliminated.

(3) The question as to whether all pipettes are made to contain or deliver a certain volume, and, if the latter, whether the last drop should be blown out is entirely avoided.

(4) Supposing the weight of these burettes is carried to the third decimal place it is equivalent to having a burette accurately graduated to one thousandth parts of a cubic centimetre.

(5) The difficulty of reading correctly and uniformly the ordinary burettes owing to the unevenness of the meniscus, or from the fact of some of the solution adhering to the sides of the burette—particularly noticeable in dark solutions, such as potassium permanganate or from other causes, is obviously overcome.

In conclusion, let me say, from practical experience, that although undoubtedly this method takes longer, and would be considered by some extremely tedious, yet the accuracy and uniformity of the results obtained fully justify the extra expenditure of time and trouble when such accuracy is required.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

A NOTE ON COMMERCIAL CARBON DISULPHIDE.*

BY W. ELBORNE, M.A.

A quantity of the best commercial carbon disulphide (about 200 C.c.), clear and bright, contained in a clear glass bottle, fitted with a "cork" capped with parchment-paper (just as received), was left unopened and undisturbed for six months in a situation exposed to strong diffused daylight. During the period it developed a surprising copious flocculent brown deposit; upon filtering off and drying the same at a low temperature, it was left as a buff-coloured powder, insoluble in water, alcohol, ether, and chloroform respectively; soluble in warm aqueous caustic soda, yielding a yellow coloured liquid, not reprecipitated by acetic acid, but copiously on addition of solution of nitrate of silver to the latter acid liquid. Fresh portions (1) charred readily on being touched with sulphuric acid; (2) on being cautiously heated on platinum foil, immediately disengaged most inflammable vapours, igniting with a luminous sooty flame, leaving a residue of carbon which readily burnt off; (3) added to a hot fused mixture of pure caustic soda and potassium nitrate, underwent vivid ignition; the cooled mass dissolved in water, copiously evolving carbonic acid gas on addition of excess of hydrochloric acid, but not precipitated on further addition of barium chloride, indicating the absence of sulphates and consequently of sulphur in the original substance. The sample of carbon disulphide in question evidently therefore contained impurities which had been decomposed or at least rendered insoluble by exposure to light (in part possibly attributable to extractive from the "cork"), or had itself undergone some decomposition.

In a recent extended research on carbon disulphide (*Journ. Chem. Soc.*, 439, p. 604) Dixon and Russell purified their material as follows: "The best commercial carbon disulphide was allowed to stand some hours with bromine in the cold, the bromine was then removed by potash, and the carbon disulphide shaken for an hour with alkaline permanganate. After washing well with water it was dried over calcium chloride and distilled, the first portion only being collected. Care was always taken to avoid unnecessary exposure to light. The substance thus obtained boiled very constantly at 46·8° C., under 772 Mm. pressure." They also showed that the pure substance underwent decomposition by exposure to light, yielding upon evaporation a brown uninviting-looking, gummy substance, not further examined. For chemical purposes carbon disulphide should consequently be stored in glass-stoppered bottles and be kept as far as possible from the action of light.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899

THE BONE CAVES OF SOUTH DEVON.*

BY R. HANSFORD WORTH.

Invited to read a short note on some local geological subject to your Conference, I selected the bone caves of South Devon as possibly the most suitable. It is impossible to do justice to the matter in the time available, but at least no other geological subject would admit of any briefer treatment, nor would be likely to prove of equal interest to those of your members who are neither geologists nor petrologists.

Wherever in Devonshire the middle Devonian limestone occurs, bone caves or fissures may be expected to exist. The list of localities includes Stonehouse, Plymouth Hoe, Cattedown, Oreston, Yealmpton, Torquay, Brixham, Buckfastleigh, Ogwell, and Chudleigh.

The most popularly celebrated cave is the Kent's Hole, at Torquay, long known as a cavern to which access was easily obtainable. It has formed from early ages a den, a human residence, an object of curiosity, the subject of wild antiquarian speculations, and last in the recent series, but greatest, the object of a classical investigation by a committee of the British Association, of which the late William Pengelly, F.R.S., was the dominant spirit.

For at least three centuries past the scientifically minded or merely curious have frequented this cave. In 1824 the first quasi-scientific exploration was undertaken by Northmore, who visited the cavern "with the double object of discovering organic remains and of ascertaining the existence of a Temple of Mithias." In the first object he was successful; the second is of the nature that brings its own fulfilment. With ingenuous frankness he remarks: "And happy am I to say that I was successful in both objects; in the former pursuit indeed I have been followed by hundreds, in the latter by none." Which, be it observed, is matter for congratulation, since this ardent explorer found to his own satisfaction, "the baptismal lake of pellucid water," "the creeping path of stone purification," and, if he was not quite mistaken (for he spoke doubtfully) "the mystic gate of obstacle"; the "even month"; and possibly one more "arcane memorial," which sufficiently satisfied my mind upon the Temple of the extensively-worshipped and thousand-named deity Belin. All this was in 1824, and it is calculated that had Northmore found equally enthusiastic followers the whole of the mythologies of the world would now be lodged in that cave.

Fortunately the "discovery of organic remains" was the object that appealed more strongly to his successors, and MacEnery, Goodwin Austin, and Pengelly obtained results from their investigations which have made the place classic ground.

The earlier investigators neglected, or else deliberately suppressed, the occurrence of human remains side by side with those of the beast fauna, and to this, coupled with the same policy pursued at Preston, it is due that Windmill Hill Cavern, Brixham, holds the proud position of having first afforded recognised evidence of the great antiquity of man.

The deposits in Kent's Cave consisted of three distinct mechanical accumulation: The black mould, or uppermost, a layer of dark mud from three to twelve inches thick; the cave earth, a light, red clay with angular fragments of limestone separated from the black mould by a layer of granular stalagmite from an inch to over five feet in thickness; the Breccia, consisting of fragments of dark red grit "imbedded in a sandy paste of the same colour"; this was separated from the cave earth by a layer of crystalline stalagmite in some places close on twelve feet in thickness.

All the deposits contained the remains of animals. To quote Mr. Pengelly—

"In the black mould, or more modern deposit, the remains were those of species still existing, and almost all of them now occupying the district. They were man, dog, fox, badger, brown bear, *Bos lengifrous*, roe deer, sheep, goat, pig, hare, rabbit, water-rat, and seal. In the granular stalagmite, black band and cave earth, and especially the last, extinct as well as recent animals presented themselves, the cave-hyæna being the most prominent, but followed very closely by the horse and rhinoceros. Remains of the so-called Irish elk, wild bull, bison, red deer, mammoth, badger, the cave grizzly and brown bears, are by no means rare; those of the cave-lion, wolf, fox, and reindeer were less numerous; and those of beaver, glutton, and *machairodus latidens* were very scarce. In the crystalline stalagmite and the Breccia remains of animals were less uniformly distributed. So far as is at present known, they were exclusively those of bear. There were no bones of hyæna, and no bones fractured after his well-known fashion. Remembering his cavern-haunting habits, it may in all probability be safely concluded that the era of the crystalline stalagmite, and the Breccia it covered, was prior to the advent of the hyæna in this country."

In the bottom of the deepest excavation and thence up through the ascending series of deposits were found flint flakes and implements. It may not be without interest to remark that the cavern exhibits to us more and more ancient men; it shows that they were ruder and ruder as we proceed into antiquity. The men of the black mould had a great variety of bone instruments; they used spindle-wheels, and made pottery, and smelted and compounded metals. The older men of the cave earth made a few bone tools; they used needles, and probably stitched skins together; but they had neither spindle-wheels, nor pottery, nor metals; their most powerful weapons were made of flint and chert, many of them symmetrically formed and carefully chipped; but it seems never to have occurred to them to increase their efficiency by polishing them. The still more ancient men of the Breccia have left behind them not even a single bone tool; their flint implements are rude and massive, show but little attempt at regularity of outline, and are but rudely chipped.

It will be noted that at Kent's cavern the feature of constant accessibility and occupation is dominant. Let me not be understood to suggest that there have been no breaches in the continuity.

The early history of man is carried back by the contents of this cave to a period antecedent to the British hyæna.

It was Colonel Hamilton Smith, however, who first recognised man as a member of the cave fauna. On his pointing out the upper portion of a humerus of man among a collection of bones from Oreston, its should-have-been fortunate possessor immediately threw it away. For long from that early date in the cave hunting around Plymouth no further human remains came under the observation of persons sufficiently honest to publish their existence to the world. At least sixteen distinct series of finds were made between 1816 and 1887 in caves, in fissures, and among fluviatile deposits, at Oreston, Deadman's Bay, the Hoe, Stonehouse, and Mount Wise.

In 1887, however, a cave was disturbed in the course of quarrying operations at Cattedown, which proved to be of extreme value as a geological find. The cave was comparatively small, as far as explored, consisting of two chambers each about 20 ft. in length, the one some 8 ft., the other 5 ft. in width. Excavations were carried down to the rock floor of one chamber, but had to be stopped in the other on reaching a point below the tide level in Cattewater adjacent.

The deposits formed a descending series of stalagmite floor; stalagmitic Breccia, "concrete floor," and cave earth, all members of the series, were not everywhere present.

The stalagmitic Breccia yielded to no gentler persuasion than blasting, and it was purely heartrending to have to resort to this violent expedient, regarding the possible havoc played on fragile remains. The Breccia contained remains essentially representing the complete skeletons of the animals concerned: man, deer, hyæna, wolf. The cave earth below the Breccia contained no practically

THE CONFERENCE AT PLYMOUTH.

THE annual meeting of pharmacists, which has been held this year in the capital of the West Country, commenced most auspiciously and, up to the time of writing, the proceedings have been conducted in a manner which calls for the highest praise. The weather has been excellent, the hospitality offered to the visitors has been magnificent, and all the arrangements have worked with the smoothness of clockwork, thanks to the untiring energy of Mr. C. J. PARK, President of the Local Committee, and Mr. J. DAVY TURNEY, the Hon. Local Secretary, aided by the other members of the Committee. The reception by the PRESIDENT of the Conference and Mrs. PAYNE was held at the Assembly Rooms, Plymouth, on Monday evening, and a most enjoyable programme had been prepared for the occasion. Some three hundred were present, and great animation prevailed during an evening without a single dull moment. On the following morning the members of the Conference were formally welcomed by the Mayors of Plymouth and Devonport, the Chairman of the Stonehouse District Council, and Mr. MAY, who represented the Plymouth Medical Society, and Mr. PAYNE subsequently delivered his presidential address.

The subject of the address was the history of pharmacy in Ireland, and Mr. PAYNE showed how progress has proceeded in the sister isle on similar though not identical lines with Great Britain. He concluded by referring to the bonds of friendship which are growing between the pharmacists of Ireland and Great Britain. The fact that the members of the Conference assembled last year at Belfast is, he thinks, significant, and he is hopeful of a closer union and a stronger harmony being brought about during the new century between the pharmacists of Great Britain and those of Ireland, so tending to the advancement of pharmacy and all concerning it. Naturally, the address was received with great enthusiasm, and the speeches which followed were happily conceived and to the point. The reading and discussion of the numerous papers communicated to the Conference was subsequently proceeded with and continued, after the usual luncheon interval, until four o'clock.

Most of the members and their friends then made their way to the Millbay Docks, where the Great Western Railway Company's tender "Sir Richard Grenville" was waiting to convey them to Looe. The weather was perfect, the sea calm, and altogether this trip along the Cornish coast and up one of the prettiest Cornish rivers was most enjoyable. The Conference photograph was taken in the Guildhall Square on Wednesday morning, and short excursions were arranged for the benefit of the lady visitors during the sessions of Conference. The whole party again assembled in the Western Law Courts during the afternoon, to take part in the concluding business. Chief amongst this was the selection of London as the place of meeting for 1900, and the election of Mr. E. M. HOLMES, Curator of the Pharmaceutical Society's Museums, as President for the year 1899-1900. Business over, there was a brief interval before the smoking and drawing-room concerts, dancing, etc., on Wednesday evening. The whole of Thursday was devoted to the excursion to Mount Edgcumbe and up the river Tamar, and the chief attraction for Friday was the garden party given by the Mayor of Plymouth at his country residence on Dartmoor. A more pleasant week it would be difficult to conceive of, and the prevailing feeling at the close of the meeting must be one of regret that the time spent in the beautiful West Country—amongst such generous and hospitable friends—has been so brief.

PAPERS READ AT THE CONFERENCE.

THE papers read or taken as read at the thirty-sixth annual meeting of the British Pharmaceutical Conference numbered about thirty, and they are printed in full in the current issue of the Journal. The substance of them is briefly given here.

FARR AND WRIGHT ON IPECACUANHA.

E. H. FARR and R. WRIGHT deal with the assay of the official liquid extract, wine and vinegar of ipecacuanha. They consider that the process for the determination of the alkaloids in the liquid extract possesses every fault possible to such a process, without a single compensating advantage. WILSON's process is much more satisfactory, but not an ideal one, and the authors have experimented with the view of devising a process which shall combine economy, simplicity, and accuracy, with rapidity of working. In the suggested process the extract is mixed with diluted sulphuric acid and evaporated, the alkaloids are shaken out with chloroform and ammonia, and subsequently extracted from the chloroformic solutions with sulphuric acid. They are recovered from the acid solution by repeated treatment with ammonia and chloroform, and finally titrated. A more rapid process is also described for employment in laboratories where economy of time is of especial importance. The wine and vinegar of ipecacuanha may be assayed in a similar manner to the extract.

NAYLOR AND BRYANT ON IPECACUANHA ASSAY.

W. A. H. NAYLOR and J. J. BRYANT have attempted to devise a better process than the official one for the assay of liquid extract of ipecacuanha, and describe four:—A lime process, a kieselguhr process, a process which is practically identical with that suggested by FARR and

WRIGHT, and one which they regard as superior to the latter. It is objected to the third process that though yielding accurate results, it consumes much time owing to the great difficulty with which the separations are effected, even when the separator is immersed in hot water. In the process to which preference is given, the liquid extract is freed from alcohol, treated with very dilute sulphuric acid, shaken with chloroform, then made alkaline with ammonia, and shaken out with chloroform. The residue left on evaporating the chloroform is weighed and titrated with decinormal hydrochloric acid. The assay is performed with rapidity, and the results of this process appear to give strictly comparable results with the same sample of liquid extract. The distinctive feature claimed for it is the removal of the resinous substances by a rapid and simple method without loss of alkaloid, thereby making possible the quick separation of the chloroformic solutions. The process is also adapted for the assay of ipecacuanha wine.

BIRD ON IPECACUANHA.

F. C. J. BIRD is of opinion that the B.P. liquid extract of ipecacuanha is a great improvement on the dried acetic extract, as it possesses the advantages of standard strength, good keeping properties, and the fine aroma of the root is retained. Precipitation occurs, however, on diluting the extract with weak alcoholic or aqueous liquids, and the author suggests that, by adding an equal bulk of water to the extract, and allowing the mixture to stand in a cool place for twenty-four hours, a perfectly miscible liquid may be obtained after filtering and adding a little acetic acid, then distilling off the alcohol, evaporating the residue and adding the bright liquid to the distillate. The finished product gives a bright mixture with detannated wine, yields from 2·0 to 2·5 per cent. of alkaloid by the B.P. assay process, and compares favourably as regards aroma with the official liquid extract. Mr. Bird also contributed "Laboratory Notes" on Liq. ferri perchl., and on detannated wine.

UMNEY AND SWINTON ON JOHORE IPECACUANHA.

J. C. UMNEY and R. S. SWINTON have examined Johore ipecacuanha, the root of *Psychotria emetica*, and state that it differs but little in character from the same root imported from Brazil. The proportion of total alkaloids present was found to be 1·7 per cent., and the mean of three experiments showed the percentage proportions to be emetine 72·94, cephaeline 22·94, other alkaloidal matter 4·12, the figures corresponding closely with those recorded for the Brazilian root. It is suggested that there appears to be no reason why the root should not be used for making standard preparations of ipecacuanha.

HENDERSON ON THE ASSAY OF BELLADONNA PLASTERS.

H. J. HENDERSON gives the details of a process for assaying belladonna plasters prepared in accordance with the B.P. formula. The plaster is allowed to disintegrate with ether and the mixture is then shaken with acetic acid. Sulphuric acid is next added to the separated acid liquor, the lead sulphate allowed to subside, and the belladonna extract separated from the other constituents of the plaster. The alkaloids are then shaken out with ammonia and chloroform, next taken up with hydrochloric acid, and finally obtained in crystalline form and weighed. Applying the process to a plaster prepared by himself from liquid extract of belladonna, the author found the plaster contained exactly 0·5 per cent. of alkaloid.

FARR AND WRIGHT ON SYRUP OF TOLU.

E. H. FARR and R. WRIGHT point out that the loss of volatile matter in the process of boiling tolu balsam with water, and the subsequent copious separation of crystals, appear to indicate that the official method for preparing syrup of tolu is somewhat defective. As the result of experiments they find that the official syrup is liable to vary considerably, according to the time of year when it is made, and further that the solution obtained on boiling the tolu with water should be filtered as soon as it reaches a given temperature, and immediately converted into syrup. Several samples of the syrup have been prepared by different processes, and the authors suggest the replacement of the official process by one in which the tolu is first dissolved in 90 per cent. alcohol, the solution added to water previously heated to 70° C.; the mixture is shaken well and set aside for twenty-four hours, then filtered bright, and mixed with seven times its volume of simple syrup. The solution may be kept and diluted as required, any crystals which deposit in cold weather dissolving when the bottle is removed to a warm place.

PECK ON FERRUM REDACTUM.

E. SAVILLE PECK has compared his results of the determination of ferrum redactum by the methods of the British and United States Pharmacopœias with that of the "iodine method." He finds that the mercuric chloride and iodine methods give almost similar results with samples differing widely in percentage of pure iron, and, from that fact, he thinks it may be inferred that one corroborates the other. Attention is also again directed to the fact that the copper sulphate method invariably gives a higher reading than the mercuric chloride method, the average difference varying in different samples, whilst the lower the percentage of pure iron in the sample the greater is the difference in the results of the two methods. The copper sulphate method is, therefore, held to be less satisfactory in use than the other two methods.

FARR AND WRIGHT ON JABORANDI.

E. H. FARR and R. WRIGHT having experienced great difficulty in preparing standard preparations of jaborandi from commercial samples of the leaves, have conducted an investigation into the strength of the tincture and liquid extract as found in pharmacy, the process employed for the determination of the alkaloids being the one devised by the authors in connection with their former work on tincture of jaborandi. As a result, they find that the galenical preparations of jaborandi found in retail pharmacies at the present time are very deficient in strength, only containing about one-fifth the proportion of active constituents which, judging from the official doses, they are supposed to contain. The explanation suggested is that the best jaborandi leaves are being withdrawn from the drug markets, and so prevented from coming into the hands of pharmacists.

DRUCE ON THE DEVONIAN FLORA.

G. C. Druce, following up what has now become almost an established custom, gives a slight sketch of the botany of the district visited by the members of the Conference. Contrasting the district with others in which the Conference has recently met, he states that the county of Devon possesses more than a hundred species which are not native in Ireland, nearly a hundred and forty which are not native in Scotland, and nearly a hundred and eighty which do not occur in Oxfordshire.

HOLMES ON DELPHINIUM STAPHISAGRIA.

E. M. Holmes directs attention to the fact that the true *Delphinium staphisagria* is practically unknown in botanic gardens in this country, and that the plant which passes under that name is in reality another species —viz., *Delphinium pictum*, Willd. The two species are distinguished as follows:—*D. staphisagria* has very hairy stems, glandular hairs being mixed with the long spreading soft hairs, flowers that when well developed have an ultramarine blue tint, and a calyx with a very short or almost obsolete spur, and carpels containing only four or five large seeds. *D. pictum*, Willd., has shorter soft hairs, but no glandular hairs on the stems, and the flowers are of a pale lilac colour, the spur is as long as the calyx segments, and there are in each carpel ten or twelve seeds, which are only half the size of those of *Delphinium staphisagria*, Linn. The author accounts for the absence of the true plant in botanic gardens partly by the fact that it is only half-hardy in Britain, requiring the protection of a greenhouse in winter, whilst *D. pictum* is hardy, and partly by the reason of illustrations of the plant in several works on medicinal plants being incorrect. Even the illustration in Bentley and Trimen's 'Medicinal Plants,' quoted in the British Pharmacopœia, is unreliable, the drawing having evidently been made from a fresh specimen of *D. pictum* supplemented by details of stem and leaf from dried museum specimens of the true *D. staphisagria*, and being therefore a composite and worthless illustration. Mr. Holmes exhibited dried specimens and coloured drawings of the two plants. His experience in growing the plants showed that it is almost impossible to grow the true plant from the stavesacre seeds of commerce, which will not germinate, or only very rarely indeed, and that the plant requires shade and warmth and a damp atmosphere, whilst *D. pictum* grows well in sunlight and in the open air, and in the south of England, at all events, is quite hardy. He recommends that in the next Pharmacopœia the figure given by Nees von Esenbeck, 'Pl. Med.,' tab. 394, should be referred to, unless a better one be published before the appearance of the next edition.

OUGH ON TEREBENE.

Lewis Ough has attempted to ascertain to what extent commercial specimens of terebene correspond with the B.P. requirements for that article and, as a result, he finds that it is most varied in its composition, only one sample out of twelve being in strict accordance with those requirements. The solubility of the samples in 90 per cent. alcohol varied from 4·75 to 6 per cent., the solubility in pure ether (s.g. 0·720) from 1 in 10 to 1 in 20, and the solubility in methylated ether (0·717) from 1 in 1·4 to 1 in 2·5. The optical rotation also varied greatly in the different samples.

PARKER ON GLUCOSE DETERMINATION.

R. H. Parker compares the picric and Fehling methods for the determination of glucose in diabetic urine, and shows that the advantages of the latter when dealing with high percentages may be realised in an equal degree by adding a known quantity of glucose before determination. He finds that the production of opacity in Fehling's solution by alkalised urine is characteristic of glucose. "Interfering substances" do not produce that opacity, and rarely occur in greater quantity than a picric indication of 0·35 per cent. of glucose. When the picric indication falls below 0·4 per cent. the actual amount of glucose present may be approximately ascertained by noting the point at which opacity appears. Finally, samples of urine giving the non-subsiding yellow cuprous oxide may be rapidly assayed with Fehling's solution, if previously mixed with an equal volume of 6 to 8 per cent. glucose solution.

TYRER ON HYDROGEN PEROXIDE.

C. T. Tyrer has endeavoured to give some idea of the rate of decomposition and the protective value of various agents in solutions of hydrogen peroxide. The results are given in his paper of experiments in which glycerin, sulphuric acid, hydrochloric acid, boroglyceride, alcohol, and phosphoric acid respectively were used as the protective agents. Hydrochloric acid appears to be the worst protective agent and phosphoric acid the best, glycerin coming second. Champagne quarts and soda water bottles are found to be less liable to break in transit than other containers of hydrogen peroxide solution; beer bottles with patent screw stoppers come next in order, as they rarely break. Stone bottles with screw stoppers, corbyn quarts and carboys are all, more or less, liable to break. It is recommended that the containers should always be filled to within about two inches of the corks. Concentration of hydrogen peroxide to 100 volumes or more can be effected by careful evaporation; for higher volumes the operation must be effected *in vacuo*. Freezing may also be resorted to as a means of concentration. For storing the peroxide in a laboratory, the author advises the use of a receiver with a tap at the base, the solution being protected by a layer of petroleum carefully poured on the surface.

MOOR AND CRIBB ON DRUG STANDARDS.

C. G. Moor and C. H. Cribb suggest the voluntary adoption of standards of purity for foods and drugs. There are, as they point out, no legalised standards except in the case of spirits, though, in the case of a few articles of food, such as milk, etc., the limits adopted by the Inland Revenue authorities are known and adopted by most analysts. Assuming the need for other standards, therefore, the authors have taken upon themselves the task of collecting trustworthy figures respecting the composition of some three hundred articles which have been, or might be, purchased under the Sale of Food and Drugs Acts. They are of opinion that, in the case of many of the articles included in their list, some mutual agreement

might be come to by pharmacists, analysts, and other interested persons, and that such an agreement might well result in the adoption of a provisional standard which would be of general convenience. The drugs, etc., selected as typical for the purpose of this paper are tincture of aconite, dill fruit, tincture of arnica, cantharides and tincture, caraways, cayenne, cloves, ginger, tincture of hyoscyamus, mace, malt extract, pimento, tincture of rhubarb, and saffron. All are dealt with in accordance with a definite scheme which appears worthy of serious consideration by everyone concerned.

PECK ON A WEIGHT BURETTE.

E. SAVILLE PECK describes a burette which can be weighed before and after titration, thus giving the weight of the solution used instead of its volume. By its use the errors arising from inaccurate calibration of the ordinary burette are entirely eliminated, and changes and differences of temperature exert no influence upon the results. The method suggested takes longer than the ordinary volumetric process, but the accuracy and uniformity of the results obtained are held to justify fully the extra expenditure of time and trouble when great accuracy is required.

TYRER AND LEVY ON MELTING POINTS.

T. TYRER and A. LEVY record the results of a series of determinations of melting points, five methods being employed for each substance —phenacetin, sulphonal, acetanilide, and phenazone. The methods were that official in the British Pharmacopœia, GRAEBE'S, LANDOLT'S, PICCARD'S, and LOEWE'S. Somewhat high results were obtained with the B.P. method, but GRAEBE and LANDOLT'S methods were found to agree fairly well.

JOWETT ON PILOCARPINE.

Dr. H. A. D. JOWETT deals with the assay of preparations containing pilocarpine and the characters of salts of that base. Having extracted the mixture of amorphous bases from jaborandi or its preparations, he dissolves them in a small quantity of a saturated alcoholic solution of pilocarpine nitrate, adds some strong alcoholic solution of nitric acid, and then sets the mixture aside to crystallise. The crystals which form are filtered off, drained by the filter pump, washed with more saturated alcoholic solution of pilocarpine nitrate, dried and weighed. The percentage of bases in the total alkaloid yielding crystalline nitrate can then be calculated. In most cases the total alkaloid may be assumed to be pilocarpine, but if a very accurate determination be required, the melting point and specific rotation of the nitrates should be determined. With regard to the characters of the pilocarpine salts, the author thinks that the nitrate should consist of permanent white crystals, soluble in 6 or 7 parts of water and 146 parts of 95 per cent. alcohol, fairly soluble in boiling alcohol but almost insoluble in ether or chloroform. When heated in a capillary tube the salt should melt at 176° to 178°, and its specific rotatory power in aqueous solution should be +81° to +83°. No residue should be left on ignition, and there should be no precipitate on adding ammonia, water, or sodium or potassium hydroxide to a concentrated aqueous solution. The hydrochloride should form deliquescent crystals, soluble in less than their own weight of water and in 10 parts of absolute alcohol, but almost insoluble in ether or chloroform. The dried salt should melt at 200° to 204°, and its specific rotatory power should be +90° to +92°. No residue should be yielded on ignition, and a concentrated aqueous solution should give no precipitate with ammonia water, and only a few oily drops, which quickly redissolve, on the addition of sodium or potassium hydroxide.

DOWZARD ON ARAROBA.

E. DOWZARD finds that very poor samples of araroba may yield more chrysarobin than the British Pharmacopœia stipulates for, and, as araroba containing from 65 to 75 per cent. of chrysarobin is easily obtainable, he suggests that it would be advisable to make the former figure the minimum limit. He is also of opinion that the amount of water present in araroba should not be allowed to exceed 15 per cent. Pure dry araroba is stated to contain from 70 to 85 per cent. of chrysarobin, and from 0·3 to 3 per cent. of ash.

UMNEY AND SWINTON ON ALMOND OIL.

J. C. UMNEY and R. S. SWINTON are of opinion that the B.P. test for almond oil is not defined with sufficient accuracy, but that inability to comply with its requirements indicates admixture with apricot kernel oil. Certain marked differences are also shown when the test is applied to apricot and peach kernel oils.

IDRIS ON TERPENELESS OILS.

T. H. W. IDRIS has examined the terpeneless oils of lemon and orange on tho market, and records the results, which show great difference in the value of the respective products. Users of terpenless oils are warned to exercise caution in purchasing so-called "terpeneless" and "concentrated" lemon oils offered at absurd prices.

DUDDERIDGE ON LIQ. BISMUTHI.

F. R. DUDDERIDGE has adopted a method for the assay of liquor bismuthi et ammonii citratis, which differs slightly from the official method; the solution of bismuth oxynitrate in equal volumes of nitric acid and distilled water is not diluted at all, the order of mixing is reversed, and the potassium salts are dissolved in a definite quantity of water, the quantity of carbonate being increased by one third. It is claimed that, with those slight modifications the process may be easily and quickly carried out in any pharmacy. The author suggests that the official formula for liquor bismuthi should be modified so that the preparation may contain an excess of ammonium citrate, and indicates how the alteration may be simply effected.

ELBORNE ON CARBON DISULPHIDE.

W. ELBORNE has found commercial carbon disulphide develops a copious flocculent brown deposit when left unopened and undisturbed in a bottle secured with a cork and exposed to strong diffused sunlight for six months. The disulphide apparently contained impurities —possibly extracted from the cork—which became decomposed or rendered insoluble by exposure to light, or it must itself have undergone decomposition. For chemical purposes it is recommended that the disulphide should be stored in glass-stoppered bottles and not exposed to the action of light.

STUART ON BLAUD'S PILL.

C. E. Stuart has had occasion to examine a number of capsules containing Blaud's pill, and in each case he found the iron salt was rendered semi-fluid by admixture with liquid paraffin or some other oily body. The iron contents of the capsules varied considerably, but, judging from some of the samples examined, the author is of opinion that the problem of a small and active Blaud's pill capsule is not an insoluble one.

PARRY ON CARDAMOM OIL.

E. J. Parry points out that the chemistry of oil of cardamoms is in a very "hazy" condition, owing to the fact that those who have reported on the subject rarely state what they mean by "cardamoms." For experimental purposes the author has had Malabar and Mysore cardamoms specially distilled, and has examined the resulting oils. The Malabar cardamoms yielded 1·3 per cent. of oil and the Mysore variety 2·6 per cent. They were both light yellow in colour, scarcely distinguishable in odour, and having a specific gravity of 0·948; but whilst the optical rotation of the Malabar oil was +40° 41′, that of the Mysore oil was +46° 39′. The oils were soluble with a slight opacity in 40 to 45 volumes of 60 per cent. alcohol, and but little difference was apparent between them. Seeing, however, that the Mysore cardamoms yield twice as much oil as the Malabar variety, the former are preferable for distillation purposes.

DYER ON SODIUM BICARBONATE.

C. S. Dyer deals with the liberation of carbon dioxide from sodium bicarbonate when heated, and doubts the accuracy of Cowie's statement that the salt decomposes at a temperature between 50° and 60° C. In his opinion, the detection of traces of carbon dioxide by a delicate test on exposing a bicarbonate to a temperature of about 55° C. is not sufficient evidence that the salt decomposes at that temperature to any practical extent, and he asserts that dry sodium bicarbonate scarcely decomposes at all below 60°, only slowly below 100°, but rapidly above 120°.

DAVIS ON LOZENGES.

F. Davis gives the results of a series of analyses of B.P. lozenges, showing the quantity of active ingredient found in each lozenge, six samples having been taken. The figures closely accord with the official requirements, except in the case of sodium bicarbonate and sulphur lozenges.

HOOPER ON RUBBER SUBSTITUTES.

D. Hooper describes three elastic gums which have been suggested as rubber substitutes. The first is obtained from the stem of *Ficus bengalensis*, and dissolves without previously swelling in ether, chloroform, and carbon disulphide. It contains a large proportion of resins. The second is the product of *Calotropis gigantea* and *C. procera*, and contains but little caoutchouc. The third substance is the coagulum of the milky juice of *Excœcaria azallocha*, Linn. It possesses irritating properties, and that fact, conjoined with the presence in the substance of alcohol-soluble resins, contra-indicates its fitness to serve as a rubber substitute. None of the three substances, in fact, appears suitable for that purpose.

ANNOTATIONS.

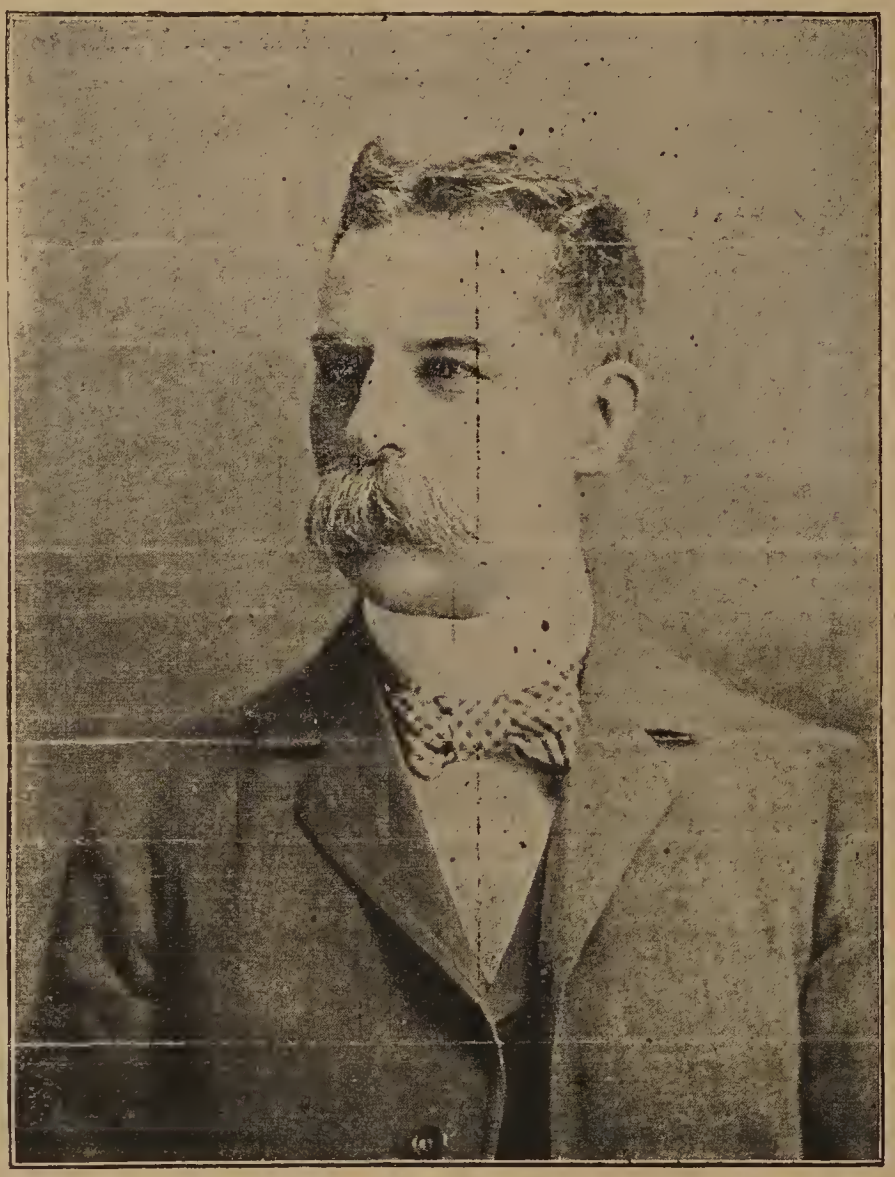
Mr. J. Chilcott Chas. Payne, J.P., the President of the British Pharmaceutical Conference at the Plymouth meeting, is a native of Wellington, Somerset. He was the eldest son of William Payne, a member of the Society of Friends, a first cousin of whom, named Alfred Payne, was at one time with Messrs. Balkwill and Co., chemists, Plymouth. After being educated at a private school at Weston-super-Mare and at the Independent College, Taunton, Mr. J. C. C. Payne served a four years' apprenticeship with Mr. T. H. Flooks, of Sherborne, Dorset, and he subsequently acted as assistant to Mr. Cumine, of Southport, and Mr. Acfield, of Surbiton Hill. In 1867, he was engaged as manager of the Belfast Apothecaries' Hall, conducted by Messrs. Wheeler and Whitaker, and he has since been domiciled in Belfast, where he owns one of the leading pharmacies. When the Irish Pharmacy Act passed in 1875, Mr. Payne was amongst the first to present himself for examination, the date of his registration as a pharmaceutical chemist being April 6, 1876, and he was the first examined licentiate of the Pharmaceutical Society of Ireland to serve on the Council of that body. When he resigned his seat in 1888, after having devoted twelve years to the Society's administrative work, the regret of his fellow-councillors was embodied in a formal resolution, wherein reference was made to the valuable services he had rendered. Mr. Payne's name first occurs in the list of members of the British Pharmaceutical Conference published in the 'Year-Book of Pharmacy' for 1877, and he was elected a vice-president of the body at Glasgow in 1897. It is due to the action taken by him at Cardiff in 1891, and again at Edinburgh in 1892, that the decision was arrived at to break the rule in accordance with which the members of the Conference had always met at the same time and place as the British Association, of which body, by the way, Mr. Payne has been a member since 1877. He was placed upon the Commission of the Peace for the City of Belfast in 1892, and was chairman of the Ulster Committee formed for the purpose of arranging for the entertainment of those attending the Conference at Belfast last year.

Mr. Robert J. Downes, President of the Pharmaceutical Society of Ireland, has, we understand, experienced a miraculous escape from a fearfully sudden death. It appears that Mr. Downes was proceeding by the electric tram to Lower Sackville Street, on business, and on arriving at Carlisle Bridge, where he wished to alight, he walked with that object to the exit portion of the car. The conductor at the moment was engaged collecting fares, and taking advantage of a momentary slowing up of the vehicle, Mr. Downes essayed to alight without waiting for the car to stop. Through some mischance, however, he missed his footing and fell heavily to the ground, the rear part of the tram passing over his head and shoulders. The tram was at once stopped, and Mr. Downes, who narrowly escaped decapitation by the sharp edge of the "fender," was helped to his feet, when it was found that although dazed and suffering from shock he was apparently uninjured. He proceeded unaided to a medical hall in Westmoreland Street, a few yards distant, where restoratives were administered. Beyond a feeling of intense soreness in the left arm, due it was thought to the sudden fall, nothing more serious than a bruise or slight abrasion was apprehended, but on examining the arm the same day, the doctor who was called in pronounced the limb broken close to the shoulder, and subsequent examination showed that the break was of a very serious nature. We are pleased to know that Mr. Downes is progressing favourably. Owing to the accident referred to Mr. Downes has been prevented from attending the Conference at Plymouth this week.

British Pharmaceutical Conference

THE thirty-sixth Annual Meeting of the British Pharmaceutical Conference opened under very favourable circumstances on Tuesday, July 25, in the New Law Courts, Plymouth, under the presidency of Mr. J. C. C. Payne, J.P., L.P.S.I., Belfast. There was a very large attendance, both of members and ladies. Letters and telegrams expressing regret at their absence had been received from Mr. Martindale, President of the Pharmaceutical Society of Great Britain, Mr. Downes, the President of the Pharmaceutical Society of Ireland (owing to an accident), Messrs. Walter Hills, C. Umney, J. C. Umney, John Moss, Newsholme, Wright (Buxton) and Louis Siebold.

The names of the delegates from various bodies and local associations were also read by the Hon. Sec., Mr. Naylor (see end of Report).



J. C. C. PAYNE, J.P., M.P.S.I.

Report of the Executive Committee.

Mr. F. RANSOM, Hon. Gen. Secretary, next read the following report of the Executive Committee:—

"In presenting the 36th annual report your Committee recognises that the Conference continues to fulfil the objects for which it was established, and believes that there is no diminution in the interest taken in its work. The question of membership which has been repeatedly referred to in these reports continues however to be a source of some anxiety.

"During the past year 74 new candidates have been elected, while 16 members have resigned, 10 have been removed by death, and 23 names have been erased owing to the subscriptions being 4 years in arrears, thus showing a net increase of 25. The number now on the list is 1,302, but of these the subscriptions of 360 are in arrears.

"In order to obtain new members and prevent the annual loss caused by resignations and arrears of subscription, a sub-committee was appointed in December last to devise some method by which this object could be attained. This sub-committee carefully considered various suggestions, and finally reported that it considered the best plan to adopt would be the appointment direct representatives in various districts throughout the country who, by their personal influence and interest in the Conference, might be able to obtain nominees for membership by putting before them the advantages to be obtained from such association. It was felt that it would be necessary to apply some distinctive title to the members so appointed, and the name suggested for such honorary appointment was 'Local Corresponding Secretary.' The report of the sub-committee was adopted by your Executive, and as a result 37 appointments have been made of gentlemen who were willing to undertake the duties in important centres. There remains other populous districts throughout the kingdom which are at present unrepresented, and it is hoped that offers to serve in this capacity will be made by members who are resident in such districts.

"Since the last general meeting the following gentlemen have been elected as Honorary Members of the Conference:—Dr. Charles Rice, of New York, M. A. Petit, of Paris, and Professor A. Tschirch, of Berne.

"The Committee regrets that owing to his departure from India, Mr. J. G. Prebble has found it necessary to resign his position as Honorary Colonial Secretary for Bengal. The vacancy thus occasioned has not yet been filled.

"The Blue List has as usual been revised by a Sub-committee appointed for the purpose, and various additions and alterations have been made.

"No applications for grants in aid of research work have been received during the year.

"Mr. Louis Siebold, F.I.C., F.C.S., has been reappointed Editor of the 'Year-Book,' and the MS. of Parts I. to III. of the forthcoming volume is already in the press.

"By the death of Mr. J. Bosisto, C.M.G., of Melbourne, the Conference has lost a distinguished member, who showed his appreciation of the work done by the association, and assisted in furthering its interest by contributing valuable papers to its annual meetings. As an authority on Australian drugs and the products of the Eucalypti in particular, he had held for many years a foremost position."

In the absence of the Treasurer, Mr. NAYLOR presented the financial statement (which will be found on page 112*a*), drawing particular attention to the reduction in receipts from advertisements in the 'Year-Book' and also in the annual subscriptions, which he hoped would show better next year.

Welcome by the Mayor of Plymouth.

At this juncture the Right Worshipful the MAYOR OF PLYMOUTH (Alderman J. Pethick) entered the hall, and being placed in the chair for the time, said he had great pleasure in welcoming the Conference to Plymouth, which had been rightly described as the Metropolis of the West. He hoped when the members returned to their homes they would all say that they had enjoyed their visit, and would recommend their friends to visit Plymouth and the district.

The MAYOR OF DEVONPORT, W. Hornbrook, Esq., who suggested that before long the borough of Plymouth would be glad to avail itself of the shelter and protection which the borough that he represented would be able to afford it, also added a few words of welcome to the Conference. He alluded briefly to the many natural beauties to be found in the locality, and to the great privileges possessed by pharmacists in eliciting and making known the laws of nature, and in applying them for the benefit of suffering humanity. He hoped all visitors would long retain pleasing memories of their sojourn in the three towns.

The CHAIRMAN OF THE DISTRICT COUNCIL OF STONEHOUSE (Mr. J. E. Bone) also welcomed the members of the Conference. They

were no doubt well acquainted with anatomy, and that being so he would say that he looked upon Plymouth as a great body, and Devonport as the head piece, but he looked upon Stonehouse as the neck which held the two together, and on behalf of Stonehouse he welcomed the members of the Conference to the district.

Dr. May, Vice-President of the Plymouth Medical Society, in the unavoidable absence through ill-health of the President, Dr. Bulfield, added a few words of welcome on behalf of his own profession, which he thought had benefited very greatly by the establishment of the Pharmaceutical Society of Great Britain in 1841 by Jacob Bell and his colleagues. It was much better that drugs and medicines should be dispensed by scientifically educated and qualified men than in the haphazard fashion which once prevailed. It was to be desired also that members of his own profession should abstain from dispensing their own medicines, and leave it in the hands of those better trained for the purpose. Indeed, the old proverb *ne sutor ultra crepidam* might be applied to them all.

Mr. S. R. Atkins then rose to propose that the heartiest thanks of the members be returned to the Mayors of Plymouth and Devonport and the Chairman of the District Council of Stonehouse for their welcome. He could thoroughly support all that had been said with regard to the natural charms of Plymouth and the district; the only thing remaining to make the meeting a success was to have fine weather, and that seemed assured to them. Their thanks were also due to the Mayor of Plymouth for the use of the New Law Courts for their meetings, and other public buildings which had been placed at their disposal.

The Mayor of Plymouth briefly returned thanks, and said that he would do his best to make their visit a pleasant one.

Mr. Branson then moved the adoption of the report and financial statement, which was seconded by Mr. Longton, both of whom referred to the desirability of an effort being made to increase the number of subscribers.

The President having enforced this appeal, put the resolution which was carried unanimously.

The report of the Unofficial Formulary Committee was then read by Mr. Naylor, as follows, and was unanimously adopted.

Report of Formulary Committee.

During the year the members of the Formulary Committee as the result of intercommunication by correspondence have suggested a provisional list of important preparations to take the place of those that must necessarily be omitted from the next issue of the Unofficial Formulary owing to their absorption by the present British Pharmacopœia. It has also suggested certain modifications of formulæ that remain unappropriated.

Your Committee has concluded that it would be unwise to do more until the drugs and preparations to be included in the proposed Indian and Colonial Addendum to the British Pharmacopœia have been agreed upon.

Wm. Martindale,
July 17, 1899. Chairman.

The President then proceeded to deliver

THE PRESIDENTIAL ADDRESS.

Mr. Mayor, Ladies, and Gentlemen,—Twenty-two years have passed since I first had the privilege of attending a meeting of the British Pharmaceutical Conference. By a strange coincidence it was at this historic seaport town of Plymouth. I distinctly remember the active general secretary, Professor Attfield, who appeared to know everybody, calling me by name to address the meeting. The object of my visit was to convey an invitation from the Council of the Pharmaceutical Society of Ireland to the members then assembled to hold the following year's meeting for the first time on Irish soil, in the City of Dublin. No doubt your executive committee had misgivings as to the wisdom of accepting the invitation, for reasons which will be apparent to you at a later period of my address. Nevertheless, the invitation was accepted, the members unanimously agreeing to venture across the Irish Channel. The hospitality of Plymouth pharmacists was again offered for a second time at its meeting last year, which was held in the commercial capital of Ireland—Belfast. On the former occasion we adjourned to an Irish meeting-place, to-day's meeting is an adjournment from one. For the benefit of those who are present for the first time, I may be pardoned if I inform them that the Conference has not met in Ireland during the intervening years, and Irish members hope the meetings in their country will be more frequent in the future than they have been in the past. Before passing from what may be described as the introductory portion of my address, let me call your attention to the presence this day of one member of our Conference who in its early days worked unceasingly for its success, and to whom we owe much of its present position among the scientific bodies of this country. I refer to Professor Attfield, who I am delighted to find is still ready to combat all statements not in accordance with chemical laws. For the first time in its history the Conference has elected an Irish pharmacist as its President. The greatest difficulty that presented itself to me was to find a subject your long list of distinguished Presidents had not already brought before you. It occurred to me that a short account of the history of pharmacy in Ireland would be not only fitting to celebrate an occasion which marks an epoch in the lives of the societies represented, but also acceptable to you who have honoured me by placing me in the position I now occupy. Many of the facts which I shall relate will no doubt be familiar to you; but if they interest you half as much as they have interested me, being the story of an evolution of order from disorder, and law from the absence of it, in the land of my adoption, I shall be quite satisfied. We are so accustomed to the phrase that it almost seems bathos to say that it has been a century of progress. Probably in no field of labour employing the highest powers of the intellect have such strides been made as in the scientific, and I think I am justified in saying that the healing art has made as great progress, and with equal benefit to the human race as any branch of science.

Specialisation in Medicine.

A necessary consequence of the resulting accumulation of knowledge has been specialisation in medicine and the allied professions, and this is not to be wondered at. In the dark days when there was so little to know, apothecary, physician, barber, and surgeon might find it a matter of difficulty to keep from encroaching on one another's domains. Now the barber is perhaps the only one who can begin the study of his occupation in life with the hope of ever attaining a perfect knowledge of it; and things have come to such a pass that we have one of the greatest thinkers and scientists of the day, Professor Huxley, declaring:—"I would abolish materia medica from the medical curriculum. I cannot understand the arguments for obliging a medical man to know all about drugs and where they come from. Why not make him know all about cutlery because he uses knives?" As far as is known from public records the first legal recognition of apothecaries in Ireland was contained in a Charter granted in 1446 to a guild numbering among its members apothecaries and surgeons besides others. This guild, which seems to have been somewhat heterogeneous, was broken up in James II.'s reign, and one limited in its membership to barbers, periwig-makers, surgeons, and apothecaries was established. Ultimately, in the reign of George II., the union between the last two was dissolved, and the Apothecaries' Hall received a separate Charter. These apothecaries, although they kept open shop and compounded and retailed drugs and medicines, are not to be confounded with the class bearing the same name in England, as they had considerable medical knowledge, and in later days, at least, had to pass an examination in medical subjects, and they were in the practice of giving advice to those who could not afford the expense of a physician. In 1695 we read of an attempt on the part of the Dublin College of Physicians to obtain an Act of Parliament granting its members the sole right to practise medicine in Ireland. This, however, proved

abortive owing to the opposition of the apothecaries and surgeons, the former continuing their own business as well as the compounding of the physicians' prescriptions, in which work they were the only persons legally qualified up to the passing of the Pharmacy Act of 1875.

The Dublin Pharmacopœia.

The guide book on pharmacy used in the earlier part of the present century was the famous Dublin Pharmacopœia. This was published by the King's and Queen's College of Physicians under powers granted them by an Act passed by the Irish Parliament in the first year of George III.'s reign. By it it was declared lawful for the President and Fellows of the college to publish a code containing "a catalogue of such drugs and medicines as they should judge necessary for the prescriptions of the physicians and surgeons, together with forms and rules for compounding the same chemically and galenieally." And the Act directed that any person who should manufacture or compound drugs by any other rule should be penalised. The first editions of the work appeared in 1794 and 1805. Their circulation was confined to members of the college. However, in 1807, Dr. Percival, professor of chemistry in the college, acting under a committee, wrote a new edition open to the public. Though a man somewhat advanced in years, he set about revising his work, assisted by Mr. Donovan, the inventor of the *liquor arsenii et hydrargyri iodidi*, which is often prescribed as *liquor Donovani*, and still adorns the British Pharmacopœia, but, unfortunately, he broke down and was forced to desist from his labours, the work being finished by Dr. Barker, his successor in the Chemical Chair. The new edition appeared in 1826. Shortly afterwards, on a proposal to issue another edition of the London Code, it was suggested that a Pharmacopœia common to Great Britain and Ireland should be published. This proposal did not come to anything, and we read the reasons in the London edition, published in 1836, that "it was requisite to consult with the Fellows of both colleges," and, as on account of the great distance, this was with difficulty accomplished—there were neither railways nor steam packets in those days—it became necessary to abandon the negotiations which had been commenced. When we add to this that all three colleges would have been called upon to make sacrifices, the consideration of which they could not at the time entertain, the difficulties became almost insurmountable. Consequently, in 1847 the Dublin College set about the preparation of a new edition of their work, which was published in 1850. It has the distinction of being the first edition written in English, those preceding it having the knowledge they contained hidden from the vulgar mind by the employment of Latin. Among other improvements it directed the use of a system of weights and measures comprising the troy grain and the avoirdupois ounce and pound, with a new scruple and drachm. This change was considered necessary, as the old system was the cause of considerable confusion to the apothecary, who had to buy the drugs wholesale by one measure and sell them by another.

In the course of a discussion which took place at a meeting of the Pharmaceutical Society of Great Britain concerning the 1850 edition, the late Professor Redwood is reported to have expressed the opinion that the alteration was illegal, but the Act which gave the college power to publish the Pharmacopœia also gave them authority to direct "the measures, weights, and scales" by which the drugs named in it should be sold, and enacted that any persons using any other should be fined. In the nomenclature the term *confections* was applied to the old *confections*, *conserves*, and *electuaries*, and to remove the confusion existing in the case of the chloridic compounds the term *chlorinata* was borrowed from the London edition of 1836. The chemical names of the salts of mercury were abandoned, and names such as *calomel*, *corrosive sublimate*, and *red* and *green* iodides adopted. The Medical Act of 1858 brings the history of the Dublin Pharmacopœia to a close, as by it powers were vested in the General Medical Council to publish the British Pharmacopœia, and by another Act it was arranged that that book should supersede the publications of Edinburgh, Dublin, and London. The first edition of the new work was published, as you know, in 1864. With regard to poisons, under powers granted them in the Act of 1760, the Dublin College ordered that all prescriptions for external use should be made up in angular bottles, all for internal use in round, and that certain poisonous drugs named should be kept in angular, the remainder in round bottles, and that they should be delivered in the same. We do not hear of any further legislation in the matter until 1851, when an Act was passed putting certain restrictions on the sale of arsenic, with which you are familiar. This Act possesses a certain interest from the fact that it is one of the few Acts relating to our profession which have effect on the whole of the United Kingdom. I do not mean to suggest the usual injustice to Ireland, but there seems to be a large amount of time wasted making laws for England, and remaking them for the sister-country, and to one unversed in the ways of Westminster, the matter is difficult of comprehension.

Suggested Reciprocity with Ireland.

It would appear that after the passing of the English Pharmacy Act of 1868 our Saxon friends were anxious to include Irish pharmacists in their embrace, and Mr. Abraham gave notice at the August meeting in 1869 of the Pharmaceutical Society, that he would move at the October meeting "That steps be taken to assimilate the laws which regulated the practice of pharmacy in Ireland and Great Britain respectively."

The following letter from Mr. John Grattan, a well-known and high-respected apothecary of Belfast, appeared in the *Pharmaceutical Journal*, dated October, 1869:—

Sir,—I have just observed with great satisfaction Mr. Abraham's notice relating to pharmacy in Ireland, reported in the August number of the *Pharmaceutical Journal*, having long considered that the transfer to the Pharmaceutical Society of Great Brtiain of the misapplied powers entrusted to the Dublin Apothecaries' Hall in 1791 could be but a question of time; and I am strongly of opinion that no time could be more opportune than the present. Compulsory pharmaceutical education is now the law of England as it has been that of Ireland for upwards of seventy years, however much of late overlaid by a press of conditions, neither required for the efficient discharge of the duties of the apothecary, nor authorised by the Irish Apothecary's Act of Incorporation; and I can see no valid reason why the holder by *examination* of the Pharmaceutical Society's Major diploma should not be at liberty to practise pharmacy in Ireland, as well as in any other section of her Majesty's dominions. I must, however, strongly deprecate the extension to this country of the Modified examination devised to protect in England interests of an uneducated class of dispensing chemists, such as has no existence here. With this single reservation, I trust the proposed movement will receive the cordial co-operation of every person in Ireland at all desious of the advancement of pharmacy. A short Bill extending to Ireland the authority of the Pharmaceutical Society, and authorising the *immediate* introduction of its full curriculum, would not interfere with any existing rights; no individual at the present moment being legally entitled to keep open shop for dispensing medicine in Ireland without a licence from the Dublin Apothecaries' Hall—only to be obtained by an examination which, I must do the Hall the justice to say, has always been of a very efficient character, though of late years, constituting but a portion of the examination for its medical certificate. With regard to the Dublin Apothecaries' Hall, I conceive there can arise no difficulty whatever. Having long since looked down contemptuously upon its original constitution, and having succeeded in transforming itself into a school of medicine, it should rejoice exceedingly at being relieved from the burden of an irksome duty, derogatory to its present dignified position and exalted functions, the distasteful duty of educating the mere apothecary—a requirement no longer to be postponed. Wishing Mr. Abraham's proposed movement therefore the success to which sound policy and simple justice fully entitle it,

I remain, your obedient servant,
John Grattan.

At the October meeting of the Council I find Mr. Abraham brought forward his motion, and it was referred to a committee to report upon. The report did not result in the Pharmaceutical Society of Great Britain extending its influence to Ireland, as I shall presently show you.

The Sale of Poisons (Ireland) Act.

As a set-off to the English Pharmacy Act of 1868 a Bill regulating the sale of certain drugs in Ireland passed through the Houses of Parliament in 1870. The restrictions were somewhat similar to those put upon arsenic, with the exception of the clause directing that it should be coloured with indigo or soot. It also ordered that they should be labelled poison, and that the name of the vendor should be inscribed on the parcel containing them; of course these laws did not apply to the prescriptions of legally qualified medical practitioners. The Act also gave power to the King's and Queen's Colleges of Physicians to recommend such substances as they thought fit to Her Majesty's Privy Councils to be added to the Poisons Schedule Bill. Thus the sale of phosphorus, chloral hydrate, nux vomica and its preparations, ether (owing to its increased consumption among the poorer classes in the North as a stimulant), phenol, all oxalates, biniodide of mercury, and pre-

parations of strychnine have been brought under control. There was also a clause in the Bill extending the Adulteration of Food and Drink Act to drugs.

From what I have said it will be understood that all this time the only pharmacists recognised by law were those who held the qualification of the Apothecaries' Hall, and they were also permitted to prescribe; but the qualification was not so widespread as the fact seems to suggest, and in many of the small towns those requiring medicine were often compelled to make use of druggists, whose only qualification was an apprenticeship, more or less, served in the shop of an equally qualified, or, rather, unqualified, druggist, where he might learn a great deal if he were so inclined and if his master understood his business, or having served his time, and perhaps wasted it, go into the world to bring discredit on an honourable profession. In those days we fear that Samuel Garth's criticism on some English pharmacy could have been applied with some truth to the practice in Ireland:—

"Some fell by laudanum and some by steel,
And death in anguish lurked in every pill."

In some towns even these gentlemen did not exist, and in those days, when railways were scarce and carriers' carts the commonest means of conveying parcels, this was a matter of some concern to those residing in them. There is no doubt that the chemists and druggists had a grievance. Many of them were men of good education and in every way fitted for their work, but debarred from obtaining the apothecary's licence by the unnecessary breadth of the qualifying examinations, which included papers in medicine, surgery, midwifery, and anatomy.

Now I do not wish to suggest that the average chemist and druggist was unequal to the mental effort which those subjects would have demanded from him; but to one desirous of perfecting himself in pharmacy they were more or less waste of time and of what is usually associated with that valuable commodity, money. Consequently, those who wished to take up the profession of pharmacy were often forced to attain their object by other means, though that meant the constant risk of prosecution by the Apothecaries' Hall. Nor does the case of the unlicensed appear any weaker to us when we remember that occasionally an apothecary kept more than one shop in which there might or might not be a qualified assistant. Of course, one can sympathise with men who, having spent considerable time and labour in obtaining a qualification, saw the wicked unqualified flourishing like the green bay tree.

Formation of the Irish Pharmaceutical Society.

The feeling between the two classes became gradually more intense, and things came to such a pass that when, in 1874, the British Association was to meet in Belfast and the Pharmaceutical Conference, as was its wont, proposed to follow its example, a deputation from the apothecaries in Ireland, consisting of Dr. H. Whitaker, Mr. R. W. Pring, and Mr. Harrington, was received, who stated that it would be impossible for them to meet the unqualified men as brethren. As a consequence the meeting was held that year in London. I think it is only fair to these gentlemen to say that they were not merely desirous of making their degree a *sine quâ non* in the pharmaceutical profession, but had applied for leave to create a second grade of compounders who should not prescribe. On this, however, a third element was introduced into the quarrel in the shape of the Irish College of Physicians, who practically reiterated their demand of 1695 by opposing all tendency to give the Apothecaries' Hall powers to grant separate licences in prescribing and compounding. The college was successful in preventing them in their efforts, and the dispute resulted in what was undoubtedly the best result for all parties, in the formation of a new Society on lines somewhat similar to the existing English one by the Pharmacy Act of 1875.

This Act constituted a Society of Pharmacists to be called the Pharmaceutical Society of Ireland, and one of its first clauses nominated certain professional men as members, and directed that they should form the first Council. It had been originally intended that one-third of these should be drawn from the physicians and one-third from the apothecaries, and one-third from the chemists and druggists. But this arrangement was found to be unworkable, and the first Council consisted largely of licensed apothecaries. Every person registered under the Act as pharmaceutical chemists was to be considered qualified for election to the membership of the Society, and the Council had power to determine upon allowing certain persons to acquire the title chemist and druggist subject to such conditions as they should think proper in this connection. I may say that the first regulation passed by the Council was to the effect that for the present there should be but one qualification—that of pharmaceutical chemist. Queen's Counsel opinion having been taken on the matter, with the result that they were warned that to register chemists and druggists under the Act would be to licence them to compound medicines, an act which would have created an anomaly of having two classes of pharmacists in Ireland, one of which would have been compelled to pass an examination to obtain licences, while the other would not be compelled to do so.

This and all the regulations of the Council were to become law by the approval of the Lord-Lieutenant and the Privy Council.

The members of the new Society were to consist of:—

(1) Members of the Council as nominated.

(2) Persons examined.

(3) Licensed apothecaries on payment of fees, while chemists and druggists, had the Council decided to register them, would have had the right to be elected as associates.

The Irish Examinations.

The Bill caused some unnecessary alarm among English pharmacists. Some thought that the examinations would be made too easy, and that Englishmen having crossed the Channel to obtain the Irish qualification, would return to practise in their native land with the hope that the "I" at the end of the letters after their name would pass unnoticed. The title pharmaceutical chemist was thought to be in danger not only of injury but destruction, and when the Bill was before the House of Commons a deputation from the Pharmaceutical Society of Great Britain was received by the Chief Secretary for Ireland, which strenuously advised the exclusion of the reciprocity clause which it contained, with the result that the Government withdrew it. The feeling was perfectly natural, as the Bill could not of necessity force the Council to keep their examinations at a high standard, though it dictated the subjects upon which candidates were to be examined. The new Society soon demonstrated that it was to their interest that the standard should be high, for though for the first two years, as was only fair to those already in practice as chemists and druggists, the examinations were kept at a moderate level, they have been getting more difficult every year, and as test of the efficiency of the pharmaceutical chemists they are second to none. The candidate is now required to pass a preliminary examination, the subjects in which he is examined being Latin, English, mathematics, physics, botany, chemistry, and a modern language; afterwards he has to pass an examination in materia medica, botany, pharmaceutical and general chemistry, practical pharmacy, and reading, and translation of prescriptions. He must present certificates of having attended classes in botany and materia medica at a recognised school and one stating that he has worked for 100 hours at a bench in a chemical laboratory, and make a declaration before a magistrate that he has been for four years an apprentice or assistant with a qualified pharmaceutical chemist or four years with a registered druggist and two years with a pharmaceutical chemist. Having accomplished all this successfully, he is, after certain forms and the payment of certain fees, at liberty to style himself pharmaceutical chemist, and he may be elected a member of the Pharmaceutical Society of Ireland. The year following the passing of the Pharmacy Bill, Government brought in a Juries Act for Ireland. Under the list of "professions" we find pharmaceutical chemists exempt from service.

The Registration of Irish Chemists and Druggists.

Owing to the action of the Council in refusing to register a second grade for the reasons I have given, there still remained a body of men labouring under a grievance, and to remove this the Pharmacy Act Amendment Bill was introduced into the House of Commons in 1890, and eventually became law. It repealed all reference to chemists and druggists in the old Act and made arrangements for their present registration. All who were in business in 1875 were entitled to registration, but any who had come into business since that date, or who intended going into business, were required to pass an examination. Successful candidates were, on payment of certain fees, entitled to be elected associates of the Pharmaceutical Society, but were forbidden to style themselves as such, and they were not permitted to compound the prescriptions of medical men. The only question which remains to be considered is, has the new Society been a source of benefit to the public and to pharmacists in Ireland? I am of opinion that it has, not only in the large cities, where the facilities for purchasing medicines and having prescriptions compounded have been immensely increased, but in the smaller towns, very few of which are without a qualified pharmacist. Now, I do not mean to convey the impression that there were not clever men in the business before the entry to it was by examination, but, as is the way with examinations, while those aiming at a maximum of proficiency are not greatly affected, those aiming at a

minimum, or at none at all, are awakened to the fact that pharmacy is not the life work for which Nature intended them, and the average standard is considerably raised. To pharmacists the Act has been of undoubted value, inasmuch as it has opened the world to them, the Irish licence being now recognised in all the Colonies, in South Africa, and in some American States. Ireland's apothecaries and chemists have had many outstanding men in their ranks whose names will always be remembered in the history of pharmacy in their native land. Among others we may mention Higgins, on whose work Dalton based his atomic theory; Donovan, whose name we have mentioned, and whose papers are still read; Kane, who wrote on the elements of practical pharmacy as far back as 1831; Whitla, author of a materia medica, with a wide reputation, professor of the subject at Queen's College, Belfast; and Tichborne, a well-known professor of chemistry in Dublin, who has been a member of the Council since the inception of the Society.

I cannot close my address without reference to the bonds of fellowship which are growing between the pharmacists of Ireland and those of Great Britain. The fact that the last Conference met in Belfast is significant, and it is with no egotism that I appreciate my position in this chair, but rather as an honour done to my profession on the other side of the Channel. How far these bonds may continue to grow I cannot say; but though the time is not yet ripe for the accomplishment of it, I have a vision of a closer union and a stronger harmony tending to the advancement of pharmacy and all concerning it in all three countries during the new century now so fast approaching.

Mr. A. P. BALKWILL moved a vote of thanks to the President, for his address, which was especially satisfactory to him, as he was a lover of and believer in history. They were making history there that day, and he trusted it would be a history worthy of the past. He had always been of the opinion that Great Britain and Ireland should be drawn more close together, and was very glad when one Pharmacopœia was made operative in both countries; indeed, years ago, he was deeply interested in the idea which was then talked about of one universal Pharmacopœia for all countries. He could not discuss the address, but he might say he regretted one remark, that the author was unversed in the ways of Westminster, and he thought it much to be regretted that pharmacy as a profession was not represented at Westminster. It was fully entitled to be so represented, and if it were, there would perhaps be less sanction given to the notion that the pharmacist was, above all others, the man to be harassed. Pharmacy was indebted to Ireland in many respects, and it was a great pleasure to welcome a representative of Irish pharmacy amongst them as President. A great deal had been said about the advance of knowledge, and it was quite true that as they stood on the heads of their fathers and predecessors they could see farther, but he was rather sceptical as to there being greater athletes in science now than there were in days past. In the adjoining chamber there was a memorial window to a pharmacist of that town who flourished more than a century and a half ago, and he trusted it would be a stimulant to young men to remember that there had been fine men in the past whom they would do well to emulate. He rejoiced to know that Mr. Payne had always been an encourager of young men. For himself his lifework had been in connection with forlorn hopes, and if there was a forlorn hope in England it was the profession of pharmacy. It was a profession which gave to the public much more than it received from it, which was very satisfactory from one point of view. In old days the bag at the back of a professor's gown was intended to receive fees, so that he should not see them. He did not know where the pharmacist's bag was, but he certainly did not see fees to such an extent as made his work pecuniarily successful. It was necessary, therefore, that no young man should enter the profession without a genuine love for it, otherwise he would soon be disgusted with the dreary drudgery it involved. If, however, he loved science and the practice of beneficence, he would renew his youth continually, and would go on cheerfully until he reached a second childhood, as he had almost done; but he must say he enjoyed it as much as he did his first. He concluded by again thanking the President for his address.

Mr. J. DAVY TURNEY (Plymouth), in seconding the vote of thanks to the President, said the Conference held last year at Belfast had no doubt quickened their interest in, and their desire to know, more about Irish pharmacy. The President that day had given them a full history of the troubles and difficulties which had arisen from time to time with regard to the pharmacists of Ireland.

Prof. ATTFIELD, in putting the resolution to the meeting said he could not refrain from saying how particularly appropriate he thought it was for Mr. Payne to come there and give them the history of Irish pharmacy, considering that twenty-two years ago the President of that day, Prof. Redwood, first gave them the history of pharmacy in Great Britain. The closer pharmacists in different parts of the kingdom could be brought together the better would it be for pharmacy and pharmacists, for medical men and for the public generally.

The resolution was then put and carried unanimously.

The PRESIDENT briefly thanked the members for the kind way in which the resolution had been received. It had given him great satisfaction to have the opportunity of telling them something about Ireland. He quite agreed that the time had come when the various Pharmaceutical Societies should have at least one representative in Parliament.

Papers on Ipecacuanha.

The reading of papers was then proceeded with, the first four being taken together as each dealt with Ipecacuanha, viz., those by Messrs. Farr and Wright, Naylor and Bryant, F. C. J. Bird, and J. C. Umney and Swinton. They are printed at pp. 85-89, and gave rise to the following discussion.

PROFESSOR ATTFIELD, in opening the discussion on these papers, said he might say, recognising his official position, how delighted they all were to welcome any improvement on any of the processes in the Pharmacopœia. In saying that the processes recommended in the papers would no doubt be less wasteful than the ones in the Pharmacopœia, and that the total alkaloids would be purer than the corresponding process in the official assay, he thought he was going as far as the readers of the papers would wish him to go. He most strongly deprecated the language in which the criticisms on the Pharmacopœia were couched in the papers. There seemed to be an impression that at the back of the Pharmacopœia there were a body of workers who tested all processes, rejected the bad, accepted the good, and added further processes of their own; but he would remind them that to do this for the whole of the Pharmacopœia would take twenty years, and cost £20,000. He would say, in conclusion, that the Pharmacopœia was a casket of natural gems more or less polished by different workers, and more or less well set by other workers. It was not a stuffed sack on which to practice pugilism.

Mr. BIRD said when the process of the B.P. first appeared it occurred to him that there was grave doubt whether the alkaloidal residue consisted entirely of alkaloids, and he was pleased to find that its true nature had now been shown. In making some assays of ipecacuanha preparations recently, in trying to assay by Paul and Cownley's process with lime and amylic alcohol he only got from 1·2 to 1·7 per cent. of alkaloids, as against 2 or 2·1 per cent. yielded by the Pharmacopœia process. He then put it down to decomposition of the alkaloid by evaporation, but it was evidently due to the presence of impurities. Mr. Naylor had been rather severe on the tediousness of the official process, but with a little ingenuity, and the use of a Bunsen filter pump, it could be accomplished in a quarter of an hour. Mr. Wright had sent him his process for trial, and he only experienced one little difficulty in the determination of the end point of the reaction, when he found the alkaloidal residue on solution in alcohol was yellow, which to a certain extent obscured the colour of the cochineal. He got over that by using a solution of burnt sugar of a similar tint, placed in a beaker by the side for comparison. He would like to know if Mr. Farr had found any fairly constant factor by which the results might be multiplied so as to give the equivalent of the B.P. assay.

Mr. JONES said he took it the B.P. process would be taken as the standard, and unless some factor were found by which the result of the new and improved process could be compared with the quantity found by the official process they would not be of much use. Secondly, by Wilson's process a slightly higher result was obtained, and by Mr. Farr's a little more, about 2 per cent. as against 1·6 by the B.P. method; but he took it that manufacturers would not be able to reduce his liquid extract, because he used Farr's method. A question was raised as to the weight of the alkaloid, and the titration afterwards by an acid. They knew the titration method was theoretically better than taking the weight of the crude residue, but it had yet to be shown how far either represented the amount of alkaloid present. At the Aberdeen meeting he read a paper on Ipecacuanha, in which he showed that you could not take your mixed alkaloids and evaporate them without producing some change, and that the weight was affected by time. When a practically pure residue

was evaporated, heated, re-dissolved in acid, and treated with chloroform the chloroform became coloured, and in proportion to the time occupied in drying, was the greater or less change effected by the chloroform. It was admitted that trade samples were not what they should be, but was that really on account of want of care in the preparation, or did the alkaloid pass off with lapse of time. The official process was first to take out the alkaloids in connection with natural acids, with spirit ; after a certain time the marc was treated with lime, and the last portion of spirituous liquor you got out was distinctly alkaline, not, as he thought, from the lime being dissolved, but from the liberated alkaloid. In the finished extract you got the alkaloid plus the natural acid, and alkaloid in the free state. There might be sufficient acidity in the first spirituous portion to neutralise that free alkaloid, but he did not think that was so with some samples, and would suggest this as a line which might be worked upon.

Mr. Bird said when Umney and Braithwaite introduced their process they made samples which were kept for six months, and on assay showed no loss of alkaloid. It was known that lime was soluble in 90 per cent. alcohol.

Mr. Rutherford Hill said a case had been brought under his notice in which the wine had been prepared with the standardised extract and estimated when made ; but, after six months, on being re-assayed, there was a very considerable difference in the total alkaloids. The estimation was not done with such care as to warrant one in founding an opinion upon it, but it was a matter of some importance, because it affected the whole question of making ipecacuanha wine from a standardised extract. He should like to know if Mr. Naylor had any evidence that wine prepared in that way retained its percentage of alkaloid.

Mr. E. M. Holmes thought the B.P. had been somewhat unjustly criticised, because the information available at the time of its publication was utilised as far as possible, and the Committee could not be blamed for not having information which was not at their command. One question which arose was this: if a chemist were proceeded against for having dispensed ipecacuanha wine not containing the proper percentage, would he not be judged by the B.P. process, not by the more recent ones? With regard to the Johore ipecac. there seemed a doubt whether this was the genuine drug or not, but he could say positively that it was. It was a cultivated plant obtained, he believed, from Brazilian sources. There were two plants known in Brazil, one of which had long styles and short stamens, and the other long stamens and short styles; in fact, it was dimorphous, one being more robust and easily grown than the other, but which of the two it was he had not been able to ascertain. There, might, however, be some difference in the chemical yield, and that Carthagena yielded more cephaeline than Brazilian they knew. The Johore plant was more of the Brazilian kind, and he was told by Mr. Umney that it contained more of the third alkaloid than either of the other two. They knew that ipecacuanha had a great reputation in India for the cure of dysentery, but neither emetine nor cephaeline were known to have any specific action on that disease. The third alkaloid they knew practically nothing about, and it would be interesting to investigate it further, and see how far it was useful in dysentery.

Mr. Gadd (Exeter) hoped to have heard something telling him how to distinguish the nature of the different alkaloids and the percentage of emetine in them. He was glad that Mr. Jones and Mr. Holmes had raised the point as to whether they might use these alternative processes for assay. From a commercial point of view it was very important to know that if they assayed their liquid extracts by Messrs. Farr and Wright's process, and diluted them down because they were too strong, they would be completely out of court, because the public analyst assayed them by the Pharmacopœia process.

Dr. Symes said he took it that the authors of the first two papers had only expressed themselves in the way they had to justify them in their method of working. He thought it was unfortunate that Prof. Attfield should feel hurt at the language that had been used, because they would rather have heard him criticise the suggested processes. He took it that a public analyst examining a sample would say that it must be an ipecacuanha which would yield the amount of alkaloids shown by the Pharmacopœia process.

Prof. Attfield observed that it would be found that the Medical Council had more and more depended upon the intelligence and the knowledge of pharmacists as each successive Pharmacopœia had been produced, and with regard to the figures now given there were certain definitions of strength given which were fairly rigid, but there was considerable latitude given with regard to processes of manufacture and testing, whether gravimetric or volumetric. He hoped it would be realised by everyone that the Pharmacopœia, notwithstanding the practice of tribunals and the principle on which barristers made speeches, was not a legal standard under the sale of Food and Drugs Act, and if one had the courage to test a case in the Superior Courts he was not afraid to forecast that the Judges of the Superior Courts would agree with what he had stated.

Mr. Farr said he and his colleagues reported on liquid extracts obtained from different sources, and had not experienced any particular difficulty. He thought there was a slight loss in Mr. Naylor's process. With reference to the colour reaction he had been in the habit of adopting the process recommended by Mr. Bird.

Mr. Naylor said he was sorry to have been charged with any lack of courtesy in the language he had used. He had merely said that the B.P. process was tedious, complex, a waste of time, and wasteful of alkaloid, and should not object if at any future time the same thing were said of his own process. All that they had tried to do was to suggest something that might be of service in the future, and they hoped before the next Pharmacopœia was published the processes now recommended would be improved upon.

The Conference then adjourned for luncheon.

The next paper read was by Mr. Henderson on

The Assay of Belladonna Plaster.

It is printed on p. 110.

Mr. Bird said this paper emphasised the fact which had been already established that day that two operators working independently might arrive at the same result. Some years ago he made a number of analyses of belladonna plaster, and found great difficulty in extracting the amount of alkaloid which he knew it contained. He therefore devised a process (which was published in February last) very similar to the one now described. He dissolved the belladonna plaster in a mixture of chloroform and glacial acetic acid, then warmed it and agitated with water and dilute sulphuric acid. This deposited the lead and liberated the alkaloids, which were treated by a vacuum filter. The official process for determining the alkaloids in this plaster presented a good deal of difficulty, and it was very satisfactory to find that these two perfectly practical processes had been devised by pharmacists.

Mr. Jones said Mr. Bird's paper was published in full in the *Analyst*, and he had found it work very well. A filter pump was recommended, but it was not really necessary. The paper would probably appear in the Year-Book, which contained everything of importance to the profession, and he must say that if the Conference and the Year-Book went down it would be a national calamity.

Prof. Attfield, having emphasised Mr. Jones's remarks, said a good many analyses of this plaster had been recently made in Canada, and severe censures were passed on the weakness disclosed ; but he never could quite understand the methods adopted by the analysts concerned.

Mr. Gerrard pointed out that the amount of alkaloid contained in a plaster of the strength of 0·5 per cent. would be about 3½ grains in a large plaster, such as was often used, and he feared the absorption of such a quantity of atropine would produce very unpleasant results. In fact, he had known of complaints being made in some cases.

Laboratory Notes,

by F. C. J. Bird, were then read (See p. 133).

Mr. T. Tyrer observed that one of the difficulties which manufacturers and pharmacists had was to comply with the double requirements of the Pharmacopœia. From a manufacturer's point of view he could confirm what Mr. Bird had said. There were many standards of reference, and not the least convenient were those admirable tables going through pretty nearly every substance, notably, ferri chloride solution, and it was remarkable to see how the different authorities differed in the tables given. He thought, perhaps, the recent controversy had done good, because it was the contents of the active materials which the compilers of the Pharmacopœia had to take into account. A reference to the table by Franz in the *Chemiker-Kalender* of Dr. Biedermann would show that he gave a very complete table, ranging in specific gravity from 1·0146, equivalent to 2 per cent. of Fe_2Cl_6 to 1·5317, equivalent to 60 per cent. Fe_2Cl_6. The gravity of 1·4118 was equivalent to 44 per cent. Fe_2Cl_6, and 1·4367 for 46 per cent. of Fe_2Cl_6. The B.P. solution should contain 45·97 per cent. Therefore, taking this table as correct the B.P. solution should have a gravity of 1·4363. The B.P. also said 5 cubic centimetres should be 1·6 Gm. of Fe_2O_3. This worked out about 45·75 per cent. Fe_2Cl_6,

which by Franz' table gave a specific gravity of approximately 1·4336.

Professor ATTFIELD said he had been much interested in what had been said with respect to liquor ferri perchlor. fortis, but he had seen a letter in the *Pharmaceutical Journal* accusing Mr. Bird of being wrong in his arithmetic, and, therefore, he would wish to suspend his own judgment. With regard to the second note, powdered gelatine could now be had in any quantity of best quality. If the mill were kept cool gelatine could be ground up to any degree of fineness desired.

Mr. KNIGHT was of opinion that vin. ipecac. as now often used and sold was of no use at all as an emetic.

Mr. JONES hoped to live to see a Pharmacopœia published which had no vin. ipecac. in it all. He did not see that sherry was required at all in pharmacy.

Dr. MCWALTER said his experience was that the wine prepared according to the new process was utterly unreliable. They were told to use only the Brazilian ipecac. root, the consequence being that the process was so tedious that the ordinary pharmacist found it not worth his while to make it. It was absurd that intricate processes should be gone through for the purpose of standardising the liquid extract of definite strength when it was certain that the cephaeline was more potent than the emetine, and that the third alkaloid would possibly be found to be more potent than either.

Mr. BIRD, in reply, explained that his reason for bringing his note before the Conference was not to find fault with the Pharmacopœia. He thought Mr. Jones would find that the public would not be satisfied with a tincture of ipecac. The compilers of the Pharmacopœia were in the hands of the medical men, and had to supply what the medical men required.

The next was a

Note on Syrup of Balsam of Tolu,

by Messrs. E. H. Farr and R. Wright (see p. 107).

Prof. ATTFIELD said it was generally admitted that there was a waste of tolu in making syrup of tolu according to the B.P. It had not been found that the product was a syrup of very little taste, but according to the opinion of a number of pharmacists the product was a good article. Then came the question whether a good article could not be made by using less tolu. The use of tolu was not new. It had been many times suggested that a tincture should be used. He did not think it desirable to economise tolu and put spirit into a syrup.

Mr. JONES asked whether the syrup made from the concentrated liquor proposed would keep its colour. He had had during the last few months to examine a few samples of liquors to produce syrup, and without exception they all changed colour. In one case a very distinct yellow syrup resulted at the end of four weeks, and the syrup that kept best of all was made from a fictitious liquor, inasmuch as it was not made from balsam, but from benzoic acid.

Mr. BIRD asked if the syrups made by this process developed the well-known benzene order.

Professor ATTFIELD thought they had been told that cinnamic acid under certain circumstances decomposed into carbonic acid and acetylene.

Mr. BIRD suggested that the presence of spirit in this syrup would prevent that taking place.

Dr. SYMES thought the syrup Mr. Farr prepared would be different to that of the B.P. and would contain a larger percentage of resin. Some years ago he made a number of experiments on balsam of tolu, chiefly with a view to economy, and he found that where a smaller quantity of balsam was used than that given in the B.P., the syrup was not so good or aromatic. If filtered warm and then mixed with the sugar, the cooling would deposit the cinnamic acid, which was intended to be got rid of, and which, he understood, had a rather irritating effect. He thought the gain in balsam would be counterbalanced by the loss of spirit.

Mr. RUTHERFORD HILL drew attention to a paper by Mr. F. Stephenson, read some years ago before a meeting in Edinburgh, in which he suggested the preparation of this syrup by grinding up the balsam with sugar, and percolating with cold water. The product was more highly flavoured than that produced by the B.P. process, and judging by the taste it seemed quite as strong. He could confirm Dr. Symes's statement that syrup prepared with alcohol was distinctly acrid in taste, and it was objected to on that ground. The cold percolation process was very simple, and well within the reach of the ordinary pharmacist. With regard to the benzene odour, he thought it generally arose where concentrated liquor was added to a syrup which had been some time in stock. Possibly simple syrup underwent some change when mixed with tolu liquor, which did not occur to the same extent if the syrup and tolu were mixed at the beginning of the process.

Prof. ATTFIELD thought Mr. Stephenson had admitted that in his process it was not very easy to dissolve the sugar, and suggested using less sugar; and also that the product was not bright.

Mr. HILL said there was no difficulty in dissolving the sugar if the percolation were properly conducted.

Mr. KNIGHT said the present process was not satisfactory, and Mr. Squire suggested an improvement in his Addendum, though he did not where he got it. He found that when filtered warm there was a difficulty, cinnamic acid and the benzene odour were often developed when the whole process was not conducted on the water bath. There was no difficulty with the cold process in the winter time, when the balsam was hard enough to be broken up and well mixed with the sugar.

Mr. FARR, in reply, said the introduction of alcohol was not a serious matter, as it only amounted to less than 20 drops per fluid ounce. He had not noticed any development of the peculiar odour in syrup made by this process, but he had known it to develop in B.P. syrup. He had tried cold percolation, but the result was not altogether favourable. It was rather tedious, and the result did not contain as much acid in the syrup as he had expected. He did not advocate filtering when warm, but mentioned the temperature, namely, that which would occur in summer. He had never noticed any development of colour in the syrup, but he believed there were a great many samples of balsam in commerce, some of which were not altogether genuine, and possibly the colour might be due to that cause. With reference to the crystallisation he referred to the concentrated liquid, not to the syrup.

A paper was then read on

The Bone Caves of South Devon,

by Mr. Handsford Worth (see p. 112).

The PRESIDENT remembered having on the last occasion of the visit of the Conference to Plymouth visited the Bone Caves. There was one point which the reader of the paper had not mentioned, and that was that on one of the rocks was to be found the name of an Irishman inscribed, with the date 1647. So that Irishmen were there, even at that date, which was no doubt after the time of the lions and bears.

A Further Note on Ferrum Redactum, B.P.,

was next contributed by E. Saville Peck, B.A. (see p. 109).

Mr. T. TYRER said he had pursued an investigation on similar lines to Mr. Peck, and was scarcely a decimal point out in his results. He agreed with what Mr. Peck said about mercuric chloride.

Prof. ATTFIELD said he was never quite satisfied with the copper sulphate method. He thought that heat should be used throughout the process, though it was true that the Pharmacopœia did not say so in so many words. He was inclined to think from some experiments that he had witnessed that the mercuric chloride method was more easily accomplished, and was more accurate. One was glad to hear that, after all, the iodine method was not so bad as it was feared.

The PRESIDENT said this paper was a very useful one for a Conference of that kind, as it pointed out the best way of making their preparations.

Mr. PECK said he used heat throughout. He was particularly pleased when he found that the iodine method was not entirely unreliable, but he thought an error might have crept into the 'Year-Book of Pharmacy'; it might have been that 1 C.c. was mentioned instead of 10 C.c. With regard to the copper sulphate method, after exhausting the ferrum redactum with the iodine, he carefully washed the oxides remaining with water until there was no trace of iodine left. He then exhausted those oxides with the ordinary copper sulphate method, and he got an extra 2 per cent. He had treated ferrous carbon in the same way. He should like to see a standard volumetric solution of permanganate included in the Pharmacopœia.

The next paper was on

The Alkaloidal Strength of Commercial Samples of the Official Preparation of Jaborandi,

by Messrs. E. H. Farr and R. Wright (see p. 90).

Mr. WARDLEWORTH said there was a great diversity in the samples of jaborandi now arriving, and the genuine kind was not very plentiful, but still it could be obtained. Some years ago *Pilocarpus microphyllis*, the small leafed variety, began to arrive in this country, and he understood it yielded 3 per cent. of pilocarpine, whilst the official variety only yielded ·5 per cent. For some

time the *Pilocarpus microphyllis* went to the Continent for the purpose of being made into pilocarpine, but then for some reason that ceased, and its price fell to a few pence per lb., but now they were taking it again. It seemed to him the better plan would be to use the strong variety, the *microphyllis*, as the other was practically valueless as a source of pilocarpine; it had a green leaf, downy on the underside, and was generally associated with a great many stalks.

Mr. Naylor said he could confirm what was said as to the difficulty experienced in obtaining pure jaborandi. He had submitted leaves, which appeared on the London market, to Mr. Holmes, who assured him they were not genuine. Still, the genuine could be obtained, but he doubted if it could be in sufficient quantity for pharmaceutical purposes.

Prof. Attfield sympathised with all that had been said on this subject. The difficulty was that they did not really know where they were. Even the question whether pilocarpine was the active principle, and the only active principle, they could not answer positively; nor did they know how far they could trust to total alkaloids. Further chemical and pharmacological investigation was required before they could answer these questions. If pilocarpine were the active principle, no wonder makers of that substance were absorbing all the samples which were strongest, and that pharmacists had to use the other leaves for their preparations. But if it proved that pilocarpine were the sole active principle the question would arise, why use other preparations at all?

Dr. Symes thought the action of pilocarpine was now fairly well known, and it was generally supposed to possess the medicinal qualities of jaborandi. The effect desired was produced either by hypodermic injection or by a small dose of pilocarpine. Both varieties, the small and large leaf, were on the market, and at present there was no scarcity of either. He did not say that jaborandi might not contain other alkaloids which had a medicinal effect, but as far as was known, all the effects attributed to it could be procured with pilocarpine. He thought the inference was that some standardised preparations of pilocarpine should be introduced, and it would not then matter from what particular source they were obtained.

Mr. Jones said, according to his experience, pilocarpine was much more used than preparations of jaborandi.

After the rising of the Conference, the members proceeded by steamer to Looe, an ancient fishing village in Cornwall. The trip was in every respect a most enjoyable one, the weather being perfect.

SECOND DAY'S BUSINESS.

On the Conference resuming the sitting on Wednesday morning, July 26, the first paper read was:—

The Salient Features of the Flora of Devon,

by G. C. Druce, M.A., F.L.S. It is printed at p. 98.

Mr. E. M. Holmes said he regretted he was not a native of Devon, though he had spent several happy years in Plymouth. Mr. Druce had omitted to mention the name of another gentleman present who had recently done far more than himself for the botany of Devon—Mr. Oswald H. Reade. Recently at the Natural History Museum, South Kensington, he noticed a specimen of *Lobelia urens*, which had been found a few years ago near Kingsbridge by Rajah Low, of Sarawak, who sent it to the Museum; but it did not seem to have been recorded. Some years ago he met the Rev. W. S. Hore at Barnstaple, who told him that one day when walking near the Mewstone he found *Scrophularia scorodonia*, which had been supposed to be confined to Cornwall and the Scilly Islands, and was only placed doubtfully in the flora of Plymouth. He hoped to be able to rediscover it during his present visit. To show the enthusiasm of botanists of Plymouth he might mention that the Rev. W. S. Hore, on the occasion referred to, told him that although he had already walked ten miles, seeing in a pool near the Mewstone a very bright red seaweed, which he thought worth examining, he walked into the water up to his middle and obtained it. It proved to be *Griffithsea secundiflora*, a species up to that time unknown as British. He subsequently walked home, wet as he was, to Plymouth.

Mr. Oswald Reade acknowledged the compliment paid him by Mr. Holmes. He could not claim to be a Devonshire man, and, with regard to the flora, had only followed on the lines of investigating the plants mentioned in Briggs. There was one plant, *Eryngo campestre*, which appeared to be unable to extend itself in the country, though it had managed to withstand extermination. With regard to *Linaria supina*, that appeared to be extending itself remarkably. *Althœa officinale* he had found three years ago, but he believed that was now extinct. It would be very interesting if they could place on record the plants that were once common in the neighbourhood, but were now extinct. *Hyoscyamus* was mentioned by Briggs as being very common, but he was sure it would not now be found within ten miles of Plymouth.

Dr. Symes said Mr. Druce's papers on the flora of the various districts visited by the members had become one of the features of the Conference, which, he trusted, would be continued, because he was sure they would be universally enjoyed.

The President, in thanking Mr. Druce, said that gentleman had not referred to the shamrock, but he presumed that was because it would only grow on Irish soil.

The next paper was by Mr. E. M. Holmes on

Delphinium Staphisagria.

(see p. 93).

Professor Attfield said Mr. Holmes was the great pharmaceutical botanist, and they were much indebted to him for this paper on an important subject. One or two practical questions arose from it; one which affected him personally related to the Pharmacopœia, and he must acknowledge the kindness of Mr. Holmes in relieving him of some of the responsibility in this matter. He never set up for an authority on botanical questions; he was, as old Wotton said, merely a gatherer of other men's stuff; and when that stuff was such as Mr. Holmes gave them, he was weel content tobe merely an editor. The practical point was, which of these two plants yielded the seeds on which the reputation of stavesacre was founded? If it were the *D. staphisagria*, all they would have to do in the next Pharmacopœia would be to alter the reference from that to Bentley and Trimen's 'Medicinal Plants' to the one Mr. Holmes mentioned, Necs von Esenbeck. If it turned out that the seeds of *D. pictum* were those which were really operative, the botanical description would have to be altered.

Mr. Rutherford Hill said this paper had cleared up a point which had troubled him, as to the size of the seeds. He noticed that the seeds in the Edinburgh botanical garden were much smaller than those found in commerce. Probably the reputation of stavesacre seeds was founded on the commercial seeds, which would be those of *D. staphisagria*, not *D. pictum*. He had no doubt that the latter plant was the one in the Edinburgh gardens, and it was very hardy, and differed in that respect from some plants cultivated at Chelsea, which were annual, whilst the Edinburgh one was biennial. Evidently the difference of climate between Edinburgh and Chelsea modified the plant.

Dr. Symes said the difficulty alluded to by Prof. Attfield did not exist, as no medicinal value had ever been attached to *D. pictum*. It was, therefore, only a question of altering the reference to the plate in the Pharmacopœia.

Mr. Druce said he had an old collection of plants, which he had recently purchased, dating back some seventy or eighty years, in which the *D. staphisagria* was correctly figured. The mistake was probably of recent origin, and was due to some confusion in the seeds grown in various botanical gardens.

Mr. Holmes, in reply, said the only alteration required in the Pharmacopœia was the reference to the plate. He had some of the fresh seeds from both plants from the south of Europe, which he intended to distribute, and get them grown at the Oxford and other botanical gardens, so that next year they might have some really good specimens from which drawings might be made. His experience was that the plant at Chelsea was not annual but biennial, and the only way in which he could account for it having an apparently annual habit was that it might have been grown from seeds very early in the year, and possibly flowered the same year. The reason it was not more cultivated in gardens was that it would not grow in the open, only under glass. The *D. pictum* was easily grown in the open.

Notes on Terebene, B.P.,

were next read by Mr. Lewis Ough, F.L.S., F.C.S. (see p. 104).

Mr. T. Tyrer said the question of terebene had had their attention, and a number of experiments had been made, one of the chief results being that they had come to the conclusion that the large latitude allowed by the Pharmacopœia in the matter of boiling point was inconsistent with obtaining an optically negative product. It must be borne in mind that terebene rapidly changed from an optically negative article to one having rotation. As an instance, a sample optically negative six months ago was now +3.2. Experiments led them to think that the boiling point should be altered from 165 to 175°. Oil of turpentine rapidly oxidised, altering the sp. gr. and boiling point as well as the

optical rotation, and no two authorities were agreed on the constituents either of the turpentine oil (which, of course, varied from different sources), or from the products resulting from the action of sulphuric acid on oil of turpentine. All authorities agreed that the product was a mixture and variable. The B. P. gave a boiling point 160° to 180° C. Tilden gave 156° C., and Jager and Chase 173° to 180° C. for pure terebene, although Tilden stated that he had some experiments spoilt because the terebene he worked on was contaminated with cymene. Regarding the presence of cymene Richter represented the formula of turpentine oil as containing benzene ring of six carbon atoms, and as being cymene with two atoms of hydrogen added. Riehan in the *C. S. J.*, 1873, stated that the liquid resulting from the distillation of turpentine from oil of vitriol, and to which the name of terebene had been given, was a mixture of pure terebene and cymene. Bright, in the *C. S. J.*, 1873, considered that cymene was pre-contained as such in the original turpentine. Roscoe said terebene $C_{10}H_{16}$ was contained in Swedish and Russian oil of turpentine. Dipentene and its derivatives were optically inactive, boiling point 180° to 182°, sp. gr. ·853. On agitation with sulphuric acid it was partly converted into a resin, sulphurous acid was evolved, and cymene separated out on addition of water. Cymene was also formed by the action of sulphuric acid on oil of turpentine, this being first converted into dipentene. Cymene occurred in old oil of turpentine, and was formed in this in considerable quantity by treatment with oil of vitriol. Therefore, from the above remarks, it seemed probable that even taking a comparatively pure product terebene would be mixed with cymene. A reference to the works of Brand, Dumas, Berthelot, Thorpe, Richter, Watts, Tilden, Roscoe, Kingzett, and Armstrong would show what different views various authorities held on the varying constituents of turpentine oil and commercial terebene, so called. Regarding the reversion of dextroratory terebene to levorotatory, it might not be common know edge, but by the action of oil of vitriol during a definite time and at a certain temperature a dextrorotatory article could be made levorotatory terebene, or that by fractional distillations of terebene and of turpentine no products of a higher dextrorotatory power than the original turpentine or terebene could be obtained, and also levorotatory fractions. The fractions could be bulked, giving an original rotation. Armstrong, in the *Journal of the Society of Chemical Industry*, 1882, in a paper on different samples of turpentine, showed how greatly they varied, particularly when obtained from Russian turpentine +30° 20′ to 46° 45′, and American 24° 29′ to 32° 38′. He attributed the comparatively low rotatory power of the latter to the presence of a levorotatory substance. On several occasions, by submitting American turpentine to air oxidation and afterwards distilling off the unaltered hydrocarbon by steam, he obtained products of considerably higher rotatory power from the original oils, and thought American turpentine a mixture of isomeric hydrocarbons. They had come to the conclusion that the mere steam blowing of oil recommended by the Pharmacopœia and as generally practised was inefficient, but an inactive result could be obtained in a variety of ways with the latitude of temperature allowed by the B.P. He might venture to remark that the making of terebene on a small scale was a comparatively easy matter, but not by any means so on a technical scale. This all went to confirm the conclusions of Mr. Ough that there was great difficulty in obtaining the exact conditions of the B.P.

Dr. SYMES said this paper and Mr. Tyrer's remarks would be of great importance to the dispensing chemist, whose difficulty was that he might obtain two samples, obtained from different sources, which would not be sufficiently identical in odour to satisfy the patient and the medical man. He had had considerable trouble on that point. One sample would smell of turpentine, while another would have a sweet and agreeable odour. His experience was that age mellowed it somewhat, and a very good plan was never to run quite out of terebene, and always to add the new supply to some of the old stock.

Mr. NAYLOR could confirm Dr. Symes and Mr. Tyrer as to the difficulty of making terebene so as to be optically inactive on a large scale. As to the difference in the odour it was not infrequently complained of, and he could not imagine why the authorities of the Pharmacopœia introduced into that most valuable book a terebene which was optically inactive, and which was one of the nastiest preparations as compared with the one introduced by Dr. Morrell.

Professor ATTFIELD said the subject was an immensely interesting one. The importance of it just now was that there had been an impression during the last two or three years that terebene was not so useful as it was supposed to be, and was going out of fashion, but that statement had been met by one of their most eminent pharmacologists. Dr. Leach, who had publicly stated that terebene had fairly well maintained the importance that was given to it at and soon after its introduction. It was important that they should know what they were dealing with under the name "terebene." He was afraid that they never could quite know satisfactorily, because they must give the article a single name, and yet it must be a mixture of different things which they could not be certain should always be alike, and that was the reason why the statements in the Pharmacopœia respecting it were designedly indefinite. With regard to the optical qualities and all the other physical constants, it must be remembered that they could not have what vendors required, viz., a substance of this kind which should always have similar properties. They did not know where they were in the matter of terebene, and it was because that was the fact that such contributions as those of Mr. Ough and Mr. Tyrer were so valuable.

Mr. HOLMES said he gathered from the remarks which had been made that the question of flavour was an important one to chemists. He took it that the variation arose not merely from the process by which the turpentine was produced, but from the fact that it was obtained from fir trees in different countries. It seemed to him quite open a subject for discussion by the Conference as to which of the turpentines from the different fir trees yielded the most fragrant fluid. The same difficulty arose with the different cucalyptus oils.

The next paper was by Mr. R. H. Parker on

Glucose Determination,

which is printed at p. 97.

Mr. BIRD said the suggestion here made of adding glucose of a known strength was very useful. Every one must have experienced a difficulty in analysing samples of urine containing very little glucose owing to the length of time required. Polarimetry as a check on the use of Fehling's solution was useful, and he had found gave very accurate results. Of course, albumen in the urine would interfere with the rotation, but that could be removed by boiling.

Mr. GERRARD agreed with what had been said by Mr. Bird. He had had to analyse a number of samples of urine where the amount of sugar was very small, and in such cases it was extremely difficult to decide the exact percentage. Mr. Parker had referred to the normal colour constituents as interfering with the reaction in Pavey's or the cyanocupric test, but he had found little difficulty on that ground. It must be a very highly coloured urine which would observe the blue colour produced by the addition of the sulphate of copper, and it was not difficult to see when the blue colour had gone.

Mr. BRUCE said the method of adding a strong solution of glucose to bring down the copper more rapidly had been used for many years in the sugar trade, in estimating the glucose in samples of beetroot sugar. He believed Mr. Blacklock, of Glasgow, the sugar analyst, was the first to introduce it.

Professor ATTFIELD said there was no doubt that the method referred to was known in the sugar trade, but he had never heard of its being applied in pharmacy until Mr. Parker suggested it, and therein lay its value. The paper was also valuable because it facilitated a kind of analysis which was particularly within the province of chemists, from which they might expect some little remuneration, and need not fear much competition from public analysts.

Dr. SYMES said the point made in the paper with regard to the colour was not without justification. Although, as Mr. Gerrard said, an average sample of urine might not be highly coloured, but the larger number of samples of diabetic urine which he had examined were highly coloured.

After a few remarks from Dr. MCWALTER, which the President thought might tend to cause unpleasantness with the medical profession if published,

Mr. PARKER, in reply, said the use of the polarimeter was hardly applicable in cases where there was only a trace of sugar, which were just the cases he was dealing with. The difficulty with regard to the colour came in where the urine was highly coloured, and there were considerable quantities of creatinine, uric acid, xanthine, etc. When treated with the cyanocupric or Fehling's solution, these substances gave a yellowish colour with the alkali, and this rendered it exceedingly difficult to see exactly when the blue colour disappeared. If it were diluted the dilution gave rise to another difficulty—the greater the dilution the more difficult it was to find the dividing line.

The next paper was by Mr. Tyrer on

Hydrogen Peroxide.

It is printed at p. 100.

Professor Attfield said Mr. Tyrer had given a valuable series of results, which would form a guide to makers, dealers in, and users of hydrogen-peroxide. The principal point of interest to himself was the suggestion that there should be a test for this substance in the Pharmacopœia, as to which he was not in a position to state an opinion.

Mr. Tyrer said he had quite recently received a letter from Mr. Sutton, one of H.M. Inspectors of Factories, in which he pointed out the great value of hydrogen-peroxide in many analyses as an oxydiser; in fact, some determinations could only be effected accurately by its aid. It was necessary, however, that the hydrogen-peroxide should be perfectly pure and the exact quantity known.

The next paper was by Mr. C. G. Moor and Mr. C. H. Cribb on

Standards for Food and Drugs,

which is printed at p. 129.

The President said it was impossible to discuss this paper properly in the time at their disposal, and he thought they would be in a much better position to do so twelve months hence, after carefully reading it. He would only ask Professor Attfield to make a few general remarks upon it.

Professor Attfield quite agreed with what the President had said as to the impossibility of properly discussing this paper at present. Not only was there not time, but there were important questions of policy connected with the subject, to some of which he had referred on the previous day in connection with the establishment of standards, and their relation to the Sale of Food and Drugs Act. On some of these points they would be touching on rather tender ground, and his opinion was that the subject would be far better discussed in the Press than in that room, where the temperature, already fairly high, would probably rise rapidly.

Mr. Glyn-Jones asked if no discussion at all was to be allowed on this paper, which many had been looking forward to as the most interesting one on the list.

Dr. Symes said he did not understand the President to say there should be no discussion. It was obviously impossible to discuss it in detail, but the necessity for standards of purity seemed more evident than ever. They had heard yesterday that the British Pharmacopœia was not a standard by which the work of public analyists was to be tested, though, as they all knew, it was the authority under the Pharmacy Act. At present public analysts were endeavouring to get the Government to appoint a Committee of Reference, and owing to the diversity which often arose between public analysts and the Somerset House authorities there seemed a great want for some such tribunal. But the question of the accuracy of analyses was not the only one. The analyst had no authority under the Act to advise the magistrate whether a particular thing was good or bad, but had simply to examine it and report the result. The magistrate knew nothing about it, and had no authority to refer to. There were articles undoubtedly genuine, and others undoubtedly adulterated, but between the two there were a great many which it was difficult to classify. The difficulty arose with low standard articles which were not adulterated. For this reason it was desirable that there should be a duly constituted authority, not only to check the correctness of analyses, but to which reference might be made as to what might be passed as pure. There, he thought, was the great value of the paper.

The President said he had not yet answered Mr. Glyn-Jones's question; he might say that the Committee had considered the matter and decided there should not be a general discussion of this paper, because there would not be time for it.

Mr. Glyn-Jones said it was a pity that no notification of this had been given.

Mr. Atkins supported the President's statement. He much regretted there was not time to discuss this paper, for which they were much indebted to the author.

Mr. Samuel Maitland said he was one of the few present who attended the last Conference in Plymouth, and, being over seventy years of age, it was doubtful if he would be able to attend the next one, and he should like to ask if there would be no opportunity of discussing this most important question between that day and Friday next.

Mr. Moor, in acknowledging the thanks of the members, said the Society of Public Analysts had asked him for a paper so that it might be discussed when they held their next meeting in October. If any of the members would furnish him with figures he should be very glad to make use of them.

A Weight Burette

was then described by E. Saville Peck, B.A. (see p. 111).

Mr. Bird said Mr. Peck had brought forward a very useful instrument, which would be very applicable to the titration of small alkaloidal residues. In titrating belladonna for example, the inaccuracies in the calibration of the ordinary instrument affected the volumetric estimation considerably; it would make a difference of four milligrammes in a determination of 100 grammes of alkaloids. This would prevent one from getting those concordant results which it was the pleasure of the analyst to obtain.

The President thanked Mr. Peck for his paper, which, he said, would be very useful to small pharmacists as well as to large pharmacists.

Mr. Peck said he quite agreed with Mr. Bird that the instrument would be applicable in the case of alkaloidal residues.

A Comparison of Different Methods of Determining Melting Points of Certain B.P. Substances

was then made by Thos. Tyrer and A. Levy (see p. 131).

Professor Attfield said he understood from Mr. Tyrer that he was personally well satisfied with the treatment that the suggestions made by pharmacists in relation to the Pharmacopœia received. Mr. Tyrer had said that he had made a few comparatively unimportant suggestions which had not been attended to in the way he desired; which was to be explained by the fact that suggestions had been made which were inconsistent with each other, but with regard to suggestions generally, he could vouch Mr. Tyrer as one whose experience was that suggestions made by competent pharmacists were attended to. He could assure the members that such suggestions always had, and always would have, the best attention of the compilers. Mr. Tyrer had alluded to the figures showing the melting points in the official book, and said they seemed somewhat inconsistent with the directions for taking melting points given on page 436 of the Pharmacopœia. Those memoranda as to the method of taking melting points had been very carefully drawn up, and it might be assumed that they did represent the opinions of the referees as well as the gentlemen who had written the papers, but whilst those memoranda should be adhered to by all those who dealt with the question of melting points, in the future it must be distinctly understood that the method described in the appendix had not necessarily been the method by which the melting points given in the Pharmacopœia had been determined. The taking of melting points was one of the most difficult operations of physical chemistry, as everyone who had done anything in that work would agree with him. The best sources had been drawn upon in order that they might get the melting points most generally recognised, but it must not be for a moment supposed that those who had helped to compile the Pharmacopœia had in all cases verified those figures so published by competent authorities. However desirable it might be to do anything of that kind it would be quite out of the question, as it would take too much time and cost too much. As it was, the cost of the Pharmacopœia had been raised from something like 6s. or 7s. up to 10s. The Medical Council made no profit on the Pharmacopœia; the Government took good care of that. They could only estimate what it had cost, and then the Privy Council fixed the price accordingly. That being so, it would be seen that it was absolutely impracticable for any Pharmacopœia Committee in anything like three or four years to go into the question of verification. A good deal in that direction had been done in the production of the present Pharmacopœia, hence the increased cost, but it was quite impossible to adopt that as a general principle. Mr. Tyrer was quite right in insisting on the importance of methods in regard to melting points, and on the importance of the details of the construction of apparatus, and, if he might add to those two important factors, that of the individual manipulators—the personal equation, as it was called—then he was sure they would be prepared to find that no two good authorities would ever be in absolute agreement respecting melting points. He hoped Mr. Tyrer's tables would be published for reference in the future, as also his diagrams as to the treatment of suggestions; there was nothing to be hidden on the subject. Once for all, he would point out that every attention was paid to the researches of pharmacists; the only things that went into the waste paper basket were the envelopes and the wrappers.

Mr. Naylor asked why, in taking the melting points of chemical substances of a very expensive nature, in one case atmospheric moisture was taken into account and in others not? For instance,

the melting point of acetanilidum was given as 113.5 when dry, but in the case of some of the other substances named, such as sulphonal, and which had lately risen largely in price, there was no such condition imposed. He should have expected that the melting point of all substances would be taken when dry, with an indication that the moisture should not exceed a certain amount.

Professor Attfield said the good horse consistency must not be ridden too hard, and in nine cases out of ten an attempt at absolute consistency in one direction involved inconsistency in others. To adopt any particular method of dealing with articles before taking their melting points would involve a number of fresh inconsistencies. The anxiety of the compilers of the Pharmacopœia was to help medical men to cure their patients, and if it seemed that taking the melting point of an article in the commercial condition was best it was taken in that way; if it seemed best to dry the article, it was dried. The real consistency they wanted was that of common-sense.

Mr. Rutherford Hill said the question put by Mr. Naylor seemed to emphasise the point put by Professor Attfield that statements were put in the Pharmacopœia without being verified by the authorities responsible. It did not seem to him that that was a satisfactory way of compiling a national Pharmacopœia, and he doubted if the United States Pharmacopœia was prepared on that principle. It seemed rather to indicate that some readjustment was necessary in the method of producing the Pharmacopœia. The determination of these melting points was not by any means so elaborate and expensive a matter as Professor Attfield's remarks might lead them to imagine. The proudest and richest nation in the world ought to be able to produce a Pharmacopœia under the best possible conditions, and should not be content with a book which was admittedly a mere collection of extracts, produced by the use of scissors and paste.

Professor Attfield said the inference was utterly erroneous. The Pharmacopœia was not such a book as Mr. Hill described.

Mr. Jones said he had found on taking the melting point of some of these substances that they were not quite in accord with the figures given in the Pharmacopœia. He did not, however, complain to the makers, but inferred, as Mr. Squire had apparently done, that the difference arose from the presence or absence of moisture. In the last edition of Squire there was a recommendation to dry the acetanilidum.

Professor Attfield said the melting point of acetanilidum was given in the Pharmacopœia as 236.5° F., when dry.

Mr. Tyrer, in reply, said the main question which seemed to have arisen was a moral one affecting the compilers of the Pharmacopœia, and he could only congratulate the Committee on having such an able advocate in Professor Attfield. But there was an old proverb, *Qui s'excuse s'accuse*, and he was very sorry that the learned professor had thought it incumbent on him to be so much on the defensive. The great question was, were the interests of the public to be safeguarded; it was not a question of the wholesale or retail trade, or of the manufacturer, but only of the public. The name of the Privy Council had been introduced, which meant that Government money was concerned, directly or indirectly. It seemed to him that the great Pharmaceutical Society, with its enormous resources and its research laboratory, ought to begin to do something, with the aid of an endowment from the State and a contribution from the medical authorities, to settle some of these questions, which amateurs were trying to solve, mainly in their own interest. He concluded by saying that he should have much pleasure in having blocks prepared of the diagrams illustrating his paper and to contribute towards the expense.

Mr. Atkins said a great deal of good work had been done by members of the Pharmaceutical Society, and if the Research Laboratory had not yet done much in this way, he believed it would.

Mr. Tyrer said his point was that the State ought ti contribute to the elicitation of the facts which were demanded, in what was practically the handbook of the magistrate.

The President thanked Mr. Tyrer, not only for his very valuable paper, but also for his very generous offer in connection with its preparation and publication.

The Assay of Preparations Containing Pilocarpine and the Characters of Pilocarpine Nitrate and Hydrochloride.

was next dealt with by H. A. D. Jowett (see p. 91).

Mr. Ransom said this was a particularly valuable paper. It was important to determine what the standard should be, on which question he hoped Dr. Jowett would work and give his results at the next Conference.

Professor Attfield said the point to be ascertained was as to what salt should be used. At the time of the preparation of the B.P. the salt was not pure. If in the next two or three years a pure nitrate should be the commercial article, then the solubility might be stated to be very much that which Dr. Jowett had mentioned.

Mr. Gerrard said the substance known as pilocarpine nitrate was by no means a constant substance. He had twice seen the pilocarpine in a crystalline condition. There was undoubtedly a mass of crystals embedded in a viscous mass, and he had endeavoured, unsuccessfully, to reproduce those conditions. He was hopeful that they would some day be able to say that the pure base was a crystalline body. All the evidence went to show that the body known as nitrate of pilocarpine was still a mixture.

A paper was then read on

The Composition of Commercial Araroba.

by Edwin Dowzard (see p. 106).

Mr. Holmes said he thought he was the possessor of the first large commercial sample of araroba which came into this country. The drug as it had come into commerce in recent years was very inferior to what it was in earlier times. At first it contained up to 80 per cent. of chrysarobin, and then it went down as low as 23 per cent. He had obtained analyses from two wholesale houses and one retail house of samples of araroba, and the mean was that given in the Pharmacopœia. It had been shown that chloroform dissolved out more of the active ingredients of the drug than any other solvent. It had been stated that the proportion of araroba constituents which were left when the drug was exhausted by petroleum spirit still left the active principle of the drug, and that there was a residue which could be taken out by chloroform, and had still the same active properties as those which were taken out by the petroleum spirit.

Dr. Symes confirmed Mr. Holmes in stating that the araroba now imported into this country was not nearly of the same quality as it was originally. The question of moisture was a very serious one, it being stated that it was sometimes added to prevent the dust flying from it. By repeatedly heating and pouring off it could be very soon exhausted with very little loss. The powder so obtained was a soft velvety powder, which would mix readily to form an ointment.

Mr. Naylor thought that the question of the amount of ash should be taken into consideration. It was a fact that it was by no means an easy matter to get hold of samples of Goa powder which contained as small a quantity as three per cent. of ash.

Mr. Wardleworth thought the factor of the percentage of water was a very small matter indeed, for the simple reason that the man who bought the araroba ought never to think of taking it until he had ascertained exactly the percentage of water in the sample.

Almond and other Kernel Oils

formed the subject of the next paper by J. C. Umney and R. S. Swinton. (See p. 106).

Mr. Allen said he had been associated for thirty-six years in the production of the oils dealt with in the paper. He had been surprised to see it stated that the nitric acid test was considered to be valueless as demonstrating the presence of apricot or peach kernel oil in almond oil. Years ago a large amount of kernel oil was added to the almond oil in commerce. Now it was considered that nothing was easier than to demonstrate its presence; the only thing they regretted was that they could not say exactly the amount or the absolute character of that adulteration. The experience of manufacturers would tend to show that commercially there was no difference in the relative value of oil derived from peach kernels or apricot kernels. It was undoubtedly a fact that ninety-nine packets out of 100 that came into this country were not peach, but apricot kernels. Any druggist, with the aid of Beber's test, could easily satisfy himself as to the difference between kernel oils and almond oils, and if their scientific friends could show them a ready means by which they could always ascertain what was the exact adulteration of the kernel oil, and the amount of that adulterant, then a great gain would be secured for the trade at large.

Mr. Holmes said that on keeping a bottle of almond oil that he had bought for his own use, he found that the bottle became sticky outside, which was not a characteristic of true almond oil. He had been told that there were two kinds of kernels which came into commerce, one from Persia and the other from France, but he did not know whether there was any means of ascertaining the botanical sources of the kernels. He thought it would be advisable for all wholesale druggists, on behalf of their retail customers in this line, if they would state the origin of the products which they sold.

Mr. Wren said the whole question resolved itself into a matter of £ s. d.

Mr. Lescher said if oleum amygdili were asked for it was always the English oil that was supplied.

Mr. Allen said with regard to the source of supply, the question of their coming from Persia was almost a myth; as a matter of fact, a large proportion of the supply really came from Syria, and also from Barbary.

The next paper taken was that by Mr. Wm. Idris on

Examination of the Terpeneless Oils of Lemon and Orange in the Market.

which was read by Mr. Ransom. It is printed at p. 103.

Mr. Wren said he regretted the author's absence, as he desired to put a few rather pointed questions to him. At the International Conference at Brussels a few years ago he was awarded a premium for a paper on this subject, and Mr. Umney had also written upon it. They seemed to be drifting in a wrong direction with regard to the active principles of these oils, and paid too much attention to the isolation of one or two products, aldehydes, ketones, or alcohols. In this case especially it was a mistake to try to isolate one ingredient, because the oil changed so easily that the slightest chemical action or the application of heat destroyed all the character of what they understood by the odour of lemon. He based his remarks on work on the spot, both at Mycenae and Palermo, for three or four successive seasons. You might obtain terpeneless lemon oil by fractional distillation, and obtain only about 7 per cent. of the total volume of the oil, but it represented in no way whatever the true oil of lemon. He looked rather to that unknown body, neither lemonine nor citronel, as being the really odoriferous principle of lemon oil.

Mr. Holmes thought Mr. Umney had pointed out that geraniol was an important ingredient in essence of lemon. In most perfumes there were bodies which, though present in only very small quantities, considerably modified the remainder. Most people thought the chief element in essence of lemon was citral, but its odour was modified by other matters. At the Colonial Exhibition some years ago he found a sample of essence of lemon which had a peculiarly natural odour, if he might use the expression; it was exactly like scraping a piece of fresh lemon peel on sugar, and everyone knew that the odour of fresh lemon was very different to that of the essence. Those who made terpeneless oils separated a quantity of terpene, which often had an odour of lemon, and was largely used, he believed, as a perfume for soaps, but chemists must be on their guard to ascertain how much more than the normal proportion of terpene was present in any cheap essence of lemon. The whole thing was a matter of price; if they asked for an article at a price below the cost of production they could not expect to have it pure.

The next paper taken was that by Mr. Dudderidge, on

Liquor Bismuthi et Ammonii Citralis,

which is printed at p. 101.

Professor Attfield said he must protest against the compliment the author had paid him of giving a formula for this substance. He only suggested it, for he had never analysed it, and had yet to learn what was its true composition.

The next paper was a

Note on Commercial Carbon Disulphide,

by Mr. Elborne, which appears at p. 111.

Professor Attfield said Mr. Elborne had not added much to their knowledge. He had suggested that corking had something to do with the matter, but had not proved it. The action of light on pure carbon disulphide was well known, and they would all be glad if someone would ascertain its cause, and how it could be prevented.

Mr. Tyrer said the only answer he ever gave to numerous and troublesome inquiries on this subject was that it could not be helped.

The next paper was that by Mr. Stuart on

Blaud's Pills,

an abstract of which was read by Mr. Naylor. It appears in full at p. 108. There was no discussion on this paper, beyond the usual vote of thanks.

A paper by Mr. Parry, on

Oil of Cardamoms,

which appears at p. 105, was next read by Mr. Ransom. This also was passed without discussion.

The next paper was by Mr. C. S. Dyer on

Carbonic Anhydride,

which appears at p. 96. The summary at the end of it was all there was time for, and was read by Mr. Naylor.

The next paper was by Mr. F. Davis, on

B. P. Lozenges,

extracts of which were read by Mr. Naylor. The paper appears at p. 99.

Prof Attfield said the results shown in this paper reflected credit on all concerned. It was evident that formerly there was considerable ignorance amongst manufacturers as to the proper standards of strength, and the best excipients to use, but these differences seemed now to be removed.

Dr. McWalter said he should have asked Mr. Davis, had he been present, if he had tested for glucose, because he had found it in many B. P. lozenges which he had tested.

Prof. Attfield said there might be any adulteration in any lozenge, but so far as the author had gone, he negatived the inference Dr. McWalter had drawn.

The President said the next paper on the list, one by Mr. Hooper on Indiarubber Substitutes, was too important to abridge, especially considering the standing of the author, but it would be printed in full in the *Pharmaceutical Journal* (see p. 94). One other paper on a new condenser, by Mr. Lucas, would have to be omitted (see p. 102), as the author had not sent the necessary illustrations.

Presentation from the Bell and Hills Fund.

The President having explained the origin of this fund proceeded to hand over to Mr. Park, as President of the Local Association of the Three Towns, the books which they had chosen to receive as a memento of the visit of the Conference. He noticed that there were five volumes on botany, three on chemistry, and others on materia medica, pharmacy, and the use of the microscope.

Mr. Park, on behalf of the Local Association, acknowledged the gift, which he was sure would be much prized. Mr. Reade, one of the most distinguished field botanists in England, had aided the committee in the choice of books, and he had no doubt they would prove very useful.

Election of Formulary Committee.

Mr. Rutherford Hill, after alluding to the marvellous assiduity and matchless skill with which the British Pharmacopœia was produced, moved the election of Messrs. E. C. Abraham, F. C. J. Bird, T. Greenish, N. H. Martin, D. Martindale, J. Ransom, C. Symes, H. Wilson, R. Wright, and W. A. H. Naylor as members of the Formulary Committee for the ensuing year

Dr. McWalter seconded the resolution.

The resolution was passed unanimously.

Place of Meeting for 1900.

Mr. Harrington, on behalf of the Western Chemists' Association of London, invited the Conference to meet next year in London. He need not say anything about the attractions of London, but he might say that the invitation did not come from the Western Chemists' Association alone, but from the whole of London and the neighbourhood, and he had no doubt the meeting would be a happy and profitable one.

Mr. Warren seconded the invitation, which was supported by Mr. Cooper.

Mr. Naylor then read a letter from Mr. Martindale, President of the Pharmaceutical Society of Great Britain, offering the use of the Society's house for the meeting of the Conference.

Mr. Druce then moved that the invitation from London be accepted. He referred to the opportunities for botanising which might be found in London, which he hoped some at any rate would avail themselves of.

Mr. Beggs seconded the resolution, and hoped members would at once write or telegraph to London to secure accommodation.

The resolution was at once carried by acclamation.

Mr. Wells then, on behalf of the Pharmaceutical Society of Ireland, invited the Conference to meet in Dublin in 1901, where he could promise them a truly Irish welcome.

Mr. Beggs said he had much pleasure in supporting the invitation.

The President said it was not usual for the Conference to tie itself two years in advance; but he thought from what he knew of the feelings of those who had visited Dublin before and Belfast last year, that if this invitation were renewed next year it would receive very favourable consideration.

Election of Officers.

Mr. Naylor proposed the election of the following officers:—

President.—E. M. Holmes, F.L.S. (London).

Vice-Presidents.—R. J. Downes, Ph.C. (Dublin), Walter Hills, Ph.C., F.C.S., J. F. Harrington, Ph.C. (London), John Moss, F.I.C., F.C.S. (London).

Honorary Treasurer.—J. C. Umney, Ph.C., F.C.S. (London).

Honorary General Secretaries.—W. A. H. Naylor, F.I.C., F.C.S. (London), and F. Ransom, Ph.C., F.C.S. (Hitchin).

Honorary Local Secretaries.—W. Warren (London), and Herbert Cracknell (London).

Other Members of Executive.—Leo Atkinson, Ph.C. (London), G. C. Druce, M.A., F.L.S. (Oxford), F. C. J. Bird (London), Professor Greenish (London), J. W. Bowen (London), E. Saville Peck, B.A. (Cambridge), H. Collier, Ph.C., F.C.S. (London), J. Davy Turney (Plymouth), and Edmund White, B.Sc. (London).

Auditors.—J. Maitland (Stonehouse) and J. H. Mathews (London).

Mr. HOLMES said he felt sure that his name could not have been selected on account of any special fitness he possessed for the office of President, either as a public speaker, or as one especially conversant with ceremonial and social duties, since there were many other Plymouthians, as, for instance, Mr. Breeze, Mr. Park, and Mr. Turney, who were far more suitable for the office. He evidently owed the honour that had been conferred upon him partly to the kindly feeling of old Plymouth friends, who felt, perhaps, that as an old resident in Plymouth, and partly to the fact that many friends in all parts of the country wished thus to recognise his humble efforts to increase our knowledge of materia medica. Of one thing he felt sure, viz., that any deficiencies on his part would be fully compensated for by the hearty moral support that Plymouth friends would accord him by their presence at the meeting in London next year, and by the London Committee of the Conference. He felt that he had been especially honoured in being selected to fill the office of President of the Conference at a time when it met in the greatest city of the world and in the last year of the century, and at a time when, by the strange attraction of gravitation that all large cities possessed, London would draw people from all countries. He hoped that it would be one of the largest meetings of British pharmacists on record, and that as a result the Conference would receive a large accession of members.

Votes of Thanks.

Mr. S. R. ATKINS moved that their thanks be tendered to Mr. Park, Mr. Turney, and other members of the Executive Committee for the very excellent arrangements which they had made, and which had tended to make, the meeting at Plymouth so pleasant and successful.

Mr. ALLEN seconded the motion, and referred in glowing terms to the arrangements which had been so successfully carried out by the Local Committee.

The vote of thanks having been carried by acclamation,

Mr. PARK briefly returned thanks.

Mr. DAVY TURNEY also thanked the members.

Mr. WELLS then proposed that the best thanks of the meeting be accorded to the Mayor and Corporation of Plymouth for kindly granting the use of the Law Courts and the Corn Exchange to the Conference during their visit to Plymouth.

Mr. BRANSON seconded the resolution, which passed unanimously.

Dr. SYMES moved that the best thanks of the meeting be accorded to the President for his able and enthusiastic discharge of the duties of his office during the Session of the Conference and throughout the year.

Mr. HOLMES seconded the resolution. The way in which the President had conducted the whole of the proceedings of the Conference had earned their admiration and gratitude.

Professor ATTFIELD put the resolution to the meeting.

The vote having been unanimously agreed to,

The PRESIDENT briefly returned thanks.

A vote of thanks to the Honorary Secretaries, Mr. Ransom and Mr. Naylor, concluded the proceedings.

PLYMOUTH LOCAL EXECUTIVE COMMITTEE

List of Delegates.

Delegates:—*Pharmaceutical Society of Great Britain.*—Messrs. S. R. Atkins, W. G. Cross, W. S. Glyn-Jones, N. M. Grose, J. F. Harrington, C. J. Park, C. Symes, W. Warren, and R. Bremridge.

Pharmaceutical Society of Ireland.—Messrs. G. D. Beggs, W. F. Wells, jun., and P. Kelly.

Bristol Pharmaceutical Association.—Messrs. G. F. Turner, J. B. Keen.

Cambridge Pharmaceutical Association.—Mr. E. Saville Peck.

Exeter Association of Chemists and Druggists.—Messrs. P. F. Rowsell, Henry Gadd, J. H. Lake, and H. W. Gadd.

Edinburgh Chemists' Assistants' and Apprentices' Association.—Messrs. David McLaren, W. B. Cowie, and J. Rutherford Hill.

Forfarshire and District Chemists' Association.—Messrs. D. Ferrier and A. Naysmith.

Leeds Chemists' Association.—Mr. F. W. Branson.

Liverpool Chemists' Association.—Messrs. J. Bain, A. S. Buck, E. Evans, jun., J. Smith, T. H. Wardleworth, and J. H. Evans.

Manchester Pharmaceutical Association.—Messrs. C. A. Johnstone and A. J. Pidd.

Newcastle-on-Tyne and District Chemists' Association.—Messrs. F. E. Schofield. Geo. Foggan, G. F. Merson, and F. Gilderdale.

Leicester and Leicestershire Chemists' Association.—Messrs. Thomas Howard Lloyd (President), E. H. Butler, and Lewis Ough, F.L.S., F.C.S.

Swansea and District Chemists' Association.—Mr. J. Hughes.

Ulster Pharmaceutical Association.—Messrs. J. W. Nichols and Jas. Tate.

Bradford Chemists' Association.—Mr. R. W. Silson.

Oxford Chemists' Association.—Messrs. Matthew and Druce.

Midland Counties Chemists' Association.—Mr. Gerrard.

Western Chemists' Association of London.—Messrs. Matthews and Harrington.

Glasgow and West Scotland Chemists' Association.—Messrs. T. H. Lloyd, Ough and Butler.

Wigan Chemists' Association.—Messrs. Johnson and Phillips.

Tunbridge Chemists' Association.—Mr. Hobbs.

N.E. Lancashire Chemists' Association.—Messrs. R. L. Gifford and Sherrcck.

SUGGESTED STANDARDS OF PURITY FOR FOODS AND DRUGS.*

BY C. G. MOOR AND C. H. CRIBB.

In dealing with the analysis of articles purchased under the Sale of Food and Drugs Acts, one of the principal difficulties encountered by the public analyst is the lack of information on which he is to base the conclusions to be drawn from his work.

In other words, in the case of many articles which may be submitted to him, where and how is he to draw the line separating the genuine from the adulterated sample? In the case of very many articles there might be a third class, in addition to the genuine and the adulterated, namely, specimens "of inferior quality but not of necessity adulterated." In the case of many natural products it seems that such a class must always exist, and it is in respect of the doubtful cases that attention is specially required.

In the case of articles distinctly good or distinctly bad, there is little or no difficulty in determining how to deal with them.

The object of the present paper is to attempt to ascertain whether the dividing line between the three above-mentioned classes can be drawn somewhat more distinctly than at present. For this purpose we require to know both the average composition of genuine articles, and also the composition of articles not of the highest quality, but of proved genuineness.

Dealing with the question of standards, we have no legalised standards at all except in the case of spirits, and in the case of a few articles of food the limits adopted by the Inland Revenue authorities are known (as in the case of milk) and are probably used by most analysts. In addition certain standards were proposed by a committee in the early days of the Society of Public Analysts, which dealt with milk, cocoa, vinegar, mustard, and a few other articles, but at the present day some of the standards then agreed on would not find general acceptance.

In addition to the question of the composition of articles, the names and definition of many substances deserve attention, as a very slight change of description in the article sold may result in its composition being entirely different.

To show the need of standards in relation to articles of food (omitting drugs for the moment) we may consider the following questions:—What is the composition of the ordinary articles in everyday use which we should consider as satisfactory evidence of their genuineness, or, in other words, what limits are we to place on the various substances which are determined by analysis?

To take bread, how much water is to be allowed? Or cocoa, how much fat ought there to be in it, or need there be any at all? Or in the case of vinegar, how much acetic acid should there be? Or in mustard, should we have a limit depending on the amount of fixed oil or not? It will be seen that in the case of almost every article of food there is an important question to be answered which is at present unsettled.

There are some 300 articles which have been, or might be, purchased under the Food and Drugs Acts, and we are of opinion that in the case of many of them some mutual agreement might be come to which would result in the adoption of a provisional standard, which would be of general convenience.

We are engaged in collecting as far as possible reliable figures on the composition of the 300 odd articles mentioned, but space will, of course, only permit of the mention here of a few, which we shall select as typical. To complete the task of collecting the information (much of which is probably in existence, though unpublished), of course, necessitates the co-operation of those whose life is spent in examining the products dealt with, and it is in the hope of obtaining such help that we venture to appear to-day with this very unfinished and incomplete paper.

The scheme under which we are dealing with each article is as follows: first the name of each article, its definition and description, its adulterations, the standard where possible, or where sufficient information does not exist to formulate a standard, its average composition, next references to recent literature, and finally remarks.

In this paper, for the sake of brevity, we have omitted almost all references.

*Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

Tinct. Aconite.

Preparation.—Aconite root in No. 40 powder, 50 Gm. Alcohol 70 per cent. to make one litre (prepared by percolation).

Composition of Genuine Samples.

Sp. Gr. at 15·5.	Total Solids.	Alcohol.	Alkaloid.
0·890 (Barclay)	—	—	·02*
0·893 (Lucas)	1 (M. & P.)	—	—
0·896 (P. and M.)	1·2 (M. & P.)	64·3 per cent. (P. and M.)	—
0·893 (Caines)	—	—	—

Remarks.—On account of the variability of the alkaloid even in the best roots it does not seem possible to suggest a standard, but a single drop placed on end of the tongue should produce the characteristic numbness.

Anethi Fructus (Dill Fruit).

Definition.—"The dried ripe fruit of *Peucedanum graveolens*." B.P.)

Description as in B.P.

Adulterations.—Excess of mineral matter. Exhausted fruits.

Standard.—*Volatile* oil should be about 3 per cent. *Ash* should be about 5 per cent.

Tinct. Arnicæ.

Preparation.—Arnica rhizome in No. 40 powder, 50 Gms. alcohol, 70 per cent. (to make 1 litre).

Composition of Genuine Samples.

Sp. Gr. at 15·5.	Total Solids.	Alcohol.
·894 (Lucas).	·6*.	—
·894 (Barclay).	·46 (M. and P.)	69·0 per cent. (M and P.
·891 (M. and P.).	·92 (M. and P.)	—

Bread.

A porous substance obtained by moistening, kneading, and baking wheat-flour with provision for the mechanical separation of the dough by air or carbonic acid gas.

Adulteration.—Excessive water, foreign starches, alum, or mineral matter.

Standard.—Water not to exceed 45 per cent. Total ash not to exceed 2 per cent. Ash insoluble in acid not to exceed 2 per cent.

Remarks.—Is the separation of the germ legitimate?

Butter.

Definition.—"The fatty substance obtained on churning cream." (Murray.)

Adulterations. — Foreign fats, excess of water, salt, and preservatives.

Standard.—Water not to exceed 16 per cent., salt not to exceed 5 per cent. Fat must be true butter fat, as shown by the Reichert and Valenta tests.

Remarks.—Where both Reichert and Valenta tests concur in showing adulteration, the amount of foreign fat present should be calculated on the basis that true butter, when examined by the Reichert process, gives an acid distillate equal to 24 C.c. of decinormal alkali when 5 Gm. of butter are operated on.

Nothing is gained by multiplying tests or by more elaborate processes, and the above suggestion would secure uniformity of procedure and reporting.

Cantharides.

Definition.—"The dried beetle, *Cantharis vesicatoria*." (B.P.)

Characters.—As in B.P.

Adulterations.—Exhausted insects, mineral matter, beetles of similar appearance.

* Suggested as a standard by Barclay.

† Suggested as standard by Barclay.

Average Composition.—Water should not exceed 5 per cent. Fat, by petroleum ether, about 20 per cent. Total ash should not exceed 8 per cent. Cantharidin (total) should be about 0·5 per cent.

TINCTURE OF CANTHARIDES.

Preparation.—Cantharides in No. 40 powder, 12·5 Gm.; alcohol, 90 per cent., 1 litre (prepared by maceration).

Composition of Genuine Samples.

Sp. Gr. at 15·5.	Total Solids.	Alcohol.
0·834 (Lucas) ..	0·26* ..	—
0·838 (Barclay) ..	— ..	88·5 (P. and M.)
0·835 (P. and M.) ..	0·24 (M. and P.)	—
0·834 (Caines) ..	— ..	—

Adulteration.—Excess of mineral matter.

CAPER TEA.

Standard.—Mineral matter insoluble in dilute acid not to exceed 3 per cent.

CARAWAYS.

Definition,—

Adulteration.—

Standard.—Ash not to exceed 8 per cent. Volatile oil, about — per cent.

CAYENNE PEPPER.

Definition.—"The dried fruit of the *Capsicum minimum*." (B.P.) (This applies only to that employed in medicine.)

Adulteration.—The addition of starchy matters, mineral matters.

Standard.—Ash not to exceed 6 per cent.† B.P. Resin should be not less than 15. per cent. Water should not exceed 10 per cent.

CHEESE.

Definition.—A solid substance prepared by curdling milk and pressing the curd after draining off the whey.

Adulteration.—The addition of foreign fat. The use of skim milk. The addition of extraneous matters.

Standard.—Cream cheese should contain not less than 40 per cent. of fat. "Cheese" sold without any qualifying description should contain not less than 30 per cent. of fat. If it contains less than 30 per cent. of fat it should be sold as prepared partly from skimmed milk.

Remarks.—Several American States have fixed standards for fat in cheese.

CLOVES (CARYOPHYLLUM).

Definition and Description.—As in B.P.

Adulteration.—Exhausted cloves and excess of mineral matter.

Standard.—Moisture should not exceed 5 per cent. Extract to ether about — per cent. Ash should not exceed 7 per cent. B.P. "When indented with the nail, cloves should emit oil." B.P.

COCOA.

The roasted and ground seed of the *Theobroma cacao*, with part of the natural fat removed.

Adulterations.—The addition of starch and sugar.

Standard.—Water should not exceed 8 per cent. Ash should not exceed 5 per cent. except in samples prepared with an alkali, when it should not exceed 9 per cent.

CONDENSED MILK.

Adulteration.—The addition of preservatives, deficiency of fat, addition of any substances except sugar.

Standard.—The fat should not be less than 10 per cent., and must be true butter-fat. The nitrogenous matter should not exceed the fat. The ash should be between 2·0 and 2·4 per cent.

Remarks.—There is little actual adulteration of condensed milk in this country, but the misrepresentations on the labels as to the dilution with water are frequent, more particularly in the directions for the feeding of infants.

* Proposed as standard by Barclay.

† We have examined a genuine sample containing a higher ash.

COPPER IN FOODS.

Copper sulphate is used to improve or fix the colour of various preserved green vegetables, such as peas, French beans, gherkins spinach, etc.

The method in which it is employed results in the formation of an insoluble "leguminate" of copper, and the quantity used is so small that it would be probably quite innocuous even if such vegetables were continuously eaten in large quantities.

Copper is frequently a natural constituent of many articles, such as wheat, coffee, cocoa, oysters, etc., and might very probably be contained in peas grown on a soil containing copper, so that we suggest that in those samples, where the copper reckoned as metal does not exceed 1 grain per pound, on the mixed sample, the sample should not be regarded as adulterated.

The question of sampling such preparations is of importance and was discussed at a meeting reported in the *Analyst* for June, 1897.

The estimation of copper in peas is best carried out by completely ashing the sample and dissolving the ash in sulphuric acid, afterward depositing the copper as metal by electrolysis.

FLOUR.

Definition.—The meal produced on grinding wheat, the husk having been removed.

Adulteration.—Foreign starches, excess of water, mineral matter, alum.

Standard.—Water should not exceed 10 per cent. Total ash should not exceed 1 per cent. Alum must be absent. Microscopic appearance must be normal.

GINGER.

Definition.—"The scraped and dried rhizome of the *Zingiber officinale*."

Adulterations.—The addition of exhausted ginger, excess of mineral matter.

Average Composition of Genuine Samples.

Ash	about	5 per cent.
Soluble Ash	„	2 „
Cold water extract	„	10 „

As a provisional standard we suggest that any sample showing less than 2 per cent. of soluble ash, or less than 10 per cent. of matter extracted by cold water, is almost certainly adulterated.

The ash *may* be considerably higher than 5 per cent.

Remarks.—From the B.P. definition, any whitewashing, soaking or other treatment is excluded.

HONEY.

Definition.—"The saccharine substance collected by bees and deposited by them in the honeycomb."

Characters.—The B.P. describes "mel depuratum," but it appears that commercial honey should correspond to the same tests.

Standard.—Sp. Gr. about 1·365 (U.S.P.). Ash not to exceed 0·25 per cent. (B.P.). Water not to exceed 25 per cent. Absence of starch. Sulphates not to exceed traces (B.P.).

Remarks.—The B.P. should include the test with polarimeter.

HUMANISED MILK.

Definition.—"A preparation of cow's milk so adjusted as regards fat, albuminoids, milk and sugar as to closely approximate to the composition of human milk."

It should not vary much from the following composition:—

Fat	3·4 per cent.
Milk—sugar	6·4 „
Albuminoids	1·7 „
Ash	0·2

TINCT. HYOSCYAMI.

Preparation.—Hyoscyamus leaves and flowering tops, in No. 20 powder, 100; alcohol, 45 per cent. to make a litre.

Composition of Genuine Samples.

Sp. gr. at 15·5.	Total Solids.	Alcohol.
0·950 (Lucas).	—	45·5 (P. and M.)
0·953 (Barclay).	—	—
0·955 (P. and M.)	—	—

Barclay suggests ·008 per cent. of alkaloid as a standard.

MACE.

Definition.—The outer coat or arillus of the nutmeg *Myristica fragrans.*

Adulterations.—Bombay mace, exhausted mace, starches and mineral matter.

Standard.—Water should not exceed 10 per cent. Ash, 5 per cent. Ether extract should be about — per cent. Starch must be absent.

MALT EXTRACT.

"A honey-like substance, prepared by concentrating an aqueous extract of malt at a temperature not exceeding 130° F.

Adulterations.—Deficiency in diastatic power, excess of water, etc.

Standard.—Acidity, as lactic acid, should not exceed 1 per cent Water should not exceed 25 per cent. Diastatic power, the sample must be capable of converting its own weight of starch in ten minutes. Preservatives should be absent,

PIMENTO (ALL-SPICE).

Definition.—"The dried full-grown unripe fruit of *Pimenta officinalis.*" (B.P.)

Adulterations.—Oxide of iron, mineral matter.

Standard.—Water should not exceed 10 per cent. Ash 6 per cent. Ether extract, about — per cent. Microscopic appearance normal.

PRESERVATIVES.

The question as to the propriety of adding "preservatives" to foods is one that has recently excited much attention and is still a source of frequent contention.

The question appears to us to have a different bearing according to the kind of article in question, and we consider that in some articles they should be permitted (with disclosures of their presence), and that in certain other articles they should not be permitted at all.

In the following articles they should be absolutely prohibited:—Infants' foods, condensed milk, wines, tinned meat, fresh fruit.

In the following they might be allowed in certain stated proportions:—Milk, butter, cream, potted meat, lime juice and fruit syrups, beer, and other beverages.

TINCT. RHEI CO.

Composition altered in '98 B.P.

Composition of genuine samples:—

Sp. Gr. at 15·5.	Total Solids.	Alcohol.
0·971 (Lucas)	—	—
0·970 (Barclay)	16·7 (Caines)	51·9 (P. and M.)
0·972 (P. and M.)	—	50·8 (M. and P.)
0·974 (Caines)	—	—
0·971 (M. and P.)	—	—

SAFFRON.

Definition.—"The dried stigmas and tops of the styles of *Crocus sativa*" B.P.

Adulterations.—Barium sulphate, gum, oil safflower, dyed marigold leaves.

Standards.—As in B.P., with addition, that if 1 Gr. is extracted in the cold with 60 per cent. alcohol and the extract dried it should weigh about 0·06 Gm.

WINE VINEGAR.

Adulteration.—The substitution of acetic acid prepared from other sources.

Standard.—Acetic acid about 6 per cent. Total solids about 1 per cent. Ash about 0·25 per cent.

DETERMINATION OF CORRECT MELTING POINTS.*

BY THOMAS TYRER AND ALBERT LEVY.

The difference found in the melting point of various pharmaceutical compounds as compared with those given by the Pharmacopœia has suggested a series of determinations of melting points by various methods. A reference to the work of Arnold Reissert, *Ber.*, **23**, 2 (1890), p. 2239, and to that of Landolt, *Z. physik.* Ch. 4, 352, will show the necessity of extreme caution and care in this work.

The above-mentioned show how different results are obtained amounting to several tenths of a degree by using capillary tubes of different bore, and also the need of using exact thermometers and for correcting the same frequently. Besides these points they show the corrections for exposed portions of a mercurial column must be made, and for this purpose Reissert recommends Rimbach tables, *Ber.*, **22** (1889), p. 3075. (See tables.) The first published formula for this correction was given by Kopp, *Ann. Chem. Pharm.*, 94, p. 262, and is that the correction $= \alpha N (t-t')$, where α stands for the apparent co-efficient of expansion, that is the difference between the co-efficient of expansion of quicksilver and of glass, and then stands for the number of degrees of the exposed mercury column; t stands for the observed melting point, and t' the mean temperature of the exposed column.

In the *Handwirtebuch d. Chem.*, **7**, 368, and *Journal of the Chem. Soc.*, **37**, 160, the correction is made, using, instead of the true value of alpha, which is 0·000154, the factors $\alpha = 0{\cdot}000135$, or 0·000143.

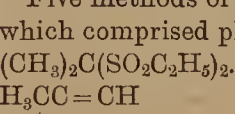
Landolt in the above reference uses this latter value, which is also adopted by the P.B.

The table of corrections according to this formula is given to serve, as Rimbach's, as a means of obtaining the correction at a glance. There is also a table given in the *Chemiker Kalender*, by Dr. R. Riedermann calculated from the formula correction $= t + (t - t')\ N\ 0{\cdot}000154$.

In our experiments, Centigrade thermometers were used, graduated from −0·5 to +360° in single degrees, which were compared with two standard thermometers, one graduated from minus 10 degrees to plus 50 in tenths of a degree, and the other from minus 10 degrees to 100 in fifths of a degree.

An additional thermometer was used to take the average temperature of the exposed column.

Five methods of determination have been used for each substance, which comprised phenacetin, $C_2H_5O{\cdot}C_6H_4{\cdot}NHCOCH_3$. Sulphonal, $(CH_3)_2C(SO_2C_2H_5)_2$. Acetanilid, $CH_3{\cdot}CO{\cdot}NH{\cdot}C_6H_5$. Phenazone,



(1) The B.P. method. (B.P., 1898, page 436.)

(2) Method described by Graebe (*Ber.*, 228-320) in which the substance is placed in a capillary tube attached as usual to thermometer, inserted in a test tube containing sulphuric acid, which test-tube in turn is warmed by sulphuric acid heated in a small flask.

(3) Landolt's method (*Z. physik.*, p. 353) also recommended by Reissert. The substance being placed in a test-tube of 30 millimetres bore, and 175 millemetres length. This tube is surrounded by one of 40 millimetres diameter, the whole being surrounded by a cylinder open at both ends and heated by a Bunsen burner so as to practically compose an air bath. The inner tube is closed with a cork through which a thermometer and glass stirrer pass. For protecting the outer glass from the direct flame a small disc of asbestos covered with wire is advantageous. Accurate results are obtained by this method, if the temperature is taken at the beginning and completion of melting, and at the re-solidification point of the substance. The only objection to this method is the comparatively large amount of substance required.

* Read before the British Pharmaceutical Conference, at Plymouth, July, 1899

(4) Piccard's method (*Ber.*, **8** (1875), p. 687), in which the substance is heated in a capillary tube on the end of which is blown a bulb at an acute angle and attached to thermometer in the usual way. On heating, the air in the bulb expands and forces the substance up the capillary at the moment of melting, so that this point is easily seen. This method tends to give high results.

(5) Loewe's method (*Z. analyt.*, ch. 11, 211) and Chrystomane's (*Ber.*, **23**, 1093), slightly modified where a very small quantity of the substance to bo tested, prevents contact between the platinum wire and mercury. The mercury is heated, causing the substance to melt, which allows the platinum wire more contact with the mercury, completing a circuit in which is included an electric bell which thus rings at the moment of melting. This method gives rather high results, as the substance must be entirely liquid before contact can be made.

Regarding the B.P. method, somewhat high results are obtained, as when the substance is melted the second time, this is almost invariably observed. Graebe and Landolt's methods agrec fairly well. A remarkable difference was found when comparing the melting points of the commercial article, the same dried, and the same purified until two consecutive crystallisations showed the same melting point. Rimbach states, *Ber.*, **22** (1889), p. 3,075, that the corrections of Kopp, Holtzmann, and Thorpe give too low results if the exposed columns are long, and too high results if they are short. In fact, the difference of Thorpe (B.P.) and Holtzmann are more than 1 degree Centigrade (see curves of acetanilid and phenazone, which also show that different values of alpha produce a marked difference). Again, it cannot be too strongly insisted on that the precautions advisad by Reissert should be strictly followed out. The diffcrence between the B.P. and other methods is due to the fact that in the first the melting point of the substance is taken on its being melted for the second time as above noted.

In any of these determinations a fact often overlooked is that the thickness of the capillary tubes walls should be as near as possible the same as the thickness of the walls of the thermometer bulb.

At some future time we propose to show some discrepancies in the Pharmacopœia boiling points which are even more marked than in the melting points.

It becomes necessary to add that some experience in manipulation and chemical physics is essential to correct results, such as the standardising of thermometers, the construction of suitable apparatus and the condition of the substances made by examination. We fear the training of many pharmacists is scarcely covered in these particulars by the course of education provided. We point out, too, how certain physical conditions are improved in the Pharmacopœia, such as melting and boiling points—the data for testing which are in some cases inconsistent. Further, no margin appears to be allowed for the normal conditions of business. For instance, as in the case of acetanilid the normal condition of the atmosphere considerably affects the melting point, as shown by the diagram. These determinations were conducted in the laboratories of Messrs. Thomas Tyrer and Co., Limited.

LABORATORY NOTES.*

BY F. C. J. BIRD.

Liquor Ferri Perchloridi Fortis, B.P.—Most commercial samples of this liquor will be found to answer to the official test of official gravity (about 1·42). Manufacturers generally have therefore relied on the specific gravity as indicating agreement with the Pharmacopœial standard of strength in ferric chloride, but, as has recently been shown, the official figures are not concordant, a liquor made strictly by the B.P. process being only capable of yielding a maximum of 1·43 Gm. of F_2O_3 per 5 C.c., instead of the 1·6 Gm. required. That 166 indicates the proportion of iron salt desired by the compilers may be inferred from the statement in an earlier paragraph of the formula, that "100 C.c. contain 22·5 Gm. of iron;" one-twentieth part accordingly is represented by 1·6 Gm. of ferric oxide. The following table gives in parallel columns the calculated quantities of material contrasted with the amounts actually ordered in the Pharmacopœia, and it is suggested that when making this preparation the figures in the last column should be substituted for the corresponding official quantities in order to produce a liquor which will yield on analysis 1·6 Gm., Fe_2O_3 per 5 C.c.

The point at which evaporation may be considered to have proceeded far enough for the complete removal of nitrous compounds is usually marked by the appearance of a pellicle on the surface of the liquid rather than by a precipitate commencing to form as described in the B.P., and as the extent to which evaporation is carried may vary under different conditions, more or less free hydrochloric acid remaining in the solution, the advisability of stating an approximate specific gravity (*e.g.*, *about* 1·42) becomes apparent.

* Read before the British Pharmaceutical Conference at Plymouth, July, 1899.

A sample of liquor ferri perchlor. fort. made exactly according to the directions of the Pharmacopœia, but using the metric quantities suggested in the fourth column of the table, had a specific gravity of 1·488 at 15·5 C., and on analysis yielded 1·604 gm. ferric oxide per 5 C.c.

Detannated Wine. — The use of detannated wine for the dilution of "miscible" extracts of alkaloidal drugs is almost a necessity on account of the slight, but oftentimes annoying, precipitation caused by the astringent matter usually present in ordinary wine.

The process given in the B.P.C. for the preparation of detannated wine is as follows:—Sherry (or orange) wine, one gallon; gelatin, cut small, ½oz. Macerate together for fourteen days and decant. The product of this formula is perfectly satisfactory, but the time during which the ingredients are directed to be macerated together, is inconveniently long and here, at least, there is room for improvment in the formula. Gelatin when immersed in a weak alcoholic liquid such as wine, absorbs water and swells considerably. Any astringent bodies which the wine may contain gradually combine with the moist gelatin forming an insoluble compound which to a certain extent is probably deposited on the surface of the gelatin thus retarding further action. For this reason it may be inferred that the rate at which the tannin is withdrawn from solution is largely dependent on the surface exposed by the gelatin and it appeared likely that by submitting a larger surface (such as would be offered by gelatin in fine powder) to the action of the liquid the rapidity of combination might be increased and the time of maceration consequently shortened. On trial this supposition proved correct, and it was found possible by substituting gelatine in No. 100 powder (now obtainable in commerce) for the gelatin cut small of the B.P.C. formula, to completely detannate an average sample of sherry in twenty-four hours with the aid of occasional shaking, or in eight hours if frequently agitated. The same wine treated with sheet gelatin cut small, in similar proportion, required days for the completion of the process. Care must be taken to keep the temperature of maceration at or below 15·5° C., or during extremely hot weather the gelatin will probably pass into solution.

A sherry wine such as is ordinarily used for pharmaceutical purposes, on treatment with perchloride of iron solution strikes a dead brownish-green colour, followed by a greenish opalescence, and, on standing, a dark coloured precipitate falls. After detan-

nation a brownish-green tint is still produced, but it is much lighter and there is no opalescence.

Contrary to what is generally supposed, a portion of the gelatin (in hot weather at all events) dissolves in the wine, as is evidenced by the increased precipitation on the addition of three volumes of absolute alcohol to one of the wine after it has been detannated.

Lead acetate, although an excellent precipitant of tannic acid, is not reliable as a test for the absence of astringent matter in wine. Other bodies present affect it, and render its indications uncertain. The coloration, etc., produced by iron perchloride has been already alluded to 5C.c. of detannated wine should be diluted by 5C.c. of water and three drops of the B.P. solution of iron perchloride added. Not more than a faint greenish-brown tint is obtained in a wine free from tannin; imperfectly detannated wine becomes opalescent on standing.

A solution of quinine hydrochloride (8 gr. to the fl. oz.) forms the most serviceable test for this preparation. One volume added to two volumes of detannated wine should not show the slightest turbidity even after standing several hours, but the mixture should remain permanently bright.

DENTAL NOTES.

When Backing Teeth, some dentists take hold of the pins too near the backing, thus laying too much strain on the porcelain. If in bending the pins they took hold of them nearer the ends, they would have less cracked porcelain.—*Items.*

To Clean an Oil Stone.—Smear a flat block of wood with glycerine and fine pumice, and rub the stone, face down, till all traces of previous usage have disappeared. This will greatly improve the working qualities of the stone. To ruin an oil stone clean it with kerosene.—*Brit. Jour. Dent. Science.*

Duplicates of Dentures.—To make an exact duplicate of a full denture in the absence of the patient, first cleanse thoroughly, then cast the mould upon the palatal portion of the plate, not necessarily extending posterior to the condyles. In order to duplicate the "fulness" of the lateral portions and the mould and size of the teeth, cast two sections of plaster, extending from condyle to median line, and from median line to opposite condyle, and from base of the model to the cutting edge of teeth. When plaster comes in contact with plaster, use separating fluid. In order to duplicate the exact thickness of the denture, cast the lingual portion, extending from condyle to condyle, and covering the lingual surface, to the edge of the cast, labial sections extending thus over the cutting edges of the teeth. With these four parts set and removed, the teeth may be selected to fit the labial models, proper shade, and ground exactly to fit; then set up and waxed upon the model—the labial moulds being in position relative to the model—the thickness of the wax determined by the lingual cast in its proper relative position. When vulvanised and finished, an exact duplicate should result.—*Cosmos.*

Local Anæsthesia with Orthoform.—Dissolve orthoform chloride in 40 times its weight of water, warm slightly, and add an equal weight of neutral orthoform. This meets all the requirements for a local anæsthetic. The anæsthesia lasts longer than with cocaine, there are no bad after effects such as swelling or sloughing, the solutions are non-toxic, and several injections can be made at one sitting. There is very little hæmorrhage, and the wounds heal quickly.—*Ohio Dent. Jour.*

To Remove Plaster from Vulcanite use strong cider vinegar. Rub the surface of vulcanite coated with plaster, and all traces will be removed.—*Brit. Dent. Jour.*

The Use of Asbestos Fibre for packing the bed of vulcaniser is much easier and more lasting than using lead. It makes it perfectly steam tight, and will last for years.

EXTRACTS FROM CONSULAR REPORTS.

Experiments in Tobacco Cultivation are being made, according to a recent report, in Venezuela, where it is considered by some that the soil is adapted for producing tobacco equal to that grown in Cuba. Tobacco has always been grown in Venezuela, but on a small scale, and it is now suggested that it should be made a staple product, and by a judicious selection of soil and the planting thereof with good seed under the direction of experienced hands it is expected that good results will be obtained. So far, the results of the experiments have been fairly encouraging. One gentleman, who is experimenting on a large scale, was not very successful last year, but this year the plants are said to look extremely healthy, and the Cubans imported to work the field state that the leaves are just as good as in Cuba. Some months must, however, elapse before the final result is known, and even if it is good, it is probable that the experiments will not pay on account of the great cost of labour, every leaf requiring careful attention in the removal of insects. Another obstacle against the cultivation of tobacco in Venezuela appears to be the fact that only Havana seed can be used to produce good tobacco, and this seed has to be yearly renewed otherwise it degenerates, a fact which, as Her Majesty's Minister at Caracas remarks, is rather curious with tobacco, an indigenous plant.

A Vast and Inexhaustible Supply of Wealth is reported to be practically untouched in the Venezuelan deposits of asphalt, which are said to be almost unlimited, and in some respects of better quality than those of Trinidad. The asphalt lakes of Venezuela apparently form part of the same system in which is included the famous pitch lake in the neighbouring Island of Trinidad, a source of revenue to the Colonial Government last year of £33,998, while the total value of asphalt exported from Trinidad was £113,817. In the case of the Venezuelan deposits there seems to be, at all events with regard to one or two of the lakes, every facility for working and transport as they lie close to the sea. It is reported, however, that an American company has been in negotiation for working the lake of "Guanoco" in the State of Bermudez, and has begun operations there recently having already sent one or two shiploads of asphalt to the United States.

The British Drug Trade with Venezuela does not compete with the German, probably owing to the fact that while there are numbers of German commercial travellers, there are no British. This, Mr. W. H. D. Haggard thinks, is to be regretted, as an immense amount of medicine is dispensed, and the chemists' shops are said to be out of all the usual proportions to the number of the inhabitants. It is thought that British patent medicines would have a ready sale.

The Balata Rubber Industry in the Republic of Venezuela has increased in importance during 1898, over 500 tons being exported from Ciudad Bolivar. This rubber is extracted from the bullet-wood tree, of which vast forests exist in the country south of the Orinoco, but as Vice-Consul de Lemos points out, the system followed for obtaining this rubber is likely to make its collection more and more difficult. Instead of tapping the bark, which would admit of an annual crop, the trees are cut down to facilitate the extraction of the juice. The consequence is that the workers have to move on as the forests become exhausted, and they are even now in some places working at considerable distances from the centres, and it is to be feared that this waste will within an appreciable time exhaust the supply.

The Same Remark also applies to the destruction of birds for the supply of aigrettes for ladies hats, and although this matter has no direct bearing on pharmacy, the figures quoted by Mr. de Lemos may perhaps interest the lady members of the pharmacist's household. The Vice-Consul at Ciudad Bolivar states that the quantity of egret feathers exported during 1898 reached the high total of 2,839 kilos.; that 870 birds have to be killed to produce 1 kilo. of the smaller feathers, and about 215 for 1 kilo. of the larger. If therefore the average is taken, the number of birds killed last year, in one country only, was 1,538,738, but if the highest number is taken it was 2,469,930, while even the lowest accounts for the slaughter of 610,385. This, Her Majesty's Minister at Caracas exclaims, is really appalling.

NEW REMEDIES.

Sodium Meta-vanadate in Medicine.—Sodium meta-vanadate, acting as a powerful oxidising agent, although toxic in large doses, is a powerful stimulant to the organs of nutrition, when given in minute quantities. It may be administered without inconvenience or danger in doses of 1 to 5 milligrammes in 24 hours. It is better to allow an interval of two or three days after each week of treatment; it should be taken before meals. The administration is rapidly followed by an improvement of the appetite, with increased strength and weight. In tonic properties it appears superior to salts of arsenic.—*Nouv. Rem.*, **15**, 241.

Dormiol, Amylenechloral.—The name dormiol has been applied by Fuchs to a compound of chloral hydrate and amylene hydrate which is stated to be an efficient hypnotic. It is an oily, colourless liquid, with a camphoraceous odour; sparingly soluble in water, but readily dissolved by alcohol, the fatty acids, and ether. The dose is 50 centigrammes to 1 Gm.—*Rev. Med. Pharm.*, **6**, 164.

Methyl Salicylate for Pruritus.—Leredde finds that methyl salicylate is one of the best and most universally effeotive remedies for allaying itching in various skin diseases. It is best applied in the form of a thick ointment combined with zinc oxide such as the following:—Zinc oxide, vaseline, of each 30; methyl salicylate, 1; the salicylate does not occasion cutaneous irritation.—*Bullet. Comm.*, **27**, 230.

Ipecacuanha in Chronic Constipation.—R. Blondel finds that ipecacuanha gives excellent results in the treatment of chronic constipation, particularly in the case of women, who are notoriously liable to this functional disorder. In order to avoid the feeling of nausea which frequently attends the administration of the drug in the usual way, the author employs a rectal injection of 0·4 to 0·8 Gm. of the official (Codex) extract in 150 Gm. of water. The extract is prescribed as a 1:5 aqueous solution, a teaspoonful of which is directed to be used in 150 Gm. of water, as an enema, which should be retained for half an hour. The action takes place some hours afterwards, and is not attended by any feeling of nausea or pain.—*Bull. gen de Therap.*, **137**, 725.

Aspirin.—This substance introduced as a remedy in articular rheumatism, having the formula $C_6H_4 < \begin{matrix} COOH \\ OCOCH_3 \end{matrix}$ is obtained by the action of acetic anhydride on salicylic acid. It occurs in minute white crystalline needles, which melt at 135 C. It is sparingly soluble in tepid water, but readily so in ether and alcohol. The gastric secretion is without action upon it, but it is decomposed by the pancreatic secretion liberating salicylic acid. It is given in doses of one gramme three times daily in the form of powders.

Galloformin.—This product, $C_6H_2(OH)_3COOH(CH_2)_6N$, is a condensation product of hexamethylene tetramine and gallic acid. It occurs in needles which are slightly soluble in ether, alcohol, and water. It is employed both internally and externally, as it readily liberates formaldehyde.—*Rev. Med. Pharm.*, **6**, 69, *after Rev. de Flandres.*

Ovarian Extract as a Remedial Agent.—From a review of the modern literature of the therapeutic employment of ovarian extract, W. A. Newman-Dorland concludes that the ovaries, in common with the other glandular organs in the body, exert an occult, but very positive influence upon the general organism. When this influence is removed, either by the natural atrophy of the glands at the climacteric, or by the destruction of the ovarian stroma by pathological processes, or by extirpation of the organs, there results a series of distressing phenomena, hot and cold spells, nervous and mental derangements, and neuralgic attacks. The administration of ovarian extract, or of the ovarian substance, is promptly and very generally followed by a marked amelioration of these symptoms. The average dose required varies from 2 to 5 grains of the extract thrice daily. Excessive doses are followed by cardiac or nervous disturbances. In some cases, a tolerance to the remedy appears to be developed, lessening the intensity of its effects. It is better, therefore, to commence the treatment with small doses, gradually increasing the amount administered according to the requirements of the case.—*Therap. Gaz.*, **23**, 225.

Sodium Cacodylate.—As a means of administering arsenic, J. Rénaut strongly recommends sodium cacodylate, especially in cases of phthisis; the tonic effects are very marked, but no gastric irritation is caused by doses as high as 2 to 4 grains in 24 hours, and even a gramme of the salt may be taken without harm. In pulmonary phthisis, however, he prefers to administer the drug in the form of rectal injections or hypodermically, the dose for the latter being from ½ to 1 grain in 24 hours, given for 8 days, then a rest for a week, when the injection should be resumed. The salt affords also the most suitable means of administering arsenic by rectal injections, since it is absolutely without irritant action on the mucous membrane of the bowel; the results, too, are more constantly satisfactory than with the dilute Fowler's solution hitherto employed in this way. For this purpose a solution of 25 centigrammes in 200 grammes of water, the dose for rectal injection being 5 C.c. of this solution.—*L'Union Pharm.*, **40**, 252.

Chinosol in Leprosy.—From results obtained in the Leper Hospital in Java, Müller concludes that chinosol is a valuable remedial agent in the treatment of leprosy. Not only have good results followed the local application of the remedy, but internal doses of 15 grains per diem have given immediate beneficial results.—*Therapist*, **9**, 156.

Credé's Silver Salts, Itrol, and Actol, and Soluble Silver.—For fistulas, deep wounds, and for endometritis Credé uses itrol in sticks, composed of itrol 2·5, white wax 1·0, cacao butter 9·0. Melt and divide into thirty sticks of 2·4 Cm. in length and 0·4 Gm. in weight. In fetid middle ear discharges, itrol introduced in the form of pills produces surprisingly quick healing. Itrol 1·5, bol. alb. 4·5. Mass and divide into thirty pills (0·05 itrol in each). The stains produced by these salts on the linen may be removed by successive treatment with the following solutions:—(1) The articles to be cleaned are placed for five minutes in a sublimate salt solution and rinsed two or three times in pure water. (2) A solution of ammonium chloride is prepared 1:5, and iodine tincture is added to it until it is coloured yellow to brown. This solution is allowed to act for five minutes on the stains. Subsequently 300 C.c. water and a few crystals of sodium sulphite, or thiosulphate, and a little solution of ammonia are added, the cloth being rubbed in it. If the stains have not disappeared the process is repeated. (3) The cloth is moistened with eau de Javelle after five minutes' washing in water containing 5·0 hydrochloric acid to each litre. Rinse until the stains disappear.—*Therap. Monatsh.* **13**, 162.

Alcornoco Bark.—Hartwich recommends alcornoco bark as a substitute for jaborandi leaves, which are seldom obtainable of good quality. The bark is much more active, and is identified as being derived from *Browdichia virgilioides*, Kunth., a member of the Cæsalpiniæ.—*Oest. Zeit. für Pharm.*, **53**, 115, after *Apoth. Ztg.*

Oxaphor.—This name is given to a 50 per cent. solution of oxycamphor in alcohol. Oxycamphor was formerly recommended as a remedy for dyspnœa, and is now introduced by Rumpel for respiratory troubles produced by organic heart complaints, constipation, emphysema, bronchitis, and consumption. It is given in a single dose, 0.5 to 1.0 Gm., or 1.5 to 2.0 Gms. in twenty-four hours.—*Oest. Zeit. für Pharm.*, **53**, 115.

Benzozol in Chronic Pulmonary Tuberculosis.—In cases of phthisis which were complicated by gastro-intestinal lesions, J. L. Salinger has obtained good results with benzozol. This body, which is a compound of benzoyl and guaiacol, is not affected by acid solutions, but is decomposed in the alkaline secretions of the intestines. The exhaustive diarrhœa of phthisis was usually promptly relieved by its use, in 5 or 10-gr. doses, in the form of a powder or compressed pill, given three times a day.—*Therap. Gaz.*, **23**, 150.

Lactic Acid in Ringworm.—Balzer finds that lactic acid gives good results in many cases of ringworm of the scalp. The parts are first thoroughly washed with a mixture of alcohol and ether; and then rubbed twice a day with a solution of syrupy lactic acid, 1 fl. pt., in alcohol, 2 fl. pts. The rubbing is continued until redness is obtained; the pain occasioned by the application is not very sharp, and subsides in a quarter of an hour. To complete the treatment, the patient is directed to wash the parts with a 1-2000 solution of mercuric chloride.—*Med. Press*, **87**, 432.

SELECTED PRACTICAL FORMULÆ.

IMPROVED COPPER DRESSING FOR PHYLLOXERA.

It is well known that the effect of the various forms of copper dressings applied as remedies for phylloxera is more or less transient, owing to the non-adhesive properties of the mixture, to their instability, or to separation of the active constituents. E. Crouzel proposes to overcome these defects by the employment of milk as an ingredient in the wash, thus—2 kilos. of cupric sulphate are dissolved in 10 litres of water, 4 litres of milk are then added with vigorous stirring for five minutes. The emulsion thus formed is then diluted to 100 litres with more water. The dressing thus made adheres well to the plants; the finely suspended copper caseinate does not choke the pipes of the spraying apparatus used to distribute it, and it keeps well.—*Repertoire* [3], **11**, 241.

CREAM FOR SEA-SIDE SHOES.

(1) Melt yellow wax, 300, on the water bath, and add oil of turpentine, 1,000. Resin soap, 120, are dissolved separately in water, 1,000, and the mixture stirred in with the wax and turps; when cold, a frothy paste results, which is coloured with a solution of Nankin brown, 15, in alcohol, 75. (2) For renovating brown boots a cream is prepared in yellow vaseline, 1,000; olive oil, 70; ceresin, 500; leather yellow, 1. The last ingredient is added as a colouring matter to the hot mixture.—*Pharm. Zeit.*, **44**, 349, after *Seifenfabrikant.*

HINTS FOR MAKING TABLETS AND PASTILLES.

E. Witzenberg finds that sodium chlorate, potassium permanganate, potassium chlorate, antipyrine, sodium bromide, and sodium bicarbonate may be formed into tablets without the addition of any binding material. These bodies are placed into a tablet machine in a crystalline condition and compressed simply by pressure. Antifebrine, phenacetine, sulphonal, and quinine salts are first mixed with a little sugar and compressed without moisture, the machine having been previously dusted over with French chalk. The mixture of cream of tartar and sulphur may be treated in the same way. Dry extracts are compressed in a roughly-powdered condition without employing French chalk or oil. Effervescing powders and similar mixtures must be quite dry, they are compressed with very little French chalk. *Camphor Tablets* of camphor, 5 centigrammes; sugar 50 centigrammes; peppermint oil, ½ a drop; are prepared by powdering the camphor finely by the aid of a little ether, then mixing the sugar and oil and compressing without other aid. A mixture of camphor and sugar alone may be compressed into tablets, the latter coated with chocolate, when cold again compressed, the mould being rubbed over with a little oil. The tablets should then be coated with a little gelatin or collodion. *Phosphorus Tablets:* These are composed of phosphorus, 1 milligram. cocoa paste and cocoa butter aa q.s.; cinnamon oil, ½ a drop. A little cocoa butter is melted, the weighed dry phosphorus introduced into the warm oil, the solution shaken, and the concentrated phosphorus oil thus obtained is allowed to congeal. Equal parts of this oil are mixed with sugar and cocoa freed from oil. Cinnamon oil is added and the mixture rolled out on the pill machine into pills, which are then compressed into tablets. *Santonin Tablets* of chocolate are prepared by adding the santonin to a melted mixture of cocoa and sugar. The mass is left to congeal and pressed out. *Mouth Tablets* for cosmetic purposes may be prepared thus: Anise oil, 4 drops; cinnamon oil, 1 drop; lemon oil, 5 drops; cherry laurel oil, 1 drop; tincture of musk, 10 drops; clove oil, 4 drops; peppermint oil, 5 drops; gum arabic, 5 Gm.; powdered sugar, 25 Gm. The substances are mixed and compressed out into tablets without the addition of any other ingredients. *Mouth Water Tablets*: Compress heliotropine, 1 centigamme; saccharine, 1 centigramme; salicylic acid, 10 centigrammes; menthol, 1 Gm.; milk sugar, 5 Gms.; spirit of rose, q.s. *Sublimate Pastilles*: Mercuric chloride, sodium chloride, aa 100 Gm.; distilled water, 14; eosin q.s.; divide into 100 tablets. (Label poison.) If the tablet press is used the water is not necessary. *Tamarind Pastilles:* Tamarinds, 350 Gms., are boiled to a paste with water 700, and pulped. The pulp is evaporated to 175, and sugar, 225, added. The mixture is rolled out and cut into 120 oval pieces of equal weight. The pastilles are fastened on a needle, dipped into fluid chocolate and dusted over with crystals of sugar. *Castor Oil Pastilles:* Castor oil, 3; almond meal freed from oil, 4; lemon oil, 1. The oil is mixed with the almond meal, the lemon oil added and the mass formed into pastilles which are coated with chocolate.—*Pharm. Ztg.*, **43**, 917, after *Nederl. Weekbl. v. Pharm.*

ADHERENT COPPER DRESSING FOR GRAPE VINES.

In order to render the copper insecticides applied to vines more adherent, and, therefore, more efficacious, J. Perraud advocates the use of resin soap; he has devised the following formula to replace the "bouillie Bordelaise" or "bouillie Bourguignonne" used for the purpose. Water, 100 litres; copper sulphate, 2 kilos; resin, 500 Gms., washing soda sufficient to make a slightly alkaline mixture. The resin should be dissolved in a hot solution of the soda and the mixture added to the sulphate of copper, previously dissolved.—*Repertoire* (3), **11**, 214.

FLUID GLYCERIN SOAP.

(1) Olein, 100 parts, are heated on the water-bath, glycerin, 300 parts, are stirred in, and the mixture heated to about 62.5° C.; of 38 per cent. potash solution, sp. g. 1.36,52 parts, previously diluted with 1 part of distilled water, are added, when the soap commences to form. The thick mass is set aside to cool, 6 parts pearlashes dissolved in hot water, 10 parts, are then added, and the mixture is set aside for three days, well covered up. It is finally poured into a bottle and 20 parts perfume, dissolved in 30 parts 96 per cent. alcohol, are added; the whole well shaken and set aside for several days and filtered. (2) 2 parts of transparent soft soap, prepared without resin, are dissolved in 1 part water and 1 part alcohol; the solution is filtered, mixed with 1½ parts glycerin, and perfumed. (3) 1 part of soft soap prepared from saponified oleiu is dissolved in 1 part glycerin and 6.8 per cent. of alcohol is added. (4) Fine Provence oil, 9 parts; cocoanut oil, 4½ parts; caustic potash solution (sp. g. 1.38), 7 parts; diluted with water, 3 parts, and alcohol (90 per cent.), 1 part. After standing for a day the soap is dissolved on the water bath in glycerin, 20 parts, perfumed with equal parts of geranium oil, citronella, and lavender oil, dissolved in alcohol.—*Pharm. Ztg.*, **44**, 135, after *Seifen Fabrikant.*

ANTACID POWDERS.

Lyon prescribes the following powders for hyperacidity:—(1) Sodium bicarbonate, 6 grs.; prepared chalk, 2 grs. One such powder to be taken three times a day. (2) Sodium bicarbonate, 15 grs.; prepared chalk, calcined magnesia, of each 2 grs. (3) Sodium bicarbonate, 6 grs.; borax, 2 grs.; sodium salicylate, 3 grs. To be taken before breakfast and also after that meal in a small glass of seltzer water to stop fermentation and to relieve flatulence and pain. Einhorn prescribes calcined magnesia, 2 drachms, powdered rhubarb, 2 drachms; sodium carbonate, sodium bicarbonate, powdered sugar, of each half an oz. Oil of peppermint enough to flavour. A saltspoonful of this to be taken in Vichy water two hours after each meal. Rosenheim employs calcined magnesia, 90 grs., sodium bicarbonate, powdered rhubarb, of each 1 drachm; extract of belladonna, 2 grs. A saltspoonful to be taken three times a day in half a tumblerful of water.—*Therap. Gazette*, **23**, 231.

LETTERS TO THE EDITOR.

NOTICE TO CORRESPONDENTS.—All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received, if specially arranged for, as late as Thursday morning. Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 5, Serle Street, Lincoln's Inn, London, W.C., and Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

A Pessary Mould.

Sir,—The preparation of a dozen or so of one or two drachm theobroma pessaries is not perhaps an everyday task in country pharmacies; therefore a hint on the selection of a convenient mould may not be thrown away. The little earthenware medicine measures known as Proctor's may be used to obtain a smooth and shapely product, uniform in size and correct in weight. Fill them with glycerin—drain it off, and having prepared your mass, pour it into the measures while it is just warm enough to flow. When set, a sharp penknife may be run round the edge, and a sharp tap of the inverted mould on a sheet of paper will release the finished article.

Dover, July 21, 1899. J. F. Brown.

Liquor Ferri Perchlor. Fort., B.P.

Sir,—I have revised my calculations regarding Liquor Ferri Perchlor. Fort., B.P., as desired by Mr. Athey, but fail to see any reason for altering the figures given in my previous letter. The quantity of hydrogen chloride contained in 14½ oz. by weight of acid. hydrochlor., B.P., is ascertained by the following calculation :—

$$\frac{14{\cdot}5 \times 31{\cdot}79}{100}$$

which, with me, works out to 4·609.

Will Mr. Athey kindly explain how he obtains 5·1 oz. as the hydrogen chloride content of 14½ oz. by weight of acid. hydrochlor., B.P. ?

London, July 23, 1899. F. C. J. Bird.

The Sale of Benzene.

Sir,—I have just received the printed instruction from the County Council as mentioned in this week's Journal. It is true the Executive of the Society have gained a concession, but not so great as I expected. In my other letter I alluded to the fact that a great many chemists, especially in London, only keep a pint bottle in stock, in those cases I consider they should be totally exempt from the operations of the Petroleum Acts, as they practically stand in the same position as private individuals who go to the licensed retailers and can purchase any quantity of petroleum without any restrictions as to its after-use. I trust the Society's Executive will see their way to hammer again at the County Council with the idea of obtaining some further concessions.

East Dulwich, July 18, 1899. F. W. Sandy.

*** The London County Council has conceded all that the Statute allows, and further "hammering" would be futile.—[Ed. *P J.*].

The Company Trading Question.

Sir,—There are two facts which you refer to in your able article on pharmaceutical legislation which are of more than passing importance. The first is that chemists are perceiving more and more that it is hopeless to demand prohibitive legislation, and second (by inference), the growing feeling in favour of a regulation scheme. The proposals of the Edinburgh Chemists' Trade Association (*Ph. J.*, June 17), whereby companies would be brought under the direct control of the Pharmaceutical Society; their shops and managers registered; titles restricted to registered persons, and proprietors made responsible for the acts of their unqualified assistants would, in my opinion, form a basis of settlement that would bring about the best obtainable results. Now it may seem strange that we should be prepared to receive into our fold those who have stolen our titles and usurped our functions, but we are bound to recognise that they have carried on the business by means of registered assistants, and, so far as the safety of the public is concerned, have placed themselves on an equal footing with chemists and druggists. The Pharmaceutical Society has hitherto had difficulty in enforcing the Pharmacy Act, and especially in regard to the sale of poisons by unqualified assistants, the unqualified "victims"—who are usually unable to pay—being fined, while the real offenders (the proprietors) have escaped. Just one word in reply to Mr. Gifford. I have been "thinking this matter over again," and have come to the conclusion that there is something wrong either in my reasoning or with Mr. Gifford's. I have offended Mr. Gifford by asking questions and answering them. In Clause 2 of the Council's suggestions no one except registered chemists may sell, dispense, or compound medicines. In Clause 3 the penalty for contravening Clause 2 is £5. Will Mr. Gifford tell me if this means that a grocer would be fined £5 for selling cream of tartar, Epsom salts, castor oil and such-like medicines? Of course Mr. Gifford has condemned the Council's suggestions himself, but says that "efforts can be based upon these suggestions." In what way can we base our efforts upon Clause 2? When Mr. Gifford answers these questions I shall then be able to explain "cap in hand" my reference to the principles of free trade.

Edinburgh, July 24, 1899. W. S. Glass.

"Income-tax Overcharge."

Sir,—The Chancellor of the Exchequer, judging from his recent speech at the Mansion House, does not appear to entertain the opinion that there is any probability of a reduction in the rate of income-tax. The popularity of this tax with successive Chancellors of the Exchequer is readily understood when it is remembered that when it was first imposed, a century since, it produced £7,000,000, and now, although its incidence has been altered by certain exemptions and abatements, it produces the prodigious sum of £18,000,000. Being so easily collected, it is to be feared that taxpayers will never be free of income tax, while there are very many persons who even pay tax twice upon the same income when derived from dividends declared "free of income-tax," they being under the impression that these words mean that such dividends have not been taxed. Of course this is a mistake, as the tax is in such cases charged upon, and deducted from the total profits before they are divided, whereas in the case of dividends not paid "free of income-tax" the profits are first divided and tax deducted from each individual shareholder's dividend. We suggest that the growth of joint-stock companies renders it imperative that in future whenever the tax is deducted from the profits before division, such dividends should be declared as "income-tax paid," instead of "free of income-tax," and we ask directors of companies to take care that the latter misleading phrase does not again appear on their dividend warrants or in their reports. With few exceptions, all persons whose incomes are derived from rents, dividends, annuities, etc., and did not exceed £500 for 1896-7 and 1897-8, or £700 for 1898-9, can now make claim for repayment of tax overpaid in those years. Claims can also be made in respect of diminution of business profits (on furnishing a proper account, which is easily possible by using "The Taxpayers' Cash Book"); losses in farming or business can be set off against income from other sources; partners in a business can claim abatement or exemption if their incomes are within the limits, etc., etc., while a claim can be made by any person in respect of life insurance premiums or contracts for deferred annuities even when the income exceeds £700. All claims should, however, be made with the least possible delay, as the time allowed for making some of them is strictly limited. We shall be glad to advise any of your readers gratuitously whether they can make a claim for repayment of income tax, on their sending us full particulars of their incomes and a stamped addressed envelope.

The Income Tax Adjustment Agency.

12 *and* 13, *Poultry, London, E.C., July* 26, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Botanical (J. S. W.—31/28).—It is a specimen of.

Botanical Druggist (G. F.—31/26).—There is no such qualification, but it is illegal to use the title "druggist," however qualified, unless the person using it is registered under the Pharmacy Act, 1868. Anyone is free to dispense, but only duly registered persons may sell and dispense poisons.

Index (D. and Co.—31/25).—A general index for the last seventeen volumes of the third series of the Journal (to the end of June, 1895) has been in course of preparation for some time past, but failing the promise of a sufficient number of subscriptions to cover the cost of producing it, there is no immediate prospect of it being published. Apply to the Secretary of the Pharmaceutical Society, 17, Bloomsbury Square, W.C., for a copy of the early index you require.

Lactopeptin (J. S., 31/21).—The following has been published as the composition of lactopetin:—Milk sugar, 80; pepsin scales, 16; pancreatin, 12; diastase, 1; lactic acid, 10; hydrochloric acid, 10. Mix, and dry. For filling prescriptions you should obtain the original article, and not substitute a preparation of your own compounding.

Prescription Difficulty (J. T.—30/11).—Most probably the cause of your trouble is combination between the magnesia and some resinous constituents of the cascara. Resins are acid in constitution and combine with magnesia (and lime) to form usually insoluble compounds. Try making up the mixture, leaving out the cascara from the syrup. If our suggestion proves correct, we see no way of avoiding the difficulty except leaving out one or the other of the constituents mentioned.

Dispensing Pills (L. E.—30/25).—We see no difficulty in making the pill mass by the aid of the ordinary plastic excipients. Of course, the pill will be very large, and probably the prescriber does not realise this. We should suggest making the quantity given into two pills.

Makers of Paraffin Wax (T. C. K.—31/27).—Price's Patent Candle Company, Limited, 7, Belmont Works, Battersea, London, S.W.

Mercuric Oleate (T. G. W.—30/32).—There is no doubt that the percentage figure should refer now to the oleate itself, although a certain amount of ambiguity will still remain in the case of prescriptions written before the publication of the present pharmacopœia.

Apomorphine Hydrochloride and Sodium Nitrite (A. B. 28/24).—Apomorphine in aqueous solution alone is anything but stable; you will find the B.P. recommends the official injection to be "recently prepared." The presence of a nitrite would certainly tend to hasten decomposition.

Potassium Chlorate (T.G.W.—30/32).—It does not explode spontaneously. When heated strongly the oxygen is evolved with almost explosive rapidity. The danger with chlorate is chiefly due to proximity to carbonaceous materials. If a small portion of a mixture of such bodies be ignited by flame or the heat generated by friction or percussion, the combustion rapidly spreads throughout the entire mass and the gases so generated are the cause of explosion.

Presence of Oil in Tinct. Nucis. Vom. (C. H. W. 29/9).—Probably the liquid extract of nux vomica you have used is at fault; if it has been prepared with a stronger alcohol than that prescribed by the B.P. it will contain an undue proportion of oil. This will show itself as you describe when you convert it into the tincture. There is no need to extract the nux vomica first with ether if a properly diluted alcohol be used for the preparation of the fluid extract. Such a procedure would unnecessarily increase the cost of the preparation and unduly lengthen the process.

Sol. Cupro-Ammonii (E. W.—29/8).—You do not state for what purpose your solution is to be used. Probably the "aqua cupri ammoniati" of the Dubl. Ph., 1826, is what you require. This is made by dissolving 1 part of ammoniated copper in water 100 parts. It was used chiefly in veterinary practice as a lotion for ulcerated sores. Ammoniated copper is prepared by mixing in a mortar, copper sulphate, 2; ammonium carbonate, 3; triturating until effervescence ceases, drying first between folds of bibulous paper, and then by exposure to the air.

Concentrated Magnesia Mixture (E. B.—28/3).—Try suspending the magnesium carbonate with a little tragacanth, and substitute glycerin for the syrup employed as a sweetening agent.

Strength of Opium (E. J. W.—31/24).—If you refer to the B.P. monograph on opium you will find that any suitable variety of opium may be used for preparing the tincture and extract, provided that when dry it contains not less than 7·5 per cent. of anhydrous morphine. For other purposes, opium, when dried and powdered, should yield from 9·5 to 10·5 per cent. of anhydrous morphine. Since the tincture and extract are directed to be standardised, it is immaterial what the exact strength of the opium is to begin with. With the samples you refer to, you would probably get satisfactory results by mixing them in equal proportions or thereabouts. But in any case you must standardise the official preparations in accordance with the B.P. instructions.

Precipitate in Mixture (E. A. G.—31/2).—We do not get any precipitate in making up your prescription. Nor did we expect any, seeing that quinine hydriodide is sufficiently soluble and that so much free acid is present. On standing for some time probably a little iodine would be set free: in this case a black precipitate of quinine iodo-sulphate or some similar compound would be formed.

"Sugaring" for Attracting Moths (S. T. F.—31/35).—The following has been found to give far better results than any of the mixtures generally sold or recommended for the purpose;—Foot's sugar, 1 lb.; black treacle, 1 lb.; beer, 10 fl. oz. or q.s. Heat together until the sugar has dissolved, then thin down with a little more beer, until, when cold, the product is just workable with a brush. Then add common methylated spirit, 3 fl. oz. or more; essence of pineapple, ½ fl. oz. Several times this summer over 250 noctuæ have been counted at a dozen patches of this "treacle" exposed on a fence in a suburban garden. You may confidently recommend to your entomologist clients essence of pineapple as a lure for moths, as being far more attractive than rum or aniseed when combined with the sugar and beer basis.

Preserving Eggs (J. B.—32/1).—Immerse the eggs in solution of sodium silicate, sp.gr. 1·1, so that they are wholly covered: take them out carefully and dry in a warm place, moving them occasionally to prevent them from sticking.

Elder Wine (D. B.—31/22).—Pour boiling water, 3 gallons, on ripe elder berries, free from stalks, 20 lbs. Let stand for twenty-four hours, then break up the fruit, strain, press, and filter through a bag. To every gallon of juice obtained add white sugar, 3 lbs.; freshly crushed ginger, ½ oz.; cloves, 1 drachm; stoned raisins (not sultanas), 1 lb. Boil the mixture for an hour, skimming thoroughly during the process. Let it cool to 98° F., strain into a clean cask, add two ozs. of yeast for every 9 gallons of liquor; let it ferment for fourteen days, then add brandy, 5 fl.-oz., for every gallon of liquor. Then bung up tight, and let it alone for six months before bottling off.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

SYMBIOTIC SAPROPHYTISM.

Professor D. T. Macdougal regards saprophytism as an adaptation of absorbent mechanism or of the metabolic capacity of an organism. Symbiotic saprophytism is the natural result of the supplemental capacities of two organisms brought into nutritive contact chemotropically. The fungi which form mycorhiza are capable of independent existence, and undergo modifications of the hyphæ and reproductive organs in the portion of the mycele in contact with the protoplasm of the host-plant. The changes in the host-plant are of two kinds—degeneration of normal structure, and the formation of special cells for the accommodation of the fungus. The velamen of roots, as those of Orchideæ, and the trichomes of coralloid structures, are devices which facilitate absorption by endotropic fungi. The acquisition of the habit of symbiotic saprophytism renders a group of plants extremely unstable as to specific characters. The penetration of non-absorbent organs by the fungal symbiont affords opportunity for the utilisation of these organs for absorption in case of a diminished supply of food from the ordinary sources. There are but few constaut anatomical characters indicative of partial or complete saprophytism. Absence of chlorophyll is the only invariable accompaniment of holosaprophytism, while degeneration or alteration of the vascular bundles does not always follow. In the formation of mycorhiza the fungus may be associated with prothallia, roots, or stems.—*Ann. of Botany*, 1899, p. 1.

ORIGIN OF STORAX.

J. Moeller, in his investigation of the origin and development of storax, has determined that this balsam is not produced in the bark, but is formed in the wood; that it is not a physiological secretion, but a pathological product which arises after damage to bark or wood. The first effect of a wound is the development of schizogenous glands which are subsequently converted into lysigenous spaces. These facts were verified both for styrax liquidus from *Liquidambar orientalis*, and for sweet gum from *L. styraciflora*. In both cases the balsam does not exist in normal plants; it was found only after the tree was wounded. Circular cuts were made in a tree of *Liquidambar styraciflora* six metres high. When the branches were not wounded there was no trace of balsam, but where the damage had affected the cambium, rows of balsam glands could be detected with a lens. There seems, therefore, no doubt that storax is a pathological product.—*Centralbl. f. Bakteriologie u. Parasitenkunde*, 2te Abth., **5**, 412.

ACETONE DICARBONIC ACID.

G. Denigès finds that the body which gives the insoluble precipitate with mercuric sulphate in his test for the presence of citrates, in which the citrate is first oxidised with permanganate and then treated with an excess of the mercuric sulphate, is acetone dicarbonic acid—$HO.OC.CH_2.CO.CH_2.CO.OH$. The composition of the mercury compound is $HgSO_4.2HgO.2(C_5H_4O_5.Hg)$.—*Bulletin de la Soc. de Pharm. de Bordeaux*, **39**, 97.

ANTHEROZOIDS IN ANGIOSPERMS.

Professor S. Nawaschin, of Kieff, and M. L. Guignard have made some very remarkable observations on the mode of impregnation in *Lilium Martagon* and in *Fritillaria*, which serve further to bridge over the gulf between the processes in the higher Cryptogams and in Angiosperms. Before entering the embryo-sac the two generative nuclei of the pollen-tube elongate into vermiform bodies, which display indications of one or two spiral coils. Although not provided with cilia, M. Guignard claims for these bodies the term "antherozoid," in order to emphasize their homology with the corresponding bodies in Gymnosperms and the higher Cryptogams; and Professor Nawaschin believes them to be endowed with the power of spontaneous motion. At the period of the entrance of the pollen-tube into the embryo-sac, the union of the two "polar" nuclei to form the secondary vegetative nucleus of the embryo-sac has not been completed. When the two nuclei of the pollen-tube enter the embryo-sac, one of them, usually the posterior one, fuses with the oosphere, while the other unites with one of the two polar nuclei which have not yet completely fused together. This is not regarded by M. Guignard as a process of true sexual impregnation, but rather as one of "pseudo-fecundation." It is the origin of the formation of the endosperm, which has advanced as far as an 8-celled structure before the impregnation of the oosphere by the other pollen-cell nucleus. These observations have been confirmed, in the main, in this country, by Miss Ethel Sargant.—*Bonnier's Rev. Gén de Bot.*, 1899, p. 129: and *Bot. Centralbl.*, **77**, 62. See also *Proceedings of the Royal Soc.*, **65**, 163.

TOXICITY OF HEDERIN.

A. Joanin states that hederin has a markedly toxic action on warm-blooded animals, from 5 to 7 centigrammes for each kilo. of body weight being the lethal dose to rabbits and guinea-pigs for hypodermic injections; and 2 to 3 centigrammes for intravenous injections. On dogs it acts as a powerful emetic and purgative, and is doubtless the cause of the sickness and cathartic effect observed in cases of ivy poisoning. *Comp. rend.*, **128**, 1467.

ALBUMINOIDS AND ALKALOIDAL TOXICITY.

S. Pouchet finds that the juice of the fly agaric contains certain albuminoids, which, although not themselves powerfully toxic, by their action on the intestinal mucous membrane, greatly increase the toxicity of the muscarine contained in the juice. The lethal dose of the juice deprived of these albuminoids is much larger than that in the normal state. The observed symptoms differ: the simultaneous injections of what alone would be non-toxic doses, both of the alkaloid and of the albuminoids, is speedily followed by death. Experiments are being conducted to determine if the observed toxicity of other organic substances, such as curare, may, not in part, be due to the action of some such albuminoids, which alone are of comparatively low toxicity, but which aid the absorption of the toxic alkaloids.—*Bull. Gen. de Therap.*, **137**, 901.

CHEMISTRY OF PECTINS.

Summarising the results of his investigation on the pectins, Borquelot states that all those hitherto examined by him are strongly dextrogyre in their action on polarised light; all give arabinose when hydrolised with dilute sulphuric acid; all are susceptible to the influence of a ferment, pectinase, which probably exists in the tissues of all plants, being derived for the purpose of experiment from untorrified germinating barley. All pectins are coagulated by the ferment pectase, but after being treated with pectinase they no longer coagulate with pectase. Moreover, if pectinase be added to the coagulum already produced from pectin by pectase, liquefaction results. These results appear to be analogous to those obtained with rennet ferment and trypsin on casein; the former coagulating casein, the latter, if added first, preventing its coagulation, or if added subsequently, digesting the coagulum.—*Journ. Pharm. Chim.* [3], **9**, 563.

OXYDASE IN HELLEBORUS FETIDUS.

The fact that the leaves of *Helleborus fetidus* turn colour when dried, has led P. Vadam to suspect the presence of an oxidising ferment. He finds by chemical tests that this is the case, and that the plant contains a powerful oxydase, which reacts with the usual tests; it is precipitated by alcohol, and is destroyed at 100° C.—*Journ. Pharm. Chim.* [3], **9**, 515.

ESSENTIALS OF VEGETABLE HISTOLOGY
AS APPLIED TO PHARMACOGNOSY.

Temporary Mounting and the Examination of Objects.

AIR-BUBBLES.—Upon placing a small quantity of a vegetable powder upon a glass slip, adding to it a droplet of water, covering with a thin glass disc, and then examining under the microscope by transmitted light, there will probably be observed well-defined rounded bodies, which invariably command the attention of those unfamiliar with the microscope. They are air-bubbles (Fig. 5), and may be identified by these characters: they have a broad black

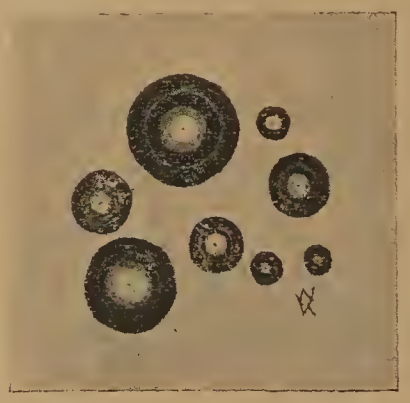

FIG. 5.—AIR-BUBBLES IN WATER.

ring tending to greyness on the edges and enclosing, when properly focused, a small bright centre; when the microscope tube is depressed the centre increases in brightness but diminishes in size, and when the tube is raised it becomes less bright and increases in size, encroaching upon the surrounding ring. The appearances are due to the strong refraction of light caused by the difference in the refractive power of water and air. In very small air-bubbles the bright spot of light may be altogether absent; these have the appearance of a black spot with margins shaded grey so as to suggest a bevelled edge. Upon raising the microscope tube, a more or less pronounced grey disc spreads from the centre towards the periphery. Air enclosed in cells or fibres may give rise to appearances which are very misleading. If the cell lumen be large and filled with air, the walls will apparently have thick black walls; but if the lumen be small or narrow, as in a fibre, it will be almost uniformly black. To expel air from a powder or a thin section, if other considerations are not unfavourable, it is sufficient to use a drop of alcohol before adding the mounting fluid. Or the powder may be well mixed on the slip with the mounting fluid by means of a needle; or the section, if not too thick, may be gently warmed on the slip with a little of the fluid. Occasionally circumstances arise when alcohol and heat would be equally objectionable; then the material should be subjected to prolonged soaking in some inert fluid, and in a last extremity diminished air pressure may be resorted to. In botanical work it very rarely happens that the air-pump needs to be called into requisition. Alcohol, gentle heat, and patience generally conquer this enemy.

OIL-DROPS.—These may very easily be mistaken for air-bubbles and *vice-versâ*. The limiting black ring is narrowed almost to a line (Fig. 6), and has the lighter shading on the inner margin when properly focused. The central area is light grey, and when the objective is lowered overspreads the black ring. Upon raising the objective from the original position concentration of light is produced in the centre of the area, and there results, with a high power, a bright spot, or, with a low power if the drop be spherical, a bright image of any object reflected from the microscope mirror. The alterations in the focusing adjustment cause appearances precisely the reverse of those which are characteristic of air-bubbles. Concerning the reactions of oil-drops it will be better to treat under the heading of cell-contents.

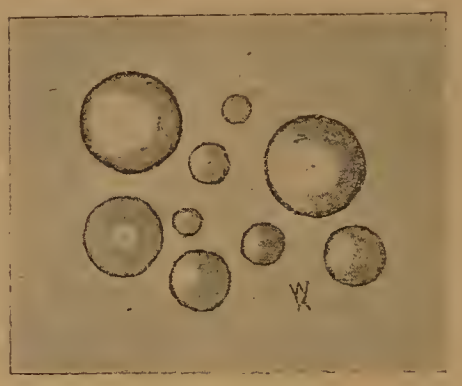

FIG. 6.—OIL-BUBBLES IN WATER.

In the examination of a powder, unless some care is taken, deceptive appearances may be presented to the observer. A little vegetable powder containing sclerotic cells or mineral matter may quite easily be put up on a slide so as to produce the impression that a much larger proportion of the sclerotic elements or mineral substances is present than is actually the case. For example, the powder is mixed with an aqueous or glycerin mounting fluid upon the slip, and either so small a cover-glass or so large a quantity of fluid is used as to cause a ring of fluid containing a portion of the powder to surround the cover-glass. The less heavy particles are those which will float out in the fluid, and the heavier ones will remain where originally placed. Thus there is a separation of the various particles according to their varying size and specific gravity, and a considerable proportion of the smaller and lighter particles is carried out of the range of observation. It is, therefore, always a safe rule to never permit a fluid mountant to escape beyond the verge of the cover-glass except in special cases when putting up permanent mounts. Under the most favourable conditions, powders consisting either of one or several constituents undergo in mounting fluids a certain amount of separation, the lighter elements in heterogeneous powders, such as fragments of parenchyma and small starch granules, and the lighter particles in homogeneous powders being found towards the margin of the fluid. The attempt to estimate the proportion of elements in a mixed powder by counting them in given areas or fields should be done with due regard to this possible source of error.

A little care is also needed in the application of the cover-glass to a fluid mount. A good firm thin section of a drug will often permit of the cover glass being firmly pressed down, and by so doing the details may be seen with greater clearness than would otherwise be the case. But if a delicate transverse section of a leaf, for instance, were to be examined, it would almost certainly happen, upon pressing down the cover glass, that the relation of the parts would

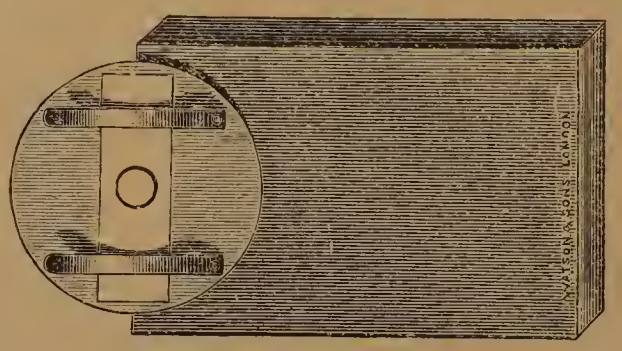

FIG. 7.—TURNTABLE FOR RINGING SLIDES.

be altered, the epidermis probably presenting a surface view instead of a sectional one. Masses of soft tissues and delicate crystals in powders would also be injured by this procedure. In fact, powders

should always be examined either with a loosely applied cover glass or in a shallow cell, as well as with one pressed down. An extemporary cell can be made quickly by sticking narrow strips of gummed paper on the glass slip so that the cover glass may rest upon them. Better still, cells may be made by ringing the slips by means of a turn-table (Fig. 7), with an alcoholic shellac varnish to which a small proportion of Canada balsam or castor oil has been added to make it less brittle. For this purpose there is nothing quite so useful as Ward's brown cement,* which answers for both cement and varnish. By avoiding pressure upon the powder the various components are not only preserved entire, but they may be made to present different aspects to the eye—a matter of very considerable importance, because for the most part, in monocular microscopes the single eye only sees one plane of an object. This is especially the case with objectives having a high angle of aperture. Low power objectives with low angle of aperture possess a certain amount of so-called penetrating power, which enables the observer to ascertain the relations subsisting between the planes immediately above and below the one in focus, but it does not avail in obtaining a stereoscopic view of a body. To make amends for this limitation of vision, the next best thing (as already suggested) is to secure a view of every aspect of the body, and this may often be done by causing it to slowly revolve at will in the field of the microscope by very carefully producing a movement in the mounting fluid with the aid of a mounted needle pushing the loosely-placed cover-glass.

SALINE SOLUTIONS FOR INJECTION IN INFECTIOUS DISEASES.†

Luton's Serum.—Crystalline sodium phosphate, 4; sodium sulphate, 10; boiled distilled water, 100.

Hayem's Serum.—Pure sodium chloride, 5; pure sodium sulphate, 10; boiled distilled water, 1,000.

Surgical Serum.—Sodium chloride, 7·5; boiled distilled water, 1,000.

Crocq's Serum.—Sodium phosphate, 2; boiled distilled water, 100.

Cantani's Serum.—Sodium chloride, 4; sodium carbonate, 2; boiled distilled water, 1,000.

Leclerc's Strong Serum.—Sodium chloride, 40; sodium phosphate, 5; sodium sulphate, 5; boiled distilled water, 1,000.

Cheron's Serum.—Crystalline phenol, 1; sodium chloride, 2; sodium phosphate, 4; sodium sulphate, 8; boiled distilled water, 100.

Latta's Serum.—Sodium chloride, 3 to 5; sodium carbonate, 1·7; water, 3,400.

Kronecker and Lichtenstein's Serum.—Sodium chloride, 6 to 7; sodium carbonate, 0·1; water, 1,000.

Schwartz's Solution.—Sodium chloride, 6 Gm.; solution of caustic potash and soda, 2 drops; water, 1,000 C.c.

Herard's Solution.—Sodium chlorate, 0·5; potassium chloride, 0·25; sodium phosphate, 1·26; sodium chloride, 4·5; distilled water, 1,000.

Dujardin-Beaumetz's Solution.—Sodium carbonate, 1; potassium sulphate, 1; sodium lactate, 1; sodium phosphate, 0·5; sodium chloride, 3·1; distilled water, 1,000.

Sapelier's Solution.—Sodium chloride, 60; potassium chloride 5; sodium carbonate, 32; sodium phosphate, 1·5; potassium sulphate, 3·5; boiled water, 900.

Sydmann's Solution.—Sodium chloride, 6; sodium bicarbonate, 1; water, 1,000.

Mathieu's Solution.—Sodium sulphate, 6; sodium phosphate, 4; sodium chloride, 1; glycerin, 20 fluid parts; water, 100 fluid parts.

Huchard's Solution.—Sodium phosphate, 10; sodium chloride, 5; sodium sulphate, 2·5; distilled water, 100.

Renzi's Solution.—Pure iodine, 1; potassium iodide, 3; sodium chloride, 6; distilled water, 1,000.

REVIEWS AND NOTICES OF BOOKS.

The Cold-Bath Treatment of Typhoid Fever. By F. E. Hare, M.D. Illustrated. Pp. 191. Price, 6s. net. London: Macmillan and Co., Limited.

This work contains a detailed account of the cold-bath method of treating typhoid fever as practised at the Brisbane Hospital, and it is based upon personal observations made by the author in the fever wards and the post-mortem room in the same institution. The origin of the method is traced to the late Dr. Brand, of Stettin, whose rule was to have the patients' temperature taken in the rectum every three hours night and day, and on each occasion that it attained or exceeded 102°·2 F. a full length bath of a temperature about 68° F. was administered for an average period of fifteen minutes. The author quotes Dr. J. C. Wilson as to the individuality of this plan of treatment: "The treatment stands by itself as a definite procedure, not to be confounded with the treatment of enteric fever by graduated baths, the cold pack, cold affusions, sponging, continuous immersions, or other hydrotherapeutic measures. It is especially to be looked upon as a method entirely distinct and different from any *merely* antipyretic treatment." It is to be regarded as essentially a prophylactic against the consequences of protracted pyrexia. "Hence, *to obtain the greatest possible benefit from it, it is above all things necessary that it be commenced at the earliest possible period of the fever, before signs of danger have appeared; and in direct proportion as this indication is responded to is the success of the treatment.*"

In ten years 1902 consecutive cases were treated by this method and a careful record of the clinical course in each case was kept under Dr. Hare's supervision. Thus was obtained an extensive basis for comparing the results of the expectant treatment previously employed at the same hospital with those of the cold-bath treatment.

Sixteen pages are devoted to a detailed account of the mode of administering the baths, and the value of this section of the work is greatly enhanced by numerous and excellent photographs.

The succeeding sections deal respectively with the influence of the method of treatment on the temperature, the circulatory, the respiratory, the nervous and the digestive symptoms; perforation and hæmorrhage, the renal and cutaneous symptoms, and finally on the general nutrition. The gross results of 1828 cases treated by the expectant method are compared with those of 1902 cases treated by the cold bath method; in the former the mortality came out at 14·8 per cent., against but 7·5 per cent. in the latter. Dr. Hare considers his statistics from various aspects—*e.g.*, according to the immediate or "secondary" causes of death. He also enters fully into the consideration of modifications rendered necessary by the supervention of serious events, such as hæmorrhage or perforation.

Many physicians in this country will probably fail to be convinced of the superiority of the cold-bath method as a routine measure in the treatment of typhoid, but every physician will accept Dr. Hare's work as a most thorough, careful, and reliable statement of an extensive experience of the most tedious and trying of all the zymotic fevers.

The production of the work leaves nothing to be desired.

The Administration of Castor Oil.—Castor oil, cod-liver oil, and other fatty oils are stated by Löwy to be rendered easy to take by the following method:—Beer is poured into a conical wineglass to the height of about a centimetre, then the dose of castor or other oil, and finally the froth of beer to the height of another centimetre is added. The whole may be swallowed at a draught without experiencing any other taste than that of the beer. Beer froth is quickly obtained by beating up powdered sugar with beer.—*Pharm. Centralh.*, **40**, 152, after *Therap. Monats.*

PHARMACEUTICAL SOCIETY.

MEETING OF THE COUNCIL.

WEDNESDAY, AUGUST 2, 1899.

Present :—

Mr. WM. MARTINDALE, President.

Mr. G. T. W. NEWSHOLME, Vice-President.

Messrs. Allen, Atkins, Bateson, Carteighe, Corder, Cross, Glyn-Jones, Grose, Harrington, Harrison, Hills, Johnston, and Park.

The minutes of the previous meeting were read and confirmed.

Letter from the Privy Council.

The PRESIDENT announced that a letter had been received from the Privy Council acknowledging receipt of the resolution relative to carbolic acid. He did not think that the matter would be dealt with by that body before the autumn.

The Conference at Plymouth.

Mr. ATKINS said he should like as one of the delegates from the Council to the British Pharmaceutical Conference to express their great indebtedness to the chemists of the Plymouth district for the great hospitality extended to them. He did not think he ever saw a more effective organisation, the whole of the details being thought out and carried out to an extent which was quite unique. He need hardly say that the President was missed. The weather, if rather warm, was superb. They were welcomed by three mayors. The papers were so numerous that only abstracts of some of them could be read, but the quality was high, and so was that of the discussions, though they, too, had to be curtailed for want of time. The proceedings extended over an extra day, and those who stayed over the Friday would agree with him that the garden party given by the Mayor of Plymouth at his country residence on the moors was immensely enjoyable, and would never be forgotten. They then went on to visit the works undertaken at vast expense by the Three Towns for the provision of an efficient water supply, which were well worth examination. The only drawback to the pleasure of the visit arose from a circumstance which the local committee were in no way responsible for, the simultaneous meeting of the Conference of Mechanical Engineers, which led to their own members being more scattered about in different hotels than usual, and he hoped this would not occur again. Looking back to his correspondence of twenty-two years ago, he came across a letter from a pharmacist of that district who was still living, in which he expressed the conviction that the meeting of the Conference, under the presidency of Professor Redwood, had levelled up pharmacy very considerably in the West of England, and had also brought chemists into much closer union amongst themselves. He hoped this renewed visit would have a further influence in the same direction, and again, on behalf of the delegates, expressed their thanks to the local committee.

Mr. CROSS wished to re-echo the remarks made by the Treasurer. He had attended many conferences, but could not remember an occasion on which the delegates from the Council had received a warmer welcome than they received at Plymouth. If any visitor to Plymouth had not enjoyed himself it was his own fault. He had noticed with pleasure the way in which the chemists of Plymouth co-operated not only with each other, but with the visitors to the Conference. It was in every respect a record meeting.

The PRESIDENT regretted that his official duties at the Society, in connection with the examinations, had prevented his attending the Conference. He had also had a lot of anxious private business of his own requiring his attention.

Election of Members and Student-Associates.

ELECTION OF MEMBERS.

The following persons having tendered their subscriptions for the current year, were elected "Members" of the Society :—

Aird, George H.; Newcastle-on-Tyne
Andress, Richard; Beaminster
Atkins, John; Brighton
Baker, Cyril H.; Westbourne Grove
Barley, Maurice Arthur Hurd; Cardiff
Beynon, John Thomas; Whitland
Bindloss, Herbert Meynell; Harlesden
Birt, Henry; Birmingham
Bloor, Richard Hardy; Holborn
Bonello, Francis; Malta
Boyd, Thomas; Glasgow
Buckingham, Frank E.; Harleston
Cable, Alice Mildred; London
Cain, John; St. Leonards-on-Sea
Clarke, Henry Pitman; Plumstead
Dyson, John George P.; Horwich
Exon, Frank H.; Clacton-on-Sea
Fairburn, Henry; Northallerton
Ferguson, Wiliam Cross; Motherwell
George, Enos Davies; Aberfan
Gray, Percy Bunting; Rugby
Griffiths, Edwin; Kidsgrove
Harris, John; Merton
Hodgson, Baron Cuthbert; Halifax
Kneale, James Coole; Sparkhill
Lane, Sydney William; St. Leonards-on-Sea
Lee, Arthur; York
Lloyd, Gwilym Henry; Solva
Lord, Walter; Denton
Manning, Frederick William; Fairford
Martin, Edwin George; Ingatestone
Meakins, John James; Dorking
Miner, William Harold; Ryecroft
Morgan, Howell; St. John's Wood
Nursaw, Edward; Plymouth
Owen, William Hibbert; Saltburn-by-the-Sea
Panchaud, Frederick; Cambridge
Pell, Alfred; Bombay
Pratt, Leonard Dudley; Ongar
Roberts, John; Bangor
Robertson, David Coutts; Galashiels
Ruoff, Francis Hermann; Reading
Schneider, Edward Paul; Bischweiler
Sim, William; Paisley
Spilman, John James; Ripley, Yorks
Sutcliffe, William; Manchester
Taylor, George Alan; Brinsley
Thompson, Edgar Joseph; Birmingham
Tilley, Ernest Alfred; Thetford
Trick, Percival William Clement; Stoke Newington
Whitaker, Joseph Edward; Bradford
Widdowson, George William; Aldeburgh
Williams, William Thomas; London
Wilson, Alexander Watson; Aberdeen

ELECTION OF STUDENT-ASSOCIATES.

The following persons having passed the First examination, and tendered their subscriptions for the current year, were elected "Student-Associates" of the Society :—

Barnes, James Hector; Birmingham
Bevis, George Frederick; Portsmouth
Salt, Leonard Thomas; Harrow
Stoneman, John Edey; Dawlish
Tinker, George; Holmfirth
Ward, William John; Manchester
West, Edward Mortimer; Stoke Damerel.

Several persons were restored to their former status in the Society.

Diplomas.

The undermentioned being duly registered as Pharmaceutical Chemists were respectively granted a diploma, stamped with the seal of the Society.

Bennett, Charles Thomas
Bunting, Sydney
Clarke, Frederick Stanley
Evans, John
Fisher, Sidney Ralph P.
Forster, William
Garbett, Charles
Hurst, Frederick Beaumont
Hyde, Charles
Livesey, Henry Ayrton Alexander
Meadeley, George Holmes
Millidge, Philip Henry
Pattison, George
Thackray, Charles Frederick
Vallet, Cyril Edward Franklin
Wheeler, Alice Maud
Wild, Thomas Jabez

The names of the following persons who have severally made the required declarations, and paid a fine of one guinea, were restored to the Register of Chemists and Druggists :—

Richard Jackson, Longtown, Cumberland
Edwin Stovell, 32, Laurel Grove, Penge, S.E.

Finance Committee.

The PRESIDENT, in moving the adoption of the Report of the Finance Committee, said the expenditure during the past month was somewhat large owing to the examinations.

The report was adopted.

Benevolent Fund Committee.

The Report of this Committee included the recommendations of grants amounting to £23 in the following cases :—

The widow of a member and subscriber (54). She is in ill health and has no one to look to for support. Previous grants have been made. (Morecambe.)

The widow (42) of a member who died two years ago. Grant made to aid in supporting one of the children, so that applicant might be at liberty to take a situation. (Coventry.)

One case was deferred for further particulars.

The VICE-PRESIDENT moved the adoption of the report. He said there were only a small number of cases brought up for consideration, two of the applicants had been granted sums of money, and

one other case was deferred for further consideration. In dealing with the latter case the Committee felt that it was desirable to see how far the friends of the applicant could help her, and then if necessary to supplement what the friends did in this respect.

The report was adopted.

Library, Museum, School and House Committee.

The PRESIDENT moved the adoption of the report of this Committee, which stated that the Librarian had presented his usual report, including the following particulars regarding attendance at the Library :—

Attendance.	Total.	Highest.	Lowest.	Average.
June.....	502	29	8	19

Circulation of Books.	Total.	Town.	Country.	Carriage Paid.
June	144	75	69	15s. 2½d.

Several donations to the Library and Museum had been received (see *Ph. J.*, July 15, page 59), and the Committee had directed the usual letters of thanks be sent to the respective donors.

The Committee recommended that the undermentioned books be purchased for the Library in London :—

Tilden, History of Chemistry, 1899.
Green, Ferments, 1899.

The Curator's report had also been received, and included the following particulars :—

Attendance.	Total.	Highest.	Lowest.	Average.
June.....	795	65	19	30

The Curator had presented a report on the meeting of the Museums' Association at Brighton, July 6-8.

The Committee recommended that the Librarian be authorised to attend the meeting of the Library Association in Manchester in September.

Certain work in connection with the Society's premises, including electric lighting of the lecture theatre, library, etc., was recommended to be carried out under the superintendence of the President.

The admission of Mr. Tickle to the Research Laboratory was approved, and the Committee recommend the appointment of Mr. T. E. Wallis as a junior demonstrator in the Chemical Laboratory.

The Committee, on the recommendation of Professor Collie, had nominated Mr. E. M. Chapman for appointment as the Salters Research Fellow.

The PRESIDENT said he had also received a report from Professor Collie as to the work done in the Research Laboratory. He stated that good work had been done by Mr. Tickle, the Salters' Fellow, and Mr. Chapman, the Burroughs Scholar. The results of some of the investigations had been published in the *Transactions of the Chemical Society*, and he appended a list of the papers which had been published. He was still engaged, with Mr. Tickle, in an investigation on the salts of chelidonic and meconic acid.

The following report was then read :—

PROFESSOR COLLIE'S REPORT ON THE RESEARCH LABORATORY.

In the Research Laboratory good work has been done by Mr. T. Tickle (Salters Fellow) and Mr. E. M. Chapman (Burroughs Scholar). The result of two investigations by Mr. Tickle and myself has been published in the *Journal of the Chemical Society*, whilst Dr. Lapworth and Mr. Chapman have also finished and published in the same Journal an investigation on the derivation of camphor. The actual number of publications from the Research Laboratory I give below :—

1. N. Collie and T. Tickle.—Production of some nitro and amido-oxy-lutidines.

2. N. Collie and T. Tickle.—The salts of di-methyl pyrone, and the quadrivalence of oxygen.

3. A. Lapworth and E. M. Chapman.—Homocamphoronic and camphoronic acids.

4. A. Lapworth.—Hydroxy di-bromo camphor sulphonic acid.

5. A. Lapworth.—Note on nitration substitution in nitro compounds.

6. A. Lapworth.—Sulphonation of benzo-phenone and of di-phenyl methane.

7. A. Lapworth.—A possible basis of generalisation of intra-molecular change in organic compounds.

8. A. Lapworth.—Action of silver compounds on di-bromo camphor.

Besides these I have completed, in conjunction with Mr. C. Frye, but not yet published, an investigation of the salts of chelidonic and meconic acids. Also the chief piece of work by Mr. Tickle and myself on meconic acid and its derivations has not yet been finished, but I hope that shortly it may be brought to a satisfactory conclusion.

Mr. CARTEIGHE remarked that these investigations had not cost the Society anything extra. He was sorry there were not more workers in the laboratory, but he thought the work done was very satisfactory.

The PRESIDENT said the investigation now being pursued was interesting to pharmacists, being concerned with some derivatives of opium.

Mr. GLYN-JONES said before the report was adopted he wished to ask two questions. He noticed reported in the *Pharmaceutical Journal* that some action had been taken by the Society with regard to the sale of benzene in connection with the County Council. He did not know the scope of the Library, etc., Committee, and whether it would deal with that matter? His other question was whether a suggestion which he would respectfully make was at all feasible, and that was that reports of committees, where possible, might be circulated with the agenda calling the Council Meeting together. That course was adopted by other bodies, such as the General Medical Council, for whose methods of procedure they had the very greatest respect. The reason he made the suggestion was that it was somewhat difficult for members of Council who knew nothing at all about the subjects dealt with by the Committee, to follow the report read at that meeting. If it were at all possible that the reports could be sent out with the agenda it would certainly help him, at all events, in taking an enlightened interest in what was going on. Some of the committees only met the day before the Council, and no doubt there would be a difficulty with regard to them; but when committees met earlier in the month he thought a printed copy of the reports which they were asked to adopt might be circulated.

The PRESIDENT said with regard to benzene (petroleum) the action referred to had been taken by Mr. R. A. Robinson, who he thought had got the matter so carried out as to meet the wishes of retail chemists. With regard to printing the reports of committees, he thought the matter had better be considered by the House Committee. It would certainly not be possible in the case of committees which met the day before the Council meeting.

Mr. CARTEIGHE said the spirit of Mr. Glyn-Jones's suggestion had been carried out for many years. The details of the reports were printed in the Journal, and the practice had been that when there was anything to refer to that was out of the general routine, that was printed and sent round to the members.

The Jacob Bell and Manchester Scholarships.

The report of the Committee appointed to award the Jacob Bell and Manchester Pharmaceutical Association Scholarships was read

JACOB BELL MEMORIAL SCHOLARSHIPS.

The Examiners appointed to conduct the examination for the Jacob Bell Scholarships had reported that twenty-seven candidates had competed for the scholarships at the following centres :—

Brighton 1		Liverpool 2
Canterbury 1		London 11
Carlisle 1		Manchester 1
Edinburgh 3		Newcastle 1
Exeter 2		Plymouth 3
	Shrewsbury 1.	

The envelopes bearing the mottoes of the successful candidates having been opened by the Committee appointed to make the award had been found to contain the following names:—

Harold Deane,

Charles W. B. Heslop.

The Committee had awarded the scholarships to Mr. Deane and Mr. Heslop, subject to the approval of the Council.

The competitors who adopted the following mottoes had obtained upwards of two-thirds of the total number of marks obtainable (which is the minimum for the award of a Bell Scholarship). The arrangement is in order of merit:—

3. *Virtute, non verbis.*
4. *Galen.*
5. *Nec vi nec Virtute.*
6. { *Labor omnia vincit.*
   { *Ne quid nimis.*
7. *Rursus.*
8. *Aquilo.*

Manchester Pharmaceutical Association Scholarship.

The Committee reported that four candidates had competed, but that not one of them had obtained a sufficient number of marks to entitle him to the award of a scholarship.

The President moved that the report be received and adopted, and that Mr. Harold Deane, Clapham, and Mr. Chas. W. B. Heslop, Newcastle-on-Tyne, be appointed Bell scholars for the ensuing session. He mentioned that the senior Bell scholar was a grandson of Mr. Deane, of Clapham, a former President of the Society, and he had no doubt, would do credit to his lineage. Twenty-seven candidates sat for the examination, and he was glad to find that nine of the number obtained sufficient marks to warrant an award of the scholarship. He regretted that none of the candidates for the Manchester Scholarship obtained sufficient marks to justify an award.

The report was adopted, and a vote of thanks was passed to Messrs. Pinches and Lucas for conducting the examination.

The Hanbury Gold Medal.

The President announced that the Daniel Hanbury Gold Medal had been awarded to

Professor Ladenburg, Ph.D., of Breslau,

who was specially distinguished for his work on the solanaceous alkaloids. He would be in England in September attending the meeting of the British Association, and it was hoped that he might be able to stay until October 2 and receive the medal personally, on the occasion of the opening of the School of Pharmacy.

Correspondence.

The President announced that a memorial had been received from Preston in favour of the course taken by the Council with regard to their opposition to the Lord Chancellor's Bills as brought forward in the House of Lords.

Mr. Harrison moved that the memorial be referred to the Law and Parliamentary Committee.

The resolution was carried unanimously.

The Herbarium Competition.

The President moved the adoption of Professor Green's report on the Herbarium Competition, awarding the Silver Medal to

Reginald Robert Bennett.

The resolution was carried unanimously.

The President moved that the best thanks of the Council be given to Professor Green for his report on the Herbarium Competition.

The resolution was carried unanimously.

The President said that concluded the public business, but he might make a remark with regard to the position of matters in Parliament. It was generally understood that the Companies Bill would be brought forward next session in the House of Commons, and would in all probability be pushed forward. It would, therefore, be necessary to watch the matter carefully, and possibly to formulate a clause which the Council should endeavour to get inserted. The Bill brought in by the Lord Chancellor had not been advanced, and he thought, therefore, the policy adopted of not taking any active steps in regard to it until it reached the House of Commons had been justified. Certainly, Members of Parliament would be just as well pleased not to have been worried by pharmacists on this matter. He had been down to the House several times for the purpose of seeing members he knew, and being introduced to others and feeling their pulse a little, as they would probably take a broader view than was sometimes taken by pharmacists themselves of these questions. The whole matter would have to be carefully considered before the autumn.

Mr. Glyn-Jones said as far as he could make out the only thing the Society was pledged to was the resolution passed in June by which the Watch Committee was given instructions to deal with the Lord Chancellor's Bill, to wait until it reached the House of Commons and then to oppose Clause 2 and to endeavour to secure the inclusion of pharmaceutical chemists and chemists and druggists in Clause 3. He believed the idea was that if this were done it would put a stop to companies—as the term was generally understood—carrying on business as chemists There were different opinions as to the chance of this being accomplished, but he thought it would be more satisfactory to the members if the President assured them that before October the Law and Parliamentary Committee or the General Purposes Committee would take the whole subject into consideration, and be prepared with a definite policy, which at present seemed to be wanting.

Mr. Carteighe said it was not usual to have a discussion on observations made from the chair with a view to giving information, but he could not allow Mr. Glyn-Jones' statement that the Council had no policy to pass uncontradicted It had a most definite policy, which was, if the Lord Chancellor's Bill reached the House of Commons, to endeavour to amend it in a definite direction. The Bill was not dead, and if it were introduced again next session it might or might not be expedient to adopt the same policy, but he could not allow the statement to be made that the Council had not a definite policy, because it was not true. It had a policy, and that policy remained until the Bill of the Lord Chancellor was dead. What might come afterwards was a question to be considered in due course.

The President said he thoroughly agreed with what Mr. Carteighe had said. The policy of the Council had been consistent throughout, and had been under consideration long before Mr. Glyn-Jones joined the Council. Their policy was to keep a watchful eye on any legislation affecting pharmacy, and to meet difficulties as they arose. He saw no cause as yet for deviating from that policy.

The Council then went into committee to hear and consider the legal portion of the report of the General Purposes Committee. On resuming, the report, and recommendations were unanimously adopted, and a special resolution passed authorising the Registrar to take proceedings against the persons named.

Report of Examinations.

July, 1899.

	Candidates.		
	Examined.	Passed.	Failed.
England and Wales:—

First Examination.

Certificates were received in lieu of the Society's Examination.

"FIRST" EXAMINATION RESULTS.

A meeting of the Board of Examiners for England and Wales was held on Tuesday, August 1.

A certificate presented by James Casketter Williams, of London, was accepted in lieu of the Society's examination.

The report of the College of Preceptors on the examination held on July 11 was received. **453** candidates had presented themselves for examination, of whom **244** had failed.

The following **209** passed, and the Registrar was authorised to place their names upon the Register of Apprentices or Students:—

Ainsworth, Charles; Preston
Allan, George; Scarborough
Anderberg, Axel: Peckham
Archer, Bertram Fred; Ipswich
Arkell, John; Swindon
Arnold, Charles; Bourne
Ascroft, Jane: Hindley
Ashworth, Albert Edward; Blackburn
Barltrop, Georgina E.; Walthamstow
Barraclough, James; Falkirk
Benjamin, Leopold; Edinburgh
Bennett, Sampson Taylor; Burslem
Berriman, Francis J.; Upper Brighton
Bird, Eustace Osborne; Penzance
Bollen, Clement Roderick; Bromley
Booker, George; Boston
Bosworth, S. McGregor; Bedworth
Boyle, Nicholas W. E.; Birmingham
Braid, John Andrew; Cambridge
Breen, Bernard Martin; Manchester
Bridges, John; Portobello
Briggs, Henry Hall; Todmorden
Brooke, Rupert Woolby; Sudbury
Brown, Benjamin John; Leamington
Brown, Peter Kinninmonth; Leith
Buckner, Harry; Whitstable
Burwell, James Arthur; Colwyn Bay
Calvert, Ernest Dixon; Hull
Campbell, Alexander; Paisley
Campbell, Collin; Ardrishaig
Carruthers, Charles J. M.; Hawick
Chislett, Charles Game; Lanark
Clarke, Alfred John; Northampton
Clarke, Stanley; East Dulwich
Cohen, Emanuel; Merthyr Tydvil
Compton, Charles Britt; Cirencester
Cooper, Geoffrey; Sandbach
Coultman, Matthew Robert; Malton
Court, Alexander; Bolton
Craine, George Lloyd; Douglas
Crawford, David; Thornton
Creal, George Lionel D.; Poplar
Cross, John William; Guildford
Crossley, Percival Charnock: Allerton
Curric, John; Glasgow
Currie, John Forbes; Glasgow
Davidson, Andrew; Stroud
Davies, Thomas Price; Fishguard
Dean, Edward E.: Newcastle-on-Tyne
Dennis, Henry Haywood: Atherstone
Dewar, Katherine; Dundee
Dey, Adam Dempster; Aberdeen
Dingle, Sampson P.; Southampton
Dobie, Robert Flint; Glasgow
Dobson, Arthur S.; Heckmondwike
Donaldson, Charles G.; Stenhousemuir
Doughty, John; Dalkeith
Dow, Robert; Perth
Dunn, Frederick George; London
Ellis, William George; New Brompton
Eslick, John James R; Redruth
Evans, Charles Henry; Holborn
Farquhar, William Alan Kemp; Insch
Fenton, Peter; Coatbridge
Ferris, Robert Henry; Kingsbridge
Fettes, David; Dundee
Ford, Alfred; Newtown
Fowler, Richard William, Oxford
Galbraith, Sarah A.; Wolverhampton
Gallop, Frank; Poole
Gaman, Stanley George: Swansea
Gates, Wilfrid; Rochester
Geddes, George; Thurso
Geddes, William; Cullen
Giddings, David: Morecambe
Gordon, John Lewis Stewart; Crieff
Gray, Horace G.; Glasgow
Green, Thomas Stevenson; Halifax
Greig, John; Stirling
Hall, Lilian; Morton
Hall, William Thomas; Redruth
Hammond, Garnet Oliver; London
Hanna, Frederic; Ashton-under-Lyne
Harbordt, Paul Harold; London
Hardy, John; Maryport
Harley, John Rogers; Crieff
Harold, George; Macduff
Hartley, Fred Arthur; Burnley
Henderson, Harold Eugene; Keswick
Heuchan, William; Castle Douglas
Heywood, John R.; Southend-on-Sea
Higgins, Frederick Samuel; London
Hill, Alfred John; Sutton Coldfield
Hill, Edward; Leven
Hilton, Norman Rushbourne; Coventry
Hitchen, Robert, jun.; Burnley
Hodgkiss, Thomas William; Ilkeston
Hope, Alexander Thomas; Kelso
Hopkins, Sherriff Bassett; Birmingham
Hudson, John William; Douglas
Isherwood, Joseph Ernest; Blackburn
James, David John; Llanelly
Jones, David John M.; Ammanford
Kaighin, William H.; St. John's Wood
Kenway, Bertha Anne; Bristol
Kingston, Thomas Edward; Bath
Knight, Alfred W. Percival; Wincanton
Laing, Thomas; Kirkcaldy
Laws, Karl A.; Newcastle-on-Tyne
Lee, Cecil Smith Bovelle; Strichen
Leslie, Thomas Spence; Stromness
Levi, Caleb; Manchester
Lewis, Benjamin Reymond; Fishguard
Lewis, E. M. E.; Newington Causeway
Lewis, Frank Edwin; Holt
Lindley, James Alhert; Prescot
Lindsay, George John; Dundee
Lister, George Harry; Stalybridge
Lloyd, Norman Lindsay; Wrexham
Locke, Olive Marshall; Hawick
Lowndes, Ernest Alhert; Birmingham
MacBride, Walter; Liverpool
McKay, David Edward; Ayr
McKenzie, Donald; Aherfeldy
McKerrow, Ethel; Wilmslow
McKinlay, William; Stirling
McLaren, Donald Livingston; Dollar
McRae, Ninian Finlayson; Blackburn

SHELLAC IN PHOTOGRAPHIC TECHNICS.

For some reason unexplained, if indeed, explainable, this substance, one of most extensive employment in the arts generally, and in photography in particular, is the subject of such misrepresentation, such erroneous description, such misleading instructions, as almost to approach the mysterious. Let us, for example, turn to that monumental example of patience, industry, and, usually, of scientific precision, Watts' *Dictionary of Chemistry*, under the heading of "lac" (incidentally we may observe that the word lac itself has a specific application to the dye-stuff, while the resin is commonly known with a qualifying addition—thus, shellac, stick lac, seed lac, button lac, white lac, the former again being described, according to its colour, as orange lac, garnet lac, etc.).

We read, referring to stick lac: "These twigs are called stick lac. The lac is removed by melting and squeezing through canvas, when the hardened drops are known as seed lac. After bleaching by chlorine or charcoal, and making into sticks, it is known as shellac or shellac." As a matter of fact, shellac means lac in the form of shells or scales, not sticks; it does not require to be bleached to earn the name; it is not bleached by charcoal; seed lac is not the melted drops of lac exuded from the canvas. This, it will be admitted, is a fair crop of errors to be found in half-a-dozen lines of scientific description; but that work is by no means the only one that sins in this connection. One of the cherished fables of photographic recipes is, that if we dissolve shellac in spirit, and shake it up with charcoal, it becomes decolorised. We can only say that

we have tried the plan with many samples of shellac, using both vegetable charcoal and freshly burned animal charcoal, and the result has been just the same as if we had read a page of Bradshaw to it. Again, we are told in many places that, if we expose it to sunlight, decolorisation takes place. We have placed narrow phials full of varnish, for six months, in a window with a south light, and we have been unable to detect the slightest alteration of colour. Possibly if we had employed a spectroscope we might have detected a change, but the colour of a varnish is not usually tested in that manner for commercial purposes.

Dealing now with the practical aspects of our subject, we meet at the outset one particular disadvantage in the manufacture of shellac varnish, the staple basis of all the best photographic varnishes; we refer to the great wastefulness that cannot be avoided when the lac is dissolved in methylated spirit. A very large volume of the liquid becomes useless, owing to the presence of a flocculent precipitate that never dissolves, and, even after months of standing, will not settle into a small bulk, and, moreover, will not satisfactorily filter out. It soon clogs a filter, and, consequently, very little of the thick part of the varnish can be saved that way. This thickened liquid may, however, be used with advantage, with a further quantity of shellac added, as a varnish for woodwork—printing frames, dishes for holding liquids, and so on. It has often been stated that the liquid can be cleared and the precipitate compacted by adding such substances as plaster of Paris, etc. We may say that our own experience has been quite unsatisfactory with all or any of these methods. We consider there is most promise in a suggestion of Mr. Watmough Webster, that the precipitate might be reduced in bulk by placing the crude lac solution in a centrifugal machine.

Ordinary white lac is especially liable to this waste; but the fresher the lac the smaller the waste. If used when too old, we have seen the solution remain without any perceptible clearing for months after the soluble portion has been taken up.

Aqueous solutions of shellac subserve a variety of uses; they are used for varnishing negatives by simple immersion while the film is still wet; when put up to dry and drain, they dry as soon as under ordinary conditions, and are then ready-varnished. Aqueous lac solution has been used for rendering paper impervious to water for the autotype process, but it has the defect of becoming discoloured by age. The modes of making aqueous solutions are many and various. The plan adopted in some trades the hatter's, for instance, of dissolving in a boiling solution of borax, is not suitable for photographic purposes. When small quantities only are needed, the best plan is to add a few drops of strong ammonia solution to, say, an ounce of varnish; the varnish so treated will mix with water in any proportion without precipitation. When required in quantity, the shellac may be soaked for some time in a solution of carbonate of soda or carbonate of ammonia; it is then soluble in boiling water. For a useful, strong, hard light-coloured varnish, a mixture of two parts of best orange shellac and one of fresh white lac makes a varnish difficult to surpass. The addition of gum sandarac or benzoin is often recommended; the addition heightens the brilliant glossiness of the surface, but renders the varnish less tough and less able to resist ordinary wear and tear.

There is still room for the publication of a really good method of making shellac varnish, or a way of treating shellac that will render it soluble, or at any rate do away with waste in its making. As an aid in experimenting, it may be useful to know the chemical composition of lac, and we will conclude our remarks by quoting from a paper by Herren Schirch and Farmer, which gives it as follows: Wax, 6; colouring matter, 6·5; purified resin, 74·5; (of which sixty-five per cent. is soluble, the remainder insoluble in ether); residue, 9; and water, etc., 3·5 per cent.—*British Journal of Photography.*

THE ASSAY OF BELLADONNA PLASTER.*

BY F. C. J. BIRD.

The determination of the alkaloidal value of samples of the belladonna plaster of the Pharmacopœia is an operation which has presented some difficulty on account of the interference of the soap, resin, and other ingredients which enter into its composition. Belladonna plaster (B.P.) should contain 0·5 per cent. of the alkaloids of belladonna root (atropine and hyoscyamine), and there are present in addition lead plaster, resin, and hard soap, together with the evaporated residue of the liquid extract, consisting of fatty and resinous bodies, colouring and extractive matters. During the process of manufacture a certain amount of evaporation takes place, so that the alkaloidal content of the plaster should really be a trifle over 0·5 per cent.

Solvents such as petroleum spirit, chloroform, etc., were at first tried, but they failed to completely dissolve the plaster, and the attempt to wash out the alkaloids merely resulted in hopeless emulsification. Finally a mixture of glacial acetic acid and chloroform was found to be the most satisfactory solvent, only a small and negligiable quantity of colouring and extractive matter remaining undissolved. On addition of dilute sulphuric acid the lead oleate, stearate and soap are decomposed, lead sulphate being precipitated, and the liberated fatty acids and resin going into solution in the chloroform. The alkaloids as sulphates are taken up by the aqueous liquid, and if the whole be thrown on a Buchner's vacuum filter the lead sulphate can be removed as a solid cake whilst the chloroform and aqueous layer pass through in a clear and easily separable condition.

The following is the process in detail:—

Belladonna plaster (B.P.)	15 Gm.
Chloroform	35 C.c.
Glacial acetic acid	5 C.c.

Warm gently to dissolve, and add

Water	40 C.c.
Dilute sulphuric acid (1 in 12)	35 C.c.

Again warm and pour on a 4-inch Buchner's filter connected with a vacuum of 8 to 10 inches of mercury. Remove the nearly dry cake of lead sulphate, break it up, and warm with

Chloroform	10 C.c.
Dilute sulphuric acid	5 C.c.
Water	10 C.c.

Again filter, and transfer the mixed filtrates to a separator. Run off the chloroform (aiding its separation, if necessary, by warming), wash twice with

Dilute sulphuric acid	1 C.c.
Hot water	4 C.c.

and return the washings to the aqueous portion.

To the mixed aqueous liquids add

Chloroform	20 C.c.
Solution of ammonia	A decided excess.

Warm gently, and agitate. Continue the process according to the directions given in the Pharmacopœia, as follows, assisting the separation of the chloroformic layer, whenever necessary, by the application of a gentle heat: "Separate the chloroformic solution, and twice repeat the agitation with 10 C.c. of chloroform and the separation. Shake the mixed chloroformic solutions with 5 C.c. of diluted sulphuric acid (1 in 12), mixed with twice its volume of warm water; separate the chloroformic liquid, and repeat the agitation with acidulated water. Wash the mixed acid liquids with 3 C.c. of chloroform; then agitate with 10 C.c. of chloroform and an excess of solution of ammonia. Separate the chloroformic solution; twice repeat the agitation with chloroform and the separation; wash the mixed chloroformic solutions with 5 C.c. of water containing one drop of solution of ammonia; draw off the chloroformic layer into a counterpoised dish, evaporate on a water-bath, dry the residue below 100° C., and weigh. Dissolve

* Read before the Society of Public Analysts, and reprinted from the *Analyst*.

the residue in 10 C.c. of a decinormal solution of hydrochloric acid, and add centinormal solution of soda, free from carbonate, until the liquid is neutral, using tincture of cochineal as indicator. Deduct the measure of the soda solution thus required from 100 C.c., and multiply the remainder by 0·00287; the product will be the weight in grammes of alkaloids present in the 15 grammes of plaster operated upon." The figures obtained by weighing and by titration should agree within about 5 milligrammes.

This method has been in use, with satisfactory results, during the past three months, and its accuracy has been verified by the analysis of samples of known composition.

SELECTED PRACTICAL FORMULÆ.

Fly Powder.

Eucalyptol, 5; talcum, 10; starch, 85. Powder the head and hands several times per diem.—*Pharm. Zeit.*, **44**, 350.

Fly Essence.

Eucalyptol, 10; oil of bergamot, 3; acetic ether, 10; eau de Cologne, 5; alcohol (90 per cent.), 100. Mix with ten times the volume of water, and spray over the rooms several times a day.—*Pharm. Zeit.*, **44**, 350.

Fly Ointment.

Hard paraffin, 50, and liquid paraffin, 45, are melted; then add eucalyptol, 4, and anise oil, 1. The exposed portions of the body are rubbed with this mixture.—*Pharm. Zeit.*, **44**, 350.

For Moths.

An experienced fur merchant says there is absolutely no preventative for moths, except constant airing and absolute cleanliness. The articles should be stored in an air-tight box, and kept in a cool and dark place. Every four to six weeks turn the furs on a dry cloudy day, and comb out the fur carefully with a metal or horn comb; exposure to sunlight is absolutely injurious to all furs.—*Pharm. Ztg.*, **44**, 350.

Remedies for Insect Bites.

(1) Moisten the affected parts with alcoholic solution of ammonia, 7; collodion, 3; salicylic acid, 0·3. (2) A preventative is said to consist of a saturated solution of napthalin in liquid paraffin applied every two or three hours to the face and hands. (3) Liquid carbolic acid, 5; spirit of soap, 100. *Insect Cream.*—Corrosive sublimate, 1 centigramme; distilled water, 0·5 Gm.; menthol, 0·3 Gm.; cold cream, 10 Gm.—*Pharm. Zeit.*, **44**, 350.

Fumigating Pastilles for Insects.

(1) Powdered charcoal, 500; potassium nitrate, 60; carbolic acid, 40; insect powder, 250, are massed with mucilage of tragacanth. (2) Powdered charcoal, 500; potassium nitrate, 50; insect powder, 150; benzoin, 100; tolu balsam, 100, are massed with mucilage of tragacanth, shaped into pastilles, and dried. (3) Insect powder, 240, are moistened with potassium nitrate, 25, dissolved in a little water and dried at a gentle heat. The dry powder is massed with tragacanth and formed into truncated cones, each weighing 2½ Gm. when dry. (4) Saltpetre, 10, are mixed with tragacanth, 10; then finely powdered insect powder, 10; fine marshmallow root powder, 1·5; fine tragacanth powder, 1·5, are mixed separately The two powders are massed with mucilage of tragacanth containing potassium nitrate, and are formed into pastilles. While fresh the pastilles are painted over with fine red or yellow bronze powder and dried at 40-50 C.—*Pharm. Zeit.*, **44**, 349.

To Keep Away Moths.

Naphthalin, 20; carbolic acid, 20; camphor, 50; are covered in a flask with oil of turpentine, 50, and alcohol (90 per cent.), 800. Dissolve the ingredients and add patchouli, 5; oil of mirbane, 5. Spray the solution in the room drawers, cupboards, etc.—*Pharm. Zeit.*, **44**, 350.

Fruit Juices for Aerated Beverages.

Strawberry Juice.—(1) Cover strawberries in a wide glass with fine sugar, draw off the fluid and strain. Then boil the juice with the addition of 1 Gm. salicylic acid dissolved in cognac for each kilo. Mix the syrup with a little rum or arrack and store in small bottles. *Natural Strawberry Essence.*—Ripe fresh berries are pulped, macerated with the equal weight of alcohol for fourteen days, pressed slightly and filtered. *Artificial Strawberry Essence.*—Natural strawberry, 2·5 kilos; amyl acetate, 500 Gm.; raspberry wine, 1 kilo; cherry laurel oil, 2 drops; rose oil, 1 drop; sugar, 40 kilos; water, 60 litres; alcohol, 25 litres; red vegetable colouring matter, q.s. *Essence of Lemon.*—(1) Macerate the fresh peel of forty lemons and thirty oranges with alcohol, 8 litres, and water, 2 litres, for 2 to 3 days, then distil off 8 litres. Dissolve in every 100 Gm. of this distillate, citric acid, 75 Gm., and add water, 200 Gm.; colour with a trace of orange and filter after shaking with talcam. Mix 100 Gm. of the filtrate with simple syrup, 2 kilos. (2) Lemon oil, 11·25, rose oil, 0·03, are dissolved in alcohol 80 per cent., 200·0, tincture of orange peel, 9 tincture of lemon, 9, prepared from fresh peel, and tincture of vanilla, 1·5, are added. Of this essence 3 parts are sufficient to flavour 1,000 of simple syrup. *Lemon Juice* is best prepared from freshly pressed and filtered juice; 10 parts are boiled in a porcelain dish with sugar, 18 parts, or citric acid, 1 to 2 parts, may be mixed in an equal volume of water mixed with simple syrup, 100 parts, and flavoured with 1 to 2 parts of a tincture prepared from fresh lemon peel and alcohol. *Artificial Lemon Juice.*—Citric acid, 4, tartaric acid, 4, are dissolved in alcohol, 12, and water, 25, lemon essence, 40, simple syrup, 1,000, are added. Lemon essence is composed of lemon oil, 7·5 Gm.; alcohol, 5 litres. *Lemon Juice for Drinks.*—Sugar, 100; distilled water, 50; citric acid, 7·5; tincture from fresh lemon peel (1-5) 5 to 8, and orange-flower water, 15 to 20. *Essence of Raspberry.*—Raspberry syrup Ph. G. may be used with the addition of citric acid dissolved in water and red colour. (2) Raspberry juice, 1,000; sacch. alb., 1,600; acid tartaric, 35 to 40; alcohol, 30; red colour, q.s. The syrup is prepared in the cold; the acid being dissolved in a little warm water.—*Pharm. Zeit.*, **44**, 348.

Cold Cream.

Skinner recommends the following formula for cold cream:—Benzoated lard, 4 oz.; white wax, ½ oz.; spermaceti, 1 drachm; borax, 30 grains; eau de Cologne, 2½ fluid ounces.—*Brit. Journ. Derm.*, **14**, 237.

Essence of Rennet.

A calf's rennet is well washed, cut up small with a scissors, then add salt, 100; distilled water, 500; alcohol, 150; black peppercorns, cloves, bayberries, of each 5. Macerate for twelve days and filter. Keep in brown glass bottles.—*Pharm. Zeit.*, **44**, 348.

Floor Waxes.

(1) Yellow wax, 1 kilo., water, 1 litre, are heated to boiling; potash, 63 Gm., are added, dissolved in a little water; the mixture is boiled for a few minutes, removed from the fire, and oil of turpentine, 50 Gm. added, boiling water, 1 litre, and annatto, 15 Gm. Stir continually until cold, and apply on a rag. (2) Yellow wax, 100, are dissolved on the water bath with oil of turpentine, 200. (3) Yellow wax, 40 parts, are boiled with water, 160 parts, and potash, 5 parts. Oil of turpentine, 4 parts, are now added, and the whole diluted to 200 parts, with continual stirring until cold. (4) Potash, 32 parts, are dissolved in water, 314 parts, and the solution brought to boiling point. Yellow wax, 32 parts, are then added, and the whole coloured with annatto, 8 parts.—*Pharm. Zeit*, **44**, 349.

THE COMPANIES ACTS AMENDMENT BILL.

In the *British Medical Journal* for July 29 appear some interesting editorial comments on the article "In What Direction is Pharmaceutical Legislation to be Attempted," which was published in the *Pharmaceutical Journal* of the previous week. That article is considered by our medical contemporary to sound "rather a despairing note upon the subject of future pharmaceutical legislation. It appears that unanimity has not yet been attained. Many chemists are very reluctant to give up the so-called Widows' Clause, which permits a business to be carried on by the executors of a deceased chemist; that is to say, by unqualified masters. The abandonment of this clause must be a necessary antecedent to the imposition of further restrictions. Opinion seems to be becoming more favourable to the Lord Chancellor's proposition, namely, that a company might conduct the business so long as it employs qualified assistants, though it may be presumed that the chemist will as strenuously as ever contest the unjust assumption of title. The article goes so far as to say that, although there is ample opportunity for seeking amended legislation, 'with many others disinclination to accept the other consequences of such an amendment has prevailed to such an extent as to prove an insuperable obstacle,' and 'the prospect of obtaining practically unanimous support from all registered persons seems to be at least as remote as that of securing the equally indispensable support from the Government.' These remarks are obviously intended to have a wider application than to the pharmacy clause of the Companies Bill. Without straining their meaning, they may be fairly read as bearing upon this, and as marking a material change of front so far as practical action is concerned. The Companies Bill has passed the stage of committee in the House of Lords without amendment, and we may confidently look forward to its being introduced into the House of Commons at an early period of the next session. If the pharmaceutical chemists will let the medical clause alone—and the opinion of the *Pharmaceutical Journal* appears to be tending in that direction—then and only then can we cordially promise them all the support we are able to offer in enabling them to get passed such a pharmacy clause as shall be found acceptable. This is the position we have taken all along, and it is gratifying to see that some who were at first inclined to deny that any difficulties existed in their case from which the proposed medical legislation was free, have now modified their views upon this question."

CHLORAL-TANNIN.

BY HAROLD WILSON.

Pharmacist to University College Hospital.

Some little time ago one of our leading physicians asked me to try and prepare for him some condensation product of tannin and chloral. This I succeeded in doing, and the preparation, which may conveniently be called chloral-tannin, is now frequently used in this hospital.

As this substance will probably be prescribed in private practice its characters and mode of preparation are here given:—Chloral hydrate and tannin are mixed in a porcelain dish and then heated on a water-bath; as the temperature rises the mass becomes fused, and between 60° and 70° C. a brown resinous-looking substance separates out; this substance can be made to aggregate by stirring, and is then easily removed from the brown liquid with which it is mixed; it is allowed to cool in a desiccator, and may be powdered for convenience in dispensing.

Chloral-tannin yields about 38 per cent. of chloroform when its solution is treated with potassium hydroxide: it is soluble in water and in alcohol.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.
Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, AUGUST 5, 1899.

THE COUNCIL MEETING.

At the opening of the meeting the President announced that a letter had been received from the Privy Council Office acknowledging receipt of the resolution again recommending the addition of carbolic acid to the Poison Schedule, in pursuance of the intimation recently given by the Home Secretary that the previously existing objections to scheduling carbolic acid as a poison in England having now been lessened, the Privy Council was prepared to consider the matter if called upon to do so (see *ante* p. 12*a*).

Mr. Atkins and Mr. Cross then spoke of the great satisfaction they had experienced in attending the meeting of the British Pharmaceutical Conference as delegates from the Council, both agreeing in their high appreciation of the hearty hospitality of the West Country chemists, and the excellence of the arrangements made for the entertainment of visitors. The business proceedings of the Conference were also spoken of as having been exceptionally good, though the abundance of papers necessitated curtailment of their full discussion.

The additions to the Society comprised 54 members, 7 associates, and a considerable number of restorations.

The report of the Finance Committee was adopted, on the motion of the President, without comment.

On the recommendation of the Benevolent Fund Committee two grants amounting to twenty-three pounds were ordered to be paid.

The report of the Library, etc., Committee referred to several details connected with the introduction of electric light in the lecture theatre, library, and other parts of the Society's premises, the admission of Mr. Tickle to the Research Laboratory, the appointment of Mr. T. E. Wallis as junior demonstrator in the School laboratory, and the recommendation of Mr. E. M. Chapman for the Salters Scholarship, besides mentioning the work that has been done in the Research Laboratory during the past session.

Before the motion to adopt the report was put, Mr. Glyn-Jones asked a question as to the action recently taken in approaching the County Council with regard to petroleum, and also whether printed reports of committees could not be supplied to members of the Council together with the agenda paper, so as to afford greater opportunity for considering those reports before they are read at the Council meeting.

In reply, the President said that the petroleum matter had been carried out so as to meet the wishes of retail chemists through the aid of Mr. Robinson. The question of printing reports of committees should, he thought, be considered by the House Committee, and Mr. Carteighe added that the spirit of Mr. Glyn-Jones' suggestion had been acted upon for many years, partly by printing in the Journal the details of reports and also by sending printed copies of any reports that were of an unusual nature.

On the recommendation of the House Committee and of the examiners appointed to award the Jacob Bell and Manchester Scholarships, Mr. Harold Deane, of Clapham, and Mr. C. W. B. Heslop, of Newcastle-on-Tyne, were respectively appointed Bell scholars. The candidates for the Manchester Scholarships did not obtain sufficient marks for an award. Professor Green's report, awarding the Herbarium prize to Mr. R. R. Bennett, was adopted, and resolutions were passed expressing the thanks of the Council to Messrs. Pinches and Lucas, and to Professor Green for conducting the examinations.

The President announced that the Hanbury Medal has been awarded to Professor Ladenburg, of Breslau, and a hope was expressed that he might be able to receive the medal personally on the occasion of the opening of the School session in October next.

Mention was made of the receipt of a memorial from Preston chemists, expressing approval of the course taken by the Council in reference to the Lord Chancellor's Bills now before the House of Lords, and on the motion of Mr. Harrison, it was referred to the Law and Parliamentary Committee.

Speaking of the present position of these Bills in Parliament, the President referred to the probability of the Companies Bill being brought forward in the House of Commons next Session, and the necessity of watching its progress carefully.

Mr. Glyn-Jones spoke of the idea that companies would be prevented from carrying on business as chemists if Clause 2 could be opposed and chemists included in Clause 3, as having given rise to differences of opinion concerning the chance of that being accomplished, and he thought the more satisfactory course would be for the President to assure members of the Society and the trade generally, that the Law and Parliamentary Committee would take the whole subject into consideration before October, and be prepared with a definite policy, which at present seemed to be wanting.

Mr. Carteighe protested against Mr. Glyn-Jones' assumption that the Council has no policy, pointing out that the Lord Chancellor's Bill was not dead, and that the policy of the Council was to amend that Bill in a definite direction if it reached the House of Commons. If the Bill were introduced again next Session, the same policy might or might not be expedient, and that position would have to be maintained until the Lord Chancellor's Bill was dead. What might follow after that event would have to be considered in due course.

The President expressed perfect concurrence with Mr. Carteighe's remarks, and saw no reason for deviating from the consistent policy on which the Council had acted throughout.

After consideration of the legal part of the report of the General Purposes Committee, a special resolution was passed authorising the registrar to take proceedings in various cases of infringement of the Pharmacy Act.

ANNOTATIONS.

The CONFERENCE PAPERS communicated at last week's meeting of the British Pharmaceutical Conference proved, as usual, to be much too numerous. There were thirty altogether, and the whole time available for the business meetings was only ten hours. Deducting only two and a half hours for the introductory and concluding business, the time left allows no more than fifteen minutes for the reading and discussion of each paper. The obvious remedy is to take another day for business purposes, but there are serious difficulties in the way of adopting that plan, and something less drastic must therefore be considered. It is a question worth consideration whether authors should ever read more than abstracts of their papers. If thought desirable, advance proofs of all papers might be in the hands of members of the Conference for reference, and, if that were done, the reading of abstracts would serve every purpose. Another point has more especial regard to the order in which the papers were read. It seems distinctly unfair that authors who are present at the meeting should have their communications crowded into the last few minutes, and taken as read or not discussed, whilst papers by absent authors are read and discussed at length at an earlier period. The relative importance of papers must, of course, be considered to some extent, and papers on similar topics should, as far as possible, be considered together. But apart from those considerations, there should be a definite rule that papers by authors who attend in person should take priority over the rest. If then any general slaughter of unread papers became inevitable the chief and probably the only sufferers would be the absent authors.

THE STANDARDS OF PURITY FOR FOODS AND DRUGS suggested by Messrs. Moor and Cribb in the paper communicated by them to the Conference at Plymouth were not discussed at the meeting, but it is hoped that the matter may be freely debated in our correspondence columns. At all events, space will be available for that purpose, and, on the whole, it seems desirable to face the difficulty—caused by the lack of statutory standards—boldly rather than to shirk it because of the assumed danger of compelling chemists and druggists to supply drugs, etc., of definite strength and quality. If the retailer is to give a personal guarantee with regard to such points, it is better to have a reasonable than an unreasonable standard. And as strong attempts are being made to secure the recognition of the British Pharmacopœia as a statutory standard generally, though that would be distinctly unreasonable in some instances, registered chemists should seriously consider the suggestion that they and other parties interested should endeavour to agree upon factors which may result in the adoption of a provisional standard for certain substances. As was announced last week, a paper on the subject is to he communicated to the Society of Public Analysts in October next, and any figures which our readers can furnish on the subject should be sent to Mr. C. G. Moor, M.A., 4, Dane's Inn, Strand, London. W.C.

SHERIFF MAIR OF AIRDRIE has been amusing himself again by venting his spleen upon the Pharmacy Act of 1868. Some time ago a woman died from the effects of laudanum which had been sold to a child without any inquiry being made by an unqualified person employed by a medical man at Airdrie. The seller was proceeded against for breach of the Pharmacy Act, and the case came before Sheriff Mair. That sapient individual, however, thought the offence was a purely technical one and imposed a fine of half-a-crown only. The reason he gave for this display of leniency was that it is quite impossible always to have such sales made by qualified persons. Apparently, the safety of the public does not count for much in Airdrie, and the fact that a woman has lost her life owing to an unqualified person assuming a duty for which he was not fitted is of no weight with Sheriff Mair. Costs were refused in the case because the Sheriff does "not approve of the Pharmacy Act," and a suggestion by the Pharmaceutical Society's solicitor that such disapproval does not constitute a proper reason for refusing to carry out the provisions of the Statute met with no other response than that the Sheriff had no sympathy with the Pharmacy Act. Under the circumstances, it would not be unseemly if some Scottish member of Parliament were instigated by his pharmaceutical constituents to ask a question in the House on the subject of Sheriff Mair's dispensation of justice (?).

EVERY MERE LAYMAN can see the utter absurdity of the position taken up by Sheriff Mair, for the editor of the *Dundee Evening Telegraph*, commenting on the matter, remarks that the Sheriff may have been very well satisfied that a non-qualified assistant employed by a qualified person, who sells a fatal dose of laudanum to a young girl, commits only a technical offence, and should only suffer a nominal penalty, but he hardly thinks he took sufficient cognisance of the public interest, and he surely overlooked the plain purpose of the Pharmacy Act, under which the prosecution was instituted. Children, it is stated, should not be served with poisons at all, and no unqualified assistant should be permitted to sell them under any circumstances. "So much is required for public safety, and so much was supposed to be safeguarded by the Act. But f half-crown penalties are to be the punishment—unless something serious happens—then it might as well be a dead letter. It should be noted that the prosecution was brought by the Pharmaceutical Society, who were allowed no expenses for their trouble. To put it mildly, Sheriff Mair's decision is not an encouragement to do right."

MR. G. C. DRUCE, OF OXFORD, had prepared for inclusion in his paper on the salient features of the Flora of Devonshire (see *ante*, p. 98) a tabular statement showing the distribution of certain types, but, unfortunately, it was received too late for publication last week. Since, however, it possesses considerable interest, it is given below:—

Types.	British Species.	Irish Species.	Oxfordshire Species.	Devonshire Species.
English.....	961	785	737	761
Germanic.....	127	18	39	29
Atlantic	70	41	3	58
Scottish	117	66	3	14
Highland	120	40	—	1
Total	1,395	950	782	863

THE OCTOBER MINOR AND MAJOR EXAMINATIONS, which, it will be remembered, will be conducted under the new Schedule, will commence about September 22. The Major written work—in botany, materia medica, chemistry, and physics—will be taken on Tuesday and Wednesday, October 3 and 4, in London and in Edinburgh.

INSTRUCTION IN PHARMACY must be received by candidates for medical qualification at the Royal University of Ireland, and it has been customary for the University authorities to accept certificates of having compounded medicines under the supervision of a pharmaceutical chemist; but at last month's meeting of the Council of the Pharmaceutical Society of Ireland, a letter was read in which the secretaries of the University stated that such certificates would no longer be accepted. The future requirements were specified as including, in practical pharmacy, attendance during a three months,

course, with lectures on at least two days a week, given in a recognised school in a properly equipped laboratory, by a duly appointed lecturer in pharmacy. Naturally, the Council of the Irish Society strongly disapproved of the change thus intimated, and it was decided that the President should write to the Senate of the University on the subject. Commenting on the decision not to recognise instruction in pharmaceutical establishments in future, the *Medical Press* remarks that it has no confidence whatever in courses of instruction in pharmacy conducted at the colleges as proof of pharmaceutical education. It does not believe in the possibility of communicating a sufficiency of the required knowledge in a few prelections in a lecture theatre, and the suggestion is offered that the medical licensing bodies should surmount the difficulty "by abolishing the pharmacy certificate altogether and leaving the candidate to 'get up' the subject for examination any way he can."

Education for its Own Sake is a beautiful theory, but experience shows that an occasional stimulus in the shape of concrete encouragement counts for a good deal in educational as in other matters. The Edinburgh Chemists', Assistants', and Apprentices' Association appears to have wisely realised this fact, and has determined that the acquisition of useful knowledge in pharmaceutical subjects by the youth of Edinburgh and district shall not languish for want of prize competitions. In the syllabus forwarded by the secretary, Mr. James Lennox, of 139, Princes Street, particulars are given of five competitions, namely, The McLaren Prize of two guineas (which is to be expended in the payment of school fees); The Ewing Pharmacy Prize of one guinea (in books); The Pottage Herbarium Prize, value two guineas; The Bowman Botanical Prize, value one guinea, and the Dott Physics Prize, value one guinea—a very respectable list for a small association, the objects of which are not primarily educational, but rather of the social order. Lest it might be imagined that the foregoing prizes are given whether they are earned or not, it should be mentioned that the conditions governing all the awards insist upon a certain standard of excellence being attained by successful competitors. Local associations desirous of inaugurating a similar system of practical promotion of pharmaceutical education would do well to write to Mr. J. Lennox for a copy of the Edinburgh Prize Scheme for 1899-1900.

The University of London is henceforth to be housed in the Imperial Institute buildings, a Treasury Minute dealing with the necessary arrangements being described by *Truth* as a sort of official announcement of "the death and burial of the ill-starred Imperial monument of the Queen's first Jubilee." The ground lease of the whole premises is to be transferred to the Commissioner of Works, as representing the Crown. The main portion of the building will be handed over to the University, and the rest is to be assigned for the use of the Institute, assuming as *Truth* suggests that the Institute has any use for it. The problem in connection with the affair which worries our contemporary is why the University need be ejected from Burlington House, which does not appear to be required for any other purpose, and set down at South Kensington on an undesirable site. The Institute buildings are also alleged to be utterly unsuited for the purpose to which they are now assigned, and it is asserted that considerable sums will have to be spent before the business of the University can possibly be carried on in them.

Schemes for Hastening the Millennium are produced with pleasing frequency in these advanced days, and it is astounding what a number of highly moral measures are born and die in the course of a single Parliamentary Session. This year the private members have been particularly prolific in suggestions for the purification of public manners, and the removal of that small residuum of the "Old Adam" which is still to be found in nineteenth-century human nature. One is led to these observations by the introduction on Tuesday of a Bill to amend the Indecent Advertisements Act of ten years ago. The promoters of the Bill are Mr. Channing, Sir J. Kennaway, and Mr. Samuel Smith—gentlemen who are well known in connection with various reform movements usually promoted by societies which prefix "anti" to their titles. Perhaps they are unduly sensitive, but, at any rate, these gentlemen deserve praise for having the courage to deal with what they deem to be a public scandal. The proposal in effect is to extend the Statute of 1889 to all printed or written matter offering to provide drugs, instruments or surgical or other means for the purpose of procuring, or of enabling others to procure, the miscarriage of any woman *whether she be with child or not*. The concluding words are so rich as to be well worthy of italics. The penalty for the insertion of such a notice in a newspaper is to involve the person inserting it in liability to a fine of ten pounds or three months' imprisonment, and the same punishment awaits the sender of indecent printed matter through the post. The Courts will have to define what is or is not a print of an indecent nature.

The Classification of Weighing Instruments was instructively dealt with by Mr. Allan Granger, hon. secretary of the Incorporated Society of Weights and Measures Inspectors, at the recent Congress of the Federation of Grocers' Association. He explained that there are three classes of weighing instruments, and the inspector's test for sensitiveness varies according to the class which is marked upon the instrument. For compound lever machines, which comprise platform machines and weighbridges, there is a special table of allowances, and they do not fall within the classification mentioned. A scale marked "Class I." is put to a more severe test than a "Class II." scale, which in its turn is tested more severely than a scale marked "Class III." For instance, a beam-scale of 56 lbs. capacity "Class I." when presented for verification would not be passed by an inspector unless it turned with one drachm when loaded up to its full capacity. A similar instrument, but marked "Class II.," would be passed if it turned with four drachms; and six drachms would be allowed if it were marked "Class III." It will thus be seen that the degree of sensitiveness required of "Class II." scales is one-fourth, and of "Class III." scales one-sixth of that of "Class I." scales. The model regulations issued by the Board of Trade for the guidance of inspectors in the discharge of their duties state that weighing instruments such as those used for bread and meat should be marked "Class II." when submitted for verification, and those which are used by itinerant vendors or for weighing coals, vegetables, wood, and metal should be marked "Class III."

The Arrangement Described is considered by Mr. Granger to be hardly satisfactory. A manufacturer classifies the scales he makes as he thinks fit, and if they are submitted by him for verification, as is often the case, the inspector is not in a position to know to what purpose they are likely to be put. As soon as the official stamp is affixed to a scale it becomes a legal instrument, and may certainly be applied to what use the owner thinks fit. But here the user and the inspector sometimes clash. The latter finding, say, a "Class III." scale used for what is considered a "Class II." purpose, takes objection to it, and perhaps he defaces the stamp. It is thought that this cause of trouble might be avoided by classifying scales according to their construction, and not according to the purpose for which they are to be used. Particular tests should be laid down for beam-scales, counter machines, compound lever machines, steelyards, and spring balances, and such a classification would, it is thought, be more satisfactory and more logical than the existing one. At the

present time the beam-scale is practically the only one which meet the requirements of "Class I.," and the largest possible use of that scale was strongly urged. "The beam-scale, whilst it is the most ancient, is the simplest and most sensitive form of weighing instrument. It should be employed to the fullest extent in trade, as it undoubtedly gives the best results. The shopkeeper buys wholesale and sells retail. The loss occasioned by a sluggish scale will sometimes make all the difference between a profit and a loss."

AT THE PASTEUR INSTITUTE during the year 1898, 1,465 persons underwent treatment, of whom four only died, and one of those succumbed ten days after the treatment ceased, experiments made on dogs indicating that when death occurs within a fortnight the poison has got into the blood before the cure can take effect. That leaves only three deaths out of 1,465 cases. The table quoted below from the *Annales de l'Institut Pasteur* shows the result as compared with previous years since the treatment was commenced:—

Year.	Number of patients.	Number of deaths.	Rate of Mortality.
1886	2,671	25	0·94
1887	1,770	14	0·79
1888	1,622	9	0·55
1889	1,830	7	0·38
1890	1,540	5	0·32
1891	1,559	4	0·25
1892	1,790	4	0·22
1893	1,648	6	0·36
1894	1,387	7	0·50
1895	1,520	5	0·33
1896	1,308	4	0·30
1897	1,521	6	0·39
1898	1,465	3	0·20

Of the 1,465 persons inoculated 141 had been bitten by persons experimentally proved to be mad, 855 by animals declared to be mad, and 469 by animals suspected of being so; while 132 had been bitten on the head, 914 on the hands, and 419 on other parts of the body.

THE DUTIES OF PROVINCIAL PROFESSORS constitute the subject of an article in *Nature*, which may be commended to all who are interested in the improvement of university education. During the past twenty years, it is pointed out, numerous centres of university education have grown up all over the country, and much public money has been spent in their endowment, Some of these colleges have already risen to the rank of universities with the power of conferring degrees; others are eagerly pressing forward in the same direction in the hope of competing with their more fortunate rivals. It is urged that if this multiplication of universities is not to result in lowering the prestige of British university degrees, but to enable us to compete in the matter of scientfic education with foreign countries, it is of the utmost importance that the professorial staffs of our younger colleges should be placed under the most favourable positions for establishing the reputations of both themselves and of their colleges in the matter of higher study and research. "The time appears to have come when we must face much more boldly than hitherto the question whether the conditions attaching to provincial professorships and lectureships, even in some of our most successful university colleges, are conducive or inimical to progress in such respects." The manner of improvement which is favoured by the writer of the article is the shortening of the hours during which professors may lecture, and the devotion of the rest of their time to research, on the lines of what is done in Germany and America. Our modern centres of university education are said to be largely bound down to the policy of attracting the greatest number of students, not by the reputations of their professors, but by the attractions they offer in small bursaries and in facilities for cheaply acquiring pass degrees. Under this system a professor may give fifteen lectures a week or more, and spend most of the rest of the day in the laboratory; but there is no limit to the extraneous work required of him by his Council or Governing Board, beyond that research work forms no part whatever of his obligations.

THE ALLEGED PRACTICAL RESULT of the system described above is that our modern university centres, whether chartered or not, are devoting their endowments to competing for cheap pass degrees with one another, and with private institutions and tutors who prepare for London University and similar examinations. The students spend the whole day in class-rooms and in laboratories, and when they have done the exercise work required by their teachers the day is gone, and they are too tired to think over what they have learnt. Their professors are thus required to do the thinking for them. In conclusion, the following are suggested as directions where reform is most needed:—(1) Discontinuance of matriculation preparation—work which naturally belongs to the province of schools and crammers; (2) recognition of research work rather than tutorial instruction of pass candidates as the main duty of a professor outside his class-room; (3) reduction of the hours of class work, both of teachers and students; (4) revision of the now precarious conditions under which provincial appointments are tenable; (5) attraction of public attention to the importance of providing facilities for professorial research; (6) the appointment of more and better paid assistant-lecturers and demonstrators; (7) a more judicious expenditure of scholarship money, which should be restricted to honours students.

A CURIOUS ARCHÆOLOGICAL DISCOVERY is reported from Paris, where the excavations in progress in connection with the widening of the Rue du Plâtre have resulted in bringing to light an apothecary's laboratory dating from the seventeenth century. The objects discovered include apparatus employed by the chemists of the period in the manufacture of drugs. Information as to the nature of these drugs has also been found in the laboratory, as the jars and other recipients in which they were kept have been unearthed with their inscriptions intact. Among the substances sold to confiding patients by this bygone chemist were tincture of pebbles, oil of bricks, viper's oil, and toad salt.

BEECH TREES INJURED BY LIGHTNING AND FUNGI at Belvoir Castle and Harlaxton Manor form the subject of an instructive report by the consulting botanist to the Royal Agricultural Society, a summary of which appears in the *Times*. The greater number of the injured trees presented the appearance of dead tracts of bark and wood from eight to twelve inches wide, running for a long way down the stem of the tree. The bark had begun to crack and fall off. The wood exposed below was hard and dead, and cracked with numerous shallow fissures. It was not injured by fungi. Along the edges of the injured tract the uninjured bark and stem were developing a healthy and vigorous callus, which was gradually covering the dead wood, and repairing the injury. This thickening callus assisted in pushing off the dead bark. In the early stages of the injury water obtained access to the space between the dead bark and the wood. The water gradually found its way through cracks and small openings in the bark lower down the stem. In oozing slowly out, the water supplied food for the growth of *Nostoc* and other more minute Algæ, which formed dark patches on the bark. The injury to these trees seems to have been caused by lightning, the active tissues between the bark and the wood having been killed. A smaller number of trees were being destroyed by a parasitic fungus. The mycelium of the fungus was penetrating the wood in every direction, and two or three specimens of the fungus were observed, which exhibited the beginnings of fructification. The fungus was a *Polyporus*, most probably *P. fomentarius*, but the specimens were too young to permit the species being determined with certainty.

NOTES ON THE PLYMOUTH CONFERENCE.

The Plymouth Meeting of the B.P.C. is now an event of the past, but pleasant recollections of it are likely to be ever-present with a large number of British pharmacists and their friends. Specially favoured in every possible way—with superb weather, boundless hospitality, and well thought-out arrangements that worked without the least hitch—the visitors to the West Country during the past week have spent a most enjoyable holiday and combined an unusual amount of business with much unalloyed pleasure. The only drawback was the fact that each day contained only twenty-four hours, whereas the most tempting opportunities were afforded for occupying a much longer time during each revolution of the earth upon its axis. Everything, in fact, conspired to tempt the visitors to expend more energy than they could well spare during the time available, and it speaks well for the skill with which the exceptionally heavy programme was devised and carried out that so many persons should have been induced to miss nothing and to persevere to the very end of the week's alternation of work and play. The Sessions of Conference were probably never better attended during recent years, and the various social gatherings were all extremely well supported, so that interest appears to have been equally well sustained all round.

The Reception at the Assembly Rooms on Monday evening was an exceptionally brilliant affair. The President and Mrs. Payne, assisted by Miss Turney, welcomed some three hundred persons who were, for the time being, solely on pleasure bent, Mrs. Payne holding a magnificent bouquet presented to her by the chairman of the Local Committee. The elaborate programme of music prepared for the occasion was thoroughly appreciated. Major Rendle, V.D., an old friend of the pharmacists in Plymouth, had charge of the musical arrangements, and, thanks to his great experience in matters of this kind, they worked like a charm, the numerous items being most expeditiously got through, without too great a tax on the patience of those who wished to converse with their many friends. Everything was good, the overture and selections by the members of the band of the Royal Marines, the recitation by Mr. J. Kinton Bond, the violin solos by Miss Lily Dyke, the cornet solo by Sergeant Ough, the 'cello solo by Mr. Pike, and the songs by Miss Maud Stephens, Mr. J. Skelton, Mr. T. W. Balhatchet, and Major Rendle. The reception and concert were held in a convenient and artistically-decorated room, refreshments were served in another capacious apartment, and in a side room were the scientific exhibits. Mr. R. Hansford Worth had a fine show of local Foraminifera, together with a calculating machine; Mr. T. V. Hodgson exhibited some interesting marine biological specimens, and Mr. J. D. Turney had on view the lantern slides which he had prepared to illustrate his recent lecture on the life history of *Ranunculus acris*. Regarded as a whole, no reception of late years has approached the Plymouth one in point of interest, and its success gave the note to all the subsequent proceedings.

The Opening of the Sessions of Conference on Tuesday morning was remarkable for the crowded audience, for the number of ladies seated on the official bench, and, above all, for the interest taken in the meeting by the local authorities, as evidenced by the attendance of the Mayors of Plymouth and Devonport, and the Chairman of the Stonehouse District Council, all these being resplendent in their chains of office. Each one seemed to feel it incumbent upon him to attempt to outvie the others by the heartiness of his greeting, and Dr. May, the Vice-President of the Plymouth Medical Society, gave the finishing touch in that respect, whilst also gratifying his audience by the expression of opinion that all drugs and medicines should be dispensed by scientifically educated and duly qualified persons. The start being thus happily given, the President found the audience in a fitting condition of receptivity when he rose to deliver his address, and, owing to the commendable brevity of his remarks on the history of pharmacy in Ireland, those who left the Law Courts before the reading of papers was proceeded with were not too exhausted to take a short stroll around the town before lunch. Some paid a visit of inspection to the fine exhibition of oil paintings and water-colour drawings, thrown open freely to the members of the Conference at Messrs. Harris and Sons' galleries, and others spent the interval in securing formal election, as honorary members, of the local Conservative and Liberal Clubs, both of which institutions kindly and freely admitted the members of the Conference to all the advantages at their command.

The Luncheons on Tuesday and Wednesday were better served than any others within the memory of persons who regularly attend the annual meetings. Possibly this was in great measure due to the fact that no tickets were supplied after Monday, July 17, the date fixed by the local committee as the latest for receiving applications. So widely and clearly had it been made known that this restriction would be rigidly enforced, that no applications were received after the appointed day, but the Hon. Local Secretary was almost overwhelmed by the crowd of telegrams which reached him on July 17. As a result of this early closing of the lists, a clear week was left to conclude all the arrangements and, as the event proved, nothing was left incomplete. More than two hundred sets of tickets were disposed of, and yet every individual who sat down to luncheon on any of the three days found ample accommodation, was promptly served, and went away without any sense of grievance. So much for perfect organisation and the maintenance of rules. But praise must also be accorded to the caterers who performed their duties so well, whilst the comfort of the party was materially conduced to by the excellent ventilation of the Corn Exchange, where the luncheons were served. After luncheon on Tuesday came more business for some, and more pleasure for most, personally conducted parties visiting various places of interest, and so occupying the interval until 4.30 p.m.

The Excursion to Looe on one of the Great Western Railway Company's tenders then attracted all but a few faint-hearted ones. Starting from the Millbay Docks, the s.s. "Sir Richard Grenville" passed Drake's Island and Mount Edgcumbe and so proceeded out of Plymouth Sound on its westward path, close in by the wonderful Cornish coast, and passing various points of interest *en route*. Tea and other refreshments were served on board to such as were not disinclined to take the risk of feeding the fishes, and when Looe had been reached without any casualty, boats were found to be in waiting to convey the visitors ashore or up the beautiful rivers from which the picturesque village takes its name. The time thus spent were well repaid, and regrets were freely expressed when the signal was given for return. The voyage to Plymouth was as unclouded by disaster as the outward trip, except that one or two individuals were overcome by the terrors of the deep and gave freely of that which they had, without thought of return, though not without qualms. Landing at 9 p.m. the party broke up to spend the evening in such ways as seemed best to its individual components, and from private information to hand those ways were in many instances merry ones.

The Concerts and Dancing on Wednesday, filled the day's cup to the brim. Those who attended the Sessions of Conference—perspiring freely and hoping for the end—met their cooler pleasure-seeking companions at luncheon and again during the last hour of the serious business of the meeting, when the selection of London as the place of meeting for 1900 was vigorously applauded, and the

election of Mr. E. M. Holmes as President for the year 1899-1900 no less appreciated. An excursion to the Barbican and up the river Plym had occupied the ladies during the morning, and the ramparts of the Citadel were visited during the early afternoon. At the close of the final business meeting, tea was served in the Assembly Rooms, and there was then an adjournment until 8 p.m., the time at which the concerts were announced to begin. A quite unusual feature of the concerts was the large number of men who had summoned up energy to don evening dress, and so were in fit condition to attend the ladies' drawing-room concert and to take part in the dances which followed. Mr. C. J. Park, the popular president of the local association, was the chairman of the smoking concert, and Major Rendle again distinguished himself by the extremely capable manner in which he conducted the musical part of the programme. Mrs. Theodore Wright, with her marvellous recitations, was undoubtedly the great attraction of the evening, but special reference must also be made to Mr. J. Pardew's perfect accompaniments, to the special glees by the St. Andrew's Quartette, and to Mr. Richards' rendering of the "Death of Nelson," and "The Queen of the Air." Mrs. J. F. Harrington, of London, was in excellent voice, Miss Elsie Harrington's violin solo gave great pleasure, Mr. Glyn-Jones sang a hunting song, Mr. J. D. Turney gave a recitation—"The Revenge," and the solos by Mr. Pike on the 'cello and Sergeant Ough on the cornet were also amongst the performances to be recalled with a sense of satisfaction. Brock's band discoursed exquisite music for the benefit of the dancers and, despite the high temperature indicated by the thermometer, dancing was kept up till after midnight. Rumour has it, by the way, that long after "God Save the Queen" had been played, sleepers in neighbouring hotels were awakened by an extremely hearty rendering of "Auld Lang Syne," but that performance no more constituted part of the official programme than did the nightly engine whistling competition near Farley's Hotel, a treat specially reserved for those who stayed at that establishment.

The Excursion on Thursday started in glorious weather, and it was not long before all the visitors were disporting themselves in Mount Edgcumbe Park and Gardens, which were thrown open for the day by kind permission of the Earl of Mount Edgcumbe. From the beautifully wooded heights magnificent views were obtained of the Three Towns, the Sound, and the open sea, and subsequently a merry company assembled on Cremyll Beach to await the return of the steamer to Plymouth and imbibe modest liquid refreshment at the neighbouring inn meanwhile. Returning to the Promenade Pier, luncheon was found waiting in the Pavilion, and at the conclusion of that repast there was the usual round of toasts and responses. The retiring president, the local committee, the Earl of Mount Edgcumbe, and the ladies were the subjects of the toasts, all of which were happily responded to. But in no case was the applause heartier than when a lovely bouquet of flowers was presented to Mrs. Theodore Wright by Mr. Park, acting on behalf of the local committee, as a slight acknowledgment of the assistance given by her at the concerts on the previous evening. After a brief interval, the steamer was boarded once more, and the party was away for a cruise round the Sound and up the beautiful river Tamar. Tea was served on board by the willing hands of the members of the local committee, and everyone was satisfied on deck without any confusion. To quote the effusion of a local scribe, it was afternoon tea of the kind ladies love to dawdle over, "especially when, as in this case, they were waited on like princesses, and the mere men were useful for once in a while." Subsequently the boat stopped at Pentillie, permission having been secured to visit the beautiful grounds, and afterwards the party proceeded to Calstock, where the natives did a brisk trade in baskets of fresh fruit. The boat was then turned for home again, and during the return trip a portion of the Royal Marine Band made the proceedings cheery, a vocal concert being also started and kept up with much spirit. The performers were Mr. J. Richards, Mr. Balhatchet, Mr. Glyn-Jones, Mr. Silson, and others, the choruses being such that all could assist. Mr. J. Kinton Bond added a disquisition on "physic," which was highly diverting, and "as the shadows of the evening crept o'er the sky" further refreshments were supplied in abundance. Altogether a most enjoyable day was spent, everyone having a most delightful time. Arrived at Plymouth once more, hearty cheers were given for the local committee and others who had been instrumental in providing entertainment for the visitors, after which a general dispersal took place, and the official programme of proceedings was at an end.

The Mayor's Garden Party on Friday, however, had proved to be a sufficient inducement for a large number of members and friends to spend another day in the West Country. The morning was spent in visiting the dockyards at Devonport and the Marine Biological Laboratory, or in sailing around the Sound, and after an early lunch the visitors hastened by train or coach to Yelverton. A large party took part in the coaching excursion organised by Mr. Park, leaving the Guildhall Square shortly after 1 p.m., and proceeding direct to Yelverton by way of Roborough Down. Alighting near Roborough Rock, the visitors wended their way on foot across the moor for the remaining distance, a few leading lights of pharmacy narrowly escaping being run over by the reckless driver of a conveyance. Mr. George Breeze, Secretary of the Plymouth Association, was actually knocked down and run over, but, although badly shaken and obliged to return home at once, he was, fortunately, not seriously injured. The garden party was a dream of loveliness. Some eight hundred guests attended during the afternoon, and the surrounding moors and tors served as a fine setting to the brilliant array of picturesque finery, flashing in the bright sunshine. Surely there never was a more successful garden party. The ladies present were all dressed in their daintiest and best; the gentlemen had for once agreed to adopt a common-sense view and dress in accordance with the place and the weather. As a result, everyone was content, and Alderman Pethick must have felt well satisfied with the success of his attractive outdoor entertainment.

The Return Drive of the Coaching Party, after leaving the garden party, was by way of Burrator, Sheepstor, Cadover Bridge, and Plympton. There were some half-dozen coaches, each holding twenty-two persons, and a few smaller conveyances, the occupants of which took advantage of the arrangements which had been especially made on behalf of those who had engaged seats in the coaches. Soon after leaving Yelverton the beautiful wooded valley in which the new Burrator Reservoir is situated came in sight, and the coaches then crossed the dam, skirted Sheepstor, and proceeded by narrow and circuitous downward paths to Cadover Bridge, where tea was served to invited and non-invited alike. After rest and refreshment, the new President of the Conference ascended to the summit of a grassy slope, and there proceeded to expatiate upon the undoubted virtues of the members of the Local Committee, and particularly of the Ladies' Committee and Mrs. W. H. Woods, their Hon. Secretary. All persuasion having failed to induce Mrs. Woods to respond in person, Mr. Park took up the tale and told a wondrous story of a draft Pharmacy Acts Amendment Bill, the effect of which, if it became law, would be to render unqualified company pharmacy illegal, abolish chemists and druggists, prohibit branch shops, and limit the sale of all drugs, etc., to pharmaceutical chemists. To say that the welkin rang as the provisions of this proposed measure were gradually unfolded would be to describe the effects but mildly. Cheer after cheer startled the few living creatures within earshot of the erstwhile deserted spot, now so abruptly invaded by the representatives of British pharmacy, and the ever-popular member of Council for Plymouth and the West Country became transformed for the time being into a demi-god. But all things must end, so the

coaches were loaded up once more, and the visitors prepared to leave Dartmoor and its manifold beauties. As the evening wore on a most magnificent sunset was witnessed, then Plymouth Sound and the Eddystone Light hove in sight, and as the darkness descended the Guildhall Square was reached for the last time prior to the departure of the Conference visitors from Plymouth.

LEGAL INTELLIGENCE.

Proceedings under the Pharmacy Acts.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN *v.* THOMSON.

At Airdrie Sheriff Court, before Sheriff-Substitute Mair, on July 27, John Thomson, in the employment of Dr. J. Martin Thomson, Graham Street, Airdrie, and residing at 113, Hallcraig Street, Airdrie, was charged, at the instance of Richard Bremridge, 17, Bloomsbury Square, London, W.C., Registrar under the Pharmacy Acts, 1852 and 1868, with concurrence of the Procurator Fiscal for the Airdrie district, with an offence against the 1st and 15th sections of "The Pharmacy Act, 1868," in respect that the said John Thomson, not being a duly registered pharmaceutical chemist or a chemist and druggist within the meaning of the Pharmacy Act, 1868, sold on May 22 last within Dr. Thomson's premises, No. 141, Graham Street, Airdrie, a quantity of laudanum or tincture of opium to Maggie Waddell, residing at 70, Clerk Street, Airdrie.

Mr. Peter Morison, jun., S.S.C., of Messrs. P. Morison and Son, S.C.C., Edinburgh, the solicitors in Scotland for the Pharmaceutical Society, appeared for the prosecutor.

Mr. Morison: This is merely a pleading diet, my lord. If there is any defence, I must ask that the case be adjourned for proof.

Sheriff Mair: He is going to plead guilty.

The accused having pleaded guilty, Sheriff Mair asked him if there were any special circumstances regarding the sale about which he wished to give an explanation, The accused remarked that there were none.

Mr. Morison: On behalf of the prosecutor, I have to ask the Court in this case to impose a substantial penalty. The facts are that on the date libelled in the complaint and at an early hour in the morning the accused sold the laudanum to the child Maggie Waddell without making any inquiry whatever. The quantity sold was a lethal dose, and the child's mother died in consequence of having taken the laudanum in question.

Sheriff Mair: I think this a purely technical offence. Everyone knows that there is a properly qualified man in the premises. It is quite impossible always to have such sales made by qualified persons. If that were so there would be no end to these prosecutions. I fine accused one half-crown.

Mr. Morison: I ask your lordship to find the accused liable in costs.

Sheriff Mair: There can be no costs awarded under the Act.

Mr. Morison: That is not so. By the statutes under which the complaint is brought, it is competent for the Court to award costs against the accused up to the sum of £2.

Sheriff Mair: I refuse costs here. I do not approve of the Pharmacy Act, and I will not award expenses.

Mr. Morison: With deference, my lord, I submit that that is no proper reason for refusing to carry out the provisions of the Statute and for refusing the prosecutor costs, although I admit that the question of costs is always one within the discretion of the Court.

Sheriff Mair: I am not going to give expenses. I have no sympathy with the Pharmacy Act, and that is also the reason why I have made the penalty so small.

The Supply of Methylated Spirit to Chemists.

IMPORTANT CASE AT EXETER.

At the Exeter Police Court last week Mr. Charles Edward Rowe, of the firm of Messrs. E. James Rowe and Company, oil and colour merchants, 192, High Street, was summoned by the Excise authorities for selling between March 12 and April 26 more than one gallon of methylated spirit at a time, to wit, thirty gallons, in contravention of the Spirits Act.

Mr. G. H. Dennis, barrister, of Somerset House, prosecuted on behalf of the Excise authorities, and Mr. G. H. Harris (Messrs. Ford, Harris, and Ford, Exeter) appeared for the defence, and pleaded not guilty to the charge.

Mr. Dennis, in laying before the Bench the facts of the case, said that the Act under which these proceedings were taken stated that if more than one gallon of methylated spirit was sold by the retailer at one time, the retailer incurred a penalty of £50. The licence to sell methylated spirit as a retailer cost 10s., but a methylator's licence, which entitled one to supply the spirit, cost £10 10s. If Mr. Rowe wished to sell more than one gallon at a time, he could take out a methylator's licence. The facts in this case showed that a list sent round by this firm to its customers and the public included methylated spirit. On March 13 last Messrs. Rowe received a requisition from Mr. F. Cutmore, chemist, of St. Marychurch, Torquay, for thirty gallons of methylated spirit. He sent the usual order, signed by the supervisor of the district, which showed that he was duly licensed to receive the goods. Messrs. Rowe received this order, and they sent a communication thanking him for the same, and intimating that they had ordered it to go forward to Messrs. Preston, of Liverpool. They also asked Mr. Cutmore to alter the name of the methylator on the counterfoil of the order; they had already done so on the order itself. The goods were duly supplied by Messrs. Preston and Co., and on April 11, the defendant sent the account, amounting to £4 11s. 3d., excluding discount, to Mr. Cutmore. This showed that a contract had previously been entered into with the defendant to sell. Messrs. Preston and Co. also sent an invoice to Mr. Cutmore. He (Mr. Dennis) submitted that the defendants clearly accepted the order and entered into the contract to sell. The law was distinct on the question of supply and sale.

The Chairman (Mr. J. W. Petherick): Are the facts admitted?

Mr. Harris: With one exception and that is that the invoice referred to from Messrs. Preston and Co. was sent off at the same time as the spirit, and, of course, arrived before.

Mr. Harris, in defence, said that the sole question in the case depended mainly in what order the facts occurred. His friend argued that there was an acceptance of the order; and he would say distinctly that a careful examination of the facts showed that there was no acceptance of the order from Mr. Cutmore, but that the defendants assisted in making a contract between a third party. If they looked at the letter sent to Mr. Cutmore they would notice that he said he was "obliged for the order for the spirit, and had ordered the same to go forward at once." And then the communication went on, "Will you please alter the name of the methylator in your book to Messrs. Preston, Liverpool; we have already altered your request note." What was the intention in the alteration of the order? Why, the defendant wished to imply that he had no intention to supply the spirit. In the first place he had not got it, and in the second place he had no right to under the Act. On the receipt of the letter what did Mr. Cutmore do? He probably thought, "Oh! yes. I made a mistake, I should not have ordered from Rowe, but from Preston and Co. I'll alter it in my book." Whether Messrs. Rowe had a right to pass on Mr. Cutmore's order to Messrs. Preston and Co. had nothing to do with the Excise authorities. He would also draw the magistrates' attention to the fact that the first words on the invoice sent by Preston and Co. were "Bought of Messrs. Preston and Co." His friend had tried to convince the Bench that there was a contract before the order was sent on to Liverpool, but he (Mr. Harris), said that it was exactly the reverse. Messrs. Rowe's letter to Mr. Cutmore was to the effect: "No, we cannot execute the order, but we will send it on for you to Messrs. Preston and Co., and we will alter the order." Supposing the order was originally made out to Messrs. Preston and Co., what could the Excise authorities have done then? Surely Messrs. Rowe would not have had anything to do with it. The summons might in that case be just as well taken out against the Postmaster-General for forwarding the order. With regard to the sending of the bill to Mr. Cutmore by the defendants, he (Mr. Harris) said that had nothing whatever to do with the contract. Mr. Dennis had said that the contract had been entered into when the defendants received the order and had dealt mainly on that fact. The magistrates had simply to consider the case as set before them by the prosecution, and if the contract was entered into as Mr. Dennis had alleged, then what came afterwards did not bear upon it.

Mr. Dennis submitted that the alteration in the permit was made in order that no inquiry should be made by the Inspector, who, if the permit did not correspond with its counterfoil, would naturally investigate.

Mr. Harris said that Mr. Dennis had no right to make such remarks unless he could prove them.

The Bench were of opinion that there had been a sale of spirit, and inflicted a fine of £5 inclusive.

FEDERATION OF LOCAL PHARMACEUTICAL ASSOCIATIONS.

A meeting of delegates of various local associations was held at the Royal Hotel, Plymouth, on Tuesday evening, July 25, 1899, and by adjournment at the same place on the afternoon of Wednesday, July 26, Mr. J. Rutherford Hill, Edinburgh, in the chair. The following gentlemen were present:—

Mr. J. Rutherford Hill, Edinburgh District Chemists' Association.
Mr. Geo. Foggan, Newcastle Chemists' Association.
Mr. H. L. Everson.
Mr. Jas. Cocks, Plymouth, Devonport, Stonehouse and District Association.
Mr. J. M Heaton, Burnley and DistrictChemists' Association.
Mr. R. L. Gifford, North-east LancashireChemists'Association, Blackburn.
Mr. George Breeze, Plymouth.
Mr. R. Shorrocks, Darwen.
Mr. F. H. Ferrier, Forfarshire Chemists' Association.
Mr. P. F. Rowsell, President Exeter Association of Chemists and Druggists.
Mr. A. E. Hobbs, Tunbridge Wells and District Chemists' Association.
Mr. J. Hinton Lake, Exeter Association of Chemists and Druggists.
Mr. R. W. Silson, Bradford and District Chemists' Association.
Mr. R. Brodie, Glasgow and West of Scotland Pharmaceutical Association.
Mr. N. V. Pidd, Manchester Association.
Mr. Chas. G. Gates, Brighton Association of Pharmacy.
Mr. T. H. Wardleworth, Liverpool Chemists' Association.
Mr. E. Saville Peck, Cambridge Pharmaceutical Association.
Mr. John Smith, Liverpool Chemists' Association.
Mr. G. H. Brunt, Midland Chemists' Assistants' Association.
Mr. J. Poole, Midland Chemists' Association.
Mr. J. Park, Plymouth, Devonport, and Stonehouse District Association.

The minutes of the last meeting held in Belfast were read and confirmed.

The Hon. Secretary's report for the session just closed was read by Mr. T. H. Wardleworth, in the unavoidable absence of the Hon. Secretary.

The Hon. Secretary's report showed that during the past year seven communications were addressed to the secretaries of local associations, and same received varying amounts of attention from the associations interested, the details of which have been fully reported in the trade papers from time to time. Some of the questions brought before the trade were very highly approved in some instances, and almost every local association of importance, whether affiliated with the Federation or not, had discussed the programme fully.

The company question naturally occupied a great deal of attention during the year, and in response to the point raised by the Federation the individual opinion expressed by many of those connected with historic firms is that they are quite prepared to modify the title of their businesses, provided the majority of chemists consider it to the advantage of the calling generally.

The additions to the Federation during the year have been very gratifying, and many associations are still coming in.

Considerable satisfaction was expressed with the action of the Pharmaceutical Society in reference to the regulations regarding the storage of poisons.

The Secretary attributes the increased support to the excellent programme laid out by the Federation in Belfast.

In conclusion, the report pointed out that the general weakness of the Federation was the want of official recognition; the want of a permanent executive, as the Chairman and Secretary cannot always represent the voices of the various local bodies, and the necessity for arrangements being made for more frequent meetings.

It was resolved that the gratifying and excellent report as read be adopted, and that an abstract of the proceedings be sent to the various trade papers.

The Treasurer's report, showing a balance in hand of £1 7s. 11d., was passed, and it was resolved that the associations who had not yet paid should be pressed to pay their contributions at once.

It was resolved that:—

It is desirable that nominations of local secretaries of the Pharmaceutical Society should proceed from local associations and local organisations. That the objects of the Federation would be more effectually served if local secretaries were appointed by the associations to represent them on the Federation, and that the rules of the Federation be altered wherever it may be necessary to effect a closer co-operation between local associations and the Pharmaceutical Society's local secretaries in promoting the interests of these associations and of the Pharmaceutical Society.

It was resolved that the undermentioned rules be altered as follows:—

Rule 2.—That it shall consist of representatives from each properly constituted and subscribing local Pharmaceutical or Chemists' Association, or other organisations of chemists in England, Scotland, and Wales. That each association shall have the right to appoint one delegate for each twenty-five members. An association having under twenty-five members shall send one delegate; from twenty-five to fifty members, two delegates; from fifty to seventy-five, three delegates; above that number, four delegates.

Rule 3.—That the objects of the Federation are:—

1. To establish more intimate communication and co-operation between local associations and between the Pharmaceutical Society's local secretaries.
2. To advise and assist in the promotion of local associations and local organisations.
3. To assist the Council in securing a sufficient number of efficient local secretaries.
4. To promote the interests of the Pharmaceutical Society and of local associations in every possible way.

Rule 4.—That a chairman, secretary, and executive committee, consisting of chairman, secretary, and three other members shall be appointed annually.

Rule 5.—That every local association of fifty members and upwards shall pay an annual subscription of £1 1s., excepting associations and committees whose membership is less than fifty; these shall pay an annual subscription of 10s. 6d.; or, less than ten members, 5s.

Rule 6.—That the annual meeting, subject to the approval of the Executive Committee, be held in the same town and during the same week as the annual meetings of the British Pharmaceutical Conference. Representatives of five associations shall form a quorum.

Rule 7 to be made Rule 8, and an additional rule to become Rule 7, viz.:—

That all local secretaries to the Pharmaceutical Society be admitted to the annual meetings, but that only those representing subscribing associations and committees be empowered to vote in the appointment of officers and Executive Committee.

It was further resolved that the following resolutions should be sent to the various organisations comprising the Federation for consideration and discussion:—

1.—That it is the urgent business of the Federation to bring about:—
(1.) The earliest possible settlement of the question of chemists' titles.
(2.) A large extension of Part II. of the Schedule.

2.—That all the associations affiliated shall be so arranged as to form sectional groups or districts, each association to have its own representative. These to meet at the most convenient centre whenever occasion requires. The country to be divided into five sections, namely:—

SCOTLAND.
Forfarshire Chemists' Association, Dundee.
Glasgow and West of Scotland Chemists' Association.
Inverness Chemists' Associatio.
Aberdeen Chemists' Association.

ENGLAND—NORTH EASTERN.
Newcastle and District Chemists' Association.
Hull Chemists' Association.
Sheffield Chemists' Association.
Bradford and District Chemists' Association.
Halifax Chemists' Association.
Dewsbury Chemists' Association.
Grimsby and District Chemists' Association.

NORTH WESTERN.
North-East Lancashire Chemists' Association.
Burnley and District Chemists' Association.
Bury Chemists' Association.
Liverpool Chemists' Association.
Manchester Chemists' Association.

MIDLAND.
Midland Chemists' Assistants' Association, Birmingham.
Midland Pharmaceutical Association, Birmingham.
Nottingham and Notts Chemists' Association.

SOUTHERN.
Cambridge Pharmaceutical Association.
Tunbridge Wells Chemists' Association.
Brighton Chemists' Association.
Plymouth Chemists' Association.

The representatives of each section shall constitute the Executive Committee of the Federation.

3.—That a meeting of the whole of these representatives may be called at any time during the year, providing representatives from three sections send in a request to the secretary for such meeting to be called.

4. That the Secretary of the Federation send out circulars to all local associations that have not joined the Federation, explaining its object and work.

5. That a definite programme of the proceedings at the annual meeting of the Federation be sent to the secretaries of the various local associations, at least ten days before the date of that meeting; also that more explicit instructions as to the time and place of the meeting be given.

It was resolved that the heartiest vote of thanks be accorded to Mr. W. L. Currie for his efficient and painstaking work in connection with the presidency during the past year; and the meeting wished it to be placed on record that they deeply sympathised with Mr. Currie in the cause of his absence from the meeting. In view of his emphatic statement that he could not again occupy the chair of the Association, it was resolved to appoint Mr. J. Smith, of Liverpool, to the position of President.

It was resolved that the best thanks of the meeting be conveyed to Mr. R. C. Cowley for the indefatigable and highly successful work he had carried out on behalf of the Federation during the past year. As Mr. Cowley had definitely declined to again hold the post of Secretary, in consequence of the pressure of other work, it was unanimously resolved to appoint Mr. J. Cocks, of Plymouth, as Secretary and Treasurer of the Federation.

Members of the following five associations were unanimously appointed to constitute the Executive Committee for the ensuing year:—Glasgow, Cambridge, Liverpool, Midland and Plymouth.

EXTRACTS FROM CONSULAR REPORTS.

The Quantity of Borate of Lime exported from Arequipa (Peru) in 1898 was 154,939 quintals, or 7,127,194 kilos., worth about £5 per ton of 2,240lb, o.b. Mollendo. The previous year 277,790 quintals (12,777,340 kilos.) were exported, and in 1896 146,451 quintals (6,735,090 kilos.). The lake from which the borate is extracted is said to have been sold to an English company for £100,000. The area is set down as 1,294 estacas of 40,000 square smetres each.

The Ruling Price for Persian Opium in some of the Persian markets is frequently higher than the price quoted for the same article at Hong Kong. This is accounted for by the fact that at Yezd, which takes most of the drug in its unprepared state, it is adulterated with Sarcocolla gum or resin (*Penaea mucronata*) and other ingredients, the proportions being ten of opium to six of the ingredients. It is then made up and sent to China, where it is said that opium so prepared finds a ready sale. According to a recent report, the merchants of Yezd tried very hard to keep the secret of this adulteration in their own hands, but their competitors in Ispahan found it out, and are now hard at work in the same line; for it is stated that the Chinese authorities do not analyse the opium for the morphine contained it; as long as it complies with certain conditions they are content, and this adulterated opium appears to fulfil the conditions.

Various Effects are Produced by the adulteration of Persian opium referred to in the previous paragraph. In the first place the Yezd merchants engaged in the trade, as indicated above, can afford to pay much higher prices for the opium than those engaged in the legitimate business. Then, too, the demand for the Yezd and Ispahan markets has caused a rise in the price of Sarcocolla resin, which now costs about 40 krans per mân, whereas formerly it cost only 8 to 10 krans per mân. Also, as Consul Preece points out, by this wholesale adulteration a very grave injustice is being done to British traders in the East. Opium was one of the few means by which they were able to remit home at a fairly remunerative rate. Now, by reason of the adulteration, the market is closed to them. And, again, if this trade is largely extended, and there appears to be no reason why it should not be, it may compete with and affect the Indian opium trade.

Another Disadvantage under which the European merchant in Persia labours is that while he has to pay 5 per cent. export duty on opium, the Persian only pays something under 2½ per cent. This just makes the difference enabling the Persian to export to the home market, while the European is debarred from it.

The People of Kermanshah (Persia) and its villages, after the grain harvest is garnered, distribute themselves all over the districts in search of gum tragacanth (Katira), which, when collected, they send into the town, where it is sorted and exported. The prices realised are said to be fairly remunerative, and the trade to be extending.

The Olive Oil Crop of the Ionian Islands (Greece) last year is reported once again to have been a failure, estimated not to exceed 2,000 tons. Consequently prices ranged too high to compete with other exporting markets. Only about 80 tuns of white oil were exported, and cost about £29 per tun of 256 imperial gallons, f.o.b. The greater part is sold for local consumption for the supply of markets on the mainland opposite, and also for soap-making. Pyrene, or green oil, extracted from the stone of the olive, is also produced, and used principally in soap boiling, its cost, according to the season of the year, and quality varying from about £24 to £30 per tun, f.o.b.

A Large Chemical Mill is reported to be under construction at Katfos (Norway). The production of chemical and mechanical pulp during 1898 at Drammen was about the same as the year before, but prices, especially of mechanical pulp, were lower.

A Project is Under Consideration to manufacture caustic soda in the Iea district (Peru), where large deposits of the necessary raw material are reported to be found.

LETTERS TO THE EDITOR.

The Company Trading Question.

Sir,—I am sorry to find the *P.J.* giving currency to the views of an Edinburgh correspondent who proposes, in reference to the company question, nothing short of compounding a felony. In the issue for July 29 he says, companies "have stolen our titles and usurped our functions," but, nevertheless, he coolly proposes that we should be prepared to receive them "into our fold." I should like to know who would be party to such a precious bargain, and the price to be given and received. I, for one, say no, for if companies have the same rights as we have, what need is there for fresh legislation to give them? If not, let us defend our rights, tooth and claw. The only means by which companies carry on their nefarious business is the assistance of blacklegs in "our fold." They are few, and that they may speedily become fewer is the earnest aspiration of the writer. The policy of masterly inaction hitherto pursued in regard to this matter is admirably hit off in an old couplet written about a certain stage in the Peninsular War:—

> "Earl Chatham, with his sabre drawn,
> Stood waiting for Sir Richard Strachan,
> Sir Richard, longing to be at 'em,
> Stood waiting for the Earl of Chatham."

In regard to the flagrant breach of Sec. 17 of the Pharmacy Act exposed in the Spalding case, the Council seems to say that the police should prosecute, while the police doubtless say the Pharmacy Act is the business of the Pharmaceutical Society, and so, perhaps, the offender may escape scot free. Such a chance of putting into force Sec. 26 may not occur again between this and the end of the world. Were the Privy Council urged to use the power conferred by that section it could not for shame's sake avoid doing so, otherwise that section would evidently be a dead letter. There seems to be a vast amount of *vis inertia* in the Council of the Pharmaceutical Society, which seems only capable of pettifogging attacks on village hucksters, like Mr. Winkle's valiant onslaughts on small boys.

London, July 29, 1899. E. Warrell.

Sir,—The *British Medical Journal*, April 8, 1899, says, "Experience has shown that it is practically impossible to secure a conviction, either against a company or its employees, for infringement of the Medical Acts," but it does not propose to remedy that mischief by registering Medical Companies. To see the lack of grip of the question at issue in our own case makes one almost despair of seeing that essential desideratum, a unanimous opinion; though we must presume that qualified chemists desire unanimity. How can we arrive at our desire by registering drug companies? Every other suggested remedy is subject to equally fatal objection, except the one embodied in the Council's suggestions. Why should chemists draw such preposterous conclusions from those suggestions? Why not look for and be satisfied with a reasonable definition—take this—(1) The chemist's title should be his alone; (2) On acquiring that title he should have work to do. Such a definition is made up of two just and elementary principles, which cover everything. The Council's suggestions—if clearly defined—are likely to get acceptance, because they are the least that an impartial tribunal can give. There cannot be a single argument brought against them, for the very sufficient reason that there is none. And as to the supposed contempt of the Lord Chancellor—fudge!—a mere figment of the imagination. He merely says your requirements are contentious; therefore, help yourselves—which is exactly what the *B. M. J.* says this week (*see p.* 148). Further, the Council's remedy tackles *the cause* of the mischief, whereas every other suggestion deals only with effects. The Council's suggestions—reasonably interpreted—give a common ground for uniting in the fight everyone who has passed the examinations of the Pharmaceutical Society; because they embody two principles which are fundamental, essential, and necessary for dignified existence—two questions of principle which must never be compromised, however accommodative we may be with details. Chemists, in following the Council's lead, are not asking for the moon (they who say so know it to be false). They are asking for the least they should take, they are asking for what can be got, but when that can be obtained it is to be decided only by thorough com-

bination amongst qualified chemists. I respectfully ask from fellow chemists a more than superficial consideration of these views,

Blackburn, August 1, 1899. R. LORD GIFFORD.

Standards for Drugs.

Sir,—It was a matter of regret to many that lack of time prevented adequate discussion of the paper on this subject communicated to the British Pharmaceutical Conference by Messrs. Moor and Cribb. The question is of vital importance to the drug trade, wholesale and retail alike. Whether the Pharmacopœia is a legal standard under the Food and Drugs Act may be left to lawyers to decide; but to the unsophisticated lay mind it would seem that a book which is the official standard under the Pharmacy Act must at least be good evidence in prosecutions under another Act framed by the same Legislature. However that may be, most of us are willing that our products should be tried by the Pharmacopœia, interpreted by the light of common-sense, and with an intelligent appreciation of the exigences of commerce with regard to storage, deterioration, and the effect of variations of temperature. In some cases the official processes for assay need slight modification, but alternative methods cannot be indiscriminately used, unless the results obtainable are directly comparable with those obtained by the pharmacopœial methods. For instance, in the standardisation of the preparations of ipecacuanha, it has been shown that there is undoubtedly waste of alkaloid in the B.P. process, but although in the interests of exact chemical and medical science it is highly desirable that the improved methods which have been suggested should be adopted in future editions of the Pharmacopœia, for the present commercial samples must stand or fall, according as they conform to the official tests or not. For supposing a manufacturer adjusts the strength of his preparations by the official process, and the public analyst judges them by (say) Naylor's method, the preparations will be found by the latter to be over strength, and in pharmacy it is as criminal to make things too strong as too weak. The case of the liquid extract of nux vomica is different. Here it is directed that the impure precipitate of ferrocyanide of strychnine shall be washed until free from bitterness, which direction, if followed conscientiously, may result in almost the whole of the strychnine being lost and the extract condemned. There are other details which require modification to ensure success with this somewhat difficult process, and I trust all analysts have studied or will study the valuable paper on this subject, by Harvey, which appeared in the *Chemist and Druggist* in January of this year (vol. liv., p. 61). A third class of official preparations are those for the analysis of which no directions are given, for example, Gregory's powder. Some extraordinary results have been obtained in the analysis of this powder, samples which have been prepared in exact conformity with the Pharmacopœia having been reported adulterated with magnesium carbonate to a considerable extent. For a full discussion of this subject, I would refer those interested to a paper by J. C. Umney (*C. and D.*, **53**, 515, Sept., 1898). With regard to the Conference paper, it was admittedly rather suggestive than decisive, and it is not my intention to criticise it in detail. One point may, however, be noted. Under malt extract it is stated that "the sample must be capable of converting its own weight of starch in ten minutes." No temperature at which this is to be tried is given, nor is the kind of starch specified, although Cripps showed, nearly ten years ago, that this has a very material bearing on the results. In conclusion, I would express a hope that the whole subject may be thoroughly discussed in your Journal during the next few weeks. Standards for foods may be left for others to determine. The use and abuse of preservatives is essentially a medical question, but in fixing standards for drugs the druggist should be consulted.

Exeter, August 1, 1899. H. WIPPELL GADD.

Conference Photographs.

Sir,—Doubtless many who attended the recent B.P. Conference meeting at Plymouth secured interesting snapshots during their visit to the West Country. I venture, therefore, as president of the local association, to ask any of your readers who may have obtained good negatives to favour me with two or three prints from each, as mementoes of one of the chief events in the history of the Association.

23, *Mutley Plain, Plymouth, August* 1, 1899.

C. J. PARK,
President.
Plymouth, Devonport, Stonehouse and District Chemists' Association.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Botanical (J. S. W.—31/28).—*Vicia villosa*, Roth.

Apprenticeship (H. J. H.—32/26).—The conditions vary greatly in different parts of the country, and even in the same town, but the tendency is to abolish premiums.

Hand Camera (R. H. R.—32/2).—Refer to our "Photographic Supplement" of April 15 last for particulars of suitable cameras. Several are described there, and all are equally good.

Dental and Medical Examinations (E. A. T.—32/4).—Write to the Registrar, General Medical Council, 299, Oxford Street, London, W.

Books for the Major (W. C. S.—31/29).—The books mentioned in your list should amply suffice for your purpose. See the article on the subject in the Students' Number of the Journal, published September 10 last. Messrs. Watson and Sons, 313, High Holborn, London, W.C., will furnish you with a suitable microscope (1 in. and $\frac{1}{6}$ in. objectives) from five guineas upwards.

Recent Works on Diet (A. B.—28/23).—Yeo's 'Food in Health and Disease,' revised in 1897, 10s. 6d. Dobell's 'Diet and Regimen in Health and Disease,' 5s. Mrs. E. Hart's 'Diet in Sickness and Health,' 3s. 6d These are all standard works.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Abel, Addison, Andrews, Ashford, Ayrton, Boot, Bramley, Bulwer, Carr, Chase, Cummings, Devereux, Dodge, Eastwood, Ferreira, Fleming, Hall, Hubbard, Jowett, King, Mack, Porter, Rowell Stanford, Tichborne, Tilley, Warden, Wardleworth, Watson, White.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

CELLULOSE ENZYMES. Professor F. C. Newcombe has made a series of experiments on those enzymes which have the capacity of dissolving reserve cellulose or starch (cytases or diastases). He finds that the enzyme extracted from *Aspergillus oryzæ* attacks reserve cellulose with greater intensity than it attacks starch. The enzyme from the cotyledons of seedlings of *Lupinus albus* is very strongly cyto-hydrolytic, but very feebly amylo-hydrolytic. The same is the case with the enzyme from the cotyledons of seedlings and from the endosperm of *Phœnix dactylifera*. These enzymes act so feebly on starch, and so energetically on reserve cellulose, that they may be regarded as cytases, as distinguished from diastases. The very dilute enzyme of the malt of barley attacks reserve cellulose. With all the enzymes examined, those of *Aspergillus oryzæ*, *Phœnix dactylifera*, *Fagopyrum esculentum*, *Pisum sativum*, and *Lupinus albus*, the walls of the cells attacked become at first hyaline and gradually more and more transparent, and finally are altogether dissolved.—*Ann. of Botany*, 1899, p. 49.

PRODUCTION OF ALCOHOL IN PLANTS. From observations made on wheat and hazel, M. Berthelot finds (*Comptes rendus*, **128**, 1899, p. 1366) that under normal conditions of respiration and assimilation, minute quantities of alcohol are produced, probably formed from the decomposition of carbohydrates, in a similar way to that in which methyl-alcohol is produced in many plants. M. P. Mazé (*Tom. cit.* p. 1608) corroborates these results, and believes that the alcohol is formed in the living cells at the expense of the glucoses by a normal diastatic process.

VARIATION IN THE GRAFT AND INHERITANCE OF ACQUIRED CHARACTERS. M. L. Daniel publishes the results of a large number of experiments on the grafting of woody and herbaceous plants. The phenomena of grafting afford no exception to the general rules of the influence exerted on the development of a plant by its external conditions, and especially by those connected with the supply of nutriment; but this influence is not invariably exerted. These acquired characters of a graft may be exhibited only in the seed and embryo, and the author sums up strongly in favour of their perpetuation by heredity. The effects of grafting may be either the fixing and perpetuation of varieties or races already in existence, or it may be the direct production of new varieties, and hence the actual improvement of the race. This latter is especially the case with herbaceous plants.—*Ann. des Sciences Naturelles* (*Bot.*), **8**, 1-126.

CONDUCTING TISSUE OF VANILLA FRUIT. A. Tschirch has made a careful study of the so-called *tela conductrix* of the fruit of the vanilla, and decides that it is a true conducting tissue, through which the pollen-tubes penetrate. Not only the outer, but also the lateral walls of the epidermal cells which face the ovary are converted into mucilage, the pollen-tubes passing through the gelified cell-walls.—*Schweizerische Wochenschr. f. Chemie u. Pharmacie*, 1899, p. 105.

ABSORPTION OF NITROGEN BY PLANTS. From experiments on *Pisum sativum*, *Polygonum Fagopyrum*, *Avena sativa*, and *Sinapis alba*, L. Richter concludes that of these plants the pea only, and not mustard, oat, or buckwheat has the power of making direct use of the free nitrogen of the air; and that this power is independent of the tubercles. Combination with nitrogen in the soil takes place when there is otherwise a deficiency of assimilable nitrogen.—*Landwirthsch. Vers.-Stat.*, 1898, p. 221.

DIASTATIC FUNCTION OF INDIGOFEROUS PLANTS. From experiments made on *Isatis sativa* M. L. Bréaudat concludes that in those species of *Indigofera* and *Isatis* which yield indigo, the presence of alkaline bases or those of the alkaline earths, or their soluble or insoluble carbonates, is necessary for the formation of indigo, while the presence of acids or neutral salts is inhibitory. The oxidising power of the soluble oxydase contained in the sap is but feeble; but this power is increased by the presence of alkalies or alkaline carbonates.—*Comptes rendus Acad. Sci., Paris*, **128**, 1478.

REFRACTIVE INDICES OF SOLUTIONS. In a paper on determinations of the refractive indices of solutions, communicated to the Isis Society of Dresden, W. Hallwach gives an account of a differential method with grazing incidence, for which a double-trough refractometer has been used. The process described has been applied to solutions of brome-cadmium, sugar, di- and tri-chloracetic acid and their potassium salts; and the author investigates the relation between the refractive index and the degree of concentration, with a view of determining whether it is influenced to any extent by dissociation. The experiments show that such an influence, if it exists, is too small to be measurable with exactitude. This result is at variance, in the case of brome-cadmium, with those obtained by Le Blanc and Rohland, but the discrepancy is attributed to an error.—*Nature*, **60**, 329.

PURIFICATION OF ACETYLENE. P. Wolff states that the method of purifying acetylene proposed by Frank gives good results. It consists in the use of acid solutions of certain metallic salts, particularly copper chloride, and results in the transformation of part of the acetylene into aldehyde. It is claimed that 1 litre of the solution employed will purify 14 cubic metres of acetylene, and that the liquid can be regenerated by boiling, followed by aëration. As an alternative process the use of chlorinated lime containing a small quantity of an alkaline chromate is proposed. In this method the free chlorine is absorbed, and the acetylene does not undergo any decomposition.—*Journ. f. Gasbeleuchtung*, through *Chem. News*, **80**, 40.

CRYSTALLISATION OF EGG ALBUMIN. T. B. Osborne finds that the crystallisation of egg albumin is promoted on adding acetic acid to the half-saturated ammonium sulphate solution, as pointed out by Hopkins (*Journ. Physiology*, **23**, 131), because the crystallised egg albumin is a compound of the protein substance with acid. When the albumin is first mixed with the ammonium sulphate solution an alkaline reaction towards litmus can be detected, and a decided odour of free ammonia develops. After this solution has stood for some hours all evidence of free ammonia disappears, and the solution is then perfectly neutral to litmus, continuing so during the gradual separation of the albumin. The deposited substance, whether in the form of spheroids or crystals, reacts distinctly with litmus and with phenolphthalein, when filtered out and dissolved in water. By the addition of acetic acid, as directed by Hopkins, the albumin is obtained completely crystallised by a single precipitation, and without any concentration by evaporation. But Osborne finds that the substitution of a molecularly equivalent quantity of hydrochloric acid for the acetic acid causes the separation to take place even more quickly.—*Journ. Am. Chem. Soc.*, **21**, 477.

ON A SUPPOSED NEW GENUS OF THE N.O. MYRTACEÆ.*

BY R. T. BAKER, F.L.S.
Curator, Technological Museum, Sydney.

The plant which forms the subject of this paper was obtained on one of the high spurs radiating from Mount Corricudgy and forming the watershed between the Red Water and an unnamed stream; these waters eventually join and then enter the Widdin Brook which flows north into the Goulburn River—a feeder of the Hunter River.

Mt. Corricudgy is the culminating peak of the main dividing range which forms the watershed between the Hunter and Capertee or Colo Rivers, and reaches a height of over 3,000 feet. The spurs running north towards the Red Water are very rugged and precipitous, and it is only with the very greatest difficulty they can be ascended or descended. It is doubtful if they had ever been visited by white men previous to this trip, which was only possible through the courtesy of Mr. J. Dawson, L.S. for the District, who had been authorised by the Government to "traverse" this hitherto unsurveyed portion of N.S. Wales.

Mr. Dawson admitted it was the roughest piece of field work he had performed during his twenty-four years' experience of surveying.

As this district had never before been botanically "worked," and is almost inaccessible, one naturally expected to find some undescribed plants, and I cannot say I was disappointed. From my collection I now describe what I believe is an unrecorded plant. It was found on the extreme end of a bold headland facing Nulla Mountain, Widdin Brook meandering at the foot of the ranges.

RYLSTONEA, gen. nov.

A delicate, slender, upright plant, rarely with more than one or two stems, under 3 feet high. Leaves small, decussate, terete or laterally compressed. Flowers axillary near the ends of the branches, pedicellate in pairs, borne on a common peduncle. Bracteoles scarious only on the edges, concave, enclosing the bud, not very deciduous, not keeled. Calyx-tube cylindrical, adnate part prominently 5-ribbed; lobes 5, divided into digitate lobes about twice as long as petals. Petals 5, entire, on a constricted base. Stamens 10, alternating with staminodia shortly united at the base in a single ring; anthers globular, opening in two minute pores, connective prominent. Ovary 1-celled, about 8 ovules on a peltate placenta, with two processes at the summit; style exserted, longer and thicker than in the cognate genera, bearded towards the end; stigma terminal, small. Fruits unknown.

Species one.

RYLSTONEA CERNUA, sp.nov.

An erect, glabrous, rather slender shrub, from 1 to 2 feet high. Leaves decussate, crowded, terete or laterally compressed and then channelled above, narrowing below the middle, with a recurved point shortly petiolate, articulate on the decurrent portion of the stem, 4 to 6 lines long, the floral ones almost of equal length.

Flowers cream-coloured with a pinkish base, 4 to 6 lines long, pedunculate near the ends of the branches, peduncles filiform, recurved, 4 to 6 lines long, nodding, on pedicels of 1 to 1½ lines long, *consistently in pairs*. A single bract of about 1½ lines long between the two pedicels.

Bracteoles forming a hood over the corolla and folded over each other on the flower bud, and not falling off till the petals expand, scarious on the edges, *not keeled*, pinkish at the base and toning off to a cream colour at the hood or free end. Calyx-tube cylindrical, 5 to 6 lines long, prominently 5-ribbed (as in *Darwinia*) in the adnate part, lobes simply divided into about 5-10 divisions, except outer lobes which have accessory lobes. Petals entire, imbricate, obtuse, semi-circular, contracted at the base. Stamens 10, in a ring at the base of the petals, filaments inclined to vary in length, being alternately long or short. Staminodia alternating with the stamens, ligulate, rather shorter than the stamens. Anthers globular, with two parallel cells opening by minute pores at the summit, or in centre of cells. Connective prominent, forming a central column to which the anthers are adnate for their entire length. Ovary 1-celled. Ovules about 8, attached to a peltate placenta connected with the base of the ovary by a filiform attachment, the top of the placenta bifurcating into two horn-like processes. Style well exserted, twice the length of the calyx-tube, thick at the base and tapering upwards.

* From the Proceedings of the Linnean Society of New South Wales.

Analysis of cognate genera.

Calyx cylindrical, *lobes broad, entire* or shortly ciliate, flowers in heads. DARWINIA, Rudge.

Calyx cylindrical, *lobes* 5, *subulate, entire*, flowers in heads. HOMORANTHUS, A. Cunn.

Calyx, cylindrical, lobes 5-10 digitately, *divided*, flowers nodding *not in heads*. RYLSTONEA, g.n.

Calyx *hemispherical*, lobes 5 or 10 *deeply divided into subulate plumose or hair-like processes, flowers in corymbose heads*. VERTICORDIA, DC.

In Bentham and Hooker's 'Genera Plantarum,' vol. iii., p. 692, the three genera *Darwinia*, *Homoranthus*, and *Verticordia*, of Rudge, Cunningham, and De Candolle respectively, are kept distinct, as in Bentham's 'Flora Australiensis,' although Baron von Mueller, in his 'Second Census of Australian Plants,' has synonymised *Homoranthus* under *Darwinia*.

Speaking generally, *Darwinia* is distinguished from *Homoranthus* by its broad, entire calyx-lobes, the latter genus having subulate entire lobes. There are of course some minor differences, but the two genera, a though closely allied, are distinct, and I think the systematist is justified in separating them. The gradation of generic characters between the former genus and the latter is much more marked than between the latter and the genus *Verticordia*. One of the characters wanting in this hiatus will be found, I think, in the new genus.

The most constant character of this plant is its nodding, pedunculate cluster of two flowers. A sub-section of *Darwinia* has some of the flowers nodding, but the calyx-lobes and pedicels differ from those of the species now described.

Another character which distinguishes it from the three genera above mentioned is that the flowers are not crowded in heads as in *Darwinia* and *Homoranthus*, nor in corymbs as in *Verticordia*.

It is allied to *Darwinia* and *Homoranthus* by its calyx and anthers, but differs from them in its calyx-lobes as above mentioned, and also by its few pedicellate flowers.

It differs from the two sections of *Verticordia* mentioned by Bentham ('B. Fl.' vol. iii.) principally in the shape of its anthers, as well as in other minor points.

The bracteoles are not thick or scarious as in its congeners, nor are they keeled as in *Darwinia;* they are folded well over each other and are rather persistent.

The lobes of the calyx are fewer than generally pertain to *Verticordia*, and thus the gradation from the single lobe of *Homoranthus* to the extreme, subulate, plumose lobes of *Verticordia* is apparently complete.

It is only the calyx-lobes and peltate placenta that connect it with *Verticordia*, and therefore I do not think I am justified in placing it under that genus.

The anthers and staminodia are identical with those of *Darwinia* and *Homoranthus*, but differ in shape from both the porose and the longitudinally opening anthers of *Verticordia*.

The inflorescence of *Verticordia*, which is mostly corymbose, is quite different from that of *Rylstonea*. Through the kindness of Mr. J. G. Luehmann, F.L.S., Curator, National Herbarium of Melbourne, I have had the opportunity of comparing the latter with a large number of species of the former, and the difference is quite marked.

The pedunculate, pedicellate inflorescence is very characteristic, and the two pedicellate flowers have, I believe, no parallel amongst the species of the cognate genera.

Homoranthus has rarely, if ever, only two flowers, and then these are not pedicellate nor pedunculate.

The distinct exsertion of the style is a character which allies it more with *Darwinia* than with the other two genera.

Of all the Verticordias it is perhaps more closely related to *V. wilhelmi*, F.v.M., than any of the others, and this is the first species of that genus, so that *Rylstonea*, having calyx and anthers similar to those of *Darwinia* and *Homoranthus*, and calyx-lobes and placenta of *Verticordia*, I place it in botanical sequence between this latter genus and *Homoranthus*.

FORMULÆ, METHODS, AND REACTIONS,

KNOWN BY THE NAMES OF THEIR AUTHORS.

(Supplementary List.)*

Magnanini-Ciamician (Skatol).—See Ciamician-Magnanini.

Mayrhofer-Donath (Glycerin).—See Donath-Mayrhofer.

Millard (Podophyllum Resin).—(1) The resin of Indian podophyllum (*P. emodi*) gives an orange to red colour when a minute quantity is sprinkled on a few drops of strong sulphuric acid placed on a white surface. Under similar conditions the resin of American podophyllum (*P. peltatum*) gives a yellow to brown coloration, according to the quantity used. (2) Add 3 C.c. of diluted alcohol (s.g. 0·920) and 0·5 C.c. of solution of potash, B.P., to 0·4 Gm. of podophyllum resin in a test-tube, and shake by gently rotating the tube. In the case of Indian resin, the mixture forms a semi-solid gelatinous mass in a few seconds. It may be necessary to heat the mixture to boiling-point and then cool before gelatinisation takes place. The American resin shows no signs of gelatinising when similarly treated, even after some days. See *Pharm. Journal* [4], **6**, 304.

Monsel (Solution).—This is a solution of persulphate of iron.

Nadler (Morphine).—(1) A greenish-blue colour is produced on making the liquid containing morphine strongly alkaline, and boiling with barely sufficient solution of copper ammonio-sulphate to colour it light blue. (2) A rose-red colour is produced on heating morphine with a few drops of sulphuric acid diluted with half its bulk of water, cooling, adding ammonia water in excess, again cooling and shaking with chloroform.

Napier (Water in Ether).—Paper impregnated with cobalt chloride is changed from blue to rose-red.

Naylor-Braithwaite (Arsenious Acid).—Dissolve (1) copper sulphate, 200 Gm., in water, 50 C.c., and (2) sodium tartrate, 0·5 Gm., and sodium hydroxide, 5 Gm., in water, 50 C.c. The two solutions are mixed when required, and arsenious acid causes a reduction.

Nencki (Indol).—With nitric acid containing nitrous acid indol gives a red reaction or red precipitate. The reaction does not occur with scatol. Compare Baeyer's reaction.

Nessler (Citric Acid).—Citric acid in wine, the presence of which points to probable adulteration with raspberry juice, is separated as calcium citrate.

Nessler (Sulphuric Acid in Vinegar).—Add 2 to 3 per cent. of cane sugar to the vinegar, and dip a strip of filter paper in it. The paper becomes brown to black when dried.

Nessler (Tartaric Acid in Wine).—A crystalline precipitate is formed on evaporating the wine to a syrupy consistence, extracting with alcohol, and adding solution of sodium or potassium acetate.

Neubauer (Phenol).—A blue colour appears on adding phenol to an aqueous solution of ammonia, then adding chlorinated soda solution and heating.

Neukomm (Biliary Matter).—A violet colour is produced on extracting with alcohol, evaporating to a small bulk, placing one drop in a porcelain capsule, adding one drop of diluted sulphuric acid and a trace of sugar solution, and finally heating gently.

Nicholson (Nitric Acid).—A red colour is produced on evaporating a solution containing nitric acid to dryness, moistening with one or two drops of sulphuric acid, and adding a slight trace of brucine.

Nicklés (Fixed Oils).—These oils are distinguished according as they are or are not emulsified by means of hydrated lime. For particulars see *Am. Journ. Pharm.*, **38**, 299.

Nobel (Copaiba or Gurjun Oil in Urine).—A red colour is produced on adding hydrochloric acid to urine containing copaiba or gurjun oil.

Noel (Biliary Matter).—A drop of nitric acid is applied to filter paper which has been dipped in the liquid and dried. The colour changes from violet to red and yellow.

Nowak-Kratschmer (Alkaloids). — Note the colour reactions produced with syrupy phosphoric acid.

Obermayer (Indican in Urine).—The urine is mixed with concentrated hydrochloric acid containing ferric chloride and shaken out with chloroform. In the presence of indican the chloroform turns blue in consequence of the formation of indigo. An excess of the reagent does not affect the test. Compare Hammarsten's reaction.

Obermueller (Cholesterin).—If cholesterin is carefully melted over a naked flame with a few drops of propionic anhydride, the melted mass, on cooling, turns violet, then blue, green, orange, carmine, and finally copper red.

Otto (Strychnine).—The sample (for instance, evaporation residue of an ethereal or alcoholic extract), is mixed with a few drops of diluted potassium bichromate solution. A glass rod is brought into contact with the mixture and then drawn through a basin of concentrated sulphuric acid. The presence of strychnine is indicated by blue streaks.

Overbeck (Woollen Fibre).—If the fibre is saturated with 10 per cent. aqueous alloxanthin solution and treated, after drying, with ammonia gas, it is coloured carmine.

Pasteur (Culture Medium).—The culture for bacteria consists of sugar candy, 10 Gm., yeast ash, 0·075 Gm., dissolved in water, 100 Gm.; or else sugar candy, 10 Gm.; ammonium carbonate, 1 Gm., dissolved in water, 100 Gm.

Pavy (Albumin).—The test is performed with tablets of citric acid and tablets of potassium ferrocyanide. The urine is acidulated with the former, and the usual white yellowish precipitate indicative of the presence of albumin results on the addition of the potassium ferrocyanide tablets. See Oliver's reaction paper.

Peltier (Silk and Woollen Fibres).—A mixture of equal parts concentrated sulphuric acid and nitric acid. Silk is dissolved in this mixture while wool is coloured yellow.

Penot (Oils).—The oils are mixed with chromic acid and identified by the distinctive colour reactions obtained.

Penzoldt and Fischer (Phenol).—The test is carried out with Ehrlich's reagent (diazobenzol-sulphonic acid). A deep red colour is produced with an alkaline phenol solution.

Pesci (Alkaloids).—The reagent is prepared by mixing solutions of copper sulphate and sodium hyposulphite, and acidulating the mixture with diluted sulphuric acid.

Petermann (Corn Cockle Seeds in Flour).—The test is based on the isolation of the saponin contained in the corn cockle seeds. 500 Gm. of flour is heated with 1 litre of alcohol (85 per cent.). The extract is filtered off while hot, concentrated, and the saponin precipitated by the addition of pure alcohol and a little ether. The saponin is collected after 22 to 24 hours dried at a 100°, dissolved in a little water, and again precipitated with alcoholic ether. It is characterised by an acrid taste, frothing of the aqueous solution, and its reducing action on silver solution, and on Fehling's solution (especially after hydrolising with hydrochloric acid).

Petri (Proteids).—The reaction consists of an adaptation of Ehrlich's reagent (diazobenzol-sulphonic acid). Proteid or peptone solutions furnish a light yellow coloration with the reagent, which changes on the addition of alkali from orange yellow to brown, and on shaking gives a red froth.

Pfeiffer (Serum Reaction for Cholera).—A trace of blood serum of a cholera-immune guinea-pig destroys the vitality of true cholera bacilli, contained in the serum of a normal guinea-pig and a little bouillon. Vibrios similar to those of cholera are not killed by the serum; other tests such as that for typhoid bacilli may be carried out in the same manner. Gruber states that the

* After Wilder, Schneider, Altschul, etc. Concluded from page 82.

reaction may be conducted in a test tube. Compare Widal's reaction.

Picard (AMMONIACUM).—This is a modification of Plugge's reagent for ammoniacum with the substitution of sodium hypobromite for sodium hypochlorite.

Piffard (SUGAR IN URINE).—A paste is prepared by mixing in the mortar copper sulphate, 1; sodium-potassium tartrate, 5; caustic soda, 2. See Fehling's solution.

Pinerna (ORGANIC ACIDS).—A solution of β-naphthol, 0·02 Gm. in concentrated sulphuric acid, 1·83, 1 C.c. If 0·05 Gm. of the organic acid is carefully tested with 10 to 15 drops of the reagent, distinctive colour reactions are obtained; tartaric acid gives a blue then green colour, on dilution, a reddish-yellow tint. Citric acid reacts with a blue colour, on dilution colourless, to light yellow: malic acid greenish yellow, then light yellow, and orange on dilution.

Piotrowski (PROTEIDS).—This consists of the biuret reaction. Compare with Rose, Bruecke, and Posner.

Pohl (PRECIPITANT FOR GLOBULIN).—This is ammonium sulphate. The solution is half saturated with the salt.

Pollet (REAGENT) is Kopp's reagent.

Rabuteau (HYDROCHLORIC ACID IN GASTRIC JUICE).—The reagent for gastric juice is a mixture of starch solution, 50 C.c.; potassium iodate, 1 Gm.; and potassium iodide, 0·5 Gm. The reagent turns blue with free hydrochloric acid,

Ranvier (FIXING LIQUID).—Potassium gold chloride solution with lemon juice.

Raulin (CULTURE MEDIUM FOR BACTERIOLOGICAL CULTURES).—Contains sugar candy, 0·7 Gm.; tartaric acid, 0·04 Gm.; ammonium nitrate, 0·04 Gm.; ammonium phosphate, 0·6 Gm.; potassium carbonate, 0·6 Gm.; magnesium carbonate, 0·4 Gm.; ammonium sulphate, 0 25 Gm.; zinc sulphate, 0·07 Gm.; ferrous sulpbate, 0·07 Gm.; potassium silicate, 0·07 Gm.; dissolved in water, 1,500 Gm.

Ree (PRECIPITANT FOR ALBUMIN).—Alcoholic tannin solution.

Reichl-Mikosch (ALBUMIN).—If 2 to 3 drops of alcoholic benzaldehyde solution are added to the solution to be examined, then a larger volume of dilute sulphuric acid (1 : 1), and finally a few drops of ferric chloride, a deep blue colour reaction results in the presence of albumin. The reaction is hastened on warming.

Remsen (SACCHARIN IN PRESENCE OF SALICYLIC ACID).—The ethereal extract is evaporated, the residue dissolved in water, neutralised with soda, and mercuric nitrate added in slight excess. The precipitate is tested for saccharin, after drying, by Boernstein's method.

Reoch (OXALIC ACID IN URINE).—Calcium oxalate is precipitated on the addition of alcohol.

Richardson (SERUM PAPER).—Paper saturated with the serum of typhoid patients, and dried, may be used for Widal's reaction instead of fresh serum.

Richmond and Boseley (FORMALDEHYDE).—If fluids containing formaldehyde are boiled with a solution of diphenylamine in water and the necessary volume of sulphuric acid, a white flaky precipitate results. The presence of nitric acid or nitrates is indicated by the resulting green colour. See Hehner's reaction.

Riegler (ALBUMIN).—Asaprol, 8; citric acid, 8, are dissolved n distilled water, 200; 10 C.c. of urine is mixed with 10 to 20 drops of the reagent. Traces of albumin are indicated by a turbidity, larger volumes by a precipitate. Quantitative determination may be made with an albuminimeter.

Riegler (ALBUMIN, ALBUMOSES, AND PEPTONES).—10 Gm. β-naphthalin-sulphonic acid is well shaken with 200 C.c. water and filtered. The production of a turbidity or precipitate on adding 20 to 30 drops of the reagent to 5 to 6 C.c. of the fluid is indicative of the presence of albunim. Sensitiveness 1:40,000. Albumoses and peptones react in a similar manner, but the precipitate disappears on warming, and reappears on cooling.

Riegler (NITRITES).—A mixture is made of equal parts naphthionic acid and pure β-naphthol. 15 C.c. of the fluid to be examined is mixed in a test tube with 0·02 to 0·03 Gm. of the naphthol reagent and 2 to 3 drops concentrated hydrochloric acid, shaken, and 1 C.c. strong ammonia added down the side of the tube, while held in a slanting position. The presence of nitrites is indicated by the appearance of a red circle, and on shaking the whole solution turns red.

Riegler (URIC ACID).—p.-Nitraniline 0·5 Gm., water 10 C.c., pure concentrated sulphuric acid 15 drops, are put into a glass flask of 150 C.c. capacity, and heated with agitation until dissolved. Water 20 C.c. is now added, the mixture is cooled quickly, sodium nitrite solution, 2·5 per cent., 10 C.c. is added, and diluted, after 15 minutes, with water 60 C.c. The mixture is shaken up repeatedly and filtered. The production of a blue or green reaction on the addition of the reagent and 10 per cent. caustic soda solution, is indicative of the presence of uric acid.

Roberts (ALBUMIN IN URINE).—The urine is poured upon a saturated solution of salt containing 5 per cent. of hydrochloric acid sp. g. 1·052 or on a mixture of 5 parts saturated magnesium sulphate solution, and 1 part of strong nitric acid; in both cases the presence of albumin is detected by the formation of a white zone between the two liquids.

Robbert - Hammersten (THYMOL).—See Hammersten-Robbert.

Roch (ALBUMINOIDS).—Also known as MacWilliam's reagent. Bourreau modifies this by employing a solution of oxyphenylsulphonic acid 3, and salicylic-sulphonic acid 1 part in water 20.

Rupeau (PICRIC ACID IN BEER).—Ferrous sulphate, 5 Gm.; tartaric acid, 5 Gm., are dissolved in water, 200 Gm., and the solution mixed with an equal volume of saturated sodium chloride solution. From 1 to 2 C.c. of the reagent is covered half a C.c. of the beer and 2 drops of solution of ammonia added. The presence of picric acid is shown by a red coloration.

Sachs (NUTRIENT MEDIUM).—Potassium nitrate, 1 Gm.; sodium chloride, 0·5 Gm.; calcium sulphate, 0·5 Gm.: magnesium sulphate, 0·5 Gm.; calcium phosphate in fine powder, 0.5 Gm.; and a few drops of ferric chloride solution are dissolved in 1 litre of water.

Sachsse (GLUCOSE).—Two solutions are made, composed respectively of mercuric iodide 18 Gm., potassium iodide 25 Gm., in 500 C.c. water, and of potassium hydrate 80 Gm. in a similar quantity of water. Before use for titration equal volumes of the two solutions are mixed; as an indicator, paper, saturated in an alkaline solution of stannous chloride is employed. A black spot is produced by a drop of the solution as long as any unreduced mercuric salt is present.

Salkowski (ALBUMOSE).—The author amends his previously recorded test, since he finds that the presence of uribilin may occasion a precipitate and give the biuret reaction similar to albumose; if, therefore, uribilin is present, it must first be removed from the phosphomolybdic precipitate before the biuret reaction is obtained.

Salkowski (CHOLESTERIN AND PHYTOSTERIN).—A few centigrammes of cholesterin or phytosterin are dissolved in 2 C.c of chloroform, 2 C.c. of sulphuric acid, (sp. gr. 1·76) is added and the mixture shaken: the chloroform is coloured blood red.

Salkowski (INDOL).—See Baeyer's reaction.

Savalle (FUSEL OIL IN ALCOHOL).—The alcohol is heated with an equal volume of concentrated sulphuric acid until boiling commences. Fusel oil is indicated by the production of a brown colour; all the aldehydes and even the higher alcohols give this reaction. If the latter are to be tested for, the aldehydes may be removed by heating for half-an-hour with a little meta-phenylenediamine hydrochloride and subsequent distillation; the distillate thusfreed from aldehydes is tested with sulphuric acid. If the

amount of fusel oil is very slight, from 10 to 20 drops of 1 per mille of an aqueous solution of furfurol may be added, in this case a pink coloration is obtained, in the presence of the higher alcohols, on heating with sulphuric acid. The test may be employed quantitatively for the colorimetric determination of fusel oil.

Schiff (Cholesterin).—Cholesterin crystals heated with a mixture of hydrochloric acid, 2, and ferric chloride, 1, gives a red coloration; on evaporating, a violet residue is left; cholesterin crystals evaporated to dryness, with a little nitric acid, leave a residue which is coloured red by a drop of ammonia.

Schiff (Glucose).—Papers saturated with equal volumes of acetic acid and xylidin, with a very little alcohol, are employed for detecting glucose; on heating the substance with sulphuric acid furfurol is formed if glucose be present, the vapours of which colour the test paper red.

Schlen (Solvent for Urinary Deposits). — When testing urine for tubercle bacillus, it is necessary to redissolve any sedimentary matter; this is donc with a solution of borax, 4, and boric acid, 4, in water, 100.

Schneider (Alkaloids).—Concentrated sulphuric acid added to an intimate mixture of cane sugar and certain alkaloids affords characteristic colour reactions; morphine and codeine give from purple red to violet green and then yellow colours. The reaction depends upon the formation of furfurol and may therefore be obtained by the use of furfurol and sulphuric acid.

Schuchardt (Reagent).—This is a saturated solution of tropoeolin (see also Van Der Velden's reagent).

Schuyten (Nitrous Acid).—The reagent is obtained by diluting 10 C.c. of a solution of 1 part of antipyrine in 10 parts of acetic acid, in 100 parts of water. 5 C.c. of the reagent are added to an equal volume of the solution to be tested; the presence of nitrous acid is indicated by a green coloration. This is also known as Curtmann's reagent.

Schweiger-Seidel (Acid Carmine Solution).—This is obtained by saturating ammoniacal carmine solution with acetic acid and filtering. The stain is particularly adapted for colouring cell nuclei; after staining, sections are macerated in glycerin containing one half per cent. of hydrochloric acid, then washed with acetic acid, and finally in water. The preparations are mounted in glycerin; only the nuclei of the cells are stained.

Seliwanoff (Fructose or Levulose).—An aqueous solution of resorcine and fructose becomes red on being heated with hydrochloric acid, and furnishes a precipitate which dissolves in alcohol with a red colour. Cane sugar, invert sugar, and mellitose behave similarly. Compare Conradi's reaction

Sieben (Ketoses and Aldoses).—Boiled for 3 hours with 7·5 per cent. of hydrochloric acid, the ketoses (fructose, sorbose), are decomposed with formation of humic acid, while the aldoses (glycose, mannose, galactose), are not affected.

Smith-Chapman (Tartaric and Citric Acids).—See Chapman-Smith.

Soltsiens (Sesame Oil).—Two to three parts of the fat to be examined are melted in a test tube on a boiling water bath, a solution of stannous chloride in hydrochloric acid 1 part is added and well shaken and replaced on the water bath. The presence of sesame oil is shown by a raspberry or wine red colour in the stannous chloride solution. The reaction will detect 1 per cent. of sesame oil.

Sprengel (Nitric Acid).—Phenol, 1, is dissolved in concentrated sulphuric acid, 4, and water, 2. One to 2 drops of this solution gives, in the presence of nitric acid, a reddish brown coloration, sometimes green, which changes to yellow on the addition of ammonia. Hager recommends the solution of a small volume of the sample in concentrated sulphuric acid the introduction of a crystal of phenol and gentle heating. Hydrochloric acid may be used instead of sulphuric acid, but in this case the heating must be carried to 80° or 90° C. Grandval and Lajoux base a colorimetric test for nitric acid on Sprengel's reaction.

Storch-Morawski (Resin Oil and Resin).—The resin is dissolved out in acetic anhydride, and mixed with sulphuric acid (1·53), when a red coloration results, which may be taken as an indication of the additionof resin to fats and varnishes. Copals give a brown colour reaction with this test.

Szabo (Hydrochloric Acid in Gastric Juice).—The reagent is a mixture of equal volumes of 0·5 per cent. solutions of ammonium rhodanate and sodium ferritartratc. The reagent is coloured brown by free hydrochloric acid. See Mohr's reagent.

Thiersch (Borax Carmine).—A stain for miscroscopical preparations, prepared by mixing carmine 0·5 Gm., with a solution of borax in 2 Gm., water 28 C.c. Absolute alcohol, 60 C.c., is then added, and the mixture filtered. The sections should be soaked in boric acid solution before staining.

Thiersch (Oxalic Acid Carmine). –A carmine solution prepared from carmine, 1 Gm.; ammonia, 1 C.c.; and distilled water, 3 C.c. It is mixed with a solution of oxalic acid, 8 Gm., in distilled water, 175 Gm., then 16 C.c. of absolute alcohol is added, and the mixture filtered.

Thoms (Copper Sulphate).—A solution of potassium iodide is mixed with a little starch. Traces of copper sulphate are shown by the resulting blue coloration.

Thormaehlen (Melanin in Urine).—On the addition of sodium nitro-prusside, potassium hydrate, and acetic acid, the urine is coloured a deep blue in the presence of melanin.

Thudichum (Egg Colouring Matter).—The colouring matter of yolk of egg extracted by ether, alcohol, or chloroform, is coloured blue by nitric acid, and gives characteristic absorption spectra. Commercial products cannot be tested by this reaction as the colouring matter in them is decomposed.

Toepfer (Hydrochloric Acid in Gastric Juice).—A solution of dimethyl-amido-azo-benzol (dimethyl orange), is coloured red by the combination of hydrochloric acid with albuminoids.

Tollen (Pentose).—Pentoses are coloured cherry red on being heated with hydrochloric acid and phloroglucin.

Tucholka (Bisabol-Myrrh).—Six drops of petroleum ether extract of the sample (1:15) are mixed in a test tube with acetic acid, 3 C.c., and covered with 3 C.c. of concentrated sulphuric acid. At the zone of contact a pink line appears immediately, gradually spreading to the acetic layer, and remaining for some time. Herabol myrrh gives only a very slight pink colour, the zone of contact first shows a green colour changing to brown with a green fluorescence after standing for some time.

Udransky (Gallic Acids).—One C.c. of the aqueous or alcoholic solution is mixed with one drop of a 0·1 per cent. aqueous furfurol solution. One C.c. of concentrated sulphuric acid is poured to the bottom of the mixture, in the presence of gallic acid, a violet red reaction appears at the zone of contact.

Uffelmann (Lactic Acid).—Phenol solution, tinted with ferric chloride is coloured yellow by lactic acid. Butyric acid gives a similar reaction.

Unverdorben-Franchimont (Resins and Terpenes).—The reagent is a concentrated aqueous solution of copper acetate. Sections of tissue exposed for several days to the action of the solution have their resinous portions coloured emerald green.

Uschinsky (Culture Solution for Bacteria).—Glycerin, 30 to 40 Gm.; sodium chloride, 5 to 7 Gm.; calcium chloride, 0·1 Gm.; magnesium sulphate, 0·2 to 0·4 Gm.; potassium phosphate, 3 to 2·5 Gm.; ammonium lactate, 6 to 7 Gm.; sodium asparagate, 3 to 4 Gm.

Uslar-Erdmann (Alkaloids).—See Erdmann-Uslar.

Valser (Alkaloids).—A modification for Mayer's reagent prepared by the solution of potassium iodide 49·8 Gm., in water 1 litre. The solution is shaken with mercuric iodide, in excess, and filtered.

Van de Vyvere-Franqui (Glucose).—See Franqui-Van de Vyvere.

Van Ermengen (STAINING CILIA OF BACTERIA).—See Ermengen, Van.

Velden (HYDROCHLORIC ACID IN GASTRIC JUICE).—See Suchard's reagent.

Verven (ALKALOIDS).—See Marmé's reagent.

Vitali (CHLORATES).—If a drop of aqueous aniline sulphate solution be mixed with a few drops concentrated sulphuric acid and added to a solution of a chlorate, a deep blue coloration results, which is intensified on dilution with a few drops of water. This reaction is not given by nitrates.

Vogel (QUININE).—If potassium ferro-cyanide and bromine water be added to a quinine solution until a faint yellow tint results and diluted ammonia be then added a red coloration is produced. Blaise states that the potassium ferro-cyanide is not essential to this reaction, tending only to render the colour more permanent. If strong ammonia be added to the red solution, the colour changes to green. If half saturated bromine water be added to the one-fourth per cent. solution of quinine until the commencement of a yellow reaction and if 1 to 2 per cent. ammonia be dropped in after half a minute a red colour reaction is obtained which changes to green on the addition of strong ammonia.

Vogl (FLOUR).—This is a mixture of alcohol (70 per cent.), 85, and hydrochloric acid, 5. A small sample of the flour is heated to boiling in the test tube, with the reagent after shaking, and is left to subside. If the flour be pure, the fluid is colourless; the presence of gruffs, with bran, is indicated by a straw-coloured tint. Corn-cockle flour is betrayed by an orange yellow, vetches by a pink, ergot by a flesh colour, buck-wheat by a green coloration.

Vrij, De (ALKALOIDS). —The reagent is phospho-molybdic acid. See Sonnenschein's reagent.

Waage (BOMBAY MACE).—Potassium bichromate in 3 to 5 per cent. solution colours the secretion of mace reddish brown. The alcoholic mace extract may either be examined or miscroscopical sections may be warmed with the reagent, and the colorations produced examined. In yellow Bombay mace green bodies are observed as well as brown.

Wallach (SESQUITERPENE).—The ethereal oil to be examined, or a fraction of it, is dissolved in a large volume of acetic acid, and a little concentrated sulphuric acid is gradually added; a green, then a beautiful indigo blue coloration is obtained, which is considered to indicate the presence of a sesquiterpene.

Weber (INDICAN IN URINE).—Is similar to MacMunn's test, but advocating shaking out with ether instead of chloroform. In the presence of indican the ether is coloured red to violet, and forms a blue froth.

Weigert (HÆMATOXYLIN STAIN).—One C.c. of a cold saturated solution of lithium carbonate is added to 100 C.c. of a solution of 0·75 to 1·0 Gm. haematoxylin in 10 Gm. of alcohol and 90 Gm. water. The washing of the stained sections is effected by a borax-potassium ferricyanide solution (borax, 2; potassium ferricyanide, 2·5; water, 100).

Weingaertner (BASIC AND ACID COLOURS).—Tannin, 25 Gm. and sodium acetate, 25 Gm., are dissolved in water, 250 Gm. Basic colours are precipitated by the reagent, but not acid colours.

Wemince (OILS).—Nitric oxide gas is passed into a suspension of the oil with water. The nitric oxide is produced from iron turnings and nitric acid. (Compare Barbot's, Behren's, Boudet's, Cailletet's, Poutet's reagent.

Werther (META-VANADATES).—An acidulated solution of a meta-vanadate shaken with hydrogen peroxide gives a red coloration; if highly diluted a brownish rose-red colour results; when shaken with ether the coloration remains unchanged, and the ether colourless

Wetzel (CARBONIC OXIDE IN BLOOD).—Three volumes of a 1 per cent. tannic acid solution are added to the blood after dilution with 4 volumes of water. Normal blood is gradually coloured grey, but blood containing carbonic oxide remains red.

Widal (TYPHOID).—One drop of the serum of the blood of a patient suspected of typhoid is added to 10 drops of a typhoid bacillus culture, 24 hours old, and stirred together. If the disease is typhoid, small particles will be observed under the microscope consisting of coagulated motionless bacteria. If the case be not typhoid the organisms will be freely motile. The serum of other infectious diseases exhibits the same conduct. As the reaction originally emanated from Gruber, it is latterly described as Gruber-Widal's reaction (compare also Pfeiffer's reaction).

Wittmack (WHEAT AND RYE FLOUR).—One Gm. flour is heated with 50 C.c. of water on the water bath to exactly 61° C., so that the temperature rises to 62·5° after removal from the bath. When settled, the deposit is examined microscopically The starch grains of wheat will not have changed their form, except a slight swelling; those of rye will be nearly all burst and distorted.

Wolfbauer (COTTON SEED OIL).—Ten Gm. of oil are shaken for two minutes with 7·5 Gm. concentrated nitric acid; when separated, 1 Gm. mercury is added and the mixture shaken for four minutes. Olive oil retains its colour, while the presence of 5 per cent. of cotton seed oil occasions a brown coloration.

Zaleski, Yon (CARBONIC OXIDE IN BLOOD).—On the addition of 2 C.c. of water and 2 drops of super-saturated copper sulphate solution to 2 C.c. of blood, a brick-red precipitate results in the presence of carbonic oxide. Normal blood produces a brownish green precipitate.

Zeller (MELANIN IN URINE).—The addition of bromine water to urine containing melanin produces a yellow precipitate, which changes to black on standing.

Zencker (FIXING SOLUTION).—Mercuric chloride, 5 Gm., potassium bichromate, 2·5 Gm.; sodium sulphate, 1 Gm.; water, 100. Before use, a few drops of acetic acid are added.

Zouchlos (ALBUMIN).—A mixture of 10 per cent. potassium rhodanate solution, 100, and acetic acid 20. With albumin it produces a precipitate or turbidity.

Zune (CULTURE SOLUTION).—Gelatin 50 Gm., agar 2·5 Gm., are dissolved in 600 to 700 Gm. sterilised filtered culture-broth. The white of an egg is added, the mixture heated until this is coagulated, then filtered, and the filtrate sterilised at 105° to 110° C.

AUSTRALIAN INDIGENOUS VEGETABLE DRUGS.*

BY J. H. MAIDEN,

Government Botanist and Director of the Botanic Gardens, Sydney.
(Corresponding Member of the Pharmaceutical Society of Great Britain.)

MONIMIACEÆ *(Continued).*

I have for some years now occasionally used a tincture of the bark of *Daphnandra micrantha* in the treatment of heart cases, apparently with good results; my patients expressed themselves as feeling much better, and the sphygmograph showed some improvement in the condition of the pulse. Daphnandra kills frogs by its action upon the heart, and kills warm-blooded animals by its paralysing effect upon the spinal cord. Although I did not anticipate that any good would result from the use of any substance having a paralysing action upon the cord in the treatment of tetanus, yet I tried Daphnandra in a severe case of tetanus in a man. He derived no benefit therefrom, and the last two days of his life he was kept, at his own desire, under the influence of chloroform. Should a remedy ever be discovered for tetanus, I believe it will be a substance having an injurious effect upon the microbes that cause the disease, like the effect of salicine in rheumatic fever, and quinine in ague." (*Trans. Intercol. Med. Congress*, 1890.)

Queensland.

*From the *Agricultural Gazette of New South Wales* (Continued from page 70).

Doryphora sassafras, Endl. "New South Wales Sassafras."

The sassafras-smelling bark is used as a tonic medicine. The odour is rather fugacious. It is taken in the form of an infusion. Dr. T. L. Bancroft informs the writer: "I have tried the bark on frogs, and found it to be inert."

New South Wales.

LAURINEÆ.

Cassytha filiformis, Linn. "Dodder-Laurel."

The whole plant pulverised and mixed with dry ginger and butter, is used in the cleaning of inveterate ulcers in India. The juice of the plant, mixed with sugar, is occasionally applied to inflamed eyes. (Rheede.) It is used in native practice as an alterative in bilious affections and for piles. (Dymock.)

Dr. Thomas Bancroft, of Brisbane, informs me that our *Cassythas* are physiologically inert, or practically so.

Queensland, Northern Australia.

Cinnamomum.

See a paper by R. T. Baker, *Proc. Linn. Soc., N.S.W.* [2], xii., 275. "On the Cinnamomums of New South Wales, with a special research on the oil of *C. oliveri*, Bail."

In this paper a new *Cinnamomum* (*C. virens*) is described, and full account of this and *C. oliveri* given.

Reference may also be given to Dr. J. Lauterer's paper on "The Sassafras-trees of Queensland and the chemistry of *Cinnamomum oliveri*" (*Proc. Roy. Soc., Queensland*, xi., 20). Following is a note by the late Dr. Joseph Bancroft on *Nesodaphne obtusifolia*, Benth. (a synonym of *C. oliveri*), taken from *A Contribution to Pharmacy from Queensland*, p. 11 (1886), published for the Colonial and Indian Exhibition.

"The bark has a strong aromatic odour, and pleasant astringent taste. It is frequently used by bushmen to improve the flavour of their tea, a little bit of bark being infused therewith. The active principles are a volatile oil with an odour like the North American sassafras, and a peculiar tannin. The bark has been used by me as a convenient aromatic astringent in diarrhœa and dysentery, having the properties of cinnamon and catechu in combination. It is most conveniently used in the form of a tincture made with 2 oz. of the bruised bark in a pint of rectified spirit."

New South Wales and Queensland.

Cinnamomum Tamala, Th. Nees. "Cassia Cinnamon."

The leaves are used both as a condiment and as a medicine in India. They are considered to be carminative, stimulant, diuretic, diaphoretic, lactagogue, and deobstruent. (Dymock.) The bark is also used for almost similar purposes.

Queensland.

Cryptocarya australis, Benth. "Laurel," or "Moreton Bay Laurel," and "Grey Sassafras."

The bark has a persistently bitter taste, due to the presence of an alkaloid which crystallises from its solution in stellate masses of acicular crystals. When administered to warm-blooded animals the alkaloid produced difficulty of respiration, ending in asphyxial difficulty and death. (Dr. T. L. Bancroft, in *Proc. R. S. Queensland*, iv., 1887.)

See also the same author, in *Proc. Intercol. Med. Congr.*, 1890, as follows:—

"The genus Cryptocarya contains a curare-acting principle. It is, I believe, an alkaloid closely resembling Curarine. Professor Fraser has promised to experiment with this poison, so before long something definite about it may be known. There are several species of Cryptocarya in South America, and notably one, *C. Guianensis*. It is Guiana where curare is obtained, and it is to the interest of the natives, who collect this substance, to keep its source secret. It seems that to inquirers, the natives always point to a Strychnos (chiefly *Strychnos Guianensis*—see Wittstein's *Organic Constituents of Plants*), as the tree from which they obtain the curare. Some samples of curare contain curarine, brucine, and strychnine; other samples contain only curarine, which fact seems to point to the juice of a Strychnos being added at times to enhance the poisonous nature of curare."

New South Wales and Queensland.

Litsæa.

Many of the Javanese species of Lauraceæ contain, in addition to other not yet clearly-defined bases, a crystalline alkaloid, termed *laurotetanine*, which has a strong tetanic action on animals. It is contained in quantity in the cortex of the stem of *Litsæa chrysocoma*, Bl., and is sparingly soluble in ether, more readily in chloroform. Greshoff, *Ber.* xxiii., 3537; *Journ. Chem. Soc.*, lx., 337.) *See* also *Sohn*, p. 60. It would appear desirable for at least our common *Litsæa* (*L. dealbata*, Nees) to be carefully examined.

PROTEACEÆ.

Grevillea mimosoides, R.Br.

N. Holtze points out that an acid secretion exudes from the seeds of this species. The secretion, which is powerful and acrid enough to produce sores, the scars of which remain for many months after, is thought to be useful in protecting the seeds from the attacks of cockatoos. (*Victorian Naturalist*, March, 1891.) What is the nature of this secretion? It is specially worthy of examination in view of the rarity of irritant principles in this natural order.

Northern Territory.

Isopogon ceratophyllus, R.Br.

The bark of this shrub is used as a bitter tonic in Victoria. (Tenison-Woods, *Proc. Linn. Soc.*, N.S.W., iv., 136.)

All the Colonies, except Western Australia and Queensland.

THYMELACEÆ.

Wikstræmia Indica, C. A. Mey.

Fijian native physicians apply the root-bark externally to sores, and give the leaves and bark of the stem and branches for coughs. (Seemann.) (See my paper on fish poisons of the aborigines in the *Gazette* for July, 1894.)

Coastal New South Wales to Northern Australia.

EUPHORBIACEÆ.

Cleistanthus.

The bark of *C. collinus*, Benth., is recorded as a fish-poison. (See *Pharm. Journ.*, July 23, 1898, p. 74.) Examination should be made of our *C. Cunninghamii*, F.v.M., for active principle.

Croton phebalioides, R.Br. "Native Cascarilla."

The bark contains an agreeable aromatic bitter.

Dr. T. L. Bancroft suggests that *C. insularis*, Bail., may possess medicinal value.

New South Wales and Queensland.

Euphorbia spp.

It is stated that the natives of the Northern Territory use the juice of a species of *Euphorbia* as a specific in smallpox.

Another species affords a juice said to be a remedy in cancer. Without committing oneself to an expression of opinion as to the utility of the *Euphorbias* alluded to, our native species will doubtless well repay a thorough examination of their medical properties.

Throughout the Colonies.

Euphorbia alsinæflora, Baill.

This herb is used in infusion by bushmen in cases of chronic dysentery and low fever. (Bailey.)

Northern Australia.

Euphorbia Drummondii, Boiss., "Caustic Creeper"; "Milk Plant," etc.

In 1887 an alkaloid called drumine was stated to have been extracted in Australia from this plant. It was stated to have the same local action as cocaine. The so-called alkaloid has been examined in England, and found to consist mainly of calcium oxalate. (*Pharm. Journ.*, January 7, 1888.)

In Western New South Wales the aboriginals use an infusion or decoction of the plant in genital diseases, and use rather strong

doses, but it is said that an overdose simply causes headache. Mr. P. A. O'Shanesy observes that this plant is said to be an infallible remedy for dysentery and low fever.

This is a plant that is very well known as a reputed poisoner of stock. It will suffice for me to refer to the *Gazette* for January, 1897, p. 18, for full references to the evidence. Personally, I do not think these *Euphorbias* have established their claim to be drugs of any value. C. T. Musson's paper in *Proc. Linn. Soc. N.S.W.* [2], iv., 389, "On the effects of eating pigeons that have fed on the seeds of *Euphorbia Drummondii*" may be referred to.

Throughout the Colonies.

Euphorbia pilulifera, Linn. "Asthma Herb," or "Queensland Asthma Herb."

This plant having obtained some reputation in Australia in certain pulmonary complaints, has acquired the appellation in the Colonies of "Queensland Asthma Herb." Nevertheless, it is by no means endemic in Australia, for it is a common tropical weed.

It was first introduced to notice by Dr. Carr-Boyd, of Townsville, Queensland, about 1880, as a remedy in asthma, bronchitis, and other diseases of the respiratory organs.

The herb from Fiji is said to be of better quality than that from Queensland, but inasmuch as it is a common weed in many countries, and, moreover, easily cultivated, any demand for it could be readily supplied.

The direction usually given by vendors is to simmer 1 oz. of the dried herb in 2 quarts of water, and to reduce the liquid to 1 quart; a wineglassful of this decoction is to be taken three times a day. If the fame of this drug be maintained, doubtless some enterprising pharmacists will present it to the public in a more elegant form.

The smoke, also, of the herb should be inhaled, either by means of an ordinary tobacco pipe, or by burning it on a slab. In either case care should be taken to get the smoke well into the lungs.

It is said that alcohol fails to extract the medicinal properties of this plant as efficiently as water.

It is reported to be of service in phthisis, relieving the distressing cough in that disease. Nevertheless, it is not an infallible cure, nor does it always even give relief in cases of asthma. I have known cases in which it has apparently utterly failed. Dr. Thomas Dixson, lecturer on Materia Medica at the University, Sydney, says that from his own observations the virtues of the plant have been vastly overrated, and that in reality it is but of little value. From careful and repeated pharmacological investigation he was unable to find any traces of actions of a definite and distinctive nature. From similar results, after investigating *Euphorbia Drummondii*, he suggests that the active principle must be of an unstable nature, and, therefore, to be found with certainty only in fresh specimens. Still, many cases have come under my notice in which it has unequivocally given relief, and I have no doubt that when the drug shall have longer stood the test of experience, members of the medical profession will largely record their experience of its use, and it will be assessed at its proper value. At present, as far as I have learnt the opinion of medical men in Sydney on this plant, it is only to be considered as one of the numerous remedies which give more or less temporary relief, and must on no account be regarded as a specific.

An exhaustive account of the drug, entitled "A contribution to the study of *Euphorbia pilulifera*, Linn., by Dr. A. Marsset, of Paris, will be found in the *Therapeutic Gazette* (Detroit, U.S.A.) for February, 1885.

I notice that Merck offers an *Extractum Euphorbiæ pituliferæ fluidum*. (See *Bericht*, 1892, 67.)

Queensland and Northern Australia.

Excœcaria agallocha, Linn. "River Poisonous Tree"; Milky Mangrove"; "Blind-your-eyes."

It produces, by incision in the bark, an acrid, milky juice, which is so volatile that no one, however careful, can gather a quarter of a pint without being affected by it. The symptoms are an acrid, burning sensation in the throat, sore eyes, and headache. A single drop falling into the eyes will, it is believed, produce loss of sight. The natives of Eastern Australia, as well as those of New Guinea, etc., use this poisonous juice to cure certain ulcerous chronic diseases, *e.g.*, leprosy; but in Fiji the patient is fumigated with the smoke of the burning wood. (*Vide* Seemann, *Flora Vitiensis.*) Mr. C. Hedley (*Prov. R. S. Qd.*, v.) states that the milky juice of this tree was formerly used by the Port Curtis blacks as a poison for their spears. In India the sap of the tree is called "Tiger's Milk," and is said to be applied with good effect to inveterate ulcers. The leaves also are used in decoction for this purpose. A good caoutchouc may be prepared from the milk. (See also *Pharm. indica*, p. 314.)

Northern New South Wales to Northern Australia.

Excœcaria parvifolia, Muell. Arg. The "Gutta Percha" of the Gulf of Carpentaria.

Dr. T. L. Bancroft mentions that people often cut a stick of this tree, and so get some of the juice into their hands and into their eyes; they then become for a time blind. This blindness is only of short duration, leading to no after effects.

"The natives use the bark mashed up in water in a wooden kooliman, and heated with stones from a fire close by. The wash is applied externally to all parts of the body, rubbing it in. Used for pains and sickness." (E. Palmer.)

Queensland and Northern Australia.

Mallotus phillipensis, Muell. Arg. "Kamala" of India.

The reddish powder from the capsules of this plant, called "Kamala" by the Hindoos, is a useful vermifuge, especially adapted for the expulsion of tænia.

Anderson found that a concentrated ethereal solution of "Kamala," allowed to stand for a few days, solidified into a mass of granular crystals, which by repeated solution and crystallisation in ether were obtained in a state of purity. This substance, named by him *Rottlerin*, forms minute, platy, yellow crystals of a fine satiny lustre, readily soluble in ether, sparingly in cold alcohol, more so in hot, and insoluble in water. The mean of four analyses gave its composition as $C_{22}H_{20}O_6$.) (*Pharmacographia.*)

New South Wales and Queensland.

Petalostigma quadriloculare, F.v.M. "Crab Tree"; "Native Quince"; "Emu Apple"; "Bitter Bark"; "Native Cinchona"; "Quinine Tree"; "Muntepen" of some Queensland aborigines.

The bark contains a very powerful bitter, said to have the same properties as cinchona. (Hill.) Tenison-Woods, however, states (*Explorations in Northern Australia*): "It is usually covered with fruit like a small yellow plum, of eminently nasty taste. This is, I believe, its only claim to be called a 'quinine.'"

This surmise is not correct, as the bark is regularly employed as a bitter. I have seen the fruits of the colour of red tomatoes, the tint varying between yellow and red.

Dr. Joseph Bancroft states that its bitterness is due to a peculiar tannin. Dr. Thomas Bancroft informs me that this bark is physiologically inert, or practically so.

Armit (*Proc. Linn. Soc.* [Bot.], xx., 69) states that it is a useful remedy in fever, low or intermittent; 10-grain doses of dried bark three times per diem often producing a favourable result.

"It is one of the best tonics I know of. I use it often, especially the kernels. I believe it is as good as pepsin for giving an appetite. (Mr. McGregor.)

The stem-bark is said to contain, together with the ordinary plant-constituents, a camphoroidal essential oil, and an indifferent bitter principle belonging to the glucosides.

The ash of the bark is 8·3 per cent., and an analysis is given by K. Falco, *Chem. Centralbl.*, 1867 ("Rinde eines Baumes aus Süd-Australien"). See also Wolff, *Aschen-Analysen*, i., 128, and Watts' *Dict.*, vi., 1st *Suppt.*, 904.

Northern New South Wales and Northern Australia.

Phyllanthus.

An intensely bitter, poisonous principle called Phyllanthin has been found in *P. niuri*, from Java, by Ottow. In view of the numbers and abundance of our species of *Phyllanthus* they should be investigated. See Sohn, p. 78.

(*To be continued*).

LEGAL INTELLIGENCE.

Proceedings under the Pharmacy Acts.

Pharmaceutical Society *v.* J. H. White.

At the Worcester County Court, on Tuesday, Sir Richard Harington tried an action by the Council of the Pharmaceutical Society against Joseph Hill White, seedsman and florist, of Broad Street, Worcester, claiming £5 penalty under the Pharmacy Act for "having sold or kept open shop for retailing, dispensing, or compounding of poison," viz., arsenic, contained in and forming part of a compound known as Climax Weed Killer. Mr. T. R. Grey (barrister) appeared for the plaintiffs, and Mr. T. G. Dobbs (solicitor) for the defendant.

The defence was that the defendant was not the seller of the poison within the meaning of the Act, and also that he did not keep open a shop within the meaning of the Act. It was admitted that the weed killer contained poison, and that the defendant was not a person qualified to sell poison.

Mr. Grey, in opening the case, said the question at issue was of very serious public interest and importance; and the facts were not in dispute. The defendant had at his shop handbills holding himself out as a person able to sell certain weed killer. He (Mr. Grey) would call a witness who went to the defendant's shop and asked for two gallons of the weed killer. The defendant himself took the order from him, asked his name, took the money, and finally handed him a receipt. That document bore upon the heading, "Bought of the Boundary Chemical Company, Limited, Railway Arches, Luton Street, Liverpool," and was signed by the defendant as agent for the company. The drum of weed killer was afterwards delivered direct from Liverpool to the witness at Edgbaston. It was analysed and found to contain as much as 6 lbs. of arsenic, which was sufficient to kill 20,000 adults if administered in a certain way. The real question for them to decide was who was the seller within the Act. Section 1 of the Pharmacy Act required the seller to be registered as qualified to sell, and Section 15 imposed a penalty of £5 on any unqualified person keeping open a shop for retailing poison. He quoted the cases of Templeman and Trafford, 8, Q. B., p. 397, Law Reports, and the Pharmaceutical Society and Wheeldon, 24, Q. B., p. 683, in support of the argument that the defendant was the seller.

His Honour pointed out that in those cases the goods were sold over the counter, which was not the case here.

Mr. Grey admitted that there was not a case on all fours with this. He submitted that the defendant was the seller, and that none of the restrictions imposed by Section 17 of the Act in selling could be performed by the company in Liverpool.

William Painter, a former Detective Inspector of the Birmingham Police, said he made the purchase on behalf of the Society at the defendant's shop. When he asked the defendant if he sold weed killer he said "yes." Defendant asked him to pay for the weed killer there and then, and the defendant said to his son "give him (witness) a receipt on the bill-head of the Liverpool firm." Defendant said the killer would be forwarded direct to him. He picked up a handbill from the counter about the weed killer, in which defendant was described as agent. When he received the drum he handed it to Mr. Moon.

Cross-examined: Defendant told him that he did not keep the weed killer in stock, and impressed on him that he was only the agent of the company.

Harry Moon, clerk in the office of the Registrar of the Society, said he instructed the last witness to make the purchase, and he had the authority to sue in this case.

Ernest John Eastes, analyst, said he analysed the contents of the drum and found it contained six pounds of arsenic, sufficient to poison over 20,000 adult "persons."

Joseph Hill White, defendant, said he told Painter that the law did not allow him to keep the weed killer in stock. He told him that he could order the stuff direct, or send his money direct. He (witness) had not the slightest control over the forwarding of the weed killer. He had never kept any in stock, and had never sold any in his shop.

Cross-examined, he added that the company allowed him a commission of 25 per cent. on the amount of his orders. He sold about £16 worth in 1898.

The Judge thought that could only be elicited from the defendant with the view to expose him to further penalties.

Mr. Grey said that was not the motive of the question.

Defendant, in answer to further questions, said the only instruction he knew of was that he was not allowed to keep the weed killer in stock.

Harry Joseph White, son of the defendant, and assistant to him, corroborated, saying he was present in the shop during the transaction. He maintained that his father told Painter he did not keep the weed killer in stock.

Mr. Dobbs submitted that there was no evidence before the Court that there was a sale within the meaning of the Act. The 15th Section seemed to point to the keeping open of a shop and the selling together. There was no case giving a definite decision against a seller having sold such goods where he had not had the means of supplying them. Mr. Justice Grove in Templeton *v.* Trafford laid it down that the seller was the person who actually conducted the sale. He emphasised the fact that Mr. White could not control the sale. He simply took the order and forwarded it for execution by the company, who kept a registered chemist on the premises. The company could have refused, if they had liked, to execute the order. He urged, therefore, that Mr. White could not be regarded as the seller.

Mr. Grey replied that the place of sale within the meaning of the Act was where the essential part of the sale took place, and did not imply necessarily that the material should be in the shop. He submitted, too, that the seller was the person with whom the contract was made, not only within the Pharmacy Act but within the common law and the Sale of Food and Drugs Act.

The learned Judge asked if the goods must not needs be in the shop capable of being delivered.

Mr. Grey submitted that they need not, but that the defendant, the retailer, had control over the sale. Here was a company of four or five people of very small capital, formed in order to prevent the Act of Parliament touching them. The case of the Pharmaceutical Society against the London and Provincial Supply Association held that "person" under Section 15 did not apply to a company or corporation. This company might perhaps have fifty or sixty agents, and if the contention for the defence held good they might manufacture weed killer, laudanum, or any other drug or dangerous poison, and if this was not an evasion of the Act they could supply any quantity of them through the agents without their having passed through the hands of one registered person from beginning to end. And by that means the Act must become in a great many cases a dead letter. He (Mr. Grey) referred to the case, lately heard by the magistrates of Exeter, of Sanders and Morny, 14, *Times* Law Reports, p. 346, and to Stallard and Marks, 3, Q.B., p. 412.

The learned Judge held that the latter case was an authority for the inference that the Boundary Company were liable to any penalty for the conduct of the sale in this case. The agent who was convicted under the Licensing Acts in that case made a bargain at Cheltenham for his principals who had premises at Worcester, and the principals were held responsible.

Mr. Grey said that the inference would be so under any Act but the Pharmacy Act. The defendant must be held to be the servant of the company. Clearly it could not be the person who put the drum on the railway dray.

The learned Judge said that argument was one akin to that if you could not hang the highwayman you must hang the person who saddled his horse.

Mr. Grey contended that the decisions of the cases he had quoted tended to hit the person who set the sale in motion. If the defendant was not the seller the case opened out an easy way of evading a most useful Act of Parliament, because any body of persons could form themselves into a company and would be able to supply dangerous drugs and poisons through their agents, and they could not be touched by the Pharmacy Act.

The learned Judge said the case suggested developments that might bring the Act into ridicule, but it was inconceivable that any mischief could result from the supply of the weed killer in this particular way. The argument that it was unlawful for any unqualified person to sell it would apply equally to anyone who sold paint containing arsenic. If that principle was pushed to its utmost limit it would mean that a drysalter would not be able to sell paint containing arsenic, but that it would have to be sold by a chemist. It was scarcely conceivable that the Legislature intended such a thing. He did not think the case turned upon any technical question as to what the word sell meant. It meant the act of the person who had the conduct of the transaction. Where the evidence varied as to facts he preferred to take the word of Mr. White, a respectable tradesman, and that of his son, to

that of a professional spy. Throughout the transaction Mr. White appeared to have represented himself as the agent of other persons, and whether those persons were acting within the law was not for that Court to inquire. He was not there to decide whether the Boundary Chemical Co. committed any offence by what they did, but whether Mr. White committed any offence. The result of Mr. White's action in taking and forwarding the order might render the company open to a suit for breach of contract if they refused to fulfil the order, but it did not impose any liability on him, as the control of the sale appeared to remain with them. He quite thought that if Mr. White had kept this material in stock, and had handed it over the counter to the customer it would have been no sort of answer to the suit for him to say that he was only selling as agent. If Mr. White had kept the drug in the cellar, and had said to the purchaser, "We will send it by your cart," he would have been just as much the seller as if he had handed it over the counter, because the sale would have been under his control. Accepting an order and sending it on to somebody else for fulfilment did not make a person the seller of the goods and the person responsible. That being so, he thought the goods were not sold in the sense of the Statute by Mr. White. If they were sold in the sense of the Statute it was by the Chemical Company. Whether, notwithstanding the case in the House of Lords, they had exposed themselves to any penalty, was not for him to say. But he did not think that, according to the facts, Mr. White had subjected himself to any penalty, nor did there appear any reason for holding that he had enabled other persons to avoid the law. It was those other persons who had broken the law if anybody had done so. There must be judgment for the defendant.

Mr. Grey asked his Honour to allow an appeal.

The Judge said he would consider the question, and subsequently he gave leave to appeal.

Pharmaceutical Society *v.* Edith Gardner.

This case came on before his Honour Judge Yate Lee, at the Ashton-under-Lyne County Court, on July 27.

The action was brought by the Pharmaceutical Society of Great Britain for the recovery of the amount of one penalty (£5) under Section 15 of the Pharmacy Act, 1868, incurred by the defendant by having sold poison contrary to that Act.

The defendant is an unqualified assistant at the shop 160, Stamford Street, Ashton-under-Lyne, kept by the Thompson Drug Co., Limited, who are also proprietors of another shop at 291, Stamford Street, Ashton-under-Lyne.

Mr. Harold Hyde, Solicitor of Ashton-under-Lyne, instructed by Messrs. Flux, Thompson and Flux, of London, represented the plaintiffs.

Previous to the date for hearing, the defendant had signed a confession of judgment, but had made no proposal under the County Court rules as to payment of the amount of the debt and costs.

Upon the case being called on, Mr. Hyde, after drawing his Honour's attention to the nature of the action and the facts as above mentioned, pointed out the desirability of an order as to payment being made so as to act as a warning and deterrent to others which could only be obtained by the publicity consequent upon the taking of these proceedings under the Pharmacy Act.

The plaintiffs were charged by the Legislature with the administration of the Pharmacy Act, and not only had a public duty to perform, but (as the preamble of the Act stated) they performed same for the "safety of the public."

In the end His Honour gave judgment for the plaintiffs in accordance with the confession, the amount with the costs to be paid by instalments of the nature contended for by the plaintiffs.

Condensation Products of Cotoin and Formaldehyde.—Tasteless and odourless derivatives of cotoin have been obtained by the action of formaldehyde on the base in the presence of an acid corresponding to the equation—$2C_{14}H_{12}O_4 + CH_2OCH_2 (C_{14}H_{11}O_4)_2 + H_2O$. In this way either monomolecular or polymeric methyl-dicotoin are obtained. The first body crystallises from acetone in brittle shining prisms, readily soluble in acetic acid, chloroform, and acetone, dissolving with difficulty in alcohol, ether, and benzene, insoluble in petroleum, ether, and water. The body is readily decomposed by alkalies; it melts at 211° to 213° C. with decomposition. The polymeric compound forms a yellow or brownish amorphous powder, which is much more difficult to dissolve.—*Oest. Zeit. für Pharm.*, **53**, 295.

THE COMPANIES ACTS AMENDMENT BILL.

THIRD READING PASSED.

In the House of Lords on Thursday, August 3, on the motion for the third reading of the Companies Bill, the Lord Chancellor said:—My Lords, there are one or two observations which, I think, it is desirable I should make to your lordships. There were some clauses introduced in the Bill in Committee having relation to questions which, I think, are very interesting to the medical and pharmaceutical professions. I have received a very large number of communications upon the subject, and I am fully alive to the necessity of guarding very carefully the language by which the intentions of the measure, as manifested by the amended form of the Bill, should be carried out. I am still very strongly convinced that a company ought not to be permitted to do what a private person is prohibited from doing, and that the public must be protected against practising of that sort. It is impossible to resist the propriety of subjecting those companies who are at present carrying on business as chemists and druggists to restrictions such as are proposed in the Bill. I daresay your lordships will remember that cases have been decided—in my opinion rightly decided—that the language which calls upon a person to qualify in any of the professions does not in turn apply to companies; and that the word "person" in the Acts which form the code upon that subject must be construed as meaning a natural person and not a company. The idea of an ideal personage such as a company practising and undergoing an examination is absurd, and cannot cohere with the language of the Statute. In my view, the learned judges who came to the conclusion that that was the true construction of the Statute were perfectly right, and that decision left the law that a company could be formed to do the very thing which an individual is not permitted to do without examination as to qualifications. I think I may say that the Committee to whom this matter was referred was unanimously of opinion that the formation of companies to practice any profession and who intended really to take advantage of the company machinery to do that which an individual without qualification may not do, should be stopped. As I have said, I have received a large bulk of correspondence on the subject, and in some of the communications which have been sent to me it is suggested that this is an effort to prevent proper enterprise, and so forth. As a matter of fact, I think the writers were not familiar with the state of the law. It is true to say that although a company can do it, and that at present a company cannot be prosecuted for doing it, and a company cannot undergo an examination to enable them to do it, yet if an individual dispenses without qualification you can catch him and prosecute. And it was in view of that state of the law on the subject that the Committee to which this matter was referred came to their conclusion. I must say that I quite agree that if this matter is to come forward, as it probably will in another session, it is desirable that we should guard very carefully the language used, so as not to interfere with any proper vested interest; but, on the other hand, that we should not allow the public generally to be exposed to the dangers of the practising of unqualified persons as dispensers. What I said on a former occasion, that the Committee were practically unanimous, appears to have given rise to controversy. I say so still. It is true there were certain divisions on matters of detail during the investigations, which lasted three years—some members of the Committee went one way and some the other—but they were not important questions. What I said before, and what I adhere to now, was that on the main lines of the Bill, the important matters under the Bill, the measure as now presented represents the practically unanimous decision of the Committee. I think, my Lords, that it is a subject of congratulation that on such a subject practical unanimity has been attained. At this period of the session I think it is, perhaps, not worth while that I should go through the whole clauses of the Bill. I have said all that is necessary on the report of Amendments to the Bill. I can only add that I believe the Bill will be a very great improvement on the state of the law as it exists at present, and that it will in a great measure check the creation of fraudulent companies, which, I think, is the proper thing to do, and not to enact a penal code against persons engaged in the conduct of such enterprises.

The Earl of Kimberley and the Earl of Dudley expressed approval of the Lord Chancellor's views, and the Bill was read a third time.

THE COMPANIES BILL AND THE PRACTICE OF PHARMACY.

THE statement made by Lord HALSBURY at the third reading of the Companies Bill in the House of Lords and in explanation of the two clauses introduced into the Bill while in the Committee stage was extremely important on account of the further and. as some may be disposed to think, unexpected disclosure of the views of the Government, and of legal authorities, concerning company legislation as it may affect persons engaged in various occupations of a more or less professional nature and requiring, for their exercise, qualification of the individuals carrying on the business. From the time when the LORD CHANCELLOR first expressed his opinion that the state of the law relating to the business of a chemist and druggist was extremely unsatisfactory, and when he proposed to remedy the consequent anomaly in the Society's Pharmacy Bill of last year, there has been much uncertainty as to the precise direction in which the LORD CHANCELLOR desired amendment of the law and as to the particular influence of such contemplated amendment upon the privileges of persons registered under the Pharmacy Act, 1868, and legally entitled to describe themselves as chemists keeping open shop for retailing. dispensing, and compounding poisons. That uncertainty has now been entirely removed by the LORD CHANCELLOR'S explanation of the reasons for introducing into the Companies Bill provisions having special application to the business of pharmaceutical chemists. Some readers of this journal will probably be surprised to find that the tendency of the LORD CHANCELLOR'S remarks last week was entirely in accord with the principle of the suggestions made by the Council of the Pharmaceutical Society, last February, as to the lines upon which general amendment of pharmacy law is desirable, and was also in accord with the view that company trading should be prevented from interfering with persons qualified under the Pharmacy Acts. But such is actually the case, as will be seen from the report at page 168. Though the decision of the House of Lords as to the natural construction of the word "person" as it stands in the Pharmacy Act, has been accepted by his Lordship as being the only one possible in that case, the acceptance of that construction is coupled with a distinct indication that a company, as such, is to be considered outside the scope of the statute, not only for that reason, but also for the much more cogent reason that a company is as incapable of performing the functions of an individual qualified under the Act, as it is of undergoing the examination essential for obtaining qualification.

That the highest legal authority in the Kingdom gives emphatic expression to that view is of no small importance, for if it does not amount to an admission that the decision in question was technically erroneous, it shows, at least, that the decision, as hitherto understood, is now recognised to have been acted upon in a manner contrary to the spirit of the Pharmacy Acts, and directly opposed to the intention of their promoters. That view of the decision—which has always been maintained by the Pharmaceutical Society—appears, moreover, to have been entertained by the LORD CHANCELLOR from the time when he first attempted to give effect to it, last year, by an addition to the Society's Pharmacy Bill, which could not then be carried out in face of the undertaking that contentious matter should not be introduced into that Bill. The anomaly that a company was not liable to penalty, complicated by the misleading suggestion of the widow's clause, led then to a one-sided view, leaving the reasonable claims of registered chemists out of consideration. Hence the defects of the LORD CHANCELLOR'S earlier proposal, which appears now to have been largely corrected by his adoption of the principle embodied in the Council's suggestions.

Whenever the provisions of the Companies Bill, relating to the business of a chemist and druggist, come before Parliament in definite shape, for the purpose of giving full legal effect to the intention of the Pharmacy Acts, they will probably be treated as contentious matter. The unqualified persons who have, in defiance of the law, kept open shop for retailing, dispensing, and compounding poison, and have assumed the title of chemist in connection with their business, will no doubt be active in their defence. Reference to the report of the LORD CHANCELLOR'S speech will show that such a contingency has been anticipated by his Lordship and that he is fully alive to the necessity of avoiding interference with rights and privileges other than those intended to be conferred by the Pharmacy Acts, or, as he expresses himself, "with any proper vested interests." At the same time it will be seen that Lord HALSBURY is decidedly of opinion that the public should not be exposed to danger by unqualified persons practising as dispensers. In those respects the arguments put forward in this journal during the last few months find complete support in the utterances of the LORD CHANCELLOR. The expectation may also be entertained than when the subject comes to be considered by the Legislature, in regard to the claims of legally qualified persons to enjoy the privileges consequent upon and essential to their qualification, the justice of those claims will be duly recognised. It will be seen that the statutory provisions conferring those privileges have not been enacted for the benefit of chemists and druggists; but in the interests of the public, and that their observance is requisite, for that reason as well as in justice to persons who have complied with the requirements of the law. If some of those who take part in the settlement of this matter, as one of national importance, happen to be shareholders in companies that have exceeded their rights and, either inadvertently or otherwise, trespassed upon those of registered chemists, there need be no fear that claims of a reasonable nature will suffer on that account provided that qualified chemists are united in their efforts to obtain redress for the injury they have suffered.

ANNOTATIONS.

WHATEVER ENCOURAGEMENT MAY BE GIVEN by the proverb that everything comes to those who wait, is perhaps more frequently followed by the effect of hope deferred than by tangible consolation; but, in regard to the long-continued and hitherto fruitless efforts made by the Council of the Pharmaceutical Society to obtain a remedy for the company grievance affecting registered chemists and druggists, the statement made by the Lord Chancellor at the third reading of the Companies Bill in the House of Lords seems to furnish reasonable prospect of speedy compensation for the patience with which a great injustice has been endured. As bread cast upon the waters and found after many days, the labour expended some years ago in bringing to the notice of government departments the mischief resulting from abuse of the Companies Acts, and from the defects of the Pharmacy Act, 1868 seems at length to have had such effect as to give promise of a satisfactory legislative result. Mr. Carteighe and his colleagues, who took part in the work referred to, may first of all be especially congratulated on the ultimate recognition of their claim that evasion of the Pharmacy Act by companies of unregistered persons was a matter to be dealt with in a Companies Bill. That point is now secured by the insertion of a clause for the purpose in the Companies Bill introduced by the Government, and though the terms of that clause will require further amendment than they have already undergone in the transfer of the clause from the Lord Chancellor's Pharmacy Bill, the probable nature of that amendment may be inferred from his Lordship's very emphatic expression of his own strong conviction that a company ought not to be permitted to do what an individual is prohibited from doing, as well as from the further statement that the Committee to which this matter was referred was unanimously of opinion that the formation of companies to practise any profession and to take advantage of the company machinery to do that which an individual without qualification may not do, is contrary to the present state of the law and should be stopped.

THE LEGAL POSITION OF REGISTERED CHEMISTS in regard to the practice of their business is, as stated in the Pharmacy Act, of such a nature as to give them individually the exclusive privileges of carrying on that business and of using the title of chemist in connection with it. Consequently the usurpation of their privileges by unqualified persons incorporated as companies is as inconsistent with the object of the Pharmacy Act as a public measure as it is with a common-sense view of its intention, and in that respect registered chemists are very much more favourably situated than the members of some other professions. For, though the idea of such a company carrying on any practice requiring individual qualification is absurd in itself, as the Lord Chancellor remarked, the business of chemists and druggists is by statute restricted to qualified persons, while the practice of medicine has no such legal limitation. While the right to use the title of physician is matter of dispute, and practice as an apothecary is difficult to define, the actual practice of medicine is open to anyone, and there is very much less legal reason for prohibiting seven persons—who individually have that right in common—from practising medicine as a company, than there is for prohibiting seven persons, individually unqualified, from carrying on, as a company, the business of a chemist and druggist. Though the generosity indicated by the professed disposition of the medical profession to support registered chemists in the defence of their legal privileges is entitled to recognition, the condescending manner in which that disposition has been expressed by our contemporary, the *British Medical Journal*, does not quite suit the relative legal position of the two parties in regard to company legislation. Pharmacists have led the way in impressing governmental departments as to the legal and common-sense claims of persons engaged in occupations for which some kind of qualification is demanded in the public interest, and there is no reason whatever for unequal appropriation of the fruits of their labour.

THE CIRCUMSTANCE THAT PRIVILEGES, lawfully acquired by some fifteen thousand British subjects, are unjustly interfered with by persons who have not satisfied the requirements of the Statute by which the privileges referred to were established, points to a state of affairs which deserves and requires greater attention than it has hitherto received either in connection with the interests of the general public, or in a more limited relation, as a matter prejudicially affecting chemists and druggists registered under the Pharmacy Act, 1868. In both respects there has long been need either of amendment of the law or of such more rational interpretation of it as would obviate the flagrant abuse of the Companies Acts for the purpose of evading the salutary provisions of the Pharmacy Act and filching from legally qualified persons the privileges exclusively belonging to them as a consequence of their qualification. That such a necessity exists was made evident in an unexpected quarter by the opinion expressed last year by Lord Halsbury as to the effect that has been produced by the decision that the word "person" in the Pharmacy Act, 1868, is not to be held applicable to any other than an individual person, capable of being examined and registered as the Act provides. That effect he regarded as an anomaly so serious that it required correction by further legislation, because he held that common-sense demands that an incorporated company should be subject to penalty for any infringement of the Pharmacy Acts, just as much as an individual. The drift of those remarks of the Lord Chancellor does not appear to have been quite clearly apprehended at the time by registered chemists; but it is remarkable that his evident interest in the matter was not taken advantage of by them with a view to remedy a grievance of which they have complained so long and stop misuse of the chemist's title.

THE CASE WAS DIFFERENT WITH THOSE PERSONS who were at that time disregarding the provisions of the Pharmacy Act, and, though unqualified, were carrying on the chemist's business under the assumption that as companies they could not be brought within the penalties imposed on unqualified individuals. They, perhaps naturally, appear to have had a keen perception that they were on dangerous, if not forbidden, ground and became apprehensive. The inference drawn by them from the Lord Chancellor's remarks was that the existence of drug companies was threatened, and that the Lord Chancellor's intention was to remedy the anomaly he had recognised by a legislative measure which would prevent companies from continuing to carry on business as chemists. From that point of view many of the communications which the Lord Chancellor speaks of as having been addressed to him have no doubt suggested that these piratical companies had acquired a vested interest, by defying the law, and that making them subject to its penalties would be an endeavour to prevent proper enterprise. It is satisfactory therefore to find that, in referring to such arguments, his Lordship expresses the opinion that the writers who took that line of argument were not familiar with the state of the law. In that connection his further remarks appear intended to convey the common-sense idea that a company is just as incapable of anything for doing which an individual requires to be qualified, as it is incapable of being prosecuted under the Pharmacy Act, and that consequently registered chemists have a right to claim such interpretation, or, if need be, amendment of the law as may be requisite for giving legal effect to that view of the matter in their own interest as well as for that of the general public.

But if the Fact of Companies constituted of unqualified persons carrying on the business of a chemist without being liable to penalties under the Pharmacy Act, appears to the legal mind an anomaly from a common-sense point of view, there is another aspect of the matter upon which the influence of common-sense may be usefully brought to bear for the purpose of correcting another anomalous result by which legally qualified chemists are especially prejudiced. The use of titles indicative of qualification for retailing, dispensing, and compounding poison is exclusively the privilege of individuals, and the assumption of such titles by companies is still more inconsistent with the object and intention of the Pharmacy Acts than keeping open shop for retailing, dispensing, or compounding by the agency of a legally qualified assistant or manager. Though such an assistant would be entitled to sell or dispense on his own account, nothing can justify the lending of his qualification to a company of unqualified persons, and he could not in any case transfer to the company the right to use the title indicating qualification. If, as some have thought, the objects of the Pharmacy Act may be to some extent secured so far as the interest of the public is concerned, by requiring companies to employ qualified assistants, that plan would not give chemists their due if the use of their titles by companies were allowed. Such improper use of title has not been brought before a court, and though it might be contended that it is really an infringement of the Act, there is a danger of the precedent of of the House of Lords decision—as it has hitherto been understood—being held to extend legal immunity to a company for any act contrary to the provisions of the Pharmacy Act.

The Lord Chancellor when speaking of personal qualification as being a condition essential in the interests of the public, particularly mentioned the business of the pharmaceutical chemist and the dispensing of medicine as occupations in the exercise of which he considers that condition should be secured by statutory provisions which would not allow the public to be exposed to danger by the practice of unqualified persons. Apparently, the inference may be drawn that he makes some distinction between those occupations and the business of a chemist and druggist partaking more of the nature of ordinary trade. While admitting the impossibility of resisting the propriety of subjecting companies to restriction even as regards carrying on business as chemists and druggists, Lord Halsbury also holds that companies should be altogether debarred from carrying on the more professional occupations because of their inability to acquire the necessary personal qualification. That appears also to have been the unanimous conclusion arrived at by the Committee on considering the matter in connection with the present state of the law. That view is quite in harmony with the Council's suggestion that the dispensing of medicine should be carried out only by persons qualified within the meaning of the Pharmacy Acts, and it is in accord with the system obtaining in all countries where the practice of pharmacy is regulated with due regard for the public interest and also for the just claims of pharmacists.

Assuming that the Limitation of liability contemplated by the Companies Acts was intended to relate only to financial matters, and that limitation of liability to penalties for statutory offences is properly outside the intention and scope of those Acts, the introduction, into a Bill for amending the Companies Acts, of provisions as to the mode in which the business of a chemist and druggist should be conducted appears to be somewhat inappropriate. Such abuse of the Companies Acts requires a general prohibition, and that object might be suitably effected by a clause prohibiting companies from the exercise of any professional practice or business requiring a personal qualification. Thus, for example, if Clause 3 of the Companies Bill ran as follows that purpose would be served without depriving qualified persons of any advantage they might derive from incorporation under the Companies Acts, should they find that desirable. It shall be unlawful for a company, or other association of persons, to carry on any professional practice or business requiring for its exercise any kind of personal qualification or to use any title or designation implying such qualification, unless the persons constituting the company or association severally possess a qualification that would entitle them to carry on professional practice or business individually, and if any company contravene this enactment it shall be liable, on summary conviction, to a fine not exceeding five pounds for every day during which the contravention happens.

Any Further Regulation of the business of a chemist and druggist for which good reason can be shown, or of the practice of pharmacy, might be effected more suitably in a Bill to Amend the Pharmacy Act, 1868, by clauses providing: That it shall be unlawful to sell poison by retail, or to keep open shop for dispensing or compounding medicines, and to assume in connection with such business any title or designation implying qualification for those purposes, unless the proprietor or manager conducting the business in such shop be registered as the Pharmacy Act, 1868, provides, and the name and qualification of each proprietor or manager be conspicuously posted in each shop or other place in which the business is carried on and printed on all labels required to be used in conformity with the provisions of the Pharmacy Act, 1868, and for any infringement of these provisions such proprietor or manager shall be liable to penalty. Any person keeping open shop for retailing poison or dispensing or compounding medicine, and using in connection with that business the title of chemist and druggist or any other designation implying registration under the Pharmacy Act, 1868, who shall fail to conform with any regulations as to the keeping, dispensing, and selling of poisons, made in pursuance of that Act, or who shall compound any medicines of the British Pharmacopœia otherwise than according to the formularies of the said Pharmacopœia, shall for every such offence be liable, etc. Any person retailing, dispensing, or compounding poison, unless registered as a chemist and druggist, or acting under the direction and personal supervision of a person so qualified, shall for every such offence be liable to pay a penalty, etc.

The Conduct of Urine Analysis by Chemists is thought by the *Medical Press* to have much to commend it, but it is suggested that their training is, as yet, hardly such as to fit them for the task. Medical men, it is pointed out, are not likely to have recourse to the services of chemists merely in order to ascertain qualitatively the presence of albumin or sugar in urine, as that much can easily be done within the time at the disposal of the busiest man. What is more likely to be required is an exact quantitative analysis, not only in respect of albumin and sugar, but also in regard to urea, uric acid, and the various abnormal constituents of morbid urine. But ability to furnish trustworthy reports on those lines is said to require special training and experience of a kind not at present within the reach of most retail chemists. It is suggested that, when British universities "awaken to the opportuneness of instituting a degree in pharmacy," urine-testing and the analysis of alimentary substances might well form a conspicuous item of the curriculum. "By the time a chemist reaches this stage of graduation, however, he would probably relinquish counter-prescribing and the sale of toothbrushes and soaps in favour of the more purely scientific departments of his calling, and it is probable that his fees would be on a scale which would indispose the average practitioner from having recourse to his assistance." But, having placed the chemist and druggist in this dilemma, the *Medical Press* concludes with the more comforting prophecy that at some time in the future the medical practitioner "who by that time will have given up dispensing his own medicines," will probably get his

analyses and bacteriological examinations done by the chemist, presumably in spite of the advanced fees.

IN REFERRING TO THE CONFERENCE PAPERS last week it was pointed out that the number communicated at Plymouth was much in excess of what was justified by the limited time available, and the suggestion was offered that a remedy might be found for such a state of affairs by asking authors to read abstracts only, whilst advance proofs of their papers were in the hands of those members of the Conference present at the meeting. If that remedy were to be adopted, however, it would be necessary for the contributors of papers to send their manuscripts to the Hon. Gen. Secretaries much earlier than they have acquired the habit of doing. It is, or ought to be, well known that, in the Blue List issued about the beginning of June each year, containing a list of subjects suggested by the Executive Committee of the B.P.C. for investigation, a request is made that all manuscripts of papers should be sent in to the Hon. Gen. Secretaries at least ten days before the annual meeting. This year, therefore, the manuscripts should all have been delivered to the Secretaries by July 15 at latest, and—in accordance with the arrangement by which the Editor of the *Pharmaceutical Journal* undertook to have the papers put in type as soon as they reached him—they ought to have been in the printer's hands by July 17 or 18. As a matter of fact, only eight out of the thirty papers arrived within the prescribed time, four arrived on July 18, five on July 19, seven on July 20, one on July 21, three on July 22, one on July 24, and the last was not in the printer's hands until July 27. Nevertheless, proofs of all papers received by the Editor up to Friday, July 21, were promptly sent direct to the authors for correction—in most cases on the same day as the papers arrived—and proofs of all the remainder were in Mr. W. A. H. Naylor's possession, at Plymouth, when the meeting opened on Tuesday, July 25. There is, of course, no obligation on the part of the Conference Executive to furnish any proofs to authors prior to the meeting, but, as the above record shows, everyone whose paper was received within four days of the annual meeting had a proof sent to him in advance for correction, and further proofs were awaiting every author—except one who had not sent off his manuscript in time—when the Conference opened.

THE ABOVE DETAILED EXPLANATION of the procedure adopted in connection with the proofs of Conference papers is published in refutation of an erroneous statement to the effect that "the conditions under which the manuscript and prints of papers are placed hamper the spread of the knowledge contained in them." The organ in which this untruthful statement appears is evidently densely ignorant of the conditions under which the manuscript and prints of papers are placed, and has been decidedly ill-advised to go out of its way to attack the Senior Hon. Gen. Secretary, who is alone responsible in the matter. It does not appear to be generally known that no paper is actually accepted until the Executive Committee of the B.P.C. meets at the town selected for the annual meeting, on the day prior to that meeting. Until that date, therefore, the papers are strictly confidential and cannot be distributed broadcast. At the same time, Mr. Naylor has always been prepared to do whatever may lie in his power to facilitate the preparation of abstracts, for publication in the event of the papers being accepted and submitted to the Conference, and it is distinctly unfair to charge him, by implication, with securing an author's manuscript and withholding proofs from him and everybody else as long as possible. Directly Mr. Naylor received a paper he sent it to be put in type, and within twenty-four hours, in most cases, proofs were despatched by the same post to Mr. Naylor and the authors—the only persons entitled to receive them. The manuscripts were also returned to Mr. Naylor, and facilities for preparing abstracts were, we understand, afforded by him to every person who had a right to expect the courtesy and who made proper application for such a privilege to be accorded. Unfortunately, Mr. Naylor's courtesy has not been reciprocated in this one instance, but all who have any acquaintance with the painstaking manner in which he attempts to serve the best interests of the Conference in every possible way, will join in expressing disapproval of this veiled attack, and of the suggestion that difficulties have been interposed which interfere with the efficient working of the Conference business. In no previous year have the arrangements for printing and publishing papers worked more smoothly, and on no other occasion have the efforts to secure full publicity for the doings of the Conference been so successful.

A CASE OF FAR-REACHING IMPORTANCE was heard at Worcester County Court on Tuesday, when a local seedsman was sued for selling arsenical weed-killer, against the provisions of the Pharmacy Act, 1868. The defendant did not make the weed-killer, but he advertised the fact that he was an agent for the manufacturers and took orders for the preparation. Those orders were executed by the manufacturers, who sent the weed-killer direct from their works, and allowed the defendant a commission of 25 per cent. on the amount of his orders. The question raised in the case was who was the seller within the meaning of the Act, and to that question the County Court Judge, Sir Richard Harington, replied that the weed-killer was sold by the manufacturers, and that they had committed the offence, if any had been committed. The control of the sale, he contended, remained with the manufacturers, and the defendant could not be regarded as the seller, inasmuch as he did not keep the weed-killer in stock and hand it over the counter to the customer. Accepting an order and sending it on to somebody else for fulfilment did not, in the Judge's opinion, make a person the seller of the goods and the person responsible. That being so, the seller in this case was not the defendant, but the company which executed the order. Leave to appeal was asked and granted.

THE SALE OF HEADACHE POWDERS is referred to in the *Druggists' Circular*, where it is remarked that headache seems to the laity a very simple ailment, and a dose of something to "cure" it is naturally regarded as an equally simple thing in medicine. As a result, any remedy advertised as a headache cure is unhesitatingly taken by the public, without any thought of danger. Nevertheless, danger does exist in connection with many of the preparations which have sprung into use for the relief of headache during recent years, their therapeutic effect being depressant and sometimes so pronounced as to paralyse the heart's action. Several deaths in America have been caused or hastened by the use of these preparations, and it is stated that the druggists in one locality have decided to attach a special warning label to headache powders. The label reads: "Contents unknown. Not responsible to the user," and is presumably attached to all powders not prepared by the retailer himself. Caution ought to be stimulated by the presence of such a label, but if the ultimate effect is simply to encourage the public to purchase headache powders prepared by the retailer, at the expense of the proprietors of advertised preparations containing the same ingredients, it is difficult to see where any real benefit will accrue. Obviously, druggists attaching to other people's preparations a label of the kind referred to should not continue to sell without a warning similar articles prepared by themselves.

THE EXPERIMENTAL METHOD advocated by Bacon and Harvey has been extremely rich in results, and a writer in the *Edinburgh Review* points out how physiologists and biologists have enriched practical surgery with antiseptic methods and with anæsthesia, with control over hæmorrhage while operating, with a rational and successful treatment of aneurism and of glaucoma, with the power

in not a few cases of removing a tumour even from the brain itself. In medicine proper, again, all that is summed up in the phrase "heart disease," all knowledge of arterial tension and its influence on the whole organism, have been evolved gradually from the basis of Harvey's discovery. All our knowledge of nervous disease is based upon vivisectional experiments, from Charles Bell to Hitzig and Ferrier. Almost all our knowledge of the digestive processes, of angina pectoris and of methods of relieving it, has been gained through experiment. Practical medicine has been enriched, through experimental research with such drugs as digitalis, cocaine, croton-chloral, nitrite of amyl; with the method of auscultation; with a knowledge of the cause of tuberculosis, typhoid fever, cholera; with the life-history of parasites; with the cause of myxœdema and related conditions and how to relieve them, and with a life-saving remedy for diphtheria. It is, in fact, asserted to be no figure of speech, but the simplest of truths, to say that everything of solid value in medicine and surgery is based upon knowledge gained by the experimental method. Quoting from the article referred to, *Nature* expresses the conviction that it will prove of much assistance in the spread of truth and the advancement of science.

The Standardisation Question is considered by a writer in *Merck's Report*, who suggests that the progress of pharmaceutical science seems to be a new source of trouble to laymen. The latter are said to want to know if people were not better off when doctors prescribed old-fashioned decoctions and tinctures, firmly believing in their efficacy, than they are now, when it is asserted that but little dependence can be placed upon such preparations because of their variability. But whilst the existence of such variability affords cause for serious thought, the writer quoted urges the adoption of some plan that will overcome the difficulty rather than a policy of retrogression. The remedy suggested is to standardise every galenical kept in stock, if it contains definite active principles. Nux vomica, cinchona and opium preparations are already so standardised, and it is anticipated that the revisors of the U.S. Pharmacopœia will add materially to the list in the 1900 issue of that work. It is urged that every reason that existed in 1890 for standardising nux vomica, cinchona and opium can be advanced with equal force in the case of belladonna, hyoscyamus, stramonium, coca, veratrum, colchicum, conium, hydrastis, ipecacuanha, physostigma and cantharides. All of these, it is asserted, can be standardised chemically, and many other drugs—including ergot and digitalis—should be standardised by physiological tests. It is thought that the chief galenicals could be brought down to exactness of dose by this method, but the fact appears to have been overlooked that—both from a chemical and a physiological point of view—it is infinitely more advantageous to employ pure principles as remedial agents than to continue the administration of large quantities of more or less inert matter which only serves to hinder and mask the effects of the active constituents of the drugs. The objection that the physiological effects produced by a drug are never exactly the same as those caused by a single constituent of it, or by any combination of constituents that fails to represent the whole drug, possesses but little validity. Exact effects can only be produced by pure principles, and the whole tendency of modern medicine is in the direction of employing substances of definite chemical composition. The adoption of the principle of standardisation in modern pharmacopœias represents a compromise, and the more widely it prevails the more will the pharmacist be called upon to exercise his individual ability, unless he intends to become dependent upon the wholesale druggist and manufacturer of galenicals. A resort to physiological standardisation will prove even worse in that respect than dependence upon chemical standardisation, and on the whole it would appear preferable that, if uniformly standardised medicaments are to become the rule, the sooner pure chemical products come to be exclusively used in medicine the better.

OFFICIAL EXAMINATION OF WOOD NAPHTHAS.

We are enabled, through the courtesy of the officials at the Government Laboratory, to give the following details of the tests for wood naphtha referred to in our issue of July 15 (*ante*, p. 56):—

Bromine Decolorisation.

A standard bromine solution is made by dissolving 12·406 Gm. of potassium bromide and 3·481 Gm. of potassium bromate in a litre of recently boiled distilled water.

50 C.c. of this standard solution (=0·5 Gm. bromine) are placed in a flask of about 200 C.c. capacity, having a well-ground stopper. To this is added 10 C.c. of dilute sulphuric acid (1 in 4) and the whole shaken gently. After standing for a few minutes the wood naphtha is slowly run from a burette into the clear brown solution of bromine until the latter is completely decolorised. Not more than 30 C.c. of the wood naphtha should be required for this purpose.

Methyl Orange Alkalinity Test.

The naphtha should be faintly acid to phenolphthalein, slightly alkaline or neutral, rarely acid to litmus, and always alkaline to methyl orange. 25 C.c. of the wood naphtha is placed in each of two beakers, and titrated with deci-normal acid, using in the one case a few drops of litmus solution, and in the other of a solution of methyl orange as indicator. With litmus usually 0·1 to 0·2 C.c. of deci-normal acid is required to neutralise. With methyl orange the total alkalinity should be greater—at least 5 or 6 C.c. of deci-normal acid being required for neutralisation.

The total alkalinity, less that given with litmus, is the "methyl orange alkalinity," and, for the 25 C.c. of wood spirit, should not be less than is required to neutralise 5 C.c. of deci-normal acid.

Estimation of Methyl Alcohol.

22 Gm. of coarsely powdered iodine and 5 C.c. of distilled water are placed in a small flask and cooled by immersion in ice-cold water. Then 5 C.c. of the wood spirit (60·0 o.p.) is added, the flask corked, the contents gently shaken, and allowed to remain in the ice-cold bath for 10-15 minutes.

When well cooled 2 Gm. of red phosphorus is added to the mixture of spirit and iodine in the flask, and the latter is immediately attached to a reflux condenser.

The reaction soon commences, and must be moderated by dipping the flask into a cold water bath. (Spirit may be lost if the reaction is too violent.) After about 15-20 minutes, when all action appears to have ceased, the water-bath under the flask is gradually heated to a temperature of about 75° C. (167° F.), and the flask being occasionally shaken is allowed to remain at this temperature for 15-20 minutes. The source of heat is then removed and the apparatus left for an hour till it has cooled, when the condenser is reversed, and the methyl iodide slowly distilled off—first at a low temperature—the bath being allowed to boil towards the end of the operation only. The end of the condenser dips into water in a measuring tube, and the iodide is collected under water and measured at a temperature of 15·5° C. (60° F).

The percentage (by volume) is found from the formula:—

$$\frac{\text{C.c. methyl iodide found} \times 0{\cdot}647 \times 100}{\text{C.c. wood spirit taken.}} = \text{Percentage (by volume) of methyl alcohol.}$$

Or when 5 C.c. of spirit is taken:—

C.c. methyl iodide × 12·94 = percentage (by volume).

Esters, acetals, etc., also yield methyl iodide by this process, and from the percentage of methyl alcohol calculated as above an amount equivalent to the percentage of these substances present must be deducted. Practically, however, methyl acetate is the only compound usually found in quantity sufficient to materially affect the result. The Gms of methyl acetate per 100 C.c. of spirit multiplied by 0·5405 give the equivalent of methyl alcohol to be deducted from the total percentage by volume calculated from the methyl iodide found.

The Acetone Reaction.

25 C.c. of normal soda is placed in a flask similar to those used in the bromine reaction. To this is added 0·5 C.c. of the naphtha. The mixture is well shaken, and allowed to stand 5-10 minutes. Into it from a burette n/5 iodine solution is run slowly, drop by drop, vigorously shaking all the time till the upper portion of the solution, on standing a minute, becomes quite clear. A few C.c. more of n/5 iodine solution are added, as to get concordant results an excess of at least 25 per cent. of the iodine required must be added. After shaking, the mixture is allowed to stand for 10-15 minutes, and then 25 C.c. normal sulphuric is added. The excess of iodine is liberated, titrated with n/10 sodium thiosulphate solution and starch, and half the number of C.c. of thiosulphate solution used is deducted from the total number of C.c. of iodine solution used. The difference gives the amount of acetone by weight in the naphtha by the formula :—

C.c. n/5 iodine solution required × 0·3876 = Gms. of acetone per 100 C.c. of wood naphtha.

This includes as acetone any aldehydes, etc., capable of yielding iodoform by this reaction.

If the quantity of "acetone" is excessive, a less quantity of the spirit is taken, or 10 C.c. are diluted with 10 C.c. of methyl alcohol free from acetone, and 0·5 C.c. of the mixture is used.

Estimation of Esters.

5 C.c. of the wood naphtha is run into a silver pressure flask of about 150 C.c. capacity, together with 20 C.c. of recently boiled distilled water. 10 C.c. of normal soda solution is added, the flask securely closed and digested for at least two hours in a water-bath at 100° C. (212° F.). The contents are then washed into a beaker, and titrated with normal acid and phenolphthalein. The difference between the number of C.c. of soda taken and of the acid required for neutralisation may be calculated as methyl acetate (weight in volume) from the formula :—

$$\frac{0{\cdot}074 \times \text{C.c. soda required} \times 100}{\text{C.c. naphtha taken.}} = \text{Gms. per 100 C.c.}$$

Or if 5 C.c. of spirit is taken as above :—

1·48 × C.c. soda required = Gms. of methyl acetate per 100 C.c. of spirit.

SELECTED PRACTICAL FORMULÆ.

FORMULÆ COMPOUNDED WITH COGNAC, ARRACK, AND RUM.

Tea Tincture; Finest Pekoe tea, 30; vanilla, 1; white sugar, 5; distilled water, 200; cognac, 150. Digest for 3 days. The vanilla should be rubbed down with the sugar, and the mixture should not stand longer than 3 days in a moderately warm place. *Superfine Cognac :* Oil of cognac, 120; cognac, 20,000; spirit of wine, distilled water of each 7,000; tincture of tea as above, 30; Malaga wine, 2,000. *Fine Champagne Cognac :* Tincture of tea, 50; oil of cognac, 100; cognac, 20,000; spirits of wine, distilled water of each, 10,000; Tokay, 3,000. *Rum Flavour Essence :* Tincture of saffron, 250; tincture of vanilla, 500; cinnamon oil, 20; spirit of wine, 22; rum, 500. *Essence of Rum :* Rum flavour essence, 200; acetic ether, 40; cinnamon tincture, catechu tincture of each 10; formic ether, 75; tincture of vanilla, 10; angelica root tincture, 2; tincture of cinchona bark, 15; triple orange flower water, 100; essence of woodruff, 30; butyric ether, 20; spirit of wine, 650; rum, 1,000. *Jamaica Rum :* Essence of rum flavour, 30; essence of rum, 125; rum, 15,000; spirit of wine, 9,000; sugar candy, 150; distilled water, 8,000; Malaga wine, 2,000. The mixtures are greatly improved by keeping.—*Essence of Arrack*: Colourless essence of rum, 500 Gm.; acetic ether, 20 Gm.; birch tar oil, rectified, 5 drops; spirit of wine, 500 Gm. *Aromatic Arrack Essence*: Oil of celery, 5 drops; essence of maraschino, oil of cognac, of each, 12 drops; tincture of vanilla, 5 Gm.; tincture of saffron, 2 drops; spirit of wine, 500. *Arrac de Goa :* Butyric ether, 4; acetic ether, 5; tincture of vanilla, 10; essence of arrack, aromatic essence of arrack, of each 85; spirit of wine, 20,000; arrack, 10,000. These ingredients are mixed and filtered, and a hot solution of honey, 200, in distilled water, 7,000, is added.—*Pharm. Zeit.*, **44**, 153.

EMULSION OF COD LIVER OIL.

E. Leger employs moist casein as the emulsifying agent in the preparation of emulsion of cod liver oil. The moist casein is prepared as follows :—Milk is warmed to 40°-45° C., and for each litre taken, 30 Gm. of solution of ammonia are added. The mixture is placed in a separating funnel, and set aside in a cool place for 24 hours. The lower layer of liquid is then run off, heated to 40°-45° C., and acidified with acetic acid, when the casein is precipitated. This is washed with tepid water, collected on a cloth and pressed. To prepare a litre of emulsion, the casein prepared as above, derived from a litre of milk, is taken; sodium bicarbonate, 5 Gm., are dissolved in cherry laurel water, 100, and distilled water, 50. The casein is rubbed down with the solution; at first it swells, then passes into solution, forming an opalescent liquid, which is strained into a 2-litre bottle. Cod liver oil, 500 Gm., is now gradually added to the solution, with vigorous shaking after each addition, to complete emulsification. When this is effected, simple syrup, 250 Gm., is added, and finally enough water to bring the volume up to 1 litre. The cherry laurel water is used not only as a flavouring agent but also as a preservative.—*Journ. de Pharm.* [6], **9**, 575.

DOUBLE STAINING OF FLAGELLATES, FUNGI, AND SPIRILLA.

Ziemann's method is an elaboration of Romanowski's staining process, by which chromatin is coloured carmine red, or carmine-violet, and protoplasm blue. The author uses a mixture of 1 per cent. methyl-blue solution, 1 part, with 0·1 per cent. eosin solution, 6 parts. The staining is performed in concave well slides, which are covered to avoid evaporation. Any pellicle which forms on the surface is removed with blotting paper. The staining is accelerated by the addition of 2·5 per cent. of borax to the methyl-blue solution. The time required for staining blood preparations is about half-an-hour. On the addition of borax, however, only ten minutes is necessary for organisms of low development, without borax fifteen minutes. Flagellates take longer than blood. The objects are fixed either by being passed thrice through a flame, or are immersed for half-an-hour in absolute alcohol. Flagellates are fixed by immersion in hot sublimate alcohol (saturated aqueous sublimate solution, 2 parts, absolute alcohol, 1 part), and washing with 63 per cent. iodine alcohol. The results with bacteria are not yet satisfactory.—*Pharm. Cent.*, **40**, 144, after *Centralh. f. Bact.*, **1**, 945.

AMYL ACETATE AS A SOLVENT.

To clean brushes and vessels from dry paint or other resinoid impurities, amyl acetate is an excellent and inexpensive solvent. The odour of the acetate may easily be removed from the treated articles by means of methylated spirit.—*Scient. Amer.*, **80**, 361, after *Farb. Zeit.*

FLOOR WAXES.

(1) Hard paraffin, 6, yellow wax, 2, are melted and coloured with powdered tumeric. (2) Yellow wax, 1 kilo; oil of turpentine, 1½ kilos; spike oil, 10. (3) Yellow ceresin, 2 kilos; liquid paraffin, 0·5 kilo; French oil of turpentine, 1·5 kilos, benzene, 2 kilos. (4) Wax petroleum, 8, are placed in an earthenware vessel and melted on a hot-plate. The mixture is painted thinly on the floor while hot, leaving only a thin layer of wax after the evaporation of the oil. Polish lightly with a dry rag.—*Pharm. Zeit.*

PHARMACY IN AUSTRALASIA.

(From Our Melbourne Correspondent.)

The British Medical Council may possibly consider that Australian pharmacists and medicos have been somewhat dilatory in responding to its invitation for suggestions in connection with the proposed Addendum to the British Pharmacopœia. In Victoria at least, however, the matter is receiving careful consideration, and at the June meeting of the Council of the Pharmaceutical Society of Australasia, the committee appointed (consisting of Drs. Plowman and Cole, and Messrs. Francis, Woolnough, and McAlpine) presented a preliminary report. This was to the effect that they had discussed the several suggestions made by the British Medical Council, and had also addressed communications to the various medical societies in Victoria, asking that a representative might attend and confer with them. The Medical Society of Victoria has appointed Drs. D. Grant and Jamieson, and the Melbourne Medical Association, Dr. P. B. Bennie, to act as their representatives, but so far no reply had been received from the Victorian Branch of the British Medical Association. It was hoped that a meeting of the joint representatives would be arranged for an early date, after which a further report would be submitted.

In the Meantime considerable interest is being taken by Victorian pharmacists in connection with a suggestion made by Mr. Rankin, a member of the P.S.A. Council, that a conference of medical men and pharmacists should be held to deal with a matter of what is perhaps felt to be of more immediate and practical importance, and which I daresay will also be looked upon in the same light by English and foreign manufacturers. Briefly put, the objects of the conference are (1) to instruct Victorian chemists by means of printed formulæ in all the processes peculiar to private pharmacy (Nostrums), and many similar preparations; (2) so that all Victorian chemists will dispense from the formulæ of a recognised and authorised body; (3) to decide formulæ and processes of manufacture; (4) to authorise the issue of a leaflet or book with formulæ at a rate to be fixed.

In Introducing the Subject at the Council meeting, Mr. Rankin said that he felt the time had come when some such action as he now proposed should be taken. It was ridiculous, he contended, that in dispensing a prescription the dispenser had to use a compound the composition and dose of which he is totally ignorant, while the prescriber knew perhaps just as little; and while the charge to the patient was doubled, the whole advantage went to the manufacturer, either English or foreign. His idea was that by means of printed formulæ, authorised and recognised by the medical and pharmaceutical professions, a higher standard of uniformity would be obtained. In looking up formulæ pharmacists would turn to their B.P. first, then to such works as Squire and Martindale, and failing these their own book, to be known as the V.P.C., would be referred to. It was, of course, necessary to get good formulæ, to which end the aid of the medical profession should be invited; and they could then make the preparations themselves, or obtain them from the wholesale houses. In time medical men in the colony would get to recognise the formulæ, and prescribe no others.

During the Subsequent Discussion one speaker expressed a fear that as soon as the English manufacturers became aware of the proposed scheme they would combine and send out first-class men to "squelch" it; while another, apparently forgetting our protective tariff, wanted to know what was to prevent the home manufacturer from utilising a recognised formula, sending it out here as his own, and underselling the local houses. On the whole, however, councillors were favourably impressed, and on the motion of Mr. Tompsett it was resolved that "a Committee consisting of the President, Vice-President, and Mr. Rankin, be appointed to deal with the matter, and to place themselves in communication with the various persons and societies, so that a report could be presented at the next meeting."

The Vacancy in the Council of the Pharmaceutical Society of Australasia, caused by the resignation of Mr. D. A. Simpson, has been filled up by the election of Mr. Thomas H. Buzza, of Footscray.

The Dental Board of Victoria has recently had a nut to crack in the application of a student, who had served his articles of indenture in South Australia with two dentists, both of whom were registered Victorian dentists, to be allowed to enter for examination *sine curriculo*, under the clause of Dentists Act, 1898, preserving the rights of present students. The Board eventually refused the application on the strength of the following opinion furnished for their guidance by the Crown Solicitor:—"In my opinion Section 10 of Act No. 1,595 only applies to an apprentice who has served in Victoria with a Victorian dentist, and would not apply to a person who had served his articles outside Victoria, even though the master may have been registered for Victoria."

The Failure of the Negotiations entered into between Victoria and New South Wales some two years ago was a severe blow to the friends of Intercolonial Reciprocity, and there seemed but little likelihood of the subject being reopened for some time to come. Western Australia has now, however, stepped into the breach, and in a communication addressed to the various Australasian Pharmacy Boards—but more especially to that of New South Wales, which as representing the mother colony "should be the one to take the most active interest in the matter"—emphasises the disadvantages of the present condition of affairs, and submits for consideration several suggestions bearing on the differences as regards examination and apprenticeship which now operate as a barrier to a mutual understanding. So far as it goes, the evidence of the interest now felt by West Australian pharmacists in the subject meets with a hearty welcome from the *Australasian Journal of Pharmacy*, which from the first has been the sturdy and enthusiastic champion of the movement. But it does seem as if the *Journal* had just a little cause of complaint against the authors of the document, a very striking peculiarity of which is thus commented upon:—"But while welcoming everything and anything that will help to make for reciprocity, we may be excused for expressing the opinion that in a document of this kind we might have looked for some appreciative acknowledgment of the services rendered by previous workers in the cause, who have borne the heat and burden of the day. So far as we can see, there is not in the whole document a single proposition of practical value that has not already been suggested by ourselves or been fully discussed in our pages. But of all this, or of the past history of the reciprocity movement, not the slightest mention is made in the communication, the tone of which would, indeed, almost lead a cursory reader to conclude that our West Australian friends had just awoke to the disadvantages of the present condition of affairs, and were endeavouring to enlist the sympathy of their *confrères* in the other colonies in the initiation of an entirely new movement for reform."

As Regards the Object in view itself, however, the *Journal* expresses the hope that the parent colony will accept the responsibility cast upon it, and even at some small sacrifice to herself initiate one more effort; and adds:—It would be a sad commentary if, while the Australian Colonies have been found prepared to make important economical concessions to each other to secure their political federation, pharmacists should any longer be prevented from professional union by such paltry obstacles as those which at present operate to keep them divided.

At the June Meeting of the Pharmacy Board of New South Wales the lot for retirement fell upon Dr. J. Ashburton Thompson and Mr. J. C. Hallam. The latter offers himself for re-election; and three other candidates have also been nominated, viz., Messrs. H. A. Rose, G. S. C. Wells, and C. A. Marshall.

The Pharmaceutical Society of New South Wales have appointed a committee, consisting of Messrs. Williams, Hallam, Brothwood, Short, Maiden, Smith, Baker, and Haswell, to deal with the report of the General Medical Council *re* the proposed Addendum to the British Pharmacopœia. The following gentlemen have been elected honorary members of the Society:—J. H. Maiden, Director of Botanical Gardens; Professor Anderson Stuart, Sydney University; Professor A. Liversidge, Sydney University; Professor Haswell, Sydney University; Dr. James Dickson, Sydney University; Henry G. Smith, F.C.S., Technical College; R. T. Baker, F.L.S., Technical College.

The Registered Pharmacists' Society of New South Wales, which has now been duly registered "with limited liability without the addition of the word 'limited' to its name,"

has had engraved for it a very handsome and artistic diploma of membership, which it is issuing to members on payment of a fee of 10s. 6d. each. The picture is in black and white, on the lines of the diploma of the Pharmaceutical Society of Great Britain. The design comprises the Australian coat of arms, topped by mortar and pestle, festooned with a wealth of native flora, such as the flannel flower, boronia, Christmas bell, fuchsia, wattle, palms, ferns, etc. The shield, bearing the inscription and certificate of membership, is supported by figures representing Britannia and New South Wales. Britannia is shown upon a rock accompanied by the Union Jack and tripod, while a ship at anchor symbolises Great Britain's dominance of the sea. At her feet are entwined the rose, shamrock, and thistle. New South Wales is represented by a shepherdess with crook standing on a bale of wool, with sheep in repose. Beneath her feet nestles the beautiful waratah, the national flower of the colony. The panel for the officers' signatures is set between the alembic and other instruments of the chemist's art, and the whole rests upon a fancy design in tiles, with a medallion centre-picce bearing the letters, M.R.P.S. of N.S.W.

At a Recent Meeting of the chemists of Christchurch, N.Z., it was determined to form an association to be named the Canterbury Pharmaceutical Association, and the following office bearers were elected:—President, Mr. Hobden; Vice-Presidents, Messrs. Papprill and R. S. Cooke; and Messrs. Kiver and Smith-Ansted, secretary and treasurer respectively. The following gentlemen were elected to serve as committee:—Messrs. Barrett, Hean, Ross, Cole, Painter, Bates and Parnham. Mr. L. Bonnington was chosen auditor. The subscriptions were fixed as follows:—21s. for chemists residing in town, 10s. 6d. for those residing in the country, and 10s. 6d. for associates; subscription for apprentices to be 5s. At a subsequent meeting, on May 30, rules were submitted for approval and adopted, and the opportunity was availed of to present Mr. Frank Renshaw, travelling representative of Messrs. Kempthorne, Prosser, & Co., in Canterbury, but who is now taking up the management of Messrs. Sharland & Co.'s Auckland branch, with a handsome marble clock and an illuminated address.

Taking Advantage of a Recent Visit to Dunedin, the Rt. Hon. R. J. Seddon, the Premier, was waited on by a deputation from the Otago Pharmaceutical Association, who drew his attention to several of their grievances, such as their exemption from the compulsory half-holiday list, their unsatisfactory position under the sale of poisou regulations, and their liability to jury service. The Premier promised that the requests of the deputation would be brought under the consideration of the Government, but humorously assured them that there was so much intelligence among chemists that it would be a great loss to the colony if their services were to be barred. If they exempted chemists he did not know where they would stop.

NEW REMEDIES.

IODISED SULPHUR AND SULPHUR IODIDE.—*Iodised Sulphur.*—When roll sulphur is heated to between 115° and 120° C. and iodine is gradually added to it, with gentle agitation, in any prescribed proportion, such, for example, as equal parts, the iodine is gradually dissolved, and, on cooling, a crystalline blackish-brown mass is obtained, which should be preserved in well-stoppered bottles, since the iodine is readily volatilised. L. Prunier determines the amount of iodine in this substauce by digesting a known weight with four parts of iron filings and ten parts of water. The water is decanted from time to time and renewed as long as ferrous iodide is formed. The united liquids are then precipitated with sodium carbonate, filtered, and the precipitate washed free from alkaline iodide. The filtrate and washings are then acidulated with nitric acid, and the iodine determined in the usual manner by means of silver nitrate. *Sulphur Iodide* for medicinal use is the combination of plastic sulphur with iodine in molecular proportions, that is, four parts of sulphur to one of iodine. Roll sulphur is heated to about 250° C. to its second melting point, and a thermometer is plunged into the melted mass; when the temperature falls to about 200° C., the mass assuming a pasty condition, iodine is gradually added, the temperature being regulated between 170° and 200° C. When all the iodine has been added, the mass is cooled, powdered and sifted. It always contains a certain proportion of iodised sulphur. Any free iodine, which, from its irritant action, is objectionable in a preparation intended for internal administration is then removed by agitation with a five per cent. solution of sodium thiosulphate. The iodine in the reddish powder thus obtained may be determined in the manner described above for iodised sulphur. The amount of insoluble sulphur is approximately estimated by treatment with carbon disulphide; to the violet solution thus obtained, solution of caustic soda is added until complete decolorisation. The bisulphide removes all the soluble sulphur; that in the insoluble condition is collected, washed and weighed. Iodide of sulphur is less irritant than iodised sulphur, but must be employed in a diluted form, rubbed down with precipitated sulphur in such proportion that the mixture may contain from 2 to 4 per cent. of combined iodine.—*Nouv. Rem*, **15**, 169.

NEW DERMATOLOGICAL REMEDIES.—*Lenigallol* or pyrogallol triacetate is a white insoluble powder. It is best prescribed with zinc paste, thus—lenigallol, zinc paste, lanoline, equal parts. This application is without effect on the healthy skin; in the presence of alkaline secretion it liberates pyrogallol, and becomes darkened. For eczema, both chronic and acute, the following ointment is used: lenigallol, 1 or 2; zinc paste, 200. *Eugallol*, the monoacetate of pyrogallol, forms a treacly mass, readily soluble in water. Like pyrogallol, it gives rise to marked inflammation of the healthy skin, but is more easily applied than that body, since when exhibited dissolved in a volatile solvent, such as acetone, it forms a varnish-like layer, the action of which is strictly limited to the area covered by it. It is prepared in solution in acetone in the strength 1 : 1 or 1 : 2. It should be employed with caution. *Salligallol*, the di-salicylate of pyrogallol, is a resinoid body. It is much less energetic in its action than eugallol; like that body it is prescribed dissolved in acetone, or in chloroform, in the form of a varnish. The two may be compounded together thus: Saligallol, from 2 to 15; eugallol, from 1 to 40; acetone, *q.s.* to make 100. The solution of salligallol met with in commerce contains 40 per cent., dissolved in acetone. *Lenirobin*, or tetracetate of chrysarobin, is less active than the latter body and does not stain the linen. *Eurobin*—chrysarobin triacetate—although even more irritant than chrysarobin, may be prescribed in much smaller doses, and is best prescribed in conjunction with the milder eugallol or saligallol as a varnish thus: eugallol, from 10 to 20; eurobin, from 1 to 2; acetone or chloroform, *q.s.* to produce 100. Or, saligallol, 5 to 10; eurobin, 1 to 20; acetone or chloroform to make 100. Like eugallol, eurobin should be employed with caution.—*Nouv Rem.*, **15**, 121.

BROMETHYLFORMIN IN EPILEPSY.—Féré has given bromethylformin ($CH_2)_6N_4C_2H_5Br$, as a sedative in epilepsy in doses of 1 to 5 Gms. per diem; as much as 9 to 12 Gms. may be given in twenty-four hours as an anti-epileptic, without producing bromism. For children it may be compounded as follows:—Bromethylformin, 10 Gm.; distilled water, 10 Gm.; syrup of orange, 90 Gm.; one to two teaspoonfuls to be given daily.—*Nouv. Rem.*, **15**, 278.

ICHTHYOL IN MEASLES.—Good results have been obtained by Strisower *(Klin. Therap. Woch.)* with ichthyol ointment in the treatment of measles. He prescribes an ointment of ichthyol, 7, lard, 3, with which the patient is anointed from head to foot, morning and evening. If this is begun at the commencement of the disease, when the rash is confined to the pharyngeal mucus membrane, it is possible to obtain a perfectly abortive course, without skin eruption or fever. If used later, the rash quickly disappears and a perfect cure is effected in four to five days, when a warm bath will remove all the ointment from the body.—*Pediatrics*, **7**, 274.

TANNOCASUM (CASEIN TANNATE).—G. Romijn prepares this by dissolving purified casein 1,000 Gm. by the aid of sodium carbonate, in 10 litres of water; a solution of tannin 700 Gm. in water 300 Gm. is stirred in, and formaldehyde solution 100 C.c. added. The mixture is now saturated with very dilute hydrochloric acid, the resulting precipitate pressed and dried by heat. A light grey substance is obtained which easily powders. The author recommends the preparation as an astringent for intestinal disorders.—*Pharm. Post*, *3M.* (**13**), 180, after *Pharm. Wekbl. v. Nederl.* (**35**), 44.

PIPERIDINE BITARTRATE—Occurs in colourless pleasant-tasting crystals, readily soluble in water. For uric acid diathesis, powders of 60 to 100 Cgm. are given three times per diem, dissolved in a little aërated water.—*Merck's Report*, 1898, **127.**

LETTERS TO THE EDITOR.

A Microscopical Fragment.

Sir,—Your article of August 5 on air-bubbles in microscopic sections suggests the propriety of my giving publicity to a dodge which I have sometimes found useful for obviating these little disfigurements by means of an extemporised substitute for an air-pump. Take a small syringe of the well-known pattern having a glass barrel, vulcanite mounts and leather packing to the piston. These usually work so nearly air-tight that if the piston be drawn up while the nozzle is closed with the finger it will spring back to its original position. Unscrew the top and remove the piston, close the nozzle with a fragment of beeswax, and half fill the barrel with water; into this drop the section or tissues to be treated. Then replace the piston and screw on the top. The syringe being inverted and the plug of wax removed, the air is to be driven out of the barrel by raising the piston till the water begins to flow out of the nozzle, close the aperture with the finger and lower the piston. A partial vacuum is thus formed and the air rapidly escapes from the cells of the tissue, collecting in the point of the syringe. By removing the finger and raising the piston the liberated air is forced out; this may be repeated several times so long as air is given off. The same mode of operating is applicable to objects to be mounted in Canada balsam if oil of turpentine be used instead of water and the objects to be mounted are quite dry before immersion in the turpentine.

Bradford-on-Avon, August 7, 1899. B. S. Proctor.

The Sale of Benzene, etc.

Sir,—With reference to the sale of "benzine" in small quantities, being in doubt as to whether the Sun Fire Office would allow this under their policy, unless special arrangements were made for storing the liquid, I wrote to them on the subject. In their reply they stated there would be no objection if the "benzine" did not come under the category of mineral oils or liquid products thereof used for lubricating or illuminating purposes. This seems rather ambiguous. Will you kindly inform me through the Journal if the "benzine," such as is sold for cleaning purposes, would also come under this category?

August 8, 1899. Fortior (32/17).

*** The purport of the inquiry put by the Sun Fire Office appears unintelligible.—[Ed. *P.J.*]

Company Trading in Pharmacy.

Sir,—There are those who support the suggested proposals of the Council in the hope that by including "persons" in the proposed Bill "companies" might thereby be kept out of our fold. No chemist can object to such a favourable proposal being passed into law, and, if there was a reasonable hope of attaining such an end, we would all no doubt readily unite for its accomplishment. Previous to the framing of the historic Council's suggestions, the late President of the Society asked the trade to consider the pharmacy question, but to do so from a practical rather than from a theoretical or idealist point of view. To assist him in preparing a Bill, the Lord Chancellor tendered similar advice to the Council. It looks as if this commission had been exceeded in both cases. The Lord Chancellor has twice made honest attempts at legislation on our behalf. These have been made after full consideration of the question, and with the aid of interviews and suggestions, but they have been far from satisfactory to us. If we have experienced difficulties in piloting the non-contentious measure of last year through Parliament we may calculate on these being increased a hundredfold if we insist on bringing forward a Bill which is to strike at the root of such a favoured institution as the "store." By asking too much we may lose all. We have no sinister motive or felonious intention in seeking the restriction and regulation of company pharmacy. It is desirable, however, that a scheme for regulating pharmacy shall provide for dispensing being placed on a more satisfactory footing, and this in the interests of the public as also in justice to the chemist who has been fitted by education and experience to undertake the arduous and responsible duties of his calling. The Pharmacy Act makes the chemist at present a seller of poisons. Medical prescriptions, whether containing poison or not, should find their way to and be dispensed by registered men only. There are many medical prescriptions containing no scheduled poisons which, were they dispensed by unskilled and unqualified persons, might lead to disastrous results. Nor is this danger confined to the pharmacy and the "store." In the infirmaries, hospitals, asylums, army and navy, incompetent persons are frequently engaged in compounding and distributing potent medicines. Chemists have had to remonstrate with public bodies as to this disgraceful state of affairs, and frequently without effect. This reform we can demand in the public interest, and it is hoped it may be granted.

Edinburgh, August 8, 1899. W. S. Glass.

Complimentary Dinner to Mr. A. C. Wootton.

Sir,—The arrangements in connection with the complimentary dinner to Mr. A. C. Wootton are now completed. It will take place at the Hotel Métropole, London, W.C., on October 5. The price of the dinner ticket has been fixed at one guinea. As already announced it is proposed to present Mr. Wootton on that occasion with an album containing the signed photographs of those taking part in the function. As this album will necessarily take some time in preparation the Committee trust that the earliest application shall be made for dinner tickets, and that those applying for tickets should send a signed photograph for inclusion in the album. Correspondence in reference to the matter should be addressed to the Secretaries, The Wootton Complimentary Dinner, 157, Queen Victoria Street, E.C.

(Signed) John Thompson, *Chairman.*
W. Edwards, Jun. } *Hon.*
W. S. Glyn-Jones } *Secs.*

London, August 9, 1899.

The Retail Prices of Homœopathic Preparations.

Sir,—Having fixed the minimum retail price at which our homœopathic tinctures, pilules, and perloids are to be sold, we find some misunderstanding has taken place, as we merely mentioned a sixpenny and a shilling size. We should like to explain that we have abandoned the old sixpenny size, and fixed the minimum retail price of the old shilling size at 6d. We have introduced a new size, double that of the old shilling bottle, and have fixed the minimum retail price of that at one shilling. Our wholesale terms will be half the price of the retail, viz., 3s. for the old 1s. (now retailed at 6d), and 6s. for the new. This allows a profit of 100 per cent. on the outlay, or 50 per cent. on sales. Perloids from their first introduction have always been protected at face value, and the trade price is now well known to chemists.

74, *New Bond Street,* Keene and Ashwell, Limited.
London, August 9, 1899.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured.*

Powder (G. D.—32/15).—It is potato starch.

Botanical (T. J.—31/32).—They are not British species, but we hope to identify them for you shortly.

Botanical (H. J.—31/31).—(1) *Viccia cracca;* (2) *Epilobium hirsutum;* (3) *Bryonia dioica;* (4) *Knautia arvensis.*

Mercury on Gold Ring (A. S.—32/18).—The most satisfactory plan is to heat the ring carefully until the mercury volatilises.

Botanical (A. L.—32/11).—It is *Solanum nigrum.* The leaves of the plant are variable, sometimes entire, and sometimes toothed.

Botanical (J. W. H.—32/3).—(1) *Hydrocotyle vulgaris;* (2) *Lycopus europæus;* (3) Send lower leaf of this umbelliferous plant; (4) *Alisma plantago;* (5) *Filago germanica.*

Machinery and Plant for Soap Makers (F. E.—32/8).—Messrs. Houchin and Co., Bridport Place, N., will supply you with what you require.

Unqualified Person Keeping Open Shop (R. T.—31/30).—Unless he holds himself out as a registered chemist or sells scheduled poisons we fear you have no remedy.

Contents of Mixture (H. W.—32/5).— t appears to contain spirit of chloroform, tincture of gentian, and a little tincture of capsicum, together with a bismuth salt, and sodium or potassium bicarbonate. We cannot undertake a complete analysis of the mixture.

Blue Fire (H. J. H.—32/7).—(*a*) Potassium chlorate, 25; potassium nitrate, 50; copper carbonate, 20; sulphur, 16; charcoal, 12. (*b*) Potassium chlorate, 30; potassium nitrate, 40; copper ammonio-nitrate, 20; sulphur, 12; charcoal, 16; burnt alum, 10.

Loofah (J. G.—31/34).—This is the parenchymatous skeleton of the interior fibres of the pepo of *Luffa egyptica;* it is indigenous to Egypt and Arabia. The use of the fibre as a vegetable sponge is common in the East, whence it was introduced originally as a washing material in the Turkish bath.

Rodent Ulcer (J. B. P.—32/10).—We do not know of any work on rodent ulcer by Dr. Schultza, but are making inquiries for you. Adequate information on this and kindred affections may be found in works on diseases of the skin, such as those by Malcolm Morris (second edition Cassells) and Radcliffe Crocker (second edition Lewis).

Book on Soap Making (F. E.—32/8).—Watt's "Art of Soap Making," published by Crosby, Lockwood and Co., 7, Stationers' Hall Court, Ludgate Hill, is the book most likely to be useful to you. Another useful work is "Soaps and Candles," by James Cameron, one of Churchill's Technological Handbooks, published by J. and A. Churchill, Great Marlborough Street, W.

Ringworm in Cattle (R. F.—32/12).—(*a*) Tar, 15; yellow wax, 6; carbolic acid, 1. Melt the wax and tar together. Then stir in the phenol. (*b*) The following remedy is stated to be very efficacious. Wash the parts well with soft soap and water, dry, and then rub vigorously with a large fresh onion cut in half. Repeat the process daily.

Epilepsy (E. N.—32/16).—Sir William Gowers is one of the senior physicians who have made a special study of nervous disorders such as epilepsy. Other senior physicians similarly experienced are Sir William Broadbent and Dr. Hughlings Jackson. There are also very many younger physicians whose names are familiar as skilled neurologists. The case may, however, be a surgical one, and it would be well to take the advice of your family physician as to whom to consult.

Salicylic Acid in Beer (W. W. S. N.—31/33).—To 50 C.c. of beer in a separator add 5 C.c. of alcohol, 5 C.c. of sulphuric acid, and shaken out with 50 C.c. of a mixture of equal volumes of petroleum ether and ether. The extraction is repeated with another portion of the solvent, the bulked ethereal solutions distilled, and the residue extracted with water: to a known volume of this aqueous solution a drop of very dilute neutral ferric chloride is added, and the colour produced matched by an aqueous solution of salicylic acid of known strength.

Boric Acid in Beer (W. W. S. N.—31/38).—This is best determined by Gooch's method, which consists of distilling with methyl alcohol (not methylated spirit) on to a known weight of CaO; then determining the increase of the weight of the lime due to the formation of calcium borate. If the boric acid is present as borax, it must first be liberated by means of acetic acid before distilling. You should note that according to Brand and Deltour, boric acid is a natural constituent of hops, and that therefore it is possible to get a minute trace, sufficient to react with turmeric, from beer which contains no added boric acid. The quantity which must be added to effect a preservative action, however, would be considerably more than this.

Saccharin in Beer (W. W. S. N.—31/33).—500 C.c. of beer are treated with a few crystals of copper nitrate, which combines with the bitter resins and prevents their subsequent extraction with the saccharin. The solution is then evaporated to a syrup, sand is added, and a few C.c.'s of phosphoric acid. The mixture is then extracted with petroleum ether (b p. 60°), the solvent distilled off, and the residue treated with a slight excess of sodium carbonate. If saccharin be present the solution will have a sweet taste. The amount is determined by evaporating to dryness, adding a little potassium nitrate and fusing. From the amount of sodium sulphate thus formed, determined in the usual way with barium chloride, the amount of benzoyl sulphonic-imide is deduced.

Formalin in Beer.—(W. W. S. N.—31/33).—To the distillate from a known volume of the beer, add a drop of dilute aqueous solution of phenol, and pour the mixture upon strong sulphuric acid. If formalin be present a bright crimson colour appears. According to O. Hehner, to whom this test is due, a white, milky zone appears above the red ring when more than 1:100,000 is present, or even a milky solution is formed. The precipitate thus obtained is so insoluble that it might be utilised for the quantitative determination of the formalin. Another method is to distil a relatively large volume of the beer, concentrate the distillate by again distilling; determine the acidity of a portion of the distillate; add perfectly neutral hydrogen peroxide to the rest, warm gently, and again determine the acidity; the increase, due to formic acid, will give the amount for formalin present.

Sale of Poisons (F.H.R.—32/13).—If any appreciable quantity of prussic acid be present, the article must be treated as a preparation of that poison. The sale of the syrup of codeine might be regarded as equivalent to the sale of codeine—a poisonous vegetable alkaloid. Ferricyanides are not scheduled poisons. Preparations of nux vomica are specifically mentioned in Part 2 of the Schedule, and should be treated accordingly. Tincture of savin is not scheduled as such, but any preparation containing oil of savin would come within the Schedule. Emplastrum cantharidis actually contains cantharides, but emplastrum calefaciens does not. Whilst, therefore, the sale of the former might be regarded as equivalent to a sale of cantharides, the sale of emplastrum calefaciens could hardly be regarded in the same light. Homœopathic preparations containing scheduled poisons must be treated accordingly.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Abram, Alcock, Allan, Ashwell, Dunn, Fenton, Fraser, Glass, Keene, Kilmer, Kimpton, Knight, Lander, Lloyd, Lothian, Marshall, McHattie, Medley, Naylor, Nurse, Pickles, Proctor, Reynolds, Richardson, Ruoff, Slater, Summers, Wallace, Wilson, Wright.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

IGNITING A JET OF HYDROGEN.

C. G. Hopkins describes a method by which a jet of recently generated hydrogen can be ignited with absolute safety and without loss of time. As soon as the action begins, collect the escaping gas in a test-tube, and, when the latter is thought to be full of pure gas, remove it two or three feet from the generator and ignite the hydrogen in it; then immediately attempt to light the jet of hydrogen with the hydrogen flame contained in the test-tube. If the gas is explosive it will explode in the test-tube and leave no flame. If, on the other hand, a flame remains in the test-tube with which the jet can be ignited, it is certain that the gas in the generator is no longer explosive. By adopting the precaution, therefore, of never lighting the hydrogen jet except with the hydrogen flame obtained as described above, absolute safety can be insured. Attempts may be made to ignite the jet by this method as often as thought proper, and if the hydrogen is properly generated the gas will be ignited in less than a minute.—*Journ. Am. Chem. Soc.*, **21**, 634.

DETERMINATION OF CARBON AND HYDROGEN.

O. F. Tower finds that amido compounds—of which urea, hippuric acid and paratoluidine were taken as types—yield no oxides of nitrogen absorbed by concentrated sulphuric acid or by soda-lime, when ignited in a combustion tube, and that it is, therefore, not necessary to use a copper spiral when burning them. Of the nitro substances burned—nitraniline, dinitro-benzene and picric acid—only the last gave oxides absorbed by the reagents, and, judging from the increase in weight of the absorbing tubes, the nitrogen was probably for the most part absorbed as nitrogen peroxide. Nitric oxide, it is thought, may have been produced to a limited extent in any of the combustions; for, unless that oxide is further oxidised, it is not absorbed by either concentrated sulphuric acid or soda-lime, and consequently has no effect on the accuracy of the determination of carbon and hydrogen. The Kjeldahl method was found to be accurate for determining small amounts of nitrogen existing in the nitro condition.—*Journ. Am. Chem. Soc.*, **21**, 596.

ABSORPTION OF NITROGEN.

It is pointed out in *Nature* that, in connection with the preparation of argon, whilst Professor Ramsay used magnesium for the absorption of nitrogen, Ouvrard subsequently proposed lithium and Maquenne recommended a mixture of lime and magnesium. Dr. Hempel, however, has investigated the subject systematically, and finds that a mixture of calcium, magnesium, and sodium is much more effective. He mixes 1 Gm. of finely divided magnesium with 5 Gm. of coarsely powdered lime and 0·25 Gm. of sodium. In a comparative time experiment the rates of absorption of nitrogen by magnesium, lithium, lime-magnesium, and lime-magnesium-sodium were in the ratio 1, 5, 8, and 20.

DIGITALIS AND ITS PRINCIPLES.

J. W. England is of opinion that, whilst digitoxin is probably the most distinctive chemical compound in digitalis leaves, the entire therapeutical activity of the leaves cannot be due to that compound. Dr. Karl Hofmann (*Wien klin. Wochensch.*) has shown that the physiological effects of digitoxin are not manifested in less than six to thirty-six hours, but digitalis and its preparations yield physiological effects in thirty to sixty minutes, and this great difference, together with other considerations, is thought to preclude the acceptance of Kiliani's claim that digitoxin is the most important therapeutic principle of the leaves.—*Am. Journ. Pharm.*, **71**, 379.

SILVER AND ITS SULPHIDE.

H. Pélabon states that below 180° C. silver is not attacked by dry sulphuretted hydrogen, nor is silver sulphide reduced by hydrogen. Above 280° the two reactions take place, and their speed increases as the temperature rises. The silver liberated by the reduction of the sulphide assumes the form of filaments when the reduction occurs at a temperature below 580°; at higher temperatures it covers the surface of the sulphide uniformly.—*Bull. Soc. Chim.*, **21**, 402.

CONSTITUENTS OF ARALIA NUDICAULIS.

Dr. W. C. Alpers has extracted and examined the fixed oil of *Aralia nudicaulis*, which he describes as perfectly clear; of a dark red colour; soluble in petroleum spirit, benzene, ether, and chloroform; sparingly soluble in absolute alcohol; insoluble in alcohol and water. It has a bitter, acrid, pungent, and persistent taste, causing a feeling of dryness in the mouth, and slightly resembling castor oil in odour. At the ordinary temperature it is rather thick, it solidifies at 3° C., and decomposes at about 300°. Its specific gravity is 0·921 at 20°, and under the influence of nitrous acid it solidifies, forming a greyish-yellow, sticky, doughy mass of elaidin. The oil was present to the extent of 1·726 per cent. in the dried rhizome, and was combined with a small quantity of a volatile oil. On distillation of the powdered drug, from 0·04 to 0·12 per cent. of this volatile oil was obtained. It is described as having an odour resembling that of young carrots, and a clear, light yellow colour. Its boiling-point at normal pressure is from 260° to 270°. On analysis the volatile oil was found to consist principally of a sesquiterpene, $C_{15}H_{24}$, for which the name "araliene" is proposed, and an alcohol, $C_{15}H_{25}OH$ (?), together with a small quantity of azulene. The sesquiterpene has a specific gravity of 0·9086 at 20°; boiling-point, 270°; $[\alpha]_D = -7$ to -8; $N_D = 1{\cdot}49936$. It forms oily compounds with hydrochloric acid and bromine, and derivatives with nitrous acid. Treated with hydrochloric-acetic acid it forms a compound of a permanent blue colour, chloroform and sulphuric acid produce a purple red colour, acetic acid and sulphuric acid a wine-red colour.—*Am. Journ. Pharm.*, **71**, 370.

HEADACHE PREPARATIONS.

G. A. Wilson has obtained thirty-six different headache preparations and submitted them to qualitative analysis. Twenty-nine of the samples were obtained through the wholesale houses and the remaining seven were purchased from different retail stores of good standing, being sold on inquiry for "something for headache." In the analysis chief attention was paid to the active ingredients, and little or no consideration was devoted to diluents, colouring matters, aromatics, etc. The following is the list of substances detected in the thirty-six preparations and the number of samples in which each was found:—

Acetanilid	in 30	samples
Sodium Bicarbonate	,, 19	,,
Caffeine	,, 14	,,
Phenacetine	,, 5	,,
Tartaric Acid	,, 4	,,
Potassium Bromide	,, 3	,,
Camphor	,, 3	,,
Camphor Monobromate	,, 2	,,
Sodium Salicylate	,, 2	,,
Quinine Sulphate	,, 1	,,
Potassium Bicarbonate	,, 1	,,
Antipyrine	,, 1	,,
Sulfonal	,, 1	,,
Ammonium Carbonate	,, 1	,,
Ammonium Bromide	,, 1	,,
Salicylic Acid	,, 1	,,
Potassium and Sodium Tartrate	,, 1	,,

In addition to the above, some of the preparations contained sugar, milk sugar, celery, charcoal, calcium carbonate, and sanguinaria, while two evidently contained belladonna and gelsemium.—*New England Druggist*, **11**, 524.

ALKALOIDAL ASSAY OF BELLADONNA PLASTERS.

BY CHARLES E. PARKER, PH.C., ORANGE, N.J.

The following process of determining the alkaloidal content of belladonna plasters has been very successful and satisfactory in the writer's hands during an extensive experience in the examination of these products. In its esential features, the disintegration of the plaster mass with chloroform, precipitation of rubber with alcohol, and shaking out by the Rodgers and Girdwood method with chloroform, the process was described by S. W. Williams in a paper read before the American Pharmaceutical Association in 1890, and again by Carl E. Smith in a report from the Committee on Research of the U.S. Pharmacopœial Revision Committee.* It is well known, and probably the only process used by the limited number of analysts who have had occasion to examine commercial belladonna plasters, and while not especially adapted for the use of tyros it should enable the competent pharmacist to determine the comparative strength of plasters with a very fair and useful degree of accuracy, and the total alkaloidal strength after some practice. The process as here given embodies some slight and heretofore unpublished modifications, which the writer had found advantageous.

Take two plasters, or, if supposed to be much under pharmacopœial strength, take four, and double the quantities of solvents here given. Remove all cloth but that upon which the mass is spread, weigh the plasters, cut into strips ½ inch wide, and digest in a beaker of 150 C.c. capacity with 30 to 40 C.c. of chloroform, keeping the beaker covered with a watch glass. It is permissible to warm the mixture slightly to hasten solution, but not higher than blood heat, and disintegration of the mass should be promoted by frequent stirring with a glass rod. When the cloth appears nearly free of mass (usually requiring ten or fifteen minutes), decant and drain off as much as possible of the thick mixture into a similar beaker and precipitate rubber, etc., by adding with constant stirring a minimum amount (10 to 20 C.c.) strong (91 per cent.) alcohol, sufficient to effect complete separation. Let stand a few minutes that the precipitate may settle and become coherent, and then decant the supernatant liquid in portions into a small funnel, the throat of which is loosely plugged with a pledget of absorbent cotton, and which is so arranged to drain into a 250 C.c. separatory funnel. Treat the cloth in the first beaker with a further quantity (about 20 C.c.) of chloroform, and decant the washings into the second beaker, dissolving with them the precipitated rubber with the aid of gentle warmth and stirring. When the mixture is free from lumps, precipitate again with the minimum necessary amount (about 10 C.c.) of alcohol, and proceed as before, filtering the chloroform-alcohol solution into the separator. Repeat this procedure once more with a small quantity of chloroform, which should this time be made alkaline with five drops of 10 per cent. ammonia water, and without application of heat. This treatment should remove all the mass from cloth and beaker. Dry the cloth, cool and weigh it, and deduct this from the gross weight of the plaster to obtain the net weight of mass used.

In prescribing the amounts of chloroform to be used in the several extractions of the plaster mass, some latitude has been allowed to the judgment of the operator. It is well to use first the smaller amount, and then add more should it be needed. While sufficient should be used to thoroughly disintegrate the mass, and to produce a mixture not too thick and viscid to drain readily from the cloth and beaker, an excess over this necessary amount should be avoided. The amount actually required will vary according to the composition of the mass, and the amount of mass in the plasters. No ammonia being used in the first two extractions, the application of gentle heat is harmless and facilitates the operation. Overheating should be carefully avoided.

Filtering the chloroform-alcohol solution removes particles of suspended matter, and facilitates separation in the shaking out process which is to follow. If the pledget of cotton is of moderate size, and properly (not too tightly) adjusted in the throat of the funnel, the liquid will filter readily; or, if the cotton becomes clogged, it will be only at the upper surface, and a slight kneading with the end of a glass rod will start the flow.

In this extraction, with successive portions of solvent, care should be taken that no portions of material adhering to the sides of beakers or funnel escape from its action, and it is well as a check on the completeness of the extraction to repeat the process with a fourth small portion of chloroform, the proceeds of which are to be shaken out separately and tested for residual traces of alkaloid.

If not already so, the combined chloroform-alcohol solutions in the separator are made plainly alkaline with a few drops of ammonia water, and the chloroform caused to separate by the addition of sufficient water, perhaps 50 C.c. The chloroform portion is drawn off and shaken out in other separators with three successive portions of 25 C.c., each of 2 per cent. hydrochloric acid. The alkaline hydro-alcoholic solution in the first separator is extracted with three or more 25 C.c. portions of chloroform, or until a few drops of the chloroform, evaporated and taken up with dilute sulphuric acid, give no precipitate with Mayer's reagent. These portions of chloroform are also shaken out with the portions of dilute acid before mentioned. The portions of acid being united in one separator, with addition of the rinsings of the separators from which they were taken, are made alkaline with ammonia, and shaken out with several portions of chloroform. The chloroform extracts are washed in separators with two portions of water and united in a flask, from which the chloroform is distilled off. The alkaloidal residue may be titrated by the pharmacopœial method for liquid extract of belladonna, or any other suitable method, of which the writer prefers the one given below.

In "shaking out" violent agitation is to be avoided, as it causes troublesome and time-wasting emulsions. Great care should be taken to obtain perfect separation of the liquids, as a mixture containing emulsion may be washed until apparently free of alkaloid, and yet be found to contain appreciable amounts when the emulsion has broken down. Chloroform carries mechanically small amounts of liquid from one separator to another, which may cause an unsuspected change of reaction unless the separators each contain a small piece of litmus paper. Chloroform also retains in solution traces of alcohol, which may convey non-alkaloidal (resinous) matter. Therefore, the first alkaloidal residue cannot be considered pure. Make a preliminary titration by dissolving it in 10 C.c. of N/20 hydrochloric acide, and titrate with N/50 barium hydrate solution, using a few drops of tincture of cochineal as an indicator. Shake out the titrated solution carefully once more, and collect the purified alkaloid in a small tared distilling flask.

Dissolve the alkaloidal residue in a little ether and evaporate (to expel traces of chloroform); dry and weigh. Dissolve in N/20 hydrochloric acid, and titrate as before. If carefully done there need be no appreciable loss in the purification. Indeed, the second titration sometimes yields higher results, owing to (acid) resinous impurities in the first residue. If the alkaloid consists of atropine or hyoscyamine the titrated result is more reliable; otherwise, the gravimetric.

* See the *American Journal of Pharmacy*, April, 1898.

LUTE FOR ALCOHOL BOTTLES.—The following cement is used by Camerano for sealing specimen jars containing preparations preserved in alcohol in the Zoological Museum at Turin. It is stated that it gives a perfect hermetic seal, which is impervious to alcohol and will last indefinitely. Caoutchouc, 200; suet, 125, are melted together (caoutchouc in the form of old rubber tubing cut in small pieces may be used); French chalk, 200, is then stirred in. The mixture is allowed to cool and keeps indefinitely. To use it, it is warmed, and a little taken up on a glass rod or a piece of wood is applied to the parts to be luted.—*Petit Mon. Pharm.*, **49**, 3,315.

AUSTRALIAN INDIGENOUS VEGETABLE DRUGS.*

BY J. H. MAIDEN,

Government Botanist and Director of the Botanic Gardens, Sydney.
(Corresponding Member of the Pharmaceutical Society of Great Britain.)

URTICEÆ.

Ficus glomerata, Roxb. "Clustered Fig."

This tree possesses an astringent bark; this, as well as the fruit, which is considered to have similar properties, is prescribed in hæmaturia, menorrhagia, and hæmoptysis. The dose is about 200 grains. The fruit, filled with sugar, is considered to be very cooling, and the small, blister-like galls which are common on the leaves, soaked in milk and mixed with honey, are given to prevent pitting in smallpox. Ainslie tells us that "from the root of the tree, which in Tamil is called 'Attievayr,' there exudes, on its being cut, a fluid which is caught in earthen pots, and which the Vytians consider a powerful tonic when drunk for several days together." In Bombay the sap is a popular remedy, which is locally applied to mumps and other inflammatory glandular enlargements, and is used in gonorrhœa. (Dymock, *Materia Medica of Western India.*)

Queensland and Northern Australia.

Laportea gigas, Wedd. "Giant Nettle."

The poisonous fluid secreted from the foliage is very powerful, particularly in the younger leaves, and their sting is exceedingly virulent, producing great suffering. Cattle become furious when they come in contact with the leaves. It is stated that the pain caused by the sting of this plant will be instantly relieved by the milky juice of the lower part of the stem of *Colocasia macorrhiza* ("Cunjevoi" of the natives), being rubbed on the affected part.

"The genus of Laportea has some interest to pharmacologists, inasmuch as, after being nettled, one is reminded of the fact for several days, and in exceptional cases for weeks, whenever the nettled part is wet. Upon touching water, there is produced a sudden severe pain; it is only momentary, however. If the hand be the part nettled, the secondary pain starts in the spot nettled, and runs up the arm and down the corresponding side. No explanation has ever, as far as I am aware, been given to account for the secondary pain. A juice made by pounding the green leaves in a mortar gave no decided reaction with litmus paper; it was tasteless, and when injected into frogs had no action upon them. If the stinging hairs be carefully examined, and the tops shaved off with a razor, a few will be seen to contain a minute quantity of fluid; so small a speck is it, however, that even with the microscope it is impossible to test its reaction with litmus. The juice of *Colocasia macrorrhiza* plays the part of the dock in England as a remedy for application to parts nettled; it, however, seems quite useless.

"The adage, 'If you gently touch a nettle, it will sting you for your pains,' is not applicable to tree nettles, for in order to be stung it is necessary to handle the leaves roughly, or brush against them with some force. The fracture of the points of the stinging hairs is quite audible, and one feels a prick when the point enters the skin; in a second or two afterwards he is conscious of having been nettled." (Dr. T. L. Bancroft, *Trans. Intercol. Med. Congress*, 1888.)

Mr. A. R. Crawford, of Walcha, wrote me the following interesting letter a few years ago:—

"The bark supposed to possess medicinal properties is that of *Laportea gigas*, Wedd., said to have been used by the blacks in the olden times for the cure of rheumatism, also for 'giggle giggle,' a skin complaint, also for mange on their dogs. I can remember one man, said to have been cured of rheumatism, and said to have been so bad that he could only crawl round the room, supporting himself by the wall. The blacks took him in hand, stripped him, laid him out on a sheet of bark, rubbing him with the young leaves and bark of the *Laportea*, pounded up and boiled until it was of the consistency of treacle. It is said that they almost rubbed the man's skin off, but they cured the patient. I do not know if you are aware of it, but the best cure for sting of the leaf is a piece of the bark (from a young plant is most convenient, chewed up and rubbed on the spot); it is as if you wiped the pain away with a cloth. It has the same effect used for sting of the large nettle found in the shrubs—a native nettle, I think."

New South Wales and Queensland.

CASUARINEÆ.

Casuarina equisetifolia, Forst., "Bull Oak."

The bark, according to Dr. Gibson, is an excellent astringent, and may be used with advantage in chronic diarrhœa and dysentery. It is not used medicinally by the natives of India. The Chinese in Bombay say that it is used as an astringent in China (Dymock). Doubtless the barks of the numerous other Australian species possess similar properties.

New South Wales, Queensland, and Northern Australia.

PIPERACEÆ.

Piper Novæ-Hollandiæ, Miq., "Native Pepper."

An excellent stimulant tonic to the mucous membrane. Used by Dr. Joseph Bancroft in the treatment of gonorrhœa and other mucous discharges with considerable success. This is one of the largest native creepers, the root being at times from six inches to a foot in diameter. The plant climbs like ivy to the top of the tallest trees, and when full grown weighs many tons, so that a good supply of the drug is readily obtainable. The active principle, as dissolved out by ether, is a brownish, oily fluid, soluble in water to a limited extent only, the insoluble portion producing an oily emulsion. It has a warm, aromatic, pleasant taste, and a benumbing effect on the tongue when applied to it in minute quantity.

Dr. Bancroft further states that he has used a tincture internally and in other ways without any remarkable effect, but has not made sufficient advances to speak of it as a valuable drug for any particular purpose. The ethereal extract, mixed with water, inserted under the skin of frogs or small animals causes death.

Northern New South Wales and Queensland.

SANTALACEÆ.

Exocarpus cupressiformis, Labill., "Native Cherry."

The twigs prove as good a bitter tonic and astringent as the South American Rhatany, *Krameria triandra* (Dr. Lauterer, *Proc., R.S., Qd.*, x., 101).

CYCADEÆ.

Macrozamia spiralis, Miq.

See a paper by Dr. George Bennett on "A case of poisoning by the seeds of *Macrozamia spiralis*." I merely draw attention to the highly indigestible, if not poisonous, character of Macrozamia seeds. They caused the death of some French sailors during the very first year of Australian settlement. For information in regard to these plants as stock poisons, see *Agricultural Gazette*, January, 1897, p. 20.

New South Wales and Queensland.

ORCHIDEÆ.

Dendrobium teretifolium, R.Br.

The bruised leaves are used in the South Sea Islands for severe headache or other pains. (Bennett, *Gatherings of a Naturalist*, etc.)

New South Wales and Queensland.

AMARYLLIDEÆ.

Crinum.

For notes on the medicinal value of *C. asiaticum*, Blanco, see *Pharm. Indica*, 464. It is not likely that any species of this genus possesses properties not shared by the others.

* From the *Agricultural Gazette of New South Wales* (Concluded from page 166).

TACCACEÆ.

Tacca pinnatifida, Forst.

The starch from the tubers is far preferable to that of any other arrowroot for dysentery. (*Treasury of Botany.*) This plant is not endemic in Australia.

Queensland and Northern Australia.

DIOSCORIDEÆ.

Dioscorea.

An "Extractum *D. villosæ* fluidum" is made by Merck. See Rep. 1894, p. 59. Attention is invited to the reputed medicinal properties of *Dioscorea*, of which we have three species in Australia.

LILIACEÆ.

Asparagus racemosus, Willd.

The roots of this plant are used medicinally by the natives of India, but they appear to be wholly unworthy of notice. (*Pharm. of India.*) An account of some of the uses to which it is put by them will be found in Drury's *Useful Plants of India*, p. 56.

Queensland and Northern Australia.

Flagellaria indica, Linn. "Supple Jack."

The leaves are said to be astringent and vulnerary (Bailey). This plant is not endemic in Australia.

New South Wales to Northern Australia.

Smilax glycyphylla, Smith. "Native Sarsaparilla"; "Sweet Tea."

This plant has been recommended as an alterative and tonic and anti-scorbutic. It is one of the earliest plants pressed into the service of medicine in New South Wales. At p. 230, *Journal of a Voyage to New South Wales*, by John White, Esq., Surgeon-General to the Settlement, London, 1790 (the information must have been furnished almost immediately after the foundation of the colony), occurs the passage . . . . "good for the scurvy. The plant promises much in the last respect, from its bitter, as a tonic, as well as the quantity of saccharine matter it contains." The decoction is made from the leaves, and is similar in properties but more pleasant in taste than that obtained from the roots of *S. officinalis*, or Jamaica sarsaparilla. The herb is a common article of trade amongst Sydney herbalists.

"*Glycyphyllin.* Glucoside of the leaves of *Smilax glycyphylla*; a brownish-yellow, amorphous mass, or by slow evaporation of the ethereal solution, concentrically united tufts of crystals of aromatic odour and bitter-sweet taste; dissolves better in hot than cold water, easily in alcohol and in ether; breaks up on boiling with dilute sulphuric or hydrochloric acid into sugar and another product." (Mueller and Rummel, in Witstein's *Organic Constituents of Plants.*)

See also a paper by Professor Rennie, of Adelaide, on *Glycyphyllin*, the sweet principle of *S. glycyphylla*, in *Journ. Chem. Soc.*, December, 1886.

"Sarsaparilla has been found growing in the Port Phillip district of Australia, and has been shipped thence in small quantities." (Simmond's *Com. Prod. of Veg. Kingd.*) This statement has been made inadvertently. *S. australis*, R.Br., is found in Victoria, but it does not appear to possess the properties of *S. glycyphylla.*

"Under the name of *Akar Restong*, *S. glycyphylla** is used in the Straits Settlements in the form of a lotion for syphilitic ulcers and for syphilitic ozæna; the lotion is made by pounding the leaves and roots with an equal quantity of water." (E. M. Holmes in *Bulletin of Pharmacy*, vi., 108.) For notes on the active principles in *Smilax*, see Sohn, p. 89.

XYRIDEÆ.

Xyris indica, Linn.

The juice of the leaves, mixed with vinegar, is applied externally in cases of itch. The leaves and root boiled in oil are considered useful in leprosy on the Malabar Coast. In Bengal the plant is reckoned of great value as an easy and certain cure for ringworm. (Roxburgh.) See *Pharm. Indica*, 510.

In Australia there are no less than nine species of *Xyris*, some of them being exceedingly abundant.

PALMÆ.

Cocos nucifera, Linn. "Cocoanut Palm."

Various medicinal qualities are attributed to this palm. The flowers are employed by the natives of the tropics as an astringent, the roots as a febrifuge, the milk in ophthalmia, etc.

Queensland.

AROIDEÆ.

Colocasia antiquorum, Schott.

The acrid juice of the petioles of several varieties of this species is a common domestic remedy in India, on account of its styptic and astringent properties. The petiole is slightly roasted, and the juice expressed. "I have seen a purulent discharge from the ears of children stopped by a single application. The tubers of these plants, chopped fine, tied in a cloth, and heated, are used as a fomentation in rheumatism." (Dymock, *Materia Medica of Western India.*) It is said that the juice of the petioles will even arrest arterial hæmorrhage. (*Pharm. of India.*)

Queensland.

Colocasia macrorrhiza, Schott. "Cunjevoi" of the aborigines.

This plant possesses much acridity in the fresh state, and it is employed by the natives of India as an external stimulant and rubefacient. The acrid principle is, however, very volatile, and by the application of heat, or simple drying, the roots became innocuous. (*Pharm. of India.*) As an antidote to the stings of plants, see *Laportea gigas.*

For an account of a case of poisoning through eating the tubers of this plant, see the *Gazette* for May, 1896.

New South Wales and Queensland.

TYPHACEÆ.

Typha angustifolia, Linn. "A Bull-rush."

The root-stock, which abounds in starch, is somewhat astringent and diuretic, and is employed in Eastern Asia in dysentery, gonorrhœa, and the measles.

All the Colonies.

GRAMINEÆ.

Andropogon citreus, R.Br.

Makes a useful tea in fevers. (Armit., *Journ. Linn. Soc.* [Bot.], xx., 69.)

Queensland.

LYCOPODIACEÆ.

Psilotum triquetrum, Sw.

This plant is used in infusion in visceral complaints in the South Sea Islands. (Bennett, *Gatherings of a Naturalist*, etc.)

Victoria to Queensland.

FILICES.

Adiantum æthiopicum, Linn. Common "Maidenhair Fern."

This plant is said to possess medicinal properties, being slightly astringent and emetic. It has been used in Europe in making *Sirop de Capillaire*, a demulcent drink, employed in diseases of the chest.

All the Colonies.

Pteris aquilina, Linn., var. *esculenta*, "Brake Fern," or "Bracken."

The European plant is astringent, bitter, and anthelmintic, and the rhizome has been used as a substitute for hops.

All the Colonies.

* This is *S. glycyphylla*, Hask.; *S. leucophylla*, Blum.

QUALITATIVE EXAMINATION OF POWDERED VEGETABLE DRUGS.*

BY HENRY KRAEMER.

In this communication are embodied the principles of a scheme for the determination of unknown powders. While the paper has primarily to do with the consideration of official vegetable drugs, still it has been found necessary to incorporate with it also the important non-official vegetable drugs and food products, as well as the pulveres (composed of inorganic and vegetable substances), some of the compound powders for making various preparations, and all of the principal plant constituents, as opium, guaiac resin, etc. The proximate principles of plants, other than starch, have been omitted, owing to the fact that they require a somewhat different treatment. Somewhere in the neighbourhood of 300 powders are considered. The whole scheme is but tentative, and will doubtless require some changing, but gives us a basis for subsequent work, at least. It has not been possible, up to the present time, owing to the pressure of duties, to finish the drawings for publication of the points considered, but even without these, those who are familiar with the microscopical characteristics of crude drugs and the general principles of chemical analysis will find little or no difficulty in the utilisation of the same. The drugs under consideration are divided, according to the varying shades of colour, into seven classes :

I. Colour, some shade of light green to grey.

II. Colour, nearly white.

III. Colour, some shade of yellow.

IV. Colour, varying from some shade of tan or ecru to dark brown, or even dark blue or black.

V. Colour, some shade of red.

VI. Powders that vary in fineness from Nos. 20 to 30 or less, and are with difficulty examined by means of the microscope without further treatment, as sectioning, etc.

VII. Drugs that do not occur in the powdered condition.

The author was some time in coming to the conclusion that powdered drugs could be arranged along colour lines before taking them up scientifically for identification. It is true it is necessary to arrange samples of the powders in convenient vials and mount on white cardboard to appreciate the ground for the classification adopted. It will also be found that there are a few of the powders under the different groups, as No. I., that might be considered advantageously under others, as No. IV. In such cases samples must be arranged under both, and this has been done as far as possible by the author.

The largest groups are Nos. I. and IV., and it will be found that they include a more natural grouping than we would at first suppose. Under No. I. we find chiefly the herb and leaf drugs, while under No. IV. are chiefly roots, rhizomes and barks. It has been found necessary, owing to the difference in predominating constituents or tissues, to work up each group differently.

GROUP No. I. COLOUR GREEN TO GREY.

Coca, Buchu, Mentha viridis, Matico, Chelidonium, Guaiaci resina, Gaultheria, Lobelia (herb), Passion flowers, Pulsatilla, Pilocarpus pinnatifolius, Lobelia (leaves), Buchu (long), Calumba, Eucalyptus, Absinthium, Pilocarpus, Senna (Alexandria and India), Scutellaria, Castanea, Eupatorium, Tanacetum, Mentha piperita. Lobelia, Anisum, Fœniculum, Conium, Belladonnæ folia, Coca, Insect powder (Persian), Salvia, Eriodictyon, Hamamelis, Matico, Uva ursi, Scoparius, Grindelia robusta, Chimaphila, Gaultheria, Hyoscyamus, Stramonii folia, Galla (Chinese or Japanese), Cypripedium, Aletris, Digitalis, Marrubium, Piper nigrum, Ergota, Hedeoma, Sarsaparilla (Mexican), Cimicifuga, Spigelia, Leptandra, Arnicæ radix, Chenopodium, Sarsaparilla (American), Xanthoxylum fraxineum, Xanthoxylum americanum, Aralia spinosa, Senega, Sarsaparilla (Honduras), Sumbul, Taraxacum, Serpentaria, Piper album, Aurantii amari cortex, Aurantii dulcis cortex, Limonis cortex, Helonias dioica, Caulophyllum, Angelica, Kava kava, Nux vomica, Belladonnæ Radix.

* From the *American Journal of Pharmacy*.

I. Without Fibro-Vascular Tissue.

1. *Ergota.*—Oil globules ; red or violet coloration in choral and sulphuric acid ; odour.

II. With Fibro-Vascular Tissues.

A. WITH CALCIUM OXALATE CRYSTALS.*

a. CRYSTALS ROSETTE OR STAR-SHAPED.

a. Containing starch.†

2. *Aralia nudicaulis.*—Crystals 35–70 μ ; starch, 10–15 μ; secretion reservoirs (yellow and brown) ; sklerenchyma.

3. *Aralia spinosa.*—Crystals about 50 μ; starch about 10 μ; reservoirs containing oil and resin ; cork brownish ; sklerenchyma fibres ; also sometimes fine needle-shaped crystals.

4. *Galla (Chinese or Japanese).*—Few crystals, 20 μ ; starch 40 μ; non-secreting hairs ; milk vessels accompanying ducts ; mounts in glycerin show acicular crystals of gallic acid.

5. *Passion Flowers.*—Crystals 15 μ ; starch ; pollen 35–45 μ ; sklerenchyma.

6. *Podophyllum.*—Crystals 50 μ in diameter ; starch 5–8 μ diameter ; single grains to 2–6 compound ; numerous single or groups of cells coloured yellow ; sklerenchyma fibres and ducts.

7. *Spigelia.*—Crystals 5–15 μ ; starch 4 μ ; parenchyma and long light-coloured sklerenchyma fibres characteristic ; apparently at one stage or in an admixed drug calcium carbonate is present.

β. Without starch.

8. *Anisum.*—Crystals 2–3 μ in aleuron grains 6 μ in diameter ; non-secreting hairs ; secretion reservoirs ; epidermis of seed coat and pericarp characteristic.

9. *Buchu.*—Crystals 15–20 μ ; sphere-crystals of a carbohydrate 35 μ ; mucilage ; sklerenchyma very characteristic ; non-secreting hairs ; heavy cuticle ; oil secretion reservoirs.

10. *Castanea.*—Crystals 15 μ; wavy epidermis ; sklerenchyma ; some pollen grains ; presence of few or no non-secreting hairs distinguish it from *Castanea pumila.*

11. *Cannabis Indica.*—Crystals 20 μ; characteristic crystolith (200 μ long) with or without broad base (containing $CaCO_3$ in granular masses) attached ; oil secretion hairs ; characteristi cells of pericarp.

12. *Chimaphila.*—Crystals 55 μ ; tannin masses ; chimaphilin, red with H_2SO_4.

13. *Conium.*—Crystals 2 μ in aleuron grains about 5 μ ; no oil secretion reservoirs of Umbelliferæ ; characteristic outer epidermis of seed coat and pericarp ; odour alone or when rubbed with KOH.

14. *Eriodictyon.*—Crystals 20–25 μ ; long 1-celled, non-secreting hairs ; also secreting hairs.

15. *Eucalyptus.*—Three kinds of crystals, rosette shaped, 15 μ diameter, tetragonal 4 $\times$ 14 and 25 $\times$ 15 μ ; thick greenish cuticle ; oil secretion reservoirs and characteristic sklerenchyma.

16. *Fœniculum.*—Crystals 2 μ in aleuron grains about 6 μ ; oil secretion reservoirs with characteristic inner epidermis of pericarp

* If there are any doubts about the presence of calcium oxalate crystals, sulphuric acid may be added to the powder, when numerous needle-shaped crystals of calcium sulphate will generally separate. It must be also stated that in plants containing calcium oxalate the form may be in needles in addition to the characteristic form given.

† If there are any doubts about the presence of starch, the reaction of which is sometimes hid by the presence of resinous or other principles, a small quantity of the powder may be boiled for a minute with a few drachms of water in a test-tube, the liquid filtered and tested with iodine and potassium iodine solution. Regarding the presence of reserve starch and calcium oxalate crystals in plants, the amount of these constituents is an uncertain one owing to the changes induced by certain Fungi. J. H. Wakker, in Pringheim's *Jahr. f. Wissench. Bot.*, xxiv., p. 499, states that he found in *Rhamnus frangula* the calcium oxalate crystals to be fewer and the starch grains more numerous when plants were diseased. See also Hartig's *Lehrbuch der Baumkrankheiten* and Byron D. Halsted's paper before the A.A.A.S., 1898.

running at right angles to length of the former; peculiar thickened latticed parenchyma.

17. *Gaultheria.*—Crystals 20 μ, look as though made up of little plates; stomata numerous with 2 "Nebenzellen"; tufts of fan-shaped crystals (28 μ); stone cells with reddish colouring matter; in chloral glycerin some tissue coloured purplish; with Fe_2Cl_6 tannin and oil coloured dark purple.

18. *Hedeoma.*—See No. 57. In glycerin mounts have sphere-shaped crystals separating.

19. *Insect Powder.*—Pyrethrum roseum, or Persian—numerous rounded and prickly pollen grains, 25 μ; some few crystals (2 × 8 μ), in stone or in parenchyma adjoining; sklerenchyma fibres being 17 × 105 μ, and 20 × 160 μ in Dalmatian; fragments of T-non-secreting hairs less numerous than in Dalmatian; characteristic, isolated, somewhat rounded or elliptical parenchyma cells (75 × 95 μ), also occurring in papillæ-like fragments. Fragments of papillæ (epidermis of corolla), acute and more numerous than in Dalmatian. In latter rounded and scarcely perceptible; secretion hairs 50 μ, being smaller than in Dalmatian; rose-coloured fragments in choral mounts possibly more numerous in the Persian powder.

20. *Pilocarpus.*—Crystals 17 μ; few non-secreting hairs; long sklerenchyma fibres; oil secretion reservoirs; few palisade cells.

21.—*Senna.*—Possesses four kinds of crystals—rosette, cubical, tetragonal and coffin-shaped, of which the rosette occurs least, and the other three in greatest amount; 1-celled hairs more numerous in Alexandria than in India senna. Boil a small quantity with water, filter, and to the light lemon-coloured filtrate add KOH and solution becomes red, due to chrysophanic acid reaction.

22. *Stramonii Folia.*—Crystals 10–15 μ, occurring in a characteristic line through the middle of the leaf just below the palisade cells; some secreting and non-secreting hairs.

b. CRYSTALS CUBICAL, RHOMBOHEDRAL, PRISMATIC, TETRAGONAL OR COFFIN-SHAPED.

a. Containing Starch:

23. *Cardamom.*—Crystals very small; starch in single small grains, and in masses; fragments of thick, dark sklerenchyma cells, being the outer and particularly inner epidermis of seed coat. The Malabar is distinguished from the Ceylon in that the latter has a few 1-celled hairs; the starch grains and crystals are larger and sklerenchyma cells are more prominent.

When the pericarp or fruit wall is present, this is determined by its large parenchyma cells containing brown masses; also sklerenchyma fibres.

24. *Calumba.*—In the stone cells are cubicle crystals 15 μ; starch grains characteristic, 35 × 25 μ.

25. *Gelsemium.*—Crystals of three kinds; diamond-shape, 15 × 15 μ, tetragonal, 15 × 20 μ or twin, large prismatic as in quillaja, 8 × 28 μ; starch, 8 × 8 μ; numerous sklerenchyma fibres. In overground stem find remains of chloroplastids in collenchyma; root distinguished from stem by absence of fragments of altered sieve (*i.e.*, internal phloem).

26. *Guaiaci Resina.*—See note No. 94.

27. *Pulv. Glycyrrhizæ Co.*—Cubical crystals 3 × 2 μ in crystal fibres in fragments of about 117 μ in length; starch about 5 μ in diameter; characteristic crystals and hairs of senna (see No. 21). The powder made from Russian liquorice contains few or no fragments of cork.

28. *Spigelia.*—See No. 7.

29. *Xanthoxylum.*—Crystals 7 × 10 μ; starch 10 μ; oil secretion reservoirs; in chloral mount numerous oil globules: sklerenchyma cells and fibres in *X. fraxineum.*

β. Without Starch:

30. *Coca.*—Crystals cubical 3 × 3 μ, coffin-shaped, 3 × 10 μ; peculiarity of epidermis, absence of hairs; *odor.*

31. *Eucalyptus.*—See No. 15.

32. *Gaultheria.*—See No. 17.

33. *Hamamelis.*—Crystals 7–10 μ; 1-celled non-secreting hairs; tannin and resin masses.

34. *Hyoscyamus.*—Crystals of two kinds—rosette-shaped and more or less cubical (10 × 10 μ), the latter chiefly. Numerous secreting and non-secreting hairs.

35. *Senna.*—See No. 21.

36. *Stramonii Folia.*—See No. 22. The rosette-shaped crystals are generally in greater abundance.

37. *Uva Ursi.*—Prismatic and coffin-shaped crystals (7 × 10 μ), in crystal fibres, tannin masses; characteristic sklerenchyma fibres; no oil-cells or reservoirs.

c. CRYSTALS ACICULAR (RAPHIDES).

38. *Cypripedium.*—Crystals 35–58 μ long; starch 2–4 μ; root hairs; oil and resin cells; characteristic odour.

39. *Helonias.*—Characteristic small acicular crystals (35 μ long) in small groups; starch.

40. *Sarsaparilla.*—Crystals 68 μ long; starch 10–20 μ; sklerenchyma fibres. In Mexican sarsaparilla find a pronounced yellowish hypodermis and endodermis, the walls of which are unequal in thickness. In Honduras the latter is not so pronounced. Starch in both rather characteristic.

Needle-shaped crystals other than calcium oxalate are sometimes found in the following:

41. *Buchu.*—See No. 9.

42. *Coca.*—See No. 30.

43. *Chelidonium.*—See No. 52.

44. *Gaultheria.*—See No. 17.

45. *Lobelia.*—See No. 61.

d. CRYSTALS AS FINE SAND-LIKE PARTICLES IN PARTICULAR CELLS. LIKELY TO FIND ALSO ACICULAR CRYSTALS.

46. *Belladonnæ Folia.*—Characteristic grayish or dark-coloured cells containing small angular crystals of calcium oxalate; few secreting and non-secreting hairs.

47. *Dulcamara.*—Crystal-sand; starch, 5–7 μ; acicular crystals in parenchyma of bark; ducts with bordered pores; ducts 35–45 μ in width, and accompanied with sklerenchyma fibres; occasional single bast fibre; cork.

B. CALCIUM OXALATE CRYSTALS FEW OR WANTING.

a. Simple hairs present:

48. *Absinthium.*—T-non-secreting hairs; secreting hairs.

49. *Belladonnæ Folia.*—Might be considered here as crystal-sand; could be overlooked. See No. 46.

50. *Buchu.*—See No. 9.

51. *Castanea.*—See No. 10.

52. *Chelidonium.*—Non-secreting hairs; milk vessels contain reddish masses; epidermis with papillæ and cells with sinuate margins on surface view; acicular crystals sometimes observed in glycerin mounts.

53. *Digitalis.*—Characteristic non-secreting and secreting hairs; stomata each with 4–5 nebenzellen.

54. *Eriodictyon.*—See No. 14.

55. *Eupatorium.*—Non-secreting and secreting hairs; pollen grains 15 μ; characteristic style.

56. *Galla.*—See No. 14.

57. *Hamamelis.*—See No. 33.

58. *Hedeoma.*—Non-secreting hairs, 2–3-celled; peculiar thickened or reticulated cells of anther; in glycerin mounts, crystals of carbohydrate in "Athemhohle."

59. *Insect Powder.*—See No. 19. Crystals may not be observed.

60. *Hyoscyamus.*—See No. 34.

61. *Lobelia.*—Non-secreting hairs; sklerenchyma; pollen grains 30 × 15 μ; reticulated seed coat. Leaves distinguished from herb in that in the former fewer pollen grains and seeds are present.

62. *Matico.*—Non-secreting hairs of two kinds, few short, but numerous long and peculiarly jointed; oil secretion reservoirs, numerous in tissues of fruit; spiral ducts; pollen grains nearly cubical; much sand in among the fruit fragments.

63. *Marrubium.*—1–4-celled, non-secreting hairs, either single or in groups; large oil-secreting hairs.

64. *Mentha Piperita* and 65. *Mentha Viridis.* In chloral mount violet-coloured fragments of petals; pollen grains; jointed non-secreting and secreting hairs. In *Mentha piperita* sometimes find in the secretion hairs crystals of Menthol. Non-secreting hairs peculiar and apparently more abundant in *Mentha viridis* than in *M. piperita;* taste test characteristic for each.

66. *Nux Vomica.*—Non-secreting hairs give the characteristic reaction for lignin; endosperm, with thick walls, contains oil and protein; blue with $H_2SO_4 + K_2Cr_2O_7$.

67. *Pulsatilla.*—Non-secreting hairs, long and 1-celled; sklerenchyma (mechanical cells).

68. *Salvia.*—Non-secreting hairs; 1–4-celled and jointed; also two kinds of non-secretion hairs; stomata, each with two "Nebenzellen."

69. *Scoparius.*—Non-secreting hairs; pollen grains are cubical and may be mistaken for crystals; sklerenchyma with brown contents in lumen.

70. *Scutellaria.*—Non-secreting hairs long, jointed (5 cells); two kinds of secretion hairs; sklerenchyma characteristic and prominent.

71. *Senna.*—See No. 21.

72. *Stramonii Folia.*—See No. 22.

73. *Strophanthus.*—Long secretion hairs, in diameter 10–15 μ; starch grains, 4 μ; parenchyma containing oil, aleuron and starch; narrow, almost colourless collapsed cells; Strophanthin reaction.

74. *Tanacetum.*—Characteristic, bent, non-secreting hairs, made up of 4–5 cells; pollen grains 15 μ: odour characteristic.

(*b*) CONTAINING SECRETION HAIRS OR RESERVOIRS; AROMATIC AND OF CHARACTERISTIC ODOUR.

α. With oil-secreting hairs.

75. *Absinthium.*—See No. 48.

76. *Arnicæ Flores.*—Characteristic 5–6-celled, jointed, non-secreting hairs of corolla; also double hairs on outside of ovary; pappus; pollen grains; sklerenchyma.

77. *Belladonnæ Folia.*—See No. 46.

77*a*. *Digitalis.*—See No. 53.

78. *Eriodictyon.*—See No. 14.

79. *Eupatorium.*—See No. 55.

80. *Grindelia.*—Pollen grains, 20 μ; large number of palisade cells; sklerenchyma cells and fibres.

81. *Hedeoma.*—See No. 58.

82. *Mentha Piperita* and 83. *Mentha Viridis.* See Nos. 64 and 65.

84. *Pulsatilla.*—See No. 67.

85. *Salvia.*—See No. 68.

86. *Scoparius.*—See No. 69.

87. *Scutellaria.*—See No. 70.

β. *Containing secretion reservoirs:*

88. *Angelica.*—Starch; size of parenchyma cells containing starch characteristic; sklerenchyma; odour.

89. *Arnicæ Radix.*—Inulin masses or crystals soluble in hot water; sklerenchyma fibres; resinous masses.

90. *Caulophyllum.*—Parenchyma cells containing starch characteristic; sklerenchyma; odour.

91. *Cimicifuga.*—Reserve starch; sklerenchyma fibres; ducts.

92. *Eucalyptus.*—See No. 15.

93. *Gaultheria.*—See No. 17.

94. *Guaiaci Resina.*—Numerous lemon-yellow or dark brown resin masses, which on mounting in choral have a wine-coloured halo around them; few fragments of tissues, with characteristic sklerenchyma cells and fibres few crystals of calcium oxalate (cubical or coffin-shaped) in parenchyma

95. *Kava Kava.*—Starch; yellowish resin and oil; sklerenchyma more of nature of that found in fruits and seeds.

96. *Leptandra.*—Starch characteristic; brown stone cells.

97. *Matico.*—See No. 62.

98. *Pilocarpus.*—See No. 20.

99. *Piper Album* and 100. *Piper Nigrum.* Starch and oil in perisperm; stone cells. *Piper album* has fewer stone cells than *Piper nigrum.*

101. *Sabina.*—Starch, 4 μ; characteristic hypodermis, consisting of long fibres (15 μ wide), associated with epidermis.

102. *Sumbul.*—Starch; sklerenchyma fibres numerous.

103. *Tanacetum.*—See No. 74.

C. SKLERENCHYMA CELLS (STONE CELLS) OR FIBRES (WOOD OR BAST).*

104. *Aletris.*—Starch; yellowish or reddish-yellow coloured sklerenchyma.

105. *Arnicæ Radix.*—See No. 89, sklerenchyma fibres.

106. *Calumba.*—See No. 24, stone cells.

107. *Cimicifuga.*—Starch; resin cells; sklerenchyma fibres; ducts.

108. *Chenopodium.*—Characteristic reddish-brown pericarp and seed coat; numerous starch grains, in size up to 10 μ; fine granular contents = aleuron.

109. *Chirata.*—No starch; few small pollen grains, 4 × 10 to 7 × 10 μ; parenchyma large, with simple pores; many sklerenchyma fibres, in width 20 μ, walls 4 μ thick; scalariform ducts, 30 μ in width, also isolated spiral ducts; yellow epidermis, with some collenchymatic parenchyma, latter with brown contents; with the latter are associated mycelial-like development, containing blackish-brown coloured substance, few seeds in shape like Hyoscyamus, and reticulated like Lobelia, but cells larger and walls 4 μ thick.

110. *Cydonium.*—Without starch or calcium oxalate crystals; outer clear mucilage cells as in Linum; beneath the latter are thick-walled cells, containing brown contents, which react like tannin; parenchyma containing oil and aleuron.

111. *Grindelia.*—See No. 80, stone cells and fibres.

112. *Guaiaci Resina.*—See No. 94, very few stone cells and fibres.

113. *Lappa.*—Numerous irregular transparent fragments or sphere crystals (more or less fan-shaped) soluble in hot water = Inulin; no secretion reservoirs; more wood fibres and possibly larger reticulated ducts (as much as 70 μ wide) than Inula; cells of periderm brownish becoming yellow.

114. *Leptandra.*—Starch characteristic; brown stone cells.

115. *Piper Album* and 116. *Piper Nigrum* See Nos. 99 and 100, stone cells.

117. *Physostigma.*—Starch, 25 × 40 μ; oil and protein in irregular granular masses; characteristic sklerenchyma and stone cells whose contents are reddened by alkalies.

118. *Podophyllum.*—Crystals sometimes appear wanting; starch grains single (5–8 μ) or in groups of 4 to 6 grains; numerous single cells or groups with yellowish resinous contents; ducts and sklerenchyma fibres.

119. *Sarsaparilla (Honduras)* and 120. *Sarsaparilla (Mexican).* See No. 40.

121. *Senega.*—Parenchyma and sklerenchyma fibres characteristic; mounts in chloral show some pinkish (or strawberry-coloured) cells.

122. *Scoparius.*—See No. 69.

123. *Scutellaria.*—See No. 70.

124. *Spigelia.*—Rosette crystals, 10–15 μ; tetragonal crystals, 3–10 μ; sklerenchyma fibres; parenchyma containing pink-

* If thought necessary, can isolate characteristic stone cells and sklerenchyma fibres by treatment of powder with Schulze's macerating fluid or sulphuric acid.

coloured contents; starch, 4 μ; peculiar hypodermis; may contain $CaCO_3$.

125. *Sumbul.*—Starch; resin secretion reservoirs; numerous sklerenchyma fibres.

D. SEEDS WITH THEIR CHARACTERISTIC SEED COATS.

126. *Chenopodium.*—See No. 108.

127. *Lobelia.*—See No. 61.

(E) RESERVE STARCH.

128. *Aletris.*—See No. 104, sklerenchyma.

129. *Angelica.*—See No. 88, parenchyma, odour.

130. *Aralia nudicaulis.*—See No. 2, crystals.

131. *Aralia spinosa.*—See No. 3, crystals.

132. *Caulophyllum.*—See No. 90, parenchyma, odour.

133. *Chenopodium.*—See No. 108, stone cells.

134. *Cimicifuga.*—See No. 91, fibres.

135. *Cypripedium.*—See No. 38, crystals, resin.

136. *Helonias.*—See No. 39, crystals.

137. *Kava Kava.*—See No. 95, sklerenchyma.

138. *Leptandra.*—See No. 114, stone cells.

139. *Physostigma.*—See No. 119, sklerenchyma cells and fibres.

140. *Piper Album* and 141. *Piper Nigrum.*—See Nos. 115 and 116, stone cells.

142. *Sarsaparilla (Honduras)* and 143. *Sarsaparilla (Mexican).*—See No. 40, sklerenchyma.

144. *Spigelia.*—See No. 124, parenchyma.

145. *Serpentaria.*—Starch, 10 μ, grains as a whole apparently larger than in spigelia; sklerenchyma fibres and ducts; many parenchyma cells contain a yellowish or reddish-brown substance, as also the cork cells.

146. *Sumbul.*—See No. 125, sklerenchyma fibres.

147. *Xanthoxylum.*—See No. 29.

F. CONTAINING POLLEN GRAINS.

148. *Castanea.*—See No. 10, crystals.

149. *Chelidonium.*—See No. 52, milk vessels.

150. *Eupatorium.*—See No. 55, hairs.

151. *Grindelia.*—See No. 80, hairs and sklerenchyma.

152. *Hedeoma.*—See no 58, hairs, stomata.

153. *Insect Powder.*—See No. 19, hairs and sklerenchyma.

154. *Lobelia.*—See No. 61.

155. *Marrubium.*—See No. 63, hairs.

156. *Mentha Piperita* and 157. *Mentha Viridis*—See Nos. 64 and 65, hairs.

158. *Passion Flowers.*—See No. 5, pollen.

159. *Pulsatilla.*—See No. 67, hairs.

160. *Scoparius.*—See No. 69, hairs.

161. *Scutellaria.*—See No. 70, hairs.

162. *Tanacetum.*—See No. 74, hairs.

G. INULIN MASSES OR CRYSTALS (SOLUBLE IN HOT WATER).

163. *Arnicæ Radix.*—See No. 89, sklerenchyma and resin masses.

164. *Lappa.*—See No. 113, ducts and wood fibres.

165. *Taraxacum.*—Numerous crystal-like groups, or sphere-crystals, giving in glycerin mounts the parenchyma a characteristic appearance; yellowish-brown milk vessels 10 μ in width; reticulated ducts are 45 μ wide, and associated with them are characteristic non-lignified "Ersatzfasern."

H. CONTAINING TANNIN MASSES.

166. *Chimaphila.*—See No. 12, crystals.

167. *Galla.*—See No. 4, crystals and starch.

168. *Caultheria.*—See No. 17, crystals.

169. *Hamamelis.*—See No. 33, crystals and hairs.

170. *Uva Ursi.*—See No. 37, crystals.

(To be continued.)

A CLASSIFICATION OF GUMS, RESINS AND SIMILAR SUBSTANCES.*

BY FREDERICK L. LEWTON.

The terms "gums," "resins," and "similar substances," as here used, include only those plant exudations and prepared substances of similar appearance, which are properly or commercially known as gums, resins, balsams or rubbers.

It will be at once readily seen that the above definition excludes pectic substances and numerous gums, resins and mucilages occurring in small amounts in the tissues of many plants, which should find a place in a complete scientific classification of resinous and gummy substances.

The classification of gums, resins and similar substances, particularly those included by the commercial world under the general name of "gums," presents a number of difficulties which probably account for the want of uniformity among the different systems of classification that have been proposed from time to time. This want of uniformity is no doubt due to the fact that the majority of these substances are complicated bodies, bearing no general relationship as regards chemical affinities, and are widely distributed in the vegetable kingdom, originating therefrom in several ways.

Some are secretion products, others have been clearly proved to be formed from the walls of plant cells by chemical metamorphosis, and others again are inspissated saps or extracts.

The following classification is based chiefly on physical properties and chemical composition and divides these substances into nine sections, each of which may be divided into a number of sub-sections.

SECTION I. TRUE GUMS.

Plant exudations, or prepared vegetable substances, which dissolve or soften in cold water, forming a mucilage, or at least a liquid of a gelatinous consistency.

They are insoluble in 60 per cent. alcohol. Treated with nitric acid, they yield mucic and oxalic acids. Sulphuric acid converts them into dextrin and finally into sugar.

They may be divided into five sub-sections according to their chemical composition.

Sub-section 1. *Arabic Group.*—These gums chiefly consist of arabin. They are almost entirely soluble in cold water, forming a mucilage.

Examples: All kinds of acacia gums, mesquite, feronia, or wood-apple, buchanania, and acajou gums.

Sub-section 2. *Cherry Group.*—These gums consist chiefly of cerasin, and swell in cold water, forming a poor mucilage.

Examples: Cherry, peach, and apple tree gums.

Sub-section 3. *Tragacanth Group.*—The gums comprising this group consist chiefly of bassorin, and swell in cold water, forming a mucilage.

Examples: Tragacanth, kuteera, nopal, Moringa, and cocoanut gums.

Sub-section 4. *Dextrin Group.*—The representation of this group consists of almost pure dextrin. It is soluble in cold water, forming a thick viscous solution, which has strong adhesive properties.

Examples; Dextrin, British gum or gommeline.

Sub-section 5. *Seaweed Group.*—The representative of this group consists chiefly of gelose. It forms a jelly with 500 times its weight of water.

Example: Japan isinglass from *Gelidium corneum.*

SECTION II. TRUE RESINS.

Hard, friable, lustrous vegetable substances, externally resembling gums, but which neither dissolve nor soften in cold water. They burn with a bright smoky flame, contain much carbon, but little oxygen, and no nitrogen.

Resins are not definite chemical compounds, but are complicated mixtures of the resin acids. They may be divided into six groups.

*From the *American Journal of Pharmacy.*

Sub-section 1. *Copal Group.*—These resins are insoluble in ordinary solvents unless fused.

Examples: Amber, animi or Zanzibar copal, Angola, Sierra Leone, pebble, and other East and West African copals.

Sub-section 2. *Dammar Group.*—The resins comprising this group are more or less soluble in ether, chloroform, benzol, acetone, oil of turpentine, etc., and are almost entirely insoluble in alcohol.

Examples: Singapore and Batavia dammars, Kauri or Australian dammar, and American copal or eourbaril resin.

Sub-section 3. *Sandarac Group.*—These resins are more or less soluble in alcohol without warming.

Examples: Sandarac, mastic, Manila copal. the black, white and sal dammars of India, and guaiacum resin.

Sub-section 4. *Colophony Group.*—These resins are obtained in the distillation of crude turpentine or other oleo-resins, or they may be natural products which have lost their volatile oil through evaporation. They are entirely soluble in alcohol.

Examples: Common resin or colophony.

Sub-section 5. *Benzoin Group.*—The resins of this group are soluble in alcohol and contain benzoic or cinnamic acids or yield them when subjected to heat.

Examples: Benzoin, dragon's blood from the East Indies, yellow and red grass-tree gums or acaroid resin.

Sub-section 6. *Lac Group.*—This group includes the resinous incrustation, as well as the purified products obtained therefrom, which is found on the twigs of many species of trees, and is elaborated from the sap by the female of the lac insect (*Coccus lacca*). They are partially soluble in alcohol, forming a turbid solution.

Examples: Stick lac, seed lac, shellac, button and garnet lac.

SECTION III. INODOROUS GUM-RESINS.

Plant exudations, having no pronounced odour, and which consist essentially of gum and resin associated together in various proportions, sometimes accompanied by waxy matters. They form an emulsion with water and contain no volatile oil.

Examples: Gamboge, South American hog-gum.

SECTION IV. ODOROUS GUM-RESINS.

Plant exudations, composed of mixtures of gum, resin and volatile oil in varying proportions. They have a distinctive odour which may be fetid or fragrant in character.

Sub-section 1. Asafetida Group.—This group includes gum-resins having a fetid or more or less disagreeable odour. The most important of them are yielded by plants belonging to the order Umbelliferæ.

Examples: Asafetida, galbanum, ammoniacum, opopanax, and "cumbi" or gardenia resin.

Sub-section 2. Myrrh Group.—These are gum-resins having a more or less fragrant odour. The majority of them are yielded by plants belonging to the order Burseraceæ.

Examples: Myrrh, bdellium, olibanum, and "gomart" resin.

SECTION V. OLEO-RESINS.

Plant exudations consisting of resin mixed with volatile oil in various proportions; the resin frequently being dissolved in the latter, forming a liquid.

Sub section 1. *Lacquer Group.*—This group includes the natural varnishes and desiccating lacquers, which have the property of drying hard with considerable lustre. They are mainly yielded by trees belonging to the order Anacardiaceæ.

Examples: Chinese, Japanese, Burmese and Indian lacquers and cardol.

Sub-section 2. *Copaiba Group.*—These are fragrant liquids, usually classed with the balsams, but which differ from them in consisting of a comparatively small amount of resin dissolved in volatile oil.

Examples: Copaiba balsam and gurjun balsam or "wood-oil."

Sub-section 3. *Turpentine Group.*—This group includes the soft resins containing more or less volatile oil, which are exuded by the cone-bearing trees.

Examples: Crude turpentine, Canada balsam, "gum thus," galipot, etc.

Sub-section 4. *Elemi Group.*—These are soft resins, seldom containing more than 10 per cent. of volatile oil. They are mainly yielded by trees belonging to the order Burseraceæ.

Example: Manila and Brazilian elemi, Mexican "copal," Carana resin and tacamahac.

SECTION VI. TRUE BALSAMS.

Plant exudations consisting of resin mixed with aromatic acids, alcohols and esters.

Examples: Liquid storax, "sweet-gum" resin, or liquidambar, balsam of Peru, and balsam of tolu.

SECTION VII. VOLATILE OILS.

Sub-section 1. *Camphor Group.*—These consist of solid oxidised hydrocarbons.

Examples: Camphor, borneol, menthol crystals.

Sub-section 2. *Terpene Group.*—It comprises liquid hydrocarbons.

Examples: Wood-tar, tar and resin oils, spirit of turpentine, etc.

The majority of the essential oils are of the same composition, but they are not classed with the gums and resins.

SECTION VIII. MILKY SAPS.

(Not included in above sections).

Sub-section 1. *Rubber Group.*—These consist chiefly of hydrocarbons, known as polyterpenes.

Examples: Rubber, gutta-percha, balata and chicle.

Sub-section 2. *Opium Group.*—They consist chiefly of gum and resin, associated with alkaloids, acids, inorganic salts, etc.

Examples: Opium, lactucarium, scammony and euphorbium.

SECTION IX. INSPISSATED SAPS AND EXTRACTS.

Plant exudations or inspissated saps, consisting of gum or resin, or both, associated with astringent and bitter principles, alkaloids, glucosides, etc.; or inspissated extracts of similar composition.

Sub-section 1. *Kino Group.*—These are plant exudations containing tannins.

Examples: Malabar, Bengal and Australian kinos, West Indian dragon's blood and Mochras or silk-cotton gum.

Sub-section 2. *Hemp Group.*—A plant exudation, containing resin, inorganic salts, etc.

Example: Charas.

Sub-section 3. *Aloe Group.*—They are inspissated saps, containing resin, bitter principles, etc.

Examples: Barbadoes, Socotrine, Cape, and other kinds of aloes.

Sub-section 4. *Extract Group.*—This includes all inspissated extracts containing alkaloids, glucosides or tannins.

Examples: Gambir, cutch or catechu, quebracho, liquorice paste, curare, etc.

Liquid Dentifrices.

Boas' Dentifrice: Anise fruits, 15; cloves, 10; chamomiles, 10; alcohol (90 per cent.), 1,200; cinnamon, 7·5. Macerate for four days, filter, and add oil of peppermint, 5; tincture of ambergris, 5. *Gunther's Dentifrice*: Tincture of alkanet (1:10), 200; compound spirit of balm (Codex), 70; alcohol (90 per cent.), 800; otto of rose, 3; oil of peppermint, 9. *Schroeder's Dentifrice*: Gunther's dentifrice as above, 100; salicylic acid, 2. *Coca Dentifrice*: Coca leaves, 100; alum in powder, 15; cochineal, 100; alcohol, 90 per cent. Macerate for four days, press, add oil of peppermint, 4; oil of cloves, 4; otto of rose, 1; compound spirit of cochlearia (Codex), 400; saccharin, 0·4. Filter.—*Monde dentaire*, **16**, 235.

REPORT OF THE GOVERNMENT LABORATORY.

The report of the Principal Chemist of the Government Laboratory, upon the work of the Laboratory for the year ended March 31, 1899, has been issued as a Parliamentary paper. The business of the Government Laboratory is divided into (1) Customs and Excise work in connection with the Revenue Departments, and (2) work in connection with other Government Departments.

Customs Department.—The total number of analyses and examinations made during the year was 8,418, as against 8,047 for the previous year. During the year 57 samples of tea, representing 1,616 packages, were examined and found to contain exhausted leaves or to be mixed with other substances within the meaning of the Act. They were, therefore, refused admission for home consumption or were forfeited and destroyed or otherwise disposed of as being unfit for human food. *Tea.*—Tea which cannot be admitted for use as a beverage is "denatured" by being mixed in bond with asafetida and lime, and used for the manufacture of caffeine. Samples of such "denatured" tea are examined in the Laboratory at the Custom House, prior to delivery, to ascertain that the Board's regulations are effectively complied with.

Excise.—The number of examinations was 66,423, or an increase of 1,110 over the preceding year. *Beer.*—3,165 samples of finished beer taken from 1,323 publicans, have been analysed, and 421, or 13 per cent. of the samples, were found to have been diluted with water or otherwise adulterated, the dilution in one case been equivalent to 10 gallons of water in the barrel of 36 gallons. All the samples from provincial towns, with one exception, were genuine, and the dilution, as in previous years, has been shown to be almost entirely confined to London. *Wood Naphtha.*—970 samples of wood naphtha intended for methylating purposes, representing 371,663 gallons, have been examined; and of those 115 samples, corresponding to 48,802 gallons, were not approved as suitable for the purpose. *Alcohol.*—56 samples of ordinary alcohol intended for methylation have been examiued and all found suitable. *Tobacco.*—157 samples of tobacco taken from manufacturers and dealers have been analysed for adulteration generally. Of these 132 were found to be genuine and twenty-six adulterated. In no case was there reason to believe that the adulteration had taken place in this country. The consumption of tobacco in proportion to the population was 2 lb., per head. The quantity of tobacco cleared for consumption was 8,728,920 lb. more than that cleared in the preceding year. The larger proportion of this increase, however, was abnormal, and caused by exceptionally heavy clearances in the last month of the year, owing to manufacturers anticipating that the duty would be increased by the Budget for the current year.

Other Government Departments.—For other departments that those of Customs and Inland Revenue, 3,530 samples were examined. The Admiralty samples consisted largely of food substances, disinfectants, and soaps; the Board of Trade sent 544 samples of lime and lemon juice, spirits, disinfectants, etc.; the Board of Agriculture sent 1,600 samples of butter, margarine, cheese, and oilcakes. *Butter.*—1,083 samples of butter were examined, of which only two were reported adulterated, as again twenty-five last year and forty-six the year before. This is a marked improvement on previous years, for not only has the number of adulterated samples rapidly diminished year by year, but the analytical results show a distinct improvement in the quality of those reported genuine. No samples have this year been reported as of doubtful purity, since, although certain samples gave reactions for cotton-seed oil, the amount indicated was not more than might be due to feeding on cotton-cake, whilst the other analytical results of these samples were such as to preclude the idea of any admixture of margarine containing cotton-seed oil. The result of the investigation made at Wye, and in the Laboratory last year, into the effect of feeding cows upon oil-cakes proved beyond doubt that the characteristic constituent of cotton-seed oil passes into the milk of cows fed upon cotton-cake. With regard to the use of boracic preservative in butter, France again heads the list of European countries, and Holland comes next, whilst Danish and Scandinavian butters were entirely free from this preservative. The majority of the butters from the more distant colonies—as Australia and New Zealand—contained boric preservative. The use of artificial colouring matters derived from coal tar is now much in vogue, particularly in the United States, and to a less extent in Holland. *Margarine.*—The great majority of the margarines examined contained cotton-seed oil, boric preservative, and aniline colouring matters.

Food and Drugs Bill.—A considerable amount of attention has been given to the provisions of the new Food and Drugs Bill introduced into the House by the President of the Board of Agriculture. The various proposals and suggestions made upon it by numerous public bodies, agricultural and other associations and traders, and amendments proposed in Committee, have been submitted to the Principal Chemist by the Board of Agriculture for criticism or comment, embracing questions concerning imported dairy products, margarine and margarine cheese, the use of preservatives and colouring matter in milk and butter, standards of purity, etc.

Poisons Bill.—Amongst the matters referred to the Chief Chemist for his consideration was the Poisons Bill promoted by the Privy Council, with a view to safeguarding the sale of poisonous preparations not included in the Schedule to the Pharmacy Act, but which affect many preparations used for agricultural purposes.

Home Office.—The work done for the Home Office has been considerably increased in consequence of the inquiries which were directed to be made by order of the Home Secretary concerning the use of lead compounds in pottery manufacture and the use of ordinary phosphorus in the manufacture of lucifer matches. The Dangerous Trades Committee of the Home Office have also sent a number of substances for examination and report.

Post Office.—The gum used for postage stamps has been examined, in view of an alleged case of septicæmia due to its use. Bacteriological cultivations were made both from the stamp paper and the gum employed as the adhesive material, but no pathogenic organism could be detected in either case.

War Office.—The samples examined for the War Department exhibit an increase of twenty-nine on those of the previous year. For the Army Medical Department a number of medicinal preparations have been examined. A good proportion of these samples exhibited satisfactory conformity with the standards of the British Pharmacopœia, but in several instances they were markedly inferior. In one case complaint was made by a medical officer that a particular sample of ether, when used as an anæsthetic, had proved very unsatisfactory. The examination of the sample revealed no explanation of the special features of which the complaint was made, but established the fact that the ether had been largely, if not entirely, prepared from methylated spirit, though the bottle bore a label guaranteeing that the preparation was made from rectified spirit.

Reference Samples.—74 samples were referred to the Government Laboratory by magistrates under the Sale of Food and Drugs Acts, the number being greater than for some years past. In the great majority of instances the Government chemists were in agreement with the analysts, but they were not always able to draw the same conclusions as to the articles being adulterated. No drugs were included among the samples referred.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, AUGUST 19, 1899.

PROSPECTS OF PHARMACEUTICAL LEGISLATION.

THE favourable prospect now presented of reasonable amendment of the law affecting the business of chemists and druggists is still so much obscured by the complicated tangle of incompatible ideas, contradictory arguments, and misconceptions, that at the risk of wearying some readers of this Journal, attention may again be directed to some essential points which have repeatedly been dealt with in these pages as of primary importance, both in the public interest and in the interest of legally qualified chemists and druggists. In that connection the importance of giving prominence to the professional aspect of the chemist's business is especially to be urged. The general principle has now been recognised that a company, as such, ought not to be permitted to carry on any professional occupation for the practice of which individual qualification is required by the State as necessary in the public interest. In that respect chemists occupy a position of great practical advantage, for while the medical profession has still to convince the public and the Legislature that none but legally qualified persons should practise medicine, the exercise of the chemist's business has already been made subject to statutory limitation in the public interest. The legal qualification that was established for that purpose has hitherto had more reference to the sale of poison and to the trade side of the business than to the important work of dispensing and compounding medicine. But the danger attending performance of such work by unqualified persons has become apparent, and, in regard to the public interest as well as for conserving the legitimate interests of registered chemists, the need for making such work the exclusive business of persons duly qualified for the purpose has now been admitted by the Government. A sound basis has thus been obtained for improving the position of qualified chemists—not only in regard to the sale of poison which was once thought to be the most important point, but in the direction originally contemplated by the Pharmaceutical Society—as the only persons specially competent to carry out the work of dispensing and compounding medicine.

The qualification of chemists demanded by the State would be unmeaning and valueless in the public interest if unqualified persons were permitted to carry on business as chemists and druggists. From that point of view the LORD CHANCELLOR has recognised the propriety of restricting companies now carrying on that business, and the House of Lords Committee was unanimously of opinion that interference with the practice of any profession by taking advantage of company machinery must be stopped. In addition to that strong public reason for preventing infringement of privileges conferred by qualification, the claim of qualified chemists, in their own interest, may also be urged as a further reason. In that sense persons registered under the Pharmacy Act are entitled to claim that the privileges they acquire by qualification are exclusively their own. They are entitled to call upon the Government to assist them in defending those rights, and, for that purpose, to rectify those defects of the Pharmacy Act which have led to the infringement of their privileges. For both reasons—public and private—there should not therefore be any idea of compromise with unqualified persons or with companies, and least of all in regard to the use of titles indicative of qualification. Among the suggestions to that end which have been put forward, more or less unwisely, the most preposterous of all is the proposal to recognise companies provided their business is conducted by a board of qualified directors. Anything more grotesquely incongruous than such an application of company machinery—really for the purpose of defeating the object of a statute passed in the interest of the public—could scarcely be imagined. Rather give full scope to the principles of free trade; let the directors of drug companies be as ignorant of the chemist's business as other directors often are of the business they are supposed to conduct. If the business of chemists and druggists is to be carried on by unqualified capitalists or by companies, let the rights of legally qualified persons conducting such a business be properly respected by putting them in a position to conduct the business, as the LORD CHANCELLOR says, *bonâ fide*, and so that they would not only be masters of the business, but of the company as well.

In regard to the practice of pharmacy, as well as the business of the chemist and druggist, there is also a prospect of amended legislation as a consequence of the position taken by the LORD CHANCELLOR. Though the principle of proprietary qualification—seriously damaged by the reduced standard adopted in 1868—was practically sacrificed when the necessity for legal qualification ceased to be identified with proprietorship of a business, the LORD CHANCELLOR'S declaration that the public must not be exposed to the danger of unqualified persons practising as dispensers affords some hope that the rights and privileges conferred by pharmaceutical qualification may be defended with success. Upon that point all interest should now be centred. Instead of seeking for extension of the Poison Schedule only, as furnishing the measure of the pharmacist's function and thus encouraging the mistaken as well as mischievous idea that the sale and dispensing of poison are branches of trade, the limitation of which constitutes a monopoly, pharmaceutical policy should aim at bringing about a more enlightened interpretation of the pharmacist's work, as, even in dealing with the most simple kinds of medicine, exercise of trained intelligence and skill is required, because the chemist's shop or dispensary is essentially a poison closet. On those lines there might even be a possibility of extin-

guishing the chemist and druggist and establishing the one qualification of pharmaceutical chemist as originally contemplated by the founders of the Society. That project has attractions as well as difficulties, and under existing conditions improvement of pharmaceutical legislation will more probably be of a less radical character. But, first of all, and in any case, it is essential that the Council should receive much more coherent support,—even from the Society, which is still the minority—that chemists collectively should show they are capable of agreement on principles and of being led in defence of their rights, not only as vendors of Mother Siegel's syrup and Beecham's pills, or even as licensed sellers of poisons, but as possessors of a qualification by which they are entitled to practise pharmacy. That result must be achieved if the rank and file of registered chemists are not to become mere tools of the company monger.

THE PLACE OF PHARMACOLOGY IN THE MEDICAL CURRICULUM.

THE presidential address delivered before the British Medical Association by Professor J. B. BRADBURY, of Cambridge, at the opening of the Section of Pharmacology and Therapeutics this month, was devoted to a brief consideration of the proper place of pharmacology in the medical curriculum. Reference was made at the outset to the growing tendency for medical corporations, other than the universities, to require less and less knowledge of the natural history, properties, composition, and action of drugs from candidates for their diplomas; a condition of things which is much to be regretted. Without any desire to revert to the state of affairs when medical candidates were expected to have a minute knowledge of the distinctions between the different species of senna, cinchona bark, etc., Professor BRADBURY considers that the danger now is that they may not be able to recognise senna at all, or to know the ingredients and doses of the most important pharmacopœial preparations. "The consequence is, when settled in practice, that they are tempted to prescribe ready-made tabloids, elixirs, etc., the purity and the precise dose of the ingredients of which have no official sanction." And whilst, in many cases, those preparations are most useful and valuable on account of their easy portability, in other cases the therapeutic results would be more satisfactory if official preparations were issued instead. The contents of the British Pharmacopœia, so far as they bear directly or indirectly on prescribing, should be thoroughly mastered by all medical students, and such knowledge should be made a compulsory part of the curriculum. A considerable part of the work of a medical man once started in practice is writing prescriptions for his patients, and yet in respect of the knowledge of drugs and their actions his education is often most imperfect. Continuing, Professor BRADBURY urged that it is not too much to expect those who are daily to prescribe remedies to be acquainted with what is known of their actions. That, he thinks, can best be taught after anatomy and physiology, and along with pathology. He would make the first part of the final examination pathology and pharmacology—the sciences dealing respectively with disease and its treatment—and then the student should at the next stage be ready to apply the principles thus acquired to actual practice in connection with his clinical medicine, surgery, and midwifery.

ANNOTATIONS.

THE ABSURDITY OF THE ATTEMPT to take advantage of company machinery for the purpose of carrying on the business of a chemist's and druggist's shop belonging to a joint stock company, or to any association of unqualified persons, is tolerably certain to become evident whenever the circumstances of the case are understood. That was shown, to some extent, by the provision in the Lord Chancellor's Pharmacy Bill, that the business of a shop belonging to a company should be conducted by a registered chemist and druggist, or pharmaceutical chemist, as the case might require. But that provision would be insufficient to meet all the requirements of the case. If the qualified person conducting the business were to be in the position of an employé of a company and subject to its control, no real improvement would be secured. How far that deficiency was intended to be met by the words *bona fide* used by the Lord Chancellor is uncertain; but the use of those words points in the same direction as the remark more recently made by the Lord Chancellor as to the absurdity of an ideal person, such as a company, conducting the business of a chemist and druggist requiring personal qualification: it agrees also with the opinion formed by the House of Lords Committee that such procedure should be put a stop to. The only reasonable condition under which the business of a chemist's and druggist's shop can be conducted in conformity with the law is that a legally-qualified person shall have absolute control and authority; then, perhaps, it might not matter whether the shop belonged to a company or even to an unqualified individual, for the proprietorship would then be a matter comparatively unimportant.

EVEN MR. JESSE BOOT considers that in every chemist and druggist's shop the business should be conducted "wholly and solely under the control of a registered chemist." That view of the matter relates, of course, to the professional part of the business, for the exercise of which legal qualification is necessary in the public interest. It supports the argument for the coincidence of legal qualification with proprietorship which was intended by the Pharmacy Act. It also supports the Lord Chancellor's opinion that companies at present carrying on business as chemists and druggists should be subjected to restrictions by which "proper vested interests" would be respected. But chemists must remember that that view is maintainable only in so far as their business is of a professional character. Though they, as well as the public, are entitled to enjoy advantage from the necessity for qualification, they cannot expect any kind of trade protection which they are not able to provide for themselves as being something more than ordinary traders.

THE CURIOUS NOTION THAT THE BUSINESS of a chemist's and druggist's shop, belonging to a limited liability company, might be conducted by a board of qualified directors, is more likely to afford some temporary amusement than to meet with approval of any of the parties who would be concerned in such a clumsy and unsuitable arrangement. The business of a chemist's and druggist's shop is very rarely so extensive as to require the assistance of the Companies Acts for limitation of financial liability in connection with it. Then imagine the business of a chemist's and druggist's shop being conducted by a board of qualified directors sitting in attendance, with the secretary of the company, for the purpose of dispensing physicians' prescriptions or for selling pennyworths of laudanum and white precipitate. Under such circumstances there would probably be but small prospect of the board being able to declare a very satisfactory dividend to the shareholders. Truly those who seek to impress qualified chemists with the suggestion that such a mode of dealing with infringement of their privi-

leges and evasion of the law, can possibly afford a remedy for the evils of which they complain, must have a very poor estimate of the intelligence of the trade.

Sir Edward Frankland, K.C.B., Ph.D., F.R.S., who died in Norway on Wednesday, August 9, had been an honorary member of the Pharmaceutical Society since 1862, and was also a member of the Society's Research Committee. He was born in 1825 at Churchtown, near Lancaster, and was educated at Lancaster Grammar School. He spent some time with a Lancashire chemist and druggist, and subsequently he proceeded to the Museum of Practical Geology and, in 1847, to the university of Marburg. There he took his degree, his dissertation upon the occasion dealing with the discovery of a method for isolating ethyl. Chemistry was, from the outset of his career, his special subject, and he was engaged in original work in pure chemistry at a very early age. To quote the *Times*, his earliest researches, undertaken in conjunction with Kolbe and prosecuted in the laboratories of Playfair and Bunsen, were at first analytical in character, their aim being the isolation and identification of the proximate radicals composing certain organic bodies. Soon, however, he began to turn his attention to synthetical problems, to the artificial building up of organic bodies, and here his efforts were rewarded by the important discovery of the organo-metallic compounds resulting from the direct union of a positive organic radical with a metal. It was in 1850 that he announced the preparation of compounds of zinc, with methyl and ethyl, and predicted the existence of other similar bodies. Intrinsically interesting as are those substances, their importance lies rather in the theoretical deductions which he drew from a consideration of their composition. In this way he evolved the conception that the atoms of zinc, tin, etc., had only room, so to speak, for the attachment of a fixed and definite number of the atoms of other elements; and this hypothesis, which was communicated to the Royal Society in 1852, was the basis of the doctrine of atomicity or equivalence of the elements, which may be said to have dominated the course of all subsequent chemical theory since its enunciation.

In Applied Chemistry, Sir Edward Frankland's first important work was begun in 1851, when he was appointed Professor of Chemistry in Owens College, Manchester, and related to the manufacture of water-gas. He also investigated the chemical composition of the gases evolved from different kinds of gas-coal. But, in the opinion of the *Times*, his most important contributions to applied chemistry had reference to water supply and sewage questions. In 1865 he succeeded Hofmann as Professor of Chemistry at the Royal College of Chemistry (Royal School of Mines), and also undertook to continue the monthly analysis of the water supplied to the metropolis, which Hofmann had begun a few months previously for the Registrar-General. Those monthly analyses he has continuously performed ever since that date, and that task involved the elaboration of a new method of water-analysis. In 1868 he was appointed a member of the second Royal Commission on the Pollution of Rivers, and the Government provided him with a laboratory in which to carry out the inquiries necessary for the purposes of that body. Those researches occupied six years, and dealt with the chemical qualities of water from various geological strata and from different sources of supply; the possibility of rendering polluted water again wholesome; the propagation of disease by drinking water; the influence of hard water on health; the deterioration of water in mains and service pipes; and the quality of London water taken from the Thames. In physiological chemistry he took part with Fick and Wislicenus in a crucial experiment to settle the vexed question of the origin of muscular power. Sir Edward held professorships of chemistry successively in the Engineers' College at Putney, Owens College, St. Bartholomew's Hospital, the Royal Institution, where he followed Faraday, and succeeded Hofmann at the Royal College of Science, South Kensington, retiring from the last in 1885. The Royal Society, which made him a Fellow in 1853, gave him a Royal medal in 1857, and he also acted as its foreign secretary. Abroad, the French Academy of Sciences made him a corresponding member in 1866, and he was also a foreign member of the Academies of Sciences of Bavaria, Berlin, St. Petersburg, Upsala, America, and Bohemia. Oxford gave him the degree of D.C.L. in 1873, and Edinburgh that of LL.D. in 1884. He was the first president, in 1877, of the Institute of Chemistry, and served as president of the Chemical Society in 1871, being one of the six ex-presidents entertained at the recent banquet. The honour of K.C.B. was bestowed on him in 1897.

The National Physical Laboratory is being founded on a wide basis, and there is to be as little delay as possible in proceeding with the planning and erection of the new buildings, for which the Government is providing the sum of £12,000. The realisation of the scheme, as the *Times* points out, is primarily due to two addresses delivered before the British Association in 1891 and 1895, by Professor Oliver Lodge and the late Sir Douglas Galton respectively. The matter was finally laid before the Marquess of Salisbury, and as a result, a committee, of which Lord Rayleigh was chairman, was then appointed by the Treasury, and, after taking evidence, reported in favour of the establishment of a public institution for standardising and verifying instruments, for testing materials, and for the determination of physical constants. It was further recommended that the institution should be established by extending the Kew Observatory in the Old Deer Park, Richmond, and that the Royal Society should be invited to control it and to nominate a governing body, on which commercial interests should be represented, the choice of the members of such body not being confined to Fellows of the Society. Those recommendations were approved, and to give effect to them the Government undertook to ask Parliament for the sum already mentioned for buildings, and for an endowment of £4,000 a year. A scheme for the management of the new institution has been approved by the Treasury, and the first instalment of the promised grants has been sanctioned by the Legislature. The Kew Observatory Committee is willing that the institution which it has managed very successfully should be merged in the National Physical Laboratory, which will thus become possessed of an endowment of £458 per annum from the Gassiot trust and of an income of about £2,700 from fees for standardising. Those receipts have, in the past, rather more than covered the expenses of carrying on the work of the observatory.

The Ultimate Control of the National Physical Laboratory is placed in the hands of the Royal Society, but the constitution of the bodies—an executive committee and a general board—which manage it directly can only be altered with the consent of the Treasury. The general board is a relatively large body, to which the executive commitee must report annually, and to which it must submit its scheme of work for the next year. Twelve of the members of the general board are nominated by the Institutions of Civil, Mechanical, Electrical, and Naval Engineers, the Iron and Steel Institute, and the Society of Chemical Industry. Six of those representatives of "commercial interests" are also to be members of the executive committee, which will ultimately consist of twelve ordinary and five official members, of whom the latter are the president of the Royal Society, the chairman of the committee, the Permanent Secretary of the Board of Trade, and the treasurer and one of the secretaries of the Royal Society. In the first instance, six members of the existing Kew Observatory Committee will also have seats on the executive committee, but their places will not be filled up when their period of

office expires. Finally, it is in the power of the executive committee to appoint sub-committees to superintend particular departments or investigations. The members of these sub-committees need not necessarily be members either of the general board or of the executive committee. Preliminary arrangements have been in progress for some time in order that the National Physical Laboratory should be organised as soon as possible after the requisite funds were voted by Parliament. The six technical societies mentioned above have nominated their representatives, the general board and executive committee have been constituted, and Lord Rayleigh has accepted the chairmanship of those bodies. On the recommendation of the executive committee, the council of the Royal Society has appointed Mr. R. T. Glazebrook, F.R.S., principal of University College, Livorpool, to the important post of director of the National Physical Laboratory. A number of sub-committees have also been organised by the executive committee, which have been requested to make suggestions preparatory to the drawing up of a detailed scheme of work and of the plans of the new buildings. A definite scheme of work will be arranged during the autumn, and the director will, it is hoped, take up the duties of his office on January 1, 1900.

THE LIABILITY OF ASSISTANTS for offences under the Sale of Food and Drugs Act does not commend itself to the editor of *Truth*, who asks what sense of justice there is in making a servant or employee liable for an offence which is morally and equitably the offence of his employer alone? The question is asked in view of a case which recently occurred at Bridlington, and has since been the subject of a fruitless appeal to the Home Secretary. An apprentice to a firm of grocers was convicted for selling two ounces of milk of sulphur which contained 55 per cent. of calcium sulphate, and he was fined £5 and costs, with the alternative, in default, of two months' imprisonment. Now, no sane man, it is urged, can suggest that the youth had committed anything but a technical offence. "The article sold was not his. He did not buy it, there is no reason to suppose that he had any knowledge, or means of knowledge, as to its quality. He sold it in the ordinary discharge of his duty as a servant." And yet, had not his employers paid the amount of the fine and costs, as they ultimately did, he must needs have gone to prison for two months. That such a thing should be possible is asserted by *Truth* to be "a disgrace to the Parliament which made the law and the magistrate who administer it." But if the employers cannot be got at in any other way than through their assistants, what is to be done in such cases? The same difficulty arises in connection with the Pharmacy Act, 1868. In many instances offences against that Act, for which employers are "morally and equitably" liable, can only be dealt with in the persons of their assistants who actually effect the sales. The ideal state of affairs would be that both employer and assistant should be liable, when the assistant acts with the full consent of his employer; and, in any case, the onus of proving that he did not authorise any attempt to evade the Statute should be cast upon the proprietor of the business.

THE LONDON UNIVERSITY EXAMINATION LISTS, just published, show that an unusually large number of pharmacists have been successful at the recent examinations, and that the Pharmaceutical Society's School of Pharmacy numbers the majority of them among its past students and prizemen. Mr. George Senter, a former Bell Scholar (1895) and Pereira Medallist, has taken honours in chemistry and physics at the Intermediate Examination in Science, and four other medallists—Messrs. P. E. F. Perrédès, E. C. Spurge, T. E. Wallis, and Harold Wilson—have passed the same examination in the first division. This record is a distinctly creditable one for the School of Pharmacy, and vouches for the thoroughness of the instruction given in that institution.

THE PHARMACEUTICAL SOCIETY is a body with excellent intentions, observes the *Worcester Herald*, and the public is indebted to it for raising an interesting point at a dull season, but it is suggested that the Society seems to have been actuated by an excess of zeal in the weed-killer case reported last week. "It may or may not be dangerous for florists to sell a weed-killer containing poison enough to kill 20,000 people. So far as we can remember there has not been a great anxiety on the part of suicides or persons with felonious motives to utilise weed-killer. But there was no evidence that Mr. White was actually the seller; in fact, he showed that he studiously kept within the requirements of the law." It is suggested by the scribe whose view of the matter is here quoted, that the Society may be satisfied at having drawn attention to a matter liable to be overlooked, even if nothing more is heard of Sir R. Harington's remarks suggesting an alteration in the law. Another lay journalist, writing in the *Worcester Journal*, expresses the opinion that Mr. White could no more be held an unlicensed seller of poisonous compounds than a brewer's agent or traveller could be held an unlicensed seller of beer. "If he were so held, it would be an absurd straining of the law, because it would saddle the agent with the risk of the principal, and it must logically follow that, like the sale of weed-killer, the sale of poisonous paints and hundreds of other substances, must pass to chemists. It is inconceivable that the Legislature intended chemists to secure a monopoly of trade in everything that contains poison, whether or not that trade implies peril to the public." The same writer also remarks that the Society is apparently seeking to apply provisions for public safety to sales quite outside the original contemplation of Parliament, but that it is not likely the Society will persuade Parliament that such sales ought to be brought within the Act. Such are the impressions produced on some lay minds by the action of a body which endeavours to secure the impartial administration of the law.

ABBREVIATED ADDRESSES ON TELEGRAMS are threatened with non-recognition by the postal authorities, even though the persons for whom the messages are intended are perfectly well known at the local post offices from which the telegrams would be delivered in the ordinary course. A question on the subject was addressed to Mr. Hanbury before Parliament closed, but no satisfactory answer was forthcoming. It appears that firms who have been in the habit of receiving telegrams addressed in an abbreviated form have received an intimation from the postal authorities that messages so addressed in the future will be returned to the senders, as being insufficiently addressed. Failing the registration of abbreviated addresses, the firms in question are advised to request their correspondents to make use in future of a sufficiently full address. Inasmuch, however, as no firm can control the action of every person who might possibly address a telegram to it, such a suggestion seems absurd. At the same time it does not seem reasonable that a telegram addressed to a person or firm whose whereabouts are perfectly well known at the local post-office should not be delivered because the address given is not the full address and not registered at a cost of a guinea a year. Anyone, therefore, who may suffer by the non-delivery of telegrams for the reason given should not fail to worry the Postmaster-General about the matter, and as an extreme measure it might also be well to communicate with Mr. Henniker Heaton.

THE DANGER OF LICKING POSTAGE STAMPS was the subject of much comment in the daily Press some time ago, and the adhesive matter upon the stamps was blamed for causing serious trouble at times. But whilst it is undoubtedly better not to lick postage stamps with the tongue, the gum upon them has now been vindicated against the charges made against it. It has been submitted to the Government laboratory for analysis, and, as the

Daily News expresses the result, it has left that institution "without a stain upon its character, other than the stain of the chemicals employed in testing." It had been alleged that the gum had occasioned septicæmia in a particular case, but Dr. Thorpe, the Principal Government Chemist, reports that "Bacteriological cultivations were made both from the stamp paper and the gum employed as the adhesive material, but no pathogenic organism could be detected in either case." At the same time, as the *Daily News* suggests, one cannot apply similar tests to every thing with which the stamp paper may come in contact. One cannot make bacteriological cultivations from the drawers in old post offices or from the fingers of the counter clerks. So the rule remains a good one that, in stamping all letters and telegrams, one should insist on using the post office damper, which too often is dry, or kept on the wrong side of the counter behind the wire barrier.

The Conference Handbook, published under the title of 'Plymouth Revisited,' was not the least notable of the local committee's successes. The matter was good, the illustrations were beautiful, and the printing and general appearance of the book were beyond criticism. The extreme thoughtfulness of the members of the local committee was shown by the fact that a copy of the book was sent by post, in advance of the meeting at Plymouth, to every person on whose behalf tickets were procured. As a result, it was possible for intending visitors to take full advantage of the information given, whilst undue waste of copies of the book was prevented. A limited number of copies still remains in the hands of the hon. local secretary—Mr. J. Davy Turney, 15, Leigham Terrace, Plymouth—and we are requested to state that those will be sent free to persons interested on application. A stamped addressed envelope, measuring not less than 9 in. by 6 in., should be sent with each application.

Some Facts and Figures Concerning Petroleum, which appear in the report, dealing with the last municipal year, by Mr. Alfred Spencer, chief officer of the London County Council's Public Control Department, are well worthy of attention. Of 304 petroleum lamp accidents which occurred during the year, 28 had fatal results, and the remaining 276 caused the turning-out of fire brigades. From July, 1890, to the end of March last—nearly nine years—there has been a total number of 1,852 accidents, with a death-roll of 253. Mr. Spencer is in favour of raising the flash-point of petroleum oil to 105°, and in his report he expresses himself as convinced that the price of oil to the consumer would not be increased by raising the flash-point. He points out that during the past year the importation of Russian oil into this country has nearly doubled; that nearly the whole of the increased quantity had a flash-point of 100°, and that this oil was procurable by consumers at as low a price as low-flash oil. It is noteworthy, by the way, that whilst no less than 333,000,000 gallons of petroleum came into the Port of London during the six years 1890–95, only 17,000,000 gallons, or five per cent., was subject to the restrictions imposed by the Petroleum Acts.

Ice Creams and Micro-organisms are now closely-associated ideas in the public mind, but it has probably never occurred to anyone that the higher-class ice creams could possibly be more dangerous to health than the street varieties. Such, however, seems to be the case, Dr. Reginald Dudfield, medical officer of health for Paddington, having reported to the local vestry that a bacteriological examination of ice cream sold by street vendors and in shops demonstrates that the compound sold by the street vendors, being made by boiling the ingredients previous to freezing, contains, as a rule, fewer micro-organisms than that sold by the better-class manufacturers, who make their cream ices from cream and fruit, not from custard. But he also insists that the premises occupied by the street vendors require supervision to ensure that the ices are not exposed to exhalations from drains, etc.

The Tonic Properties of Sea Air have been the subject of considerable speculation from time to time, and the *Lancet* has made a further attempt to explain the causes of the invigorating and tonic properties of a sea-breeze. Ozone is very commonly accepted as an important factor in this connection, since it is invariably present in air that has been in contact with sea-water, and especially agitated sea-water, and to a smaller extent in the air of the country, whilst it rarely occurs in the air of towns and crowded places. Both ozone and hydrogen peroxide are also probably formed by air skimming over the surface of fresh water, and hence the breezes coming over the lochs in Scotland and large lakes and rivers in other places become ozonised and bracing like those from the sea. The exhilarating effect of a sea-breeze may, however, be ascribed to other bodies which are foreign to inland air. Thus sea air contains a traceable amount of salt and iodides, attaining a maximum of 0·022 gramme per litre, or about one and a-half grains per gallon. Those mineral ingredients derived from the sea doubtless accentuate the tonic action of sea air, and further it is probable that ozone interacting with chlorides and iodides would lead to traces of chlorine and iodine being present. It is pointed out, in conclusion, that many persons describe the smell of strong sea air as iodous or chlorous, and it has even been said that the starch used in face-powders turns blue at the seaside on account of the iodine in the air forming blue iodide of starch. "If that be so the blue and haggard appearance characteristic of many faces exposed to a strongly salt-impregnated breeze would find an interesting, but perhaps embarrassing, explanation."

The Pending Organisation of Secondary Education by the Government has induced Professor Meldola to write to the *Times* respecting the danger—which he conceives to exist—of the inadequate representation of science and of scientific interests among those in authority. The conflict between the old classical pedagogue and the science teacher representing the "modern" side of our public and secondary schools is, he points out, a very ancient and well-known antagonism. "Time, or in other words, the advancement of science, has helped to break down this antagonism to a considerable extent, to the advantage of both parties. The scientific man who refuses to admit the humanising influence of classical subjects is as narrow in his views as the classical headmaster, who looks upon the modern side of his school as a refuge for inferior beings." But, it is urged, if, while conceding that the classical and humanitarian interests should be allowed their proper place in any scheme of secondary education, it is not, at the present crisis, insisted that the scientific interests shall be strongly and as efficiently represented, no progress will be made, in spite of the well-meaning efforts of those in authority, who have the higher education problem now before them. What this actually means is, apparently, that the officials of the Science and Art Department are not to have everything their own way in the proposed scheme, as it is suggested that if, in dealing with this problem at the present time, the Government does not avail itself to the fullest extent of the experience in the teaching of science which has been acquired by the officials of one of its own departments as the result of vast expenditure and of long years of labour carried on all over the country, "we may again awake with the painful experience of finding science pushed into the background in a code of education which, if not made more thoroughly scientific than it has hitherto been, will fail in its objects and will cause bitter disappointment to all those who have been anxiously waiting for the present opportunity of seeing much-needed reforms made possible." But it may be questioned whether it will be generally agreed by educational experts that "the officers of that department which has had the largest practical experience in this direction are those to whom the country must at the present time look for assistance." The direction of the science teaching in secondary schools may, of course, fall into the wrong hands, but it will not necessarily escape that fate if the arrangements are made at South Kensington.

NOTICES OF BOOKS AND OTHER PUBLICATIONS.

The 'Dictionary of Terms Used in Medicine and the Collateral Sciences,' compiled by the late R. D. Hoblyn, has now reached its thirteenth edition (London: Whittaker and Co. Pp. 838. Price 10s. 6d. net). Like the preceding edition, this has been revised throughout by J. A. P. Price, B.A., M.D. (Oxon.), and the numerous additions made are accountable for sixteen extra pages. For more than twenty years the book has been the most useful of its kind published, and the new words and phrases added, particularly those relating to bacteriology, will help it to maintain that position for some time to come.

'Essentials of Pharmacy for Minor Students,' by W. A. Knight, and edited by Henry Wootton, B.Sc. (London: London College of Chemistry and Pharmacy. Pp. 189. Price 4s. net), is admittedly a work produced for examination purposes, but it does not possess the chief faults of its class, and is something more than a mere cram-book. The book is, of course, a compilation, based on the standard works of Caspari and others, but is free from any great mass of detail. In fact, to quote the preface, "attention has been given more to the leading principles underlying the varied operations rather than to a detailed description of the apparatus employed." Part 1 deals with general pharmacy, and treats of the collection of drugs, operations requiring the use of heat, the disintegration of solid substances, solution, etc., etc. The various operations are described as briefly as is consistent with accuracy, and illustrations are given where they can help to elucidate the text. Official pharmacy is the subject of Part 2, the solvents of the Pharmacopœia being first considered, then the different groups of galenical preparations in order—aceta, acida diluta, aquæ, etc The notes published in this section of the book should prove particularly useful to students. The rest of the book is occupied by lists and tables of various kinds and notes on official assay processes. As an aid to the study of the British Pharmacopœia, the work must prove of considerable value.

That the 'Manual of Pharmaceutical Testing,' by Barnard S. Proctor (London: Offices of the *Chemist and Druggist*. Pp. 192. Price 2s. 6d. net), supplies a want in the world of pharmacy may be inferred from the fact that it has now attained to the dignity of a second edition. The idea underlying its production is that registered chemists and their assistants, whilst usually too much occupied in other ways to undertake exhaustive analyses of the chemicals, etc., kept in stock in the pharmacy, should roughly test those substances occasionally, and so satisfy themselves that they are up to the required standard. The tests given are the simplest and most inexpensive that can be devised, and are intended to show only whether the article under examination is fit for use, without indicating the extent of deviation from standard, when such deviation exists. The materials and appliances to be used are limited to such as are in common use at the dispensing counter. The book is not quite free from errors or misleading instructions, and it is questionable whether such rough-and-ready methods as are described should be resorted to by the trained pharmacist, but, such as it is, the book is as well done as anything else the author has ever set his hand to.

'The Botanic Brewer's Guide' (London: Potter and Clarke. Pp. 36) embodies a collection of recipes for the production of a large variety of temperance drinks, together with notes on the precautions to be taken in brewing, and instructions how to comply with the Excise regulations. Notes on the herbs and other materials used in the manufacture of botanic beverages, and extracts from various Acts of Parliament, give completeness to the work, which appears well-adapted for its intended purpose.

THE SALE OF FOOD AND DRUGS ACT, 1899.

For the information of chemists and druggists the new Sale of Food and Drugs Act, which comes into operation on January 1, 1900, is here presented in brief:—

1. *Imports of insufficiently-marked food produce.*—This section affords precautions against the importation of adulterated food products, by making the importer describe fully the nature of the goods he is introducing. The Commissioners of Customs are empowered to take samples, and to send a prescribed portion to the principal chemist of the Government Laboratories, whose certificate thereon will be legal and sufficient evidence of the facts stated in it. The penalty under this section is £20 for a first offence, £50 for the second, and £100 for any subsequent offence; and it is specifically declared that the word "importer" shall include any owner, consignor, consignee, agent, or broker who may be in possession of or have custody or control of any article which infringes the section. Drugs are not included in the operation of the section, and the employment of preservatives or colouring matter, innocuous as to quantity as well as to quality, does not constitute legal adulteration.

2. *Power to take samples of food.*—The Local Government Board, on behalf of the general public, and the Board of Agriculture, in the interest of Agriculture, are empowered by this clause to procure samples, by means of their own officers, as if such officers were authorised to procure samples under the Sale of Food and Drugs Act, 1875. The local authority of the place where any sample is taken by officers of the Boards must pay the analyst's fee, and must, if the analysis disclose an offence against the Act, cause proceedings to be taken.

3. *Power of Public Department to act in default of local authority.*—(*a*) It shall be the duty of every local authority en- and drugs, to appoint a public analyst, and put in force from time trusted with the execution of the laws relating to the sale of food to time, as occasion may arise, the powers with which they are invested, so as to provide proper securities for the sale of food and drugs in a pure and genuine condition, and in particular to direct their officers to take samples for analysis.

(*b*) If the Local Government Board or Board of Agriculture, after communication with a local authority, are of opinion that the local authority have failed to execute or enforce any of the provisions of the Sale of Food and Drugs Act in relation to any article of food and that their failure affects the general interest of the consumer or the general interests of agriculture in the United Kingdom, as the case may be, the Board concerned may, by order, empower an officer of the Board to execute and enforce those provisions or to procure the execution and enforcement thereof in relation to any article of food mentioned in the order.

(*c*) The expenses incurred by the Board or their officer under any such order shall be treated as expenses incurred by the local authority in the execution of the said Acts, and shall be paid by the local authority to the Board on demand, and in default the Board may recover the amount of the expenses with costs from the local authority.

(*d*) Makes an order of the Board conclusive as to the matter therein stated or appearing.

(*e*) Any public analyst appointed under the Sale of Food and Drugs Act shall furnish such proof of competency as may from time to time be required by regulation framed by the Local Government Board.

4. *Power of Board of Agriculture to determine what is normal milk, etc.*—These provisions are wholly applicable to dairy produce, but are novel and interesting, inasmuch as they place upon a Government Department the duty of fixing a standard of purity.

5. *Margarine cheese.*—This clause extends the Margarine Act, 1887, to the article named.

6. *Marking of margarine, etc.*—Prescribes the manner and the style of marking, as well as the size of the lettering.

7. *Regulation of manufacturers of margarine.*—Imposes upon manufacturers and wholesale dealers of the substances under this head the duty of keeping a register of sales and consignees.

8. *Mixtures of margarine and butter.*—Prohibits the manufacture, sale, or exposure for sale of margarine containing more than ten per cent. of butter fat.

9, 10, 11 refer solely to milk.

12. *Mixtures.*—The label referred to in section 8 of the Sale of Food and Drugs Act, 1875 (see Calendar, p. 210), shall not be deemed to be distinctly and legibly written or printed within the meaning of that section unless it is so written or printed that the notice of mixture given by the label is not obscured by other matter on the label; provided that nothing in this enactment shall hinder or affect the use of any registered trade mark, or of any label which has been continuously in use for at least seven years before the commencement of this Act; but the Comptroller-General of Patents, Designs, and Trade Marks shall not register any trade mark purporting to describe a mixture unless it complies with the requirements of this enactment.

13. *Amendment of* 1875 *Act as to samples.*—In the original Statute the person purchasing a sample was required to "offer to" divide the same. The words quoted have now been repealed.

14. *Taking samples in transit.*—Extension of sections 3 and 4 of the Act of 1879 respecting milk (Calendar, p. 217) to all articles of food.

15 amends the 1875 Act, section 16, by substituting "Registered parcel" for "registered letter."

16. *Obstruction of officers.*—Any person who wilfully obstructs or impedes any inspector or other officer in the course of his duties under the Sale of Food and Drugs Acts, or by any gratuity, bribe, promise, or other inducement prevents or attempts to prevent the due execution by such inspector or officer of his duty under those Acts shall be liable, on summary conviction, for the first offence to a maximum fine of £20, with increases to £50 and £100 for a second and subsequent offence.

17. *Scale of penalties.*—Establishes £50 and £100 as the respective maxima for second and third offences in all breaches of the Food and Drugs Acts carrying a first fine of £20. There is also provision in this clause for imposing a term of imprisonment not exceeding three months, with or without hard labour, on the habitual offender if the Court considers that fines will not adequately meet the circumstances of the case.

18. *Sale of tinned and similar articles.*—Notwithstanding anything in section 17 of the Statute, 1875 (that is to say, the portion dealing with refusal to sell to an inspector), where an article of food or drug is exposed for sale in an unopened tin or packet duly labelled, no person shall be required to sell it except in the unopened tin or packet in which it is contained.

19. *Limitation as to proceedings.*—When any article of food or drug has been purchased for test purposes, any prosecution based thereon must be instituted within twenty-eight days from the time of purchase. Section 20 of the original statute is therefore modified to that extent. In any prosecution under the Acts the summons must give particulars of (*a*) the offence and (*b*) the name of prosecutor, and must be accompanied by a copy of the analyst's certificate. The summons must not be returnable in less time than fourteen days from the time of service.

20. *Warranty or invoice.*—(*a*) A warranty or invoice shall not be available as a defence to any summons unless the defendant has, within seven days of service, sent to the purchaser a copy of the warranty or invoice with a written intimation that he will rely thereon for his defence. He must also specify on his intimation the name and address of the warrantor, to whom notice of the defence must also be sent.

(*b*) The person by whom such warranty or invoice is alleged to have been given shall be entitled to appear at the hearing and to give evidence, and the Court may adjourn the hearing to enable him to do so.

(*c*) Warranties from sources outside the United Kingdom shall not be available for defence unless the defendant proves that he had taken reasonable steps to ascertain, and did in fact believe in, the accuracy of the statements contained therein.

(*d*) Where a defendant is a servant of the person who purchased under warranty or invoice he shall be entitled to rely on section 25 of the Statute, 1875 (*i.e.*, the warranty clause), in the same way as his employer would have been entitled to do; but the servant must prove that he had no reason to believe that the article sold was otherwise than that demanded.

(*e*) Where the defendant has successfully defended on a warranty, any proceedings against the warrantor may be taken either before a Court having jurisdiction in the place where the article was purchased for analysis, or in a Court having jurisdiction in the place where the warranty was given.

(*f*) Every person who in respect of an article of food or drug sold by him as principal or agent gives a false warranty in writing shall be liable on summary conviction to the penalties before mentioned (viz., £20, £50, or £100) unless he satisfies the Court that when he gave the warranty he had reason to believe in the accuracy of the statements or descriptions therein contained.

21. *Reference to Inland Revenue Commissioners.*—The justices or Court referred to in the Statute, 1875, sec. 22, *shall*, if requested by the parties concerned, and *may*, without any request at all, send a food or drug to the Commissioners for analysis.

22. *Certificates of analysis.*—The production by the defendant of a certificate of analysis by a public analyst in the form prescribed by the Statute, 1875, sec. 18 (Calendar, p. 216), shall be sufficient evidence of the facts therein stated, unless the prosecutor requires the analyst to be called as a witness. The prosecutor must be furnished with a copy of the certificate three days before the hearing, or the Court may adjourn the hearing in consequence.

23. *Application to Scotland.*—Transfers all powers to Local Government Board for Scotland.

24. *Application to Ireland.*—Transfers all powers to the Department of Agriculture and Technical Instruction for Ireland.

25. *Definitions.*—"Local authority" means any local authority authorised to appoint an analyst for the purposes of the Food and Drugs Act, and "public analyst" means any analyst so appointed. All other expressions have the meanings contemplated by the foregoing Acts, with which this Act is to be construed.

26. *Definition of food.*—"Food" includes all articles used for human food or drink, other than water or drugs, and any article ordinarily entering into or used in the composition or preparation of food, and also flavouring matters and condiments.

27. *Repeal of Enactments.*—So far as the Food and Drugs Acts are concerned the following are the only deletions:—

1875 Act, sec. 2.—The definition of "food."
1875 Act, sec. 14.—The words "offer to" and "proceed accordingly and shall."
1875 Act, sec. 15.—Whole section.
1875 Act, sec. 27.—From "every person who shall give a false warranty in writing" to a "penalty not exceeding, etc."
1879 Act, sec. 10.—Whole section.

28. *Short Title* is "Sale of Food and Drugs Act, 1899."

29. *Commencement.*—January 1, 1900.

Endomentol.—Under the fanciful name of endomentol, nicotine salicylate is recommended by Volters as a specific for scabies in the form of a 0·1 per cent. ointment with vaseline or lanoline as a base. It occurs in colourless transparent crystals, with a slight empyreumatic odour. The crystals are soluble in water and other solvents, and melt at 118° C.—*Pharm. Post*, **32**, 286, after *Münch. Med. Woch.*

HORTICULTURAL RECIPES.*

Grafting Wax.—(1) Beeswax, 75; purified resin, 125; turpentine, 36; rape oil, 12; Venice turpentine, 25; zinc white, 25. Colour yellow with turmerie. (2) Japan Wax—100, yellow wax, 300; resin, 800; turpentine, 400; hard paraffin, 100; suet, 300; Venice turpentine, 600.

Fluid Grafting Wax.—(1) Resin, 1,250; pitch, 200; linseed oil, 120; turpentine, 50; yellow wax, 130. Melt with a gentle heat, stir continually until cold, and then add methylated spirit, 400 fluid parts. (2) Burgundy pitch, 500, is melted slowly, removed from the fire and mixed with alcohol, 70 to 80. Put up in wide-necked glass bottles, or in tins. (3) Turpentine, resin, 1; methylated spirit, 4.

Manure for Indoor Plants.—(1) Sodium chloride, 10; potassium nitrate, 5; magnesium sulphate, 5; magnesia, 1; sodium phosphate, 2; mixed and bottled. Dissolve a teaspoonful daily in a litre of water and water the plants with the solution. (2) Ammonium nitrate, 40; potassium nitrate, 90; ammonium phosphate, 50. Two Gm. is sufficient for a medium-sized flower-pot. (3) Ammonium sulphate, 10; sodium chloride, 10; potassium nitrate, 5; magnesium sulphate, 5; magnesium carbonate, 1; sodium phosphate, 20. A teaspoonful to 1 litre of water. (4) Ammonium nitrate, 40; ammonium phosphate, 20; potassium nitrate, 25; ammonium chloride, 5; calcium sulphate, 6; ferrous sulphate, 4. Dissolve 2 Gm. in a litre of water and water the plants with the solution. (5) Potassium nitrate, 20; potassium phosphate, 25; ammonium sulphate, 10; and ammonium nitrate, 35. This mixture produces a luxuriant foliage. If blooms are desired, dispense with the ammonium nitrate.

To Destroy American Blight and Other Plant Lice.—The use of carbon disulphide is recommended; the affected places being daubed with a rag tied to the end of a long stick. The application must be repeated every eight days. A simple method is to sprinkle the affected parts with diluted petroleum. No ill effects have, so far, been noticed from this treatment. A dilution of 1 litre of petroleum to 4 to 5 litres of water may be used as long as it is continually shaken up. The process of extinction can only be considered complete when every trace of the bluish-white web in which the insects are enveloped has been destroyed. Autumn is the best season for waging the campaign when the trees are bare; later, in spring, the bluish white web disappears, and the pests are then scarcely discernible. It is useless to attempt their destruction unless it can be done thoroughly, as the smallest remnant left multiplies to an alarming extent.

Destruction of Phylloxera.—Bordeaux mixture is rapidly prepared as follows. Water, 90 litres, is put into a wooden or earthenware vessel, and copper sulphate, 2 kilos., dissolved in it. 700 Gm. to 1 kilo. of freshly slaked lime is mixed carefully with 10 litres of water. This is gradually added with continual agitation to the copper solution; a turbid blue mixture results which becomes clear on standing. If still blue more milk of lime should be added until the solution is quite colourless. Sprinkle the vine with this solution. The solution destroys the phylloxera but has no lasting effect, so that the application must be repeated several times during the summer.

Shield Louse Wash.—(1) Calcium sulphide wash is prepared with unslaked lime, 18 kilos.; sulphur, 9 kilos.; salt, 6·75 kilos.; mixed as follows:—A fourth part of the lime is slaked and boiled for 2-3 hours with the sulphur in 22·6 litres of water. The remainder of the lime is then slaked and added with the salt to the hot mixture. The whole is boiled for another half hour or and hour, and then diluted to 353 litres. The fluid is applied luke warm when the plants are not in active growth. (2) Sodium sulphide solution consisting of sulphur, 900 Gm; caustic soda, 675 Gm. (or concentrated ammonia solution); and train oil soap, 7·5 kilos. The sulphur and the alkali are boiled in water for one hour, the soap is dissolved in 45·4 litres of boiling water. The solutions are mixed, boiled for half an hour, and diluted to 227 litres of water. Apply while warm. (3) Saponified resin solution, consisting of resin, 9 kilos.; caustic soda, 2·25 kilos.; or concentrated ammonia, 2·25 kilos.; or calcined 93 per cent. soda, 1·575 kilos.; fish or train oil, 1·4 litre. All three substances are put into a kettle, covered with 3 to 4 inches of water, and boiled from 1 to 2 hours. The mixture is then diluted with water to resemble strong black coffee. This fluid is diluted with water to 450 litres. *Petroleum.*—Undiluted petroleum may be used in frosty weather when the insects are not fully developed. The petroleum is painted on with a brush. Delicate plum or greengage trees, however, will not stand such an application. Pruning is recommended for these.

Petroleum Emulsion.—Train oil soap, 2·25 kilos, is dissolved in 45·4 litres of boiling water, petroleum, 2·25 litres, is added, and the mixture diluted to 227 litres with hot water. Wash or spray with the lukewarm solution.

Krueger's Petroleum Emulsion.—Black soap, 250 Gm., is dissolved by boiling in 4·5 litres of water, and petroleum, 9 litres, is added when the soap solution is removed from the fire. The fluid is then agitated well for 10 to 15 minutes.

Nessler's Remedies for American Blight.—(1) Soft soap, 40 Gm.; amyl alcohol, 50 Gm.; methylated spirit, 20 Gm.; water, 1 litre. (2) Soft soap, 30 Gm.; sulphurated potash, 2 Gm.; amyl alcohol, 32 Gm., to water, 1 litre. (3) Soft soap, 15 Gm.; sulphurated potash, 29 Gm., to 1 litre of water.

Destruction of Thrips.—Insect powder dusted on the plants answers admirably. (2) A decoction of tobacco stalks 500, to a pailful of water, sprayed over the beds. (3) Decoction of wormwood and dusting with a mixture of guano, gypsum and wood ashes.

Destruction of Slugs and Snails.—Strew plentifully with powdered lime in dry weather and repeat in half an hour.

Destruction of Moles.—(1) Place pieces of fresh raw meat, poisoned with arsenic powder, 1:15 or 1:20, into the hole immediately underneath every heap of earth thrown up by the mole, and cover again carefully without disturbing the passages excavated by the animal. The scent of the bait lures the moles to sure destruction. (2) Insert branches of elder into the mole runs; this is sure to drive them away. (3) A few bulbs of garlic steeped in petroleum have the same effect. (4) Hedgehogs are said to drive away moles.

Destruction of Mice.—(1) Soak wheat thoroughly in an infusion of fresh squill bulbs, 1:5, and dry quickly; this wheat is only poisonous to rats and mice, and an excellent vermin-killer if the infusion is carefully prepared. (2) A mixture of lard, 500; salicylic acid, 5; one onion; suet, 50-100; barium carbonate, 500; solution of ammonio-acetate of copper, or of verdigris, 50. The onion is cut up fine and fried with the fats until dark brown. The salicylic acid is then added and the mixture strained and stirred until the fat nearly sets. The barium is next added, and, finally, the copper solution.

Destruction of Rats.—(1) Precipitated barium carbonate, 100 Gm., and tartar emetic, 1 Gm., are mixed with baked flour and glycerin in 2 Gm. into boluses, which are fried brown in hot fat. (2) Gypsum, 2; oatmeal, 750; flavoured with anise oil. (3) Plaster of Paris and sugar, equal parts. The mixture is spread on a plate, and exposed near a vessel of water. (4) Crushed bitter almonds, 60; lard; fresh squill bulbs, equal parts. (5) Powdered almonds mixed with arsenic answer well.

Rat Cakes.—A bulb of squill is cut into thin slices, dried and mixed with sugar, flour, and a little salicylic acid. Make into cakes with glycerin and water, moisten the cakes before use, dust over with sugar, and expose them by the side of water.

Moth and Caterpillar Lime.—Venice turpentine, 200; resin, 1,000; turpentine, 140; tar, 80; lard, 500; rape oil, 240; tallow, 200. (2) Resin, 50; lard, 40; stearine oil, 40. (3) Resin, 3; rape oil, 4; lard, 2; soft soap, 1; wood tar, 10. (4) Resin, 36; rape oil, 36; Venice turpentine, 20; wood tar, 5; turpentine, 3 parts. Paint the mixture while warm on strips of paper laid smoothly on the tree-trunk about a yard above the ground. This should be done at the end of October, or the beginning of November, to prevent the females of the winter moth from climbing up the trees. (5) Instead of above mixture, cart grease may be used. (6) Mix melted resin with crude rape oil to form a mass of sticky consistence.

* From the *Pharmaceutische Zeitung.*

HYDROGEN PEROXIDE AS A MOUTHWASH.—F. Touchard states that hydrogen peroxide is one of the best agents for buccal disinfection and gargling, since it is not only perfectly harmless if swallowed, but even in dilute solution is a very active bactericide. A teaspoonful in a glass of tepid water should be used to rinse the mouth as a gargle, night and morning.—*Bull. Gen. de Therap.*, **137**, 401.

EXTRACTS FROM CONSULAR REPORTS.

Manufacturers of Artificial Indigo in Holland will have to invent new and improved processes, otherwise, at present prices, there is not much prospect of their competing successfully with natural indigo, the cost of producing the artificial product being greater than that of the natural product. The current prices per unit are 0·950d. for the artificial and 0·600d. for the natural indigo. Last year the imports of indigo into Amsterdam were considerably larger than the previous year, amounting in all to 9,595 chests, of which 5,659 chests were from Java, and the prices already greatly depressed suffered a further considerable reduction. The depression was, in Consul Robinson's opinion, no doubt partly due to fear of the artificial product, but, as intimated above, this fear is at present groundless. So discouraging is the prospect that the erection of a second manufactory in Amsterdam, which was contemplated, has not been carried out.

The Prices of Indigo at Hamburg, according to Consul-General Ward, also experienced a gradual decline in 1898, while apace with this decline the consumption increased, so that the large stocks were much reduced. Although the quantities of indigo in the market were thus brought down to their normal figure at the close of last year, and dealers as well as consumers held exceptionally small stocks, quotations for this article in December were lower than ever before known. The opinion is said to be rapidly gaining ground that indigo is not merely a very cheap article, but also well able to compete with the prices of all other dyes substituted for it. The unfavourable effects of three over-abundant crops (1894, 1895 and 1896) having thus been overcome, the prospects of a crop of average quantity and excellent quality render it likely that under these conditions business in indigo this year will develop in a normal, healthy manner.

Now is the Time for pioneers of British trade in Russia, so Vice-Consul Wardrop reports from Kertch. His remarks last year on openings for British trade, he says, still hold good, but nothing will be done until capable commercial travellers, acquainted with the country and the language are sent out. Educated men of the world, it is stated, are nowhere more likely to secure contracts and orders than in Russia. The language is not more difficult of acquisition than other languages, if it be learned on the spot. A man of average linguistic ability, Vice-Consul Wardrop states, should pick up in six months quite enough to make him a valuable travelling agent, or to enable him to start a business on his own account. Kertch, it is reported, is almost certain to grow rapidly in importance, and among the ports on the Northern shore of the Black Sea its prospects are said to be second only to those of Odessa.

Another View of the Situation, however, is taken by Acting Vice-Consul Gabriele, who reports from Berdiansk as follows:—"It is with much regret no opening for British goods can be suggested, although business is undoubtedly done by German travellers in several branches, and enquiries made at various shops confirm this, the principal advantage to the shopkeepers being that these travellers invariably speak Russian, and submit samples of goods duty free." This, although at first glance apparently directly contrary to the opinion expressed by Vice-Consul Wardrop, bears out his view that the chief obstacle to British trade in Russia is the want of capable travellers.

The Importations of Beeswax to Hamburg in 1898 exceeded those of the preceding year by about 30 per cent., and amounted to 1,262,300 kilos., the chief supplies being sent from South America, Morocco, Zanzibar, and the West Indies. Prices remained at the same figure as in 1897, and only a comparatively small stock of wax remained on hand at the end of last December. Of Japanese wax, about 420,000 kilos. were imported, as against 480,000 kilos. in 1897, the considerable fluctuations in the price of these sorts being stated to have greatly interfered with business.

The Chemical Industry, Consul-General Sir Charles Oppenheimer, reporting on the trade of Frankfort-on-Main for the year 1898, remarks, can look back upon a satisfactory year, though complaints are heard that in future some lucrative patents will lapse, and the competition of such States as Switzerland and the Netherlands, who do not recognise the protection by patents, prove injurious.

LETTERS TO THE EDITOR.

The Sale of Benzene, etc.

Sir,—As to the sale of "benzine" and the labelling thereof, we know what is meant by "highly inflammable," but with respect to a caution label, we might surely be as terse as possible. Our object is not to frighten but to inform the public, and the word "highly" may accomplish the former, but is sadly lame for the latter purpose, the adverb "highly" = in or at a high degree, and when I have to tell my clients that the words mean that "benzine" is in a high degree inflammable at a very low degree, they are disposed to think that the "merry chemist" is hoodwinking them nicely. To avoid all ambiguity I shall therefore in future use the adverb "very" *loco* "highly," and say, "N.B.," "very inflammable," until, that is, there comes a time perhaps when some Act is passed or authority promulgated by school board or consular authority to compel me to put my mother tongue upon stilts and so go hobbling along therewith, as the fashion is with the *anti*-Antediluvians so much in vogue to do.

J. C. Hyslop.

Marylebone, N.W., August 16, 1899.

Marching Backwards.

Sir,—The condition of pharmacy, on which at the present time thoughts are passing in many reflective minds, shows vast change from the palmy days of twenty-five years ago. The chemist of to-day is confronted with difficulties undreamt of by his predecessors. There seems little chance of these difficulties solving, or even partially solving, themselves in course of time. And, doubtless, the tendency of present-day trading, the move in the direction of amalgamation, the bringing of the consumer and manufacturer in closer contact, with the inevitable displacement of the middleman and small shopkeeper, are natural corollaries to economic development. It needs little logic to account for the difference in the price of goods bought from a company having a hundred shops and those obtained from a one-shop trader. It seems almost hopeless to expect the chemist in a small way of business to compete successfully with the powerful and rich drug companies. Of course, there will always be the personal element to consider. The tendency of the public trends to obtaining from the companies the patents, sundries, and household requisites they may require and going to the old-established man for anything in which personality plays a part. Then the question arises: Is it possible, after such an important section of his business has been annexed, to make an income compatible with his scientific attainments? Chemists have been blamed for not fighting the companies more vigorously. How is it possible at the present time to successfully compete with the companies? We may look upon the patent trade as hopeless; the sundries trade is fast following suit. The British public, small blame to them, buy their goods in the cheapest market. Quite true, the P.A.T.A., little credit to them, have endeavoured to regulate the price of quack concoctions. How, keeping up the price of a few obsolete nostrums is to benefit the other sections of our business 'tis not for mortal man (outside the ranks of the Association) to explain. Some pharmacists have boldly lowered their prices all along the line to the drug company level. If all chemists lowered their prices to the drug company level? A pharmacist nowadays must have double or treble the turnover he had in the palmy days of yore. And it is a moot point if the public patronise the chemist as liberally as they used to. We find drapery emporiums and stationers' shops choked with goods formerly almost exclusively dealt in by the chemist. The drug department pure and simple we know is only patronised when necessity compels. It is a debatable point if people drug themselves as of old. The present-day doctor appears to order physic in homœopathic doses and advice *ad lib.* Surely a sensible procedure. So the chemist is confronted with diminishing trade, constant fluctuating prices, and, in some instances, rising rents. Oh! happy man? That this is a true picture there can be no question. In Manchester, where a certain company is omnipotent, there is a sorry tale to tell. The closing of historic pharmacies and the triumph of a tentaculiferous outsider. It would hardly be an exaggeration to say that the trade in this particular cathedral city is in danger of being almost entirely monopolised by one firm. Much has been written and spoken these last few months of the condition of our calling. I think it is hopeless to expect any assistance from Parliament. The drug companies, to a lay mind, appear to be a neces-

sity, hence their existence. Any tinkering with titles will only be a trifling distinction between light and shade. It would be midsummer madness to expect it to turn the tide of trade back to the chemist. In my opinion, there is but one thing to be done. The Pharmaceutical Society in so far they control the examinations have in their hands a powerful weapon. They practically control the supply of qualified men. Let the standard of examination be continually raised, let there be a very real dearth of qualified assistants, then the wage bill of the companies will assume proportions that tend to level the advantage they possess over their one-shop rivals. And if the coming century is to be remarkable for great trading corporations, at least the men that work for those corporations will be adequately remunerated.

August 12, 1899. Succus Nastur (198/25).

A Disclaimer.

Sir,—In your issue of July 29, page 112e, under the heading of "Boots, a Book, and a Coroner," you say "witness had given her certain Children's Cooling Powders," and lower down there is a reference to a book which she obtained along with the powders. The certain "Children's Cooling Powders" were those of Alfred Fennings, and the book was also written by Alfred Fennings, who appears on the Register as a chemist and druggist. From the report, as it appears in your Journal, it would seem that the book was one prepared by our firm. This is not so, and we should thank you to give this letter publicity to counteract that impression.

For Jesse Boot.
(E. R. S.)

Nottingham, July 31, 1899.

*** The report referred to was copied from a press cutting taken from the *Derby Advertiser* of July 22, and nothing appeared in the original to indicate that the powders were prepared by Alfred Fennings, or that the book was issued by him. [Ed. *P. J.*]

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Stavesacre Ointment (J. B. B.—32/22).—No: stavesacre seeds and oil are not scheduled as poisons under the Pharmacy Act.

Botanical (E. J. I.—32/25).—(*a*) *Euphorbia peplus*; (*b*) *Epilobium montanum.*

Botanical (F. P. K.—32/24).—(1) *Hypericum androsæmum*; (2) *Eupatorium cannabinum*: (3) *Epilobium hirsutum*; (4) *Erythræa centaurium*; (5) *Hypericum perforatum.*

Preparation of Tannic Acid (A. N.—32/29).—Water-saturated ether is used to dissolve the tannic acid, as it is only sparingly soluble in pure ether.

Condenser (G. C.—32/27).—The condenser described by Mr. Lucas is made in glass by Messrs. Müller and Co., High Holborn, London, W.C. The price of the apparatus is 4s. 6d.

Damson Wine (J. G.—32/21).—Bruise damsons, 8 lbs., and pour upon them 1 gallon of boiling water. Let stand for 48 hours, then strain into a cask and add 3½ or 4 lbs. of sugar. Let it stand in a warm place until fermentation ceases, then add 4 ounces of brandy, and bung the cask up tight. Keep in a cool cellar for 8 months; bottle it off and keep for at least another four months before using.

Stamped Medicines (G. A.—32/31).—It is understood that the Commissioners of Inland Revenue do not object to duly stamped packages of dutiable medicines being broken and the contents retailed singly, without payment of further duty, provided the powders, etc., when handed to the purchaser are merely wrapped in paper and not enclosed in a packet fastened by string, gum, etc. The retailer, of course, must be a duly licensed vendor.

Botanical (A. A.—32/14).—(1) *Euphorbia peplus*; (2) *Polygonum convolvulus*; (3) *Capsella bursa-pastoris*; (4) *Lapsana communis*; (5) *Centaurea nigra*; (6) *Spergula arvensis*; (7) *Equisetum arvense*; (8) Same as No. 3; (9) *Chenopodium album*; (10) *Odontites rubra*; (11) Send better specimen; (12) *Mentha sativa*; (13) *Heracleum sphondylium*; (14) Send better specimen; (15) *Achillea millefolium*; (16) Same as No. 9; (17) *Fumaria officinalis*; (18) *Vicia cracca.* Though all your specimens are named, as far as possible, please do not send more than six at once in future. You would also do well to attempt to identify such common specimens yourself by the aid of a Flora.

Formaldehyde in Milk (J. B. B.—32/23).—Various processes have been recommended, but Trillat's reaction affords conclusive evidence of the presence of formaldehyde. Add to the solution (in the case of milk—a distillate) 0·5 C.c. of dimethylaniline, acidified with a few drops of sulphuric acid, and, after shaking, heat on a water-bath for half-an-hour. The solution is then alkalised and boiled until the smell of dimethylaniline has disappeared, after which the liquid is filtered through a small filter. The filter is subsequently washed a few times with water, then opened, spread on the bottom of a porcelain dish, and moistened with acetic acid. Finely powdered lead peroxide is then added, and, if formaldehyde be present, an intense blue colour appears.

Loss of Hair (F. R. C.—32/20).—We should not consider your cold bath to be the cause of the loss of your hair. Probably this arises from some constitutional debility, for which you should consult a medical practitioner. The following is a good hair tonic:—Tincture of cantharides, 10; tincture of jaborandi, 20; spirit of camphor, 20; solution of ammonia, 5; diluted alcohol to 100 fluid parts. Apply once daily with light friction. A solution of hydrochloric acid (1·5 per cent.) in dilute alcohol is also useful in some cases. An oily application which frequently gives good results may be prepared with quinine hydrochloride, 1; tincture of jaborandi, 10; oil of rosemary, 1; castor oil, 40; alcohol, (90 per cent.), q.s. to produce 100 fluid parts.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal' Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

Articles and Reports sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

Correspondents should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

Drawings for Illustrations should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

Names and Formulæ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

Reprints of Articles cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Adams, Allen, Alcock, Attree, Barker, Beech, Birt, Breeze, Burns, Cocking, Collins, Curtis, Fernie, Fletcher, Gilman, Green, Griffiths, Harrison, Hewlett, Hill, Hodge, Ireland, Keall, Kirkby, Lassasie, Lothian, Lucas, Parker, Payne, Priest, Prust, Randall, Ransom, Richtmann, Rudd, Scott, Smith, Summers, Taylor, Turner, Wild, Wilson.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

ELECTRIC LAMPS IN ETHER EXTRACTION.

C. G. Hopkins employs the ordinary incandescent lamp in extraction work and finds it preferable to the gas flame for use in ether extraction, not only on account of its safety, but also because of its greater simplicity, constancy, cleanliness, and convenience. For a set of twenty complete sets of Soxhlet extraction apparatus, five 110-volt lamps, of thirty-two candle-power each, are placed in the air-bath, and they are found sufficient to produce a distillate amounting to about sixty drops per minute in each apparatus. The air-bath employed is a galvanised iron box, thirty-six inches long, eight inches wide, and six inches deep, with double side walls and triple end walls, leaving half-inch spaces in which are placed strips of asbestos paper to decrease the loss of heat by radiation. The board upon which the bath stands is also covered with asbestos. The removable cover of the bath contains twenty holes arranged in two rows. The holes are two inches in diameter, and their centres are three and a-half inches apart. The lamps are placed seven inches apart, one under the middle point of the square formed by every four holes. This symmetrical arrangement and the precaution taken to decrease radiation at the ends of the bath should provide practically the same amount of heat for each set of extraction apparatus. With the extraction in operation the temperature of the cover of the bath does not exceed 75° C., but with all the holes covered it is possible to raise the temperature to a point at which ether vapour will ignite. If, therefore, it be desired to assure absolute safety a water-bath should be employed, the bulb of each lamp being immersed in the water.—*Journ. Am. Chem. Soc.*, **21**, 645.

DECOMPOSITION OF CALOMEL.

Miss O. St. C. Lewis has attempted to ascertain the truth of statements which have been published regarding the decomposition said to take place when calomel is acted upon by hydrochloric acid, alkaline chlorides, etc. On taking 0·5 Gm. each of calomel and sodium chloride, with 100 C.c. of artificial digestive juice, 2 C.c. of diluted hydrochloric acid (10 p.c.), 0·00335 Gm. of pepsin, and water, *q.s.* to make 100 C.c., and allowing the mixture to digest on a water bath, at 40° C. for six hours, then filtering, concentrating the filtrate, testing with the usual reagents and allowing to stand for twenty-four hours, a decomposition took place, producing quite a deep brown coloration and a very noticeable precipitate with hydrogen sulphide, also a precipitate with sodium hydrate, and an orange coloration deepening into red with potassium iodide. Three consecutive trials of this experiment were made, and each showed the same evidence of the formation of corrosive sublimate. On using 0·2 per cent. of hydrochloric acid in the artificial digestive juice, with the same amounts of calomel and sodium chloride, the same reactions were obtained, excepting that the colorations were slightly deeper in tint. Three trials of this were made and in each case evidence of decomposition was shown. By mixing calomel with peptones very thoroughly, and digesting as above, very unmistakable evidence was given of decomposition into corrosive sublimate. But pancreatin in acid medium gave the most unmistakable evidence of decomposing calomel. The precipitates were exceedingly voluminous. With 0·2 per cent. hydrochloric acid, the deep-brown coloration and a very noticeable precipitate with hydrogen sulphide were obtained; with ammonium hydrate a very noticeable precipitate, and with potassium iodide a beautiful bright-red coloration. From these experiments the investigator inclines to the opinion that calomel is converted into corrosive sublimate by the action of certain salts and by the action of the acid juices of the stomach.—*Druggists' Circular*, **43**, 176.

IODINE IN ALGÆ.

Iodine appears to be a constant and essential constitutent in the protoplasm of fresh-water algæ, as well as in marine species. In the course of his investigations on the distribution of the element, A. Gautier has detected it in notable quantities in all the species examined. Thus *Ulothrix diossecta* contained 24; *Cladophora fracta*, 9·24; *Nostoc fragilis*, 4·23; *Protococcus pluvialis*, 20·6; *Batrachospermum*, 11 9; *Beggiota*, 360 parts per million of iodine calculated on the dry substance. Similarly by the lichens, consisting, as is known, of a symbiotic association of algæ and fungi were found to contain iodine in the following quantities in each million parts of dried material:—*Parmelia*, a trace too small to determine; *Peltigeria*, 2·98. Bacteria, as far as the researches have at present gone, would appear to contain but little, if any, iodine. The bacilli of diphtheria contained none, and those of tetanus a doubtful trace. The higher fungi in the instance of the three species examined: *Agaricus campestris*, *Boletus edulis*, and *Cantharellus cibarius* each gave 2·7 parts per million of iodine on the dry material. Although iodine is evidently a constant element in algæ, the fresh-water species, containing at the most but 24 parts per million, are less rich in it than those of marine origin, which contain, on an average, 600 parts per million. The bacterial algæ of sulphurous springs, which are free from chlorophyll, occupy a place between the fresh and salt water species, containing, on an average, 360 parts per million of iodine. Microscopic algæ, especially the marine species, and those which grow as lichens are exceptionally rich in that metalloid. In fungi, the amount of iodine varies according to the medium in which the plants grow, and does not appear to be an essential constituent of their protoplasm.—*Comp. rend.*, **129**, 189.

DOUBLE SALTS OF SILVER AND COPPER.

P. Sabatier has prepared an interesting series of double salts of copper and silver, obtained for the most part by the interaction of solutions of the silver salt and blue cupric hydrate. Thus the compound $3Cu(OH)_2,2AgNO_3$ is obtained in blue-violet crystals from normal solutions of silver nitrate; from hot concentrated solutions another dicupric salt, $2Cu(OH_2),2AgNO_3$ separates in bright blue acicular needles. With solutions of silver chlorate and blue cupric hydrate a heavy blue precipitate is obtained, consisting of well-formed microscopic prismatic scales having the composition $2Cu(OH)_2,2AgClO_3$. A sulphate of analogous composition $3Cu(OH)_2,SO_4Ag_2$ is obtained as microcrystalline inclined prisms; another form in needles, containing 3 molecules of water, also exists. With silver thiosulphate blue cupric hydrate forms the salt $2Cu(CH_2,AgS_2O_6$ as a violet flocculent precipitate. Most of these compounds may also be obtained by the action of silver oxide in solutions of the various cupric salts.—*Comp. rend.*, **129**, 211.

PURIFICATION OF IRIDIUM.

Crude iridium in the form of chloride is treated in solution in water acidulated with hydrochloric acid with sodium nitrite until no more nitrous fumes are evolved, the solution is rendered alkaline with sodium carbonate, again treated with nitrite and filtered. According to E. Leidié the solution contains only ruthenium, rhodium, and iridium nitrites and osmium as sodium osmate. Ruthenium and osmium are eliminated by converting them into peroxides by means of an alkaline hypochlorite and distilling in a current of chlorine. The nitrites of rhodium and iridium are unaffected by this treatment. They are converted into the respective double sodium chloride salts; the rhodium is removed by converting it into the insoluble sesquichloride, Rh_2Cl_6, which is affected by heating the mixture to 440 in a current of chlorine. The soluble iridium sodio chloride is removed by solution, precipitated as iridium ammonio chloride, which is insoluble, which is finally decomposed at a red heat in a current of hydrogen. The iridium, cooled in a current of CO, is thus obtained pure.—*Compt. rend.*, **129**, 214.

THE PHARMACOPŒIA AND EXAMINATIONS.*

BY WILLIAM C. ALPERS, D.Sc.

The examiners on the boards of pharmacy are often severely criticised for the great stringency of their questions, while occasionally we hear complaints that they are too lenient. If these critics are asked to point out any particular branch, or any particular line of questions, which in their judgment should be omitted or altered, and give their reasons why such changes should be made, they give rather vague and indefinite answers. They say, for instance, "What is the use of examining in materia medica, organic chemistry, botany, etc.? What the candidate should know is the Pharmacopœia, and if the examiners would confine their examinations to questions relating to the Pharmacopœia no fault could be found with them." The question at issue therefore resolves itself into another one: How can we ascertain whether the candidate understands his Pharmacopœia, and what should we ask him in order to arrive at this certainty? Is it necessary, with such an aim in view, to examine in botany and pharmacognosy? Should the natural orders of plants, their growth and chemical constituents be known? Should we include organic chemistry in the curriculum? Is the testing for and detecting of adulterants necessary? These and many other similar questions might be asked.

The clear understanding of the Pharmacopœia was exactly the leading thought of the writer when he drafted the curriculum after which the New Jersey Board of Pharmacy has examined for the last four years, and, in his own judgment, there is not one subject mentioned in it that is not absolutely necessary to know in order to *read* the Pharmacopœia intelligently. The word "read" is used here purposely, for this is all we can at present expect. If by a "thorough understanding" of the Pharmacopœia is meant the ability of preparing all the preparations, pharmaceutical, synthetical and chemical, a much broader knowledge than the requirements of our curriculum is necessary.

How any opposition to an examination in the fundamental laws of organic chemistry can be entertained at our present state of medication is hard to understand. We use now many products of organic chemistry, probably more than products of inorganic chemistry; and their number increases daily. Many of them, such as chloroform, ether, chloral hydrate, salol and carbolic acid, have become official; and at the next edition of our Pharmacopœia this list will be much enlarged. If it is necessary to know the composition and formula of ferric chloride or cupric sulphate, why not also to know as much of chloroform or of phenol? The same arguments apply to all other disciplines that are so often attacked by the thoughtless.

For further illustration let us select at random some items of the U.S. Pharmacopœia, and subject the description given by that authority to a brief scrutiny. Let us first take a subject of materia medica—for instance, Rosa Gallica (Red Rose), on page 340. This is certainly a very simple article. The description begins: "The petals of Rosa Gallica." What are petals? Is it wrong to ask the candidate this question? Should he not know what part of the plant they form? and should he not also know the other parts of the flower—the calyx, the stamen, the pistils, etc.? All these are official; indeed, there is not a single part of a plant that is not official in the U.S.P. The writer was once violently attacked by some old pharmacists for asking the question, "What are the parts of a flower?" How can a candidate who is unable to answer such a simple question *read* the Pharmacopœia intelligently?

The description of Rosa Gallica continues: "The petals of Rosa Gallica Linné." What does Linné mean? If we claim that we must be able to *read* our Pharmacopœia a slight knowledge of the history of the development of the various pharmaceutical sciences is indispensable. Truly I do not advocate that a complete biography of Linnæus should be given, but the fact that he was the father of modern botany, and the first to classify plants after a well-delineated system, should certainly be known. Then come the words "Nat. ord. Rosaceæ." Have they any meaning? If so, what meaning? What are natural orders? What are Rosaceæ?

By turning only two leaves from the page first selected we find words like Coniferæ, Compositæ, Polygonaceæ, Labiatæ, Caprifoliaceæ, Leguminosæ. Should all these words, and many more, be pronounced by the young pharmacist as by a speaking trumpet that gives the sound but has no thoughts? Or shall each word have a meaning and recall a definite thing to his mind? Can he *read* the Pharmacopœia without knowing something about the natural orders of plants—at least of the official plants? Or is it not necessary to understand this part of the Pharmacopœia? If not, who is to draw the line, and where is it to be drawn—what we shall understand and what not?

Let us return to our chosen subject, red rose. The description continues: "Usually in small cones, consisting of numerous imbricated, roundish, retuse, deep purple-coloured, yellow-clawed petals." Let us stop here. Do we understand all this as we read it? Here we have the words "imbricated," "retuse" and "clawed." Shall the student attach no meaning to all this? On the same page of the Pharmacopœia from which these sentences are taken we find such words as "receptacle," "hemispherical," "coalesced," "drupes," "style," "fusiform," "annulate," "medullary rays," etc.; and there is not a page in the book that does not contain similar words descriptive of plants and their parts. Should not the candidate know the meaning of such words, and is it not right to ask him questions relating to them? Our description says further: "Slightly acidulous and distinctly astringent taste." Here we have one of the technical terms of physiology. What is "astringent"? While it relates here only to the taste, it has also a broader meaning, and every pharmacist knows that astringent medicines are often called for. Should not this word be clearly understood by the candidate, together with many others, like laxative, tonic, sudorific, anthelmintic, febrifuge, etc.? Should he not be able to give a good account of all these terms and quote examples? If he cannot do so is he able to read the Pharmacopœia intelligently?

Let us now pass to another article of our Pharmacopœia on the preceding page (339). There we read: "Resorcinum, CH_4 (OH_2) = 109·74." Here is material for many questions. What do C, H, and O mean, and why are the figures 109·74 added? Elementary chemistry in all its details appears at once; chemical symbols and atomic weights are suggested. This is not all, however. The question will also be asked: Why is the one hydrogen in the formula separated from the other? Why do we not write C_6 H_6 O_2; and if we do is it wrong to do so, and why? The synonym given in the Pharmacopœia, "Metadioxybenzol," will remain a mystery to the candidate if he cannot answer these questions. If we require of him to read the Pharmacopœia intelligently, should we not ask him what the prefix "meta" means? Are we wrong in demanding an explanation of the term "dioxy" and "benzol?" Can anybody give an intelligent explanation of the word meta-dioxy-benzol without knowing the rudiments of organic chemistry? Long chemical terms are often made a subject of ridicule or attack, and yet there is nothing easier or plainer to the student of organic chemistry than these very words. Resorcinum has no meaning as such, while meta-dioxy-benzol not only recalls the composition of the chemical but also the constitutional formula, and we know at once why the formula C_6 H_4 $(OH)_2$ is preferable to C_6 H_6 O_2. Thus the description continues; every line presupposes the study and knowledge of chemistry in some of its branches. We are told to add a few drops of ferric chloride T. S. What is "T. S."? What are test solutions for? What is ferric chloride? What other iron chloride is there? and so on ad infinitum.

There is no page in our Pharmacopœia that can be *read* intelligently without fulfilling the requirements of our curriculum. The

*Read before the New Jersey Pharmaceutical Association, and reprinted from *Merck's Report*.

two examples, which were taken at random, could be duplicated on every page of our pharmaceutical guide-book. Examiners who are at a loss as how to formulate their questions need but take any subject and ask all the questions that naturally suggest themselves in reading the descriptive remarks. The examinations would then be based on the Pharmacopœia in the strictest sense of the word, and no objection as to its severity or leniency could be raised. (It will then be seen that there is nothing in the curriculum of the N. J. board which is not warranted by actual requirements.)

By again advocating our curriculum I do not wish to be understood that I consider the demonstration of theoretical knowledge as the only, or even the most important, criterion of a candidate's fitness. Much more important, in my judgment, are practical demonstrations; but it is not the object of this paper to dwell on this feature of the subject.

As the examiners on boards of pharmacy are, or ought to be, practical men engaged in business, they are better fitted to test the practical ability of candidates than professors of colleges; while the latter are far superior as examiners of theoretical knowledge. The most sensible and simplest solution would therefore consist in separating these two parts of the examinations entirely; let the board examine practically and the colleges theoretically. To accomplish this every applicant for examination before a board should be a graduate of some recognised college of pharmacy; and not until this state of affairs is reached will the complaints about injustice and unfairness of examiners cease. At present the whole burden rests on the boards, a burden which is much more onerous and trying than is generally known or appreciated. It is therefore the duty of every professional pharmacist to assist, as far as possible, the members of the boards in the execution of their duties; and this can best be done, not by unfair criticism and continuous harassing, but by frank and forcible indorsement of their acts, thereby encouraging them to bravely face all opposition and fearlessly perform their duty.

NOTE ON GLACIAL ACETIC ACID.

BY F. H. ALCOCK.

It is a difficult thing to get glacial acetic acid of correct B.P. strength when purchasing small quantities. It seems that the plan is to keep the acid in Winchester quarts, and when some is required for sale, if there happens to be the quantity already liquefied in the bottle, no attempt is made to melt the whole, so that what the purchaser gets is somewhat aqueous. The official test of gravity is of no value, and the m.p. is also risky, and the correct way perhaps is total acidity, and even that is not alone a criterion. If, however, an equal volume of oil of turpentine, B.P., be added to it, this constitutes a simple test. As glacial acetic acid is required to dissolve an equal volume of oil of turpentine, so an equal volume of oil of turpentine should dissolve in an equal volume of glacial acetic acid, and this is a useful additional test, and might have a place in the B.P.

Lacquers for Brass.—The following are very old and tried recipes for coloured lacquers:—(1) Take of shellac, 120 parts, sandarac, 45, mastic, 30, amber, 30, black resin, 90, dragon's blood, 30, turmeric, 30, gamboge, 30, rectified spirit, 1,000. Shake occasionally till dissolved and strain. (2) Seed-lac, 120 parts, gamboge, 120, dragon's blood, 120, saffron, 30, rectified spirit, 1,000. Put in a hot place, stir at intervals, and filter.—*Brit. Journ. Photog.* [There seems no sufficient reason why non-mineralised methylated spirit should not be used for preparing the above lacquers, instead of rectified spirit, —Ed. *Pharm. Journ.*]

CHAPTERS IN PHYSICO-CHEMISTRY.

Optical Properties.

It is a matter of everyday experience, and familiar to all, that different bodies do not all behave in the same way toward light. Thus, some substances, which are called transparent, such as water and air, allow light to pass freely through them; others, such as coal or iron, are opaque, or do not allow the light to pass. Some, again, as many of the metals, reflect light to a greater or less extent, while others, like charcoal, do not reflect it at all. Such properties, however, while they are sufficiently characteristic to be of some value in describing a body, are not unvarying enough to be at all reliable in its identification. For instance, whereas a large piece of ice is transparent, when reduced to powder it is quite opaque; again, the extent to which light is reflected by a metal depends on the greater or less smoothness of its surface. The degree of transparency of substances, then, and their power of reflecting light, are not made the subject of exact measurements, nor utilised for their characterisation except in a very general way.

There are other ways, however, in which the behaviour of any substance towards light is quite unvarying, and admits of very accurate measurement. Such action upon light cannot in some cases be even detected by the unaided eye, and special apparatus is always required for its measurement. The facts ascertained by quantitative observation of the behaviour in such respects of different simple and compound bodies has not only furnished important characters for their identification, but has helped to furnish interesting and valuable knowledge about the constitution of some kinds of matter. We now proceed to consider some of the chief of these optical properties of substances.

Refractive Power.

When a ray of light passes from the medium through which it is being propagated into another of greater or less density than the first, its path in the second is not a continuation in a straight line of its previous path, but the line along which it now proceeds makes an angle with the line along which it travelled in the first medium. Thus, if in Fig. 1 the space above the line AB represents

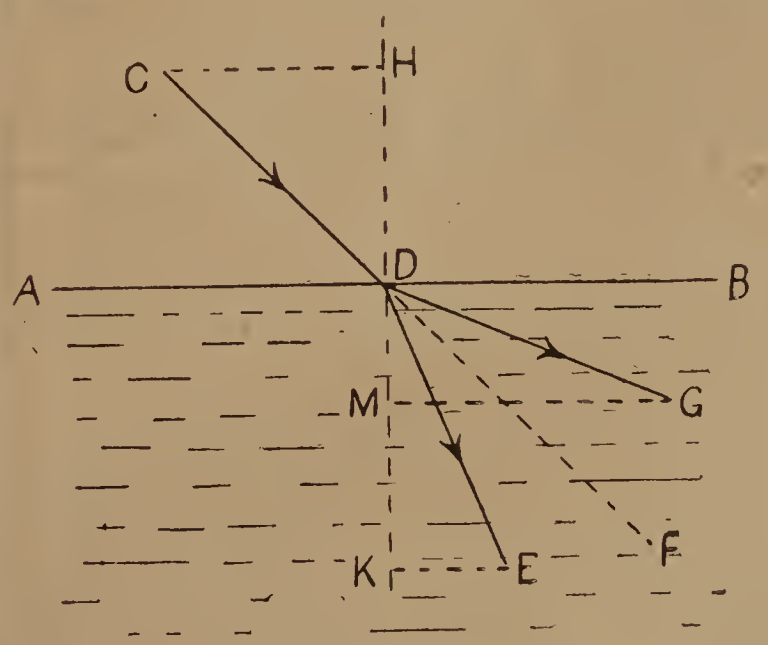

Fig. 1.

the first medium through which a ray passes, and the space below it the second, AB being thus the common surface of the two, then if the densities of the two are different, a ray having the course CD does not proceed straight on in the direction DF, but takes a course such as DE, or DG. If through the point D, where the ray meets the surface, a line HK is drawn perpendicular to the surface, the angle CDH is called the angle of incidence, and the

angle EDK or GDK, as the case may be, the angle of refraction. If from any point C in the line DC a line is drawn perpendicular to DH, and a length DE (or DG) is measured along the line DE (or DG) equal to DC, and from the point E (or G) so obtained, EK (or GM) is drawn perpendicular to DK, the lines CH and EK (or GM) furnish a means of comparing the angles of incidence and refraction; the ratio of the length of the line HC to the line EK (or GM), or, in other words, the ratio of the sine of the angle of incidence CDH to the sine of the angle of refraction EDK (or GDK) is termed the "index of refraction" of the substance lying below the line AB, with regard to the substance lying above it. If the second medium has a greater density than the first the angle of refraction will be smaller than the angle of incidence; if the second is the less dense medium, the angle of refraction (GDK) will be greater than the angle of incidence. In considering refractive indices, the ray is always supposed to pass from the less to the more dense substance; we can, therefore, at once dismiss the greater angle GDK. Theoretically, the refractive index of a substance is the ratio of the sine of the angle of incidence to the sine of the angle of refraction when a ray passes from empty space (vacuum) into the substance in question. In practice, however, air is taken instead of empty space; this produces extremely little difference in the result.

The refractive index of a substance, whether an element or a compound, is an important characteristic. It may be determined in several ways; generally the most convenient is by the use of the spectrometer (Fig. 2). This consists of (*a*) a tube called the collimator,

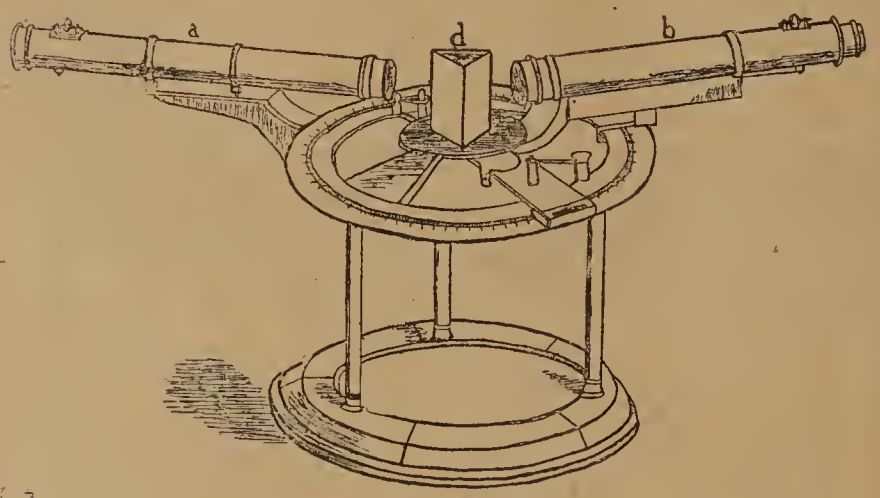

FIG. 2.

closed at one end with the exception of a narrow slit by which light is admitted, and containing a lens by which the rays are rendered parallel; (*b*) a telescope through which the rays pass to the eye, and in which the image of the slit is seen; (*c*) a stand to which these two are attached; this is circular, and graduated into degrees and minutes; the telescope can be moved round it, and fixed at any point; its position is indicated by the corresponding graduation. To use the apparatus, light is allowed to fall on the slit of the collimator; (the light must be homogeneous; this will be referred to below). The telescope is brought into a straight line with the collimator; when this position is reached the image of the slit will be seen exactly in the middle of the field in the telescope; the graduations on the scale corresponding to this position is noted. Next, a prism (*d*) of the substance whose refractive index is to be determined is placed between the collimator and the telescope; if the substance is a liquid it is enclosed in a hollow prism of glass, whose sides are of even thickness; solutions may be used, the effect of the solvent being afterwards found and allowed for. In order that the image of the slit may be received in the telescope it will now be necessary that the latter should be moved round the circle to a greater or less extent. By moving it about, and simultaneously twisting the prism round slowly, a position of the latter is found such that if it be placed in any other way the telescope has to be moved further from its original position in order to receive the image. When this position is found, the angle through which the telescope has been moved from its position before the prism was introduced is found by deducting the scale reading of the one position from that of the other. This angle is called the "angle of minimum deviation" for the prism in question; let it be represented by d. The size of the angle between those two sides of the prism through which the light passed must be measured. To do this the prism is set with this angle facing the collimator, and the telescope is successively moved to positions in which the light reflected from these sides is received in it, so that an image of the slit is seen in the centre of the field. Half the angular distance between these positions, as shown by the graduated scale, is equal to the measure of the required angle of the prism; let this be represented by a. The index of refraction of the substance (usually denoted by the Greek letter μ) is then given by the formula $\mu = \frac{\sin \frac{1}{2}(a + d).}{\sin \frac{1}{2} a}$ The temperature at the time of experiment is to be noted and recorded.

When a ray of ordinary white light is passed through a prism it is separated into a number of rays, each of which, seen by itself, gives the impression of colour. The reason of this separation is that these rays are not refracted to the same extent in passing through the prism, and hence on emerging their paths are different. On account of this difference in the refrangibility of the different rays it is necessary, as stated above, that the light used in determining refractive indices should be homogeneous; that is, it should not be composed of different rays that can be separated by a prism, but should be of one kind alone. In order that different determinations of refractive index may be comparable it is, of course, necessary that they should all be made with similar rays of light. The light generally adopted is that whose wave-length is 656 millionths of a millimetre, which corresponds to the red line in the spectrum of hydrogen.

We have said that the temperature at which the refractive index of a substance is determined should be noted. The reason for this is that it is affected by the temperature, being generally reduced by a rise in the latter. Other circumstances besides temperature which influence the density of the substance also affect the refractive index; it appears that the change in refractive index with change in temperature is really dependent on the alteration of density caused by the alteration in temperature. Attempts have been made to find an expression for the refractive power of bodies which should have the same value whatever the density, and so allow comparison between results obtained in different circumstances. Calling the density of the substance d, the expression $\frac{\mu - 1}{d}$ is found to give nearly unvarying values, whatever the condition of the substance as to density may be. The quantity represented by this expression is called the refractive constant of a substance. Another expression is also in use for the refractive constant—namely $\frac{\mu^2 - 1}{(\mu^2 + 2)\, d}$. This has been arrived at from theoretical considerations, whereas the former expression rests only on empirical results. The more unvarying result is yielded in some cases by the one, and in other cases by the other. Both are consequently in use under the name of refractive constant, but the second one is the one that is now more frequently employed.

The refractive constant of an element, multiplied by its atomic weight, gives its atomic refractive power; similarly the molecular refractive power of a compound is got by multiplying its refractive constant by its molecular weight. It is found that, with certain exceptions, if the atomic refractive power of each of the elements present in a given compound is multiplied by the number of atoms of that element existing in a molecule of the compound,

and the products so obtained added together, the resulting number is equal to the molecular refractive power of the compound found directly. It will be seen that this relation is exactly analogous to what has been found to hold for atomic and molecular volumes (*P.J.*, **56**, 305). The limits within which the rule holds are also very similar. Among organic compounds, which have been chiefly studied, irregularities are observed in those compounds in which there exists between some of the carbon atoms that relation which is commonly termed "double" or "triple linking." In these cases the observed refractive powers are higher than those corresponding to the above rule, and a definite value can be assigned to "double bonds" and "triple bonds" that must be added to the sum of the atomic refractive powers of the constituent atoms to give the molecular refractive power of the compound in which such bonds occur. Accordingly, determinations of the refractive power of compounds have been utilised to throw light on the nature of the union between the carbon atoms in cases where it was doubtful, as in benzene. Other elements besides carbon also have different values, according to the way in which the atoms are united. Oxygen attached only to one carbon atom has not the same value as oxygen which is attached to both carbon and hydrogen, and so on. We thus come to the conclusion that the molecular refractive power of a compound depends partly on the number and nature of its component atoms, and partly on the way in which these are combined.

Rotation of the Plane of Polarisation.

Leaving refraction now, we proceed to consider the behaviour of different substances towards polarised light, which is of great practical and theoretical importance.

According to the undulatory theory, light consists of vibrations in the ethereal medium, which are propagated as waves with almost incredible speed. In ordinary light these vibrations are not confined to any one plane, but occur in every possible plane. When, however, such light is passed through certain substances, of which Iceland spar is a good example, the vibrations are reduced to occurring in two planes, at right angles to each other, and these two sets of vibrations become separated from one another, forming distinct rays; when the light leaves the substance in which this change has been effected, these two rays proceed along independent paths, and in each one the vibrations continue to be in one plane only; each of them is now said to be polarised.

There are various methods by which polarised light may be conveniently obtained. The apparatus usually employed is called a Nicol's prism, and is constructed of Iceland spar in such a way that only one of the two polarised rays is allowed to pass, the other one being arrested. If now the light that has passed through a Nicol's prism is allowed to enter a second one, if the latter is so placed that its optical axis is parallel to the optical axis of the first, the light will pass through it unaltered. If, however, the second Nicol is turned round through a right angle, so that its optical axis is at right angles to that of the first one, the light which has passed through the first one will be completely arrested by the second. This property of the Nicol of allowing the passage of those rays whose vibrations are in one plane, and stopping those whose vibrations are in the plane at right angles to the former, enables us to distinguish polarised from ordinary light, which otherwise we could not do. An arrangement consisting of two Nicols in a straight line with each other, one of them being capable of being turned round freely, is called a polariscope; the Nicol which is entered first by the light is called the polariser, and the second one, by which its polarised condition is detected, is called the analyser. In order that light may pass unaltered through the second Nicol, it must reach it with the vibrations occurring in such a plane that no effect will be produced on it by this Nicol. We have already said that this will no longer be the case if the Nicol is rotated, and it is clear that the same effect will be produced if the latter remains stationary, if by any means the plane of polarisation of the light is rotated. Certain substances possess the peculiarity that, if a ray of polarised light passes through one of them, when it emerges the vibrations are no longer occurring in the same plane as when it entered, but the plane of polarisation has been turned through a greater or less angle. This is what is termed "rotation of the plane of polarisation," and bodies possessing this property are called "optically active."

The extent to which this property is possessed by a substance is measured by a form of polariscope known as a polarimeter. It consists of a polariser and an analyser placed at a suitable distance apart, together with an eyepiece, through which the light is conveyed to the eye, and a circle graduated in degrees and minutes, by means of which the exact extent to which the analyser is rotated at any time can be measured. If the analyser is put in such a position that the light reaching it is exactly stopped by it, so that none reaches the eye, it is clear that when an optically active body is placed between the two Nicols the light will no longer all be stopped in the analyser, but that to effect this the latter will have to be rotated to an extent exactly equal to the amount of rotation that has been suffered by the plane of polarisation; the amount of this rotation of the analyser can be read on the graduated circle. If, therefore, the light has passed through some standard unit quantity of the optically active body the amount of rotation that must be given to the analyser is a measure of the rotatory power possessed by the body.

In practice some modifications in the method are necessary. In the first place, it is impossible to find exactly that position of the analyser in which all the light is cut off by it, since it may be moved through a considerable range before the amount of light transmitted is sufficient to be appreciated. The field is accordingly divided into two halves, and a device (explained in more complete descriptions of the polarimeter) is introduced, by means of which one half of the field gets lighter, while the other gets darker, and the analyser is adjusted, both before and after the optically active substance is put into place, to the position in which the two halves of the field are equally bright, which can be found with great exactness. Next, the quantity of the substance is so taken that the angle to be read shall have a convenient magnitude, and this is divided by the number of decimetres length through which the light has passed, and also by the specific gravity of the substance; the number so obtained is called its specific rotatory power. Since the extent of the rotation is dependent on the wave-length of the light, ordinary white light cannot be used, as each of the different rays of which it is composed has a different wave-length, and consequently no position of the analyser could be found in which they would all be equally reduced. The light emitted by heated sodium compounds is homogeneous, that is, it cannot be resolved into different rays, and since it is very easily obtained it is almost always employed; it is only necessary to put some particles of some sodium salt on a platinum wire in a Bunsen gas flame, and to exclude other light by darkening the room. The wave-length of sodium light corresponds to the yellow line in the solar spectrum that is designated by the letter D; the symbol adopted to indicate specific rotatory power is $[\alpha]$, and to show that sodium light has been used the letter D is appended, thus, $[\alpha]_D$. When the rotation takes place in such a way that the analyser has to be turned in the direction in which the hands of a watch move, it is called dextro-rotation, and a plus sign is prefixed to the number representing the specific rotatory power; conversely, if the analyser is moved in the reverse way, the substance is called lævorotatory, and this is indicated by a minus sign. Thus, for cane sugar, $[\alpha]_D = + 66{\cdot}6$; for nicotine, $[\alpha]_D = - 61{\cdot}5$.

The optical activity of bodies may be most conveniently measured when they are in the liquid state, as the length of the column of liquid can be easily fixed. Glass tubes, enclosed in metal cases for protection, are employed, and closed at each end by a small circular

plate of glass, held in position by a cap. Whenever possible solids are dissolved in a liquid which has no optical activity itself; the observed angle is then multiplied by the number of parts of the liquid that contain one part of the dissolved substance. Since, however, the nature and quantity of the solvent, even though it is inactive, have in many cases an effect on the extent of the rotation, these particulars should always be recorded. The temperature, too, is to be noted, as this also affects the result.

In addition to the value of the specific rotatory power of a substance in aiding its future identification, it throws important light on its constitution in the case of organic substances, since optical activity in carbon compounds is found to be always associated with a particular arrangement of some of the atoms—namely, one of the carbon atoms is in direct union with four *different* atoms or groups of atoms. Such an arrangement is called asymmetric. As a good deal has been written on this subject it need not be discussed here. The reader is referred to *P.J.*, **51**, 41, etc.

Magnetic Rotation.

The very large number of substances that do not possess the molecular constitution here referred to do not under ordinary conditions show any action on polarised light. When, however, such bodies are under the influence of magnetic force, they all cause rotation of the plane of polarisation. This phenomenon has been termed magnetic rotation, and has been the subject of much work by Perkin in recent years. The tube containing the liquid to be examined is placed between the poles of a powerful electro-magnet, and the observation then conducted in the usual way. The rotation observed for unit length of the substance, multiplied by the molecular volume of the latter, gives a value which is comparable with the corresponding values for other substances. Water is taken as the standard for purposes of comparison, and the ratio of this value for any given substance to the similar value for water is called its molecular magnetic rotatory power. The term specific magnetic rotatory power is applied to the ratio of the rotation caused by unit length of the substance to that caused by the same length of water.

Much attention has been given to the molecular rotatory power of homologous series of organic substances; that is, series in which there is a constant difference of CH_2 between the adjacent members. The increase due to the additional CH_2 in the molecule is found to be constant; the molecular rotatory power of a compound is equal to the sum of the values of the CH_2 groups present, and a value which is the same for all the members of a series, and is hence called the "series constant." The mode of combination between the atoms has a certain influence on the molecular rotatory power, and, just as with the molecular refractive power, definite values can be assigned for "double bonds" and "triple bonds" between carbon atoms, the two modes of combination of oxygen, and so on. The molecular rotatory power of compounds has been employed to shed light on their constitution; that is, on the manner in which their constituent atoms are united. This is one of the latest instances of the employment of physical measurements in the solution of chemical questions. Such physico-chemical methods have already thrown much light on some of the most interesting questions of the science, and it may fairly be anticipated that in the future, as the importance of these measurements is more and more recognised, highly important results will follow from their application.

TRIBROMOSALOL AS A HYPNOTIC.—Tribromosalol introduced as a hypnotic particularly for the insane is not regarded by Vrallon as of great value. Although it gives good results in some cases, and does not occasion any digestive derangement, its hypnotic action is very inconstant, and its insolubility renders it difficult of administration in the case of many patients mentally afflicted.—*Nouv. Rem.*, **15**, 302.

QUALITATIVE EXAMINATION OF POWDERED VEGETABLE DRUGS.*

BY HENRY KRAEMER.

GROUP NO. 2.—COLOUR WHITISH.

Wheat flour, Corn starch, Wheat starch, Potato starch, Rice starch, Bermuda arrow root starch, Montserrat arrow root starch, Wheat middlings, Corn meal, Corn bran, Orris root, Resina jalapæ, Dextrin (white), Gum arabic (white), Tragacanth, Saccharum (cane), Sacch. Lactis, Scilla, Camphora, Talc, Prepared chalk, Ppt. chalk, Pulv. Cretæ Comp., $BaCO_3$, $BaSO_4$, $CaSO_4$, Heavy magnesia (MgO), Light magnesia (MgO), Antimony oxide, Antimonial powder, Tartar emetic, Calcium phosphate ppt. [$Ca_3(PO_4)_2$], Terra alba, Potassium bitartrate.

1. Plant Tissues or Cell Contents Recognizable.

A. CONTAINING STARCH.

a. Unaltered starch alone.—Grains characteristic for each; completely soluble in glycerin on heating, and precipitated on the addition of water.

171. *Arrow root starch* (Bermuda).

172. *Arrow root starch* (Montserrat),

173. *Corn starch.*

174. *Rice starch.*

175. *Wheat starch.*—Does not agglutinate on mixing with water distinction from wheat flour.

b. Altered and unaltered starch grains.

176. *Dextrin.*—Sticky mass with water; unaltered starch grains detected.

c. Plant tissues in addition to starch grains.—The former remain upon treatment with hot glycerin.

a. Do not readily dissolve or swell in cold water and become transparent and sticky.

177. *Corn meal.*—More starch and oil and little hull.

178. *Corn Bran.*—Less starch and oil and more hull.

179. *Wheat Flour.*—Agglutinates with water, distinction from wheat starch; little tissues of wheat grain.

180. *Middlings of Wheat.*—Starch and numerous fragments of tissues of wheat.

181. *Orris Root.*—Characteristic starch grains 15 × 15 to 15 × 30 μ; scalariform ducts 25 μ wide; no cork.

B. SOLUBLE OR SWELL IN COLD WATER TO FORM A STICKY MASS.

182. *Acacia* (white).—Soon affected by water; few plant tissues.

183. *Tragacanth.*—Slowly affected by water; fragments of ducts and parenchyma; more likely to find corn starch grains in commercial powder.

B. WITHOUT STARCH.

184. (*a*) *Acicular crystals.*

Squills.—Also find isolated fragments of fibro-vascular tissue.

II. Absence of Plant Tissues.

A. SOLUBLE IN WATER.

185. *Cane Sugar.*—Characteristic crystals; soluble also in mounts of glycerin and glycerin + chloral; taste.

186. *Potassii Bitartras.*—Soluble in water with acid reaction; with sodium cobaltic nitrite solution get small yellow cubical crystals, which are permanent in glycerin mount.

187. *Tartar Emetic.*—Large irregular masses; add HCl to the powder on a slide, and then pass H_2S over the same, get an orange-red precipitate, which is permanent in a glycerin mount.

B. INSOLUBLE IN WATER.

(*a*) Soluble in alcohol.

188. *Camphor.*—Liquefies in mounts of glycerin and chloral; glycerin mounts show irregular masses.

---

* From the *American Journal of Pharmacy*. *Continued from page* 186.

189. *Resina Jalapæ.*—In glycerin get irregular opaque fragments, which swell and by-and-by look like huge amœboid masses; in glycerin and chloral the fragments become rounded, transparent, and finally dissolve.

(*b*) Insoluble in alcohol.

a. With H_2SO_4 reddish colour after some time.

190. *Saccharum Factis.*—Small and large irregular-shaped crystals, insoluble in mounts of glycerin or glycerin + chloral.

β. No colour reaction with H_2SO_4.

* *Soapy feel.*

191. *Talc (or Magnesium Silicates).*—Rather lustrous long irregular crystals.

** *Effected by ascetic acid.*

† *With effervescence.*

192. *Calcii Carbonas Præcipitatus* ($CaCO_3$).—Add hot solution of ammonium oxalate to acetic acid solution on slide, get crystals of calcium oxalate. Mount in glycerin and observe rosette or cubical crystals of a rather uniform size.

193. *Creta Præparata* ($CaCO_3$).—Same treatment as above, but CaC_2O_4 crystals are triangular and cubical and not of uniform shape.

194. *Pulvis Cretæ Compositus.*—On addition of acetic acid notice peculiar gummy mass containing crystals of sugar, which are soluble in water.

195. *Barium Carbonate* ($BaCO_3$).—Add H_2SO_4, and in glycerin mount the $BaSO_4$ precipitate is bacteria-like; flame test, green.

†† *Soluble in acetic acid without effervescence.*

196. *Heavy Magnesia* (*MgO*).—Alone in glycerin mount observe small rounded masses frequently grouped together; if dissolve, a few milligrammes on a slide or watch crystal in citric acid, then add a few drops (excess) of ammonium hydrate and Na_2HPO_4 and stir vigorously with a glass rod, triangular or tetragonal crystals are formed in glycerin mount.

197. *Light Magnesia* (*MgO*).—In glycerin mount looks like heavy magnesia, but masses are larger and more transparent. On treatment with citric acid, NH_4OH and Na_2HPO_4, the crystals of $MgNH_4PO_4$ in glycerin mount are large star-shaped, and look like snow crystals.

*** *Unaffected by acetic acid.*

† *Soluble in Nitric Acid.*—If necessary, in deciding on any of the next four, they are to be fused with K_2CO_3 or Na_2CO_3, and a regular qualitative chemical separation effected.

198. *Calcii Phosphas Præciptatus* [$Ca_3(PO_4)_2$].—In glycerin mount alone get small tetragonal and cubical crystals. If to a few milligrammes of the powder on a slide, we add a few drops of HNO_3, and then ammonium molybdate solution, stirring well with a glass rod, get small yellow diamond-shaped crystals, permanent in glycerin mounts.

199. *Calcii Sulphas.*—In glycerin mount alone observe needle-shaped crystals or long crystals in masses (looks like group of sklerenchyma fibres); flame test on platinum wire = bright reddish-yellow.

200. *Barium Sulphate.*—In glycerin mount alone observe irregular-shaped crystals varying from small to large; flame test = green.

201. *Terra alba.*—This is aluminium silicate (3 : 5) and magnesia.

†† *Insoluble in nitric acid.*

202. *Antimony Oxide.*—In glycerin mount alone get irregular, transparent, small to large fragments; add drop of HCl to powder on the slide, then pass H_2S over the solution, get orange-red precipitate.

203. *Antimonial Powder.*—Small tetragonal and cubical as well as irregular transparent crystals. Add HCl, then H_2S = orange-red precipitate.

GROUP No. 3.—COLOUR, SOME SHADE OF YELLOW.

Washed sulphur, Sulphur præcipitatum, U.S.P. (Lac Sulphur or Milk of Sulphur), Mastic, Glycyrrhiza (Russian), Aurantii amari cortex, Scammony resin, Resina, Lycopodium, Sandarac, Sinapis alba, Dextrin (yellow), Aurantii amari cortex, Aurantii dulcis cortex, Ammoniac, Limonis cortex, Zingiber (Jamaica), Calendula, Angustura bark, Tr. Rhei Dulc., Rhamnus purshiana, Tr. Rhei Arom., Rheum, Hydrastis, Resina podophylli, Aloes (Cape), Chrysophanic acid, Gamboge, Turmeric, Yellow ochre (Argillaceous or Calcareous earth, Fe and Mn oxides), Curry powder.

I. Possessing Vegetable Tissues or Cell Contents.

A. CELL-CONTENTS ALMOST ENTIRELY.

a. Starch grains.

204. *Dextrin.*—Altered and unaltered starch grains.

b. No starch.

205. *Lycopodium.*—Characteristic spores entirely.

B. CELL-CONTENTS AND VEGETABLE TISSUES.

a. Without any or but little starch.

206. *Aurantii Amari Cortex.*—Thick-walled parenchyma (walls 10–15 μ thick); oil secretion reservoirs (120 μ in diameter); few ducts; brownish-green outer layer; crystals of calcium oxalate cubical (15 × 15 μ).

207. *Aurantii Dulcis Cortex.*—Parenchyma cells with walls not so thick as the bitter orange peel, being 4 μ thick; secretion reservoirs about 350 μ in diameter; few ducts; outer layer orange-yellow; crystals of calcium oxalate either cubical (30 × 30 μ), or prismatic, as in quilaja (35 × 10 μ); likely to find sphere crystals of carbohydrate in glycerin mounts.

208. *Limonis Cortex.*—Secretion reservoirs as large as in sweet orange peel; outer layer pale (lemon) yellow; walls of parenchyma 5 μ thick; calcium oxalate crystals, about as in bitter orange peel; sphere crystals, as in sweet orange peel.

209. *Sinapis alba.*—Oil, aleuron and characteristic seed coat.

210. *Calendula.*—Characteristic tissues of petals containing oily drops; few pollen grains; reaction with H_2SO_4.

b. Containing starch.

a. Without crystals of calcium oxalate.

211. *Hydrastis.*—Starch 4 μ; wood fibres and ducts yellowish; few, sometimes numerous prismatic crystals in a rosette = berberine; upon addition of H_2SO_4, get abundant needle-shaped crystals.

β. With crystals of calcium oxalate.

* Crystals very small and likely to be overlooked.

212. *Zingiber* (Jamaica).—Unaltered starch grains 15 × 30 μ; yellowish (oil) and reddish (resin) cells; fibrovascular tissue.

213. *Turmeric.*—Altered starch grains (test with iodine) in irregular masses (70 × 100 to 100 × 140 μ) of shape of cell in which formed; bright yellow oil secretion cells; pigment dissolved out by use of solutions of chloral or chloral-glycerin, as well as when essential oils are employed, characteristic colour reaction with H_2SO_4, or with boric acid + HCl, and then evaporate with NH_4OH.

214. *Curry Powder.*—A powder of varying composition, but generally find the following: characteristic yellow secretion cells and starch of *ginger* and *curcuma*; oil and seed coat of *mustard*; aleuron and oil secretion reservoirs of *coriander*; may find sklerenchyma of *Pimenta* or *cloves*.

** *Crystals of calcium oxalate rosette-shaped and numerous.*

215. *Rheum.*—Crystals 70 μ; starch grains, single, 20 μ, or double 35 × 20 μ; boil a few milligrammes of the powder with water, filter, and to the straw-coloured solution add KOH = red coloration.

216. *Tr. Rhei Aromatica.*—Chiefly the characteristics of *Rhubarb* (see No. 215); crystals (10 μ), and oil secretion reservoirs of *cloves* (see No. 346); tissues of *cinnamon* (see No. 292) and *nutmeg* (see No. 496).

217. *Tr. Rhei Dulcis.*—Characteristic aleuron, non-secreting hairs and secretion reservoirs of *anise*; seed coat and crystals of *cardamom*, crystals in crystal fibres of *glycyrrhiza*; crystals and starch of *rheum*.

219. *Rhamnus Purshiana.*—Rosette-shaped and cubical crystals; bast fibres (more numerous than in Frangula); stone cells (which are absent in Frangula); a few milligrammes of powder boiled with water, filtered and the straw-coloured filtrate, treated with KOH, gives a red colour.

**** Crystals cubical, tetragonal or coffin-shaped and numerous.*

220. *Calumba.*—Stone cells contain tetragonal crystals; starch grains. (See No. 24.)

221. *Glycyrrhiza* (Russian).—Numerous sklerenchyma fibres, adjoining which are crystal fibres containing tetragonal and coffin-shaped crystals; few cork cells, distinguishing it from Spanish (which see, No. 275); some parenchyma cells contain glycyrrhizin. and are coloured straw-yellow with H_2SO_4.

***** Needle-shaped crystals.*

222. *Angustura.*—Stone cells; bast fibres; long yellow secretion reservoirs; yellowish (oil) and reddish-brown (resin) masses.

II. Few or no Fragments of Vegetable Tissues.

A. BURN, GIVING OFF ODOUR OF SO_2,

223. *Sulphur Lotum.*—Small rounded masses in chains.

224. *Sulphur Præcipitatum.*—Small rounded masses in irregular groups in glycerin mounts,

B. ON BURNING DO NOT GIVE OFF ODOUR OF SO_2.

(*a*) *Nearly colourless in glycerin mount.*

225. *Mastic.*—Transparent irregular masses.

(*b*) *Yellowish in glycerin mount.*

(*a*) *Containing oil globules.*

226. *Scammonium.*

β Transparent or translucent.

227. *Resina.*—Irregular masses, soluble in cold alcohol (95 per cent.), forming a straw-coloured liquid, becoming milky-white on addition of water; on heating fragments of resin in water, they melt, run together and form a sticky mass.

228. *Sandarac.*—Almost insoluble in alcohol (95 per cent.), and solution remains almost colourless; on heating fragments in water, do not melt.

229. *Resina Podophylli.*—Very small more or less globular particles frequently massed together in large masses.

230. *Aloes (Cape).*—In glycerin mount some fragments are conchoidal; the particles become clear and dissolve, leaving a few colourless lens-shaped or fine acicular crystals. The latter are more abundant in the Barbadoes aloes.

231. *Chrysophanic Acid.*—Small colourless and yellowish irregular masses, with KOH, becomes yellow and then crimson-red.

γ More opaque.

232. *Ammoniac.*—Irregular, faint yellow, opaque masses, made up of small, light-coloured or greyish particles.

233. *Gamboge.*—Irregular, bright yellow masses, made up of small yellow particles.

(*To be continued*).

NOTE ON EXTRACTUM GENTIANÆ.

BY F. H. ALCOCK.

During the examination of some samples of this substance, one of them, when added to water (100° F.), gave a cloudy solution which, on the addition of solution of iodine to the cold liquid, gave strong indications of the presence of starch. When the extract was examined under the microscope no granules of starch were visible. As gentian root does not contain starch under ordinary conditions, it would appear that if such be present, accidentally or otherwise, the official process for the preparation of the extract is an unfavourable one for the elimination of starch. The boiling process would be better performed (if necessary at all) after the separation of the marc than before, under which circumstances the starch would not be removed to any appreciable extent.

It is worthy of note that the particular extract referred to above absorbed much iodine solution before a permanent blue coloration was obtained.

THE STANDARDISATION OF VEGETABLE DRUGS.*

BY BURT E. NELSON.

The pharmacist who would, without regard to the alkaloidal content, prepare his tincture or fluid extract of belladonna from only half the required amount of the drug would be denounced, and yet he would in reality have done no more injury than one who has unknowingly manufactured his preparation from a sample of the drug containing but half the usual quantity of the active ingredients. Especially is this true of our more potent plant drugs, most of which depend upon fixed alkaloids for their activity.

The chief reason for the pharmacist not attempting these determinations I have found to be inability to do analytical or assay work, or the non-possession of suitable apparatus. The correction of the former evil lies with the pharmacist himself, and as for the latter, while it may not be practicable to invest in the delicate balances, complicated extraction apparatus, and other paraphernalia usually found in assay laboratories, it is within his means to possess himself of one or two stoppered separatory funnels, a pair of burettes, a series of volume pipettes, and such other apparatus as he can himself extemporise by the exercise of some ingennity.

As for methods of assay, the escape is not so easy; many of the commonly employed processes yield results which do not compare so favourably as a conscientious analyst would hope for, and the easiest is too often the poorest method. Moreover, a process which would answer for commercial valuation, where the relative alkaloidal content was the only thing desired, might be wholly unfit for standardisation purposes where exactness must be the chief aim. Especially is this true of extraction processes; maceration, and the removal of an aliquot part of the clear menstruum for assay is a process which, on account of the ease with which it may be carried out, although requiring considerable time, strongly recommends itself and for valuation experiment as above indicated, is satisfactory, but after trying it at frequent intervals during the past seven or eight years, I have abandoned it for the more rapid and thorough hot re-percolation in an extraction apparatus wherever it is applicable and accuracy is desired. For this I most commonly use the Florence flask and glass syringe percolator originally figured by Dr. Lyons and like it as well as a Soxhlet apparatus.

The principle upon which the separation of the majority of alkaloids depends is familiar, and may be learned from the United States Pharmacopœia process for assaying nux vomica extract or from one of the works mentioned in the note, by those who are unacquainted with it. It is usually preferable to evaporate over a gentle water-bath heat and under diminished pressure where practicable.

The weight of the total alkaloid obtained by causing the mixed separates to evaporate in a tared beaker to dryness and allowing the whole to remain in a desiccator over sulphuric acid for some hours until the weight is constant is, where the bases are white, clean and crystalline, frequently accurate, but more frequently they exist as a yellowish or brownish varnish-like residue consisting of the amorphous alkaloids, together with various foreign matters. In these cases a volumetric determination with standard acid and alkali solutions is desirable. I habitually use the decinormal sulphuric or hydrochloric acids (20 C.c.) and titrate back with decinormal caustic soda, using cochineal as indicator. I have not been able to obtain greater accuracy by the use of centinormal solutions. I also prefer ammonia for rendering the liquid alkaline, as I have known small quantities of the fixed carbonated alkalies to be mechanically carried away by the solvent and left with the alkaloidal residue, thereby interfering with an accurate determination by decinormal acid. Each cubic centimetre of decinormal acid neutralised by the alkaloids corresponds to one ten-thousandth of their molecular weight expressed in grammes; for example, the molecular weight of atropine being 289, each C.c. of acid represents 0.0289

*From the *Druggists' Circular*.

grammes. Where two or more bases are present, the mean of the several weights must be chosen, and herein lies the chief drawback to the process, unless we go through the laborious process of separating them. Care must be taken to insure the solution of all the alkaloid in the acid, by patiently stirring with a glass rod, where residues contain portions of other material which might entangle them and so protect portions of them from its action.

The use of decinormal iodine and sodic thiosulphate, as in Dr. Prescott's process for assaying opium, seems to possess the same advantages as the use of acid and alkali, but I have thus far tried the process but once and cannot speak from experience. Titration by Mayer's reagent possesses few advantages, as in order to secure reliable results, the determination must be accompanied by an exactly similar check experiment which entirely does away with the supposed saving of time and labour. It is, however, very serviceable for the comparative valuation of drugs for commercial purposes. Again it is possible with some alkaloids, for example, aconitine and some of its relatives to determine certain of their products of saponification (in this case benzoic acid) and from this to calculate their amount. In three samples of aconite, tried some time ago, I did not find this method to correspond with Squibb's physiological test so closely as I had been led to suppose it did.

To prepare preparations of definite strength from these drugs it is necessary to adopt some standard of alkaloidal content for each, and then to use a proportionately larger or smaller amount of the crude drug; for example, if 0·350 per cent. of atropine be adopted for belladonna leaves and the sample on hand be found to contain but 0·250 per cent. our calculation would simply be as follows: as 0·250 per cent. is to 0·350 per cent., so is 150 grammes to x (210 grammes), the amount required for preparing extract of belladonna of the standard strength.

Such standards, with accompanying methods of assay, it is very desirable that the revisors of the United States Pharmacopœia shall adopt. Without doubt many of them would eventually be found not to be the most suitable, and in succeeding revisions would be replaced by others, but would they not be far better than no standards at all? The old assay process for opium was the cause of some considerable dissension, yet it served its purpose at the time, and to it is largely due the more satisfactory process of to-day. Even the formulæ for the galenical preparations themselves have required frequent alterations. Furthermore, it might be said that the presence of the three assay processes in our present Pharmacopœia has instilled an interest in these matters into men from whom otherwise they would have received no attention.

At present the figures adopted by manufacturing houses are principally the results of their personal experiences. and frequently differ. In hospital work I have used for some time those given in the list which follows, which differ but little from those of a well-known manufacturing house, and which I have found to represent the average content of good samples of the drugs, but not the average content of the drugs as they frequently occur in small quantities on the market for the past several years:—

Powdered opium; 15 per cent. of morphine.

Nux vomica; 1·5 per cent. of total alkaloids.

Cinchona; 5 per cent. of total alkaloids.

Hyoscyamus; 0·150 per cent. of alkaloid, calculated as $C_{17}H_{23}NO_3$.

Belladonna leaves, 0·350 per cent. of alkaloid, calculated as $C_{17}H_{23}NO_3$.

Belladonna root, 0·450 per cent. of alkaloid, calculated as $C_{17}H_{23}NO_3$.

Stramonium leaves, 0·375 per cent. of alkaloid, calculated as $C_{17}H_{23}NO_3$.

Aconite root; 0·500 per cent. of alkaloid (physiological test 1 to 600).

Coca leaves; 0·500 per cent. of alkaloid, calculated as $C_{17}H_{21}NO_4$.

Colchicum seed and root; 0·500 per cent. of total alkaloids.

Sanguinaria root; 1·000 per cent. of total alkaloids.

Kola; 2·000 per cent. of caffeine.

Guarana; 3·000 per cent. of caffeine.

Hydrastis; 2·000 per cent. of hydrastine.

Ipecac; 1·750 per cent. of total alkaloids.

Gelsemium (little used); 0·350 per cent. of total alkaloids.

Pilocarpus (little used); 0·350 per cent. of total alkaloids.

Veratrum viride (little used), 1·000 per cent. of total alkaloids.

Digitalis, strophanthus, and a number of others are regularly assayed, but we do not as yet attempt to standardise the preparations made from them, as we do with alkaloidal drugs, while those which are incapable of being assayed chemically are examined microscopically for the purpose of identification and for determining as far as possible their freedom from foreign material. All are purchased in the powdered condition. Preparations manufactured from the above drugs are made to contain their several amounts of active bases by the method before indicated, irrespective of the amount of crude drugs required; and we are able to observe a corresponding uniformity of action of the extracts, etc., made from different samples of the same drug.

Below are recorded the results of a number of assays that the reader may compare the figures with those given above. The different lots of the same drug were in each case obtained in small quantities at different times, and I think represent more or less correctly the variation which exists in these drugs as they reach the retail pharmacist.

Powdered opium: Sample (1), 14·24 per cent.; (2), 14·67 per cent.; (3), 12·72; (4), 14·11.

Red cinchona; (1), 4·740 per cent. total; (2), 3·857 per cent. total.

Nux vomica: (1), 1·234 per cent.; (2), 1·892 per cent.; (3), 1·132 per cent.; (4), 1·505 per cent.; (5), 2·518 per cent., 2·00 per cent.*

Aconite: (1), 0·321 per cent.; physiological test, 1—600; (2), 0·2043 per cent.; physiological test, 1—200; (3), 1·285 per cent.; physiological test, 1—700; (4), 0·183 per cent.; physiological test, 1—80; (5), 0·477 per cent.; physiological test, 1—700.

Hyoscyamus: (1), 0·1085 per cent.; (2), 0·1274 per cent.; (3), 0·070 per cent.; (4), 0·052 per cent.; (5), 0·242 per cent.

Belladonna leaves: (1), 0·236 per cent.; (2), 0·144 per cent.; (3), 0·382 per cent.; (4), 0·471 per cent.

Kola: (1), 2·250 per cent.; (2), 2·29 per cent.; (3) 1·254 per cent.

Stramonium leaves: (1), 0·422 per cent.; (2), 0·517 per cent.; (3), 0·281 per cent.

Coca leaves: (1), 0·415 per cent.; (2), 0·424 per cent.; (3), 0·727 per cent.; (4), 0·480 per cent.

Sanguinaria: (1), 0·918 per cent.; (2), 0·911 per cent.

Gelsemium: (1), 0·770 per cent. (crude); (2), 0·416 per cent. (crude).

Ipecac: (1), 1·762 per cent. (crude).

Guarana: (1), 1·365 per cent.; (2), 1·314 per cent.

Hydrastis: (1), 1·726 per cent.; (2), 1·314 per cent.

The opium, cinchona, and nux vomica were assayed by the United States Pharmacopœia processes; the aconite by Wright's modification of Dequesnel's process, using, however, ammonia in place of sodic carbonate. Samples one and two were titrated with decinormal acid and calculated as aconitine. Squibb's physiological test was tried with all and is by far the most reliable. The hyoscyamus, stramonium, and belladonna were assayed by Dunstan and Ransom's process; titrating with decinormal acid and calculating the alkaloid as $C_{17}H_{22}NO_3$. The coca, hydrastis, and gelsemium were assayed by Lyons' processes, titrating with acid for the first

* The first of these samples was extracted by continuous hot repercolation the second by allowing the drug to macerate four days with ten times its amount of alcohol.

two, the last simply being weighed as crude alkaloid. The guarana was assayed by Squibb's process, and the kola by extracting with chloroform, evaporating to dryness, taking up the residue with successive portions of hot water, filtering, shaking out with four portions of chloroform, evaporating and drying to constant weight. The ipecac was extracted with chloroform and alcohol, evaporated, taken up with acid water, filtered, rendered alkaline with ammonia, shaken out with chloroform, evaporated and dried for weight; while the sanguinaria was extracted with alcohol, evaporated, taken up with acid water, filtered, shaken out with ether, evaporated, and titrated with decinormal acid.

By taking the figures from some older assays, which were obtained by different methods, the above list might have been made more complete, but the comparison would not have been a just one, and even then it would probably have appeared insignificant beside the mass of figures which might be collected in a large manufacturing plant. I hope, however, that those given, showing the wide variation which some of them do, will aid in demonstrating the justness of the foregoing argument. If our revision committee could see their way clear to adopt definite, although perhaps for the present, merely provisional standards for the more important of them, I think they would have taken an advance step equal to the one taken in the introduction of the cinchona and nux vomica assays of the present volume. The naming of maximum and minimum percentages, as in the case of powdered opium, would probably be satisfactory for the drugs themselves, but the preparations made from them should be of as constant alkaloidal strength as possible.

NOTE.—For information concerning assay processes, I would recommend the United States Pharmacopœia for cinchona, nux vomica and opium; Prescott's 'Organic Analysis,' the work of Dragendorff, or the smaller one of Dr. A. B. Lyons. A very complete work on the alkaloids themselves is that of Dr. Icelus Guareschi, translated into German by Dr. Herrman Kuntzkraus, 'Einführung in das Studium der Alkaloide.'

PHOTOGRAPHY WITHOUT LIGHT.*

BY DR. VICTOR SCHUMANN.

Dr. W. J. Russel has lately discovered that certain substances exposed in the dark room for several days act upon the photographic plate. That tin is one of these is certain. I proved two years ago its influence on dry gelatino-bromide emulsion. I have also recently repeated Mr. Russel's experiments as far as they refer to tin and gelatin dry plates.

I applied the tinfoil sheets (which are sometimes manufactured of the thin commercial article, and sometimes of thicker material) in several ways. Some of the sheets were exposed at least eight days in the dark; some I exposed to the daylight, and others to sunlight. Before the application each sheet was polished with soft leather and Paris red upon a layer of plate glass, then laid in dark-room light on gelatin dry plates, and exposed from one to thirteen hours of steady light. Some of the sheets, by this process, showed a heavy impression, others rather less, and still others only a very light impression. To bring this out, pyro soda is useful with some bromide of potassium. The result of these experiments was unimportant from beginning to end. On no one slate had any reduced effect been produced; and a distinct discolouration of the plates, as I had obtained with tin, could be still less expected here. I merely mention that I had no better success in the same treatment with optical glasses of brass and steel. I found no inducement to continue my researches in this direction.

If anyone concludes that the same is true in regard to gelatino-bromide emulsion of tin, he is very much mistaken. My remarks on this subject should prove the contrary by my various experiments with tin; besides, I am far from wishing to write, in this work, of the dark rays of tin. It has rather to do with electro-chemical effects which take place between the metals and silver alloy.

To a better understanding of my remarks, I will place the results of my researches in the following order: On two glass plates rubbed with weak gelatin bromide silver (ultra-violet sensitive plates of my restoring process), I lay in dark-room light two thick tinfoil frames. To obtain a close contact, the plates and foil in the copy frames should be firmly pressed together. Then I place one frame in daylight, the other is exposed in the dark. After a few days each plate shows an almost perfect black impression of the foil. The foil itself has taken on the black spots of the plate; it has lost its mirror-like smoothness, and is of a dirty grey colour. The impression of the one exposed to the light differed very slightly. The light has consequently not acted upon the impression visibly.

That the tin had acted in a far shorter contact I perceived by developing such a contact plate. I make this exception to the unlooked-for appearance of my experiment to the lower part 1,000 A°E photographic rays.

The already-used plates must be covered almost to the full spectrum of a corresponding rectangle. I chose one with a fitted segment between the casette wall and tinfoil plate of the whole size of the plate. During from half to one and a half hour's pressure, the plates and tinfoil are in an atmosphere of hydrogen gas under a pressure from ten to twenty mercury columns. The duration of the contact was longer than the exposure to the light. I make the exposure longer, especially the exposure secondary, as the spectrum rays have not acted to a certainty on the tinfoil.

Then there, where the spectrum band falls on the tinfoil (that was on both sides of the segment), no visible effect was ever produced. The plates were coloured, with few exceptions, when the whole space was disclosed, only near the edge, which was surrounded in larger or smaller spaces with peculiarly-formed spots in lined succession. In the centre of these spots could be distinguished small silver shining rings with a high light of the colour of the negative. Feathery shapes passed through the high light-like rays coming from the centre, which, however, were produced by the metallic residuum under the action of the tinfoil in the electro-chemical process and the development of salt crystals. The spots are of several sizes. Some are as broad as the plate and disperse in the form of tiny flames; most of them seem like little aureoles around the shining ring.

Nowhere is formed a correct impression of the tinfoil layers. This circumstance should not appear strange, as an intense pressure of the plate on the tinfoil, as in copy frames, was not to be obtained. In a striking way, the larger spots extended over the cut-out segment where the direct influence of the tin was impossible. I surmise that in the contact they receive the ingredients of tinfoil (Sn.Cu.Pb.Fe.Ni.), and the silver haloids pictured in the development are spread over the plate and also over the cut-out segments, and have taken on the colouring of the unlighted remaining suffusion. It is less easy to explain where, on the contact plate, the necessary fluid acts in the electro-chemical process, for the plates are well dried and kept particularly from dampness. That the hydrogen gas which followed the exposure should be used for that purpose is not probable. On the other hand, the remaining ones without the tinfoil sheet, there, where they lay on the edge of the metal case, also show spots. That in truth a fluid has formed between the tin plates seems probable, as they cling so closely together after the exposure, quite as though they had been glued.

It may seem that these spots are surface blemishes of the plates or the work of pressure, but those produced by tin are so radically different from surface defections and from the colouring of those produced by pressure that the confusion of the two is impossible.

I did not pursue these experiments further. Therefore, as they resulted solely as sporadic appearances of other observations, they can raise a slight claim to integrity. What remains for me is to remark on the sameness of both Mr. Russel's experiments and my own. But at the same time this also shows how carefully one must go to work for an explanation of supposed photographic light workings if one does not wish to run into the danger of mistake in the work.

THE STANDARD OF EDUCATION IN SCOTLAND.

A Report on secondary education in Scotland for the year 1899, by Sir Henry Craik, K.C.B., deals with the inspection of higher class schools and the examination for leaving certificates, and possesses special interest for pharmacists in view of the fact that after August, 1900, the preliminary examination of the Pharmaceutical Society will be abolished, and the leaving certificates (honours, first grade, and lower grade) of the Scotch Education Department will be accepted, among others, in lieu of passing that examination. The number of candidates who have presented themselves this year for the leaving certificate examination is 15,377, as against 16,262 last year, but the number of separate papers worked by the candidates (51,052, as against 51,649) shows that while the number of candidates has diminished, the number of subjects taken by each has increased. It is suggested that it would not be a matter of regret if the number of candidates showed still further signs of diminishing, owing to the exercise of greater discrimination in the selection of candidates, many of whom are presented each year with totally insufficient preparation. At the same time, the candidates presented are said to be better prepared in general, a slight increase in the proportion of passes obtained when all the subjects are reckoned being attributed to that cause. It is stated, however, to be still apparent that a large number of candidates have been sent in who have not reached anything like the required standard, and that some school managers and teachers have not yet realised what that standard is. The first and principal end of the leaving certificate examination, as defined in this report, is "to fix a standard for scholars who have gone through a course of secondary education fairly suitable for the country generally, and neither to discourage schools by asking too much nor to degrade the certificate by bringing it down to the level of inadequate work." But the lower grade certificate—one of those accepted by the Pharmaceutical Society—is said to seem to be too frequently aimed at by "those who have nothing but the most elementary and fragmentary knowledge of a subject."

In regard to lower grade English the passage for dictation proved a stumbling-block for many; but, on the whole, the spelling was fairly good and the grammar was also satisfactory, whilst many succeeded fairly well with the grammatical analysis. "In the answers to the literary questions, and in those on history and geography, there is evidence of more careful teaching, but many of the examiners complain of the lack of any notion of historical proportion, of hopeless confusion as to well-known names, and of considerable second-hand knowledge crammed from a text-book. But the worst feature of the examination is the lack of general intelligence, and of power of composition, shown in the paraphrase and in the essay." In fact, it is said to be evident that composition is insufficiently taught in most of the schools, and that the power of grasping with intelligence the general drift of a passage is one in which the pupils generally are very defective. "The habit of dividing the essay into paragraphs, and even of following any principle of punctuation, is evidently neglected, and the intelligence of the pupils is not sufficiently trained in grasping and in expressing in straightforward language the general meaning of a passage." As Sir Henry pertinently remarks, since the chief objects in the teaching of English as a school subject must be "to acquire facility in the use of the language as an instrument, and a clear apprehension of it as a means of expressing lucid ideas," some knowledge of the structure and growth of the language is of great importance as an aid towards those objects. But, apparently, that view does not prevail generally throughout Scotland.

The candidates for the lower grade certificate showed considerable evidence of a good drilling in the rules of Latin grammar, but the power of applying those rules in simple composition is rare; candidates are often very weak in grasping the meaning of a passage in translation, and rarely attempt to translate into good English. Frequent instances led to the conclusion that some of the pupils had been allowed to take up a larger number of subjects than they could study with profit. The lower grade mathematics appear to have been satisfactorily taught, and in the arithmetic examination a satisfactory feature was a falling-off in the proportion of candidates who were evidently quite unprepared for the examination. There were, however, indications that the teaching of arithmetic is too often of a very mechanical kind, and that scholars have not sufficient practice in working problems. "The question on the metric system was very badly answered. Many candidates did not know what a millimetre is, while others when told to express an inch in millimetres expressed a millimetre in inches. The question on interest also revealed a great want of power to think out the meaning of a simple problem." The work in algebra was, as a whole, satisfactory, but dishonest methods prevailed in the solution of problems. In geometry there was shown an intelligent apprehension of elementary geometrical reasoning, but many answers were incomplete, and there was a want of appreciation of relative magnitudes. The lower grade French paper was also fairly satisfactory, the grammar questions being generally answered with considerable accuracy and the composition fair, though with a limited vocabulary. With regard to

the German papers, they revealed many defects, but there was evidence of some slight advance in the general standard, though both the German composition and the translation from German left room for great improvement.

In conclusion, reference must be made to the fact that, according to this report, strong representations continue to be made in favour of the issue of leaving certificates, not in single subjects, but in groups. The argument against grouping is said to be that it might appear to impose a certain fixity of curriculum upon the schools; on the other hand, it is stated by Sir HENRY CRAIK that such grouping would undoubtedly represent a more satisfactory scheme of a comprehensive secondary education. It is suggested that, as a preliminary experiment, it may be well to begin by issuing such grouped certificates, in addition to any issued in single subjects, and it is thought that the value of such grouped certificates would soon make itself felt. Ultimately, it is to be hoped, no certificates will be issued in single subjects, and with that object in view it would be as well if the Scotch Universities were to decline to accept certificates in single subjects—whether in the lower or higher grade — from candidates for registration as medical students; they should also decline to accept certificates from more than one examining body, in the case of one and the same student.

THE GERMAN APOTHEKER-VEREIN.

THE present position of chemical investigation connected with pharmacy was the subject of an interesting address delivered by Dr. THOMS at the annual meeting of the German Apotheker-Verein held this week at Danzig. After a brief reference to the conditions prevailing at the time when the apothecary's laboratory was the birthplace of modern chemistry and to the great changes that have been brought about in the practice of pharmacy by subsequent progress in commerce, manufacturing industry, and science, Dr. THOMS proceeded to deal with the opinion held by some that pharmacy as an art is in danger of extinction, and of becoming a mere branch of trade. He gave an emphatic denial to the inference that nothing can be done to prevent that result. Unfavourable as existing conditions may be in some respects for a continuance of pharmaceutical work on the same lines as formerly, the possibility of maintaining for scientific pharmacy a position worthy of its past history was strenuously affirmed. But for that purpose, adaptation to modern requirements must not be confined to acquiring a superficial or more theoretical acquaintance with the various branches of science connected with pharmacy; the pharmacist of the future must on the contrary have a thoroughly practical training in the work requisite for carrying out investigation, and for dealing with analytical and other questions that may be submitted to him in the exercise of his business. Reference was made to the publications in the *Archiv der Pharmacie* as showing that the cultivation of capacity to carry out such investigations is productive of useful results, and that the German Apotheker-Verein may well be proud of the work it has done in that direction. On such lines alone can the practice of pharmacy be maintained at a scientific level and the pharmacist become an authority in all matters relating to the use of drugs, instead of a mere vendor of medicinal articles.

ANNOTATIONS.

THE GENERAL MEDICAL COUNCIL, as is now well known, is considering the advisability of revising the list of certificates accepted from candidates for registration as medical students, and the *Athenæum* announces that the Rev. T. W. Sharpe, formely H.M. Inspector of Schools, has been invited by the Council to give an expert opinion for its guidance on the various "junior" examinations which it has been customary to recognise as preliminary literary tests for intending medical students. The opinion is to extend to "the regulations, requirements, standards, etc., as well as the answers and the markings of candidates" in the several examinations.

DOCTORING BY CONTRACT was the subject of a lengthy article in last week's *Truth*. The editor of that paper has had sundry opportunities of enlarging his knowledge of medical aid associations, partly by communications from medical practitioners in different parts of the country and partly by interviews with one or two gentlemen who may be regarded as "specialists" upon the subject. As a result, he thinks it is perfectly evident that those associations lead to serious abuses, against which the medical profession at large has the best possible right to make a stand. Most of the abuses are said to arise out of the fact that the majority of the associations are practically the speculations of one or two individuals who promote and run them for their own profit. Those individuals make their own terms with the doctors and secure as many members as they can possiby get hold of, without regard to income, age, condition of health, or any other circumstance, and the whole revenue collected from those subscribers goes into the pockets of the promoter-proprietors, after payment of the doctors' salaries and the working expenses. "Under this system the association doctor is simply reduced to the position of a paid servant of a commercial concern, carried on by a layman who undertakes to supply medical attendance to all comers at so much per head." Few people, it is urged, will contend that this is a desirable position for a professional man to occupy. "It is wrong in principle, and it leads in practice to results equally prejudicial to the doctor and the patients." For the doctor employee is necessarily sweated, his pay being fixed by competition, instead of being determined by a more or less definite professional scale.

THE SAME ARGUMENTS may well be employed in connection with the practice of pharmacy by joint-stock companies consisting of unqualified persons. In that case, of course, there is no question about the qualified persons employed being simply the paid servants of commercial concerns carried on by laymen. The latter reap the profit of the business which the registered chemists they employ are alone qualified to transact, and the public is placed at a distinct disadvantage by reason of the chemists who are supposed to be in charge not having perfect liberty of action. The latter are engaged on a purely commercial basis, with the object of doing as much business as possible for the companies employing them, and they are obviously not free to exercise the same discretion as registered chemists who are in business on their own account. The responsibility, in fact, rests with the shareholders of the company, none of whom are competent to bear or willing to accept it, and so long as satisfactory dividends are paid the safety of the public may take care of itself. If any accident should happen the chemist employee is discharged, someone else is engaged in his place, and business goes on as usual, all the blame being cast on the discharged servant who has been replaced by another chemist willing to be sweated. It will, of course, be urged that chemists employed by companies frequently earn more than would be the case if they were in the employment of individual proprietors, but

that argument does not affect the main question. In any case the duly qualified person who enables a company of laymen to carry on the practice of pharmacy by hiring his qualification, submits to being sweated unless he receives every penny of profit earned by his assistance. That is not necessarily the case when one duly qualified person acts as assistant to another. To a considerable extent the chemist's assistant is acting as such with the object of gaining experience, and his contract with his employer is a kind of limited partnership. The longer he stays in the same place the more he increases his professional capital, whereas in the store of an unqualified drug company he is providing the whole of the professional capital from the outset, and he is worse off, as a whole, when he severs his connection with the company than he was at the beginning.

It is Contrary to Public Policy and to the intention of the Pharmacy Acts that the practice of pharmacy should be undertaken as a business by unqualified laymen, through the instrumentality of qualified chemists in the position of paid servants, just as much as it is contrary to public policy and to the intention of the Medical Acts that medical treatment should be so undertaken. To get rid of the system, in the latter case, *Truth* would insist that the medical aid association should be a *bonâ-fide* one, controlled and managed by the members through a proper committee, and that the whole of the receipts, after all working expenses have been met, should go to the medical officers. But it may be taken for granted that no such plan would commend itself to the shareholders in joint-stock companies which carry on the business of a chemist and druggist, through the medium of duly qualified persons. If they are not to share the profit, their object in carrying on the business would cease to exist. The plan suggested by *Truth*, therefore, while perfectly applicable in the case of medical aid associations, will not meet the pharmaceutical difficulty. Possibly, however, the enterprising editor of that important organ of public opinion may be able to devise some other scheme, which may fit the circumstances better, and he may not be indisposed to devote attention to the subject at this dull season of the year, if pharmacists in different parts of the country will communicate with him, and more especially if one or two gentlemen who may be regarded as "specialists" upon the subject will interview him. He has already shown that he is to some extent convinced that the practice of pharmacy by companies of unqualified persons leads to serious abuses, and it may not be difficult to induce him to assist the chemists of Great Britain to exercise their undoubted right to make a stand against those abuses.

The British Association for the Advancement of Science will meet at Dover early next month, under the Presidency of Sir Michael Foster, and the meeting promises to be of especial interest, inasmuch as visits are to be interchanged with the French Association for the Advancement of Science, which will be holding its sessions at Boulogne about the same time. The first general meeting will be held at the Connaught Hall, Dover, on Wednesday, September 13, when Sir Michael Foster will take the chair in succession to Sir William Crookes, and deliver his presidential address On the following evening there will be a soirée in the School of Art, and on the Friday evening Professor Charles Richet will deliver an address on "La Vibration Nerveuse," whilst on the Saturday evening he will lecture on "The Centenary of the Electric Current." In the Mathematical and Physical Science Section, Professor J. H. Poynting will preside; in the Chemistry Section the president will be Mr. Horace T. Brown; the presidents of the other sections will be :— Geology: Sir Archibald Geikie; Zoology: Mr. Adam Sedgwick; Geography: Mr. John Murray; Economic Science and Statistics: Professor Henry Higgs; Mechanical Science: Sir W. H. White, Chief Constructor of Her Majesty's Navy; Anthropology: Mr. C. H. Read; Physiology: Mr. J. N. Langley; Botany: Sir George King. A special feature of the Association will be demonstrations of Signor Marconi's wireless telegraphy, and the Rev. Mr. Bacon is expected to give an address on his recent balloon experiments. There are also to be several excursions to places of interest in the neighbourhood of Dover and to the Continent. The members of the French Association will visit Dover on Saturday, September 16, and the members of the British Association are invited to visit Boulogne on the following Thursday.

So-called "Wireless" Telegraphy is proving itself to be well within the limits of what is practical, and Signor Marconi has given a Press representative some interesting information with reference to the arrangements for the wireless telegraphy demonstrations at the forthcoming meeting at Dover of the British Association. The headquarters of the British Association will be at the Town Hall, and it is here that the French and English scientific visitors are to have the opportunity of witnessing some wireless telegraphy experiments. During the meeting the demonstrations will be in charge of Professor Fleming, of University College, London, and messages of congratulation will probably be exchanged between Dover and different parts of Europe. Trial between Dover Town Hall and the lighthouse at St. Margaret's have been a complete success, the tests applied yielding the most satisfactory results. An attempt to send messages direct between Dover Town Hall and Boulogne will be made if circumstances permit. The installation at Wimereux, near Boulogne, is the property of the French Government, and it is said to be possible to send direct communications, if certain alterations be made on the French side of the Channel. As stated above, the French Society for the Advancement of Science will be holding its annual conference at Boulogne at the same time as the British Association at Dover, and as both societies will be co-operating and exchanging courtesies, it is thought that there will be no difficulty in obtaining the necessary consent of the French Government. Otherwise messages will be sent across the Channel between Dover and Boulogne *via* the South Foreland. The results of the demonstrations with wireless telegraphy made during the recent naval manœuvres is said to have established the fact that, even with the present installation at the South Foreland lighthouse, messages can be exchanged with a fleet as far down Channel as Cherbourg, a distance of about one hundred miles, and even further.

Russian Weights and Measures are the subject of a new regulation recently officially published. According to the *Times* the Russian pound is fixed as the standard of weight and declared to be equal to 409·512 Gm., a pail or vedro is to hold thirty pounds of distilled water at $16\frac{2}{3}^{\circ}$ (Celsius), and a garnietz eight pounds of water. The unit of length is the arshin, equal to 71·12 centimetres. The metric system is to be optional, and may be used on a par with the Russian in commerce in dealing with contracts, accounts, etc., and after mutual agreement by State and municipal authorities. Private persons, however, are to be under no compulsion to use the metric system when dealing with the above-named authorities.

Tuberculosis in the German Army is the subject of an article in the *Militär-Wochenblatt*, and quoted by the *Times*, from which it appears that the number of cases of tuberculosis in that army has fallen from 2·9 per thousand in 1890-91 to 1·8 per thousand in 1898-99, the death-rate for the same periods from this disease being 0·42 and 0·24 per thousand. In the Bavarian army the decrease in cases has been 2·3 and in the death-rate 0·32 per thousand. The number discharged from the German army on account of the disease during the five years ending in 1896 was 7,205, or 51·9 per thousand

of those discharged for any reason whatsoever. It must be remembered that no man is admitted into the army who in the medical examination which precedes entrance is found to be suffering from the disease; apparently, therefore, it is contracted in the army. The chief predisposing cause is stated to be a "cold"; the next in importance is the strain of military duty, but this does not include the blowing of musical instruments, which comes under a separate heading. The treatment was more or less successful in 23·3 per cent. of the cases; in 1·2 per cent. a perfect cure was effected. In the remaining 76·7 per cent. the treatment failed, and death resulted in 16·1 per cent. The decrease in the number of cases in recent years is attributed largely to the discovery of the bacillus of the disease by Koch in 1882, owing to which it is easy to detect the disease and reject recruits suffering from it who would otherwise have passed the medical examination.

THE BARKING SANITARY AUTHORITIES have been distributing mercuric chloride and hydrochloric acid for disinfecting purposes in a way that seems rash, to say the least. At an inquest held at Barking last week, it was shown that a woman of sixty-three had received a quantity of the above poisonous mixture from a sanitary officer, with instructions to dilute it with twenty-four quarts of water and use it for disinfecting purposes in her house, where there had been several cases of typhoid fever. According to a local newspaper, there was sufficient poison in the bottle to kill three hundred people, As the result of a family squabble, the woman drank part of the contents, and in spite of prompt attention on the part of a medical man she died shortly afterwards. The Coroner thought "it seemed a little bit loose to give such large quantities of poison to ignorant people without some care being taken to see how it was used," and the foreman of the jury agreed with him. There is, of course, no legal restriction on the free distribution of poisons by sanitary authorities, but it does seem advisable for the necessary work of disinfection to be performed by the sanitary officers or other competent persons. It is certainly unwise to put mercuric chloride into the hands of ordinary householders for disinfecting purposes.

ANTON SCHURER VON WALDHEIM, President of the Gremium of Pharmacists of Vienna, and Vice-President of the Austrian Pharmaceutical Society, died on Sunday, August 13, in his seventieth year. By his death the list of honorary members of the Pharmaceutical Society of Great Britain is still further diminished, Herr von Waldheim having been elected an honorary member in May, 1887. He was at one time with the firm of John Bell and Co., Oxford Street, London, and was chiefly known to the pharmacists of other countries by reason of his connection with the scheme for publishing an international pharmocopœia. Thus, he was Chairman of the International Pharmacopœia Commission at Vienna, and editor of the draft International Pharmacopœia submitted to the International Pharmaceutical Congress held at Brussels in 1885.

THE SCHOOL OF PHARMACY reopens for the work of the fifty-eighth session on Monday, October 2, on the afternoon of which day an address will be delivered to the students by Professor D. J. Leech, of Owens College, Manchester, and the prizes will be presented to the successful students of the past session by the President of the Pharmaceutical Society—Mr. William Martindale. Meanwhile, the accommodation in the chemical laboratory at 17, Bloomsbury Square, is being considerably extended. Last year the number of applications for benches was so great as to necessitate the absorption of the pharmacy laboratory into the chemical department, and as further pressure on space is anticipated during the coming session, the benches in the main laboratory are being rearranged so as to permit of the admission of an increased number of workers. At the same time, the electric light is being installed in the lecture theatre, museum, library, and other parts of the Society's premises.

THE STUDENTS' NUMBER of the *Pharmaceutical Journal* will be published on September 9 next, and the principals or secretaries of colleges and schools who have not yet sent particulars of special courses of instruction for pharmaceutical students are invited to send the necessary information forthwith. The essential points should be stated as briefly as possible, the object being to furnish students with a general idea of the facilities offered rather than to overwhelm them with details which can be referred to subsequently in the college and school prospectuses. In particular, the names of lecturers, length of courses, fees payable, etc., should be stated, so that students may be able to compare the arrangements of one school with another, and make their choice accordingly.

THE BACTERIAL TREATMENT OF SEWAGE is the subject of an important paper by Mr. D. Pidgeon, which appears in the journal of the Royal Agricultural Society. The author points out that, though it is more than forty years since Pasteur demonstrated that there can be no fermentation in the absence of organisms capable of breaking down into simpler forms all the organic *débris* of the world, the methods of sewage disposal have remained half-hearted attempts to assist the world's scavengers in their appointed work. Hence, the sludge tank and broad irrigation are still employed, apparently with a view of lightening labours adjudged to be too great for the unaided microbe; while such work as might be hoped for from the organism, whether on the sewage farm or elsewhere, is carried on under conditions by no means favourable to microbial life. To improve, and, if possible, perfect those conditions, is the object sought by the bacterial treatment of sewage. At the beginning of the present decade certain experiments made at the town of Lawrence, in Massachusetts, resulted in proving that success in the filtration of sewage depends upon the very slow motion of exceedingly thin films of liquid, over the surfaces of particles having spaces between them sufficient to allow air to be in continual contact with the films, certain bacteria being present to aid in the process of nitrification. The effluents from the filters were found to include less organic impurities than most of the drinking water supplies of the State.

THE MASSACHUSETTS EXPERIMENTS were speedily supplemented by others which were made in England. Notably Mr. Scott-Moncrieff began to study the "biolysis" of sewage, basing his investigations on the consideration that since all effete substances can be dealt with by nature without assistance from chemicals, the problem resolves itself into discovering such artificial methods as would enable this agency to deal with the impurities contained in sewage on any scale, however large, at a reasonable cost, without creating a nuisance, and without the use of chemicals. He devised a "cultivation tank," carrying a layer of flints about fourteen inches deep through which the crude sewage runs. This tank is really a nidus, suitable for the growth and multiplication of the anaerobic organisms. The fresh sewage, not yet deprived in the sewers of all its oxygen, is attacked, on entrance, by aerobic organisms which, as the supply of the vital element at their command in the influent becomes exhausted, leave what remains of the food supply to such anaerobes as find a congenial home in the airless layers of the flint bed. Those so thoroughly complete the work of decomposition and final liquefaction that practically no sludge results, while the effluent contains all the solids and liquids which were present in the raw sewage, resolved into simpler forms indeed, but also deprived of a considerable proportion of the original impurities, which have disappeared by conversion into carbonic acid, marsh gas, hydrogen, and nitrogen. By supplementing the cultivation tank with a nitrifying chamber sufficient assistance is afforded to the aerobic organisms to permit of the process of nitrification being carried to such an extent as to produce a filtrate containing in solution enough nitrates to give it a commercial value.

SELECTED PRACTICAL FORMULÆ.

Gelatin Serum for Hypodermic Injection.

The value of gelatin as a hæmostatic is causing it to be freely prescribed on the Continent, both as a local application and for hypodermic injection. For the latter purpose a one or two per cent. solution in artificial serum is generally employed. Thus, a general formula for hypodermic injection of gelatin is—Finest white gelatin, 10 to 20 Gms.; sodium chloride, 5 Gms.; pure sodium carbonate, 2 Gms.; distilled water to 1,000 Gms. The solution should be thoroughly sterilised. For local application a stronger solution of pure white gelatin, 10 Gms.; sodium chloride, 10 Gms.; distilled water, 500 Gms. is employed. The gelatin in both cases is cut up small, and dissolved in the saline solution with a gentle heat, filtered through a Chardon filter, previously washed with hot distilled water, then filled into suitable flasks, plugged with cotton wool, and sterilised in the autoclave at a temperature of 100° C. Care must be taken not to exceed 105° C. during this sterilisation, or the hæmostatic power of the gelatin will be destroyed. Sterilisation may be effected in a water-bath, but in this case, great care is necessary to avoid deterioration of the coagulating properties of the gelatin.—*Petit Mon. Pharm.*, **49**, 3303.

Pomades for Falling Hair.

(1) Beef marrow, 20; castor oil, 10; gallic acid, 1. Melt together. (2) Beef marrow, 20; sweet almond oil, 10; quinine sulphate, 2; balsam of Peru, 1.—*Bull. comm.*, **27**, 326.

Universal Cement.

Glass, in the finest powder, is mixed to the desired consistence with white of egg. Broken glass, marble, porcelain, and crystal joined with this cement set so hard that they may be broken again in another part, but not where first cemented.—*Petit Mon. Pharm.*, **49**, 3,315.

To Cement Broken Amber.

Moisten the fractured surfaces with solution of caustic potash; join them together, and hold them for a few minutes over a charcoal fire, then cool. When the joint has been well done, it is imperceptible.—*Petit Mon. Pharm.*, **49**, 3,315.

Nail Lotion.

Sulphuric acid, 10; tincture of myrrh, 5; distilled water, 125. Moisten the nails night and morning with a little of this liquid on a piece of cotton wool. Polish them with a piece of chamois leather.—*Petit Mon. Pharm.*, **49**, 3,315.

Lip Salve.

Hard paraffin, 160; vaseline, 160; ethereal extract of alkanet (alkannin), 1; oil of bergamot, 2; oil of lemon, 2. Melt on the water bath, run into glass tubes 1 cm. in diameter; when cold, gently warm the tubes, push out the cerate with a glass rod, and cut into suitable lengths.—*Formulary of Bull. Gen. de Therap.*, **138.**

Remedy for Anæmia.

Pilules composed of artemisin, 0·1 milligramme; crystalline quassia, 0·1 milligramme; ferrous oxalate, 10 centigrammes, are much prescribed in Vienna for anæmia. Two such pilules are to be taken twice daily, before meals.– *Formulary of Bull. Gen. de Therap.*, **138.**

Egg-laying Stimulant for Fowls.

Bone meal, linseed meal, dried meat, spent lime, and oatmeal, of each 2 lb.; red pepper and sulphur, of each 2 oz.; salt and iron sulphate, of each 4 oz. Mix, and give one teaspoonful per hen, in soft food, three times a week.—*Cape Agric. Journ.*, **15**, 125.

Paste for Juvenile Acne.

Veiel employs the following paste in the treatment of juvenile acne:—Sulphur, alcohol (90 per cent.), and water, of each 20 Gm.; mucilage of acacia, 6 Gm. Mix. To be applied night and morning to the affected parts; if irritation is produced a paste of boric acid containing from 1 to 50 per cent. of sulphur is substituted, according to the sensibility of the skin.—*Formulary of Bull. Gen. de Therap.*, **138.**

Draught of Extract of Male Fern.

Ethereal extract of male fern, 3 Gm.; tincture of vanilla, 3 Gm.; syrup of turpentine, 25 Gm.; powdered acacia, 2 Gm.; distilled water, 25 Gm. To be taken in an equal quantity of milk, and followed, after the lapse of several hours, by a dose of castor oil.—*Formulary of Bull. Gen. de Therap.*, **138.**

SOME NEW PREPARATIONS OF CALENDULA.*

BY GEORGE M. BERINGER.

Although calendula is official, it has not received very extensive use. Nor do the dispensatories look upon marigold as possessing any special remedial value, the tincture being referred to as "probably of as much value as simple alcohol."

The drug has, however, met with more favour in homœopathy, and several preparations are quite popular. Recent indications point to the fact that physicians of the old school are beginning to test it.

The fluid extract and tincture are the preparations heretofore used, and the latter is displacing tincture of arnica for local application. In dental practice it is likewise displacing tincture of myrrh, and seems to be preferable for a mouth-wash.

The florets carefully dried and finely pulverised have been used as an absorbent and healing application to chafed surfaces, and one physician informed the writer that he preferred it to iodoform as a dusting-powder for slight wounds and abrasions.

Calendula Ointment.—The following formula yields a preparation very similar to that sold by the homœopathic pharmacists:

Take of—

Petrolatum	85·0 Grammes
Yellow wax	5·0 ,,
Paraffin	5·0 ,,
Fluid extract of calendula	5·0 C.c.

Melt the wax, paraffin and petrolatum, add the fluid extract gradually, and stir till cold.

Calendula Oil.—What is called calendula oil, or more correctly calendulated oil, is a soothing application to catarrhal surfaces, and is obtaining favourable notice and use among specialists in treatment of throat and nose as a final spray or dressing after the treatment with an aqueous liquid such as a Seiler's solution.

The following formula is submitted:

Take of—

Contused calendula	100·0 Grammes
Alcohol	75·0 C.c.
Ammonia water	2·8 ,,
Pure olive oil	1000·0 Grammes

Mix the alcohol and ammonia water and moisten the drug therewith. Then place it in a can or suitable container, add the olive oil and macerate for three or four days at a temperature of 60° to 70° C. with frequent agitation. Then express and filter.

Calendulated Collodion.—At the request of a physician friend, I have also prepared a calendulated collodion to be used as a substitute for isinglass plaster and adhesive plaster.

The following is the formula:

Calendula in No. 20 powder	100·0 Grammes
Alcohol, a sufficiemt quantity	
Castor oil	20·0 ,,
Ether	700·0 ,,
Pyroxylon	20·0 ,,

Percolate the calendula with alcohol until 200 C.c. of percolate is obtained. To this add the ether, and to the mixture add the pyroxylon and dissolve, and finally the castor oil and sufficient alcohol to make 1,000 C.c. and set aside for a few days to clear.

* From the *American Journal of Pharmacy.*

COMMERCIAL VOLUMETRIC INDICATORS.

BY F. H. KNIGHT.

A wide variation is to be found in certain common indicators used in volumetric analysis, as found in the market. This is particularly true of methyl orange, perhaps the commonest and most valuable of the indicators used. It is also known as Poirrier's Orange 3P., as Helianthin and Tropaeolin D. Of six samples from various sources, no two were equal in efficiency. One was absolutely worthless as an indicator. The indicator was tried both in simple aqueous solution and in solution water acidulated with diluted sulphuric acid, which neutralises any alkali which the dye may contain and causes a partial precipitation, afterward separated by filtration. In allcases the plain solution was more sensitive and to be preferred to the official acidulated solution.

The dyes varied in colour from a brilliant red to a dark brown. Those specimens having a brown colour, and most slowly soluble in water, proved to be the .most sensitive. On adding one drop of plain solution to 50 C.c. of water the liquids required from 1 drop to 4 C.c. of decinormal sulphuric acid to show a distinct red colour When the acidulated solutions were used, more was required to show the reaction plainly. None of the specimens were sensitive to carbonates, ammonia or organic acids, and all were weakened, as indicators, by heat.

Fenorescein and genorescin, which are used in titrating deeply-coloured liquids, were compared. But little choice is to be found with these, neither being sensitive enough for satisfactory use with decinormal solutions, though semi-normal solutions give the reaction plainly.

Cochineal was found to give particularly good results in artificial light. No difficulty was found in securing this agent in satisfactory condition, and the marked colour changes, which appear plainly in gaslight, make it an excellent indicator for this purpose. It cannot be used, however, with carbonates or organic acids. Litmus was found to be the best adapted for general all-round purposes. The efficiency of this agent depends upon the care with which the solution is prepared, since there is no difficulty in obtaining litmus of good quality in the market. It was found to react well with organic as well as inorganic acids, with ammonia and with carbonates in hot solution. No other indicator was found to possess so wide a range of power as this. The greatest disadvantage in it is the necessity for waiting a few moments at the close of the titration for the colour to become permanent, and its sensitiveness to carbonic acid in cold solutions.

But one sample of Brazil-wood was tested, though it is known that some difficulty exists in obtaining true Brazil-wood in the market. The sample tried proved satisfactory, but it was found that it was necessary to boil the decoction well before using. It cannot be used with carbonates, but it is sensitive to ammonia and organic acids, and is adapted for general use with these as well as with alkaloids. It is an extremely sensitive indicator.—*New England Druggist.*

Biological Reaction for Arsenic.—Bujwid finds that a culture of the mould *Penicillium brevicaulis*, grown upon potato at a temperature of 37° C., gives rise to a strong alliaceous odour in the presence of a minute trace of arsenic, such as would give a barely visible deposit with Marsh's test. The liquid to be examined, or in the case of a dry solid, a particle moistened with sterilised water, is placed in a tube with slices of boiled potato, and maintained at the prescribed temperature for 24 hours; in the presence of arsenic the odour of AsH_3 will be very marked in the course of a few hours.—*Union Pharm.*, **46**, 293, after *Med. Mod.*

EXTRACTS FROM CONSULAR REPORTS.

THE INHABITANTS OF TRIPOLI (Turkey) are reported to have no genius for inventiveness, to be averse to all innovation, and to cling with peculiar fondness to the simple dress and habits of their forefathers. Hence it is not surprising that in such a country industry should be backward. In addition to weaving, mat and basket making and the carpet industry, there is the soap industry, which, though occupying a much less important place than the others, turns out nearly all the soap which is consumed in the country. In the town of Tripoli itself there are five soapworks, all under the management of native Jews, which produce a coarse, cheap article of a light yellow colour. According to Vice-Consul Dickson it is made from caustic soda, silicate and carbonate of soda, talc, resin, cotton-seed oil and other seed oils. It is sold in large, hard rectangular tablets, and is used for all purposes except the bath and toilet. Toilet soap is imported from England, France and Italy in small quantities, and is also made by some of the natives. The soda and silicate which enter into the composition of soap is said to be all imported from Great Britain.

"MADE IN LONDON," printed in big letters, were the words Consul Hearn was astonished to see lately in a window of a Bordeaux shop, on the labels of articles generally supposed to be of French make. On examining the labels closely, however, he noticed in very small type at the bottom the name of the printer at Lyons, and he has no doubt that the articles were also made there. The best way to combat this fraud, the Consul thinks, is to make it known that there is evidently a demand in France for certain articles, such as ladies' garters and gentlemen's sock suspenders "made in London," when no doubt the real article will be soon offered for sale there.

RUBBER IS BEGINNING TO FORM a large item in the exports of the British Central Africa Protectorate, the value exported during the past year being over £10,000. As in other rubber-producing countries, great difficulties have been experienced in preventing rubber collectors from destroying the vine when collecting the juice. Regulations have been drawn up and forwarded to the home authorities for sanction, dealing with this subject; but in spite of all regulations and laws there will doubtless still be much unnecessary destruction of rubber vines. Collectors of districts are, however, endeavouring by every means in their power to prevent natives from destroying the vines and making root rubber. In the more southern districts of the Protectorate very little rubber is found, the bulk of the supply coming at present from Lake Nyasa and South Nyasa districts.

TOBACCO WAS ALSO EXPORTED from the Central Africa Protectorate last year, although only in small amount, the total quantity being 1,700 lbs., and, in the opinion of some, it is doubtful if that quantity will increase, at any rate within the next few years. On the other hand, Mr. John Mahon in a series of notes on the vegetable products exhibited at the Mlanje Agricultural Show, held in September, 1898, remarks that tobacco afforded indications of being a product capable of considerable extension in British Central Africa planting industries. Much credit, he thinks is due to the pioneers of tobacco culture there, and when they succeed in establishing an external market, for which they are earnestly striving, the advantage accruing to the country will be important.

GERMANS DON'T LIKE FOREIGN COMPETITION when it threatens to affect themselves; at least, such is the experience of Messrs. Lever Brothers, who, not content with introducing Sunlight (soap) into the homes of Great Britain, desired to extend their operations to Germany. No sooner was it known that the firm had acquired in a newly-opened section near the harbour of Mannheim, an area covering about 85,000 square metres for the price of about 425,000 marks, in order to establish there a large factory for their "Sunlight" specialties, than the Baden soap manufacturers at once forwarded a petition to the Diet asking for Government measures to be taken against the invasion of the Sunlight Soap Company. The petitioners speak of the "great concern," and fear ruin on account of this British competition. It is needless to say, observes Consul-General Sir Charles Oppenheimer, that the laws of the country offer no ground to

interpose in the manner desired by this petition. But it must be remarked in this connection that the German press always shows the greatest pleasure at the progress of German enterprise in foreign countries, but when an English enterprise is forced to open a branch in Germany, owing to the German customs laws, these newspapers are anything but pleased.

The Export of Liquorice Root from Batoum last year was more than double that of 1897, being 9,760 tons, as against 4,423 tons. The demand in the United States of America is reported to be steady at fairly firm prices, but the producers complain of the excessive rate of transport which the Trans-Caucasian Railway charges for the conveyance of the pressed bales from the liquorice root growing districts to Batoum. There are said to be large reserves of liquorice root along the railway line, certain difficulties having cropped up to prevent its being dug in sufficient quantities. These difficulties, however, are reported to have been more or less overcome, and there are prospects of a fairly large trade being done during the present year.

The Honey Crop in Germany last year, as in Great Britain, was a total failure, and yet the import trade in honey was not as satisfactory for merchants as they had hoped, the reason being, it is stated, the serious competition of artificial honey which, in spite of measures taken by the German Government towards putting a stop to the sale of imitations, seems to continue undiminished. The total quantities of honey imported at Hamburg from foreign countries last year was, however, larger than in 1897, and amounted to 2,775,000 kilos., as against 2,140,000 kilos. The principal countries whence honey is imported are Chile, Peru, St. Domingo, Cuba, and California.

When British Merchants require information from any part of Sicily,—and what applies to Sicily will apply equally to other countries—Consul S. Churchill states it will be best to make the enquiry through the Consulate, which will then obtain the information from the Vice-Consulates. It should be specially remembered, however, that to obtain a quick answer the enquiry should not be addressed to anyone by name, but to Her Britannic Majesty's Consul, in the care of Sicily at Palermo. Letters, it is stated, are too often addressed by name to a Consul who has already been transferred to another post.

The Sulphur Industry in Sicily.—Sulphur is one of the principal articles of export from Sicily, the extraction alone of this mineral, according to Consul S. Churchill, employing some 30,000 people. During the past two years the production of ore was 3,092,382 tons in 1897, and 3,163,146 tons in 1898. In the former year there were 642 mines in activity, whilst last year 695 mines were being worked, and it is expected that this year (1899) the total mines and output will again increase. The exports of sulphur in 1897 amounted to 427,823 tons, and in 1898 increased to 462,393 tons, the increase being principally attributed to the demands of the United States, owing to the war with Spain. The demand for sulphur in manufacturing wood-pulp and for treating vines was also greater. The stock of manufactured sulphur on hand at Palermo on December 31 last year was about 235,022.

The Prospects of the Sulphur Trade, Consul Churchill states, is a delicate subject to deal with; experts have their different points of view, but it may be safely said that there is too great a tendency to over-produce. Their own permanent welfare seems to be the last thing the Sicilian sulphur mineowners think of in comparison with immediate sales. The conditions of the leases of the mines have also much to do with this unsatisfactory state of things. When a leaseholder can only obtain a lease for ten years it is natural that he should hasten the output and its quantity as much as possible. The one thing which he wants is sulphur, and as much of it as possible. The royalty paid to the landowner is about 20 per cent. of the produce, and is said to be too great to enable the leaseholder to work the mine as it should be worked. When the ten years' lease is over the landlord takes back the property if the mine has been a producing one. It may be mentioned that the mining laws of Sicily differ from those in force in the rest of the kingdom of Italy.

The Sumach Trade is almost entirely a Palermo industry, and a combination is reported to have been formed to handle the output for the next five years, during which period the present good marks will have disappeared. The result promised to the industry is better prices for the crop, which will naturally be at the expense of the consumer. Consul Churchill thinks it is not at all unlikely that an attempt on the part of the sumach syndicate to force its prices on the market may result in the employment in the dyeing trade of materials which can be substituted for sumach. It is said that in the United States chrome is now being largely used where sumach was formerly employed. The total amount of sumach exported from Palermo in 1898 was 37,120,962 kilos., of which 14,927,124 kilos. was sent to Great Britain; of the total export 16,452,826 kilos. were unground sumach and 20,668,136 kilos. of ground sumach.

The Exports of Essential Oils from Messina (Italy) in 1898 were 5,903 cwts., value £239,600, against 7,854 cwts., value £318,959, the previous year. Of concentrated lemon juice 34,141 cwts., value £9,959, were exported last year, as compared with 54,674, value £14,486, in 1897. The quantity of olive oil exported decreased by more than half that of the previous year, being 27,753 cwts., value £61,932, as against 64,233 cwts., value £143,342.

Solfuro Oil is a product made from the residue of olives, from which the oil has been extracted, and is used in the manufacture of soap. In the Milazzo (Italy) district the works for the manufacture of solfuro oil employ about 200 hands all the year round. The waste, after the oil has been extracted, is used as fuel. The average annual production is about 1,000 tons.

A Society is being Formed, according to Vice-Consul C. F. Gray, in the Marsala (Italy) district for planting a nursery of American vines of different qualities, as the nature of the soil varies very much in the different districts of Marsala. The society is the result of an invasion by phylloxera, and members will be able to have the nature of the soil analysed where they intend planting American vines, and by this means they will get the proper species of vine adapted to the ground. Each member is entitled to a certain number of American vines at the cheapest possible price, according to the number of shares that he takes.

PHOTOGRAPHIC NOTES.

Useful Hint on Mounting—G. W. Tottem objects to the use of those slip-shod things, "Slip Mounts." His plan of mounting a print is to take a large glass (cutting shape, say), spread mountant, lay print down, rub well into contact, peel off, lay on mount and rub well down, which is as simple and quick in practice as it is to write. The advantages are that one's fingers do not get messed up, only enough mountant is left on print to make it adhere to card, no dirty edges, no finger marks on face, and, in the case of glazed prints, no backing. He can mount a 23 × 17 enlargement just as readily as a pocket Kodak print in this way; and so do those to whom he has shown the method. From practical experience of the method it can be recommended.—*Brit. Journ. Photog.*

The Persulphate of Ammonium Reducer.—As might be expected when a new reagent begins to come into common use, and particularly in a case such as the present, when the precise reaction is not perfectly understood and the conditions of its employment are not settled, there have been, at recent Photographic Society meetings, many exhibits of "failures" with the persulphate of ammonium reducer. Many of those, of course, have been of the usual type, due to carelessness of manipulation; but in the hands of well-known careful workers there have been occasionally curiously erratic results. Two distinct cases have been brought to our notice where the negative, after treatment, has shown by reflected light a mirror-like deposit of presumably reduced silver, while by reflected light a pink stain occurred in the gelatin, the effect being somewhat similar to the edges of a stale plate after development with pyro-ammonia. Several workers have reported a darkening of the plate after exposure to light in printing, but this can easily be accounted for as due to the formation of a salt of silver, sensitive to light, which had not been removed by washing or otherwise, or perhaps more likely still to the formation of a salt of silver which had combined with the gelatin and which was not removeable by ordinary washing. It seems clear that for safety some method of fixing should be adopted before the final washing. With a freshly-mixed solution of ammonium persulphate immersion in the ordinary hypo fixing bath would be efficacious, and would be attended with very little risk; but in using a solution

that has become acid, or to which acid has been added) and this has been recommended) there is a certainty that the hypo would be decomposed and a risk that sulphur resulting from the decomposition would be deposited in the film. Undoubtedly the safest method, and it ought to be adopted in heating a valuable negative, is to remove the negative from the persulphate bath to one of sodium sulphite. This acts equally well with hypo in stopping the reducing action, and at the same time its decomposition product, sulphurous acid, is innocuous. Sodium sulphite is in itself a fixing agent, though under any circumstances it acts more slowly than hypo, and it may prove that, after allowing the negative to remain a reasonable time in this bath, fixation will be complete, but this has not yet been investigated. To make certain the negative should be finally treated with the hypo bath and washed as usual.

SIMULTANEOUS DEVELOPMENT AND FIXATION OF GELATINO-CHLORIDE PAPER.—R. E. Liesegang points out that if gelatino-chloride paper be faintly printed out under a negative, and then placed in a bath which fixes it and at the same time develops it to full intensity, the only other operation would be the necessary washing afterwards. It is, moreover, not necessary to print to a given depth. The combined developing and fixing bath contains no gold salt; and, further, the bath is alkaline, so that sulphur toning is absolutely impossible. Although his experiments are not quite complete, he publishes the statement in order that others may try it. Some experiments in which fixation was attempted with sulphocyanides were without result; and even the addition of an alkaline dry-plate developer to the hypo bath caused no blackening of the exposed parts. The desired result has now been obtained by adding silver nitrate to the bath. But even a mixture of silver nitrate, hypo, and a developer such as is used for dry plates, worked only very slowly, the print had to be left in it at least the whole night. A developer which would give the print the necessary vigour in a short time was only formed when amidol and caustic potash were added to the solution of silver nitrate and hypo. The print first fixes in it, and then in about a quarter of an hour attains the necessary depth. The disadvantage that amidol, pyro, etc., lose considerably in developing power by the addition of a large quantity of hypo is very noticeable. The accelerating action which the addition of small quantities of hypo exerts in dry-plate development does not lead one to expect this. If amidol is mixed with an alkali, the red and blue oxidation products are very quickly formed. In the presence of hypo this does not take place; pyro even does not colour so quickly. It is even possible to decolorise a deep blue-coloured mixture of amidol and alkali by the addition of hypo. The bath used consists of :—

Sodium hyposulphite	31 parts.
Water	150 „

This is mixed with :—

Silver nitrate	3 parts.
Water	100 „

The precipitate first formed readily dissolves by shaking, and then there should be added :—

Amidol	1 part.
Sodium sulphite	5 parts.

When solution is effected, add as much 10 per cent. solution of caustic potash solution to make the solution slightly greenish; about 25 parts will be necessary. This bath is suitable for the development and intensification of dry plates.—*Camera Obscura*, through *Brit. Journ. Photog.*

ANALYTICAL NOTES.

DETECTION OF SACCHARIN IN AERATED LEMONADE.—50 C.c. of the lemonade is evaporated, after the addition of 2 or 3 drops of solution of sodium carbonate, to a syrupy consistence; the residue is acidulated with HCl, then shaken out with ether, 20 C.c. On evaporating the solvent the residue will have a characteristic sweet taste if saccharin be present. This residue is then gently heated in a small silver crucible with a little pure caustic potash, so as to decompose the saccharin without destroying the potassium salicylate formed. If after the evaporation of the water small bubbles of vapour are given off, these are due to ammonia, as may be demonstrated with turmeric paper, or with paper moistened in Nessler's solution, or with sodium hypobromite. The crucible is then three parts filled with water, acidulated with HCl; the acid solution is extracted with pure benzene. In the decanted benzene solution a drop of ferric chloride will give a violet colour in the presence of saccharin in the original liquid, and in the aqueous residue the presence of sulphuric acid may be proved with $BaCl_2$.—*Repertoire*, **11**, 306, after *Bull. de la Soc. de Pharm. de Bord.*

SIMPLE METHODS OF DETECTING GOLD IN MINERALS.—About 100 Gm. of the finely crushed mineral is put in a bottle, and about an equal weight of tincture of iodine is added. The mixture is thoroughly shaken up several times for an hour, and then allowed to deposit. A strip of filter paper is then dipped in the clear liquor, dried, and again soaked and dried, six times in all. It is then burnt; if there be any gold present, the ash obtained will be of a reddish purple colour, which will disappear immediately on contact with a drop of bromine water. A second method is to treat the mineral as described above with bromine water; after standing for an hour and filtering, the addition of stannous chloride to the filtrate will give a precipitate of purple of Cassius in the presence of gold. According to J. Ohly, these tests will show the presence of 0·025 ounce per ton of ore. Ores which contain sulphur should be roasted before treatment, also those which contain a large excess of carbonate, the latter being again gently heated with a little ammonium carbonate.—*Engineer and Min. Journ.*, 1899, 499.

NEW REMEDIES.

ASTEROL AND HYDRARGYROL.—Asterol is a double salt, mercury parasulphocarbolate-ammonium tartrate. It possesses advantages over hydrargyrol, which is mercury parasulphocarbolate, in being readily soluble in warm water, giving solutions which remain clear. Hydrargyrol occurs in crystalline scales or crusts which have a peculiar gingerbread odour. When treated with water it forms basic salts. To avoid this decomposition the salt is combined with ammonium tartrate. The double salt asterol thus obtained which is represented by the formula—

$$([C_{12}H_{10}O_8S_2Hg].\ 4(C_4H_4O_6(NH_4)_2)8H_2O,$$

is perfectly soluble and stable in aqueous solutions. F. Steinmann recommends asterol as a substitute for sublimate, and, in many cases, for mercury oxycyanate, on account of this solubility. Its bactericidal action is very penetrating, and is maintained even in albuminous solutions; it is non-irritant. Asterol is an excellent disinfectant for the hands; instruments are not affected by its use. Although it is poisonous, as demonstrated on animals, no apparent danger results after its extensive local application as an antiseptic. *Schweiz. Woch für Pharm.*, **37**, 717.

TRIBROMO-RESORCIN is a powerful antiseptic and bactericide, properties which are not, however, shared by its sodium salt. It is stated to be but slightly toxic when introduced into the stomach, and, when injected, it accelerates the pulse and causes depression of the nervous system, and a fall of temperature.—*Pharm. Post*, **32**, 197.

VASOTHION.—This is an organic preparation containing over 10 per cent. sulphur, similar to thilanil, thiosapol, and thiosavonal. It is obtained by combining sulphur with vasogene. It is used in ointments of iodine, iodoform, creosol, or creoline for the treatment of chronic eruptions and eczema.—*Pharm. Post*, **32**, 197.

CITRIC ACID FOR OZENA.—Hamm states that citric acid mixed with equal parts of milk sugar, applied by means of an insufflator three times a day, is an active deodorant, and exerts a marked healing effect in cases of ozena.—*Therapist*, **9**, 166, after *Münch Med. Woch.*

CHRYSAROBIN FOR WARTS.—G. W. Fitz has successfully used chrysarobin in 10 per cent. solution in solution of gutta-percha, or in simple ethereal solution, as an application to warts on the feet. The wart is first scraped, or scoured with sandpaper until it bleeds, then treated with the chrysarobin application. It has practically no effect on corns.—*Bost. Med. and Surg. Journ.*, **150**, 633.

PHENOCOLL HYDROCHLORIDE IN INFLUENZA.—Having used phenocoll hydrochloride in 400 cases of influenza during a recent epidemic of that disease in Bologna, G. Villani has found it to be a specific. It was given to adults in daily doses of 3 Gms. For children only 1 Gm. per diem was prescribed. It was well tolerated, and all the symptoms of the malady rapidly disappeared under its influence. Being antithermic, analgesic, and antiseptic, it has proved a most successful remedy in all cases.—*Nouv. Rem.*, **15**, 299.

LETTERS TO THE EDITOR.

Mistura Ferri Aromatica.

Sir,—Although this preparation is omitted from the British Pharmacopœia, there is reason to suppose that it will occasionally be prescribed, and the provincial chemist who is called upon to fill a prescription for it may welcome the following attempt to construct a formula which admits of being speedily compounded. Very few patients in this age of rush and hurry will submit to waiting the three days required to make this mixture according to the whilom official directions. If made as follows it can be completed within an hour, and the product is certainly not below the orthodox standard in strength and aroma. Set on infusum caryophylli, Oss.; while it is macerating rub up ferri carbonat. saccharat., ʒi., with 2 fl. drms. of distilled water and warm gently; add extract. cinchon. liquid., ʒi.; transfer to a bottle and shake well. Dissolve ferrum tartaratum, ℈i., in aquæ destill., ʒvi., and add to the bark and iron; then, liquor calumbæ concent., ʒi.; tinct. cardam. comp., ʒiii.; tinct. aurantii, ʒss.; shaking after each addition. Strain the infusion of cloves into the mixture, and after agitation strain the whole; add aq. menth. pip. concent. (1-40), ʒiiss.; aquæ destillat. ad ʒxvi.

Dover, August 19, 1899. J. F. Brown.

The Present Pharmaceutical Position.

Sir,—Your admirable synopsis of the pharmaceutical position concludes with this statement, "But, first of all, and in any case, it is essential that the Council should receive much more coherent support,—even from the Society, which is still the minority—that chemists collectively should show they are capable of agreement on principles and of being led in defence of their rights, not only as vendors of Mother Siegel's syrup and Beecham's pills, or even as licensed sellers of poisons, but as possessors of a qualification by which they are entitled to practise pharmacy. That result must be achieved if the rank and file of registered chemists are not to become mere tools of the company monger." Your summary well touches off, for those who will see the very strong case, the irresistible claim we can make, in the public interest, to the Legislature, that pharmacy shall have a rational footing. It also indicates generally what strong forces can be brought to support pharmacists in their eminently just claims. I beg to suggest, however, that in the paragraph quoted above you put the cart before the horse. It should read "But, first of all, and in every case, it is essential that the Council should state its claims and its general policy, certainly stating its definite object, then chemists collectively would show they are capable, etc." I beg earnestly to ask chemists in all parts of the country, whether they be men who think or those who are satisfied to have their thinking done for them, to read this leader, this brief but admirable summary. If they will further trouble to do this in connection with editorials which have appeared through many months, I venture to say many would have a better appreciation of the important position the pharmacist should have in the economy of the State and of the importance of pharmacy as a branch of the healing art. When I say it is the Council's duty to declare a tangible policy, it may appear that more is asked for than discretion or prudence can allow. As to that, I would like to remark that the natural direction of a stream is the water bed. We have the right to ask the Council now which, in their opinion, is the direction a natural stream of pharmacy would flow, and we should have a diagram.

Blackburn, August 19, 1899. R. L. Gifford.

Syr. Glycerophosph. Co. (Robin).

Sir,—In the middle of June I made 60 ozs. syr. glycerophosph. co. (Robin). I dissolved the calcium, magnesium, and iron salts in 12 ozs. of water containing 60 grs. acid citric. I then added 24 ozs. syrupus (B.P.); then the sodium and potassium salts; then the pepsin (as glycerole); then the trs.; and lastly the diastase, rubbed smooth with an ounce of syrup—shaking after each addition, and finally making up to 60 ozs. Two days afterwards an opalescence crept through the syrup and it gradually increased till it seemed as if all the pepsin or diastase (judging by the colour) had been precipitated. Repeated shaking during a week made no change. The addition of an additional 3 grs. of acid citric to one (separated) ounce had no apparent effect; neither had the addition of ½ drm. of glycerin to another ounce. (Merck recommends citric acid as a solvent in making liq. calc. glyceroph.; and glycerin to prevent precipitation of fer. glycerophosph. in making vin. fer. glyceroph). No heat was used in making the syrup. That is my case. Information on the following points will be esteemed a favour: 1. What is the cause of the precipitation? 2. What is the precipitate likely to consist of? 3. Can it be remedied? 4. Can it be prevented? The syrup after standing undisturbed for six weeks has only become bright in the upper third, the precipitate seems to be too much of a magma and too light to fall further.

August 17, 1899. T. D. (199/15).

*** Carles nas recently advocated the use of the soluble acid glycerophosphate of lime in the preparation of the syrup instead of the commercial neutral salt, since it is more stable and very soluble. It is obtained by suspending the neutral salt in water, adding sufficient oxalic or tartaric acid to precipitate half an equivalent of the lime, and then filtering out the calcium oxalate or tartrate. He finds that solution of glycerophosphates are particularly liable to give rise to fungoid growths. This, he states, may be prevented by the addition of cinnamon water or, better still, of cherry-laurel water. [Ed., *P. J.*]

Dr. Jekyll and Mr. Hyde.

Sir,—In his latest utterances upon matters pharmaceutical, the Lord Chancellor spoke not one word with which qualified men will disagree. The astonishing thing is, that a man who sees matters so clearly and balances the scales of justice so evenly in his public utterances should ever have lent his name in support of the suggestions which appeared in the Companies Act Amendment Bill. We can only come to the conclusion that the speeches are made by Dr. Jekyll and the Bills draughted by the man Hyde. It appears to me that whilst we are taking full advantage of the exceedingly helpful speeches of Jekyll, it is absolutely necessary that we keep rather more than half an eye on Hyde. The Lord Chancellor delivered a speech a year or two ago (very similar to last week's speech) which sent every chemist in the country into ecstasies, and we know how it was followed up. That speech so fascinated chemists that they left their case entirely in the hands of the Lord Chancellor, and he, having succeeded by this means in disarming opposition, almost succeeded in carrying a Bill which would have handed qualified men over to unqualified slavery for all time coming. It was not the opposition of chemists which prevented this, but circumstances connected with our Parliamentary machinery. The Bill is not withdrawn, nor are the Lord Chancellor's suggestions in regard to pharmacy cancelled. Does the Lord Chancellor think that by administering a further dose of opium in the form of a speech he will so confuse us that we will forget about the doings of the man Hyde? If chemists allow themselves to be soothed to sleep by the Lord Chancellor's speeches this Bill handing them over to slavery will pass, and nothing can prevent it; but if they have learned to distrust the Lord Chancellor thoroughly and stand on their own resources it will never pass. Of course, it is possible that the Lord Chancellor is converted a second time, but is his latest conversion any more genuine than his former conversion was? Of course, if he were heart and soul on our side, his help would be invaluable, but what could weaken our position more than the existence of a man so highly placed who argues in our favour and fights in favour of our enemies? We get the words, and the enemy get the real help, and we will have none of it. We are quite able to fight for ourselves. Our position is immensely better understood now than it was five years ago—better understood by ourselves, and better understood by the general public. We now dare to say that we are not fighting for a monopoly, and five years ago this was looked upon as heresy—we now dare to say that we have certain rights under the Pharmacy Act of which we have been defrauded, and five years ago the man who dared to make this statement was as the voice of one crying in the wilderness. What is more is, that the educated public are awakening to the injustice under which we suffer, and all the professions are awakening to the fact that our fight is theirs. Victory all along the line is drawing nearer every day, and we do not need to fall back upon the help of so doubtful a friend as the Lord Chancellor. What we need to do is to go on organising our forces, schooling our members of Parliament, formulating our ideas into compatible workable order. We need, also, to be better prepared for the Lord Chancellor during the coming year than we were during this one, should he make any further attack on us. We will be fools indeed if we allow ourselves to be hoodwinked twice.

Dumfries, August 21, 1899. James Reid.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Botanical (J. W. H.—33/1).—*Sium angustifolium.*

Botanical (T. J.—31/22).—(1) *Ambrosia trifida* (Compositæ). (2) *Populus balsamifera.*

Books for the Major Examination (J.. H. B.—33/3).—A list will be given in our Students' Number, which will be published on September 9 next.

Sanitary Inspector's Examination (J. A. L.—33/8).—Write to the Secretary of the Sanitary Institute, Parkes Museum, Margaret Street, London, W.

Metol Hydroquinone Developer (W. B. R.—32/33).—The veiling is due to over-exposure of the plate, and the only thing to do is to add about 1 grain of potassium bromide to 1 oz. of the developer.

Packages for Oils (M. A.—32/9).—The capacity of the barrels is fairly constant, and the wholesale dealers will inform you what they contain. Any standard work on arithmetic will give the information you require about pipes, tuns, etc.

Allegorical Figures (B. H.—33/4).—We regret we are unable to give figures of the kind you require. As to the Pharmaceutical Society's coat of arms, that may not be used by any one without permission from headquarters.

Acetylene Generator (T. K.—32/19).—For safety, ease, and economy in working you would find the "Incanto" Generator, Pattern B, No. 2, as good as any. It is made by Thorn and Hoddle, New Tothill Street, Westminster, who also supply a purifier and the "Incanto" non-carbonising burner.

Royal Arms (W. N. G. L.—33/5).—According to 46 and 47 Vict., c. 57, sec. 106, any person who, without authority, assumes or uses in connection with any trade, etc., the Royal Arms, or any resemblance thereof, shall be liable on summary conviction to a fine of twenty pounds.

Notice to Quit (G. H. G.—33/7).—A quarter's notice would appear to be necessary. Where no agreement has been entered into or stipulation made as to repairing, a tenant can be compelled to repair damage caused by himself, but he is not bound to make good mere wear and tear. You ought to have a proper agreement drawn up by a solicitor or a friend experienced in such matters.

Sale of Ferrocyanides, etc. (P. W.—33/12).—Inasmuch as ferrocyanides and ferricyanides are not mentioned in the list of poisons within the meaning of the Pharmacy Act, there is no occasion to observe any formalities in retailing them. At the same time, registered chemists may find it advisable to treat them—together with carbolic acid and many other dangerous substances—as though they were included in Part 2 of the list of poisons.

Lawn Sand to Kill Plantains (T. T. C.—32/28).—A mixture of ammonium sulphate, 65, and fine sand, 35, is used for destroying plantains on lawns. See *P. J.* [4], **5**, 100. Try this and let us know if it is effective. A correspondent of the *Gardeners' Chronicle* [3], **26**, 114, finds that the best way to get rid of *Hypochæris radicans*, and probably other weeds, is to drop a few minims of strong sulphuric acid on the crown of each plant. Probably the ammonium sulphate mixture would answer as well, and would be harmless to the grass. Let us hear if you succeed with it.

Concentrated Infusions (J. B.—32/34).—As a general rule these may be prepared by the method of successive percolation, using eight times the quantity of the drug required for the simple infusion and a weak alcoholic menstruum, about 65 under proof. Some drugs, such as calumba, give better results by successive cold maceration in water, followed by evaporation, and the final addition of spirit. Gentian should be treated by hot maceration and expression, the second maceration only being evaporated. The orange and lemon is best added to this in the form of a strong tincture (1:2) of the fresh peel in alcohol.

To Destroy Flies (J. N. B.—32/26).—A number of formulæ were published in the *Pharmaceutical Journal* for July 29 (p. 86) and others appeared in the issue for August 5 (p. 147). It is said that house flies and blue bottles may be kept away by fresh bay leaves. If you can procure them, you might try this remedy: the bay should be kept fresh in water, and some of the bruised leaves spread on the floor. Oil of bay leaves is also used, but is a somewhat costly remedy. Possibly eucalyptus oil sprayed over the room at night might have the same effect. Flies do not like a draught: by opening doors and windows freely they may be greatly reduced in numbers. Probably you have stables near at hand; the larvæ of the common house fly feeds in stable litter and horse dung. Doubtless the beer is an attraction to them. Burning the following pastilles in the rooms will also drive them away. Insect powder, in moderately fine powder, 240; potassium nitrate, 25; water, 300; Dissolve the nitre in the water and thoroughly damp the insect powder with the solution, and dry. Then make into a stiff paste with tragacanth mucilage and shape into cones. Dry thoroughly (in a cool oven will do). For sticky fly paper use the following:—Bird lime, 6; castor oil, 7; honey, 3; yellow resin, 11. Melt the resin in the oil, and add the bird lime to the hot mixtnre; lastly, add the honey. A fly poison which is harmless to animals is made of decoction of quassia (1·10), 25; moist sugar, 6; and ground pepper, 3. Spread about on plates with blotting paper. Potassium bichromate solution may be added to the above, if desired. Powders for strewing about the rooms and on the window sills where flies are troublesome, are composed of (1), Powdered long pepper, 5; powdered quassia, 5; powdered sugar, 10; mix, moisten with 2 parts of methylated spirit and 2 parts of water. Dry and sprinkle about. (2) Powdered orris root, 2; starch powder, 15; eucalyptus oil, 1; mixed and used as above. Or, (3) Eucalyptus oil, 5; French chalk, 10; starch powder, 85.

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Bailey, Balkwill, Barlow, Brown, Cannon, Dadderidge, Dunlop, Eberlin, Elborne, Gare, Gifford, Hall Hardy, Harries, Heath, Herbert, Hurst, Lance, Lander, Lindley, Fritzche, McHattis, Mackie, Reynolds, Rhoden, Robb, Sawdon, Want, Webster.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

ISOMERIC CHROMIUM ACETATES.

According to A. Recoura there are four isomers of chromic acetate—normal chromic acetate, violet mono-acid acetate, violet di-acid acetate, and green mono-acid acetate. He considers that only one of these, the normal acetate, is an ordinary metallic salt, in the others the chromium is not precipitated by an alkali, since it exists, not in a basic form, but as an acid radicle. Since the normal acetate rapidly passes, in aqueous solution, into the other forms, it is prepared in the solid form by treating chromic hydrate with an equivalent of glacial acetic acid and drying the crystalline acetate thus formed. This normal acetate is a greyish lilac substance, giving a yellowish green solution in water, which, however, soon passes into the violet or abnormal di-acid acetate. To obtain the mono-acid acetate the violet aqueous solution of normal acetate is evaporated spontaneously over sulphuric and glacial acetic acids. A crop of small, brilliant violet crystals results, which although they have the same ultimate composition as the normal acetate, $Cr(C_2H_3O_2)_3H_2O$, differ from that body in their characters. Exposed to the air they gradually lose a molecule of acetic acid; with alkalis in the cold no precipitate of chromic hydrate is produced, and of the three acid radicles in the molecule, only one can be replaced either by acids or alkalis. Calorimetric experiments show that, when neutralised with soda, nearly the thermometric equivalent of one molecule of acetic acid is obtained. The constitution of the violet chromic acetate is therefore $Cr(C_2H_3O_2)_2C_2H_4O_2$ which acts as a monobasic acid giving, with sodium hydrate, for instance, the salt, $Cr(C_2H_3O_2)_2C_2H_3NaO_2$. It is, in fact, chromo-mono-acetic acid. Cryoscopic experiments confirm this hypothesis.—*Comp. rend.*, **129**, 208.

CHROMO DIACETIC ACID.

The violet di-acid abnormal chromium acetate or chromo diacetic acid, $Cr(C_2H_3O_2)(C_2H_4O_2)_2$ is obtained, according to A. Recoura, by allowing the solution of normal chromium acetate to stand for a few hours. That this is the constitution of the acid is shown by the fact that it requires two molecules of soda to neutralise it, and that no chromium is precipitated by alkalis. The cryoscopic results show that the resulting molecule must have the constitution $[Cr(C_2H_3O_2)](C_2H_3NaO_2)_2$. This chromo diacetic acid has not yet been isolated in the solid state, since, as previously shown, where its solutions are evaporated, it rapidly passes into chromo-mono-acetic acid.—*Comp. rend.*, **129**, 288.

GREEN CHROMO-MONO-ACETIC ACID.

By prolonged keeping, the violet solution of chromic acetate gradually assumes a green colour, due to isomeric change. The same is readily effected by boiling solutions of chromic acetate with acetic acid, and is obtained on spontaneous evaporation as a green solid, having the composition $2[Cr(C_2H_3O_2)_3]H_2O$. It is regarded as a polymer of the violet chromo-mono-acetic acid, acting as a monobasic acid having the constitution $[Cr_2O(C_2H_3O_2)_4](C_2H_4O_2)_2$.—*Comp. rend.*, **129**, 290.

CONSTITUENTS OF OIL OF LEMON-GRASS.

F. Tiemann finds that lemon-grass oil contains from 73 to 82 per cent. of citral, and only traces of citronellal, together with 1·2 to 3 per cent. of methyl-heptenone and a little geraniol.—*Berichte*, **32**, 830.

ISOPULEGOL IN CITRAL.

The same investigator in submitting a commercial sample of citral to his method for the separation of that aldehyde, by shaking it with sodium sulphite in an atmosphere of CO_2 has obtained a residue which proved to be isopulegol. It remains to be seen if this is an impurity, or the result of chemical action on citral.—*Berichte*, **32**, 825.

CHARACTERS OF CROTON OIL.

As the result of an exhaustive examination of specimens of croton oil, W. Dulière gives the following characters as distinctive of the pure official article:—Sp.g. at 15° C., 0·9437; at 100° C., 0·8874. Co-efficient for correction for each, 1° C., 0·000657; solubility in alcohol (92 per cent.), 1 : 63; Burstyn's acid number, 21·7; total acid number, 215·6; consistence of soap, soft; solidifying point of fatty acids, 16·4 to 16·7° C.; Reichert-Meissl number, 12·1; iodine absorption number, 100·37 to 101·91 in 2 hours, 103·63 to 104·30 in 12 hours; iodine absorption number of fatty acids, 111·23 to 104·39 in 2 hours; acetylation number, 38·64. Oil extracted with good petroleum ether and cold-pressed oil agrees in these particulars with the ether extracted oil of the Codex. Oil obtained by hot pressing or by ether from non-decorticated seeds differs in colour, in acidity, and in solubility in alcohol, but agrees in its chief chemical characters.—*Journ. de Pharm. d'Anvers*, **55**, 294.

ODOROUS PRINCIPLE OF JASMIN.

According to A. Hesse and F. Müller, the so-called jasmal of Verley is not the odorous principle of essence of jasmin obtained by enfleurage; they have been unable to find in it any trace of that body or any other aldehyde of phenylglycol. They state that the essence contains the acetates of benzyl and linalyl but that the odour is not primarily due to these bodies but to substances not yet isolated, which exist in the proportion of 25 Gm. in 1,000 kilos. of the oil, the nature of which they are investigating.—*Berichte*, **32**, 568.

PURIFICATION OF ACETYLENE.

The use of solutions of certain metallic salts for the purification of acetylene so as to remove phosphoretted hydrogen, the most obnoxious impurity, requires the presence of an acid to prevent the formation of explosive acetylides. The addition of an alkaline chloride, more particularly ammonium chloride, has been found by C. Göttig to materially increase the effective power of the purifying solution, whilst the presence of an acid is unnecessary.—*Berichte*, **32**, 1879.

MALIC ACID BACILLUS.

A pure culture of the microbe having the property of converting malic acid into succinic and acetic acids has been isolated by O. Emmerling. It had all the characters of the *Bacillus lactis aerogenes* of Escherich. Its action on malic acid is almost quantitative according to the equation; $3C_4H_6O = 2C_4H_6O_4 + C_2H_4O_2 + 2CO_2 + H_2O$.—*Berichte*, **32**, 1915.

DETERMINATION OF FORMIC ALDEHYDE.

The characteristic hydrazone which is produced by the interaction of diphenylendihydrazin hydrochloride and formic aldehyde is suggested by C. Neuberg for the detection and determination of formic aldehyde. One drop of the reagent gives a fine yellow precipitate with formic aldehyde, and will detect 1:5000. Other aldehydes or ketones in this dilution give either no precipitate or one which is readily soluble in alcohol. This test is said to be more characteristic than the phloroglucin and resorcin tests, which are not peculiar to formic aldehyde. For the determination of formic aldedyde, the dilution of the aldehyde should be 1:1000, and the precipitation carried out at 50-60° C. The precipitated hydrazone is washed with hot water, then with alcohol and ether, and dried at 90° C.—*Berichte*, **32**, 1961.

DETERMINATION OF GOLD.

A solution of auric chloride when warmed with an alkaline solution of hydric peroxide is immediately reduced to metallic gold, and this reaction, according to Vanino and Seeman, serves as a more ready means of determining gold than by precipitating with ferrous sulphate or oxalic acid, both of which take some hours to ensure complete precipitation. It is even better than formic aldehyde. Gold can also be separated in this way from platinum and iridium, which are not precipitated by alkaline hydric peroxide.—*Berichte*, **32**, 1968.

THE INVERSION OF CANE SUGAR IN OFFICIAL (U.S.P.) SYRUPS.*

BY F. W. HAUSSMANN

Syrup of hydriodic acid was the first preparation in which large quantities of a sugar reducing Fehling's solution were noticed. Further investigation revealed, however, that the changes to be described were not confined to this syrup, but that others, containing strong mineral acids, showed the same conditions on prolonged standing. The researches were consequently extended, and other syrups, which developed marked colour changes or heavy deposits without any apparent cause, were also examined. Such were syrup of calcium lactophosphate and syrup of the phosphates of iron, quinine, and strychnine.

The syrups mentioned change in colour, gradually turning anywhere from a straw colour to brown, which in the case of syrup of hydriodic acid is usually attributed to the liberation of free iodine. Such is, however, not the case. In an examination of a number of specimens of this syrup, which varied in colour from light straw to deep brown, and in age from six months to two or even three years, not one was found to give a free iodine reaction. Similar conditions prevail in the other two syrups mentioned.

I would offer the following explanation of this colour change:— The free acid will invert the cane sugar in the syrup, with formation of glucose and laevulose. The latter, according to Jungfleisch and Grimbart, decomposes much more readily than glucose, a pure solution turning yellow at 40° C. Prolonged action of mineral acids also decomposes laevulose, with formation of formic and laevulinic acids, together with the indefinite colouring compounds, which the Germans describe under the title of "humin substances." That high temperatures have a certain influence on the production of these colour changes was illustrated during the hot days of the past summer. Samples of syrups of hydriodic acid and calcium lactophosphate, which remained colourless through spring and early summer, in July and August almost simultaneously became straw coloured to brown. Syrups, thus inverted, will gradually deposit grape sugar. This takes place more readily in winter, as the higher summer temperatures will keep the glucose in solution. I found this to be the case with syrups of hydriodic acid, calcium lactophosphate, and syrup of the hypophosphites prepared according to Churchill's formula.

The deposit in a specimen of syrup of hydriodic acid, after being washed with small portions of water and alcohol to remove the acid, was dissolved in boiling alcohol, filtered while hot, and allowed to redeposit. The white warty mass thus obtained has a feebly sweet taste, is readily soluble in water, and strongly reduces Fehling's solution. It responds to all other reactions for grape sugar, and estimated with the alkaline cupric tartrate V. S. gave an anhydrous glucose percentage of over 75.

In the proceedings of the American Pharmaceutical Association of 1893, some observations of Kulisch are recorded on the inversion of beetroot sugar in the presence of natural fruit acids. He also finds grape sugar to deposit from such syrups on standing, and attributes it to the minor solubility of glucose in water.

Another result of cane sugar inversion in acid syrups is the diminished degree of sweetness. In preparations containing no bitter principles this is readily noticeable, and may be found in syrups of hydriodic acid and of Churchill's hypophosphites.

After examination of the official (U.S.P.) syrups containing free mineral acids, those with organic acids were likewise subjected to investigation and also gave indication of the inversion of the cane sugar, although not in as pronounced a degree. In both cases it was found that inversion is progressive, and that at short intervals the respective examinations revealed a relatively greater amount of inverted sugar from the percentage previously found. It was also observed that inversion progresses more rapidly in summer than winter.

*From the *American Journal of Pharmacy*.

The researches undertaken may be considered under the following heads:—

(1) Syrups with free mineral acids.
(2) Syrups with free organic acids.
(3) Syrups without free acids.

Syrups with Free Mineral Acids.

These are syrups of hydriodic acid, calcium lactophosphate, phosphates of iron, quinine and strychnine, and hypophosphites.

SYRUP OF HYDRIODIC ACID.

This preparation may be found in time to possess all the peculiarities resulting from cane sugar inversion from the assumption of a straw colour to a grape sugar deposit. The peculiar odour sometimes noticeable may, on the one hand, be due to the decomposition of the hypophosphorous acid present, but results in the majority of cases from the evolution of hydrogen sulphide from blued sugar. The progressive inversion of cane sugar in this preparation was repeatedly studied, and the following examples, one carried out during winter, the other in summer, are hereby submitted.

Syrup of hydriodic acid was prepared in March of the present year by the official process from simple syrup prepared by cold percolation from carefully selected granulated sugar and distilled water. The latter was examined with Fehling's solution as to the amount of inverted sugar, and was found to contain between 0·33 and 0·5 per cent. Immediately after completion the syrup of hydriodic acid was examined, and no increase in the inverted sugar percentage found. After standing twenty-four hours a noticeable increase was shown, which, on estimation, proved to be 15·1 per cent. Two weeks after preparation the percentage found was 62·5, calculated as glucose. After standing for over six months with exposure to summer heat, the syrup became straw coloured, contained no free iodine, and revealed almost the identical inverted sugar percentage of the previous examination.

During the warm days of August of this year a number of specimens of the syrup were prepared. The following example is selected from these:—The syrup was prepared by agitation without heat, the sugar being dissolved in an aqueous solution of hydriodic acid, showing after one hour's standing 1·5 per cent. of inverted sugar. Forty hours afterward it was found to contain 43·8 per cent. A subsequent examination, when the syrup was five days old, showed 62 per cent., and after one month approximately the same percentage was found.

A tally was kept on this preparation with a specimen of syrup, also prepared by agitation, containing 10 per cent. by weight of glycerin. This was done to determine if the presence of glycerin retarded the inversion of the cane sugar. Such was found not to be the case, the inversion also being progressive, eventually showing almost the same percentage of glucose as in the corresponding sample.

A number of specimens of the syrup prepared by the writer and obtained from other sources were also examined. The following table furnishes the record of the coloured syrups as to age and percentage of inverted sugar:—

Colour.	Age as Far as Known.	Per Cent. of Inverted Sugar Calculated as Glucose.	Remarks.
1. Straw	9 months.	58·4	
2. Brown	2½ years.	50·	
3. Straw	10 months.	59·5	No free iodine in any of these specimens
4. Brown	2 years.	58·1	
5. Straw	6 months.	61·7	
6. Brown	20 months.	55·4	

SYRUP OF CALCIUM LACTOPHOSPHATE.

This preparation shows changes similar to syrup of hydriodic acid, gradually becoming straw coloured, which may deepen to brown on prolonged standing, and not infrequently grape sugar

deposits may be found. The gradual inversion of the saccharose was observed in a syrup prepared in midwinter, the change being due to the low temperature, somewhat slow. The syrup was prepared according to official directions, four to five hours being required for completion. Immediate examination gave evidence of but a slight amount of inverted sugar, which was not materially increased during twenty-four hours. After three days, however, 2·8 per cent. was found; after one week, the syrup still being kept at a low temperature, the figure was 4·9 per cent., which was increased after sixteen days to 12·7 per cent. Gradual increases were found at various intervals during the following fifteen days, and after one month's standing 20·0 per cent. were found.

During the following six months the syrup retained its original colourless condition, until the heat of summer caused it to assume a straw colour, which gradually deepened. Examined after standing eight months, the syrup showed an inverted sugar percentage of 54·9. Another specimen, prepared fourteen days afterwards, examined at intervals, also showed progressive inversion, passes through the same colour changes, and after eight months contains 56·8 per cent. of inverted sugar. A brown, commercial sample of the syrup, about one year old, showed a percentage of 49.

SYRUP OF THE PHOSPHATES OF IRON, QUININE, AND STRYCHNINE.

The difficulty of preserving Easton's syrup is well known, various reasons having been advanced for the discoloration and precipitation taking place. The chief criticisms have come from British sources, and several recommendations for improvement, such as decrease in the amount of sugar and free acid, have been made. In a subsequent paper the writer will render his experience with this preparation. At present he would state that he believes the discoloration to be chiefly due to the inversion of the cane sugar with formation of brown side products, induced by the phosphoric acid.

The inversion of the cane sugar was also found to be progressive in the following instances:—The syrup was prepared according to official directions, employing simple syrup showing 0·33 per cent. of inverted sugar. Seven hours after completion this was found to have increased to 1·95 per cent., and the increase was continued during three months, at the expiration of which the percentage found was 50. This syrup was kept during the summer in filled, amber bottles, away from light, but subjected to heat, and an examination in early fall found it to be dark brown, and containing approximately the same inverted sugar percentage.

Simultaneously with the foregoing Easton's syrup was prepared by a modification of the official methods, in which sugar was directly employed and dissolved by agitation in the acid alkaloidal solution. Four days after preparation the percentage found was 19·2, while when twenty days old the syrup contained 43 per cent. On four months' standing the syrup contained 56·8 per cent., and three months later the now brown syrup showed a slight reduction from the last figure.

Other syrups examined were found to contain 54·9 and 56·4 per cent. of inverted sugar after standing two months with exposure to summer heat. A dark brown specimen, about ten months old, was found to contain 50·4 per cent.

SYRUP OF THE HYPOPHOSPHITES.

This preparation, as prepared by the pharmacopœial method, hardly deserves to be called syrup, containing only 50 per cent. cane sugar. Singularly enough this official acid syrup differed from the others so far examined by showing no signs of colour change. A specimen of the syrup, contained in a partly-filled bottle, and exposed to every condition of temperature during eighteen months, still retains its original colourless appearance while giving evidence of decomposition otherwise. This is probably due to the small percentage of free acid in the syrup. With the well-known Churchill's syrup of the hypophosphites, which contains a larger quantity of free acid, the case is different, the writer having found this preparation to turn to a decided straw colour, with a final deposit of grape sugar in cold weather.

Examination as to the amount of inverted sugar in the official (U.S.P.) syrup gave the following results:—A sample six months old contained 20·8 per cent., while one of about eighteen months showed 29 per cent. Progressive inversion was not studied in the official syrup. It was, however, recently undertaken in Churchill's syrup, prepared by cold percolation. The first portions of the syrup, dropping from the percolator, responded but feebly to Fehling's solution. A contact of eighteen hours, however, revealed an inverted sugar percentage of 2·0, while when forty-eight hours old the syrup was found to contain 3 per cent. On standing four days the percentage was found to be increased to 7·8 per cent., and in ten days to 18·1 per cent. Recent examination, seventeen days after preparation, showed 27·7 per cent.

Other specimens of Churchill's syrup examined gave the following figures:—A slightly straw-coloured syrup contained 56·4 per cent.; an old brown-yellow specimen 62·3 per cent., and a straw-coloured specimen, six months old, 58·2 per cent. of inverted sugar. The salts of hypophosphorous acid have no reducing action upon Fehling's solution.

Syrups containing Free Organic Acids.

Organic acids also have the power of inverting saccharose, although not in as pronounced a degree as mineral acids. The results, so far as decomposition or colour changes, such as precipitation of grape sugar or darkening of syrups, are concerned, do not appear as prominently. The experiments of Kulisch, mentioned before, indicate that heat and the amount of free acid are important factors in the course of inversion. The latter view is substantiated by the results of the writer, but with the possible exception of the rapidity with which inversion takes place a considerable increase in temperature is not necessary. Prolonged contact of an organic acid with a cane-sugar solution will invert the saccharose at a temperature of 60° to 70° F. This was found to be the case with syrup of citric acid.

The official syrups examined of the organic acid group were the following:—Syrup of citric acid, squill, ipecacuanha, and acacia. Syrup of garlic, being deeply coloured, was not investigated.

SYRUP OF CITRIC ACID.

The phenomena of inversion of cane sugar in syrups with free organic acids were first observed in this preparation. Due to the absence of colour, therefore permitting an accurate examination with Fehling's solution, it is particularly convenient.

The observations on the following specimen cover a period of eleven months:—Syrup of citric acid was made according to official directions, the simple syrup used in its preparation having but feeble reducing action. After standing twenty-four hours signs of the presence of inverted sugar made their appearance. After standing forty-five days it was found to be 22·7 per cent., and after three months between 40 and 41 per cent.

The four-months-old syrup showed the percentage to be increased to 49·2 per cent., and ten to eleven months after preparation the figure was 63·1 per cent. This would indicate that almost all of the sugar was inverted. Outside of a slightly terebinthinate odour the syrup at this time shows no change.

SYRUP OF SQUILL.

A number of specimens of this syrup were examined, one being kept under observation for a period of seven months. Heat is employed in the preparation of the syrup, and a more rapid inversion may therefore be expected. The above-mentioned sample, one week after preparation, contained 6 per cent. of inverted sugar. At various intervals examination showed constant increases, and after seven months 26·1 per cent. was found. Other specimens showed, respectively, 12·5, 11, and 11·2 per cent., but none are as old as the above syrup.

SYRUP OF IPECACUANHA

Syrup of ipecacuanha, containing but a small amount of free acid, shows the smallest inverted sugar percentage of all syrups examined. Being prepared by cold solution, it does not show a

favourable condition for inversion. A specimen, under observation for three months, shows a percentage of 2·1, while the highest found in any sample was 3·7 per cent. Another syrup, of unknown age, showed 1·66 per cent.

SYRUP OF ACACIA.

This syrup gives evidence of the presence of inverted sugar on standing, or at least of a compound reducing Fehling's solution. The question may be raised, if this reducing action is not an inherent property of acacia and its solution. The Pharmacopœia states that the latter has no reducing action upon Fehling's solution. This has not been the writer's experience with mucilage from either solid, granular, or powdered commercial gums. Other glucose tests, such as the alkaline bismuth and safranin tests, also react, the picric acid reaction being an exception.

Samples of syrups of acacia, prepared as follows, have these percentages:—No. 1, U.S.P. syrup, nearly four months old, examined in 1 per cent. solution by volume, showed 4 per cent. inverted sugar. No. 2, a sample prepared from granulated gum, heat being employed in its preparation, contained 3·5 per cent. of inverted sugar in 100 C.c. of syrup after standing three months. No. 3, a syrup prepared from powdered gum, showed 4·5 per cent. in 100 C.c. after four months. The sugar and syrup used in these preparations gave but a feeble reaction with Fehling's solution.

Non-Acid Syrups.

Examination of this group was undertaken to determine the question if syrups, containing no free acids, and standing the same length of time as acid syrups, may not eventually also show the presence of considerable amounts of inverted sugar. Various circumstances necessarily occurring during the preparation and keeping of such syrups, as the influence of direct or summer heat, or fermentation, render such a condition possible. But while some do undoubtedly contain small amounts of inverted sugar, in no case was the percentage found as large as in the acid syrups of either group. Even in comparison with the weakest of the latter, syrup of ipecacuanha, none was found to even approximately reach its percentage of inverted sugar.

The following groups were examined, several specimens of each in a number of instances:—

Syrup of althæa. The syrup, prepared by a method in which the mucilage was removed, possessed, after five months, practically no reducing action upon Fehling's solution. Examination of several specimens, prepared by other methods, gave similar results.

Syrup of senega, several months old, examined in diluted form, showed an almost complete absence of inverted sugar. In examining this syrup in diluted form with Fehling's solution, the blue colour of the latter is turned green, but even on prolonged boiling only a slight precipitate of cuprous oxide is found.

Syrup of lactucarium was also examined in the above manner with the identical results.

Syrup of orange peel, U.S.P., showed, on standing six months, a percentage of only 0·33 per cent. of inverted sugar, and a specimen prepared from spirit of orange showed, one month after preparation, but a feeble reducing power. After six months no material increase was noticeable.

Syrup of tolu was examined repeatedly, the percentage in all cases being low. One sample showed 0·4 per cent. on standing three months.

In simple syrup the highest inverted sugar percentage found was 0·45 in a three-months-old specimen, prepared by cold percolation. The statement that continued boiling will invert the cane sugar in simple syrup the writer has been unable to verify, unless free acid was present.

The following deductions may be briefly considered:—By the presence of directly fermentable sugars in acid syrups, a favourable condition for the liability of rapid fermentation must be taken into consideration by the pharmacist. Such syrups, therefore, require special attention concerning preservation.

The physician is confronted by an analogous difficulty—namely, the likelihood of rapid decomposition in the stomach with consequent gastric disturbance. An objection to syrup of hydriodic acid, made by a physician, was the above complaint, and was attributed at the time to the liberation of iodine. The above results, however, convince the writer that inverted sugar was the disturbing factor. In plant chemistry a field for speculation is opened by the question—What influence have organic acids in the formation of the glucose regarded as a normal plant constituent?

QUALITATIVE EXAMINATION OF POWDERED VEGETABLE DRUGS.*

α. Crystals rosette or star-shaped.

238. *Althæa (pecled).*—Crystals 25 μ; starch 14×10 μ; sklerenchyma fibres; mucilage; crystals of asparagin.

239. *Althæa (unpecled).*—As No. 238, but with appreciable quantity of cork cells.

240. *Aralia nudicaulis.*—See No. 2.

241. *Aralia spinosa.*—See No. 3.

242. *Asclepias.*—Crystals 35 μ (sometimes not numerous); starch 7 μ; numerous stone cells.

243. *Cascarilla.*—Crystals 15–20 μ; starch 3 μ; reddish brown secretion cells; sklerenchyma fibres.

244. *Canella alba.*—Crystals 20–30 μ; starch single to 3-compound (5 μ in diameter); large yellowish oil secretion reservoirs; peculiar stone cells thickened on but three sides.

245. *Composition powder.*—Starch, oil cells and crystals of Ginger (see No. 212); crystals and oil secretion reservoirs of cloves (see No. 346); oil and chromoplastids of capsicum (see No. 306); bayberry bark with characteristic crystal fibres and starch grains 7 μ.

246. *Euonymus.*—Crystals 20–35 μ; starch 4 μ; characteristic groups of bast fibres with 5–8 rows of medullary rays.

247. *Galla (Aleppo).*—Crystals 10 μ; starch single grains (10 μ) or sometimes in groups; stone cells; tannin; crystals of gallic acid.

248. *Geranium.*—Crystals, 60 μ; starch, 10–15 μ; numerous yellowish and reddish-coloured masses in cells; strong reaction for tannin.

249. *Gossypii Radicis Cortex.*—Crystals, 25 μ; starch, single (4 μ) to 3 to 4 compound (20 μ) grains; long bast fibres about 6 m.m long; secretion reservoirs; reddish and yellowish coloured masses.

250. *Jalapa.*—Crystals, 30–35 μ; much starch of characteristic form (18–36 μ); yellowish-brown secretion cells, as well as other characteristic, somewhat thickened cell with simple pores.

251. *Juglans.*—Crystals generally rosette-shaped (15–35 μ) or sometimes tetragonal (10×15 μ), occurring in parenchyma or occasionally in crystal fibres; bast fibres, 30 μ wide and very long; stone cells, 35×50 μ; oily drops and purplish-brown tannin masses in parenchyma. *J. cinerea*, L., is distinguished from *J. alba*, Mx., and *J. nigra*, L., in that each of the latter possesses numerous crystal fibres containing prismatic or rhombohedral crystals. *J. migra* has also in the medullary rays rosette-shaped crystals of calcium oxalate. *Juglans regia* appears more nearly to resemble *J. cinerea*, L. See Vogl.

252. *Myrica cerifera.*—Crystals either rosette-shaped (45 μ) or nearly cubical (15×15 μ to 15×20 μ), occurring in crystal fibres (as in licorice) accompanying the long bast fibres, which are as many as 100 μ in width and walls about 25 μ thick; starch either single (7 μ) or 2 to 4 compound.

253. *Podophyllum.*—Crystals, 50 μ in diameter; starch either single grains (5–8 μ), or 2 to 6 compound; numerous single yellow cells or groups of the same; sklerenchyma fibres and ducts.

254. *Pimenta.*—Crystals, 15 μ; starch, 7–10 μ; stone cells characteristic; oil secretion reservoirs are wine-coloured and characteristic.

255. *Pulv. Aloe et Canellæ (Hicra Picra).*—In addition to Canella alba (see No. 244) there is aloes, the appearance of which depends on the kind used (see Nos. 230, 486 and 487).

256. *Pulv. Jalapæ Co.*—In addition to Jalapa (see No. 250) has large irregular transparent crystals of potassium bitartrate (see No. 186).

257. *Pulv. Rhei Comp.*—Crystals and starch of Rheum (see No. 215); oil and starch of ginger (see No. 212), and crystals MgO (see No. 197).

258. *Hufland's Baby Powder.*—Crystals and starch of *Rheum* (see No. 215); carbonate of magnesia and sugar (as Oleo-sacch. of Fennel).

259. *Rubus.*—Crystals, 30 μ; starch, 7 μ; long bast fibres, 7 mm. long; reddish and yellowish-coloured masses.

260. *Rumex crispus.*—Crystals, 20–35 μ; starch, 10–18 μ; stone cells and sklerenchyma fibres; boil few milligrammes with water, filter, and to straw-coloured liquid add KOH = red chrysophanic acid reaction. In *Rumex hymenosephalus* starch grains characteristic, 4 × 8 to 7 × 16 μ; apparently no crystals.

261. *Serpentaria.*—Sometimes contains crystals (see No. 245).

262. *Stillingia.*—Crystals not numerous apparently (35 μ); starch (15 × 15 to 25 × 30 μ); sklerenchyma fibres very long, diameter, 20 μ; walls swell very perceptibly in KOH; oil secretion cells containing oil and reddish resin masses.

263. *Syr. Trifolii Comp.*—Rosette crystals, etc., of *Stillingia* (see No. 262); cubical crystals, stone cells and oil secretion reservoirs of *Xanthoxylum fraxineum* (see No. 29); tissues of *Lappa* (See No. 113); *Phytolacca* (see No. 301); *Berberis aquifolium* (see No. 557) *Cascara amarga* and *Red clover*.

264. *Sarsaparilla (American).*—See Aralia nudicaulis, No. 2.

265. *Viburnum prunifolium.*—Crystals, either rosette-shaped (35 μ) or cubical (15 μ), or somewhat coffin-shaped, occurring in crystal fibres like in licorice; numerous groups of yellowish stone cells (20 × 140 μ) of various shapes of numerous light cork cells; more stone cells and fewer sklerenchyma fibres in *V. prunifolium* than in *V. opulus*.

266. *Syr. White Pine Compound.*—See No. 285.

β. Tendency of crystals to cubical, tetragonal, hexagonal, or coffin-shape.

267.—*Aspidosperma.*—Crystals, 14–25 μ, in crystal fibres, about 8 mn. long, very characteristic.

268. *Calamus (pecled).*—Few crystals 7 × 10 or 5 × 5 μ in crystal fibres in outer part of cortex; sometimes get large acicular crystals in glycerin mounts about 55 μ long, which may be, however, 400 μ long; starch, 4 × 4 to 4 × 8; parenchyma characteristic; oil secretion cells; ducts and sklerenchyma.

289. *Calamus (unpeeled).*—More crystal fibres like in licorice and Uva ursi. (See No. 268.)

270. *Cardamom*—Crystals very small; starch in small grains, often in groups; thick, dark sklerenchyma being the outer and particularly the inner epidermis of the seed; the pericarp or fruit wall possesses sklerenchyma fibres and large parenchyma cells, some of which contain brown masses. The *Malabar* is distinguished from the *Ceylon* in that the latter has some 1-celled hairs; crystals are larger and more numerous; starch grains are larger; the outer epidermal cells are larger and contain one or more nearly cubical or hexagonal crystals. (See also Vogl and Mœller.)

271. *Cinnamon.*—See No. 292, sometimes find prismatic crystals.

272. *Ext. Glycyrrhizæ.*—Irregular wine-coloured fragments; starch grains altered and unaltered; few fragments of sklerenchyma and crystal fibres of glycyrrhiza. (See No. 276.)

273. *Ext. Sarsaparillæ Fld.*—Abundance of tissues and starch grains of sarsaparilla (see No. 40); sklerenchyma and crystal fibres of glycyrrhiza (see No. 275); tissues of sassafras (see No. 313); and mezereum (see No. 524).

274. *Frangula.*—Rosette-shaped crystals, 70 μ, cubical, pentagonal and hexagonal crystals (7 × 5 μ to 8 × 8 μ) in parenchyma cells or crystal fibres; starch grains not numerous, the grains occurring either singly or in groups; long, numerous bast fibres 15 μ wide; after section or powder lies in glycerin get numerous small globular and yellowish particles; boiling a few milligrams of the powder with water, filtering, and to the straw-coloured liquid adding KOH gives a red coloration. Absence of stone cells in *Frangula* distinguish it from *Rhamnus Purshiana*.

275. *Gelsemium.*—Crystals cubical (15 × 15 μ), tetragonal (15 × 20 μ) or prismatic (8 × 28 μ); starch grains 8 × 8 μ; numerous sklerenchyma fibres. Stem is distinguished from the root by the presence of groups of more or less altered sieve (*i.e.*, internal phlœm). Rhizome is distinguished from overground stem by the former having a stronger cork development and the latter chloroplastids.

276. *Glycyrrhiza* (*Spanish*).—Crystals of varying shapes, about 3 × 2 μ, occurring in crystal fibres in fragments of about 117 μ in length; starch grains about 5 μ in diameter; ducts and numerous sklerenchyma fibres. Spanish licorice is distinguished from the Russian in that a powder of the former is darker, due to the fact that the cork is retained and hence cork cells are relatively more numerous.

277. *Ginger, Charcoal and Magnesia.*—Few starch and oil secretion cells of ginger (see No. 212); crystals of MgO (see No. 197), and large number of wine-coloured or blackish wood fragments.

278. *Hufland's Baby Powder.*—Crystals and starch of rheum (see No. 215), crystals of MgO (see No. 197) and sugar (see No. 185).

279. *Iris.*—Crystals of shape like those of Quillaja; they arise in the intercellular spaces, and in powder are in broken pieces about 20 × 150 μ in size; parenchyma loose; cells contain reddish resin; ducts numerous.

280. *Krameria.*—Large crystals in shape like Quillaja, ranging from 10 × 45 to 25 × 110 μ, or even larger; starch 20–30 μ; bast fibres 400 to 875 μ long; about 15 μ wide and with a peculiar crook or bend; parenchyma containing bright, reddish-brown colouring substance. Bast in *Savanilla* rhatany longer and broader than *Peruvian* (see also Vogl).

281. *Myrica cerifera.*—See No. 252.

282. *Prunus Virginiana.*—Crystals rosette-shaped, cubical or hexagonal (20–30 μ); starch 4 μ; stone cells; bast fibres; taste and odour.

283. *Pulv. Glycyrrhizæ Co.*—Tissues of glycyrrhiza (see No. 275), and senna (see No. 21). Make chrysophanic acid test.

284. *Quillaja.*—Crystals prismatic varying from 15 × 60 to 35 × 100 μ, or even larger; starch 10 μ; sklerenchyma fibres; parenchyma with yellowish resin.

285. *Syr. White Pine Comp.*—Crystals, fibres and stone cells of *wild cherry* (see No. 281); characteristic crystals, etc., of *Aralia spinosa* (see No. 3); tissues of *sassafras* (see No. 313), sanguinaria (see No. 222), white pine bark and balm of Gilead buds.

286. *Ulmus.*—Hexagonal or coffin-shaped crystals 8 × 25 μ; starch 5–7 μ; groups of bast fibres and characteristic large mucilage cells.

287. *Viburnum Opulus.*—Crystals cubical (2 × 2 μ) or broadly prismatic (10 × 20 μ) in crystal fibres. More sklerenchyma fibres in *V. opulus* than in *V. prunifolium.* (See No. 265.)

288. *Viburnum prunifolium.*—See No. 265.

289. *Zanthoxylum.*—Tetragonal crystals 10 × 25 μ; starch 4–10 μ; large colourless secretion reservoirs; reddish cork; acicular crystals separate in glycerin mounts; apparently no bast or stone cells as in *X. fraxineum.* (See Mœller.)

β. Raphides (or needle-shaped crystals) of calcium oxalate.

290. *Cacao.*—Acicular crystals of theobromine and fat. (See No. 545.)

291. *Calamus.*—Acicular crystals in glycerin mount. (See No. 268.)

292. *Cinnamon.*—Raphides of calcium oxalate; stone cells; bast fibres; starch grains. The different cinnamons are distinguished in powder in that the *Ceylon* has little or no cork; *Cassia* has more lignified cells than *Saigon*; *Saigon* is more aromatic and pungent. The mounts of Ceylon cinnamon are lighter in appearance than those of either of the others. Regarding other characteristics the following may be of some service in distinguishing these barks; *Cassia* has on an average, starch grains 7 μ diameters; stone cells 60 μ wide; bast fibres 700 μ long; *Ceylon* has starch grains 3–7 μ diameter; stone cells 70 μ wide; bast fibres 60–100 μ long; *Saigon* has starch grains 10 μ diameter; stone cells 85 μ wide; bast fibres 750 μ long.

293 *Hydrangea arborescens.*—Needles 200 μ long; starch 4–15 μ; numerous sklerenchyma fibres.

294. *Ipecac.*—Acicular crystals 20–40 μ long; starch in single and 2–3 compound grains; tracheids, but no true ducts. Starch grains of *Rio Ipecac* on average 4–7 μ, may be 14 μ; that of *Carthagena* varies from 4–15 μ, the grains being uniformly larger. *Richardsonia* has true ducts.

295. *Pulv. Aromaticus.*—Tissues and cell-contents of Cinnamon (see No. 292) and Ginger (see No. 212) predominating; also Cardamom (see No. 23) and Nutmeg (see No. 496).

296. *Pulv. Ipecac. et Opii.*—Crystals of sugar of milk predominating (see No. 190); also Ipecac (see No. 294) and Opium (see No. 222).

297. *Tr. Catechu Comp.*—Tissues, etc., of Cinnamon (see No. 292) and Catechu (see No. 222).

δ. Crystal sand. (May occur as acicular crystals also.)

298. *Belladonnæ Radix.*—Starch in single (5–15 μ) and 2–3-compound grains; rather narrow ducts, with bordered pores; few sklerenchyma fibres; greyish-brown resinous masses. *Woody Belladonna* has more numerous ducts and sklerenchyma fibres; *Mealy B.* is richest in starch, and *Horny B.* is richest in greyish-brown resinous masses.

299. *Cinchona.*—Starch 4 μ in diameter; not very abundant characteristic bast-fibres 600 μ long by 50 μ wide; alkaloids can be crystallised out sometimes by use of KOH.

300. *Horsenettle* (*Solanum carolinense*).—Starch occurs in single (25 × 35 to 10 × 20 μ) or 2–4-compound grains; sklerenchyma and ducts.

301. *Phytolaccæ Radix.*—Acicular crystals 30 μ long or crystal sand; numerous starch grains 7–18 μ in diameter; large ducts; fragments of cork; sklerenchyma fibres short and long.

302. *Quassia* (*Surinam*).—See No. 358.

303. *Tinct. Cinchonæ Comp.*—Bast-fibres of *Cinchona* (see No. 303); parenchyma of *bitter orange peel* (see No. 206); sklerenchyma of Serpentaria (see No. 145.

304. *Zingiber* (*African*).—See No. 318.

(*b*) Containing starch, but few or no crystals of calcium oxalate and rather numerous fragments of tissues.

a. Possessing oil-cells or secretion reservoirs . . characteristic odour.

305. *Calmus* (*unpeeled*).—The crystal fibres occur only in outer portion of cortex, hence powder may contain few crystals; starch 4 × 8 to 4 × 4 μ; ducts and sklerenchyma; loose parenchyma; colourless or slightly yellowish oil-secreting cells.

306. *Capsicum.*—Starch grains very small; peculiar wavy stone-cells of seed, besides stone-cells of epicarp and endocarp; oil containing dissolved pigment of chromoplastids; characteristic secretion hairs of calyx; powder with H_2SO_4 becomes purplish and then purplish-red.

307. *Colchici semen.*—See No. 326.

308. *Cubeba.*—Starch, 1–4 μ in diameter; occurring also in aggregated masses; stone cells (50 × 50 μ), those of endocarp twice as long as wide; sklerenchyma fibres; needle-shaped crystals (cubebin) occur in stalk; much oil in numerous oil secretion reservoirs.

309. *Cinnamon.*—Crystals may not be observed. (See No. 292.)

310. *Piper nigrum.*—See No. 100.

311.—*Sabina.*—Starch 4 μ; characteristic hypodermis consisting of long fibres (15 μ wide) associated with epidermis.

312. *Sanguinaria.*—Starch grains single (4–8 μ), seldom 2–4-compound; orange and reddish-coloured secretion cells; mounts in glycerin are apt to contain sphere crystals.

313. *Sassafras.*—Starch grains single and 1–3-compound (7–20 μ diameter); bast fibres 455 μ long × 20–30 μ wide, being spindle-shaped much as Cinchona; yellowish and purplish-yellow fragments containing tannin; oil cells.

314. *Stillingia.*—Crystals may not be numerous. See No. 262.

315. *Sumbul.*—See No. 125.

316. *Syr. Trifolii Comp.*—See No. 263.

317. *Valeriana.*—Starch in single (7 μ) or 2–3-compound grains; oil in cells near hypodermis; peculiar cork; root hairs; sometimes in cells of epidermis or near them crystals (Valerianic acid salt) occur.

318. *Zingiber* (*African*).—Crystals likely to be overlooked, Distinguished from *Jamaica ginger* by possessing more numerous oil and resin cells and cork cells.

β. *Sklerenchyma as stone cells or fibres.*

319. *Aconiti Radix.*—Starch in single (4–12 μ) and compound grains, much resembling Colchici Cormis; tabular-*stone cells*; ducts; reddish-brown endodermis; taste characteristic.

320. *Apocynum.*—Starch; sklerenchyma and laticiferous vessels; ducts with bordered pores. In *A. album* starch 4–10 μ; stone cells 35×70 to 50×70 μ, with few large pores; bast fibres may not react readily, if at all, with phloroglucin; wood fibres react with phloroglucin; thick cork. In *A. androsæmifolium* starch 4–20 μ; stone cells 13×10 μ, possessing numerous fine pores; bast fibres may be absent; when present, behave towards phloroglucin like *A. album*. In *A. cannabinum* do not find stone cells or bast fibres; wood fibres are affected by phloroglucin; starch grains 7×15 to 10×10 μ, being larger than the other two; more numerous yellowish or nearly colourless fragments of laticiferous vessels than in the other two; numerous fragments of the yellowish and reddish-brown cork.

321. *Black Mustard Hulls.*—Characteristic stone cells and pigment cells of secd coat.

322. *Capsicum.*—See No. 306, stone cells.

323. *Chenopodium.*—See No. 108, stone cells.

324. *Coffee.*—Characteristic fragments of seed coat made up of parenchyma and spindle-shaped stone cells (175–200 μ long and 35 μ wide); most of the cells are those of endosperm with brownish-coloured walls, porous, 10 μ thick and contain oil, aleuron and starch. In commerce ground coffee is either made from the true coffee seed or is an artificial mixture of cereals, chicory, etc.

325. *Colocynthis.*—See No. 549.

326. *Colchici Semen.*—Starch 7–15 μ; characteristic thick-walled endosperm cells with simple pores and containing oil globules and protein; reddish-brown fragments of seed coat, the brown colouring matter soluble in KOH.

327. *Cubeba.*—See No. 308.

328. *Guarana.*—Parenchyma (60 × 70 μ) containing aggregated more or less altered starch grains (10 × 10 μ); stone cells (25 μ in diameter) nearly isodiametric; sklerenchyma fibres; on addition of KOH needle-shaped crystals (caffeine) may be obtained.

329. *Pareira.*—Yellowish stone cells (70 × 45 μ) occurring in groups; numerous starch grains, either single (7 × 10 to 15 × 15 μ) or compound; wood fibres.

330. *Physostigma.*—Starch, 25 × 40 μ; stone cells, also characteristic palisade sklerenchyma; stone cells, the contents of which are reddened by alkalies; oil and protein as granular masses.

331. *Phytolaccæ Radix.*—See No. 301.

332. *Podophyllum.*—Crystals sometimes apparently wanting; starch in single (5–8 μ) or 4 to 6 compound grains; numerous single cells or groups with yellowish resin; sklerenchyma fibres and ducts.

333. Sassafras.—Sec No. 313.

334. *Serpentaria.*—See No. 145.

(*c*) Containing starch; few tissue fragments and no calcium oxalate crystals.

335. *Amylum Iodatum.*—More or less angular grains (7–20 μ) of corn starch, coloured uniformly dark blue; on focussing above on the grain the edge is light blue.

336. *Bryonia.*—Starch in single (10–17) or two or more compound grains; somotimes find long acicular crystals (200 μ); ducts, 35–60 μ wide; cork yellow and yellowish-coloured cells, associated with ducts as in Colchici cormis; with H_2SO_4 powder coloured purplish and reddish-brown.

337. *Colchici Cormis.*—Starch in single (7–15 μ) and 2 to 4 compound (35 × 35 μ) grains; sometimes find needle-shaped crystals (70–200 μ long); few spiral ducts (21 μ wide); with H_2SO_4 powder coloured reddish-brown (port wine colour).

338. *Opium.*—In glycerin mounts consists of more or less greyish-brown and irregular granular masses (35–50 μ in diameter); little or no starch; epidermis of capsule cells, 40 × 40 μ in width, having lumen 7 × 7 μ; taste bitter and sparingly soluble in water or KOH. May get test for alkaloids with use of KOH. The *Smyrna* opium has most epidermal cells of capsule; the *India* few or none, and the *Persian* very little. The *Persian* always has an appreciable amount of starch. (See also Tschirch.)

339. *Tonka.*—Numerous starch grains, either single (5 × 7 μ) or aggregated; parenchyma containing brownish-red colouring substance; much oil.

B. WITH LITTLE OR NO STARCH.

(*a*) Containing calcium oxalate crystals.

α. *Crystals rosette or star-shaped.*

340. *Anisum.*—See No. 8.

341. *Carum.*—Crystals (1 μ) in aleuron (3 μ); characteristic brownish oil secretion reservoirs and epidermis of seed coat and pericarp.

342. *Chimaphila.*—See No. 12.

343. *Conium.*—See No. 13.

344. *Coriander.*—Crystals (3 μ) in aleuron (10 μ); light yellowish oil secretion reservoirs, with epidermis of seed coat and pericarp.

345. *Cusso.*—Crystals (20 μ); spherical pollen grains (25 μ); single celled, non-secreting hairs (210 μ long); small secretion hairs with a stalk; stone cells.

346. *Cloves.*—Crystals, 10–15 μ; numerous secretion reservoirs (125 × 125 μ to 120 × 210 μ; pollen grains somewhat triangular (15 μ); parenchyma loose; few bast fibres with the bundle. Heat powder with KOH get needle-shaped crystals possibly due to eugenol.

347. *Clove Stems.*—Numerous rosette-shaped, but also cubical (7 × 7 μ) crystals; sklerenchyma fibres 30 μ wide; numerous *stone cells* (30 × 100 μ to 100 × 100 μ); oil secretion reservoirs not so large or numerous as cloves.

348. *Fœniculum.*—Crystals (2 μ) in aleuron 6 μ; brownish oil secretion reservoirs with characteristic inner epidermis of pericarp running at right angles to the same; thickened latticed parenchyma.

349. *Quassia* (Surinam).—See No. 358.

350. *Santonica.*—Crystals 10 μ; pollen grains, spherical (15 μ); sklerenchyma fibres; secretion hairs containing crystals (santonin) soluble in alcohol and ether; powder, with H_2SO_4, becomes immediately blood-red. Santonica distinguished from *Artemisia* by the characteristic T-non-secreting hairs of the latter.

β. *Crystals cubical, tetragonal or prismatic.*

351. *Aurantii Amari Cortex.*—See No. 206.

352. *Aurantii Dulcis Cortex.*—See No. 207.

353. *Gaultheria.*—See No. 17.

354. *Gentian.*—Contains some small colourless or yellow prismatic crystals (may be calcium oxalate); in glycerin large prismatic crystals (5 × 15 μ) separate (possibly a sugar); spiral (30 μ wide), and scalariform (50 μ wide) ducts; yellowish oil globules; powder with Fe_2Cl_6 dark brown; characteristic "ersatzfasern" accompanying the sieve.

355. *Hamamelis.*—See No. 33.

356. *Illicium.*—Prismatic crystals (4–10 μ) of a stearopten in inner epidermis of seed coat; most characteristic are the sklerenchyma, of which there are 3-4 forms, of these the palisade sklerenchyma is most characteristic; loose parenchyma; oil in cells. In *I. religiosum* the stone cells are thicker than *I. anisatum*, and on treatment with KOH the latter becomes port wine red and the former a dirty orange-brown.

357. *Insect Powder.*—See No. 19.

358. *Limonis Cortex.*—See No. 208.

359. *Quassia.*—Cubical crystals (15 μ) in wood parenchyma; ducts and wood fibre. The *Jamaica quassia* is distinguished from *Surinam* in that the medullary rays of the former are 2–3 rows wide, whereas in Surinam they are but 1 row wide. In *Jamaica* we also find in addition crystal sand. When bark is ground with the wood the *Surinam* powder is distinguished by the presence of stone cells and rosette-shaped crystals of calcium oxalate. The latter are found only to a small extent in *Jamaica*.

360. *Quercus alba.*—Cubical crystals (15 μ), in crystal fibres 20 μ wide; large groups of characteristic stone cells; long bast fibres, which are 40 μ wide; colourless or light yellow parenchyma stained deep black with Fe_2Cl_6.

361. *Sambucus.*—Small crystals in calyx. See No. 474.

362. *Uva Ursi.*—See No. 37.

363. *Vanilla.*—Crystals, tetragonal and prismatic (7×17; 10×25; 7×35 μ) or needle-shaped (200–300 μ long); characteristic papillæ upon inside of pericarp; characteristic broadly ovate, brown to brownish black seeds with reticulate walls; lignified elements stained bright-red with phloroglucin; starch not found in ripe fruit. *Mexican Vanilla* has in connection with the elements of the fibro-vascular bundle a characteristic netted-pored parenchyma cell, distinguishing it from the other vanillas. Vanilla, distinguished from admixtures with *Tonka* by latter containing starch.

β. Crystals in Raphides.

364. *Vanilla.* See No. 363.

b Crystals in fine, sand-like particles.

365. *Cinchona.*—Contains small amount of starch. See No. 299.

366. *Quassia* (Jamaica).—See No. 358.

367. *Tobacco.*—Characteristic secreting and non-secreting hairs; sklerenchyma fibres; stomata characteristic.

C. NO STARCH OR CRYSTALS OF CALCIUM OXALATE, BUT MASSES OR CRYSTALS OF A CARBOHYDRATE (INULIN).

The *Inulin* occurs in numerous irregular nearly transparent or greyish fragments, sometimes perfect sphere-crystals. These masses or crystals are soluble in hot water; insoluble in alcohol and glycerin.

368. *Inula.*—Greyish-brown masses from secretion reservoirs; few sklereuchyma fibres (15 μ wide); reticulated ducts 32 μ wide; odour and taste.

369. *Lappa.*—Apparent absence of secretion reservoirs; more wood fibres and possibly larger reticulated ducts (as much as 70 μ wide) than Inula; cells of peridcrm brownish, becoming yellow with age; parenchyma very light coloured; no odour.

370. *Pyrethrum.*—Characterised by a stone cork (30 × 45 μ) with yellowish-brown contents; few sklerenchyma fibres; narrow reticulated ducts about 15 μ wide; characteristic parenchyma; oil secretion reservoirs; taste.

371. *Taraxacum.*—Characteristic milk vessels in chloral-iodine mount. See No. 165.

(*To be continued*).

THE PREPARATION OF VERMOUTH IN FRANCE.*

The manufacture of vermouth in France is confined almost exclusively to the city of Marseilles, where all the important manufactories exist. The article is made from ordinary white wine, which is produced extensively in the region of which Marseilles is the principal centre, and which on account of its aboundance is very cheap. A pure wholesome white wine may be bought in the South of France at an exceedingly low price. While returns showing the production of wine in France are published every year by the Government, no statistics are kept concerning either the production, consumption, or exportation of vermouth. The two principal points in Europe from which vermouth is exported are Marseilles and Turin. Vermouth, according to the United States Consul at Havre, is simply an infusion of certain plants and bitter aromatic herbs and roots in a quantity of wine, the degree of which has been strengthened by the addition of one-ninth of its bulk of alcohol, in order to bring the wine, which is usually of not more than 10° alcoholic strength, up to 15°. The alcohol used should be pure, clear, and of about 85° in strength. The following are the ingredients of ordinary French vermouth:—Dry white wine, muscatel wine, wormwood, bitter orange peel, camomile, water germander, Florentine iris root, centaury, Peruvian bark, aloes, cinnamon, nutmeg, alcohol at 85°, and raspberry juice. The herbs and other ingredients are sometimes allowed to remain in the wine for a period of two months, the solution being stirred every fifteen days. After the expiration of two months the wine is drawn off into another barrel and is allowed to remain therein for two weeks, after which it is drawn off a second time. In the event of the vermouth being cloudy, which is often the case, the manufacturer resorts to the simple process known as *collage*, which consists of stirring in some boiled milk in the proportion of one pint to 26 gallons of vermouth. The white of a single egg, well beaten, for each 26 gallons, or about half a fluid ounce of fish glue, is also used for this purpose. The vermouth should be allowed to remain in the barrel for about five days after the *collage*, after which time it may be drawn off and filtered. If the vermouth thus made is not sufficiently sweet, a little sweet wine or syrup may be added. Its degree of sweetness, however, should not exceed 5° to 7° on the Beaumé scale. Newly-made vermouth has a flavour of herbs, which is occasionally a little too pronounced. Age alone causes the disappearance of this. Certain manufacturers, instead of putting the herbs and other ingredients directly into the barrel, first inclose them in a linen sack, which is then suspended in the barrel of wine. The sack is withdrawn every five or six days, the liquid expressed from it into the wine, and the sack again suspended. It is left in the wine for a month, at the end of which time it is taken out, all the liquid pressed out of it, and the fluid thus expressed returned to the barrel. Other manufacturers first make an alcoholic extract of the ingredients, which extract is afterwards mixed with the wine in the proportions given below. To obtain the alcoholic extract referred to, it is but necessary to reduce the dry ingredients mentioned to powder, and to place the same in about 10 to 12 quarts of alcohol of 85° strength. The solution is allowed to remain standing for a week, after which 19 quarts of alcohol, and 7·35 quarts of white wine are added, together with the herbs cut into small pieces. The solution is then warmed in a water-bath, which should not be heated above 140° Fahrenheit. After half an hour's warming it is removed from the fire, allowed to cool, and to remain standing for eight or nine days, during which time it should be frequently stirred in order that the sediment may be brought as much as possible in contact with the liquid. The solution, when perfectly clear, is placed in a large glass vessel, and forms an extract of vermouth. To make the article of commerce, 1·58 quarts of the extract are mixed with 2·11 quarts of white wine. If, in the simple process of infusion first described, the addition of alcohol to the wine precipitates the tartar contained in the latter, and causes cloudiness, the solution should be allowed to stand a few days until it clears, after which the solid ingredients may be added. The quality of the vermouth manufacture in France depends in a great measure upon the sort of wine used. The wines most employed are those of the valley of the Rhone, certain Spanish wines, and the wines of the extreme South of France. There is a difference between the French and Italian vermouth. A number of French manufacturers make Italian vermouth, however, not for the purpose of deceiving the customer as to its origin, but merely as a type of vermouth, distinct in flavour from the article known as French vermouth. The following are the ingredients which enter into Italian vermouth:—Sweet white wine, wormwood, helenium, calamus odoratus, centaury, holy thistle, water germander, cinnamon, angelica root, gentian, nutmeg, fresh orange sliced, and alcohol at 85°. When the process of infusion, above described, is completed, the manufacturer, or an expert connoisseur identified with his manufactory, samples the vermouth in order to find whether or not it possesses the desired taste. Should the beverage be too bitter, the fault can be remedied by adding a small quantity of wine until, little by little, the proper flavour is reached. If not sufficiently bitter, a small quantity of the solid ingredients may be again infused in the wine. Nor is it necessary that vermouth should possess great alcoholic strength to be good. Some manufacturers make vermouth which contains 17° of alcohol, while others keep their product down to 12°. The average strength is from 14° to 15°.

THE COMMERCIAL ASPECT OF MEDICINE.

THE commercial aspect of medicine receives attention in the current issue of the *Practitioner*, where it is remarked that for some time past the medical world has been troubled with the loud clamour of some medical practitioners, who have asserted that medical men can no longer make a living, and that the profession is going to the dogs. There has been no stint in the amount of advice proffered to the discontented ones, but, it is observed, to give advice is an art in itself, and interviews have therefore been sought with experienced practitioners who might be assumed to be capable of throwing some light upon the matter. The first interview was with an eminent member of the profession, "well known as a shrewd, level-headed observer of his time, and unequalled in applying to the wants and perils of the present the wisdom that his many years of discriminating observance have brought him." But this distinguished individual was disinclined to discuss the subject, and contented himself with the statement that very little good comes of good advice, and each man had better buy his own experience. The next individual approached was a practitioner of "the old school," who is tirelessly occupied with a large practice, but still continues to take the deepest interest in all things relating to his profession, and enjoys the reputation of being "one of the most trustworthy authorities of the day on medical ethics." To his mind, the art of giving advice requires as much aptitude as the ability to think out a really good prescription. He began by expressing the opinion that young medical men must be regarded as inexperienced in spite of their five years' training, and all their hospital work. Before starting practice on their own account, therefore, they should acquire a fair amount of *savoir faire* by going for a few months' voyage as ship's surgeon, taking up the post of house-physician or house-surgeon to hospitals and infirmaries, or by acting for a time as assistant or *locum tenens*. A nervous manner and an irresolute method of address must, he thinks, be regarded as very serious drawbacks, and individuals so unfortunate as to possess them are advised to take some appointment for a year or two at least.

The question of dispensing by medical men came up in the course of this second interview, the authority on medical ethics being asked how he considered the fact of a doctor not dispensing affected the professional standing of his practice. In reply, he quoted from a letter in the *British Medical Journal*, to the effect that the doctor is "an orderer" of drugs, and the chemist "a mixer up" of the same, adding that there is no doubt the professional standing of a practice where the medical man prescribes only is on a higher grade than that where the practitioner dispenses his own medicines. In this matter of dispensing, it was stated, every practitioner should consider whether it is desirable for medical men to be influenced in any way with regard to the actual sale of commercial commodities such as drugs. "But whether a man should dispense or not depends to a great extent upon the circumstances of the case, for, as things stand at present, it is absolutely necessary for the doctor to do his own dispensing in some districts, from the simple fact that there is no chemist within several miles of him." The suggestion that if country doctors did not dispense, then chemists would be needed, in obedience to the law of supply and demand, was met by the rejoinder that it was difficult to see how that would result unless the chemist reduced his charges very considerably, especially in the case of the very poor. Of course, it was remarked, the whole aspect of affairs would be altered if all doctors were to prescribe only, "because then the chemists would be able to lower their rates," and it was added that nothing but good would result from such a state of things, the profession as a whole being raised to a higher level. The public, it was added, certainly has an idea that a man who prescribes only is of a higher standing than one who doles out his medicines by the bottle, and it is very desirable in general practice to study carefully and follow out any method or plan of conduct which promises to result in a man standing well in public opinion.

A third leading practitioner who was interviewed also referred at length to this question of dispensing by medical men. In rural districts, he urged, dispensing is a necessity to a practitioner, and it is in no wise derogatory to him. According to this authority, even where chemists are to be found in the country, they will not, and indeed scarcely can, dispense so economically as a medical man with a fair-sized practice. The plan of delegating all dispensing to the country chemist was, therefore, said to result in a serious drawback to income, and it was also asserted that country chemists cannot always be depended upon for keeping fresh first-class drugs. Though no evidence was advanced in support of those assertions, there is no reason to doubt that general practitioners do in many instances realise a considerable profit from the sale of medicines dispensed by themselves or their assistants. That fact is virtually acknowledged in the statement that a large saving was effected in one practice by employing a resident dispenser instead of delegating all the dispensing to a chemist in the neighbourhood, as had formerly been the custom. Whether the patients benefited, physically and pecuniarily, to the same extent is not recorded, but it is somewhat inconsequentially asserted that, socially and professionally, the character of the partners and of the practice stands as high as when the dispensing was done by the chemist. Apparently, then, so long as a medical man's dignity does not suffer, and the character of his practice is maintained at a satisfactory level, he is to be commended by his fellow prac-

titioners for intercepting the chemist's profits, even though his patients do not receive the best possible service. The *Medical Press* also appears to regard the question of dispensing by medical men as a purely commercial one, for, in an editorial note in this week's issue, it seems to propose that a sort of bargain should be entered into, the chemist agreeing to refer all who ask him to prescribe to a neighbouring medical man, and the latter to send them back to the chemist with prescriptions to be dispensed. Such reciprocity, it is suggested, would be only natural, but can it be realised ?

THE GERMAN APOTHEKER-VEREIN.

THE twenty-eighth annual meeting of the German Apotheker-Verein, held last week at Danzig, was one of the most important in the history of this Association. In many respects the questions that now agitate British and Irish pharmacists have long been under consideration in Germany, and have now reached an acute stage, which gives rise to considerable anxiety. The old system of privileges and transferable concessions, which was long a source of advantage to the apothecaries as well as to the public, belonged to a past time, and is no longer sufficiently in harmony with modern conditions to be maintainable against a system under which any person having the personal qualification requisite for carrying on a professional occupation is free to practise. The difficulty is how to deal with the properties—in some instances very valuable—which have come into existence under the old system; how to liquidate them with due consideration for all interests concerned, and let the principle of free enterprise replace that of State protection, which has in the past ensured a high professional standard of qualification in the apothecaries of Germany. Under these conditions the interest taken in the discussions at the Danzig meeting was so great that, notwithstanding the remote situation of the town, the attendance was nearly double what had been anticipated. The proceedings were, perhaps, more animated than on any previous occasion, revealing also an amount of dissent in regard to important points which seems almost to equal that prevailing among chemists and druggists in this country, and also to betray a disregard for the necessity, not only of unanimous and concerted action by the apothecaries, but also of liberal consideration of all other interests that are concerned and would be affected by change of the mode in which the practice of pharmacy is regulated. Some further particulars in reference to these matters that will be of interest to readers of the Journal will be given in future issues, and for the present it will be sufficient to report that Herr FRÖLICH has retired from the position of President and member of the Council, in consideration of his appointment as a member of the ministerial department which has to deal with pharmaceutical affairs. He is succeeded by Herr BELLINGRODT, of Cologne. The other new members of Council are Dr. BAETCKE, of Berlin, and Dr. BEDALL, of Munich. Mr. MADSEN, of Copenhagen, was elected an honorary member of the Verein, and at the concluding meeting the same honour was conferred by acclamation upon Herr FRÖLICH, the retiring President, as a mark of appreciation of the important services he has rendered to German pharmacists during the many years that he has been a member of the Council and President of the Verein.

ANNOTATIONS.

THE PROPOSED CANADIAN ADDENDUM to the British Pharmacopœia, particulars of which are published at page 231, is the outcome of the labours of a committee consisting of Dr. Blackader, of McGill University; Dr. Hernieu, of Laval; Dr. Wilson, of Bishop's; Dr. Gordon Campbell; Mr. W. H. Chapman, President of the Montreal College of Pharmacy; Mr. R. W. Williams, President of the Pharmaceutical Association of the Province of Quebec; Dr. G. Adami, President of the Montreal Medico-Chirurgical Society; Dr. Bazin, Secretary; and Professor J. E. Morrison, Editor of the *Canadian Pharmaceutical Journal*. The presidents of the various provincial medical and pharmaceutical associations were also appointed members of the Montreal Committee. Professor Morrison had previously suggested the inclusion in the Pharmacopœia of certain drugs used in Canada, and the paper embodying his suggestions is reprinted at page 230. He was subsequently requested by the committee to undertake the practical work in connection with the carrying out of his suggestions, and the work of devising the formulæ and making the preparations for exhibition to the committee was entrusted to Messrs. Lyman, Sons and Co., of Montreal.

THE APOTHECARIES' HALL is the subject of an interesting article by Miss B. H. Maxwell, in the *Humanitarian*, and it is stated therein that the charter granted to the Society in 1633 gave it the right to acquire Cobham House and grounds, which belonged to Lady Howard of Effingham. The place was destroyed in the great fire of 1666, and the present buildings were erected subsequently. They comprise a spacious court-room, a parlour, a library, laboratories, dispensary, court rooms, and other buildings, occupying three-quarters of an acre There are many interesting pictures and portraits in the apartments, including a portrait of James I. dating from the sixteenth century, paintings of the former masters and patrons, engravings of the celebrated antique mortar, of the "Physic Gardens" at Chelsea, and of the Society's Arms. In Pennant's 'London' appears the following passage:—"Until these few years this house was possessed of a most curious antique mortar. On the body were several figures, such as two griffins, supporters to a tree; and two animals, perhaps antelopes, supporters to another; two lions in the same character to a third tree; and two others supporting a castle, triple towered. There is also an effigy of Gilbert de Laune, founder of the Hall, and its greatest benefactor, who was Apothecary to Anne of Denmark, and was the ambassador sent to escort her to be the bride of James the First. The immediate neighbourhood of the Apothecaries' Hall is interesting from its many old associations. Not far off was the Palace of Bridewell, built by Henry VIII., also the playhouse of Blackfriars, where Shakespeare acted, Play House Yard, and Printing House Square. The proximity of the river, to which the Society's premises originally extended, gave the name of Water Lane to the narrow street that leads directly to the entrance.

THE OLD APOTHECARY'S ART is said to have had two practical sides—the study of poisons, regarded as an interesting, necessary and praiseworthy occupation, and the supplying of drugs and spices for the concoction of medicines and unguents. "This was, in fact, the grocery department, and the apothecaries were originally grocers, trading in such goods as rue, hyssop, fennel, mustard, elecampane, southernwood, rosemary, lovage, coriander, savin, chervil, lupin, cummin, flax, savoury, obstratum, quicksilver, brimstone, myrrh, frankincense, ginger, petroleum, vulvage, mastick, ammoniacum, scammony, and many other drugs." These traders in England in the twelfth century were called pepperers, spicers, and Easterlings (referring to their dealings in merchandise with the Orient), and even at that early date had

formed themselves into a company which paid toll to the reigning monarch in the form of pepper and spices. For a period of two centuries the incorporatien of the grocers and apothecaries continued, but gradually the apothecaries proper drew themselves apart from the mere grocers, and we find them accusing their former colleagues of adulterating their goods, and "makynge of untrewe powder, of gynger, cynamon, and sawnders." The grocers retaliated by stating that the apothecaries monopolised the buying and selling of drugs, and the distillation and selling of all waters within the City of London and seven miles thereabouts. These mutual complaints were brought before James I., who championed the cause of the apothecaries and granted them the charter which sanctioned their existence as a separate society. He also gave them privileges which raised them at once to a superior position over any mere traders. He allowed them to incorporate the two unicorns in the Royal Arms of Scotland with their arms. Every applicant who desired membership had to pass an examination in Latin, and gradually this qualification was added to, and rendered more difficult, with a view to raising the status of the Society. "Then began a war with the physicians, who desired that the apothecaries should have the right only to dispense and sell medicines, and not to prescribe them; and in this the Great Plague played the part of advocate to the Society, for the ranks of practitioners were so devastated by the disease, and the number of sufferers so enormous, that the people were only too glad to call in the apothecaries, and to pay for their medical advice as well as for their drugs. The battle raged fiercely for a century, and in 1721 the apothecaries again triumphed by receiving at the hands of the Law Courts the right to practise medically, and to refuse that the physicians should make inspection of their drugs with the power of condemnation."

THE PHYSIC GARDEN AT CHELSEA appears, according to Miss Maxwell's account, to have originated in a somewhat accidental fashion. In 1673 the apothecaries leased some ground in Cheyne Walk, for the purpose of building a house convenient for the reception of their ornamental barge; and gradually the garden became more cultivated, until in 1722 Sir Hans Sloane, President of the Royal College of Physicians and Master of the Society of Apothecaries, made a deed of gift of it, with directions that it should be preserved as a Physic Garden, "for the manifestation of the power, wisdom, and glory of God in the works of creation." The word "physic" seems to imply that the produce of the garden was to be used pharmaceutically, but that was expressly forbidden, the object of the garden being simply the advancement of botany, and especially that portion of it useful to medical science. Of four cedar trees planted there in 1683, the only survivor at the present day is dying. Evelyn wrote of the Physic Garden that it contained many rare and interesting simples and annuals, comprising "the tree bearing Jesuit's bark, which has done such wonders in the quartan agues." He mentions also as a marvel of ingenuity "the subterraneous heat conveyed by a stove under the conservatory, all vaulted with brick, so as he (the gardener) has the doors and windows open in the hardest frosts, excluding only the snow."

"WIRELESS" TELEGRAPHY with kites is reported by Laffan's Agency to have been fairly successfully carried on between Harvard College and Milton, Massachusetts. The distance was twelve miles, and there were considerable difficulties owing to electric power houses, electric trollies, etc., on the route. In spite of that, however, it was found possible to telegraph at the rate of ten words a minute, and it is thought that greater success will be achieved when the disturbing elements have been overcome. The process employed was practically the same as Signor Marconi's, but wires hanging from the kites were substituted for poles. It is claimed that such wires have an advantage over poles, as being more easily adapted for any height or distance.

THE ROYAL PHOTOGRAPHIC SOCIETY asks us to remind our readers that all entries for the Forty-fourth Annual Exhibition of the Society, to be held at the Gallery of the Royal Society of Painters in Water Colours from September 25 to November 11, close on Wednesday, September 6, at 9 p.m. Exhibits in packing cases must be delivered at 66, Russell Square, on or before September 5.

THE EXAMINATION CRAZE which has so long affected the authorities of the Department of Science and Art is apparently beginning to die out, for a notice has been issued by the Lords of the Committee of Council on Education, stating that they have under consideration the assessment of the efficiency of instruction in the Elementary Stage of Science and Art subjects by inspection only. It is proposed to discontinue examinations, as a test for the purposes of assessing the grant in that stage, after the year 1900. It is also proposed that papers shall continue to be set in that stage for students who may desire to be examined and to possess a certificate of having passed the examination; but that in those cases a fee should be charged to cover the cost of examination. Presumably, therefore, the taking of the progressive step referred to is instigated by motives of economy rather than anxiety to improve upon existing methods. But, however that may be, the proposed breaking away from old traditions is one to be cordially welcomed, in the interests of science no less than those of education.

PENNY POSTAGE TO THE CAPE OF GOOD HOPE comes into force this week, the Postmaster-General having announced that on and after Friday, September 1, the postage to be prepaid on letters from this country for the Cape of Good Hope will be 1d. per ½ oz., instead of 2½d. as at present. The postage on letters for the Australian colonies, New Zealand, and Rhodesia will continue to be 2½d. per ½ oz. These are now the only British possessions of importance which have not adopted the penny postage scheme.

STORES PHARMACY is far from being an unqualified success, if one may judge from some facts brought to the editor's attention this week by an original subscriber to one of the large service stores in London. This gentleman ordered a dozen five-grain quinine powders, and received them in a box labelled accordingly, and bearing the name of the chemist in charge in addition to the name of the stores. On taking one of the powders, however, he was seriously upset, and he therefore decided to call upon the secretary of the stores and ask for an explanation. Suspecting that the weight of the powders was probably at fault, he mentioned his suspicion to the official and asked that the remaining powders might be weighed in his presence. The dispenser was summoned with his scales, and the eleven powders were separately weighed on the spot. The weights, as subsequently marked by the secretary on the papers enveloping the powders, were as follow:—No. 1, 8 grains; Nos. 2, 3 and 4, each 9 grains; No. 5, 9½ to 10 grains; No. 6, 10 grains; Nos. 7, 8 and 9, each 11 grains; Nos. 10 and 11, each 12 grains. The average weight of each powder was, therefore, twice the weight indicated on the label, and the reason of the unusual effect produced on the purchaser was at once revealed. Needless to say, the secretary of the stores was profuse with apologies, offered to exchange the powders, and displayed great anxiety to retain the box with its label. He also stated that the stores would suffer a loss by reason of the extra quantity of quinine supplied (*sic*). The price charged, by the way, was ninepence per dozen. The purchaser declares that he will not trust the stores to supply his medicine in future, and he seems now to doubt the fitness of stores to carry on the business of a chemist and druggist, even though a duly qualified person is, or is supposed to be, in charge.

SOME SUGGESTIONS FOR A CANADIAN ADDENDUM TO THE BRITISH PHARMACOPŒIA.*

BY J. E. MORRISON.

In 1893 the General Medical Council invited the co-operation of medical and pharmaceutical associations in the preparation of an addendum or addenda for use in the Colonies and India. The Australian and Indian associations responded, and their suggestions have been embodied in a report which was recently issued and distributed. This report includes only the suggestions of the previously mentioned bodies, none having been received from Canada. As we in this country use a number of drugs which are not official in the British Pharmacopœia, we have thought it advisable to offer a list of them for consideration. It will be noticed that the most of them are official in the Pharmacopœia of the United States; and on this point I might draw attention to the peculiar condition of affairs which exist in Canada as regards the pharmacopœias in use.

The Dominion Adulteration Act recognises the British and United States pharmacopœias as standards; the Ontario Pharmacy Act, only the British; while in the Maritime Provinces and even in certain parts of Ontario the preparations of the United States Pharmacopœia are much more frequently prescribed than those of the British, and in Montreal and in other parts of the Province of Quebec, Codex preparations are often ordered.

Being in a position to judge of what drugs and preparations are most in demand by physicians from Cape Breton to British Columbia, the writer is of the opinion that the following list includes those frequently prescribed, which it would be advisable to include in a Canadian addendum if such is to be published.

APOCYNUM.—The root of *Apocynum cannabinum*, L. The fluid extract of the U.S.P. is the form in which this drug is most used.

ARNICÆ FLORES.—The flower heads of *Arnica montana*, L. Employed in the form of tincture: that official in the B. P. being very seldom prescribed by physicians and never used in household medicine.

ELIXIRIA.—Elixirs are a very popular class of preparations. The U.S.P. recognises two, Aromatic Elixir and Elixir of Phosphorus. It would be advisable to officialise a simple or aromatic elixir as a basis for other compounds or as a vehicle in dispensing.

EMULSA.—An emulsion of castor oil is now official. Why not also given a formula for an emulsion of cod liver oil, which is much more frequently prescribed? An emulsion containing 50 per cent. of oil can easily be made, and there is more need of an official formula for this preparation than there is for that of castor oil.

EXTRACTUM APOCYNI LIQUIDUM.—The U.S.P. preparation is frequently prescribed, and a similar article should be official.

EXTRACTUM BUCHU LIQUIDUM.—Tincture of Buchu is, we may say, never prescribed in Canada, but the fluid extract is one of the most frequently prescribed, as it is the best preparation of this drug. The fluid extract of the U.S.P., using alcohol as a menstruum, is a satisfactory preparation.

EXTRACTUM CANNABIS INDICÆ LIQUIDUM.—The U.S.P. fluid extract is prescribed as often as the B.P. tincture, and could profitably be recognised for use in Canada.

EXTRACTUM GELSEMII LIQUIDUM.—More popular than the tincture or extract of the B.P. The U.S.P. preparation is satisfactory.

EXTRACTUM GRINDELIÆ LIQUIDUM.—The drug is also recommended by the Australian authorities. It is frequently prescribed in Canada in the form of fluid extract. The U.S.P. directs the use of alcohol in this preparation, but the objection to this is that the fluid extract is not miscible with syrup owing to the large percentage of resin which it contains. An excellent miscible preparation may be made by percolating with alcohol, 80 per cent., distilling off the greater part of the spirit, and adding a solution of sodium bicarbonate and alcohol to make up the volume.

EXTRACTUM HYOSCYAMI LIQUIDUM.—Preferred to the tincture, as it contains less alcohol.

EXTRACTUM PRUNI VIRGINIANÆ LIQUIDUM.—The drug is now official in the B.P. with two preparations, the syrup and the tincture. The latter is never prescribed or used in Canada, and never will be, whereas the fluid extract is one of those most largely in use. The U.S.P. preparation is very satisfactory.

EXTRACUM TRITICI LIQUIDUM.—Official recognition of the drug and the liquid extract is advisable.

EXTRACTUM SENEGÆ LIQUIDUM.—The remarks applied to the tincture of wild cherry hold with the tincture of senega. The only preparations of this drug which are used to any extent are the fluid extract and the syrup, both of which are official in the U.S.P.

EXTRACTUM VIBURNI OPULI LIQUIDUM, and

EXTRACTUM VIBURNI PRUNIFOLII LIQUIDUM.—Neither of these drugs is official in the B.P., but the fluid extracts of the U.S.P. are frequently prescribed.

GRINDELIA.—The leaves and flowering tops of *Grindelia robusta* (Nuttall), and of *Grindelia squarrosa* (Dunal). Recommended by the Australian authorities; fluid extract is frequently prescribed.

MUCILAGO SASSAFRAS MEDULLÆ.—Mucilage of Sassafras Pith. Its use as a vehicle for applications to the eye is constantly increasing and an official formula is desirable.

SANGUINARIA.—The rhizome of *Sanguinaria canadensis* is used to a considerable extent in the form of fluid extract and tincture.

SASSAFRAS MEDULLA.—The pith of *Sassafras varifolium*. The mucilage, as already noted, is employed as an emollient application in conjunctivitis, etc.

SYRUPUS ACIDI HYDRIODICI.—This is in constant demand, two or three semi-proprietary makes having a large sale. It would be advisable to have an official formula for its preparation. We think a 2 per cent. preparation would be preferable to that of the U.S.P.

SYRUPUS HYPOPHOSPHITUM.—An official formula for this preparation is needed. The syrup of the U.S.P. is in increasing demand.

SYRUPUS IPECACUANHÆ.—In certain sections this is more frequently prescribed than the wine of the B.P. In the Province of Quebec the compound syrup of the Codex is popular. A formula for a syrup similar to that of the U.S.P. could advantageously be added.

SYRUPUS SENEGÆ.—With the exception of the fluid extract this is the most popular preparation of senega.

TINCTURA ARNICÆ FLORES.—As already stated under "Arnica," this is always given when Tincture of Arnica is asked for. It would be advisable to officialise a tincture of the flowers, made with 50 or 60 per cent. alcohol.

TINCTURA OPII DEODORATA.—This is official in the U.S.P. and is much used in Canada, as in some respects it is superior to the ordinary tincture. It could be made of the same morphine strength as the present official tincture.

TRITICUM.—The rhizome of *Agropyrum repens*, L. Couchgrass is one of the standard remedies, being as frequently prescribed as buchu, in decoction or as fluid extract.

VIBURNUM OPULUS.—The bark of *Viburnum opulus*, L.

VIBURNUM PRUNIFOLIUM.—The bark of *Viburnum prunifolium*, L. The fluid extracts of these drugs are much used, especially that of the latter.

Besides the foregoing, which are official in the Pharmacopœia of the United States, a few others such as the following might advantageously be recognised:—

* From the *Canadian Pharmaceutical Journal* for March, 1899.

Syrupus Ferri Phosphatis Compositus.—Parrish's Chemical Food.—Probably in greater demand than any syrup in the British Pharmacopœia.

Tinctura Jalapæ Compositæ of the Codex is much more frequently prescribed by French-Canadian physicians than the tincture of the B.P.

Hydrargyri Iodidum Flavum.—This salt is generally preferred by physicians to the mercuric iodide. The pills have a very large sale as an anti-syphilitic.

PROPOSED CANADIAN ADDENDUM TO THE B.P.

The *Canadian Pharmaceutical Journal* publishes the following draft of a proposed Canadian Addendum to the British Pharmacopœia, which has been compiled by a committee specially appointed for the purpose, and copies of which have been sent to the presidents of all the medical and pharmaceutical societies of Canada so that the matter might be brought before those bodies and discussed :—

Elixir Simplex.
Simple Elixir.

Tincture of Orange	2 ozs.	100 C.c.
Tincture of Lemon	½ ,,	25 ,,
Orange Flower Water	2 ,,	100 ,,
Alcohol (90 per cent.)	3 ,,	150 ,,
Kaolin, Water	Of each a sufficient quantity.	

Mix the tincture of orange, tincture of lemon, orange flower water, alcohol, syrup and four fluid ounces (or two hundred cubic centimetres) of water with two ounces of kaolin ; set aside for twenty-four hours ; filter ; wash the filter with sufficient water to make twenty fluid ounces (or one thousand cubic centimetres) of simple elixir.

Note.—In response to a demand for a simple dilutent.

Emulsum Olei Morrhuæ.
Emulsion of Cod Liver Oil.

Cod Liver Oil	8 ozs.	500 C.c.
Gum Acacia (in powder)	2 ,,	125 grammes
Syrup	1 ,,	62½ C.c.
Oil of bitter almonds	5 minims	12 minims
Water	a sufficient quantity.	

Triturate the cod liver oil and gum acacia together ; add five ounces (or three hundred and thirteen cubic centimetres) of water, and stir briskly ; when the emulsion is formed add the oil of bitter almond, the syrup, and sufficient water to make sixteen fluid ounces (or one thousand cubic centimetres).

Note.—For the administration of cod liver oil, or as a basis for combination with the hypophosphites, creosote, quinine, etc.

Extractum Apocyni Liquidum.
Liquid Extract of Apocynum.

Apocynum (in No. 60 powder)	20 ozs.	1,000 grammes
Glycerin	2 ,,	100 C.c.
Alcohol (90 per cent.)	a sufficient quantity to make 20 fd. ozs.	1,000 C.c,

Process the same as for liquid extract of hamamelis.

Dose—2 to 5 minims.

Note—Valuable diuretic and cardiac stimulant. Occasionally used.

Extractum Buchu Liquidum.
Liquid Extract of Buchu.

Buchu leaves (in No. 40 powder)	20 ozs.	1,000 grammes.
Alcohol (90 per cent.)	a sufficient quantity to make 20 fd. oz.	1,000 C.c.

Process the same as for liquid extract of hamamelis.

Note.—The tincture is rarely used in Canada, as it contains too much alcohol. The fluid extract is frequently prescribed.

Extractum Hyoscyami Liquidum.
Liquid Extract of Henbane,

Henbane leaves (in No. 40 powder)	20 ozs.	1,000 grammes.
Alcohol (60 per cent.)	a sufficient quantity.	

Same as buchu.

Note.—More reliable than the succus as obtained in Canada, and contains less alcohol than the tincture.

Extractum Tritici Liquidum.
Liquid Extract of Couch Grass.

Couch Grass (cut small)	20 ozs.	1,000 grammes.
Boiling water	a sufficient quantity.	
Alcohol (90 per cent.)	5 ozs.	250 C.c.

Digest the couch grass with one hundred ounces (or five litres) of boiling water for six hours ; strain ; repeat the operation twice ; mix the infusions and evaporate to fifteen ounces (or eight hundred cubic centimetres) ; add the alcohol ; let stand twenty-four hours, and filter.

Dose—1 to 2 drachms.

Note.—Very often used. All the principles are in solution.

Extractum Grindeliæ Liquidum.
Liquid Extract of Grindelia.

Grindelia in No. 40 powder	20 ozs.	1,000 grammes
Sodium Carbonate	2 ozs.	100 ,,
Water	10 ozs.	500 ,,
Alcohol (80 per cent.)	a sufficient quantity.	

Moisten the grindelia with eight ounces (or four hundred cubic centimetres of alcohol) ; macerate in a closed vessel for twenty-four hours ; pack the moistened powder in a percolator, and add sufficient menstruum to saturate it thoroughly ; when the liquid begins to drop, close the lower orifice of the percolator ; set aside for twenty-four hours ; then allow percolation to proceed, gradually adding menstruum till the grindelia is exhausted. Recover the alcohol by distillation, and dissolve the residue in the water containing the sodium bicarbonate, and after effervescence ceases add sufficient alcohol to make twenty ounces (or one thousand cubic centimetres) of liquid extract,

Dose—10 to 20 minims.

This preparation mixes clear with watery fluids as the resins are saponified by means of the sodium carbonate. It is preferable to the alcoholic fluid extract.

Extract Senegæ Liquidum..
Liquid Extract of Senega.

Senega (in No. 40 powder)	20 ozs.	1,000 grammes.
Solution of Soda	2 ,,	100 C.c.
Alcohol (70 per cent.)	a sufficient quantity.	

Moisten the powdered senega with the solution of soda and six ounces of alcohol ; pack the moistened powder in a percolator, etc., the same as for buchu.

Dose—5 to 20 minims.

Note.—Is in considerable demand.

The non-volatile alkali is preferable to the ammonia directed in the U.S.P. formula.

Extractum Sanguinariæ Liquidum.
Liquid Extract of Blood Root.

Blood Root (in No. 60 powder)	20 ozs.	1,000 grammes.
Glycerin	2 ,,	50 C.c.
Acid Acetic	¼ ,,	26 C.c.
Alcohol (80 per cent.)	a sufficient quantity.	

Mix the glycerin and acetic acid with eight ounces (or four hundred cubic centimetres) of alcohol. Moisten the blood root with the mixture ; pack the moistened powder in a percolator ; and proceed as with buchu.

Dose—3 to 10 minims.

(Less Important.)

Extractum Viburni Opuli Liquidum.
Liquid Extract of Cramp Bark.

Cramp Bark (in No. 60 powder)	20 ozs.	1,000 grammes
Alcohol (70 per cent.)	a sufficient quantity.	

Same as buchu.

Dose—1 to 2 drachms.

(Less important.)

Extractum Viburni Prunifoli Liquidum.
Liquid Extract of Black Haw.

Black Haw (in No. 60 powder)	20 ozs.	1,000 grammes.
Alcohol (70 per cent.)	a sufficient quantity.	

Same as buchu.

Dose—1 to 2 drachms.

Note.—Valuable and much in use.

LIQUOR THYMOL COMPOSITION.
Compound Solution of Thymol.

Benzoic Acid	10 grammes	½ oz.
Boric Acid	20 „	1 oz.
Borax	10 „	½ oz.
Thymol	2 „	44 grs.
Eucalyptol	10 drops	4 drs.
Oil, Wintergreen	10 „	4 drs.
Oil of Peppermint	6 „	2 drs.
Glycerin	100 C.c.	
Alcohol (90 per cent.)	300 C.c.	
Water	a sufficient quantity.	

Dissolve the thymol, oil of wintergreen, and oil of peppermint in the alcohol; dissolve the benzoic acid, boric acid and borax in twelve ounces (or six hundred cubic centimetres) of water; add the glycerin; mix the two solutions; set aside for twenty-four hours; filter through kaolin, and add sufficient water to make twenty fluid ounces (or one thousand cubic centimetres).

NOTE.—Similar proprietary preparations are in constant demand.

OLEUM GAULTHERIA.
Oil of Wintergreen.

The oil distilled from the leaves of *Gaultheria procumbens*.

Characters and tests.—Colourless or slightly yellowish tint. Specific gravity, 1·180 to 1·187. It should rotate the plane of a ray of polarised light not less than 0·25 to the left in a tube 100 millimetres long. (Powers and Kleber.)

NOTE.—A favourite aromatic oil in Canada.

SYRUPUS ACIDI HYDRIODICI.
Syrup of Acid Hyrdiodic.

Potassium Iodide	236·25 grains	27 grammes.
Tartaric Acid	223 „	25 „
Calcium Hypophosphite	17½ „	2 „
Water	525 minims	60 C.c.
Alcohol (45 per cent.)	440 „	
Syrup to make		1,000 C.c.

Dissolve the potassium iodide and calcium hypophosphite and the tartartic acid in 440 minims (or fifty cubic centimetres) of alcohol; mix the solutions; shake well and set aside in ice water for half an hour; then filter through a small filter, washing the filter with alcohol (45 per cent.) till the filtrate amounts to two ounces (or one hundred cubic centimetres). Mix this solution with sufficient syrup to produce twenty fluid ounces (or one thousand cubic centimetres).

NOTE.—Official in U.S.P. 1 per cent., but 2 per cent. is frequently demanded; this formula, therefore, meets all requirements.

SYRUPUS FERRI PHOSPHATIS COMPOSITUS.
Compound Syrup of Ferrous Phosphate.

Iron wire	37½ grains	4·3 grammes.
Precipitated Calcium Carbonate	120 „	13·7 „
Potassium Acid Carbonate	9 „	1 „
Sodium Phosphate	9 „	1 „
Cochineal	30 „	3·5 „
Sugar	14 „	700 „
Water	a sufficient quantity.	

Dissolve the iron wire in one fluid ounce (or fifty cubic centimetres) of phosphoric acid and half an ounce (or twenty-five cubic centimetres) of water in a flask, heating gently till dissolved. Dissolve the precipitated calcium carbonate, potassium carbonate and sodium phosphate in half an ounce (or twenty-five cubic centimetres) of water. Mix the solutions, filter and set aside. Boil the cochineal and six fluid ounces (or three hundred cubic centimetres) of water for fifteen minutes; cool, filter and wash the filter with sufficient water to make seven ounces (or three hundred and fifty cubic centimetres). In this dissolve the sugar with the aid of heat, and strain. When cold, add the solution of phosphates and sufficient water to measure twenty fluid ounces (or one thousand cubic centimetres).

NOTE.—Frequently prescribed by physicians.

SYRUPUS HYPOPHOSPHITUM COMPOSITUS.
Compound Syrup of the Hypophosphites.

Calcium hypophosphite	80 grains.	12 grammes.
Potassium Hypophosphite	40 „	6 „
Manganese Hypophosphite	40 „	6 „
Iron Hypophosphite	40 „	6 „
Potassium Citrate	30 „	4·5 „
Strychnine Hydrochloride	2 „	0·3 „
Quinine Hydrochloride	3 „	1·3 „
Sugar	14 ounces	700 grammes.
Water	a sufficient quantity.	

Dissolve the calcium, potassium, and manganese hypophosphites in four ounces of water. Dissolve the iron hypophosphite in four ounces of water with the potassium citrate. In this solution dissolve the quinine and strychnine hydrochlorides, mix the solutions, filter on to the sugar, dissolve by agitation and make up to twenty fluid ounces.

This formula is proposed, as there is a demand for such a preparation.

SYRUPUS SENEGÆ.
Syrup of Senega.

Liquid Extract of Senega	4 ounces	200 C.c.
Sugar	14 „	700 grammes.
Water	a sufficient quantity.	

Mix the liquid extract of senega with ten ounces (or five hundred and fifty cubic centimetres) of water; through kaolin, washing the filter with distilled water; dissolve the sugar in the filtrate; strain and add water to make twenty fluid ounces (or one thousand cubic centimetres) of the syrup.

Dose—½ to 1 fluid drachm.

NOTE.—Preferred to tincture.

SYRUPUS IPECACUANHÆ.
Syrup of Ipecacuanha.

Liquid Extract of Ipecacuanha	1 fld. oz.	50 C.c.
Acetic Acid	90 minims	10 „
Glycerin	2 ounces	100 „
Sugar	14 „	700 grammes.
Water	a sufficient quantity.	

Mix the liquid extract of ipecacuanha, acetic acid, and ten ounces (or five hundred cubic centimetres) of water, filter through kaolin into a vessel containing the glycerin, add the sugar and dissolve without the aid of heat, strain and add water to make twenty fluid ounces (or one thousand cubic centimetres) of the syrup.

Dose—1 to 2 drachms.

NOTE.—Strongly recommended.

TINCTURA ARNICÆ FLORES.
Tincture of Arnica Flowers.

Arnica Flowers (in No. 20 powder)	2 ounces 100 grammes.
Alcohol (45 per cent.)	a sufficient quantity.

Moisten the powder with four fluid ounces (or two hundred cubic centimetres) of the alcohol, and complete the percolation process. The resulting tincture should measure one pint (or one thousand cubic centimetres).

Dose—Half to one fluid drachm.

NOTE.—This tincture is the preparation exclusively used in this country.

TINCTURA JALAPÆ COMPOSITA.
Compound Tincture of Jalap.

Jalap, No. 40 powder	1 oz., 262 grains	80 grammes.
Scammony „	175 grains	20 „
Turbeth „	88 „	10 „
Alcohol (60 per cent)	a sufficient quantity.	

Moisten the powder with two fluid ounces (or one hundred cubic centimetres) of the alcohol, and complete the percolation process. The resulting tincture should measure one pint (or one thousand cubic centimetres).

Note.—Ordinary tincture never used; this preparation is a favourite among French physicians.

Tinctura Sanguinariæ.

Tincture of Blood Root.

Sanguinaria (in No. 40 powder) ..	2 ozs.	100 grammes.
Acetic Acid.....	192 minims	20 C.c.
Glycerin	1 oz.	50 ,,
Alcohol (80 per cent.)	A sufficient quantity.	

Mix the acetic acid, glycerin and alcohol. Moisten the sanguinaria with two fluid ounces (or one hundred cubic centimetres) of the menstruum, and complete the percolation process. The resulting tincture should measure 1 pint (for one thousand cubic centimetres).

Note.—This menstruum was adopted as yielding the best results after a series of experiments commencing in 1898. It differs slightly from that official in the U.S.P.

Hydrargri Iodidium Flavum.

Yellow Iodide of Mercury.

Mercurous iodide obtained by interaction of mercurous and potassium iodide.

Note.—Prepared according to this formula it is stable, and is frequently prescribed.

Syrupus Hypophosphitum.

Syrup of Hypophosphites.

Calcium Hypophosphite.....	394 grains	45 grammes.
Sodium Hypophosphite	131 ,,	15 ,,
Potassium Hypophosphite....	131 ,,	15 ,,
Tincture of Lemon	87 minims	10 C.c.
Sugar.....	14 ozs.	700 grammes.
Water to make	20 ,,	1,000 C.c.

Dissolve the salts in ten fluid ounces (or four hundred cubic centimetres) of water; dissolve the sugar in the solution without the aid of heat; add the tincture of lemon, and finally enough water to make twenty fluid ounces (or one thousand cubic centimetres) of the syrup.

Dose—1 to 2 drachms.

Note.—Less important.

Ferri Phosphas Solubilis.

Soluble Phosphate of Iron.

Made according to the process of the U.S.P.

Resina Laricis.

Red Spruce Gum.

A resinous exudation from the stem and branches of *Larix americana*.

Tinctura Resinæ Larcis.

Tincture of Red Spruce Gum.

Red Spruce gum	2 ozs.	100 grammes.
Alcohol (90 per cent.).....	20 ozs.	1,000 C.c.

Made by maceration process, as tincture of myrrh.

NEW REMEDIES.

Eudoxine.—Eudoxine is the bismuth salt of nosophene; it has been given by Landiewski in doses of 18 to 20 centigrammes in follicular enteritis, dysentery, chronic and subacute enteritis in children from two to seven years of age. Although contra-indicated in infantile cholera, it acts well in mucous or purulent diarrhœa.—*Bull. Gen. de Therapie*, **138**, 140.

Amyl Valerianate as an Antispasmodic and Anæsthetic.—Amyl valerianate has been found to be specially serviceable as an anæsthetic and antispasmodic in the treatment of female nervous affections, being readily absorbed, and well tolerated by the most delicate patients. In addition to this, it is an active solvent of cholesterin, which renders it of value in the treatment of biliary lithiasis. The ordinary dose is 10 to 30 centigrammes per diem: but as much as 1 Gm. may be taken without inconvenience.—*Union Pharm.*, **40**, 291.

LETTERS TO THE EDITOR.

Prospects of Pharmaceutical Legislation.

Sir,—Your article on the above subject clearly defines the present position, but you seem to entertain the possibility of giving away the principal rights secured to us, the only ones worth defending—viz., the privileges conferred by examination. Those privileges were upheld by law until the quibble was propounded that person is not included in the word persons. Are the Excise laws so enforced? In the law of conspiracy the greater number creates the greater crime. You say, if the business of a chemist and druggist is to be carried on by a company, let the legally qualified person conducting the business be properly respected by putting him in a position, as the Lord Chancellor says, *bonâ fide*, and so that he would not only be master of the business but of the company as well. If that is intended to be serious it is most fallacious. The qualified man might be dismissed at a moment's notice; instead of being master of the company, he would be merely the tool of the directors, to be cast aside when found to be inconvenient. The Pharmacy Act has been the cause of much inconvenience and expense to the trade; since it became law the profits of the trade have diminished principally by the action of those who, without qualification, evade the Act. Let us support no delusive half-measures. That will be worse than useless. The spirit of the Act must be upheld. I think if this is unequivocally claimed our demand will be respected and granted by Parliament. The store interest will oppose us, but our political influence throughout the country is considerable, and if we systematically exercise it for this purpose we will prevail. Nothing less than this is worthy of our consideration.

London, August 23, 1899. Wm. MacGeorge.

Application to Kill Plantains.

Sir,—As a reader of the Journal for a number of years, and noticing your reply to a correspondent last week, I feel interested to say that there is nothing more effective in the world to kill plantains than a full teaspoonful of common salt, in the heart of each, applied during dry weather. Sulphuric acid is apt to leave all the root that is necessary to grow another plant.

Botanic Gardens, Cambridge,
August 26, 1899. R. J. Lynch.

Assay of Antimonous Oxide, B.P.

Sir,—For the benefit of my fellow-students I desire to call attention to the B.P. method of assay of antimonous oxide. I gather that after solution of the oxide in cream of tartar, the solution of sodium bicarbonate should be added whilst still hot. If such a method is adopted a heavy precipitate appears, which cannot satisfactorily be titrated. If, however, the solutions are mixed in the cold, no precipitate occurs if the operation is concluded in a reasonable time. The quantity operated upon is much too large, and could well be divided by two, and two experiments made, the mean being taken as the truth.

West Bromwich, August 28, 1899. J. R. Allen.

ANSWERS TO QUERIES.

Special Notice.—*Scientific, technical, legal, and general information required by readers of the 'Pharmaceutical Journal' will be furnished by the Editor as far as practicable and as early as possible, but he cannot undertake to reply by post, even though stamped envelopes accompany the queries. All communications must be addressed "Editor, 17, Bloomsbury Square, London, W.C.," and must also be authenticated by the names and addresses of the senders. Questions on different subjects should be written on different slips of paper, each of which must bear the sender's initials. Replies will, in all cases, be referred to such initials, and the registered number added in each instance should be quoted in any subsequent communication on the same subject. When formulæ are given without definite weights and measures, it should be understood that all solids are to be weighed and liquids measured. Not more than six plants should be sent for recognition at one time.*

Coloured Poultry Food (M. P. S.—33/10).—Your sample appears to be a mixture of the red, non-pungent bird pepper and annatto, as far as we can examine it.

Satiny Appearance of Shaving Cream (H. H. C.—33/3).—The appearance is due to the use of white Naples soft soap as a basis. If that is rubbed in a mortar, with a pulling out of the mass it will assume this peculiar satiny appearance.

Household Ammonia (W. B. and S.—33/14).—Dissolve yellow soap, 2 oz., in warm distilled water, 3 pints ; add pearlashes 1 oz., and when nearly cold add strong solution of ammonia, 5 fl. oz. Keep well corked.

Titles on Labels (G. E. H.—33/15).—It is illegal for a person not registered under the Pharmacy Acts to style himself a "photographic chemist," but it is doubtful if any offence is committed by an unqualified person using the second label you submit.

Botanical (R. G. M.—33/20).—It is a specimen of *Helianthus multiflorus*, in which some of the double flowers have been developed in the normal form of single flowers, probably owing to the exceedingly dry season. Please address all communications for the Journal to the Editor.

"Cocand Fluoride" (A. S.—33/11).—There is no such thing used in medicine; probably your customer has mispronounced the name of the article he requires. It might be cocaine hydrochloride, but that salt should not be supplied for internal administration without a doctor's prescription.

Bird-lime for Fly Papers (O. S.—33/16).—This is usually nothing but a mixture of linseed oil and resin, about 40 of the latter to 20 of the oil. Much care is required in the boiling to obtain the correct degree of viscosity. You probably failed because you did not heat the linseed oil long enough.

Potassium Superoxalate (F. P. B.—33/6).—The odour you notice is frequently given off, both by powdered oxalic acid and its salts, on keeping. The dry quadroxalate is somewhat hygroscopic in the powdered state; probably in that condition it loses part of its water of crystallisation, and then becomes hygroscopic. Your sample contains a trace of lead, whether as an accidental admixture or as an impurity we cannot say; probably the latter, since many commercial samples of potassium quadroxalate contain quite an appreciable quantity of that metal.

Preserving Infusions Without Alcohol (J. B.—32/34).—We have not found that chloroform gives unsatisfactory results as a preservative for aqueous preparations of drugs. On the contrary, it is eminently satisfactory, and if the preparations are carefully stored they will keep indefinitely. Even preparations of ergot, which are notoriously difficult to preserve, will be perfectly good if properly treated. A convenient method of adding the chloroform is to emulsify it first with a little tincture of quillaia, and shake the emulsion well before each addition. We know of nothing better, or less objectionable, than this for the purpose. In many instances it is preferable to spirit. Acetic acid has several times been advocated as a substitute for spirit, for the extraction and preservation of pharmaceutical fluid extracts and the like. As to the wines, they could not, obviously, be used to substitute the B.P. tinctures without sanction. There would be no legal difficulty about the compounding of prescriptions with such preparations; but the sale of such wines as could be used as beverages would, of course, necessitate a wine licence.

Examination of Liniment of Camphor (D. W. R.—33/9).—A communication on the determination of the strength of liniment of camphor was published by Norman Leonard and H. M. Smith in the *Analyst*, **23**, 281. They state that the amount of camphor may readily be determined by exposing a known weight of the oil in a flat-bottomed dish to a temperature of 120° C. for two hours, when the camphor will be volatilised; the loss in weight is therefore taken to represent the camphor. Olive oil under those conditions gains in weight to the extent of 0·15 per cent., hence this figure should be added to that of the loss observed. An approximation of the amount of camphor present may be obtained by merely taking the specific gravity of the liniment; each per cent. of camphor raises the gravity 0·00045. The mean of the official limits for the specific gravity of olive oil being 0·9165, it is easy to calculate from these data the amount of camphor present. According to the formula—

$$\text{Camphor per cent.} = \frac{\text{sp.g. of sample} - 0{\cdot}9165}{0{\cdot}00045}$$

Rhubarb and Tomatoes for Gouty Subjects (W. T. F.—32/30).—Doubtless after partaking of rhubarb, oxalates are excreted in considerable quantities; the typical crystals of calcium oxalate are constantly met with in the urine under such circumstances. Cooking would probably not alter this; as a matter of fact, we have never heard of rhubarb being eaten raw. The preponderant acid in tomatoes is probably citric, not oxalic acid. With regard to their reputed value as a liver tonic, that may be due to the trace of volatile oil, probably containing sulphur, which they contain, or possibly to the presence of some ferment or enzyme; most fruits contain those. That of the pineapple has been shown to possess active peptic powers; probably the juice of the melon has similar properties, since a slice of melon taken on an empty stomach will often relieve the sick headache due to excessive indulgence in the pleasures of the table. If tomatoes exercise any special action on the liver, they would be likely to be more active raw than cooked. On the other hand, the tissues would be less digestible. Sorrel is so little eaten in this country that it scarcely enters into the question; the cultivated sorrel used as an ingredient in salads in France is a much larger and more succulent plant than the wild sorrel, and tastes much less acid.

Liberation of Iodine (D. G.—33/19).—It is probably due to the presence of hydrogen peroxide, which has been shown to be produced from ether under certain conditions. See *Pharm. Journ.* [3], **20**, 989.

INFORMATION WANTED.

Colonial Hospital Appointments (C. and D.—32/32).—Where can I find information *re* appointments as chemist and druggist in connection with hospitals and infirmaries in British colonies (South Africa, New Zealand, etc.), and if the Minor qualification is what is required for such situations?

Seltzogene (H. and F.—33/17).—A lady client has asked us to get a new head for a seltzogene manufactured by Monroy et Cie, Paris. Who are the agents in this country for above makers?

NOTICES TO CORRESPONDENTS.

All Communications for the 'Pharmaceutical Journal' must be addressed to the Editor, 17, Bloomsbury Square, London, W.C., and, if intended for publication in the current week's issue, should reach the Office not later than Wednesday, though news can be received as late as Thursday, if specially arranged for.

Advertisements and Orders for copies of the Journal must be addressed to the Publishers, 'Pharmaceutical Journal Office, 5, Serle Street, Lincoln's Inn, London, W.C.

Instructions from Members of the Pharmaceutical Society, with reference to the transmission of the Journal, must be sent to the Secretary, 17, Bloomsbury Square, London, W.C.

ARTICLES AND REPORTS sent for the Editor's approval should be accompanied by stamped directed envelopes, otherwise no guarantee can be given that they will be returned if not found suitable.

CORRESPONDENTS should write in ink, on one side of the paper only, and must authenticate the matter sent with their names and addresses—of course not necessarily for publication. No notice can be taken of anonymous communications.

DRAWINGS FOR ILLUSTRATIONS should be executed twice the desired size; clean sharp lines being drawn with a pen and liquid Chinese ink. Shading by washes is inadmissible. Photographs can be utilised in certain cases.

NAMES AND FORMULÆ should be written with extra care, all systematic names of plants and animals being underlined, and capital letters used to commence generic but not specific names.

REPRINTS OF ARTICLES cannot be supplied unless the authors communicate with the Editor before publication of the articles. The right to reproduce all original matter and illustrations published in the Journal is strictly reserved.

COMMUNICATIONS, LETTERS, NEWSPAPERS, etc., have been received from Messrs. Allen, Bartlett, Bostock, Burns, Burroughs, Burrows, Chaston, Coomber, Cowie, Durrant, Ferguson, Gair, Hare, Hunter, Lloyd, Lynch, Mumbray, Pollard, Prince, Shuttleworth, Taylor, Wellcome, Wyatt.

Pharmacy and the Allied Sciences.

A REVIEW OF CURRENT WORK.

PICOLINE DERIVATIVES.

In the endeavour to produce amido-oxypicoline by the action of nitrous acid on dioxypicoline and subsequent treatment with a reducing agent, Arnold Hess unexpectedly obtained trioxypicoline, $C_6H_7NO_3$. It melts at 263–265°, gives an intense blue coloration with ferric chloride, and is therefore distinct from Sedgwick and Collie's trioxypicoline (m.p. 179°), obtainod by the oxidation of dioxypicoline with potassium permanganate, although it may be the same body that they described as melting at 252° (corr. 262°).—*Berichte*, **32**, 1985.

GOSSYPOL.

From the soda liquors obtained in the purification of cotton seed oil, L. Marchlewski has separated by extraction with ether a substance, gossypol, to which the formula $C_{13}H_{14}O_4$ is provisionally assigned. Gossypol is a finely crystalline, yellow substance, which dissolves readily in alcohol, ether, benzol, and in alkalies, but is insoluble in water. Concentrated sulphuric acid gives it a cherry red colour, and hence it is concluded that the red colour produced when crude cotton seed oil is treated with sulphuric acid is due to gossypol.—*Journ. für Prakt. Chem.*, **60**, 84.

TOXIC ACTION OF SODIUM FLUORIDE.

H. B. Baldwin is of opinion that sodium fluoride should be classed among the less violent poisons, and quotes a number of facts in support of his contention. It appears that the compound is largely sold in New York as an insecticide, put up in tins resembling baking-powder boxes. In an instance, of which details are given, some fluoride was added to pancakes in mistake for baking-powder, and several persons who ate the pancakes became ill, whilst one man died. It is estimated that at least 10 Gm. of the fluoride must have been taken in the fatal case.—*Journ. Am. Chem. Soc.*, **21**, 517.

NEW ANIMAL FERMENTS.

E. Abelous and E. Gérard find that most of the internal organs of animals contain a soluble ferment in variable proportions which reduces nitrates. From the influence of temperature upon this body it would appear to be of a diastasic nature. It is most active between the temperatures of 20°–40° C. and is destroyed at 72° C. The liver and kidneys are richest in this ferment, striated muscular fibre and brain substance contain the least.—*Comp. rend.*, **129**, 56.

RESIN OF CONVOLVULUS ALTHÆOIDES.

Since the dried root of *Convolvulus althæoides* contains approximately 7 per cent. of a purgative resin, and the plant, being very common in Syria, is readily obtainable, N. Georgiades suggests that this resin might find a place in medicine as a substitute for the more costly scammony or jalap resins. The resin of *Convolvulus althæoides* is of a greenish yellow colour and is glucosidal in reaction. Only a portion of it is soluble in ether.—*Journ. de Pharm.* [6], **10**, 117.

CRYSTALLINE BLOOD ALBUMIN.

By freezing the serum of the blood of guinea-pigs and other animals, previously centrifugated, and freed from globulins by means of ammonium sulphate, S. Gruzewska has succeeded in obtaining blood albumin in a crystalline condition. The length of time necessary to expose the serum to a freezing temperature is not constant; in one case a better crop was obtained in twenty-four hours than in twice that time. Albumin crystals were obtained thus from the blood serum of the guinea-pig, cat, ox, and common snake.—*Journ. de Pharm.* [6], **10**, 125.

NEW ARSENIDES.

By reducing the arseniates of strontium, of barium, and of lithium, by heating mixtures of these salts with charcoal in the electric furnace, P. Lebeau has succeeded in preparing the three corresponding arsenides, As_2Sr_3, As_2Ba_3, and $AsLi_3$. Strontium arsenide thus prepared closely resembles calcium arsenide, being a reddish-brown substance having a micro-crystalline structure. It closely agrees with that body in its chemical reactions; it is decomposed by water into arsenuretted hydrogen and strontium hydrate; it reduces most metallic oxides, and is acted upon with much energy by reducing agents. Barium arsenide has similar properties, but is more energetic in its action. Lithium arsenide occurs as a deep brown substance, with a crystalline fracture, the chemical reactions of which are similar to the arsenides of strontium, calcium, and barium.—*Comp. rend.*, **129**, 47.

TITRATION OF ZINC.

Pouget precipitates zinc as sulphide, decomposes the ZnS with a known excess of iodine solution, the residual iodine being then titrated back with thiosulphate solution. To obtain accurate results all filtration and washing of the zinc sulphide must be avoided. The process is conducted thus: To the zinc solution 20 C.c. of sodium acetate 10 per cent. solution is added for each 0·1 Gm. of Zn present; then ammonia, drop by drop, until a permanent precipitate is formed; finally, an excess of saturated solution of H_2S. The liquid is boiled until every trace of H_2S is driven off, cooled, a known quantity, in excess, of standard iodine solution run in, and after standing to complete the decomposition of the ZnS, the excess of iodine is determined with thiosulphate in the usual manner.—*Comp. rend.*, **129**, 45.

BROMINE IN THYROID.

Baldi finds that bromine is a constituent of sheep's thyroid glands. He demonstrates its presence as follows: The aqueous solution of the ash of the glands, incinerated with potassium nitrate and caustic soda, is evaporated to dryness, and the residue treated with permanganate until distinctly coloured, then heated to 100° C. On cooling the liquid is acidulated with H_2SO_4, and transferred to a flask fitted with two tubes, one dipping below the surface of the liquid, the other shorter, merely entering the flask; the latter carries a piece of test paper saturated with fluorescein. Through the longer tube from 3 to 7 C.c. of a 16 per cent. solution of cupric sulphate is added, and gentle aspiration started. In a few minutes the test paper becomes reddened by the formation of cosin by the action of the bromine liberated.—*Repertoire* [3], **11**, 308, after *Achiv. Ital. de Biol.*

EGOLS: NEW ANTISEPTICS.

When the parasulphonic derivatives of phenols are nitrated, the ortho-nitro-parasulphonic acids obtained readily combine with an atom of mercury for each two atoms of the phenol present. In this way E. Gautrelet has obtained ortho-nitro-phenol, cresol and thymol parasulphonates of mercury and of potassium, to which the generic name egol has been given, the phenolic constituent being denoted as a prefix, thus, phenegol, cresegol, thymegol, etc. These bodies are very stable, occurring as reddish-brown powders; they crystallise with difficulty in rhombohedra from dilute alcoholic solutions. They are readily soluble in water and insoluble in strong alcohol. The aqueous solutions are odourless and tasteless, and are neither caustic nor irritant, do not coagulate albumin, and are not decomposed by organic matter, but precipitate toxins. They are non-toxic in doses of 2 Gm. per kilo. of body weight when injected hypodermically; taken in the stomach they act as emetics. They are powerful bactericides, since, in the proportion of 4:1000, they arrest all development in bacterial cultures, and added to sterilised media, prevent any development of germs.—*Comp. rend.*, **129**, 113.

THE OFFICIAL TEST FOR CHLORAL HYDRATE.

BY F. H. ALCOCK, F.I.C., AND T. H. THOMAS.

The B.P. test for the determination of the above is: "If 4 grammes be treated with 30 C.c. of volumetric solution of sodium hydroxide, no more than 6 C.c. of volumetric solution of sulphuric acid should be required to neutralise the soda which remains free on the completion of the reaction."

When experimenting in the above manner, and calculating the results in terms of chloral hydrate, the results obtained showed that the examples under examination appeared to contain considerably more than 100 per cent., which is practically what the B.P. requires. Where 6 C.c. of the sulphuric acid solution ought to have been required, in one case, only 2·4 C.c. was required. That was the experience of many other students at the same time, following the same directions.

The sample under examination was undoubtedly pure, and contained no chloral alcoholate.

An attempt was made to discover the cause of this anomaly. With this object in view, 4 grammes of chloral hydrate was mixed with 30 C.c. of volumetric solution of sodium hydroxide, shaken well, and allowed to stand for eighteen hours, at the temperature of the laboratory, which never rose above 80°F.; then 2·4 C.c. of sulphuric acid solution was required to neutralise the surplus alkali. To this same solution, now neutral, 30 C.c. of sodium hydroxide solution was added, shaken, and left at the same temperature as before for forty-eight hours, and titrated back, indicating that 4·6 C.c. of sodium hydroxide solution had been attacked. Then 10 C.c. of sodium hydroxide solution was added, and after forty-eight hours titrated back, when 5·6 C.c. of sulphuric acid was required, thus indicating that 4·4 C.c. of sodium hydroxide had been attacked. That is to say, that the yield of chloroform produced in the original experiment had used 12·2 C.c. of sodium hydroxide solution, and had suffered further decomposition.

From these experiments we infer that the sodium hydroxide solution, standing in contact with the chloroform, undergoes decomposition into sodium chloride and formate, and thus vitiates the result. An experiment was made on a sample of pure chloroform in order to ascertain this. 2·875 grammes of chloroform was taken, and mixed with 30 C.c. of sodium hydroxide solution, and allowed to stand for eighteen hours, and then titrated back with sulphuric acid, which indicated that 6·4 C.c. of sodium hydroxide solution had been used. To this 10 C.c. more of sodium hydroxide solution was added, and allowed to stand for two days, and then titrated back with sulphuric acid (3·8 C.c.), which showed that 6·2 C.c. of sodium hydroxide solution had been consumed. 10 C.c. of sodium hydroxide solution was again added, and allowed to stand for two days, and then titrated back, requiring 4·4 C.c. of sulphuric acid, indicating that 5·6 C.c. of sodium hydroxide solution had been used. That is, in 114 hours 2·875 grammes of chloroform had consumed 18·2 C.c. of sodium hydroxide solution. That the alkali does attack the chloroform with production of sodium chloride and formate would therefore seem to be really the case. This was found to be the case.

On reference to the 'Year Book of Pharmacy,' 1887, page 126, a process for ascertaining the purity of chloral hydrate is mentioned, and referred to A. Kremel.

In this note no mention is made of the quantity of chloral hydrate, nor of the amount of sodium hydroxide used. The titration of the acid is conducted after a few minutes, using normal hydrochloric acid with litmus as the indicator. It is then stated that 1 gramme of chloral hydrate requires for complete decomposition into chloroform and sodium formate 6·04 C.c. of sodium hydroxide solution, whilst chloral alcoholate requires 5·17 C.c.

Now, this requires for 4 grammes of chloral hydrate (30—24·16) 5·84 C.c. of sulphuric acid. The B.P. method differs from that of Kremel's in recommending the application of heat, whereas Kremel makes no mention whatever of heat; its use in the B.P. process seems to us to be a faulty part of the operation.

By taking 4 grammes and mixing in a stoppered bottle with 30 C.c. of sodium hydroxide solution, and shaking vigorously for a few minutes, without the use of heat, using litmus as an indicator, and then adding the acid, we found that 5·8 C.c. of sulphuric acid was necessary for complete neutralisation. We, therefore, suggest this modification, and think that concordant results will be obtained. By the use of less quantities, say two grammes, equally correct results are obtainable.

THE OFFICIAL TEST FOR CHLORAL HYDRATE.

BY F. PILKINGTON SARGEANT, PH.C.

The pharmacopœial quantitative test for chloral hydrate does not appear to be of any value in the assay of solutions of chloral hydrate, or even for the determination of real chloral in the substance itself; special precautions must be used if correct results are to be obtained. In Thorpe's 'Dictionary of Applied Chemistry' it is stated that chloroform has no action upon caustic alkali in aqueous solution even when boiled with it. That may be so with absolutely pure chloroform, but with chloroform containing traces of alcohol a rapid formation of potassium chloride is noticed on boiling under a reflux condenser with decinormal potassium hydroxide. Perhaps this reaction takes place on heating together chloral hydrate and caustic alkali, in fact, the following experiments appear to lead to this conclusion, and that the equation

$$CCl_3CH(OH)_2 + KOH = HCOOK + CHCl_3 + H_2O$$

only represents the reaction when certain precautions are taken.

The chloral hydrate used was in small crystals, and answered the B.P. chemical tests. It indicated 101 per cent. real $CCl_3CH(OH)_2$ when assayed by Wood's process (*P.J.* [3] **1**, 703), and also when treated in a tube with ammonia (Paul, *P.J.* [3] **1**, 621), and 99 per cent. by Muller's process (*Journ. Chem. Soc.*, **24**, 444); it had a boiling point of 94·8° C., and solidifying point 48·9° C.

A solution was made containing 1·677 Gm. of the substance in 100 C.c.; 10 C.c. of this solution after treatment with 10 C.c. of normal potassium hydroxide at 60° C. was found to require 6·2 C.c. to 6·8 C.c. of normal sulphuric acid (according to the length of time it was retained at 60° C.) for neutralisation, whilst when heated to 100° C. only 5·8 C.c. of sulphuric acid was required. Assuming liberation of chloroform, as in above equation, only 1 C.c. of potassium hydroxide should have been neutralised; that is, 9 C.c. of sulphuric acid should have been required, but if the liberated chloroform had been decomposed *in toto* by the caustic alkali, thus—

$$CHCl_3 + 4KOH = HCOOK + 3KCl + 2H_2O,$$

then 5 C.c. would have been required.

Five per cent. solutions of chloral hydrate also reacted in the same manner, *i.e.*, the more highly heated solutions absorbed the most alkali; thus, whilst 10 C.c. of a solution containing 5·25 Gm. in 100 C.c. absorbed 4·0 C.c. of normal potassium hydroxide when heated at 60° C. for five minutes, the same amount absorbed 5·55 C.c. when heated at 100° C. for the same time. In these cases the amount of chloride was estimated by Volhardt's method; the former solution required 9 C.c. decinormal silver nitrate, the latter 25 C.c. These figures (which were approximately obtained in a series of determinations) show that some interaction other than represented by the two equations given above must take place; for, taking the alkalinity of potassium hydroxide after the reaction, in conjunction with the chloride determination, only 70 to 80 per cent. of the chloral is accounted for.

Solutions of chloral of strength varying from 7 to 50 per cent yielded results corresponding very closely with the above secondary reactions diminishing as the strength of solution increased.

Finally the choral hydrate was added to the normal alkali solution in about B.P. quantity, *i.e.*, about 4 Gm. to 30 C.c., when secondary decompositions appeared to take place above 60° C. wi

formation of potassium chloride, while below 45° C. the primary reaction did not appear to take place. The most nearly correct results (differing only by 1 per cent. in twelve determinations) were obtained by warming for five minutes at 50° C. before titrating back.

Hence it would appear that the B.P. or Meyer's process is not suitable for determining the amount of choral hydrate in a solution, that the choral hydrate should be added direct to the alkali and not previously dissolved, and that secondary reactions take place in inverse proportion to the amount of choral hydrate and excess of alkali present, and in direct proportion to the heat applied.

THE SOCIETY'S MATERIA MEDICA MUSEUM AND ITS USE.

BY E. M. HOLMES, F.L.S.,

Curator of the Pharmaceutical Society's Museums.

It has been suggested to me that some information concerning the Museum and its contents might be useful to students of pharmacy. This has become the more necessary seeing that the Museum catalogue has been out of print for some years, and the complete catalogue of the Museum would probably not prove so useful to students as to the more limited number who utilise it for the purposes of reference. I propose, therefore, to give a few preliminary remarks concerning the scope and contents of the Museum, and then to notice in detail the specimens of more especial interest to students attending schools of pharmacy.

SCOPE.

In the *Pharmaceutical Journal* for 1842, vol. 1, p. 436, it is stated that the Museum should contain specimens of every substance comprised in the materia medica, not only of undoubted purity and of the finest quality obtainable, but also specimens of different qualities and different degrees of purity. Also preserved plants in different stages of their growth and manufactured drugs which undergo several processes in their progress from the raw state into the condition in which they are used, arranged in a connected series in order to familiarise the student with every aspect in which they exist.

CONTENTS.

In course of time the Museum naturally became the repository of specimens of historic interest, *i.e.*, specimens which had been the subject of papers at evening meetings of the Society, and of articles in the *Pharmaceutical Journal*, a considerable number of which related to matters or substances not now of interest to students, although valuable for reference, and for purposes of identification. Gradually also as members of the Society became domiciled abroad, collections of the native remedies of other countries were presented to the Society, so that it has now become one of the richest Museums of Drugs in the world. The Chomical Museum grew in the same degree, with the difference that its contents possess fewer characters which can be recognised by the eye, and that changes in the chemicals, especially those of an organic nature, rendered the specimens of value as types only for a limited period.

ARRANGEMENT.

The vegetable materia medica was formerly arranged according to the natural orders of plants, but in this way the official and non-official became so intermixed and so crowded that it was difficult for the student to find or for the Curator to render visible the rich collection of official articles. The specimens were therefore separated into two classes :—(1) Those of direct interest to students as regular articles of commerce, either official or non-official. (2) Those of historic interest, useful only for purposes of reference and comparison. The specimens of the first class were subsequently arranged under the heads followed in the lectures on the subject, *e.g.*, Leaves, Flowers, Fruits, Seeds, Herbs, stems, etc.

In this way comparison between one drug and another becomes easier, and the specimens consequently more instructive. The exigencies of space do not allow of free display of all the specimens, consequently the following plan has been adopted :—The room on the left-hand side of the Entrance Hall has been reserved for purposes of study. On the central table are placed in glazed frames dried specimens of all the plants of which a knowledge is required in the examinations, and on side tables are placed open drawers containing specimens of all the ordinary drugs dealt with in the lectures, with few exceptions, such as prunes, almonds, figs, liquorice, manna, which are apt to disappear, and with which students are evidently too familiar to need to examine—also a few poisonous drugs. Specimens of all these are, however, kept in the wall cases, and can be seen on application to the Curator. These drawers are arranged in groups under the headings adopted in the School of Pharmacy prospectus, page 14–15.

In the wall cases immediately behind, or as near as practicable, similar drugs are placed. Thus in the wall case immediately facing the drawers containing barks, specimens of the commercial varieties, or grades of barks and their adulterations, or substitutions, are so placed that the student having studied the ordinary article in the drawers can turn round and see the different commercial qualities, adulterations, substitutions, etc., without going to another part of the room.

Of course, it often happens that in the brief time available after the lecture, during which the specimens on the lecture table can be examined, the students in front press forward, and those behind cannot carefully examine the more interesting specimens. This loss can be made good in the Museum, where similar specimens in the wall cases can be seen and examined under the Curator's charge at certain hours, or at any time during which the Museum is open by making an appointment and bringing a list of the objects which it is desired to see.

There are two or three points concerning which it is necessary to make a clear statement, since some misunderstanding seems to exist in the minds of students concerning them.

(1) The use of the Museum is not confined to students of the Society, but is the right of all who subscribe to the Society, at whatever school of pharmacy they may study.

(2) Students or members of the Society have not the right to bring any friend or relative to *study* in the Museum, but can, with the Curator's permission, show any friend over the Museum who does not wish to study there.

(3) A card or letter of introduction from an ordinary or honorary member of the Society presented to the Curator is sufficient to obtain for a medical student limited admission during the vacation, or at such times as there is room.

(4) There is a large herbarium of medicinal plants in the Hanbury Room, any specimens in which can be seen on bringing a list to the Curator.

(5) A collection of microscopic slides illustrating botanical structure and the histology of drugs is in the charge of the Curator, and selections from these can be borrowed from him and examined in the Library of the Society, borrowers being answerable to the extent of 1s. for each slide broken by them. Students borrowing slides must enter their names and addresses in a book provided for the purpose. A microscope can be obtained from the Librarian, another, when required, from the Curator. Both slides and microscope must, however, be used only on the premises, and must be returned the same day.

(6) An impression seems to exist in the mind of some students that the specimens of drugs in the Museum of the Society are the exact counterparts of those that are employed in the Examination Room. This is not the case. Anyone acquainted with the commerce of drugs knows that samples vary exceedingly in appearance in different importations. It is, therefore, of no use to learn to recognise mere samples.

Distinctive characters, odour, taste, colour, and especially structure, as seen under a lens or microscope, are necessary to be learned before a drug can be recognised in all its different grades and qualities. Students are recommended to bring with them when studying in the Museum a good lens, a sharp knife, and a note-book, and their handbook of materia medica, and to map out their work at the commencement of the session, going through a definite number on the occasion of each visit. There are 182 drawers, so that making allowance for some specimens not placed in the drawers, 200 may be used as a basis of calculation.

The specimens are renewed each Monday when necessary, but it must not be forgotten that students are apt sometimes to inadvertently put specimens in the wrong drawer, aloes and substances closely resembling each other becoming sometimes thus mixed, so that "spotting" the specimens, *i.e.*, attempting their recognition by a passing glance is not advisable. Students found taking specimens from the drawers without permission will be refused subsequent admission to the Museum, since the possibility of study by others is thus affected. Small specimens, for purposes of experiment or verification, can, however, be obtained by application to the curator.

THE EXAMINATION OF MOUNTED SECTIONS OF DRUGS.

BY WILLIAM KIRKBY.

The study of microscopy is becoming of increasing importance to the pharmaceutical student in the department of materia medica. There is no need in this place to emphasise its importance beyond saying that with each change made by the Board of Examiners in the subjects of examination microscopy occupies a more prominent position. No doubt the best plan to adopt in the anatomical and histological study of drugs is for the student to prepare the material and put up his own mounted specimens; but there are many who are unable to devote the time to so long a course, and they are, in consequence, obliged to work over a few drugs, and for the rest have to be content to acquaint themselves with the microscopic characters as exhibited in drawings and mounted specimens. Drawings are always more or less diagrammatic. They should not be relied upon by the student for the recognition of microscopical preparations of drugs. To the expert a drawing may be of value, but the student should look upon it simply as a key to assist in identifying the tissues and cells in an actual specimen. Mounted sections are, therefore, greatly to be preferred; but the temptation to indulge in so-called "spotting" should be strictly avoided because of the numerous pitfalls into which the "spotter" may fall. Anyone trusting for the recognition of a section to the *tout ensemble* may be easily misled by differences between stained and unstained material, cleared and uncleared specimens, glycerin, glycerin jelly, and balsam mounting media, as well as by variations in the size and age of the plant from which the sections have been cut. For the most part the cursory examination which many students vouchsafe to specimens of this class is quite unproductive of knowledge, and in some cases may lead to positive confusion. It is clear that only a systematic examination of every specimen can be of any real value, and it seems desirable to indicate some lines upon which such an examination may be undertaken.

The characters to which attention should be directed fall into two categories, namely, those inherent in the mounted specimen, and those resulting from the methods of preparation. Dealing with the latter first, the variations due to mounting media, stains, and methods of clearing should be noted.

Mounting Media.—Those most generally used are Canada balsam and glycerin jelly; more rarely used are glycerin, dammar, carbolised water, and, still more rarely, solutions of potassium acetate and calcium chloride. Sections of plant structures put up in glycerin jelly, glycerin, carbolised water, and solutions of the salts mentioned exhibit the cell walls more nearly in their natural condition as to thickness than do those mounted in the resins; the contours of the cells and of the cell contents, starch, crystals, etc., are also much more clearly defined; but the field of view is darker and the tissue systems are not so well differentiated as in Canada balsam. Generally only stained material is mounted in Canada balsam, and the coloured cell walls stand out with great clearness, while the unstained cell contents are to a great extent suppressed from the field of vision. The various kinds of tissue may be readily distinguished, but the characters of the cells are not so evident because of the dehydrating process to which the material has been submitted, the cellulose walls being thin and often wavy. Starch is occasionally mounted in balsam for the purpose of examining it with polarised light, but the medium is a most unsuitable one for exhibiting the general characteristics of starch.

Stains.—Sections are generally stained with two colours, green and red being the favourite ones. If the cell contents have been removed it will not be difficult in such slides to distinguish between the lignified tissues, which are stained green, and the cellulose tissues, stained red. Carmino and hæmatoxylin are the stains usually used for cellulose. The former of these, when used as a general stain, does not attack the lignified tissues, but the latter does so to a varying extent, so that in the absence of a counter stain the distinction between cellulose and lignified tissue is not at all clearly marked. Indeed, the intensity of colour diminishes in proportion to the extent to which the lignification has taken place. Therefore the student cannot rely upon hæmatoxylin as a means of separating lignified from non-lignified tissues. In connection with hæmatoxylin and carmine it should be remembered that the section may have been cut from fresh material, in which case cells with protoplasmic contents will exhibit stained nuclei. In sections stained with Hanstein's violet the cellulose will be found to be violet, and the different kinds of lignified tissue will exhibit different shades of red. Some sections may have stained cell contents; proteids may be coloured red with borax carmine; starch may be coloured pink with safranin or corallin; the callose of sieve tubes may be stained pink with corallin or steel-blue with aniline blue. Sufficient has been said to indicate that stains cannot be relied upon solely to differentiate between the various elements in a specimen; they do, however, assist in differentiation being accomplished with greater clearness and certainty.

Clearing.—The student should be careful to observe whether the cell contents have been removed by clearing, as the difference between a cleared and a non-cleared slide is so great as to mislead a casual observer.

Sketches.—How can the inherent characters of the specimen best be apprehended? By observing the various tissues in a regular order, and transferring the observations to paper in the form of a sketch. The value of the observations will be greatly increased if the sketch is afterwards compared either with a published drawing or description. The characters to be noted will, of course, differ, according to the nature of the specimen; but an outline applicable to a few general cases may be useful.

Stems, Roots, Rhizomes.—Beginning with the periphery in plants in which secondary growth has not begun, the epidermis and its appendages would be noted; but in drugs, if of the dicotyledonous type, the thickness of the cork would be recorded. Then the primary cortex; the extension and comparative size of its cells; the presence and location of collenchymatous tissue; the presence and location of sclerenchyma, and whether in groups or a continuous ring, and if in groups their freequency and form, also if accompanied or otherwise with calcium oxalate crystals; the nature of the cell contents in the different parts of the primary cortex. In the secondary cortex, including the phloem, should be observed its width; the width of the phloem rays; the frequency, width, and direction of the medullary rays; the presence and location of bast fibres; the presence and location of other sclerotic elements in the phloem; the presence of sieve elements, and the proportion and arrangement of phloem parenchyma accompanying them; the

presence and location of laticiferous vessels ; the nature and quantity of cell contents, particularly the presence of crystals and their form and size. After the cambium would be noticed the xylem ; the kind and proportion of xylem fibres ; the size, proportion, kind, and arrangement of the vessels when present ; the presence of wood parenchyma, its proportion and distribution ; the presence of specialised cells, with their contents ; the medullary rays, their frequency, width, and contents. When vessels are absent from the xylem particular care should be taken to notice whether the xylem is composed of fibres only, or whether tracheids are present, and to what extent ; also the character of the fibres should be determined. This, of course, can only be accomplished by the examination of longitudinal sections. If a pith is present the character and contents of its cells should be noted, as well as the presence or absence of phloem strands, indicating bicollateral bundles. The foregoing sketch refers more particularly to structures in which a more or less concentric arrangement of the tissue systems prevails. Any eccentric arrangement of the tissues should be particularly recorded. If the fibro-vascular elements are scattered it should at once be ascertained whether the section is dicotyledonous or monocotyledonous, or whether it belongs to the Pteridophyta. In the case of monocotyledons the outer integument should be observed ; the presence or absence of fibro-vascular bundles in the cortex, their frequency, if present, especially as compared with the frequency of the bundles in the central cylinder ; the endodermis, whethe homogeneous or heterogeneous, the shape and thickening of its cells ; the frequency and arrangement of the fibro-vascular bundles of the central cylinder, the relation of the phloem and xylem to each other ; the cells of the fundamental tissue and their contents, and the presence or absence in it of intercellular spaces. In the Pteridophyta, in addition to characters which are indicated by what has already been said, attention should be directed to the characters of the endodermis and the pericycle. The limits of an article do not permit of all the various details of microscopical analysis being dealt with fully, so it will perhaps suffice to mention one or two other classes of slides, and the method of examination to which they should be subjected. Leaf sections should be examined with a view to observing if the leaf is of the bifacial or centric type ; the epidermis of the upper and lower surfaces should be compared, the size, form, and thickening of the individual cells being noted, the presence of hairs, glands, and stomata, as well as the size and other characters of the same should be observed. Attention should be directed to the palissade cells, if present, their form and location ; to the remaining parenchyma of the mesophyll, whether closely or loosely compacted, and the nature of its contents. The presence of hypoderma should be particularly recorded, as should also the presence, location, and characters of other sclerotic cells. Crystals and specialised receptacles, such as oleo-resin and tannin sacs, should be noted. The fibro-vascular system must be examined to ascertain whether it is restricted to a central strand only, or is accompanied by lateral ones. In connection with this system should be observed the relation to each other of the phloem and xylem, and the presence of stereom in the form of a continuous or discontinuous sheath. As a type of other classes of slides starch may be taken. In this case observations should be made of the form, size, position, and character of the hilum, and the presence, frequency, and direction of the striæ. It is only by a systematic survey of the characters of each slide upon similar lines to those laid down that the student can hope to obtain from mounted specimens an intelligent apprehension of the anatomical and histological features of vegetable drugs.

Turpentine Lotions for Smallpox.—As soon as the eruption appears, M. S. Nazarov has obtained good results by sponging the whole body, twice daily, with the following solution :—Rectified turpentine oil, 16 ; alcohol, 30 ; distilled water, 150.—*Bull. gen. de Therap.*, **128**, 240, after *Sem. Med.*

THE STUDY OF PRACTICAL CHEMISTRY.

Since the study of practical chemistry in the sense of laboratory practice in qualitative and quantitative analysis is necessary to pharmaceutical students in the curriculum required for success in the Minor and Major Examinations, it may be of interest to students if a short account is given of a course that may be followed with some degree of satisfaction.

It must not be supposed that the student can have much success in laboratory practice except under the guidance of a good teacher, and this may be gained by a course of study in many of the Science Institutions in the kingdom, for it must be remembered that carrying out analytical operations "with no resources but his own," as suggested in a text-book lately published, will be found uphill work to the most zealous student.

Elementary practice in chemistry so far as the preparation of the gases and the analysis of simple salts is now so general in such public schools as may be expected to be the nursery of the future pharmacist, that it is hardly necessary to dwell on this part of the subject. Failing, however, an early acquaintance with the rudiments of laboratory practice, it is certainly necessary that the student should make a start in this direction and become familiar with the preparation and the properties of the various gases, the fitting up of apparatus, glass blowing, and such incidental laboratory operations. The student would then proceed to the reactions of the metals, taking them in the order of each group, Na, K, Mg; Ba, Sr, Ca, etc. In operating with saline solutions it is a good practice to employ solutions of known strength in order to accustom the student to the relative solubility of the precipitate, and thus induce discrimination and intelligent work. It is particularly to be noted that only small quantities of material should be taken—such as a few decigrammes to a gramme. The fault of employing large quantities of material in analytical operations is a very common one with the pharmaceutical student in the early stage of his study. In all cases the reactions should be tabulated in the laboratory book, clearly, concisely, and with equations. At the same time noting the condition of the precipitate, whether crystalline or amorphous, the colour, etc., all of which will be found useful in subsequent work. Having finished the reactions of the metals, the same plan should be followed with the reactions of the acids. The student having thus familiarised himself with the action of reagents on known saline solutions, is prepared to proceed to qualitative analysis of simple salts, if necessary, then of complex mixtures. In the analysis of an unknown substance, if a solid, much information can be gained by submitting it to the dry reactions before proceeding to ascertain its behaviour in solution with the group reagents. It is well early to recognise the fact that a systematic method of analysis is more satisfactory than a premature and frequently erroneous conclusion from a simple reaction or from a preliminary observation.

Having thus become acquainted with the general outlines of qualitative analysis as applied to inorganic bodies, the student should then direct his attention to the methods of detecting the commonly occurring organic substances. The student, having now no group reagent, has to make himself acquainted with specific rather than with general reactions. In dealing, for example, with alkaloids and their salts, he should not be satisfied merely with colour tests, which are apt to lead him in the wrong direction, especially when dealing with mixtures or with impure materials. It is necessary, also, to ascertain the solubility of the base in various solvents, like ether, chloroform, etc., as well as in alkalies ; then proceed to prepare a salt of the base, in order again to note its relative solubility in various menstrua. Finally, the melting point of the base should be taken when possible. A colour test, it must be understood, is of use when dealing with pure materials, but at the best, except in a few instances, is merely to be regarded as one link in the chain of evidence.

As a further extension of the qualitative course, attention should be directed to the detection of traces of impurities in medicinal chemicals as directed in the British Pharmacopœia, with due regard to understanding the reason of each test; such as, for example, the reaction ensuing when testing for butyric acid in glycerin and the production of phenyl-isonitrite from acetanilide. If all reactions occurring in the practical work have been expressed in the form of equations there will be now no difficulty in an intelligent rendering of the B.P. tests.

Quantitative analysis is the natural sequence of the student's laboratory practice. Gravimetric and volumetric analysis become extremely simple to a student who has conscientiously performed the operations of qualitative analysis. Having carefully considered from the work of the best authorities the scheme of separation, the chief point is to be certain of the purity of the precipitate before weighing. This is generally assured either by effectual washing or by reprecipitation. In weighing the precipitate it is quite unnecessary to attempt weighing to 0·0001 Gm., as is very commonly practised. Such pretension to accuracy may be more than counterpoised by carelessness in washing the precipitate or in imperfect separation.

In volumetric analysis the student will do well not to attempt at first to operate with normal solutions, which are seldom used in practice, but with $\frac{1}{5}$ or $\frac{1}{10}$ normal solutions, as errors of reading and of manipulation are too much intensified with normal solutions to be conducive to concordant results at the hands of inexperienced operators. Pharmaceutical students will, of course, give attention to the analysis of drugs and the separation of the active principles. In the official preparations the B.P. methods, although far from being immaculate, must be accepted until the student is able to suggest improvement from his own experience. Alkaloidal determination—a frequent stumbling-block in Major Examinations—is an extremely simple operation. It merely consists in the elimination of the alkaloid in a nascent condition in the presence of a solvent such as ether, acetic ether, amylic alcohol, or chloroform, and taking the precaution of washing the solvent with water until the aqueous layer is colourless before evaporation. Moreover, the residue from the solvent should not be accepted as the basis of the determination, but invariably titrated with weak acid, preferably sulphuric acid. Litmus paper is the best indicator of neutrality in preference to cochineal, phenolphthalein, etc., which are quite unnecessary.

The Major student should not be satisfied with the course of instruction thus shortly sketched. He should proceed to the preparation of pure salts and other pure materials, and follow out the organic course as that given in Emil Fischer's little work on the subject, then to the determination of carbon, hydrogen and nitrogen in pure materials, of physical constants—boiling and melting points—of vapour densities, of molecular weights, by gold and platinum salts and by Raoult's and Beckmann's methods. After such a training the pharmaceutical student would be fairly well equipped for undertaking a research that shall be worthy of the name, and not ephemeral work for conference meetings. The field of research for the pharmacist is large, but the labourers are few, at all events in this country, and the pharmaceutical student should early awaken to the fact that on him depends whether British pharmacy is still to turn to Continental rivals for such medicinal products as result from the study of scientific pharmacy

---

TENALINE, A NEW VERMIFUGE.—Hodbay states that a new vermifuge, which has been named tenaline, derived from areca nut, is very active. It is given in the dose of 1 drop for each 500 Gms. of body weight of the subject. As it is a powerful poison, this dose must not be exceeded. In toxic doses it gives rise to diarrhœa, and tenesmus; and death may result from paralysis of the respiratory muscles.—*Nouv. Rem.*, **15**, 352, after *Therap. Monats.*

THE STUDENTS' LIBRARY.

Constant activity in the book world on the part of both author and publisher renders it necessary, year by year, to give the pharmaceutical student advice in the choice of his library. Well-chosen books are as vitally important to the student as hammer and anvil to the blacksmith, or defensive armour and weapons of offence to the soldier. The wise and far-seeing student will no more think of stinting his library at the outset than will the successful general start a campaign with a lack of ammunition or a meagre commissariat department.

In the course of these suggestions it will be taken for granted that considerations of usefulness outweigh those of cost; at the same time, a line will be drawn between text-books and others that are only of occasional service as books of reference. As a case in point, the only work on materia medica that the elementary student need buy is that lately written by Professor Greenish; though an occasional reference to Hanbury and Flückiger's 'Pharmacographia' will be necessary. If he has access to a good library there will be no need to buy the latter, whilst the former is indispensable.

It cannot be too strongly emphasised that the correct time to buy text-books is as early in the period of apprenticeship as time can be found to study them. To put off the purchase on the plea that after a lapse of four or five years much of the subject matter becomes out of date is unwise, inasmuch as the principal point to be gained is steady and quiet assimilation of knowledge from the very beginning of the pharmaceutical career.

In the following lists the text-books that are essential will be marked with an asterisk. For convenience

THE MINOR

requirements will first be studied. Many of these books will be found necessary for the Major, so that by slightly increasing the primary cost an ultimate economy will be effected.

I.—CHEMISTRY.—(1) *Theoretical:*—*Newth's 'Inorganic Chemistry' (Longmans, 6s. 6d.); Bloxam's 'Chemistry' (Churchill, 18s. 6d.); *Woodward's 'Chemical Arithmetic,' Part I. and Part II. (Simpkin, Marshall, 2s. and 3s. 6d.); Tilden's 'Chemical Philosophy' (Longmans, 3s. 6d.); *Perkin and Kipping's 'Organic Chemistry' (Chambers, 6s. 6d.); Stainer's 'Synopsis of Chemistry' (McDougall's Educational Co., Ltd., 1s. 6d.).

A brief discussion of the merits of these and subsequent works will enable the student to appreciate their separate uses, and to decide upon those which shall serve his purpose not only for his examinations, but also in every-day work in after life. Newth's 'Chemistry' is undoubtedly the book which best fits in with the requirements of the Minor syllabus in the inorganic part of theoretical chemistry. The matter is sufficiently explanatory, without being too voluminous. It is well arranged in three sections, of which the first deals with the theory of the subject—*e.g.*, the law of Boyle, electrolysis, dissociation, and the periodic law. The last-named law is very clearly expressed, and of great value in the perusal of the rest of the volume. The second section treats of the non-metallic elements, and the third deals with the metals. What little matter is superfluous is printed in small type, and may be neglected by the Minor student. Bloxam is rather too ponderous, and bewilders the beginner. It is extremely useful as a work of reference. If it be chosen in place of Newth, then Tilden's 'Chemical Philosophy' should be read, in order to gain a clear knowledge of that important branch of the subject. Indeed, the last-mentioned is so superior to any other treatise of its size that it is preferable to read it in place of the first part of Newth. Woodward's little books are essential to all. They treat of the arithmetical side of the question, explaining the fundamental principles, as found in Tilden or Newth, by means of ingenious diagrams and well-chosen numerical examples. At the end of each chapter may be found examples to be worked out (with answers), without which no real progress can be made in philosophical study. Perhaps the neglect of this part of chemistry—

viz., calculations dealing with alteration in volume of gases with varying temperature and pressure, and the like, is responsible for a large number of failures in the Minor. Certain it is that a large percentage of candidates present themselves for examination without knowledge on these points. In Part II. only certain sections are necessary, especially those dealing with the vapour density and other methods of determining molecular weights, Dalton's law of partial pressures, and Avogadro's hypothesis.

Stainer's 'Synopsis of Chemistry' is a valuable little book just before examination, enabling a rapid revision to be undertaken.

The small amount of organic chemistry required by the examiners is best obtained from Perkin and Kipping's interesting book. It will be found useful later on for the Major.

(2) *Practical.*—In few subjects is there so wide a choice of books as in practical chemistry. Some years of experience have demonstrated clearly that there is considerable danger in relying upon many authors in one part of it—viz., qualitative analysis—owing to the fact that different authors have different analytical methods. In recommending the following works, therefore, a system of rigid exclusion has been adopted, for which the Minor student will afterwards be grateful:—

*Attfield's 'Manual' (Gurney and Jackson, 15s.); *Briggs and Stewart's 'Analysis of a Simple Salt' (W. B. Clive, 2s. 6d.); *Owens College 'Laboratory Tables' (Cornish, 1s. 6d.); *Muter's 'Short Manual of Analytical Chemistry' (Baillière, 6s. 6d.); *Clowes and Coleman's 'Quantitative Analysis' (Churchill, 10s.).

In order to fulfil the requirements of the syllabus in practical chemistry it is necessary to prepare the important inorganic salts, and certain of the organic preparations of the British Pharmacopœia—*e.g.*, chloroform and ether. Information on the methods employed in those preparations, together with practical details of manipulation, can be obtained from Attfield's 'Manual.' Another part of the work is the analysis of double salts. In order to prepare for the task there is no better course open than to work carefully through the 'Analysis of a Simple Salt,' an excellent little book, containing a choice selection of tests for the commoner bases and acid radicals. Stress is laid on the preliminary examination of a substance, in accordance with the experience of the best authorities, which proves that a carefully conducted preliminary examination will give the operator a sure indication, in nearly all cases, as to the composition of the substance, thus enabling him to complete the analysis by means of the group reagents and acid chart with a saving of time and labour. Having mastered the contents of this little book, he should now turn to a 'Laboratory Series of Tables,' compiled by the demonstrators at Owens College, Manchester. These are printed on separate cardboard sheets, and are so arranged that they can be most conveniently hung up on the bench during use. The group separations are the best known to modern chemists, and are copiously annotated by means of footnotes, which clear up difficulties as they are met with, and convey a thorough grasp of the chemical principles on which the separations are based. The student is strongly urged to confine himself to these tables, and not to use others except for occasional reference, or his ideas will become confused and his methods faulty. Afterwards, when he has become perfectly familiar with this method of analysing a double salt, he will be in a position to intelligently use other works, and judge for himself as to the comparative value of certain alternative analytical methods.

II.—Botany.—*Lowson's 'Text-book of Botany' (Clive, 6s. 6d.); *Scott's 'Introduction to Structural Botany,' Vol. I. (A. and C. Black, 3s. 6d.); Bower's 'Practical Botany for Beginners' (Macmillan, 3s.); Holmes' 'Botanical Note-book' (Dulau, 3s.); Wishart's 'Botanists' Vade-mecum' (Livingstone, 2s. net).

It is fortunate for the pharmaceutical student of botany that at last a suitable text-book has been written that covers his requirements without burdening him with extraneous matter, or rendering the subject tedious with an unnecessary accumulation of technical terms. Lowson's admirably-written treatise is the very book that has been wanted for years. The various sections are well arranged, so that the beginner should have no difficulty in acquiring a good grasp of the subject in the order written. The information required by the new syllabus concerning the eight natural orders may be readily found. To those who can find the time a perusal of Scott's first volume will prove helpful. The entire book is devoted to a lucid and interesting description of three types only, the wall-flower, the lily, and the spruce-fir, representing the dicotyledons, monocotyledons, and gymnosperms respectively. In this way the reader is introduced to the three main groups, comprising the flowering plants. For those who wish for a more advanced knowledge, Green's 'Manual' forms a useful book of reference. For practical work Bower's 'Practical Botany' is a sure guide. It contains full instructions for fitting up a working bench for histological study together with formulæ for the commoner reagents and stains, and hints as to their proper use. The type system is followed, and precise manipulative details are given throughout, together with pithy descriptions of the parts examined. These last serve as a model of description, and are well worth studying on that account. The field botanist will find Wishart's 'Botanists' Vade-mecum' a handy book for the pocket, helping in the identification of plants, whilst Holmes' 'Botanical Note-book' will be of good service at home in writing out descriptions of plants in technical language.

III.—Materia Medica.—*Greenish's 'Introduction to the Study of Materia Medica' (Churchill, 15s.).

This work alone will convey all the information necessary in materia medica. Thanks to clear and precise phraseology, coupled with excellent illustrations and bold type, much of the drudgery usually associated in the student's mind with this subject is now removed. The value of the book for teaching purposes is enhanced by the frequent use of italics, thereby throwing in relief the salient points. Thus, after the description of a drug, there will be found in italics the diagnostic characters. This has never before been attempted in this class of text-book; by its means, however, the student may acquire the soundest instruction in a readily assimilable form

IV.—Pharmacy.—*British Pharmacopœia, 1898 (Spottiswoode, 10s. 6d.); Squire's 'Companion to the British Pharmacopœia' (Churchill, 12s. 6d.); *Caspari's 'Pharmacy' (Lea, 18s.); or, Coblentz's 'Pharmacy' (Blakiston, 18s.); Proctor's 'Lectures on Practical Pharmacy' (Churchill, 14s.); *Lucas's 'Practical Pharmacy' (Churchill, 12s. 6d.); Knight and Wootton's 'Elements of Pharmacy' (Wootton, 4s. net).

The British Pharmacopœia gives full details of the galenical processes employed. Where explanation is necessary it will be well to refer to a series of articles on the 1898 B.P. in the Students' Column of the *Pharmaceutical Journal*, commencing 1898, Vol. II., p. 182. This series refers back to similar notes on the 1885 Pharmacopœia when necessary. For abstract pharmacy the large work of Caspari is the best; as a book of reference it is invaluable. Lucas's 'Practical Pharmacy' is worth buying, more especially on account of the chapters dealing with the most modern methods in pharmacy—*e.g.*, the preparation of eye-discs, cachets, and capsules. It is regrettable that this book contains so many errors, especially in the chemical portion. The index, also, is not to be relied upon. Proctor's well-known 'Lectures on Practical Pharmacy' are now more suitable for the apprentice than for the student preparing for an approaching examination. It gives many simple tests that can be readily performed in any pharmacy, and illustrates important principles in galenical pharmacy.

Knight and Wootton's little book is included as a guide in the compiling of tables. The student is recommended first to make his own tabulations of the official galenicals, and then compare them with this book. In this way he will learn far more of his pharmacopœia than he will by merely committing other people's tables to memory. Scattered through the book will be found some useful notes on the official galenicals. As a work of

reference Squire's 'Companion' is too well known to need much recommendation. It should be in the hands of every apprentice.

V.—PHARMACEUTICAL LATIN.—*Ince's 'Latin Grammar of Pharmacy' (Ballière, 5s.); Will's 'Prescription Reading' (Metropolitan College of Pharmacy, 12s. 6d. net).

The grammar affords a sufficient introduction to the subject to satisfy the needs of the Minor student, to whom it is indispensable. He is advised, however, not to trouble to learn the archaic words and phrases that occasionally occur throughout the book. The latest edition is improved by the addition of an English-Latin vocabulary.

VI.—PHYSICS.—Aldous' 'Elementary Course of Physics' (Macmillan, 7s. 6d.).

The Minor syllabus demands but a small knowledge of physics; at the same time it is well to remember that the subjects mentioned therein are so disconnected that it is preferable to read rather more than bare necessity dictates. Thus, the syllabus requires a knowledge of:—"The law of the conservation of energy; the law of gravitation; the balance; specific gravity; atmospheric pressure; pressure of aqueous vapour; the barometer, air-pump, and siphon; the law of Boyle; temperature; thermometers; the law of Charles; the law of gaseous diffusion; V. Meyer's method for determining vapour densities." These points are conveniently taken under their respective headings.

(*a*) *Mechanics.*—To understand the law of the conservation of energy it is necessary to know what the term energy implies. To do this the student must become acquainted with other terms—*e.g.*, force, work, mass, inertia, and momentum. Chapters II. and III. of Aldous deal with this question, whilst gaseous diffusion is also treated of in the former. Chapter IV. discusses gravitation, and incidentally are explained the various units employed in physical calculations. The balance is described in Chapter V., but it would be unwise to neglect the sections in that chapter dealing with force, moments, couple, centre of gravity, equilibrium, and friction.

(*b*) *Hydrostatics.*—Here, again, the proper elucidation of the subjects mentioned in the syllabus necessitates a wider reading than is at first sight apparent. Thus, the whole eight chapters on hydrostatics are not too much to convey an adequate idea of the general principles involved.

(*c*) *Heat.*—Chapters I. and II. of the section on Heat treat of temperature, the thermometer, and the law of Charles. So far Aldous well covers the ground; the only point omitted is the Victor Meyer method of determining vapour densities. Woodward's 'Arithmetical Chemistry,' Part II., clearly explains this method, with numerical examples.

Physics has received fuller attention here than the other subjects, on account of the trouble it frequently causes the average candidate—(1) from the difficulty of finding a suitable text-book, and (2) from the habit, unfortunately common, of turning up in the index the items mentioned in the official syllabus, and simply learning the paragraph referred to.

A small space will now be devoted to a consideration of the

MAJOR TEXT-BOOKS.

The value of a careful choice of books for the Minor will be appreciated when commencing study for the Major. In addition to the books previously asterisked comparatively few others—about twenty-five shillings' worth—need be bought.

I.—*Chemistry.*—*Valentin's 'Qualitative Chemical Analysis' (Churchill, 9s.); Bernthsen's 'Organic Chemistry' (Blackie, 7s. 6d.); Wade's 'Introduction to the Study of Organic Chemistry' (Sonnenschein, 7s. 6d.).

Clowes and Coleman is full enough for volumetric and gravimetric work, and excels in manipulative instructions. Valentin will be found useful in supplementing the knowledge already gained in qualitative analysis, although the system learnt from the Manchester tables should still be adhered to. Perkin and Kipping will prove almost sufficient in organic chemistry; when necessary Bernthsen or Wade may be referred to in case fuller information is desired. Newth's 'Inorganic Chemistry,' Tilden's 'Chemical Philosophy,' and Woodward's 'Arithmetical Chemistry,' Part. II., will be ample in those branches of the subject.

II.—*Botany.*—*Scott's 'Introduction to Structural Botany,' Vol. II.

The books already purchased, supplemented by Scott's second volume, should carry the student well over the ground. This work is written on the type system, and deals in order with the Vascular Cryptogams, Bryophyta, Algæ, and Fungi. The Bacteria and Myxomycetes also receive attention.

III.—*Materia Medica.*—Hanbury and Flückiger's 'Pharmacographia' (Macmillan, 21s.); *Collin's 'Guide Pratique pour la Détermination des Poudres Officinales' (Octave Doin, 4s.); Planchon and Collin's 'Drogues Simples' (Octave Doin, 22s. net, unbound); *Maisch's 'Materia Medica' (Kimpton, 10s. 6d. net).

Pharmacographia is strictly a work of reference. Greenish will be found ample in the ordinary way for information concerning the sources, description, varieties, and constituents of drugs. The only work in English referring to the microscopic examination of vegetable drugs is Maisch's book. For those who read French the little book of Colin is useful for examining powders, and the larger work, by Planchon and Collin, which is generally found only in large libraries, contains good descriptions and diagrams of the histological features of vegetable drugs. For the assay of drugs the student must rely on a good teacher for the necessary information.

IV.—*Physics.*—*Woodward's 'Arithmetical Physics,' Parts IA. and IIA. (Simpkin, Marshall, 2s. and 3s. 6d.); *Glazebrook's 'Light and Heat' (Cambridge Press, 5s.); *Hydrostatics (Clive, 3s. 6d.); *Electricity and Magnetism (Clive, 3s. 6d.).

Complaints about the present syllabus in physics have long been made. It requires a knowledge of the subject such as cannot be acquired without a considerable amount of practical work. It follows that the student must either devote his attention to the subject during his apprenticeship, or content himself with such incomplete knowledge as can be got together during his six months' Major course. Aldous forms a good general basis of knowledge, but other works must be used in order to cover the syllabus. Those mentioned are all carefully chosen from a multitude of text-books. The two volumes of Woodward's 'Arithmetical Physics' will give sufficient practice in the necessary calculations involved.

The books recommended can be bought for about £6, and, for the most part, will remain useful long after the period of examination has gone by.

PREPARATION FOR THE BELL SCHOLARSHIP EXAMINATION.

BY A SUCCESSFUL CANDIDATE.

After having successfully passed the Preliminary examination, or one of its alternatives, and having been duly enrolled in the Society as a student-associate, a large number of those on the threshold of their pharmaceutical career look longingly towards those prizes which are stepping stones to pharmaceutic and, in some cases, world-wide fame. They read in the regulations for the Jacob Bell Memorial Scholarships that "a scholar is supposed to be *commencing* his studies, or, at least, to have made only that progress which may be reasonably looked for during an apprenticeship." For a few weeks, or it may be months, they work assiduously at the subjects set, but their energies fail after a time, and, when the end of their apprenticeship comes, they have done nothing. They may have nine months or a year before the examination, and they try to cover in a few months subjects over which two or three years should have been spent in slow, steady, persevering study, which has always its own reward in the fact that the knowledge so gained is permanent. To avoid the Scylla of being overwhelmed by the large amount of work to be done, they rush into the Charybdis of a coach or crammer. But, as the writer has proved in his own case such external assistance is not necessary.

To those, therefore, who wish to attain to the dignity of a Bell Scholarship without the aid of a coach, the following remarks may be in some measure helpful. A great and almost inestimable help towards the goal is to have passed some other statutory examination instead of the present preliminary. The alternative examination should be preferably the London Matriculation or either of the Senior Local Examinations of Oxford or Cambridge Universities. To those who are the fortunate possessors of one of these certificates the first paper on the Arts subjects will present no difficulty at all, and all the work necessary will be to read the set books in the Latin and spend a short time on the revision of the school work in the other subjects. For them the only paper requiring new ground to be covered is the second, or scientific, paper, which need have no terrors if they have had a grounding in elementary chemistry, such as is to be had now in most grammar schools, in a good many Board schools, and in all technical schools.

To take the subjects seriatim, we have first the Latin. The set books of Virgil are best studied in the Elementary Classics Series, published at 1s. 6d. per volume by Macmillan. The text is very good and the notes are both full and lucid, covering all the grammatical questions that can be asked on the text, and, if I remember rightly, any *variæ lectiones* which are likely to puzzle the student are mentioned. The remainder of the Latin is grammar, composition, and translation from Latin Pharmacopœia. In the grammar all the requisite knowledge can be acquired from Allen's 'Latin Grammar' (Clarendon Press, 3s. 6d.). Special attention should be paid to the sentences towards the end of the book illustrative of various constructions, as they are most helpful in the Latin prose composition. This latter is very lucidly explained in the First and Second Latin Exercise Books by the same author, from the same publisher, at the same price each. The First Exercise Book should be found to be quite sufficient if it is worked through from beginning to end. A vocabulary of pharmaceutical Latin for the translation from Latin pharmacopœias can be obtained from Ince's 'Latin Grammar of Pharmacy (Baillière, 5s.); but it is desirable that the intending candidate should have a little practice in this by trying to translate from the old London Pharmacopœia, a copy of which is likely to be found in many old-established businesses which take a pride in their dispensing.

In French the extent of the paper is a short piece to be translated from French into English, and a shorter one for translation from English into French. The chief requisites are a fairly good vocabulary, for a few uncommon words usually appear, and a general knowledge of French grammar and syntax. For the vocabulary there is no better book published than Bossert and Beljame's 'Les Mots Anglais Groupés d'après le Sens,' published by Hachette at 1s. 6d. For practice in translating French into English there is, in my opinion, nothing to equal that obtained by the use of such newspapers as the *Figaro* or such weeklies as the *Revue des Debats*, which can be obtained in most important cities. One copy of each will supply sufficient material to last weeks. For the grammar and syntax books like the Oxford and Cambridge French Grammar' (Parts I., 2s., and II., 2s. 6d., Hachette) contain far more than is required, but their value is enhanced by the fact that they contain plenty of material for French prose composition. An excellent set of books, which do not make such a prominent feature of the grammar, but are splendid for composition, are Roulier's First and Second Books of French Composition, published by Hachette at 1s. 6d. and 3s. respectively. The second one is perhaps too far advanced for the Bell Scholarship requirements.

Most of the above remarks about French may be applied to the German. For grammar and elementary composition the 'Oxford and Cambridge German Grammar,' Part I. (Hachette, 2s. 6d.), contains all that can be required. For those who wish to undertake more advanced prose composition H. Lange's 'German Composition' (Clarendon Press, 5s.) may be used. The pieces included make it easy to acquire a good vocabulary as the student goes along. If the intending candidate takes German, he may as well learn the German handwriting, which can be acquired with a little practice. I suppose it will be almost a work of supererogation to offer any remarks on the English; but I expect some will find it necessary to rub up the parsing and analysis, which will in all probability have been allowed to lapse. For this any good English grammar will suffice, *e.g.*, Meiklejohn's, Mason's, Hewitt's, etc. It is specially desirable to become acquainted with the various methods of parsing words such as "methinks," which are merely a kind of grammatical gymnastic. For the Essay a good style can always be obtained by a study of leading articles in the best dailies or in the articles of any leading literary weeklies, *e.g.*, *Spectator*, *Athenæum*, etc., which are usually to be found in the reading-room of all free libraries.

The Arithmetic is simple in the extreme, and any person with a good school education should always be able to do all the sums set correctly at the first attempt. To those who require a little practice, Pendlebury's 'Arithmetic' (Bell, 4s. 6d.) may be recommended. We have now reached the end of the Arts subjects, and it is hoped that the reader will have no difficulty in following any of the hints. Keys are published to all the books that are of such a nature as to require one, but in some cases they are only available for teachers. They may be obtained in each case from the same publishers as the book.

Turning now to the scientific side of the subjects of examination, we read in the Calendar that "an elementary knowledge of Chemistry, Pharmacy, and Botany" is required. At the outset it may be necessary to remind intending candidates that there is a distinction between the elements of a subject and an elementary knowledge of that subject. The elements usually cover just a general knowledge of the more important branches, while the elementary knowledge referred to in the Calendar demands a general acquaintance with all the divisions of the subject.

For Chemistry the first four hundred pages of Attfield's 'Chemistry' just about suffice for every possible question except those on the non-metallic elements. To those pages must be added the short note on dialysis towards the end of the volume. This must be by no means forgotten, as it has quite a fatal fascination for examiners, and is usually served up in some form or another two years out of five. In working through Attfield special notice should be taken of the reactions and the equations involved in the chief tests. To obtain a proper knowledge of the non-metallic elements a book like Newth's 'Chemistry' (Longman, 6s. 6d.) should also be consulted.

In Pharmacy a systematic study must be made of the British Pharmacopœia and a knowledge obtained of all the B.P. processes and the reasons for the various steps. Some book like Lucas's 'Practical Pharmacy' (Churchill, 12s. 6d.) will be found to be helpful; but if Lucas be taken as a guide, discretion should be employed, as the statements in his book cannot in all cases be absolutely depended upon. An excellent knowledge of pharmacy may be acquired by a study of those articles dealing with the Pharmacopœia which have been appearing for some time past in the Students' Columns of the *Pharmaceutical Journal*.

In Botany a very general acquaintance with the subject is required both from a physiological and morphological standpoint. A knowledge of Elementary Botany, as defined by the South Kensington authorities, is a good point at which to start. By this means the greater part of the innumerable confusing definitions (*e.g.*, obvolute, involute, revolute, supervolute, etc.) are learnt and a good acquaintance obtained with the vagaries of the flowering plant in its various forms. Those who are unable to attend such a class will find all they want, or, rather, more than they want—but all of which they must learn—in Edmunds' 'Elementary Botany' (Longman, 2s. 6d.). After this work—which may be made much more interesting by endeavouring to write out a correct botanical description of any plant which can be obtained—has been mastered, the most instructive book to read is Scott's 'Botany' (two volumes, Black, 7s.). The whole of the volume on flowering plants should

be read through and mastered, and in the second only those types should be dealt with which are common, *e.g.*, Fucus, Saccharomyces, Penicillium, Mucor. If a small amount of microscopic work is done the student will have a much clearer idea of the subject. The chapters on Physiology in Green's 'Botany,' vol. ii. (Churchill, 10s.), will be found to be most helpful.

To sum up, it may be stated that no assistance of any kind is required by an intending candidate, other than that which it should be possible to obtain from the principal or assistant in the pharmacy at which he is employed. If he follows out the method of study advocated here, draws up a time table of study for himself and adheres to it, and is then successful in gaining one of the scholarships, he may derive additional satisfaction from the knowledge that he has fulfilled both the spirit and the letter of the conditions under which the examination has been held. To quote from the regulations as printed in the Society's Calendar, a Bell Scholar "is supposed to be *commencing* his studies, or at least to have made only that progress which may be reasonably looked for during an apprenticeship. The object of the examination is to ascertain that the candidate has such an amount of ability, and affords evidence of having made such use of it in the acquirement of elementary knowledge as will justify the expectation of his proving a successful student, who may do credit to the appointment and become a useful and accomplished member of the pharmaceutical body."

UNIVERSITY DEGREES IN SCIENCE.

The comparative value of a University degree and the diploma of a corporate professional body lies in the fact that whereas the latter is usually accepted more as a proof of training and efficiency in some department of applied knowledge, the former is generally looked upon as a stamp of education and scholarship pure and simple, and for this reason is an honour much coveted by the studiously minded.

Except in the University of London the degrees of British Universities are only granted after certain conditions as regards residence or curricula, or both, have been fulfilled. London University, however, grants degrees (except in medicine) to all candidates, no matter where or how educated, who can pass its somewhat high standard. Its medical degrees are only obtainable after the usual prescribed course at a recognised school.

It is quite possible for any young pharmacist of average ability, who is prepared to devote his spare time to study for two or three years to obtain a London degree, provided he cultivates patience enough to keep on plodding, and method enough to make the best use of his time—and many have already done so. As the science degree is the more appropriate one for a pharmacist to take, we shall only give an account of the proceedings in Science.

The Matriculation Examination takes place twice a year, in January and June, and candidates must be sixteen years of age on or before the 14th day of the month in which he is examined. The fee is £2 at first entry, and £1 subsequently. There is no exemption from this examination by reason of any other certificate whatever. Candidates must pass in Latin, English Grammar and History, Mathematics, General Elementary Science, and one optional language *or* science. The Mathematics includes the geometry of Euclid's first four books, and Algebra up to quadratics; the General Elementary Science syllabus requires the elementary facts of Chemistry, Mechanics, and Physics (without sound). The optional languages are Greek, French, German, Sanskrit, and Arabic, and the optional sciences are Mechanics, Chemistry, Electricity and Magnetism, Sound, Light, and Heat, and Botany, all in an elementary way. Candidates are expected to show that they have witnessed experiments, but no practical work is required of them except a little very elementary work in botany.

The Intermediate Examination is held once a year, in July. The fee is £5 at first, and £2 10s. subsequently. Candidates must have matriculated a year previously, but honour men at Jan. Matric. are admitted to Inter. Sci. in July the same year. An examination must be passed in four out of the following six subjects:—Chemistry, Botany, Physics, Zoology, Mathematics, and Mechanics, the first four practically as well as theoretically. Candidates may take honours in one or more subjects, and, failing honours, will be credited with a pass if they reach that standard. Exhibitions are given to the candidates under twenty-two who stand first in honours in each subject.

Minor men under the new regulations will find that they have well covered the necessary ground in chemistry and botany, but the examination in physics is more exhaustive and more mathematical than the pharmaceutical exams.

The B.Sc. Examination is held every October. The fee is £5, and subsequently £2 10s. Candidates must have passed the Intermediate one year previously. They must pass an examination in three out of the following eight subjects, or they must take first-class honours in one subject and first division pass in a second subject:—Pure Mathematics, Mixed Mathematics (Dynamics and Theoretical Astronomy), Chemistry, Physics, Botany, Zoology, Physiology, Geology. The B.Sc. examination is undoubtedly very stiff. The Major man under new regulations will be in a fair way to pass in Chemistry, but in other subjects he will have to do a good deal more work, both theoretical and practical. The honours examination at B.Sc. is an exhaustive one on each subject, a thorough acquaintance with recent and current research work being required. Candidates for honours in practical subjects must send up a certified record of their laboratory work.

The D.Sc. Examination is held once a year, in June. The fee is at first £10, and on subsequent entries £5. Candidates must have passed the B.Sc. examination two years previously, and must present a thesis giving results or original research in some one of the subjects of the B.Sc. syllabus. A candidate must pass an examination of the subject matter of his thesis, and also, unless he took first-class honours in his subject at B.Sc., a general examination in it, and will be expected to "satisfy any test of his acquirements that it may be thought expedient to apply." As a matter of fact, he must know more than his examiners.

CHOICE OF SUBJECTS.

A student, in choosing his subjects, will do well to take as his motto *Respice finem*, as he may thus simplify matters very much. His choice will depend first on his possible objects in life, and secondly on his predilection. In the Matriculation examination, should he intend taking a medical qualification *other* than the M.B. degree, he must take one of the optional languages. (We would here remind students that after August, 1900, this certificate will be useless as a pharmaceutical preliminary unless the owner has passed in a modern foreign language.) Again, if a student is independent of the above considerations, and makes a hobby of any science, he will obviously help himself if he takes that science.

At Inter. Sci.: If the student intends taking up medicine as well as science, he must pass in Physics, Chemistry, Botany, and Zoology. A student uninterested in Zoology will find Mathematics of more use, and, indeed, should he fancy Physics as one of his B.Sc. subjects he must have Intermediate Mathematics at his finger ends.

At B.Sc. a good mathematician will, of course, take mathematics, there being no practical work, but others will be obliged to be well up in the practical work of three subjects unless they are honours candidates, and it is in this that the difficulty in obtaining the degree arises to those who are engaged in some regular occupation. At any rate, he who tries has nothing to lose, for knowledge is invaluable and no one denies that the University has done good work in offering an inducement to intelligent men and women to spend their leisure in its pursuit.

Write to the Registrar, University of London, Burlington Gardens, W., for a copy of regulations, and to Messrs. Clive and Co., 13, Booksellers Row, W.C., for a catalogue of books suitable for Matriculation.

QUALITATIVE EXAMINATION OF POWDERED VEGETABLE DRUGS.*

BY HENRY KRAEMER.

GROUP No. 4 (*Continued*). COLOUR TAN, BUFF, ECRU TO DARK BROWN OR BROWNISH, BLACKISH AND BLUISH BLACK.

IV. Possessing Secretion Hairs, Cells or Reservoirs and of Somewhat Characteristic Odour.

A. SECRETION HAIRS.

372. *Anthemis.*—Non-secreting and secreting hairs; spherical prickly pollen grains (32 μ) which may not be numerous; papillæ of corolla and stigma; sklerenchyma fibres (10 μ wide) the walls of which are very much thickened; small rosette-shaped calcium oxalate crystals sometimes found; characteristic cells of anther.

373. *Arnicæ Flores.*—Numerous spherical prickly pollen grains (30 μ); secretion hairs; sklerenchyma fibres; characteristic non-secreting hairs of pappus (like top of pineapple fruit); outer portion of corolla and ovary.

374. *Belladonnæ Folia.*—See No. 46.

375. *Cusso.*—See No. 345.

376. *Lupulin.*—Large characteristic secretion hairs (20 × 20 μ). In *fresh* Lupulin more light yellow coloured secretion hairs than in *old*. In latter there are, browner or greyish-brown resinous masses replacing the light yellow oil. The amount of *Humulus* fragments should not be too large in good quality. See No. 537.

377. *Santonica.*—See No. 350.

B. SECRETION CELLS OR RESERVOIRS.

378. *Aurantii Amari Cortex.*—See No. 206, crystals of calcium oxalate.

379. *Aurantii Dulcis Cortex.*—See No. 207, crystals of calcium oxalate.

380. *Inula.*—See No. 368, Inulin masses or crystals.

381. *Limonis Cortex.*—See No. 208, crystals of calcium oxalate.

382. *Macis.*—A peculiar starch (becomes red with iodine and called "dextrin starch") in small irregular particles; yellowish (oil) and reddish (resin) secretion cells (75 μ); few ducts; H_2SO_4 stains contents of secretion cells bright red; KOH stains contents of secretion cells a yellow. *Bombay mace* gives with H_2SO_4 a yellowish reaction; the oil secretion cells and "dextrin starch" grains are possibly larger; the epidermal cells are radially elongated and the collenchymatic layer underneath may be wanting in Bombay mace.

383. *Pyrethrum.*—Stone cork. See No. 370.

V.—Presence of Sklerenchyma Cells (Stone Cells) or Fibres (Bast or Wood).

A. STONE CELLS.

384. *Aconiti Radix.*—Starch. See No. 319.

385. *Asclepias.*—Crystals and starch. See No. 242.

385a. *Black Mustard Hulls.*—Chiefly fragments of seed coat.

386. *Cocoa Shells.*—Little or no starch; oil globules; characteristic brownish adhesive fragments, possessing more or less hexagonal epidermal cells; peculiar small tubular mucilage cells and a layer of nearly isodiametric stone cells (10 × 10 μ) the walls of which are 4 μ thick.

387. *Canella alba*,—Crystals, starch, secretion reservoirs. See No. 244.

388. *Capsicum.*—Small starch grains might not be observed; reddish-coloured oily drops; peculiar wavy cells of seed coat besides stone cells of epicarp and endocarp; secretion hairs of calyx; powder with H_2SO_4 becomes purplish, changing to purplish red.

389. *Cardamom.*—Starch and crystals. See No. 270.

390. *Clove Stem.*—The presence of stone cells distinguish it from cloves. See No. 347.

391. *Coffee.*—Oil, aleuron, starch and epidermis with spindle-shaped stone cells. See No. 324.

392. *Colchici Semen.*—Starch, oil and protein. See No. 326.

393. *Colocynthis.*—Stone cells (70 × 50 μ) of fruit, the walls of which are 15 μ thick; also find characteristic yellowish, nearly isodiametric stone cells of seed containing very thick walls and but little lumen; embryo contains oil and aleuron. The *amount of seed* in powder can be determined from the amount of oil in the form of globules. The U.S.P. directs only pulp, and not seeds or edicarp.

394. *Composition Powder.*—Tissues of ginger, cloves, capsicum and bayberry. See No. 245.

395. *Cubeba.*—Starch and secretion reservoirs. See No. 308.

396. *Delphinium.*—No starch; oil and protein; characteristic stone cells (32 × 175 μ) forming the inner epidermis and containing a reddish-brown colouring substance; also spatulate cells (outer epidermis of seed coat) with simple pores.

397. *Galla.*—Crystals and starch. See No. 247.

398. *Guarana.*—Starch. See No. 328.

399. *Hicra Picra.*—Canella and aloes. See No. 255.

400. *Illicium.*—Palisade sklerenchyma. See No. 356.

401. *Jalapa.*—Crystals and starch. See No. 250.

402. *Juglans.*—Crystals and oil. See No. 251.

403. *Pareira.*—Starch. See No. 329.

404. *Prunus Virginiana.*—Starch and crystals. See No. 282.

405. *Pulv. Jalapæ Comp.*—Jalapa and potassii bitartras. See No. 256.

406. *Quercus alba.*—Crystals and tannin. See No. 360.

407. *Pimenta.*—Crystals, starch and oil. See No. 254.

408. *Pyrethrum.*—Inulin and stone cork. See No. 370.

409. *Rumex crispus.*—Crystals and starch. See No. 260.

410. *Syr. Trifolii Comp. (Powder).*—Stillingia, Xanthoxylum fraxineum, Lappa, Phytolacca, Berberis aquifolium, Cascara amarga and red clover. See No. 263.

411. *Vanilla.*—No starch. See No. 363.

412. *Viburnum prunifolium.*—Crystals, more stone cells and fewer sklerenchyma fibres. See No. 265.

B. SKLERENCHYMA FIBRES.

413. *Althæa.*—Crystals, starch and mucilage. See No. 238.

414. *Anthemis.*—Pollen. See No. 372.

415. *Apocynum.*—Starch. See No. 320.

416. *Arnicæ Flores.*—Pollen. See No. 373.

417. *Aspidosperma.*—Crystals in crystal fibres. See No. 267.

418. *Belladonnæ Radix.*—Starch. See No. 298.

419. *Cardamom.*—Crystals and starch. See No. 270.

420. *Cascarilla.*—Crystals and starch. See No. 243.

421. *Cinchona.*—Characteristic bast fibres. See No. 299.

422. *Cinnamon.*—Starch, crystals and stone cells. See No. 292.

423. *Cloves.*—Few sklerenchyma fibres and numerous large secretion reservoirs. See No. 346.

424.—*Clove Stems.*—Stone cells, numerous sklerenchyma fibres. See No. 347.

425. *Cubeba.*—Starch, oil, stone cells. See No. 303.

426. *Euonymus.*—Crystals and starch. See No. 246.

427. *Ext. Glycyrrhizæ.*—See No. 272.

428. *Ext. Sarsaparillæ Fld.* (Powder).—Tissues of sarsaparilla, glycyrrhiza, sassafras and mezereum. See No. 273.

429. *Frangula.*—Crystals, starch, but *no* stone cells. See No. 274.

430. *Gelsemium.*—Crystals and starch. See No. 275.

431. *Ginger, Charcoal and Magnesia.*—Tissues of ginger, willow charcoal and particles of MgO. See No. 277.

432. *Glycyrrhiza.*—Crystals and starch. See No. 276.

434. *Gossypii Rad. Cort.*—Crystals, starch and secretion reservoirs. See No. 249.

435. *Hydrangea.*—Crystals and starch. See No. 293.

436. *Illicium.*—Palisade sklerenchyma. See No. 356.

437. *Inula.*—See No. 368.

* From the *American Journal of Pharmacy*. *Concluded from page 226.*

438. *Ipecac.*—Crystals and starch. See No. 294.

439. *Juglans.*—Crystals, oil and tannin. See No. 251.

440.—*Krameria.*—Crystals, starch and colouring substance. See No. 279.

441. *Lappa.*—Inulin. See No. 369.

442. *Myrica Cerifera.*—Crystals in crystal fibres. See No. 252.

443. *Pareira.*—Starch and numerous stone cells. See No. 329.

444. *Phytolaccæ Radix.*—Crystals and starch. See No. 301.

445. *Podophyllum.*—Crystals and starch. See No. 332.

446. *Prunus Virginiana.*—Crystals and starch. See No. 282.

447. *Pulv. Aromaticus.*—Tissues of cinnamon, ginger, cardamom and nutmeg. See No. 295.

448. *Pulv. Glycyrrhizæ Comp.*—Tissues of glycyrrhiza and senna. See No. 283.

449. *Pulv. Ipecac. et Opii.*—Tissues of ipecac and opium; also crystals of sugar and milk. See No. 296.

450. *Pyrethrum.*—Inulin, stone cork. See No. 370.

451. *Quassia.*—Crystals. See No. 359.

452. *Quercus Alba.*—Crystals and stone cells. See No. 360.

453. *Quillaja.*—Crystals and starch. See No. 284.

454. *Rubus.*—Crystals and starch. See No. 259.

455. *Rumex Crispus.*—Crystals, starch and stone cells. See No. 260.

456. *Sabina.*—Starch and "hypodermis fibres." See No. 311.

457. *Sassafras.*—Starch, oil and tannin. See No. 313.

458. *Serpentaria.*—Starch. See No. 145.

459. *Stillingia.*—Crystals, starch and oil. See No. 262.

460. *Sumbul.*—Starch and oil. See No. 125.

461. *Syr. White Pine Comp.*—Tissues of wild cherry, Aralia spinosa, sassafras, sanguinaria, white pine bark and balm of gilead buds. See No. 285.

462. *Tr. Cinchonæ Comp.* (*Powder*).—Tissues of cinchona, bitter orange peel and serpentaria. See No. 303.

463. *Ulmus.*—Crystals, starch and mucilage. See No. 285.

464. *Viburnum opulus*—Crystal fibres and sklerenchyma fibres. See Nos. 287 and 265.

465. *Willow Charcoal.*—In glycerin mounts, wine-coloured or dark reddish or blackish irregular-shaped fragments containing wood fibres; transverse fragments with lumen.

466. *Xanthoxylum.*—Crystals, starch and oil. See No. 289.

VI.—Absence of Sklerenchyma.

467. *Gentian.*—Yellowish oil globules; spiral (30 μ wide), and scalariform (50 μ wide) ducts; small colourless and yellow prismatic crystals (which may be calcium oxalate crystals), large (5 × 15 μ) prismatic crystals separate in glycerin mounts which may be a sugar; characteristic "Ersatzfasern" accompanying the sieve.

VII.—Characteristic Pollen Grains.

468. *Anthemis.*—See No. 372.

469. *Arnicæ Flores.*—See No. 373.

470. *Carthamus.*—Glycerin, of mount, coloured yellow; numerous elliptical, prickly pollen grains, which are more or less elliptical (50 × 60 μ); brick-red secretion vessels; cells of anther; hairs of stigma; chaff or pappus.

471. *Caryophyllus.*—See No. 346.

472. *Crocus.*—Glycerin of mount coloured deep orange; few nearly smooth, nearly spherical pollen grains (85–100 μ); papillæ of stigma; colouring principle soluble in water and not in fatty oils, being the reverse in *Capsicum;* with H_2SO_4 fragments become blue immediately.

473. *Rosa centifolia.*—Pollen grains nearly smooth and elliptical (17 × 30 μ); fragments of corolla pinkish with chloral; papillæ of corolla are somewhat rounded; cells of anther; long, 1-celled fibres around ovary and akenes being 875 μ long and 10 μ wide. In *Rosa gallica* the pollen grains are ovate (28 × 32 μ) rather than elliptical; the papillæ of corolla are acute rather than rounded; absence o many anthers or fibres of ovary.

474. *Sambucus.*—No starch; numerous smooth, nearly sphefical pollen grains (18 × 18 μ); numerous fragments of broken or whole anthers; corolla with dentate papillæ; oil globules from secretion cells; in calyx some rosette-shaped crystals of calcium oxalate; in flower stalk large spiral ducts (30 μ wide), and parenchyma with brown contents.

475. *Santonica.* See No. 350.

VIII.—Little or no Indication of Plant Tissues.

A. CONTAINING STARCH.

476. *Amylum Iodatum.*—See No. 335.

477. *Bryonia.*—See No. 336.

478. *Colchici Cormis.*—See No. 337.

479. *Ext. Glycyrrhizæ.*—Irregular, wine-coloured fragments; altered and unaltered starch grains; few fragments of bast and crystal fibres of glycyrrhiza; soluble in water and taste sweetish.

480. *Opium.*—Insoluble in water; taste bitter. See No. 338.

B. WITHOUT STARCH.

a. Particles of organised form.

481. *Corn Smut.*—Greyish-brown, nearly spherical spores (7 × 7 μ); little or no foreign substances. Spores of *Coprinus comatus*, blackish and elliptical (10 × 5 μ). Spores of *Agaricus campestris* more brownish than corn smut, are egg-shaped and in size about 5 × 7 μ.

b. Particles of inorganic form.

a. Remain Opaque (not affected) in glycerin.

482. *Aloes* (*Socotrine*).—Partially unaffected. See No. 487.

483. *Benzoin.*—Colourless and wine-coloured irregular fragments; some rosette-shaped groups and collection of small tetragonal or plates of crystals. Upon covering a fragment on a slide with a watch crystal and cautiously heating crystals of benzoic acid are sublimed on the watch crystal.

484. *Elaterium.*—Greyish and greyish-brown, more or less opaque and irregular fragments. Heat fragment with phenol, and when cool add H_2SO_4, a deep red coloration is produced. KOH has no action on elaterium.

485. *Goa Powder.*—Small, somewhat transparent, wine-coloured irregular angular fragments. With KOH a bright, reddish colour produced.

β. Become more or less transparent in glycerin.

486. *Aloes* (*Barbadoes*).—In a glycerin mount the particles become clear and behave like Cape aloes, but generally numerous acicular or large prismatic crystals remain or separate in clear yellow space where fragment of aloes was originally.

487. *Aloes* (*Socotrine*).—In a glycerin mount the fragment is not very perceptibly affected. At the most there is but a faint yellowish colour around the greyish or greyish-brown masses. In old Socotrine aloes the grey masses look like rosette crystals.

488. *Catechu.*—Large opaque dark brownish-red masses which on the edge gradually become transparent and dissolve with a sherry wine colour, also fragments of sklerenchyma.

489. *Kino.*—Fragments become clearer and a deeper red (port wine colour), compared to catechu.

GROUP NO. 5. COLOUR REDDISH.

Kino, Cochineal (black), Cochineal (grey), Lupulin (old), Macis, Myristica, Capsicum, Crocus, Carthamus, Santalum rubrum Krameria, Sanguinaria, Pine shavings, Breakfast cocoa, Illicium, Sassafras, Lupulin (new), Rosa gallica, Pulv. Rhei. Comp., Hufland's Baby Powder.

I. Animal Fragments (Test by Burning).

490. *Cochineal.*—Carmine red colour in mounts of glycerin or glycerin + chloral.

II. Vegetable Fragments.

A. CONTAINING STARCH.

a. Containing calcium oxalate crystals.

491. *Krameria.*—See No. 279.

492. *Hufland's Baby Powder.*—Fragments of Rheum, MgO and sugar. See No. 278.

493. *Pulv. Rhei. Comp.*—Fragments of Rheum, ginger and MgO See No. 257.

b. Few or no Calcium oxalate crystals.

494. *Cocoa.*—See No. 386 and 545.

495. *Capsicum.*—See No. 306.

496.—*Myristica.*—Starch grains (5–7 μ) generally in groups; numerous oil globules; parenchyma and "Hullperisperm," with reddish coloured contents; in "Hullperisperm" some prismatic crystals; some tetragonal or prismatic crystals (5 × 10 μ) of myristic acid, which are soluble in KOH; heat powder in chloral get tabular or acidular crystals. Myristica distinguished from *Macc* in that latter has no starch, and on treatment with KOH the secretion cells of Mace are coloured blood-red, whereas Myristica becomes brownish.

497. *Sanguinaria.*—See No. 312.

498. *Sassafras.*—See No. 313.

B. WITH LITTLE OR NO STARCH.

a. Containing Calcium oxalate crystals.

499. *Cocoa.*—See No. 386 and 545.

500. *Ilicium.*—See No. 356.

501. *Santalum rubrum.*—Hexagonal or coffin-shaped crystals (15 × 25 μ) in crystal fibres; long sklerenchyma fibres, 10 μ wide ducts (150 μ wide) with bordered pores; all cell walls coloured yellowish-red; some cells contain reddish granular resin-like masses. Distinguished from other woods possessing red dye in only possessing one row of medullary ray cells (in hæmatoxylon the medullary rays are 4–5 cells in width) and colouring matter not dissolved by water.

III. No Vegetable or Animal Tissues.

502. *Kino.*—See No. 489.

GROUP No. 6. CONTAINING POWDERS THAT ARE RELATIVELY COARSE.

Sugar (granulated), Sago (imitation), Sago (real), Grits (corn), Corn Bran, Quillaja, Orris Root (Florentine), Viburnum opulus, Sarsaparilla (Mexican), Sarsaparilla (Honduras), Taraxacum, Mezereum, Strophanthus, Linum, Dulcamara, Sinapis nigra, Humulus, Matricaria, Triticum, Sassafras medulla, Sweet Orange Peel, Terebinthina, Manna, Canella alba, Colocynthus, Sambucus, Pepo, Amygdala dulcis, Amygdala amara, Berberis aquifolium, Asafetida Myrrha, Gentian, Rheum, Frangula, Anise, Black Mustard Hulls Cannabis Indica, Cardamom (seeds hulled), Syr. Trifol. Co., Arnicæ Flor., Chirata, Staphisagria, Cocculus, Zea (corn silk), Juniper Coffee, Pix Burgundica, Confect. Rosæ, Rubus idæus, Lactucarium, Juglans, Mylabris, Rhus glabra, Hæmatoxylon, Chicory, Stramonii Semen, Tea, Cochineal (black), Cochineal (grey).

I. Containing Numerous Vegetable Fragments.

A. CONTAINING STARCH.

a. Containing crystals of calcium oxalate.

α. *Crystals rosette or star-shaped.*

503. *Canella alba.*—See No. 244.

504. *Frangula.*—See No. 274.

505. *Juglans.*—See No. 251.

506. *Rheum.*—See No. 215.

507. *Syr. Trifolii Comp. (Powder).*—See No. 263.

β. *Crystals cubical, tetragonal, prismatic or more or less coffin-shaped.*

508. *Berberis aquifolium.*—Crystals cubical (4 × 4 μ; starch in single (2 × 2 to 5 × 7 μ) and 2 to 3-compound grains; libriform fibres 30 μ wide; all tissues light yellow and very hard and resistant.

509. *Cardamom.*—See No. 23.

510. *Frangula.*—See No. 274.

511. *Iris Florentina.*—Crystals either like in quillaja very long and 10–20 μ wide, or long needles; starch characteristic (15 × 30 to 15 × 15 μ); parenchyma; no cork; fibrovascular tissue.

512. *Juniperus.*—Crystals hexagonal (30 × 30 μ) in stone cells which are 60 × 60 and walls 15 μ thick; small amount of starch (5–7 μ); oil secretion reservoirs; brown pigment cells.

513. *Myristica.*—Crystals are of myristic acid. See No. 496.

514. *Quillaja.*—See No. 284.

515. *Syr. Trifolii Comp.*—See No. 263.

516. *Viburnum opulus.*—See No. 287.

γ. *Crystals acicular.*

517. *Cocculus.*—Crystals are soluble in alcohol and not in dilute acids. See No. 547.

518. *Iris Florentina.*—See No. 511.

519. Sarsaparilla. See No. 40.

δ. *Crystals in fine sand* ("crystal sand").

520. *Dulcamara.*—Numerous starch grains (7 μ); ducts reticulated 55 μ wide or with bordered pores (35–45 μ) associated with libriform cells 4 μ thick; cork; all elements grey or yellowish-grey colour.

(*b*) Containing starch but no calcium oxalate crystals.

521. *Chenopodium.*—See No. 108.

522. *Corn Bran.*—Less parenchyma containing characteristic grains of corn starch but more fragments of coat (bran); oil-globules.

523. *Grits.*—More or less altered and unaltered starch grains; almost free from coat (bran); oil.

524. *Mezereum.*—Starch in single grains (7–10 μ) or in masses; numerous very long colourless bast fibres about 15 μ wide; light parenchyma; yellowish-brown or pinkish cork.

525. *Myristica.*—See No. 496.

526. *Orris Root.*—Starch of varying but rather characteristic shape (15 × 15 to 15 × 30 μ); may find tetragonal (20 μ wide) or acicular crystals; fibrovascular bundles; no cork.

527. *Pepo.*—Few starch grains (2 × 2 to 3 × 4 μ) occur in outer epidermis and endosperm; characteristic, pear-shaped, thick-walled (possessing simple pores) cells about 70 × 45 μ; yellow pigment cells of seed coat; oil and protein in embryo.

528. *Sago (True).*—Slowly affected by cold water when there separates the characteristic elliptical, or truncate-elliptical starch grains (15–20 μ).

529. *Sago (Imitation).*—Breaks down quickly in water and shows characteristic *corn starch* grains.

530. *Strophanthus.*—Starch grains (4 μ) characteristic; long non-secreting hairs (10 to 15 μ wide); narrow, almost colourless, collapsed cells and parenchyma containing starch, oil and aleuron; with H_2SO_4 should become green, indicating fresh and unimpaired strophanthus.

B. WITH LITTLE OR NO STARCH.

a. Animal tissues.—On burning fragment on platinum foil gives off odour of burning tissue.

(*a*) *Does not colour glycerin.*

531. *Cantharis.*—Green metallic particles; not hairy.

532. *Mylabris.*—Very hairy.

(β) *Gives a carmine-red colour to glycerin.*

533. *Cochineal.*

(*b*) Without starch but containing vegetable tissues.

a With secreting or non-secreting hairs.

534. *Anisum.*—See No. 8.

535. *Arnicæ Flores.*—See No. 373.

536 *Cannabis Indica.*—Characteristic crystoliths, with or without broad base attached, in latter $CaCO_3$ in a granular mass. Entire crystolith about 200 μ long; oil secretion hairs; rosette-shaped calcium oxalate crystals (20 μ); characteristic cells of pericarp.

537. *Humulus.*—Characteristic secreting hairs (Lupulin); numerous rosette-shaped calcium oxalate crystals (8 μ); non-secreting hairs; characteristic epidermis; ducts yellowish.

538. *Rhus glabra.*—Hairs may be numerous, long, broken, 1-celled or spatulate (consisting of a chain of cells), containing a red pigment dissolved; pigment cells; characteristic stone cells of pericarp (20 μ in diameter and walls 4–10 μ thick; oil in protein.

539. *Rubus idæus.*—Characteristic long, more or less curved, 1-celled hairs (7 μ diameter), containing a reddish pigment; loose parenchyma, containing pigment and rosette-shaped crystals of calcium oxalate (7 μ); also characteristic hairs of receptacle and calyx.

540. *Strophanthus.*—Starch grains might be overlooked as small grains and in small amount. See No. 530.

541. *Tea.*—Characteristic stone cells (idioblasts); numerous long non-secreting hairs (10 μ wide); rosette-shaped crystals of calcium oxalate (10 μ); characteristic stomata (28 × 28 to 30 × 35 μ), with 4 or 5 "Nebenzellen"; adulterants are distinguished by possessing chiefly other forms of calcium oxalate crystals and hairs. (See also Mœller.)

β. Sklerenchyma cells (i.e., stone cells).

542. *Amygdala Amara* and 543. *Amygdala Dulcis.* Characteristic lignified yellow epidermal cells (70 × 65 μ), the walls of which are 4 μ thick and possess simple pores; endosperm layer 15 × 15 μ; crystals, may be rosette-shaped or cubical, about 7 × 7 μ and occur near the ducts; or there may be acicular crystals, 40 μ long. Bitter almond distinguished by putting a few fragments in cold water for some hours, when odour of HCN develops; or take solution and add $(NH_4)_2S$, evaporate in a porcelain dish nearly to dryness, and add Fe_2Cl_6=a deep blood-red colour.

544. *Black Mustard Hulls.*—Consist chiefly of characteristic fragments of seed coat.

545. *Cocoa.*—Consists chiefly of protein grains and oil; starch grains 4–8 μ; fragments with brownish contents (cacao red); fat crystals in little prisms or needles; few fragments of seed coat, consisting of hexagonal epidermal cells, a peculiar mucilage layer of small tabular cells and a layer of nearly isodiametric stone cells (10 × 10 μ), whose walls are 4 μ thick.

546. *Cocoa Shells.*—Chiefly of fragments of seed coat. See No. 545.

547. *Cocculus.*—Characteristic reddish-brown pericarp with elongated stone cells of varying shape, but walls about 7 μ thick; crystals either needle-shaped (single or in groups about 35 μ long) or prismatic (10 × 100 μ long), soluble in alcohol, but not in acids.

548. *Coffee.*—Characteristic fragments of seed coat, consisting of altered parenchyma and spindle-shaped stone cells (35 μ wide and 175–200 μ long); most cells are those of endosperm, with thick (10 μ) porous brownish-coloured walls, the contents are oil, aleuron and starch. In commerce coffee generally either "straight" or artificial. Latter consists of cereals, chicory, etc.

549. *Colocynthis.*—Stone cells of fruit, 70 × 50 μ, the walls of which are 15 μ thick; characteristic, nearly isodiametric, thick-walled stone cells, with but small lumen; the cells of embryo contain oil and aleuron. The amount of seed in powder is determined by number of oil globules and fragments of seed coat. The U.S.P. directs only pulp, not seeds or epicarp.

550. *Cydonium.*—Without starch or calcium oxalate; characteristic seed coat consists of an outer layer of clear mucilage cells, as in linum; beneath these are cells with thick walls and contain a pigment reacting like tannin; parenchyma contains oil, protein, and tannin.

551. *Linum.*—Numerous fragments, possessing characteristic tabular reddish-brown pigment cells; when seen in surface view (15 × 30 μ) associated with small yellowish-coloured stone cells; mucilage layer prominent, being the outer epidermis; relatively thin-walled parenchyma, containing oil and aleuron.

552. *Pepo.*—See No. 527.

553. *Sinapis Alba* and 554. *Sinapis Nigra.* No starch, tannin or crystallisable carbohydrate; mucilage layer not so prominent as in cydonium or linum; much oil and aleuron (latter in small grains); not infrequently find complete transverse sections of seed coat in the powder. In *Sinapis alba* the coat consists of hexagonal epidermal cells (45 μ); then follows a sub-epidermal collenchyma, a light yellowish or colourless pigment layer and a layer of stone cells (8 × 10 μ), the walls of which are 4 μ thick. In *Sinapis nigra* the unequal hexagonal epidermal cells are larger, 45–70 μ, the pigment layer is reddish-brown and stone cells are about as in *Sinapis alba.* Both mustards are turned blood-red in colour by H_2SO_4. Likely to find fragments of turmeric in yellow mustard.

555. *Staphisagria.*—Characteristic fragments of seed coat with brown pigment, and possessing prominent hexagonal stone cells (80 μ wide) with thick walls (20 μ); long spindle-shaped cells, such as occur in delphinium are present; parenchyma contains oil and aleuron.

556. *Starmonii Semen.*—Peculiar greenish fluorescence of mount in glycerin or glycerin + chloral. Nothing behaves like this. Characteristic seed coat, with yellowish and brownish thick-walled stone cells; most characteristic are the groups (of train-like) brownish stone cells, whose walls are very thick, with scarcely any lumen sometimes; parenchyma contains oil and aleuron, but *no* starch.

γ. Sklerenchyma fibres.

557. *Berberis aquifolium.*—Ducts (50 μ wide), with bordered pores, wood fibres (20 μ wide, walls 8 μ thick) and medullary rays (9 rows wide, containing starch grains 10 μ) are yellow; bast fibres 15 μ wide and walls 4 μ thick; cork prominent; parenchyma of cortex contains brownish-coloured substance.

558. *Chicory.*—Inulin masses; characteristic cork; numerous fragments of ducts of varying size; parenchyma (25 × 140 μ); laticiferous vessels 7–20 μ wide.

559. *Chirata.*—No starch; pollen grains (4 × 10 to 7 × 10 μ); parenchyma large, with simple pores; spiral and scalariform ducts (30 μ wide); numerous sklerenchyma fibres (20 μ wide and walls 4 μ thick); yellowish epidermis with brownish-coloured collenchyma beneath; seeds reticulate and in shape like hyoscyamus; mycelial-like development containing dark-brown-coloured substance.

560. *Hæmatoxylon.*—Cubical crystals (20 μ) in crystal fibres associated with yellowish libriform fibres (15 μ wide and walls 4 μ thick); large ducts (140 μ wide) containing brownish masses; medullary rays are 4–5 cells wide; characteristic violet or purple coloration with alkalies; oil globules, resin and tannin masses.

561. *Matricaria.*—Numerous nearly spherical pollen grains (18–25 μ); fragments of corolla with secretion hairs; cells of anther; stigma with papillæ; peculiar ladder-like cells of wall of akene; sklerenchyma fibres of involucral scales.

562. *Pine Shavings.*—Characteristic tracheids with bordered pores.

563. *Taraxacum.*—Characteristic laticiferous vessels and inulin. See No. 165.

564. *Triticum.*—Without starch or calcium oxalate crystal; parenchyma containing irregular masses, soluble in water (sugar); yellow hypodermal cells with lignified thickening (walls 10 μ or more thick) and simple pores; three kinds of characteristic sklerenchyma of varying length and width; some of the fibres are marked here and there, apparently at regular intervals, with a tabular cell (duct) of same composition as fibre; ducts spiral and annular (30–50 μ in diameter).

δ. *Sklerenchyma cells or fibres wanting.*

565. *Aurantii Amari Cortex.*—See No. 206.

566. *Aurantii Dulcis Cortex.*—See No. 207.

567. *Gentian.*—See No. 467.

568. *Limonis Cortex.*—See No. 208.

569. *Sambucus.*—Numerous smooth pollen grains (18 × 18 μ); cells of anther; sometimes find small crystals of calcium oxalate in calyx; fragments of corolla with characteristic slight, dentate, papillæ; in flower stalk are large spiral ducts (30 μ diameter); also parenchyma, with brown contents and collenchyma.

570. *Sassafras Medulla.*—Consists only of parenchyma cells, whose walls consist of cellulose and mucilage, and hence swell perceptibly in water. Mount sticky, mucilaginous.

571. *Taraxacum.*—Characteristic (not lignified) "Ersatzfasern," laticiferous vessels and inulin. See No. 165.

572. *Zea.*—Style with spiral and annular ducts, and from the epidermis there arises secretion hairs which are 300 μ long.

II. Containing Few Fragments of Tissues.

A. POSSESSING OIL.

573. *Asafetida.*—In a glycerin mount the powder shows irregular greyish (or grey streaked with brown) masses; opaque and becoming milky white on edge from oil. The *Stony* asafetida is pulverulent and contains less oil.

574. *Myrrh.*—In glycerin mount powder appears in yellowish or yellowish brown irregular fragments made up of a greyish matrix and containing yellowish or yellowish-brown oil globules.

B. NO OIL; AND GLYCERIN MOUNTS NEARLY TRANSPARENT.

575. *Manna.*—Collection of long, transparent tetragonal or prismatic crystals of varying length and about 4 to 10 μ wide; fragments in glycerin leave clear crystal and little amorphous opaque residue.

576. *Pix Burgundica.*—More pulverulent (m. p. lower) than terebinthina; lemon-yellow transparent, or greyish, somewhat translucent, more or less rounded and opaque masses. Soluble in glacial acetic acid, giving a yellowish-brown solution.

577. *Sugar.*—Like rock candy; dissolves in glycerin without residue.

578. *Terebinthina.*—More adhersive (softer in summer) than Pix Burgundica; nearly transparent colourless or light yellowish masses of irregular rounded outline. Solution in glacial acetic acid of a light yellow.

C. NO OIL, AND MOUNTS IN GLYCERIN MORE OR LESS OPAQUE.

579. *Confectio Rosæ.*—Fragments of red rose petals with characteristic more or less rounded papillæ; few elliptical pollen grains (18 × 32 μ); mass greyish and made up of rounded grains; some transparent sugar crystals.

580. *Lactucarium.*—Greyish brown and dark brown, irregular and rather angular masses; with alkalies they become reddish brown and then a dirty brown; with H_2SO_4, but slightly (faint yellow) affected.

No. 7. Vegetable (also Animal) Drugs which do not Occur in Powders but in Masses or Liquids.

I. LIQUIDS.

581. *Balsam Peru.*—Colour blackish.

582. *Copaiba.*—Colour amber.

583. *Gurjun Balsam.*—Colour amber.

584. *Mel.*—Colourless or faint yellow.

585. *Styrax.*—Peculiar grey colour.

II. SEMI-FLUID OR NEARLY SOLID.

586. *Bals. Tolu.*—Characteristic odour.

587. *Prunum.*—Characteristic tissues of pericarp and seed.

588. *Resina Podophylli.*

589. *Tamarindus.*—Characteristic tissues of pericarp and seed.

III. SOLID.

590. *Elastica.*—Not pulverulent.

591. *Resina Podophylli.*

REMARKS.

This investigation, which has occupied the attention of the author for several years, is based on the careful study of the crude (sometimes also fresh) drug as well as authentic commercial powders (some of these have been furnished by Gilpin, Langdon and Co.) and in many instances drugs ground by the author.

In publishing these results at this time no one realises more than the author that the whole scheme is but tentative and that additional study and the application of the method outlined will, no doubt, cause some changes to be made in practice. It would be surprising, furthermore, if there are not some errors of either commission or omission in that in some cases the characteristics given or withheld may be due to the examination of diseased, deteriorated, or even spurious drugs. But all this is due to the fact that the collecting and caring for drugs is not carried out on scientific principles. Even should there be oversights or errors, the publication of this work must be of some value to pharmacognocists. We must realise that a communication of this kind to be complete in any sense must have incorporated with it the results and experiences of numerous investigators from rather widely scattered sections of the country and world.

The scheme is based on scientific principles, but it has been considered desirable at the outset to open up the subject by dividing the powders into groups depending on their colour. It is true that colour varies in the plant itself in nature and according to the time of gathering, mode of collecting and subsequent treatment, exposure to light, etc. But it is very necessary that these things be thoroughly studied before we are prepared economically to properly exhaust drugs, make preparations and pronounce on the therapeutical value of them. In this connection, it must be stated that in the study of powdered drugs the education of the eye to colour is very important, and, indeed, necessary. Old and freshly-powdered drugs are to be distinguished by this means alone, as also a properly prepared drug from one carlessly treated. To the author's mind the eye and nose, and possibly the taste are very important factors in the study of powdered drugs in connection with the microscope.

A number of interesting features have been brought out in this investigation. In fact it opens up possibly an entirely new method in the study of our drugs at large.

(1) In the first place, in the colour of the powder certain characteristic and diagnostic features are brought to light. Leaf and herb drugs in the powdered condition should be greenish or greyish, and not blackish or brownish-black; many roots and rhizomes ought to be a light tan rather than a dark brown, etc. The value of taraxacum and other more or less important drugs rich in reserve materials, as inulin, starch, etc., may be ascertained, as these reserve materials are contained, no doubt, in greatest abundance in the plant at the time that the active medicinal agents are present in likewise greatest amount.

(2) Certain facts, as the presence of pollen grains in chestnut leaves, will cause us to go into the woods and study the ecological and biological relations of the plants which yield us our drugs. For, without this study upon nature herself, we shall never know what value to place upon such observations or their real significance.

(3) The presence of reserve starch in leaves and a diminution in calcium oxalate in any part of the plant where normally it is present, will cause us to open our eyes to the study of micro-organisms and inquire as to what these things have to do with the deterioration of drugs and the spoliation of medicinal preparations.

When these pharmacognostical problems are understood then we will cease to devote our energies to indiseriminately mixing certain things together in our attempt to make elegant pharmaceutical preparations, but will start out to know what causes the difficulty, and, knowing this, we know how to proceed intelligently and in a scientific manner, just as we proceed in certain chemical pharmaceutical work.

(4) The use of the microscope in the examination of vegetable drugs (whether they be crude or powdered), as also in the examination of animal substances and chemical compounds is an application of this instrument to a degree that this communication indicates—to some extent at least—the widest practical application. In fact, it opens up the necessity for making microscopical examinations and micro-chemical tests to a much greater degree than heretofore on the crude as well as powdered drug.

The author would impress again upon all investigators the necessity for accurate measurements of tissues and contents of materials which are studied; as also the name of the media or reagent in which the specimen lies or to which it has been subjected. Potassium hydroxide, chloral, glycerin, etc.—all of these have the property of affecting the thickness and character of the cell walls and cell contents, and it is upon these characteristics that we must rely for our useful studies of crude and powerful drugs.

GOVERNMENT AND PUBLIC APPOINTMENTS.

DISPENSERS IN NAVAL HOSPITALS are appointed by Government, and on entering the service must be not less than twenty nor more than twenty-five years of age. Candidates must possess either the Minor or Major certificate of the Pharmaceutical Society of Great Britain, or the certificate of competency granted by the Irish Society. The appointments are conferred as the result of open competition conducted by the Civil Service Commissioners, to whom application should be made by intending candidates. On appointment, dispensers are required to serve in any of Her Majesty's Naval Hospitals either at home or abroad, to which they may be sent, and are included in the list of salaried officers, with all the advantages pertaining thereto, and are entitled to pensions under the Superannuation Acts. There are fifteen appointments as follow:—At Haslar, 4; Plymouth, 3; Haulbowline, 1; Chatham, 1; Malta, 2; Cape of Good Hope, 1; Jamaica, 1; Bermuda, 1; Hong Kong, 1. The rate of pay on entry is 5s. per day (with quarters and an allowance of 6d. per day in lieu of fuel and lights), gradually rising to 10s. per day after 22 years' service. Dispensers in charge of stores have an additional allowance at Haslar and Plymouth of 2s. per day, and at any other hospital at home or abroad 1s. Extra pay to meet the increased cost of living is also granted to those serving at several of the foreign stations, viz., Malta, Cape of Good Hope, Jamaica, Bermuda, and Hong Kong. Twenty-eight days' annual leave, exclusive of Sundays, is granted to dispensers serving either at home or abroad, in the latter case liberty being given to reserve it from year to year so as to obtain a lengthened period of absence, which, however, must not exceed six calendar months. When on sick leave, which must not exceed twelve calendar months, full pay is allowed for six months, and after that period half-pay only, except when the dispenser would, if superannuated, be entitled to a higher amount, in which case he may be paid at the superannuation rate. When vacancies occur they are advertised in the *Pharmaceutical Journal*, and examinations are held in London, Edinburgh, and Dublin. The subjects of examination include: (1) Pharmaceutical chemistry; (2) Materia medica, including the B.P. and its Appendix, poisons and their antidotes, dosage of remedies, and preparation of antiseptic solutions; (3) Recognition of chemicals and drugs employed in medicine; (4) Practical pharmacy, reading of prescriptions and detection of errors in prescribing. The examination in subjects 3 and 4 are *viva voce*. The fee is 10s., and successful candidates have to satisfy the Civil Service Commissioners as to their physical fitness to serve abroad.

ARMY COMPOUNDERS are selected from the Army Medical Corps non-commissioned officers who must pass certain examinations in pharmacy, materia medica, etc., conducted by the medical officers. If a qualified chemist desires to become an army compounder he must first enlist in the corps as a private and work his way up.

POOR-LAW DISPENSERS are appointed by the Local Government Board, and must be qualified chemists and druggists, pharmaceutical chemists (Ireland), apothecaries, apothecaries' assistants, or Army compounders. The salaries range from about £120 to £150 per annum.

PRISON DISPENSERS are required to possess the qualifying certificate of the Pharmaceutical Society, and must join the service as warder between the ages of 24 and 30 years. A uniform is supplied, also quarters in the prison and medical attendance, the salary paid being somewhat similar to that received by poor-law dispensers. Vacancies are advertised as they occur.

GOVERNMENT LABORATORY APPOINTMENTS.—Assistant chemists in the Government (Somerset House) Laboratory, recently transferred to new premises in Clement's Inn Passage, Strand, W.C., are selected by examination, chiefly from assistants and junior officers between 19 and 22 years of age in the Inland Revenue and Customs Department, who are appointed after competitive examination by the Civil Service Commissioners to whom application should be made for particulars. Eight assistants are appointed to the Government Laboratory annually. Candidates are required to pass an examination in (1) Elementary inorganic chemistry; (2) Elementary organic chemistry, with special reference to the chemistry of brewing, distilling, and other industries, subject to Revenue control; (3) Elementary physics, (4) Algebra (up to quadratic equations), (5) Euclid (Books I. and II.). They are then sent to the Royal College of Science, South Kensington, for instruction in theoretical and practical chemistry, a grant of £10 being given, in addition to their salaries, for books and apparatus. Two years are spent at South Kensington, after which candidates are appointed as temporary assistants in the Government Laboratory, where they remain not less than three years. Assistants who show special aptitude for their work are granted by the Treasury, on the recommendation of the principal, an allowance of £20 per year. On attaining to the rank of second-class analysts they receive a salary of £160, increasing by £15 yearly to £350; first-class analysts begin with £400 rising by £20 to £550; superintendent analysts receive £600 to £650; and the deputy principal £700, increasing to £800. After completion of the full period of service, or enforced resignation through ill-health, members of the staff are entitled to a pension in proportion to their annual pay.

PUBLIC ANALYSTS.—The Local Government Board, which has a voice in the appointment of public analysts, requires that candidates shall be Fellows of the Institute of Chemistry, and that they possess a competent knowledge of therapeutics, pharmacology, and microscopy. The student who wishes to gain his F.I.C. must first pass one of the examinations approved by the General Medical Council, when, if he is seventeen years of age, he may apply for election as a student of the Institute. Two years' attendance at lectures and classes of practical instruction in chemistry, physics, mathematics, and one other specified subject, and a further two years in the laboratory of a Fellow of the Institute, is then necessary before a student may be examined for the Associateship. Candidates are required to pass an examination in general theoretical and practical chemistry, and a Final Practical examination in one of the following branches of chemical science—mineral chemistry, metallurgical chemistry, physical chemistry, organic chemistry, and analysis of food and drugs. The fee is £7 7s. On gaining the Associateship, in due course fellowship follows without further examination. Holders of degrees such as B.Sc., Ph.D., etc., are excused certain parts of the examinations. A special course of study is recommended by the Institute to meet the requirements of the Local Government Board with respect to the subjects already mentioned. Particulars may be obtained from the Secretary, Institute of Chemistry, 30, Bloomsbury Square, London, W.C.

DIPLOMA IN VETERINARY SURGERY.

The student who desires to qualify as a veterinary surgeon, that is, to secure the diploma of M.R.C.V.S., is required to pass a Preliminary examination in general education recognised by the General Medical Council before entering for the first professional examination. He must then study at a recognised veterinary school for four years, and during that time pass four professional examinations, the subjects of which are:—

(1) Anatomy of domesticated animals: bones, ligaments, joints. Chemistry and elementary physics. Biology: elementary zoology and botany.

(2) Anatomy of domesticated animals. Histology and physiology. Stable management and manipulation of domesticated animals. Principles of shoeing.

(3) Morbid anatomy, pathology and bacteriology. Materia medica, pharmacy, therapeutics, and toxicology. Veterinary hygiene and dietetics.

(4) Principles and practice of veterinary medicine and surgery. Clinical medicine, surgery, and obstetrics (horse and other domesticated animals). Meat inspection.

The candidate must be twenty-one years of age before he can enter for No. 4. The examinations are held under the auspices of the Royal College of Veterinary Surgeons, 10, Red Lion Square, London, W.C., and are conducted by a Board of Examiners, which visits Edinburgh, Glasgow, and London about the end of the College terms. The fee for each of the four examinations is £5, and a fee of £1 is also paid for registration. Full particulars may be obtained from the Secretary of the College. Students are prepared for the veterinary examinations at the following institutions:—Royal Veterinary College, Great College Street, Camden Town, London, N.W.; Royal (Dick) Veterinary College, Clyde Street, Edinburgh; the New Veterinary College, Leith Walk, Edinburgh; and the Glasgow Veterinary College, Buccleuch Street, Garnet Hill, Glasgow.

OPTICAL EXAMINATIONS.

The Spectacle-Makers' Company, London, recently inaugurated an examination scheme whereby chemists and others interested in the optical business, who wish to have some tangible proof of their fitness to supply the public with proper spectacles, may be examined as to their knowledge of the subject, and if successful in passing are granted a diploma. The examinations are held about three times a year, the next being in November. Persons who have been engaged in the business seven years may take a Modified examination; after November, however, only those who have traded under their own name for seven years prior to January 1, 1900, will be eligible. The subjects of the Modified examination are:—

Light.—Elementary laws of light; simple laws of refraction; the index o refraction; refraction as applied to lenses and prisms; conjugate foci; formation of images; simple laws of reflexion as applied to curved and plane mirrors.

Optics Relating to Vision.—General anatomy of the human eye. The course of light passing through the media of the eye alone and modified by spherical and cylindrical lenses and prisms. Hypermetropia; myopia; astigmatism; presbyopia. Instruments commonly used for determining the refraction of the eye:—Trial lenses—test types—astigmatic chart—the optometer. The principle of the ophthalmascope. The principle of, and various forms of, spectacles.

Practical Work in Visual Optics.—Testing a plane surface; measurement of focal length of spherical, cylindrical, and compound lenses; use of the spherometer or lens meter; measurement of conjugate foci; determination of the axis of a cylinder, and the angle of deviation of a prism; analysis and neutralisation of spherical, cylindrical, and compound lenses, and lenses combined with prisms; transposing; centring and adjustment of spectacle lenses and frames; face-measurement for spectacles. Knowledge of the materials and of the workmanship employed in the manufacture of lenses and frames; use of pebble-tester. Reading of oculists' prescriptions; giving out orders for lenses and frames.

The full examination, which may be taken in two parts, comprises, in addition to the subjects already mentioned, elementary mathematics, heat, practical work with optical and mathematical instruments, and one of the following subjects:—The photographic camera, the microscope, nautical and surveying instruments, and projection instruments. The fees are from £3 5s. to £5 5s. Further particulars may be obtained from Colonel T. Davies Sewell, Guildhall, E.C. Examinations are also conducted by the British Optical Association, particulars of which can be had from the Secretary, Mr. J. H. Sutcliffe, Clifton Chambers, Blackpool.

Classes for instruction in the subjects included in the syllabus of the Spectacle Makers' Company are held at the Northampton Institute, Clerkenwell, E.C., principal, Dr. R. M. Walmsley. Mr. Lionel Laurance, 1, Vernon Place, Bloomsbury Square, W.C., the writer of the articles on visual optics which have appeared from time to time in the *Pharmaceutical Journal*, and official instructor to the Spectacle Makers' Company, also conducts correspondence and evening classes in London and the country. There is also a school of optics in connection with the Anglo-American Optical Company, 94, Hatton Garden, London, E.C.

APOTHECARIES' ASSISTANT'S CERTIFICATE.

The idea prevails amongst pharmaceutical students that the Apothecaries' Assistant's Certificate is worth possessing in addition to the Minor Certificate, but it should be recognised that the certificate is evidence of no qualification except to act as an assistant to an apothecary, and in view of the extreme rarity with which the penalty for acting as an assistant to an apothecary without qualification is enforced, it is a question for serious consideration whether the certificate is worth the expense and trouble involved in obtaining it. It should also be remembered that the certificate does not confer upon its holder any right to sell poisons or to assume any pharmaceutical title.

The examination, which is much less stringent than the Minor, is held at the Apothecaries' Hall, Blackfriars, London, E.C., in January, April, July, and October of each year, and is practical and oral only. The practical part comprises the compounding and dispensing of medicines, the oral part including chemistry, materia medica, pharmacy, and the translation of prescriptions. Candidates must be at least seventeen years old, and must give notice of their intention of presenting themselves and pay a fee of £3 3s. seven days before the examination. Candidates who fail may be re-examined on payment of £1. 1s. Fees must be paid by cheque or money order, posted to the Secretary to the Court of Examiners, Mr. F. Haydon, L.R.C.P., at the Apothecaries' Hall.

NEW REMEDIES.

Melon Root as a Substitute for Ipecacuanha.—Heberger has extracted from the root of the melon, and other Cucurbitaceæ, a bitter extractive possessing purgative and emetic properties. To this he has applied the name melon-emetine. According to Langeweiz, it produces emesis in doses of 50 to 70 centigrammes. Of the powdered cultivated root the dose of 25 Gm. cannot be exceeded without danger. Wild plants are more active; from 50 to 70 centigrammes of the powdered root acting as an unfailing emetic.—*Union Pharm.*, **40**, 304, after *Journ. de Med. de Paris.*

Tricresol in Alopecia Areata.—Tricresol applied undiluted to the scalp, or in a 50 per cent. alcoholic solution to the face, is stated by MacGowan to be a remedy of superior value in the treatment of alopecia. It causes a burning pain, which generally disappears in a few minutes, the skin becoming thoroughly blanched. It is applied by thorough infrication, with a swab of cotton; the application is repeated in from 4 to 10 days.—*Intern. Med. Mag.*, **8**, 533.

Antipyrine in Dysentery.—Ardin-Deltat has employed antipyrine, in the dose of 75 grains to 8 ounces of water, as a rectal injection in dysentery, given three times a day, and retained for 15 minutes. He claims that the relief from pain and tenesmus is immediate, that the number of stools is decreased, and that convalescence is speedily established.—*Therap. Gaz.*, **15**, 472.

Formalin for Insect Bites.—According to Gonin *(Apoth. Zeit.)* the irritation and inflammation following an insect bite are soon relieved by frequently moistening the spot with formalin.—*Therapist*, **9**, 213.

Methylene Blue in Malaria.—Boinet finds that methylene blue, although of certain value in the treatment of malarial fever, is, on the whole, markedly less efficacious than quinine. It may with advantage be employed either successively to, or together with, that alkaloid.—*Bull. gen. de Therap.*, **138**, 203.

Organotherapy in Gynecology.—*Thyroid gland* exercises, according to W. A. N. Dorland, a very marked inhibitory influence on the pelvic genital organs, especially on the uterus. It retards hæmorrhages from the uterine mucosa, and is, in this respect, antagonistic to the ovarian secretion. Its use is, therefore, indicated in hæmorrhagic affections of the uterus, and in all forms of pelvic congestion, notably in uterine fibromata, endometritis menopausal hæmorrhage, and chronic tubal disease. It also increases the metabolism of the mammary gland, and is therefore useful in the treatment of insufficient lactation. *Mammary gland*, according to Shober, gives good results in the treatment of fibroid uterine tumour. It has not given rise to any unpleasant or grave constitutional disturbances, but acts as a general tonic. Desiccated powdered mammary gland of the sheep was employed in doses of two grains, equivalent to 20 grains of the fresh gland. The same author has employed *parotid gland* in the treatment of ovarian diseases with gratifying results. The dose employed was two grains of the dried powdered gland.—*Therap. Gaz.*, **23**, 444.

SELECTED PRACTICAL FORMULÆ.

SOLUTION OF CALCIUM GLYCEROPHOSPHATE.

In consequence of the insolubility of the neutral calcium glycerophosphate employed in medicine, P. Carles proposes to make use of the readily soluble acid glycerophosphate, which he obtains by removing half an equivalent of calcium from the neutral salt by means of oxalic or tartaric acid. To avoid fungoid growth in the solution he adds 5 per cent. of official cherry laurel water, or 10 per cent. of cinnamon water. Neutral glycerophosphate of lime, 10 Gm., is suspended in 80 C.c. of water at 40 to 50° C. From 2·25 to 3 Gm. of oxalic acid is dissolved in 10 C.c. of boiling water, the liquids are mixed, and filtered after standing for two hours. To the filtrate 5 Gm. of cherry laurel water is added, and the precipitate on the filter is washed with sufficient water to bring the final volume to 100 Gm. Each teaspoonful of this solution contains 50 centigrammes of glycerophosphate. Tartaric acid may be substituted for oxalic acid in the proportion of 2·7 to 3 Gm. From this solution an excellent syrup of calcium glycerophosphate which keeps well may be made by dissolving 160 Gm. of sugar in 100 Gm. of the solution either in the cold or on the water bath. A wine of calcium phosphate is prepared from neutral calcium glycerophosphate, 10 Gm., tartaric acid, 2·7 to 3 Gm.; any wine to produce 1,000 Gms. The glycerophosphate is suspended in two-thirds of the wine, the acid dissolved in the rest, the liquids mixed, and after standing for some hours, filtered. If oxalic acid be used instead of tartaric acid the wine will be less likely to deposit acid tartrate of potassium on keeping.—*Bull. de Pharm. de Bord.*, **39**, 201.

PHARMACY OF SODIUM CACODYLATE.

Danlos prescribes sodium cacodylate in the following *mixture*:—Sodium cacodylate, 2 Gm.; rum, simple syrup, of each, 20 Gm.; distilled water, 60 Gm.; oil of peppermint, 2 drops. A teaspoonful contains 10 centigrammes of the salt. *Pills* may be made containing 10 centigrammes, massed with extract of gentian. *Rectal Injections* are employed by J. Renant in two strengths, the weaker containing 25 Gm. of the salt, the stronger 40 Gm., in 200 C.c. of water. 5 C.c. is used for a rectal injection twice daily for six days, three times a day for ten days, then allowing a lapse of thirty days before recommencing the treatment. *Hypodermic Injection* of sodium cacodylate is obtained by A. Gautier by neutralising cacodylic acid, 5 Gm., with sodium carbonate; then adding cocaine hydrochloride, 8 centigrammes; creosote, 6 drops, dissolved in alcohol, 8 Gm.; sterilised water to produce, 100 C.c. Each C.c. contains 5 centigrammes of cacodylic acid. Danlos employs the following formula:—Morphine hydrochloride, 25 milligrammes; cocaine hydrochloride, 10 centigrammes; sodium chloride, 20 centigrammes; sodium cacodylate, 5 Gm.; phenol solution (5 per cent.), 2 drops; distilled water, to 100 C.c. A medium dose of the salt by hypodermic injection is 2 to 5 centigrammes. The maximum of 10 centigrammes in 24 hours should not be exceeded.—*Bull. gen. de Therap.*, **128**, 220.

METALLIC BRONZES ON LEATHER.

Gold Bronze.—Gold chloride solution containing 15 Gm. of gold chloride, 21 Gm.; solution of soda (4 per cent.), 500 C.c.; glycerin, 15 Gm. *Silver Bronze.*—Water, 10 litres; silver nitrate, 100 Gm.; solution of ammonia, 65 Gm.; tartaric acid, 15 Gm.; or water, 10 litres; glucose, 100 Gm.; silver nitrate, 100 Gm. *Nickel Bronze.*—Nickel nitrate, 400 Gm.; solution of ammonia, 400 Gm.; water, 15 litres; sodium sulphate, 5,000 Gm. *Cobalt Bronze.*—Water, 1,000; cobalt ammonium sulphate, 1. These solutions are applied with a sponge to the leather, which should first be treated with a solution of lead acetate, or of cupric acetate, and then exposed to the action of sulphuretted hydrogen.—*Scient. Amer.*, **81**, 23, after *Schuh und Leder.*

INDELIBLE RED INK.

According to the *Hannoversche Gerwerbeblatt*, the following formula gives an excellent red marking ink. It is prepared in three solutions. (1) Sodium carbonate, 3; gum acacia, 3; water, 12. (2) Platinum chloride, 1; distilled water, 24. (3) Zinc chloride, 1; distilled water, 4. The article is first moistened with solution 1, and rubbed with a warm iron; the letters are then written with a pen dipped in solution 2. When the writing is dry it is moistened with solution 3. For linen, the following is also useful. White of egg is mixed with an equal volume of water, and stirred until it froths; it is then strained through a cloth, and made into a thick paste with cochineal red. The linen is marked with the paste on a quill or drawing-pen; the spot is then ironed on the reverse side with a flat iron, until the albumin has coagulated.—*Scient. Amer.*, **81**, 23.

DERMATOLOGICAL FORMULÆ OF THE HOSPITAL SAINT LOUIS, PARIS.

Zinc Oxide Paste.—Zinc oxide, French chalk, and vaseline equal parts. *Biniodide Ointment.*—Mercuric iodide, 10 centigrammes; potassium iodide, 10 centigrammes; vaseline, 20 Gm. *Compound Syrup.*—Mercuric iodide, 10 centigrammes; potassium iodide, 10 Gm.; simple syrup, 200 Gm. *Stimulant Lotion.*—Solution of ammonia, 8 Gm.; oil of turpentine, 25 Gm.; camphorated alcohol, 167 Gm. Employed for alopecia. *Sulphur Lotion.*—Precipitated sulphur, glycerin, of each, 10 Gm.; camphorated alcohol, 20 Gm.; distilled water, 160 Gm. *Parasiticide Lotion.*—Mercuric chloride, 25 centigrammes; oil of turpentine, 30 Gm.; glycerin, 40 Gm.; camphorated alcohol, 175 Gm. The camphorated alcohol in this and the previous formulæ is the weaker preparation "alcohol camphoratum debilior" of the Codex, composed of camphor, 1; alcohol (60 per cent.), 39. Any other aromatic spirit may be substituted for it at the option of the prescriber, *Dilute Cade Glycerole.*—Oil of cade, 10 Gm.; glycerole of starch, 90 Gm.; fluid extract of quillaia *q.s.* to emulsify (about 2 Gm.). *Stronger Cade Glycerole.*—Oil of cade glycerole of starch, of each 50 Gm.; fluid extract of quillaia *q.s.* to emulsify (about 5 Gm.). In the treatment of psoriasis an alkaline bath should be given and the crusts removed before applying the glycerole. *Tartaric Acid Glycerole.*—Tartaric acid, 1 Gm.; glycerole of starch, 20 Gm. Applied to allay itching in various non-parasitic skin diseases. *Vidal's Red Plaster.*—Red lead, 10 Gm.; cinnabar, 6 Gm.; diachylon plaster, 100 Gm. This is preferable to the old Vigo plaster, which was too strong in mercury. It is applied to various lesions, ulcerations, lupus, etc.—*Bull. gen. de Therap.*, **128**, 179.

REMEDIES FOR THE ITCH.

Vlemminek's Lotion.—Lime, 50, sulphur, 25, water, 250. Slake the lime, add it gradually to boiling water, 400, add the sulphur, boil until reduced to 250, strain, allow to settle, and decant. Keep in well-filled bottles. *Wilkinson's Ointment.*—Sulphur, cade oil, of each 18; soft soap, lard, of each 50; prepared chalk, 12. Mix. *Elmerich's Ointment.*—Sulphur 2, potassium carbonate, 1, lard, 8. As this is very irritant Hardy has modified the formula thus:—Sulphur, 2, potassium carbonate, 1,, lard or vaseline, 12. *Bouguignon's Ointment.*—Oil of lavender, oil of cinnamon, oil of clove, oil of peppermint, of each 2; powdered tragacanth, 1, potassium carbonate, 30, flowers of sulphur, 90, glycerin, 180. *Fournier's Paste*—Glycerin, 200, powdered tragacanth, 1, sulphur, 100, sodium carbonate, 50. *Naphthol Application.*—Naphthol, 5 or 10; alcohol *q.s.* water 100. *Non-Irritant Application.*—Storax ointment, (Codex), olive oil, equal parts.—*Bull. Gen. de Therap.*, **128**, 236, after *Med. Mod.*

APPLICATION FOR RHEUMATISM.

Mix salol, 6, menthol, 3, ether, 6, lanolin, 50.—*Rev. Pharm.*, **7**, 224.

MEMBERSHIP OF LEARNED SOCIETIES.

ROYAL SOCIETY.—Candidates for Fellowship of the Royal Society are elected on the recommendation of six Fellows of the Society, three of whom must certify their personal knowledge of the candidate. The certificate signed by the six Fellows must state the name, address, rank, profession, and qualification of the candidate, and must be sent in to the Secretary, at Burlington House, London, W., before the first Thursday in March. Annual subscription, £3; life subscription, £60.

ROYAL SOCIETY OF EDINBURGH.—Candidates for the ordinary Fellowship of the Royal Society of Edinburgh are required to apply in writing and to obtain a certificate of recommendation signed by four ordinary Fellows, two of whom must have personel knowledge of the candidate. Hon. Fellows are elected from amongst eminent scientists and literary men.

CHEMICAL SOCIETY.— Fellows of the Chemical Society are elected by a two-thirds majority, on the recommendation of five Fellows, three of whom must certify their personal knowledge of the candidate's qualifications. A certificate signed by the five Fellows must be addressed to the Secretary, at Burlington House, London, W., giving the candidate's name, address, profession, and qualifications, and the candidate must also submit evidence of a thorough chemical training. Entrance fee, £4; annual subscription, £2.

INSTITUTE OF CHEMISTRY.—Persons who desire to become Fellows of the Institute of Chemistry must, in the first place, become registered students of the Institute, the annual registration fee being 5s. Brief particulars, as to the examinations, etc., required for studentship and associateship of the Institute are given under the heading, "Public Analysts," at page 250. Fellowship entrance fee, £4 4s.; annual subscription, £1 1s. Address, 30, Bloomsbury Square, London, W.C.

SOCIETY OF PUBLIC ANALYSTS.—Election to Associateship and Membership of the Society of Public Analysts is by ballot. The Associates must be assistants to public analysts. Annual subscription, £1 1s. The Society meets in the rooms of the Chemical Society, Burlington House, London, W.

SOCIETY OF CHEMICAL INDUSTRY.—Members of the Society of Chemical Industry are elected on the proposition of a member to whom they are personally known. Entrance fee £1 1s. Annual subscription, £1 5s. Address, 9, Bridge Street, Westminster London, S.W.

LINNEAN SOCIETY OF LONDON.—Candidates for Fellowship of the Linnean Society are elected on nomination by three Fellows. Entrance fee, £6; annual subscription, £3. Address, Burlington House, London, W.

ROYAL BOTANIC SOCIETY.—The Members and Fellows of the Royal Botanic Society are elected on the proposition of one Fellow, and are entitled to free admission to the Society's gardens in Regent's Park, London, W.

ROYAL MICROSCOPICAL SOCIETY.—Nomination by three Fellows of the Society is required for candidates desiring to become Fellows. Entrance fee and annual subscription, £2 2s. Address, 20, Hanover Square, London, W.

ROYAL PHOTOGRAPHIC SOCIETY.—This Society has recently removed from its old address in Hanover Square to 66, Russell Square, London, W.C. Entrance fee and annual subscription, £1 1s.

THE STUDENTS' COLUMNS.

DISPENSING PROBLEMS AND THEIR SOLUTION.

In looking through the pharmaceutical periodicals one cannot but be struck with the numerous requests editors receive from their correspondents for the solution of dispensing difficulties real or imagined, and with the often recurring demands for the elucidation of certain reactions which seem to crop up at the dispensing counter of these correspondents with a regularity equal to that of the succession of the seasons. Now, whilst every editor likes to be referred to as omniscient, and is particularly pleased to answer questions which have so intimate a connection with the daily work of the majority of his readers, as have these dispensing queries, he feels that it is, to say the least, rather waste of his time and the space in his paper to have to answer the same question several times in the course of a year. There is rather too much reliance put in the pharmaceutical editor, and too little work done by his correspondents. A good dispenser is one who, in addition to his manual dexterity, possesses enough scientific knowledge to enable him to account for the various reactions undergone by the ingredients of the mixtures he compounds, and to devise means for hastening these reactions where desirable, or preventing them if it be evident that the prescriber overlooked their possibility when writing the prescription. It will be our endeavour to point out shortly directions in which dispensers may utilise their knowledge of chemistry and try and solve for themselves their own problems, an exercise they will find to their own advantage and edification, and one which they may convert to the good of their comrades if they will take the trouble to keep notes of their work and contribute them to the pharmaceutical press, or embody them in papers to be read before any of the numerous students' pharmaceutical associations, now happily to be found in most large communities.

A glance at any prescription will show a practised dispenser what to expect, and to a tyro, even with a knowledge of chemistry, any really incompatible ingredients will be certainly observed. These glaring incompatibilities really give but little trouble, it is the seemingly innocent mixtures where the changes liable to take place only do so very gradually, which are the most to be studied. These it may at once be said are usually only revealed to the dispenser after they have taken place some time, when they are brought to his notice by the patient or by the appearance of the bottle when a "repeat" is ordered.

If a precipitate of a crystalline nature be seen adhering to the sides of the bottle, the prescription will give a clue as to whether it is likely to be an alkaloid salt or a salt of an inorganic base. The reaction to litmus paper of the clear liquid will then be a useful thing to observe, as will also the bulk of the precipitate, for with a small amount of alkaloid there is not much chance of a large precipitate. A solution of the precipitate in dilute acid should then be tried with the ordinary alkaloid reagents, and if no indications are yielded, the inorganic side may be attempted. A potent factor in the formation of alkaloid precipitates is concentration of the solution by either excess of other salts or by the presence of a large amount of tinctures, or in some cases excess of dilute acids.

Most of the difficulties caused by alkaloids are due to double decomposition with inorganic salts, such as those of bismuth, mercury, lead, and iron, particularly where coloured precipitates are formed. Other organic bases or bodies give rise to characteristic reactions, such as phenazone with nitrites, as in sp. ætheris nit., and with salicylates under certain circumstances.

Glucosides also contribute to the dispenser's happiness, glycyrrhizin in the extract of liquorice being the greatest sinner and the one which is the easiest to deal with.

Colour reactions may be classed as legion, running from such simple ones as tincture of iron and solution of ammonium acetate to iodide of starch, produced in mixtures of soluble iodides with compound tragacanth powder and some agent capable of liberating iodine from the iodide.

Numerous bodies have this iodine liberating power, and one continually sees them figuring in dispensing problems. It is as well to remember that ether and chloroform if decomposed by sunlight, chlorinated bodies, nitrites, and iodates in the presence of an acid, and nearly all essential oils which contain terpenes, and which have become slightly acid or oxidised by exposure to the air, are nearly certain to give free iodine in iodide mixtures, unless there be enough alkali to absorb the iodine as liberated.

To explain a reaction make a series of solutions of the ingredients of the mixture in every possible combination and in both acid, neutral and alkaline conditions, expose to both high and normal temperatures, and to direct sunlight (an important point in many cases) and carefully observe what takes place. By this method a proper deduction may be drawn and light thrown on the knotty point. If the difficulty does not yield to this, then consult your editor, who will give you the benefit of the columns of his paper, from which a satisfactory explanation of the trouble will be soon forthcoming.

EXPLANATORY NOTES ON THE B.P. 1898.

Potassii Bromidum.—In the volumetric test a variation of 1·7 C.c. is allowed in the volume of decinormal silver nitrate solution precipitated by one gramme of the salt.

$$\underbrace{KBr}_{118{\cdot}18} + \underbrace{AgNO_3}_{168.69} = AgBr + KNO_3$$

Since, therefore, 11·818 grammes of pure potassium bromide will precipitate 1,000 C.c. of N/10 silver nitrate solution, each gramme of the salt will require 1,000 ÷ 11·818 = 84·6 C.c of N/10 $AgNO_3$. 84·6 is nearly the mean of the minimum and maximum figures—viz., 83·7 and 85·4. Any variation between these limits would probably be due to traces of iodides or chlorides, potassium iodide requiring less and potassium chloride more silver nitrate solution than an equal weight of potassium bromide.

Saccharum Purificatum.—Two other sugars, maltose and lactose, are very closely related to cane sugar. All three have the empirical formula $C_{12}H_{22}O_{11}$, and are hydrolysed by diluted acids to two molecules of sugar of the hexose class—

$$C_{12}H_{22}O_{11} + H_2O = 2C_6H_{12}O_6.$$

The nature of the hexoses yielded by the three saccharobioses is different in each case, but it is interesting to note that, whereas lactose and maltose reduce Fehling's solution and react with phenylhydrazine, cane sugar does not. These three sugars are usually regarded as ether anhydrides of the hexoses, *i.e.*, they contain two hexose molecules condensed, with the elimination of a molecule of water, in a manner somewhat similar to the derivation of ether from alcohol—

$$\left.\begin{matrix} C_2H_5OH \\ + \\ C_2H_5OH \end{matrix}\right\} = \begin{matrix} C_2H_5 \\ C_2H_5 \end{matrix} > O + H_2O$$

The difference in their behaviour towards Fehling's solution and phenylhydrazine is accounted for on the supposition that this condensation in the case of lactose and maltose only affects one of the —CO—groups, so that the resultant condensed product still manifests the properties due to the keto or aldehydic group. In the case of cane sugar some rearrangement of the groups must have occurred during condensation by which the aldehydic and ketonic groups of the dextrose and lævulose molecules have become altered, and no longer manifest the properties characteristic of those groupings.

FLORAL CALENDAR FOR SEPTEMBER.

Alismaceæ.—*Actinocarpus damasonium, Butomus umbellatus.*

Amaranthaceæ.—*Amaranthus caudatus.* Fl.

Asclepiadaceæ.—*Asclepias syriaca.* B.G. *A. tuberosa.* B.G. *A. incarnata.* B.G. *Vincetoxicum officinale.* B.G.

Begoniaceæ.—*Begonia* species. Fl.

Boraginaceæ.—*Anchusa officinalis.* B.G. *Borago officinalis.* Fl.

Campanulaceæ.—*Lobelia urens; L. inflata.* B.G. *L. syphilitica.* B.G.

Caryophyllaceæ.—*Saponaria officinalis.* (*P.J.* [3], **9,** 161.)

Chenopodiaceæ.—*Chenopodium olidum, C. ambrosioides.* B.G.

Compositæ or **Asteraceæ.**—*Chrysocoma linosyris; Calendula officinalis.* Fl. *Lactuca virosa, Cichorium intybus, Anthemis nobilis* (*P.J.* [3], **8,** 141). *Artemisia maritima, A. absinthium, A. vulgaris; Liatris spicata.* B.G. *Eupatorium purpureum,* B.G., and *E. cannabinum; Xanthium strumarium.* B.G. *Tanacetum vulgare; Erigeron canadense.* B.G.

Convolvulaceæ.—*Ipomœa purga.* B.G. *Convolvulus scammonia.* B.G.

Cucurbitaceæ.—*Ecballium officinarum.* B.G. (*P.J.* [3], **9,** p. 241.)

Cyperaceæ.—*Cyperus longus.*

Ericaceæ.—*Gaultheria procumbens.* B.G. *Pyrola arenaria.*

Euphorbiaceæ.—*Ricinus communis.* B.G.

Gentianaceæ.—*Gentiana pneumonanthe.*

Geraniaceæ.—*Geranium wallichianum.* B.G.

Hypericaceæ.—*Hypericum moserianum.* Fl.

Iridaceæ.—*Crocus sativus.* (*P.J.* [3], **8,** p. 241.) *Montbretia crocosmiæflora.* Fl.

Labiatæ or **Lamiaceæ.**—*Mentha piperita, M. pulegium, M. arvensis,* and *M. viridis, Melissa officinalis, Teucrium chamædrys, Origanum dictamnus.*

Leguminosæ or **Fabaceæ.**—*Apios tuberosa.*

Liliaceæ.—*Colchicum autumnale.* (*P.J.* [3], **8,** p. 241.) *Scilla autumnalis. Tritoma* species. Fl. *Agapanthus umbellatus.* Fl.

Malvaceæ.—*Althæa officinalis.*

Myrtaceæ.—*Myrtus communis.* Fl.

Nyctaginaceæ.—*Mirabilis jalapa.* Fl.

Orchidaceæ.—*Spiranthes autumnalis.*

Papaveraceæ.—*Glaucium luteum.*

Pedaliaceæ.—*Martynia lutea, Sesamum indicum.*

Phytolaccaceæ.—*Phytolacca decandra.*

Plantaginaceæ.—*Plantago ovata. P. psyllium.*

Plumbaginaceæ.—*Plumbago larpentæ.* B.G. *Statice limonium.*

Polygonaceæ.—*Rumex hydrolapathum.*

Ranunculaceæ.—*Anemone japonica.*

Rosaceæ.—*Spiræa tomentosa.* B.G.

Rubiaceæ.—*Psychotria ipecacuanha.* B.G.

Rutaceæ.—*Ruta graveolens.* (*P.J.* [3], **8,** 442.)

Santalaceæ.—*Thesium humifusum.*

Sapindaceæ.—*Koelreuteria paniculata.* Fl.

Scrophulariaceæ.—*Verbascum thapsus, Linaria cymbalaria.*

Solanaceæ.—*Solanum nigrum* (*P.J.* [3], **8,** 241), *Nicotiana tabacum.* Fl. *N. rustica.* B.G. *Petunia* species. Fl. *Physalis alkekengi.* Fl. *Solanum jasminoides.* B.G.

Tamaricaceæ.—*Tamarix gallica.*

Umbelliferæ or **Apiaceæ.**—*Peucedanum officinale, Fœniculum vulgare, Eryngium campestre; Cuminum cyminum.* B.G.

Urticaceæ.—*Parietaria officinalis, Humulus lupulus, Cannabis sativa* (*P.J.* [3], **8,** 141), *Dorstenia contrayerva.* B.G.

Verbenaceæ.—*Verbena officinalis* (*P.J.* [3], **9,** 161). *Aloysia citriodora.* Fl.

Violaceæ.—*Viola pedata.* B.G.

PHARMACEUTICAL JOURNAL.

A Weekly Record of Pharmacy and Allied Sciences.

ESTABLISHED 1841.

Circulating in the United Kingdom, France, Germany, Austria, Italy, Russia, Switzerland, Canada, the United States, South America, India, Australia, South Africa, etc.

Editorial Office: 17, BLOOMSBURY SQUARE, W.C.

Publishing and Advertising Office: 5, SERLE STREET, W.C.

LONDON: SATURDAY, SEPTEMBER 9, 1899.

ADVICE TO STUDENTS.

The beginning of the new session coincides with the coming in force of the new schedule for the Minor and Major examinations of the Pharmaceutical Society. The full text of that schedule is reprinted in this week's issue of the Journal (see p. 260 *et seq.*), and it is only necessary here to repeat that, with one important exception, the changes in the Minor syllabus tend more in the direction of rearrangement and simplification than of expansion. In botany, however, the candidate is now expected to know much more than formerly about the classification of plants. The new schedule, regarded as a whole, is much more definite than its immediate predecessor, and though the standard of the Minor examination is appreciably raised by the former, approximating more closely to that of the Major in years gone by, the alterations appear likely to effect a considerable lightening of the labours of candidates. The schedule should be closely and carefully studied by all intending candidates for registration as chemists and druggists and pharmaceutical chemists, not for the purpose of cutting down the work of preparation to the barest limits, but in order that there may be a clear comprehension of what it is necessary to know. Systems of cram—pure and simple—are based upon the schedule, and follow it so closely that the crammed student is rarely able to answer a single question outside the syllabus; frequently he cannot answer questions which may be regarded as coming within the borderland of what ought to be and what need not be known, and he sometimes even fails ignominiously in attempting to marshal his crammed facts at the examiner's word of command. But that, of course, is quite another story, and only serves to lend point to the fact that some seventy per cent. of the candidates who presented themselves for the qualifying examination last July failed to satisfy the long-suffering examiners.

More satisfactory schemes of work are also based largely on the examination schedule, a notable example being found in the syllabus of the Pharmaceutical Society's School of Pharmacy. But students who go through a complete course at that school are not merely taught enough to enable them to pass the examinations; the object aimed at by the Society's Executive is to turn out thoroughly accomplished pharmacists, and though the whole ground of the examinations is covered, the hard-working student—at the end of his course—is in a position to regard an examination as a mere incident and not the finishing touch to his education. And it is in that light examinations ought to be regarded by all candidates—not as obstacles in their life race, but merely as calling places on the way. Pharmaceutical students should select text-books which will well cover the requirements of the examination schedule, and study their contents as a whole, beginning at the outset of their professional career—during the early days of apprenticeship. At the end of their term of pupilage they should undergo a special course of instruction prior to presenting themselves for examination, actuated by the desire to learn all that an accomplished pharmacist ought to know. Then, as the day of examination approaches, comes the period of what may be termed legitimate cram, *i.e.*, the time during which the work of revision should be thoroughly performed. At this stage, by frequent reference to the examination schedule, the candidate will be able to economise his energy and devote himself more particularly to the task before him. To put the matter briefly, so long as examinations exist, exactly so long must candidates have available, in a readily producible form, the whole of the knowledge which they are required by the examiners to possess, and, to that end, careful revision or legitimate cram must be resorted to in its proper place. But that place is at the end of the special course of instruction, and, above all things, it is essential that dependence should not be placed upon cram alone, without a previous substantial basis of knowledge, which has been acquired with a view to fitting one for a professional career rather than to pass examinations.

MEDICAL MEN AND SECRET COMMISSIONS.

The subject of secret commissions, in so far as it affects the medical profession, is reopened by Sir Edward Fry, in a long letter addressed to the *Times* of Saturday last. He commences by referring to the report of the committee of the London Chamber of Commerce, in which the opinion was expressed that secret commissions are prevalent to a great extent in almost all professions. In the same report the statement was attributed to a pharmaceutical chemist, that "secret commissions are given by chemists to medical men on their prescriptions supplied to patients, in some cases amounting from twenty-five to fifty per cent. on the price charged by the dispensing chemist"; and an optician was quoted as having alleged that "it is an open secret that hospital doctors receive commissions from makers of surgical instruments." The Council of the British Medical Association took notice of those allegations, and passed a resolution calling upon the Chamber of Commerce to substantiate the accusation made. Since, however, the communications of the pharmaceutical chemist and the optician had been received under a promise that they would be treated as "strictly private and confidential," nothing came of the appeal to the Chamber of Commerce, and, after some correspondence, the Council of the British Medical Association reported to the annual meeting recently held, that such charges should not have been made public unless the body publishing them was in a position to substantiate them. At the same meeting Dr. Saundby, the president of the Council, referred to the subject, and

stated that inquiries had been made, which elicited the fact that presents had occasionally been offered to medical men for various services, after the event, but "there was no case in which a commission was offered to a person if he would do a certain thing. Cheques had been given to medical men to recompense them for what was supposed to be a good turn, but those cheques had always been returned."

Naturally, Sir EDWARD FRY thinks it would be satisfactory to know much more about the inquiries referred to than was disclosed by Dr. SAUNDBY. He asks by whom they were conducted, and how; were inquiries made of pharmaceutical chemists, and of how many; have the opticians and instrument makers been approached in such a way as to induce a full disclosure; were inquiries made of medical men, and how many? In fact, he remarks, to give any value to the negative conclusion on which Dr. SAUNDBY relied, the inquiry must have been very wide, general, and thorough. That it has been so he doubts, and it is pointed out as a significant fact that though the charge has been publicly made, it has not been denied by "any one acquainted with the profession of medicine or the trade of a chemist." Much is made in the letter of Dr. SAUNDBY's suggestion that the acceptance of a commission on work done is either innocent or less immoral than the acceptance of a like favour for work to be done, and the distinction is certainly a very fine one. For, if it is improper to receive a commission on prescriptions to be written, it cannot be otherwise to receive it on prescriptions after they are dispensed, whether paid in the form of a Christmas gift or otherwise. If the payment of commissions is not to be defended, the line between what is and is not permissible can hardly be drawn where Dr. SAUNDBY would apparently place it.

But the question yet remains to be authoritatively answered whether any secret commissions are received by medical men. As evidence in support of the allegation that they are, Sir EDWARD FRY quotes from the report of the legal proceedings in connection with the liquidation of a company which was formed to acquire and carry on the business of medicated wine manufacturers. The company had entered upon "negotiations with various medical men to induce them to prescribe and recommend to their patients and tradesmen the goods dealt with by the company, promising to each doctor who undertook thus to recommend the company's wares a fully-paid founder's share." Certain shares appear to have been allotted upon those terms, and when the recipients subsequently applied to be relieved from liability in connection therewith, the judge observed that it was "a sad thing that members of a learned profession should have consented to take shares on those terms." The *Times* then appealed to the General Medical Council and other representative medical bodies to take steps to discover the identity of the delinquents, but, so far as Sir EDWARD FRY is aware, no such steps have been taken. That, he thinks, is strange and even lamentable, as the case should have touched the feelings, "as it certainly touched the honour," of the profession; and yet no notice appears to have been taken of it by the British Medical Association or any other medical body, though "it is a case in which no cheque is returned, but, on the contrary, some thirty or forty medical men have the hardihood to insist on the bargain of which they ought to have been ashamed."

CHEMISTS AND MEDICAL DISPENSING.

REFERENCE is made by Sir EDWARD FRY in the letter already commented on to the result of some local inquiries made by a Glasgow paper, which reported that "a prominent member of the drug trade" had said it was a very common thing for doctors "to insist on a commission on all prescriptions sent to the druggist"; whilst a "dispensing chemist," writing to the same paper, gave the terms of a contract under which the charges for medicine supplied were to be in excess of ordinary dispensing charges and the prescriber was to receive thirty or forty per cent. on the net profits. In addition to these public statements, Sir EDWARD FRY states that he has received communications from more than one person confirmatory of the existence of the practice described. There is, of course, no doubt that a practice of the kind really prevails, but it is far from clear that it ought to be classed with the blackmailing system of demanding commissions, directly or indirectly, which alone seems to possess the evil character that the report of the London Chamber of Commerce has tended to fasten on transactions of the most varied nature. What usually happens is that a medical man who finds his practice extending enters into a perfectly legitimate arrangement with a chemist to relieve him of the necessity of dispensing for all his patients. The average patient likes to receive medicine from his medical adviser, and perhaps the easiest way to wean him from that liking is for a chemist to arrange to supply all the medicines, though the doctor continues to receive an inclusive fee. In the course of time it should not be too much to expect that the patient will have so far profited by his training as to prefer to receive prescriptions from his medical man and get them dispensed where he pleased, paying for the medicine when received, and saving money if he did but know it, whatever the chemist may charge.

The intermediate stage prevails to a limited extent in England, and more widely in Scotland, to the mutual satisfaction of prescribers and dispensers, and as suggested by a country practitioner, who writes to the *Times*, it is possible that the charges against the medical profession may be partly founded on instances of such a practice. In his own case, he explains, some years ago he went into a medical partnership in a country town, where he found an arrangement existed between the firm and one of the local chemists. At fixed hours during the day the chemist's boy called for orders. He took prescriptions to the shop, where mixtures, etc., were made up and thence sent to the patients. The chemist retained the prescriptions, and, if more medicines of the same kind were wanted, the bottles were sent back to him to be refilled. He charged a fixed price for each bottle, and the prescribers in turn charged the patient, not only for visits, but also for medicines supplied. The sum which they charged was more than double that which they paid, and the question is asked whether resort to such a plan could be regarded as equivalent to making secret commissions? But it would be absurd to return any other than a negative answer to that question; the matter is clearly nothing but a very ordinary commercial transaction, and so long as medical men choose to sink their professional status for the sake of pocketing a comparatively small profit on the medicines dispensed for their patients, it is difficult to see what there is to make so much fuss about.

ANNOTATIONS.

Pharmaceutical Students—young and old—are well provided with information, specially compiled for them, in the present issue of the Journal, and it is safe to say that no more useful "Students' Number" has ever been published. The special articles comprise a brief account of the Pharmaceutical Society's Museum, with useful hints on its use, by the veteran Curator, Mr. E. M. Holmes; a practical article on the examination of mounted sections of drugs, by Mr. William Kirkby, one of our chief authorities on the histology of drugs; an equally practical communication on the study of practical chemistry, contributed by a leading analyst, and some suggestions concerning self-preparation for the Bell Scholarship examination, by a writer whose recent success makes his advice all the more valuable. In the "Students' Columns" will be found the first instalment of a practical series of articles on dispensing problems and their solution, and Professor Kraemer's very exhaustive notes on the qualitative determination of powdered vegetable drugs are concluded this week. In addition, very complete information is provided concerning the regulations for registration in pharmacy, medicine and dentistry; university degrees in science; the membership of learned societies; veterinary and optical diplomas; prizes, scholarships, etc., open to pharmaceutical students, and much else that it is well for pharmacists and their pupils to be conversant with.

As the Selection of Suitable Text-Books is a matter requiring serious consideration, for some years past the attempt has been made to advise students to the best advantage in that respect. And though the task grows more difficult every year, it is believed that the selection given in the article on "The Students' Library," at page 240, will be found as comprehensive and useful as any previous one. No book is recommended which has not been thoroughly tested, and if students are careful not to purchase more text-books than they are likely to require during the next twelve months, they need have no fear of having a number of hopelessly out-of-date works left on their hands after new editions or more suitable books have been published. In any case, it is a safe rule to read more than one text-book on the same subject, though the most generally useful one on that subject ought to be reserved for special study and carefully annotated when fresh facts bearing on a given topic are brought to the student's cognisance in the course of extended reading. The man of one book is well-nigh as badly off as the man of one idea, but to skim many books and study none is equally unsatisfactory in its way. The pharmacist, in particular, should be a man of many parts, and consider facts from many sides, but he must have a sound substratum of knowledge if he is to benefit properly from new impressions.

The Sale of Food and Drugs Act has been put in force against several chemists by the Fulham Vestry, but, judging from the report published at page 272, the prosecutions can scarcely be said to be justified. The samples of medicines obtained and examined were dispensed from a prescription ordering four drachms of potassium iodide in a six ounce mixture, and, in the one case that was fully gone into, the analyst asserted that an excess of eighteen grains of iodide was present in the mixture. But, of course, he had only examined a third part of the mixture, and Dr. John Attfield, who was called for the defence, gave evidence to the effect that his analysis of another third part showed that the excess of potassium iodide in the six ounces could not have been more than two grains. This conflict of evidence decided the magistrates to dismiss the summons on the facts—refusing to accede to a request by the prosecuting solicitor to be permitted to submit the remaining third part of the mixture to the Somerset House analysts. He also gave expression to the opinion that the case should not have been brought; the Act, he thought, was intended to deal with frauds, and was not intended to deal with a trifling excess of an ingredient in a bottle of medicine. It is doubtful if such an interpretation of the Act could be maintained, but in any case much sympathy will be extended to Mr. Andrew, who, we understand, has been mulcted in at least ten pounds, expended in defending his reputation for accuracy as a dispenser, and for that he can secure no redress, because the prosecution—unjustified though it appears to have been—was instigated by a public body. Whilst referring to this case, it may not be amiss to suggest that chemists should not place too much reliance on the reputed capacities of bottles for dispensing purposes. It is a safe rule always to make mixtures up to the quantity specified, in a graduated measure, and not to trust to the bottle containing exactly four, six, or eight fluid ounces, as the case may be.

The Deaths by Poisoning in Scotland During 1897 were, according to the Registrar-General's report, 119 in all—males, 74; females, 45. In the case of 51 males and 38 females the poisoning was accidental, while 23 males and 7 females had recourse to poison as the means of ending their own lives. The poisons which caused death accidentally were:—Opium, in the case of 17 males and 11 females; morphine, in the case of 3 males; "Nepenthe," of 1 female; "sedative medicine," of 1 male; chloroform, of 11 males and 11 females; ether, of 1 male; chloral hydrate, of 1 male and 1 female; "Bromidia," of 1 female; carbolic acid, of 1 male; strychnine, of 1 male; phosphorus, of 1 female; potassium bichromate, of 1 male; sulphonal, of 1 male; hydrochloric acid, of 1 male; carbonic oxide gas, of 4 males; carbonic acid gas, of 1 male and 2 females; coal gas, of 1 male and 2 females; lead, of 2 males; laburnum seeds, of 1 female; alcohol, of 2 males; tobacco, of 1 male; ptomaine, of 3 females; "after eating fish," 1 female; "irritant poison," of 2 females; kind not stated, of 1 male and 1 female. The poisons by which suicide was effected were:—Opium, in the case of 11 males and 2 females; "Nepenthe," of 1 female; chloroform, of 1 male; carbolic acid, of 3 males and 2 females; carbon bisulphide, of 1 male; oxalic acid, of 1 male; salt of sorrel, of 1 male; strychnine, of 1 male; saltpetre, of 1 female; "irritant poison," of 1 female; kind not stated, of 3 males. Scheduled poisons appear to have been responsible fer 76 out of the 119 deaths, viz., 59 accidental cases—males 36, females, 23; and 17 suicides—males, 14; females, 3.

The Security and Redemption of Business Capital are the objects of a new scheme to which Messrs. Judd and Manners, the well-known transfer agents, direct attention in the advertisement columns of this week's Journal. The idea underlying the scheme is to enable private individuals to create sinking funds to replace capital, cover depreciation, or repay advances. Thus, in cases where a holding is controlled by a lease or other security of decreasing value, bonds will be issued which will secure (1) the return in full of the leasehold values, which would otherwise be lost; (2) the return on maturity of the full capital invested in terminable securities, including partnerships. The bonds will be issued on very reasonable and advantageous terms by a wealthy English corporation whose financial position is of the highest standing, and the security is ample. The holder of a bond will be relieved of all the trouble and risk of creating a sinking fund, and the intended object will be secured in a shorter time than could be accomplished by a private investor. To take as an example the case of a lease approaching its period of determination, so will its value decrease, having a corresponding effect upon the goodwill, but under this system the value will increase, and continue to do so

until the lease terminates, when the amount guaranteed becomes payable in full, notwithstanding that arrangements may have been made for a renewal of the lease. Again, take the case of the purchase of a business with borrowed capital. The borrower cannot expect his creditor to accept repayment of an advance in small yearly or half-yearly sums; nor can he himself safely, conveniently, or profitably accumulate them at compound interest; but he can pay those small sums and secure a bond for the amount of the advance payable in full on maturity. A very important feature of the bonds is that the surrender values allowed are specially large, a return of all premiums, excluding the first, with two per cent. compound interest thereon, being the guaranteed minimum. If, therefore, from any unforeseen cause, it may become unnecessary to continue the annual payments, there would be practically no loss.

THE REAL OR SUPPOSED SCARCITY OF WATER in the London district has been the subject of innumerable articles and letters in the daily Press, but it has been reserved for "One Who Knows" to explain exactly why the alleged scarcity prevails. Of late it has been customary to attribute it to the watering of gardens by people who have not paid for the water so consumed, but this genius suggests that, in times of drought, it would be as well for water companies to look after the amateur photographers. They abound, he says, in every street and square, and, while intent on developing and toning, think nothing of leaving water taps running for hours; "not only this, but often they leave their plates during their absence from home for many hours at a time under the running water for anyone to attend to as convenient. Naturally, they are frequently forgotten by those who, intent on other duties, leave them to their fate." The suggestion is offered that any of these amateur productions might be left till winter before being developed, and that no one would be much the loser, except the owner, who, bringing home hundreds of snapshots from his annual outing, feels impelled to see the result of his labours during the time of scarcity, viz., August and September, but it is more than doubtful if the amateur photographer will take this suggestion kindly. A much more practical suggestion is that all kinds of waste water from baths and bedrooms might be stored in a tank and used as required for garden purposes. Doubtless, it is said, there would be trouble in the process of saving such water instead of simply running it away down a sink. But so is it a trouble to suffer from drought, and to be put on a limited allowance daily.

AN APPRECIATION OF BUNSEN, by Sir Henry Roscoe, which was published in a recent number of *Nature*, is of especial interest as showing how, like our great countryman Faraday, Bunsen consistently refused to be drawn away from the paths of purely scientific investigation, and, though too clear-sighted a mind to belittle the importance of the application of scientific discovery to everyday life, he rightly judged that to him belonged the undoubtedly higher and nobler work of enlarging the boundaries of knowledge. Bunsen's work is noteworthy for its originality and accuracy. It matters not whether we look into his purely chemical investigations, at his chemico-geological researches, or at those—perhaps the most remarkable amongst the many questions he answered—which lie on the borderland of physics and chemistry, in every case we rise from the study not merely feeling that we have to do with a master's mind and hand, but that each investigation is stamped by an original mode of treatment and by an accuracy of thought and of manipulative power which, it is not too much to say, has rarely, f ever, been equalled. In no instance, it is pointed out, was this rare combination of mental and manual dexterity more strikingly shown than in Bunsen's investigation of the compounds of cæsium, the rarest of the two alkali metals which he discovered by means of spectrum analysis. In order to prepare the pure salts of this metal, many tons of Dürkheim mineral water had to be evaporated, and from the residue it was only possible to obtain some five or six grammes of pure cæsium chloride. Nevertheless, from this comparatively minute quantity Bunsen succeeded not only in preparing and analysing all the important salts of cæsium, but in ascertaining by goniometric methods their exact crystalline form, so that he was able to supply all the information required to a complete understanding of the position of this new element and its compounds to those of its well-known relations potassium and sodium. Bunsen was also the first to attempt anything like exactitude in the measurement of gases. And when he had perfected his methods, no improvement as regards accuracy were forthcoming. Other quicker and, perhaps, more handy processes have since come into vogue; but it was Bunsen who taught men how to handle and to separate and measure gaseous substances. In his chemical analytical methods, whether the delicate and complicated silicate analyses, blow-pipe work and flame reactions, volumetric methods, separations of closely allied metals, such as antimony and arsenic, or those of the cerite earths, the same master's touch is seen, whilst his physico-chemical researches, his ice-calorimeter, his photochemical investigations, his methods of ascertaining the specific gravity of gases by their rates of diffusion, and many other distinct lines of research, all well known and recognised as classic, exhibit the same wonderful power.

THE COMPANY DRUG STORE appears now to be beginning in earnest to attack the business of the grocer, and the leading organ of the grocery trade complains that the drug companies do not seem to know where to stop. According to information derived from a source that may be regarded as official, the manager of a large drug store has received an intimation from his superior authorities that he may, in due season, wisely display such goods as crackers, preserved fruits, etc., in his window, so as to keep pace with the strides of modern enterprise,and annex, if possible, some of the grocer's trade. From the price list of one such concern, referred to by the *Grocer*, it is clear that the "grocery, Italian warehouse, and dry goods department" is a prominent feature, all goods of course being quoted at "our reduced prices." Biscuits are quoted in this list at "wholesale prices"; and the names of two well-known firms are mentioned as providing the necessary supplies. How such firms can care to see their excellent products thus quoted "at wholesale prices" in the retail list of a "drug company (limited)" is a point that, in the opinion of our contemporary, lends itself to an ingenuity of conjecture. "They might reply, of course, that so long as their accounts are paid and the goods are sold over the counter in a *bonâ-fide*, legitimate manner, they do not profess to exercise a control over retail prices. Yet the thought arises that, if some firms had made that profession some years ago, and had acted upon it in the conduct of their business, 'cutting' would not be the serious evil it has become." Reference is also made to the fact that forms of shopping are now taking curious turns. A member of the grocery trade, for example, has mentioned that one of his customers buys only bacon from him, getting other things from the chemist's or drug store; "and here we have the remarkable fact," says this informant, "that of all the groceries bought by the lady referred to she gets none from the grocer." That is, obviously, quite an exceptional case, yet it is held to show what strange developments are taking place in regard to the work of shopping, and how unjustly certain traders may suffer from a modern craze. "People are led to believe what they are told if it is dinned into their ears often enough. The persistent and widespread distribution of these 'reduced price' lists has an influence in an unfortunate direction. Customers do not reflect that in the long run they are bound to pay the price for a good article, and that, wherever they go, excessive cheapness means the same thing—namely, inferior quality."

PHARMACEUTICAL QUALIFICATION IN GREAT BRITAIN.

PARTICULARS OF EXAMINATIONS, SCHOLARSHIPS, AND PRIZES.
