"The iron made by the three foregoing processes is equally valuable, for by any of them the metal is rendered pure; but after those different operations are finished, it is the opinion of many of the most judicious workers in iron, that laying it in a damp place, for some time, improves its quality; and to this alone, some attribute the superiority of foreign iron, more time elapsing between making and using the metal. To the latter part of this opinion I can by no means accede, as it is well known that the Swedish (o) ores contain much less heterogeneous matters than ours, and are generally much richer, as they usually yield about 70 per quintal of pure iron, whereas the average of ours is not more than 30 or 40 (p): add to this, that the Swedish ores are smelted in wood fires, which gives the iron an additional superiority.

"Iron instruments are case-hardened by heating them in a cinder or charcoal fire; but if the first be used, a quantity of old leather, or bones, must be burnt in the fire to supply the metal with carbone. The fire must be urged by a pair of bellows to a sufficient degree of heat; and the whole operation is usually completed in an hour.

"The process for case-hardening iron, is in fact the same as for converting iron into steel, but not continued so long, as the surface only of the article is to be impregnated with carbone.

"Some attempts have been made to give cast iron, by case-hardening, the texture and ductility of steel, but they have not been very successful. Table and penknife blades have been made of it, and, when ground, have had a pretty good appearance; but the edges are not firm, and they soon lose their polish. Common table knives are frequently made of this metal.

"The cementation of iron converts it into steel:—a substance intermediate between crude and malleable iron.

"The furnaces for making steel are conical buildings; about the middle of which are two troughs of brick or fire stone, which will hold about four tons of iron in the bar. At the bottom is a long grate for fire. Furnace for making steel.

"A layer of charcoal dust is put upon the bottom of the

(o) "Steel is commonly made of Swedish iron."

(p) "The iron made from the ore found in the neighbourhood of Sheffield, contains a great deal of phosphate of iron, or siderite, which renders the metal brittle when cold."

Furnace. the trough; and, upon that, a layer of bar iron, and so on alternately until the trough is full. It is then covered over with clay to keep out the air; which, if admitted, would effectually prevent the cementation. When the fire is put into the grate, the heat passes round by means of flues, made at intervals, by the sides of the trough. The fire is continued until the conversion is complete, which generally happens in about eight or ten days. There is a hole in the side by which the workmen draw out a bar occasionally, to see how far the transmutation has proceeded. This they determine by the blisters upon the surface of the bars. If they be not sufficiently changed, the hole is again closed carefully to exclude the air; but if, on the contrary, the change be complete, the fire is extinguished, and the steel is left to cool for about eight days more, when the process for making blistered steel is finished.

Blistered steel.

"For small wires, the bars are drawn under the tilt hammer, to about half an inch broad and three-sixteenths of an inch thick.

Tilted steel. "The change wrought on blistered steel by the tilt hammer, is nearly similar to that effected on iron from the refinery by the forge hammer. It is made of a more firm texture, and drawn into convenient forms for use.

German steel. "German steel is made by breaking the bars of blistered steel into small pieces, and then putting a number of them into a furnace; after which they are welded together and drawn to about 18 inches long; then doubled and welded again, and finally drawn to the size and shape required for use. This is also called shear steel, and is superior in quality to the common tilted steel.

Cast steel. "Cast steel is also made from the common blistered steel. The bars are broken and put into large crucibles with a flux. The crucible is then closed up with a lid of the same ware, and placed in a wind furnace. By the introduction of a greater or smaller quantity of flux, the metal is made harder or softer. When the fusion is complete, the metal is cast into ingots, and then called ingot steel; and that which afterwards undergoes the operation of tilting, is called tilted cast steel.

"The cast steel is the most valuable, as its texture is the most compact and it admits of the finest polish.

"Sir T. Frankland has communicated a process, in the Transactions of the Royal Society, for welding cast steel, and malleable iron together; which, he says, is done, by giving the iron a malleable, and the steel a white heat; but, from the experiments which have been made at my request, it appears, that it is only soft cast steel, little better than common steel, that will weld to iron: pure steel will not; for, at the heat described by Sir T. the best cast steel either melts or will not bear the hammer.

"It may here be observed, as was mentioned before, that steel is an intermediate state between crude and malleable iron, except in the circumstance of its reduction being complete; for, according to the experiments of Reanmur and Bergman, steel contains more hydrogen gas than cast iron, but less than malleable iron;—less plumbago than the first, but more than the latter;—an equal portion of manganese with each;—less siliceous earth than either—more iron than the first, but less than the second. Its fusibility is likewise intermediate, between the bar iron and the crude. When steel has been gradually cooled from a state of ignition, it is malleable and soft, like bar iron: but when ignited and plunged into cold water, it has the hardness and brittleness of iron.

"From the foregoing facts, we are justified in drawing the same conclusions with Reaumur and Bergman, but which have been more perfectly explained by Vandermonde, Berthollet, and Monge, that crude iron is a regulus, the reduction of which is not complete; and which consequently will differ according as it approaches more or less to the metallic state. Forged iron, when previously well refined, is the purest metal; for it is then the most malleable and the most ductile, its power of welding is the greatest, and it acquires the magnetic quality soonest. Steel consists of iron perfectly reduced and combined with charcoal; and the various differences in blistered steel, made of the same metal, consists of the greater or less proportion of charcoal imbibed.

"Iron gains by being converted into steel, about the hundred and eightieth part of its weight.

"In order to harden steel, it must be put into a clean charcoal, coal, or cinder fire, blown to a sufficient degree of heat by bellows. The workmen say, that neither iron nor steel will harden properly without a blast. When the fire is sufficiently hot, the instrument intended to be hardened must be put in, and a gradual blast from the bellows continued until the metal has acquired a regular red heat; it is then to be carefully quenched in cold water. If the steel be too hot when immersed in water, the grain will be of a rough and coarse texture; but if of a proper degree of heat, it will be perfectly fine. Saws and some other articles are quenched in oil. Harden steel.

"Steel is tempered by again subjecting it to the action of the fire. The instrument to be tempered we will suppose to be a razor made of cast steel. First rub it upon a grit stone until it is bright; then put the back upon the fire, and in a short time the edge will become of a light straw colour, whilst the back is blue. The straw colour denotes a proper temper either for a razor, graver, or penknife. Spring knives require a dark brown; scissars, a light brown, or straw colour; forks or table knives, a blue. The blue colour marks the proper temper for swords, watch-springs, or any thing requiring elasticity. The springs for penknives are covered over with oil before they are exposed to the fire, to temper. Temper it.

Explanation of the Figures.

"Fig. 28. is a plan of the furnace, and fig. 29. is a section of it taken at the line AB. The plan is taken at the line CD. The same parts of the furnace are marked with the same letters in the plan and in the section. EE are the pots or troughs into which the bars of iron are laid to be converted. F is the fireplace; P, the fire bars; and R, the ashpit. GG, &c. are the flues. HH is an arch, the inside of the bottom of which corresponds with the line IIII, fig. 28. and the top of it is made in the form of a dome, having a hole in the centre as K, fig. 29. LD, &c. are six chimneys. MM is a dome, similar to that of a glass-house, covering the whole. At N there is an arched opening, at which the materials are taken in and out of the furnace, Fig. 28 and 29.

nace, and which is closely built up when the furnace is charged. At OO there are holes in each pot, through which the ends of three or four of the bars are made to project quite out of the furnace. These are for the purpose of being drawn out occasionally to see if the iron be sufficiently converted.

"The pots are made of fire tiles, or fire stone. The bottoms of them are made of two courses, each course being about the thickness of the single course which forms the outsides of the pots. The insides of the pots are of one course, about double the thickness of the outside. The partitions of the flues are made of fire brick, which are of different thicknesses, as represented in the plan, and by dotted lines in the bottom of the pots. These are for supporting the sides and bottoms of the pots, and for directing the flame equally round them. The great object is to communicate to the whole an equal degree of heat in every part. The fuel is put in at each end of the fire-place, and the fire is made the whole length of the pots, and kept up as equally as possible."

Improved process of cupellation.

In a memoir published by Du Hamel, the inconvenience and expence which attend the process commonly in use, for refining lead or separating the silver from this metal, are pointed out, and a more economical process is proposed. This process, which is known by the name of *cupellation*, is performed in a vessel called the *cupel*, which is made of the ashes of the bones of animals, or of vegetables, after separating, by means of water, the saline parts which adhere to them. But the difficulty and expence of obtaining a sufficient quantity of these materials, led him to contrive something else as a substitute, which might be less costly and more easily obtained.

For the purpose of performing the process in the way here recommended, it is not necessary to make any alteration in the general construction of the furnace. All that is required is, to have a sufficient number of canals or openings towards its base, to allow the escape of the moisture. These canals are covered with a bed of scoria, on which is raised a pavement formed of the most porous bricks, and about a brick in thickness. On this floor or area, which should be a little concave, in the same way as the ordinary cupels are formed when they are made of ashes, is placed a quantity of casting or moulding sand, slightly moistened; and if the sand has not a sufficient quantity of earth, some clay is added, to give it consistence, and the whole is carefully mixed together. This sand is beaten together, and a concave vessel is made of it, of an equal thickness in all its parts. When the bason has been uniformly beaten, it will be proper to sift over its whole surface a small quantity of wood ashes, well washed with water, and these are also beaten down with a pestle.

The cupel being thus prepared, the head of the furnace is put on, and a moderate fire is kindled and kept up for some hours, to carry off part of the moisture of the sand. The remainder is dissipated without inconvenience, by means of the canals, during the process. After it has been sufficiently dried, the head of the furnace is again taken off, and allowed to cool a little. A quantity of straw or hay is put upon the bason or cupel, to prevent any injury from the weight of the bars of lead on the sand. To avoid this still more, it is recommended to have the lead to be purified cast into the form of hemispheres, in place of bars.

A sufficient quantity of lead being introduced into the furnace, the head is luted on with baked clay, and the fire is applied in the usual way. As soon as the lead is completely fused, the bason appears covered with the burnt straw: this is removed by means of an iron instrument, and this operation is repeated several times. When the lead begins to grow red, the action of the bellows commences, at first softly, and the blast is so directed that it may strike the centre of the cupel. To effect this more completely, a small round plate of iron is attached to the extremity and upper part of the pipe by means of a hinge, so that at each blast it is half raised, and the current of air is directed to the surface of the fused metal.

After the whole of the scum that rises has been removed, and the lead is covered with a stratum of litharge, a small gutter is made by means of a hook for the purpose, in the sand of the cupel. This is gradually and cautiously hollowed, till it is on a level with the surface of the bath, and then the litharge driven by the blast towards the anterior part of the furnace, will flow this way, and spread itself on the floor in the usual way. When the operator perceives that the litharge has been removed, he stops up the gutter with moistened ashes, till another quantity of litharge appears on the surface. He then re-opens the gutter, which is now made deeper in proportion to the diminution of the fused metal, but at the same time taking care that no part of the lead escapes, especially towards the end of the process, because then a considerable portion of silver would be carried off.

In this way the process is conducted till the separation of the silver begins to take place, observing at the same time to increase the heat as the quantity of fused metal diminishes, because then the silver is collected together; and since it is much more difficult to keep it in fusion than the small portion of lead which remains combined with it, the separation would be very imperfect, without the application of a sufficient temperature. Instead of having only one-twentieth of lead, which is the usual proportion in the common process, the quantity would be much greater, and this would render the second operation, the refining of the silver, much more difficult.

Du Hamel observes, that a cupel of sand, well made, will answer for the repetition of the process several times, without renewing it at the end of each operation, as is the case with those of ashes. The only precaution to be observed is, to remove the kind of varnish of oxyde of lead which remains on the sides of the gutter by which the litharge flowed out, that the new sand with which it is to be filled up may combine easily with the old.

The length of time which the reverberatory furnace may be employed in smelting the ores of lead, and even in reducing litharge, is a proof that the oxyde of lead acts only on the surface of the cupel, and penetrates a very small thickness. After the process has been several times repeated, this crust is removed, and it is fused for the purpose of obtaining the lead. This process will be as easy as the reduction of the metal contained in the ashes of the ordinary cupels, and in much smaller quantity.

Furnace. quantity. By the new method, therefore, a greater proportion of litharge is obtained; and it may be added, that the sand absorbing a smaller quantity of oxyde of lead, it will contain also a smaller proportion of silver; for it is well known that the lead which is reduced from the ashes, contains always much more than that which is produced from the reduction of litharge.

In place of sand, argillaceous earth may be employed in the construction of cupels; but it is necessary that this earth be well beaten together, and that this process should be several times repeated, for several days, without which the clay would be apt to crack, and the melted lead would flow into the crevices; an inconvenience which does not arise from the use of sand, even although it should be mixed with a little earth. And besides, it is to be observed, that the cupel constructed of this substance, becomes too hard to allow a gutter to be easily made for the passage of the litharge. In this case, it would be necessary that the place by which the oxyde is to flow out, be made up of sand, or of ashes.

In the formation of the bason or cupel, which is here proposed, it seems to be advantageous to employ two kinds of sand, the one fine, like that which is used by the founders, the other coarser, and free from earth. It is of the latter, the coarse kind, that the first stratum is formed; and this, after being made of sufficient thickness, is well beaten with pestles for the purpose; on this the fine sand is to be placed, containing a proper proportion of earth, and it is to be beaten together in the same way. Both the coarse and the fine sand are to be moistened a little, that they may adhere together, and afterwards acquire a sufficient degree of solidity under the pestles. The sand of the inferior layer being coarser than the other, will absorb the moisture from it as it evaporates, and will allow it to pass off easily, by means of the canals or openings which are left for that purpose. This stratum, too, is to remain in its place, when the fine sand of the cupel is removed, and that the surface of the stratum of coarse sand may not be disturbed when the other is removed, a thin layer of ashes may be thrown upon it, and beaten down, before the other stratum is laid on *.

* Mem. de l'Inst. iii. 306.

The French school of mines appointed a commission, composed of Hassenfratz, Brochant, and Miché, to consider the best form for the construction of a furnace for burning lime-stone, or plaster of Paris. After considering different forms of furnaces, and reasoning on their effects, they propose in their report to adopt the following, which is represented in fig. 30. and 31.

Fig. 30. Fig. 30. is a plan of the furnace proposed.

D, the fire-place. E, E, openings for taking out the substances which are converted into lime or plaster.

P, half of the plan taken at the height of the line AK of fig. 31.

Q, half of the plan taken at the height of the line XY of fig. 31

Fig. 31. Fig. 31. exhibits a section of the same furnace.

B, C, are places which remain empty after the introduction of the substances to be exposed to heat.

B, D, the fires.

E, the opening for the extraction of the substances after they are converted into lime or plaster.

O, the throat or vent.

a, *b*, openings for regulating the heat.

We shall now conclude this article with a short account of the construction and management of furnaces for chemical purposes.

Chemical furnace. The following is a description of an essay or cupelling furnace. 1. A hollow, quadrangular prism, 11 inches broad and nine inches high, is constructed with iron plates, and it ends at top in a hollow quadrangular pyramid, seven inches high; the latter terminating in an opening seven inches square. The prism is closed at bottom with another iron plate, which serves as a bottom.

2 Near the bottom a door three inches high and five inches broad, is opened. This leads to the ash hole.

3. Above this door, and six inches from the basis, another door is opened, of the figure of a segment of a circle, four inches broad at the bottom, and three inches and a half big in the middle.

4. Three iron plates are then to be fastened to the fore-part of the furnace, the first of them should be 11 inches long, half an inch high, and so fastened with three or four rivets, that its lower edge may rest against the bottom of the furnace. Between this plate and the side of the furnace a space must be left, so wide that the sliders of the lower door, which are made of a thicker iron plate, may move easily in the groove. The second iron plate, which is 11 inches long, and three inches high, is fastened parallel to the first, in the space between the two doors. Both the upper and lower edges of this plate form grooves with the side of the furnace, for receiving the sliders which shut the doors. The third plate, of the same dimensions with the first, is rivetted close above the upper door, and forms a groove for receiving the edge of the sliders which move that door.

5. For the purpose of closing the doors, two sliders of iron-plates must be adapted to each of them. These sliders are moved in the grooves. The two sliders belonging to the upper door have each a hole near the top; in the one there is a small hole $\frac{1}{4}$ of an inch broad, $\frac{1}{2}$ inch long; and the other a semicircular opening one inch high and two broad. To each slider there is a handle attached, to lay hold of it when it is moved.

6. Five round holes, an inch diameter, are bored in the furnace, two in the back part, and two in the fore part, five inches from the bottom; but $3\frac{1}{2}$ inches from each side of the furnace. The fifth hole is at the height of an inch above the upper edge of the upper door.

7. The inside of the furnace must be armed with iron hooks, about three inches from each other, and projecting $\frac{1}{2}$ inch. The use of these hooks is to secure the lute with which the furnace is to be lined.

8. A moveable, hollow, quadrangular pyramid, also of iron, and 3 inches high, is to be fitted to the upper opening of the furnace, 7 inches broad, and ending above in a hollow tube, three inches in diameter, about 2 inches high, nearly cylindrical, but converging a little at the top. This tube serves to support a funnel for conveying the smoke into the chimney. This cover has two handles to lay hold of it. To secure the cover on the furnace, an iron plate is rivetted to the right and left of its upper edge, and turned down towards the inside, so that a furrow may be made, open before

Furnace. fore and behind, for receiving the lateral edges of the cover.

9. A square ledge, made of thick iron plate, is fixed at the top of the upper edge of the lower door, for supporting the grate and the lute, and, that it may be easily introduced into the cavity of the furnace, it should be of two pieces.

10. Iron bars are then to be fixed in the inside of the furnace, for supporting the fuel. These must be equal in length with the diameter of the furnace, about $\frac{1}{2}$ inch thick, and $\frac{3}{4}$ inch distant from each other. They are supported at their extremities by a square iron ledge.

11. To prevent the dissipation of the heat, and the destruction of the iron, by being repeatedly made red hot, the inside of the furnace must be lined with lute, about a finger's breadth, or rather more, in thickness.

Coating for furnaces. For luting furnaces, Dr Black recommended a simple mixture of sand and clay. The proportions for resisting the violence of fire are four parts of sand to one of clay; but when designed for the lining of furnaces, he uses six or seven of sand to one of clay, the more effectually to prevent the contraction of the latter; for it is known from experiments, that clay, when exposed to a strong heat, contracts the more in proportion to its purity. The sand settles into less bulk when wet, and does not contract by heat, which it also resists as well as the clay itself.

Besides this outside lining next the fire, Dr Black uses another to be laid on next the iron of the furnace; and this consists of clay mixed with a large proportion of charcoal dust. It is more fit for containing the heat, and is put next to the iron, to the thickness of an inch and a half. That it may be pretty dry when first put in, he takes three parts by weight of the charcoal dust, and one of the common clay, which must be mixed together when in dry powder, otherwise it is very difficult to mix them perfectly. As much water is added as will form the matter into balls; and these are beaten very firm and compact by means of a hammer upon the inside of the furnace. The other lute is then spread over it to the thickness of about half an inch, and this is also beaten solid by hammering; after which it is allowed to dry slowly, that all cracks and fissures may be avoided; and after the body of the furnace is thus lined, the vent is screwed on and lined in the same manner. It must then be allowed to dry for a long time; after which a fire may be kindled, and the furnace gradually heated for a day or two. The fire is then to be raised to the greatest intensity; and thus the luting acquires a hardness equal to that of free-stone, and is afterwards as lasting as any part of the furnace.

Mode of operating with the furnace. To perform an operation in this furnace, two iron bars an inch thick, and of sufficient length to project a little beyond the holes of the furnace, are passed through four lower holes, which are placed before and behind, directly opposite to each other. These bars support the muffle, which is introduced through the upper opening of the furnace, and placed upon the bars, in such a way that the open side of it may be near the inner border of the upper door. The fuel is introduced through the top of the furnace, and the best fuel is charcoal made of hard wood. It should be reduced to small pieces, that they may readily fall between the muffle and the sides of the furnace. The muffle is to be covered with fuel, to the height of several inches. The pieces of charcoal should not be too small, because they may fall immediately through the interstices of the grate, or be too rapidly consumed, and thus increasing the quantity of ashes, obstruct the current of air.

Management of the fire. As the management of the fire is of great importance, for the success of operations in the furnace, the following directions may be attended to. To increase the heat to the utmost, the door of the ash-hole may be left open; the sliders of the upper door drawn towards each other, so as to touch in the middle, and the cover and funnel adapted to its tube, placed on the top of the furnace. The heat is still farther increased by putting red burning coals into the open upper door. By shutting the upper door with the slider, which has a narrow oblong hole in it, the heat is diminished, and it is still farther diminished by shutting the door with the other slider, having the semicircular hole. The heat is also diminished by removing the funnel at the top of the cover; and the heat is less by partially or totally shutting the door of the ash-hole, because then the current of air necessary to excite combustion is obstructed.

The heat of the furnace is also increased in proportion to the diminished size of the muffle. The heat is stronger too, according as the muffle has more and larger segments cut out of it, as the sides of it are thinner, and as the number of vessels placed in the hinder part of it is increased; and the contrary. It may be here observed, that when many of the conditions necessary to produce strong heat are wanting, the operator, with all his sagacity, will scarcely be able to excite combustion in such a degree in common assay furnaces as to succeed well in his operations; and even when he employs bellows, and introduces coals by the upper door. The grate, therefore, ought to be placed nearly three inches below the muffle, that the air rushing through the ash-hole, may not cool its bottom, and that the smaller coals, almost already consumed, and the ashes, may more easily fall through the interstices of the grate; larger coals, fit for keeping up the requisite degree of heat, must be used. The funnel is added, that the blowing of the fire being increased by means of it as much as possible, may be brought to the degree that is wanted; for the fire may be at any time diminished, but without the assistance of proper apparatus, it cannot always be increased at pleasure.

m, a hole below for the admission of air.

n, a hole in the vault, which serves to cool the furnace.

Portable furnace. A convenient portable blast furnace, contrived by Mr Aikin, and described by him in the 17th vol. of the Philosophical Magazine, will probably be useful to some of our chemical readers. "It is (he says) particularly adapted to those who, like myself, can only devote a small room and a moderate share of time to these pursuits.

"Dr Lewis, in his Commerce of the Arts (page 27.), describes a very powerful blast furnace formed out of a black-lead pot, which has a number of holes bored at small distances in spiral lines all over, from the bottom up to such a height as the fuel is designed to reach to. This is let half way into another pot, which last receives the nozzle of the bellows, so that all the air sent in is distributed through the spiral holes of the upper pot, and concentrates the heat of the fuel upon the crucible, which is placed in the midst.

"The furnace which I am going to describe resembles very closely this of Dr Lewis; with this difference, however, that the air-holes are only bored through the bottom of the pot, and this merely stands upon another piece, instead of being let into it. It is on this account somewhat more commodious, and I imagine not less powerful.

Fig. 35. & 36. "Fig. 35. is a view, and fig. 36. a section, of the furnace. It is composed of three parts, all made out of the common thin black-lead melting pots sold in London for the use of the goldsmiths. The lower piece, A, in the bottom of one of the pots, cut off so low as only to leave a cavity of about one inch, and ground smooth above and below. The outside diameter over the top is 5½ inches. The middle piece or fire-place, B, is a larger portion of a similar pot with a cavity about six inches deep, and measuring 7½ inches over the top, outside diameter, and perforated with six blast holes at the bottom. These two pots are all that are essentially necessary to the furnace for most operations: but when it is wished to heap up fuel over the top of a crucible contained within, and especially to protect the eyes from the intolerable dazzle of the fire when in full heat, an upper pot, C, is added of the same dimensions as the middle one, and with a large side opening cut out to allow an exit to the smoke and flame. It has also an iron stem with a wooden handle (an old chisel will do very well), to lift it off and on.

"The bellows (which are double) are firmly fixed, by a little contrivance which will take off and on, to a heavy stool, as is represented in the plate; and their handle should be lengthened, to make them work easier to the hand. To increase their force on particular occasions, a plate of lead may be tied on the wood of the upper flap. The nozzle is received into a hole in the pot A, which conducts the blast into its cavity. From hence the air passes into the fire-place, B, through six holes, of the size of a large gimlet, drilled at equal distances through the bottom of the pot, and all converging in an inward direction, so that, if prolonged, they would meet about the centre of the upper part of the fire. The larger hole through the middle of the bottom of the same pot is for another purpose. Fig. 37. is a plan of the same, showing the distribution of these holes. Fig.

"As a stand or support for the crucible, I have found no method so good as to fit an earthen stopper into the bottom of the pot B, through the large centre hole which is made for this purpose. This keeps the crucible in its proper place, in stirring down the coals and managing the fuel. These stoppers are made with great ease and expedition out of the softened fire-brick sold in London. A piece of this brick, made to revolve a few times within a portion of iron or earthenware tube, presently takes the form of its cavity, and comes out a very neat portion of a cylinder or cone, according to the shape of the tube, from which the stoppers may readily be fashioned. Fig. 38. represents one of those stoppers, which is also seen in its proper place in fig. 36. supporting a crucible. Fig.

"As the construction of this furnace (exclusive of the bellows and its stool) it is easy to any one at all used to these little manual operations, I trust that the *working* chemist will allow me to add a few words on the method which I have found the most convenient and economical. Almost any broken pot of the proper width will furnish the lower piece A; and often the middle and upper pieces may be contrived out of the same refuse matter. Dr Lewis advises a saw to cut these pots; but

but most saws are too thick, and when a little used, the teeth get rounded off, which makes them work intolerably slow. I have found by far the best tool to be an old table knife, or rather two of them, worn thin by use, and hacked and jagged as deeply as possible, by striking the edges strongly against each other. These work well and expeditiously, and when they become dull are again roughened by the same simple means. The holes may be drilled with a common gimlet of the largest size, and a little steadiness of hand will easily enable the operator to give them the oblique direction with sufficient accuracy; for much is not required. To make a smooth surface to the parts intended to adapt to each other, first wear them down a little with the soft fire-brick, and then grind them with water on a flat free-stone (a sink-stone for example), and lastly make them entirely fit by rubbing one surface on the other.

"No luting of any kind is ever required; so that the whole may be set up and taken down immediately. Nor is it necessary to bind the pots with metal hoops; for they are thick enough to endure considerable blows without breaking; and yet they will bear, without cracking, to be heated as suddenly and intensely as possible. In short, the black-lead crucible seems to be the best material that could possibly be devised for these purposes.

"The heat which this little furnace will afford is so intense, and so much more than would at first sight be expected from so trifling an apparatus, that it was only the accidental fusion of a thick piece of cast iron in it that led us to suspect its power. The utmost heat which we have procured in this furnace has been 167° of a Wedgwood pyrometer piece, which was withdrawn from a very small Hessian crucible when actually sinking down in a state of porcellaneous fusion. A steady heat of 150° to 155° may be usually depended on, if the fire be properly managed and the bellows worked with vigour. This is sufficient for most operations in chemistry; and the economy in time and fuel is extreme, since a furnace of the given dimensions will very well raise to the above point of heat in from five to ten minutes a Hessian crucible of such a diameter, that the average thickness of burning fuel around its bottom is not more than one inch and a half. A smaller crucible will take a higher heat, but at the risk of its softening and falling in by the weight of the incumbent fuel.

"Coak, or common cinders taken from the fire just when the coal ceases to blaze, and broken into very small pieces, with the dust sifted away, form the best fuel for the highest heat. A light spongy kind of coak, formed of a mixture of coal and charcoal, called *Davey's patent coal*, also answers extremely well. Charcoal alone has not weight enough, when broken so small as it must be to lie close in this little fire-place, to withstand the force of the blast when very violent. A bit of lighted paper, a handful of the very small charcoal, called in London *small coal*, and 10 or 12 strokes of the bellows, will kindle the fire in almost as many seconds.

"Various little alterations and arrangements, which will readily occur to the practical chemist, will fit this little apparatus for distillation with an earthern retort, heating a gun-barrel passed through the fire, bending glass tubes, &c."

FURNITURE, a term in dialling, which denotes certain additional points and lines drawn on a dial, by way of ornament, such as the signs of the zodiac, length of days, parallels of declination, azimuths, points of the compass, meridians of chief cities, Babylonic, Jewish, or Italian hours, &c.

FUROR UTERINUS, a disorder peculiar to women. See MEDICINE *Index*.

FURR, or FUR, in *Commerce*, signifies the skin of several wild beasts, dressed in alum with the hair on; and used as a part of dress, by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, rabbit, &c. See MUSTELLA.

It was not till the later ages that the furs of beasts became an article of luxury. The more refined nations of ancient times never made use of them; those alone whom the former stigmatized as barbarians were clothed in the skins of animals. Strabo describes the Indians covered with the skins of lions, panthers, and bears; and Seneca, the Scythians clothed with the skins of foxes and the lesser quadrupeds. Virgil exhibits a picture of the savage Hyperboreans, similar to that which our late circumnavigators can witness to in the clothing of the wild Americans, unseen before by any polished people.

Gens effræna virûm Riphæo tunditur Euro;
Et pecudum fulvis velantur corpora setis.

Most part of Europe was at this time in similar circumstances. Cæsar might be as much amazed with the skin-dressed heroes of Britain, as our celebrated Cook was at those of his new-discovered regions. What time has done to us, time, under humane conquerors, may effect for them. Civilization may take place; and those spoils of animals, which are at present essential for clothing, become the mere objects of ornament and luxury.

It does not appear that the Greeks or old Romans ever made use of furs. It originated in those regions where they most abounded, and where the severity of the climate required that species of clothing. At first it consisted of the skins only, almost in the state in which they were torn from the body of the beast; but as soon as civilization took place, and manufactures were introduced, furs became the lining of the dress, and often the elegant facing of the robes. It is probable that the northern conquerors introduced the fashion into Europe. We find, that about the year 522, when Totila king of the Visigoths reigned in Italy, the Suethons (a people of modern Sweden), found means, by help of the commerce of numberless intervening people, to transmit, for the use of the Romans, *saphilinas pelles*, the precious skins of the sables. As luxury advanced, furs, even of the most valuable species, were used by princes as linings for their tents: thus Marco Polo, in 1252, found those of the Cham of

Furr.

of Tartary lined with ermines and sables. He calls the last *zibelines* and *zambolines*. He says that those and other precious furs were brought from countries far north; from the *land of Darkness*, and regions almost inaccessible by reason of morasses and ice. The Welsh set a high value on furs as early as the time of Howel Dda, who began his reign about 940. In the next age, furs became the fashionable magnificence of Europe. When Godfrey of Boulogne and his followers appeared before the emperor Alexis Comnenus, on their way to the Holy Land, he was struck with the richness of their dresses, *tam ex ostro quam aurifrigio et niveo opere harmelino et ex mardrino grisioque et vario.* How different was the advance of luxury in France from the time of their great monarch Charlemagne, who contented himself with the plain fur of the otter! Our Henry I. wore furs; yet in his distress was obliged to change them for warm Welsh flannel. But in the year 1337 the luxury had got to such a head, that Edward III. enacted, that all persons who could not spend a hundred a-year should absolutely be prohibited the use of this species of finery. These, from their great expence, must have been foreign furs, obtained from the Italian commercial states, whose traffic was at this period boundless. How strange is the revolution in the fur trade! The north of Asia at that time supplied us with every valuable kind; at present we send, by means of the possession of Hudson's Bay, furs, to immense amount, even to Turkey and the distant China.

History of the FUR *Trade*.—During Captain Cook's last voyage to the Pacific ocean, besides the various scientific advantages which were derived from it, a new source of wealth was laid open to future navigators, by trading for furs of the most valuable kind on the north-west coast of America. The first vessel which engaged in the new branch of trade pointed out by that great navigator, was equipped by some gentlemen in China. She was a brig of 60 tons and 20 men, commanded by James Hanna. She sailed from the Typa the end of April 1785; proceeded to the northward, along the coast of China; passed through Diemen's straits, the south end of Japan; and arrived at Nootka in August following. Soon after her arrival, the natives, whom Captain Cook had left unacquainted with the effect of fire-arms, tempted probably by the diminutive size of the vessel (scarce longer than some of their own canoes) and the small number of her people, attempted to board her in open day; but were repulsed with considerable slaughter. This was the introduction to a firm and lasting friendship. Captain Hanna cured such of the Indians as were wounded; an unreserved confidence took place; they traded fairly and peaceably; a valuable cargo of furs was procured; and the bad weather setting in, he left the coast in the end of September, touched at the Sandwich islands, and arrived at Macao the end of December the same year.

Captain Hanna sailed again from Macao in May 1786, in the snow Sea-Otter of 120 tons and 30 men, and returned to Macao in February 1787. In this second voyage he followed his former track, and arrived at Nootka in August; traced the coast from thence as far as 53 degrees, and explored the extensive sound discovered a short time before by Mr Strange, and called by him Queen Charlotte's sound, the latitude of which is 51 degrees north, longitude 128 west.

The snow Lark, Captain Peters, of 220 tons and 40 men, sailed from Macao in July 1786. Her destination was Kamtschatka (for which she was provided with a suitable cargo of arrack, tea, &c.), Copper islands, and the N. W. coast. Captain Peters was directed to make his passage between Japan and Corea, and examine the islands to the north of Japan, said to be inhabited by hairy people; which, if Captain Cook had lived, would not have been left to the French to determine. No account having been received of this vessel since her departure, there is every reason to fear she has perished.

In the beginning of 1786, two coppered vessels were fitted out at Bombay, under the direction of James Strange, Esq. who was himself a principal owner. These vessels were the snow Captain Cook of 300 tons, and snow Experiment of 100 tons. They proceeded in company from the Malabar coast to Batavia; passed through the straits of Macassar, where the Experiment was run upon a reef, and was obliged to haul ashore upon Borneo to repair; from thence they steered to the eastward of the Palaos islands; made Sulphur island; and arrived at Nootka the end of June following. From Nootka, where they left their surgeon's mate (Mackay) to learn the language and collect skins against their intended return (but who was brought away in the Imperial Eagle the following year), they proceeded along the coast to Queen Charlotte's sound, of which they were the first discoverers; from thence in a direct course to Prince William's sound. After some stay there, the Experiment proceeded to Macao (their vessels being provided with passes by the governor-general of Goa): the Captain Cook endeavoured to get to Copper island, but without success, being prevented by constant west winds.

Two coppered vessels were also fitted out by a society of gentlemen in Bengal, viz. the snow Nootka of 200 tons, and the snow Sea Otter of 100 tons, commanded by John Meares and William Tipping, lieutenants in the royal navy. The Nootka sailed in March 1786 from Bengal; came through the China seas; touched at the Bashees, where they were very civilly treated by the Spaniards, who have taken possession of these islands; arrived at Oonalashka the beginning of August; found there a Russian galliot and some furriers; discovered accidentally near Cape Greville a new strait near Cook's river, 15 leagues wide and 30 long; saw some Russian hunters in a small bay between Cape Elizabeth and Cape Bear; and arrived in Prince William's sound the end of September. They determined wintering in Snug Corner Cove, lat. 60. 30. in preference to going to the Sandwich islands, which seem placed by Providence for the comfort and refreshment of the adventurers in this trade, and were frozen up in this gloomy and frightful spot from the end of November to the end of May. By the severity of the winter they lost their third and fourth mates, surgeon, boatswain, carpenter, and cooper, and twelve of the fore-mast-men; and the remainder were so enfeebled as to be under the necessity of apply-

ing

ing to the commanders of the King George and Queen Charlotte, who just at this time arrived in the sound, for some hands to assist in carrying the vessel to the Sandwich islands, where, giving over all further thoughts of trade, they determined (after getting a sea-stock of fish off Cape Edgecumbe) immediately to proceed. The Nootka arrived at Macao the end of October 1787.

The Imperial Eagle, Captain Barkley, fitted out by a society of gentlemen at Ostend, sailed from Ostend the latter end of November 1786; went into the bay of All Saints; from thence, without touching anywhere, to the Sandwich islands, and arrived at Nootka the beginning of June; from thence to the south, as far as 47° 30′, in which space he discovered some good and spacious harbours. In the lat. of 47° 46′, lost his second mate, purser, and two seamen, who were upon a trading party with the long-boat, and imprudently trusting themselves ashore unarmed, were cut off by the natives. This place seems to be the same that Don Antonio Mourelle calls the *Ilha de los Dolores*, where the Spaniards going ashore to water, were also attacked and cut off.

The King George of 320, and the Queen Charlotte of 200 tons, commanded by Captains Portlock and Dixon, who served under Captain Cook in his last voyage, were fitted out by a society of gentlemen in England, who obtained a privilege to trade to the north-west coast of America, from the South Sea and East India companies.

These vessels sailed from England the beginning of September 1785; touched at the Falkland islands, Sandwich islands, and arrived at Cook's river in the month of August. From thence, after collecting a few furs, they steered in the end of September for Prince William's sound, intending, it is said, to winter there; but were prevented entering by heavy storms and extreme bad weather, which obliged them to bear away, and seek some other part of the coast to winter at. The storms and bad weather accompanied them till they arrived off Nootka sound, when they were so near the shore, that a canoe came off to them: but though thus near accomplishing their purpose, a fresh storm came on, and obliged them finally to bear away for the Sandwich islands, where they remained the winter months; and returning again to the coast, arrived in Prince William's sound the middle of May. The King George remained in Prince William's sound; and during her stay, her long-boat discovered a new passage from the sound into Cook's river. The Queen Charlotte proceeded along the coast to the south; looked into Behring's bay, where the Russians have now a settlement; examined that part of the coast from 56° to 50°, which was not seen by Captain Cook, and which consists of a cluster of islands, called by Captain Dixon *Queen Charlotte's Islands*, at a considerable distance from the main, which is thus removed farther to the eastward than it was supposed to be: some part of the continent may, however, be seen from the east side of these islands; and it is probable the distance does not anywhere exceed 50 leagues. On this estimation, Hudson's House, lat. 53°, long. 106° 27′ west, will not be more than 800 miles distant from that part of this coast in the same parallel. It is therefore not improbable, that the enterprising spirit of our Canadian furriers may penetrate to this coast (the communication with which is probably much facilitated by lakes or rivers), and add to the comforts and luxuries of Europe, this invaluable fur, which in warmth, beauty, and magnificence, far exceeds the richest furs of Siberia. Queen Charlotte's islands are inhabited by a race of people differing in language, features, and manners, from all the other tribes of this coast. Among other peculiarities, they are distinguished by a large incision in the under lip, in which is inserted a piece of polished wood, sometimes ornamented with mother of pearl shell, in shape and size like a weaver's shuttle, which undoubtedly is the most effectual mode of deforming the human face divine that the ingenious depravity of taste of any savage nation has yet discovered. These ships, after disposing of their furs in China, were loaded with teas on account of the English company, sailed from Wampoa, and arrived in England, after an absence of three years.

The year after the departure of the King George and Queen Charlotte, the same society to which they belonged fitted out two other vessels, viz. the Princess Royal of 60 tons, and the Prince of Wales of 200 tons, commanded by Captains Colnet and Duncan, the former of whom had served under Captain Cook. These vessels left England in August 1786; touched at New Year's harbour on Staten Land, where they left an officer and 12 men to kill seals against the arrival of a vessel which was to follow them from England; from thence they proceeded directly to Nootka, where they arrived the 6th of July, sickly and in bad condition, and found here the Imperial Eagle, which had left Europe some months after them. Leaving Nootka, they steered along the shore to the northward, and soon after fell in with the Queen Charlotte.

In the beginning of 1788, Captain Meares sailed again with two other vessels, the Felice, which he commanded himself, and the Iphigenia, Captain Douglas, to Nootka sound. Here he purchased of the chief of the district a spot, on which he built a house for his residence and more convenient intercourse with the natives, hoisting the British colours thereon, surrounding it with a breast-work, and mounting a three pounder on the front. Having so done, he sent Mr Douglas in the Iphigenia to trade along the northern coast, while he himself proceeded to the south; and by presents to the chiefs obtained the ports Cox and Effingham, and the promise of an excellent trade with the natives of the district, and also some other places, which he took possession of in the name of the king. Captain Douglas likewise, by presents to the chiefs of the countries he visited, obtained similar privileges, no other European vessel having sailed there before him.

On their return to Nootka, they found a vessel finished which the commander had laid down before his departure. This, which he named the North-West America, he left at Nootka with the Iphigenia, while he sailed with a cargo of furs in the Felice to China.

A few days after his arrival at China, two vessels, the Prince of Wales and Princess Royal, came to Canton from their trading voyage above mentioned. Captain Meares, fearing a competition of interests might be injurious to both parties, proposed a copartnership, which was mutually agreed to; and another ship was purchased by the firm, and called the *Argonaut*. In the month of April 1787, Captain Meares gave Mr Colnet the command of the Princess Royal and Argonaut, which were loaded with stores and articles estimated sufficient for three years trade, besides several artificers, and near 70 Chinese, who intended to become settlers on the north-west coast of America, under protection of the new company.

In the mean while, the Iphigenia, and North-West America (the vessel built at Nootka), having wintered in Sandwich islands, returned to Nootka in the latter end of April. Soon after which, two Spanish ships of war, under the command of Don Martinez, anchored in the sound. For a few days mutual civilities passed between the Spanish captain and Mr Douglas; but at the end of about a week, Don Martinez summoned the latter on board his own ship the Princessa, telling him he was his prisoner, and that the king of Spain had commanded him, Don Martinez, to seize all vessels he should find on that coast. He therefore instructed his officers to take possession of the Iphigenia, which they accordingly did in the name of his Catholic majesty; and the officers and crew were conveyed as prisoners on board the Spanish ships, where they were put in irons, and otherwise ill treated. Immediately after this, Don Martinez took possession of the little settlement, hoisting the standard of Spain, and modestly declaring all the lands from Cape Horn to 60 degrees north latitude belonging to his master. To aggravate the insult, he forcibly employed the crew of the Iphigenia in building batteries, &c. and offered no kind of violence to two American vessels that were at the same time in the harbour. At this time the North-West America was sent to explore the Archipelago of St Lazarus. On her return to Nootka, she met with a similar treatment, and the skins she had collected were seized, with the rest of her cargo.

A few days after the Princess Royal (which we have mentioned as leaving Canton in company with the Argonaut) arrived. The Spanish commander, for reasons that do not appear, suffered her to depart. The skins collected by the North-west America were shipped on board her for the benefit of her owner, and she proceeded to trade in the neighbouring isles. On the 3d of July, the Argonaut arrived at the sound; and Don Martinez, after making every profession of civility to Mr Colnet the commander, took possession of the said ship in the name of his master, and made prisoners of the crew. Soon after, the Princess Royal returning to receive instructions from Mr Colnet, director of the enterprise, was seized by the Spanish captain.

The crews of the British vessels were differently disposed of; some sent to China by the American vessels, and others to Spanish America: but the Chinese were all detained, and employed in the mines which were opened on the lands purchased by Captain Mears. What these mines consisted of, we are nowhere informed. Mr Colnet was so much affected at the failure of the enterprise, as to be deprived of reason.

This, as soon as known, occasioned a spirited representation from the British court to that of Spain; at the same time that vigorous preparations were made for war in case adequate satisfaction should be refused. Matters, however, were prevented from coming to extremities, by a compliance on the part of Spain, after many delays and much artifice of negotiation, with the requisitions of Britain: in consequence of which, among other advantages unnecessary to be here recited, the whole trade from California to China is completely laid open; and the British allowed the full exercise of navigation and commerce in those parts of the world which were the subject of discussion.

In some accounts of the voyages above mentioned, the fur trade in those parts has been greatly magnified. In that published by Captain Portlock, however, this officer observes, that the gains hitherto have certainly not been enviably great; although the merchants have no doubt found the trade lucrative.

History of the FUR *Trade from Canada to the North-west.*—The following account of this trade is extracted from Mr M'Kenzie's Narrative of his Voyages and Travels from Montreal, through the North-west Continent of America, and to the Pacific ocean.

"The fur trade, he says, from the earliest settlement of Canada, was considered of the first importance to that colony. The country was then so populous, that, in the vicinity of the establishments, the animals whose skins were precious in a commercial view, soon became very scarce, if not altogether extinct. They were, it is true, hunted at former periods, but merely for food and clothing. The Indians, therefore, to procure the necessary supply, were encouraged to penetrate into the country, and were generally accompanied by some of the Canadians, who found means to induce the remotest tribes of natives to bring the skins which were most in demand, to their settlements, in the way of trade.

"It is not necessary for me to examine the cause, but experience proves that it requires much less time for a civilized people to deviate into the manners and customs of savage life, than for savages to rise into a state of civilization. Such was the event with those who thus accompanied the natives on their hunting and trading excursions; for they became so attached to the Indian mode of life, that they lost all relish for their former habits and native homes. Hence they derived the title of *Coureurs des Bois*, became a kind of pedlars, and were extremely useful to the merchants engaged in the fur trade; who gave them the necessary credit to proceed on their commercial undertakings. Three or four of these people would join their stock, put their property into a birch-bark canoe, which they worked themselves, and either accompanied the natives in their excursions, or went at once to the country where they knew they were to hunt. At length, these voyages extended to 12 or 15 months, when they returned with rich cargoes of furs, and followed by great numbers of the natives. During the short time requisite to settle their accounts with the merchants, and procure fresh credit, they generally contrived to squander away all their gains, when they returned to their favourite mode of life: their views being answered, and their labour sufficiently rewarded, by indulging themselves in extravagance and dissipation during the short space of one month in 12 or 15.

"The indifference about amassing property, and the pleasure of living free from all restraint, soon brought on a licentiousness of manners which could not long escape the vigilant observation of the missionaries, who

had

had much reason to complain of their being a disgrace to the Christian religion; by not only swerving from its duties themselves, but by thus bringing it into disrepute with those of the natives who had become converts to it; and, consequently, obstructing the great object to which those pious men had devoted their lives. They, therefore, exerted their influence to procure the suppression of these people, and accordingly no one was allowed to go up the country to traffic with the Indians, without a license from the government.

"At length, military posts were established at the confluence of the different large lakes of Canada, which, in a great measure, checked evil consequences that followed from the improper conduct of these foresters, and, at the same time, protected the trade. Besides, a number of able and respectable men, retired from the army, prosecuted the trade in person, under their respective licenses, with great order and regularity, and extended it to such a distance, as, in those days, was considered to be an astonishing effort of commercial enterprise. These persons and the missionaries having combined their views at the same time, secured the respect of the natives, and the obedience of the people necessarily employed in the laborious parts of this undertaking. These gentlemen denominated themselves commanders, and not traders, though they were intitled to both those characters: and, as for the missionaries, if sufferings and hardships in the prosecution of the great work which they had undertaken, deserved applause and admiration, they had an undoubted claim to be admired and applauded: they spared no labour and avoided no danger in the execution of their important office; and it is to be seriously lamented, that their pious endeavours did not meet with the success which they deserved: for there is hardly a trace to be found, beyond the cultivated parts, of their meritorious functions.

"The cause of this failure must be attributed to a want of due consideration in the mode employed by the missionaries to propagate the religion of which they were the zealous ministers. They habituated themselves to the savage life, and naturalized themselves to the savage manners, and, by thus becoming dependant, as it were, on the natives, they acquired their contempt rather than their veneration. If they had been as well acquainted with human nature, as they were with the articles of their faith, they would have known, that the uncultivated mind of an Indian must be disposed by much preparatory method and instruction to receive the revealed truths of Christianity, to act under its sanctions, and be impelled to good by the hope of its rewards, or turned from evil by the fear of its punishments. They should have begun their work by teaching some of those useful arts which are the inlets of knowledge, and lead the mind by degrees to objects of higher comprehension. Agriculture, so formed to fix and combine society, and so preparatory to objects of superior consideration, should have been the first thing introduced among a savage people: it attaches the wandering tribe to that spot where it adds so much to their comforts; while it gives them a sense of property, and of lasting possession, instead of the uncertain hopes of the chase, and the fugitive produce of uncultivated wilds. Such were the means by which the forests of Paraguay were converted into a scene of abundant cultivation, and its savage inhabitants introduced to all the advantages of a civilized life.

Furr.

"The Canadian missionaries should have been contented to improve the morals of their own countrymen, so that by meliorating their character and conduct, they would have given a striking example of the effect of religion in promoting the comforts of life to the surrounding savages; and might by degrees have extended its benign influence to the remotest region of that country, which was the object, and intended to be the scene, of their evangelic labours. But by bearing the light of the gospel at once to the distance of 2500 miles from the civilized part of the colonies, it was soon obscured by the cloud of ignorance that darkened the human mind in those distant regions.

"The whole of their long route I have often travelled, and the recollection of such a people as the missionaries having been there, was confined to a few superannuated Canadians, who had not left that country since the cession to the English, in 1763, and who particularly mentioned the death of some, and the distressing situation of them all. But if these religious men did not attain the objects of their persevering piety, they were, during their mission, of great service to the commanders who engaged in those distant expeditions, and spread the fur trade as far west as the bank of the Saskatchiwine river, in 53° north latitude, and longitude 102° west.

"At an early period of their intercourse with the savages, a custom was introduced of a very excellent tendency, but is now unfortunately discontinued, of not selling any spirituous liquor to the natives. This admirable regulation was for some time observed, with all the respect due to the religion by which it was sanctioned, and whose severest censures followed the violation of it. A painful penance could alone restore the offender to the suspended rites of the sacrament. The casuistry of trade, however, discovered a way to gratify the Indians with their favourite cordial, without incurring the ecclesiastical penalties, by giving, instead of selling it to them.

"But notwithstanding all the restrictions with which commerce was oppressed under the French government, the fur trade was extended to the immense distance which has been already stated; and surmounted many most discouraging difficulties, which will be hereafter noticed; while, at the same time, no exertions were made from Hudson's Bay to obtain even a share of the trade of a country which, according to the charter of that company, belonged to it, and, from its proximity, is so much more accessible to the mercantile adventurer.

"Of these trading commanders, I understood, that two attempted to penetrate to the Pacific ocean, but the utmost extent of their journey I could never learn; which may be attributed, indeed, to a failure of the undertaking.

"For some time after the conquest of Canada, this trade was suspended, which must have been very advantageous to the Hudson's Bay company, as all the inhabitants to the westward of Lake Superior were obliged to go to them for such articles as their habitual use had rendered necessary. Some of the Canadians who had lived long with them, and were become attached

Fur.

tached to a savage life, accompanied them thither annually, till mercantile adventurers again appeared from their own country, after an interval of several years, owing, I suppose, to an ignorance of the country in the conquerors, and their want of commercial confidence in the conquered. There were, indeed, other discouragements, such as the immense length of the journey necessary to reach the limits beyond which this commerce must begin; the risk of property; the expences attending such a long transport; and an ignorance of the language of those who, from their experience, must be necessarily employed as the intermediate agents between them and the natives. But, notwithstanding these difficulties, the trade, by degrees, began to spread over different parts to which it had been carried by the French, though at a great risk of the lives, as well as the property, of their new possessors, for the natives had been taught by their former allies to entertain hostile dispositions towards the English, from their having been in alliance with their natural enemies the Iroquois; and there were not wanting a sufficient number of discontented, disappointed people to keep alive such a notion; so that for a long time they were considered and treated as objects of hostility. To prove this disposition of the Indians, we have only to refer to the conduct of Pontiac, at Detroit, and the surprise and taking of Michilimakinac, about this period.

"Hence it arose, that it was so late as the year 1766, before which the trade I mean to consider commenced from Michilimakinac. The first who attempted it were satisfied to go the length of the river Camenistiquia, about 30 miles to the eastward of the Grande Portage, where the French had a principal establishment, and was the line of their communication with the interior country. It was once destroyed by fire. Here they went, and returned successful in the following spring to Michilimakinac. Their success induced them to renew their journey, and incited others to follow their example. Some of them remained et Camenistiquia, while others proceeded to and beyond the Grande Portage, which since that time has become the principal entrepot of that trade, and is situated in a bay, in latitude 48. north, and longitude 90. west. After passing the usual season there, they went back to Michilimakinac as before, and encouraged by the trade, returned in increased numbers. One of these, Thomas Curry, with a spirit of enterprise superior to that of his contemporaries, determined to penetrate to the furthest limits of the French discoveries in that country; or at least till the frost should stop him. For this purpose he procured guides and interpreters, who were acquainted with the country, and with four canoes arrived at Fort Bourbon, which was one of their posts, at the west end of the Cedar lake, on the waters of the Saskatchiwine. His risk and toil were well recompensed, for he came back the following spring with his canoes filled with fine furs, with which he proceeded to Canada, and was satisfied never again to return to the Indian country.

"From this period people began to spread over every part of the country, particularly where the French had established settlements *."

After continuing the detail of the history of the trade, for which we must refer to the work itself, Mr Mackenzie proceeds to inform us of the concern which he himself had in it, when in the year 1785, he was assumed as a partner, on condition of going into the Indian country to take an active share in the business. After some struggles, from jealousy and rivalship, with another company who had been some time in the trade, a union between the two companies was formed. This happened in 1787, and the following is Mr Mackenzie's account of its success, and of the extent and mode of conducting this trade.

"This commercial establishment," he proceeds, "was now founded on a more solid basis than any hitherto known in the country; and it not only continued in full force, vigour, and prosperity, in spite of all interference from Canada, but maintained at least an equal share of advantage with the Hudson's Bay Company, notwithstanding the superiority of their local situation. The following account of this self-erected concern will manifest the cause of its success.

"It assumed the title of the North-West Company, and was no more than an association of commercial men, agreeing among themselves to carry on the fur trade, unconnected with any other business, though many of the parties engaged had extensive concerns altogether foreign to it. It may be said to have been supported entirely upon credit; for whether the capital belonged to the proprietor, or was borrowed, it equally bore interest, for which the association was annually accountable. It consisted of twenty shares, unequally divided among the persons concerned. Of these, a certain proportion was held by the people who managed the business in Canada, and were styled agents for the Company. Their duty was to import the necessary goods from England, store them at their own expence at Montreal, get them made up into the articles suited to the trade, pack and forward them, and supply the cash that might be wanting for the outfits; for which they received, independent of the profit on their shares, a commission on the amount of the accounts, which they were obliged to make out annually, and keep the adventure of each year distinct. Two of them went annually to the Grande Portage, to manage and transact the business there, and on the communication at Detroit, Michilimakinac, St Mary's, and Montreal, where they received stores, packed up, and shipped the company's furs for England, on which they had also a small commission. The remaining shares were held by the proprietors, who were obliged to winter and manage the business of the concern with the Indians, and their respective clerks, &c. They were not supposed to be under any obligation to furnish capital, or even credit. If they obtained any capital by the trade, it was to remain in the hands of the agents; for which they were allowed interest. Some of them, from their long services and influence, held double shares, and were allowed to retire from the business at any period of the existing concern, with one of those shares, naming any young man in the company's service to succeed him in the other. Seniority and merit were, however, considered as affording a claim to the succession, which, nevertheless, could not be disposed of without the concurrence of the majority of the concern; who, at the same time relieved the seceding person from any responsibility respecting the share that he transferred, and accounted for it according to the annual value or rate of the property; so that the seller could have no advantage but that of getting the

* *Gen. Hist. of the Fur Trade*, p. 1.

the share of stock which he retained realised, and receiving for the transferred share what was fairly determined to be the worth of it. The former was also discharged from all duty, and became a dormant partner. Thus, all the young men who were not provided for at the beginning of the contract, succeeded in succession to the character and advantages of partners. They entered into the company's service for five or seven years, under such expectations, and their reasonable prospects were seldom disappointed: there were indeed, instances when they succeeded to shares, before their apprenticeship was expired, and it frequently happened that they were provided for while they were in a state of articled clerkship. Shares were transferable only to the concern at large, as no person could be admitted as a partner who had not served his time to the trade. The dormant partner indeed might dispose of his interest to any one he chose, but if the transaction were not acknowledged by his associates, the purchaser could only be considered as his agent or attorney. Every share had a vote, and two thirds formed a majority. This regular and equitable mode of providing for the clerks of the company, excited a spirit of emulation in the discharge of their various duties, and, in fact, made every agent a principal, who perceived his own prosperity to be immediately connected with that of his employers. Indeed, without such a spirit, such a trade could not have become so extended and advantageous, as it has been and now is,

"In 1788, the gross amount of the adventure for the year did not exceed 40,000l.: but by the exertion, enterprise, and industry of the proprietors, it was brought in eleven years to triple that amount and upwards; yielding proportionate profits, and surpassing, in short, any thing known in America.

"Such, therefore, being the prosperous state of the company, it, very naturally, tempted others to interfere with the concern in a manner by no means beneficial to the company, and commonly ruinous to the undertakers.

"In 1798 the concern underwent a new form, the shares were increased to forty-six, new partners being admitted, and others retiring. This period was the termination of the company, which was not renewed by all the parties concerned in it, the majority continuing to act upon the old stock, and under the old firm; the others beginning a new one; and it now remains to be decided, whether two parties, under the same regulations and by the same exertions, though unequal in number, can continue to carry on the business to a successful issue. The contrary opinion has been held, which, if verified, will make it the interest of the parties again to coalesce: for neither is deficient in capital to support their obstinacy in a losing trade, as it is not to be supposed that either will yield on any other terms than perpetual participation.

"It will not be superfluous in this place, to explain the general mode of carrying on the fur trade.

"The agents are obliged to order the necessary goods from England in the month of October, eighteen months before they can leave Montreal; that is, they are not shipped from London until the spring following, when they arrive in Canada in the summer. In the course of the following winter they are made up into such articles as are required for the savages; they are then packed into parcels of ninety pounds weight each, but cannot be sent from Montreal until the May following; so that they do not get to market until the ensuing winter, when they are exchanged for furs, which come to Montreal the next fall, and from thence are shipped, chiefly to London, where they are not sold or paid for before the succeeding spring, or even as late as June; which is forty-two months after the goods were ordered in Canada; thirty-six after they had been shipped from England; and twenty-four after they had been forwarded from Montreal; so that the merchant, allowing that he has twelve months credit, does not receive a return to pay for those goods, and the necessary expences attending them, which is about equal to the value of the goods themselves, till two years after they are considered as cash, which makes this a very heavy business. There is even a small proportion of it that requires twelve months longer to bring round the payment, owing to the immense distance it is carried, and from the shortness of the seasons, which prevent the furs, even after they are collected, from coming out of the country for that period (A).

"The articles necessary for this trade, are coarse woollen cloths of different kinds; milled blankets of different sizes; arms and ammunition; twist and carrot tobacco; Manchester goods; linens, and coarse sheetings; thread, lines, and twine; common hardware; cutlery and ironmongery of several descriptions; kettles of brass and copper, and sheet-iron; silk and cotton handkerchiefs; hats, shoes, and hose; calicoes and printed cottons, &c. &c. &c. Spirituous liquors and provisions are purchased in Canada. These, and the expence of transport to and from the Indian country, including wages to clerks, interpreters, guides, and canoe-men, with the expence of making up the goods for the

(A) "This will be better illustrated by the following statement:

We will suppose the goods for 1798;	
The orders for the goods are sent to this country - - - - - -	25th Oct. 1796.
They are shipped from London - - - - - - - -	March 1797.
They arrive in Montreal - - - - - - - - -	June 1797.
They are made up in the course of that summer and winter.	
They are sent from Montreal - - - - - - - - -	May 1798.
They arrive in the Indian country, and are exchanged for furs the following winter -	1798-9.
Which furs come to Montreal - - - - - - - -	Sept. 1799.
And are shipped for London, where they are sold in March and April, and paid for in May or June - - - - - - - - - - -	1800.

the market, form about half the annual amount against the adventure.

"This expenditure in Canada ultimately tends to the encouragement of British manufactory, for those who are employed in the different branches of this business, are enabled by their gains to purchase such British articles as they must otherwise forego.

"The produce of the year of which I am now speaking, consisted of the following furs and peltries:

106,000 Beaver skins,	6000 Lynx skins,
2100 Bear skins,	600 Wolverine skins,
1500 Fox skins,	1650 Fisher skins,
4000 Kitt fox skins,	100 Rackoon skins,
4600 Otter skins,	3800 Wolf skins,
17,000 Musquash skins,	700 Elk skins,
32,000 Marten skins,	750 Deer skins,
1800 Mink skins,	1200 Deer skins dressed,

500 Buffalo robes, and a quantity of castoreum.

"Of these were diverted from the British market, being sent through the United States to China, 13,364 skins, fine beaver, weighing 19,283 pounds; 1250 fine otters, and 1724 kitt foxes. They would have found their way to the China market at any rate, but this deviation from the British channel arose from the following circumstance:

"An adventure of this kind was undertaken by a respectable house in London, half concerned with the North-West Company in the year 1792. The furs were of the best kind, and suitable to the market; and the adventurers continued this connexion for five successive years, to the annual amount of 40,000l. At the winding up of the concern of 1792, 1793, 1794, 1795, in the year 1797, (the adventure of 1796 not being included, as the furs were not sent to China, but disposed of in London), the North-West Company experienced a loss of upwards of 40,000l. (their half,) which was principally owing to the difficulty of getting home the produce procured in return for the furs from China, in the East India Company's ships, together with the duty payable, and the various restrictions of that company. Whereas, from America there are no impediments; they get immediately to market, and the produce of them is brought back, and perhaps sold in the course of twelve months. From such advantages the furs of Canada will no doubt find their way to China by America, which would not be the case if British subjects had the same privileges that are allowed to foreigners, as London would then be found the best and safest market.

"But to return to our principal subject.—We shall now proceed to consider the number of men employed in the concern: viz. 50 clerks, 71 interpreters and clerks, 1120 canoe men, and 35 guides. Of these, five clerks, 18 guides, and 350 canoe men, were employed for the summer season in going from Montreal to the Grande Portage, in canoes, part of whom proceeded from thence to Rainy Lake, as will be hereafter explained, and are called *pork-eaters*, or *goers and comers*. These were hired in Canada or Montreal, and were absent from the 1st of May till the latter end of September. For this trip the guides had from 800 to 1000 livres, and a suitable equipment; the foreman and steersman from 400 to 600 livres; the middle men from 250 to 350 livres, with an equipment of one blanket, one shirt, and one pair of trowsers; and were maintained during that period at the expence of their employers. Independent of their wages, they were allowed to traffic, and many of them earned to the amount of their wages. About one-third of these went to winter, and had more than double the above wages, and equipment. All the others were hired by the year, and some times for three years; and of the clerks many were apprentices, who were generally engaged for five or seven years, for which they had only 100l. provision and clothing. Such of them who could not be provided for as partners, at the expiration of this time, were allowed from 100l. to 300l. per annum, with all necessaries, till provision was made for them. Those who acted in the twofold capacity of clerk and interpreter, or were so denominated, had no other expectation than the payment of wages to the amount from 1000 to 4000 livres per annum, with clothing and provisions. The guides, who are a very useful set of men, acted also in the additional capacity of interpreters, and had a stated quantity of goods, considered as sufficient for their wants, their wages being from 1000 to 3000 livres. The canoe men are of two descriptions, foremen and steersmen, and middlemen. The two first were allowed annually 1200, and the latter 400, livres each. The first class had what is called an equipment, consisting of two blankets, two shirts, two pair of trowsers, two handkerchiefs, 14 pounds of tobacco, and some trifling articles. The latter had 10 pounds of tobacco, and all the other articles: those are called *north men*, or *winterers;* and to the last class of people were attached upwards of 700 Indian women and children, victualled at the expence of the company.

"The first class of people are hired in Montreal five months before they set out, and receive their equipments, and one-third of their wages in advance; and an adequate idea of the labour they undergo may be formed from the following account of the country through which they pass, and their manner of proceeding.

"The necessary number of canoes being purchased, at about 300 livres each, the goods formed into packages, and the lakes and rivers free of ice, which they usually are in the beginning of May, they are then dispatched from La Chine, eight miles above Montreal, with eight or ten men in each canoe, and their baggage; and 65 packages of goods, 600 weight of biscuit, 200 weight of pork, three bushels of pease, for the men's provision; two oil cloths to cover the goods, a sail, &c. an axe, a towing-line, a kettle, and a sponge to bail out the water, with a quantity of gum, bark, and watape, to repair the vessel. An European on seeing one of these slender vessels thus laden, heaped up, and sunk with her gunwale within six inches of the water, would think his fate inevitable in such a boat, when he reflected on the nature of her voyage; but the Canadians are so expert that few accidents happen *."

FURSTENBURGH, a town and castle of Germany, the capital of a county of the same name, 30 miles north-west of Constance. E. Long. 8. 27. N. Lat. 47. 57.

FURTHCOMING, in *Law*, the name of an action competent

competent to any person who has used arrestment in the hands of his debtor's creditor, for having the subject arrested declared his property.

FURUNCLE, or Boil, in *Surgery*, a small resisting tumour, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin. See Surgery *Index*.

FURZE. See Ulex, Botany *Index*.

FUSANUS, in *Botany*, a genus of plants belonging to the polygamia class. The hermaphrodite calyx is quinquefid; there is no corolla; there are four stamina; the germen beneath; there are four stigmata; the fruit a plum.

FUSAROLE, in *Architecture*, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSE, or Fuze, in artillery. See Fusee.

FUSEE, in clock-work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which, see Clock and Watch.

Fusee, or *Firelock*. See Musquet.

Fusee, *Fuze*, or *Fuse*, of a bomb or grenado, is that which makes the whole powder or composition in the shell take fire, to do the designed execution.

Fuzes are chiefly made of very dry beech wood, and sometimes of hornbeam, taken near the root. They are turned rough, and bored at first, and then kept for several years in a dry place; the diameter of the hole is about one-fourth of an inch; the hole does not come quite through, leaving about one-fourth of an inch at the bottom; and the head is made hollow, in the form of a bowl.

The composition for fuzes is saltpetre 3, sulphur 1, and mealed powder 3, 4, and sometimes 5. This composition is driven in with an iron driver (whose ends are capped with copper to prevent the composition from taking fire), and equally hard as possible; the last shovelfull being all mealed powder, and two stands of quickmatch laid across each other being driven in with it, the ends of which are folded up into the hollow top, and a cap of parchment tied over it till used.

When these fuzes are driven into the loaded shell, the lower end is cut off in a slope, so that the composition may inflame the powder in the shell: the fuze must have such a length as to continue burning all the time the shell is in its range, and to set fire to the powder as soon as it touches the ground, which instantly bursts into many pieces. When the distance of the battery from the object is known, the time of the shell's flight may be computed to a second or two; which being known, the fuze may be cut accordingly, by burning two or three, and making use of a watch or a string by way of a pendulum to vibrate seconds.

FUSIBILITY, in *Natural Philosophy*, that quality of bodies which renders them fusible. Gold is more fusible than iron or copper; but less so than silver, tin, and lead. Borax and other substances are frequently mixed with metals, to render them more fusible.

FUSIL, in *Heraldry*, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and sharp than the other two in the middle. It is called in Latin *fusus*, "a spindle," from its shape.

FUSILIERS, Fusileers, or *Fuzileers*, in the military art, are soldiers armed as the rest of the infantry, but formerly wore caps like the grenadiers, though somewhat shorter. There are three regiments in the British service: the royal regiment of Scotch fuzileers raised in 1678; the royal regiment of English fuzileers raised in 1685; and the royal regiment of Welsh fuzileers raised in 1688-9.

FUSION, the state of a body rendered fluid by fire. See Fluidity, and Chemistry *Index*.

FUST, or Faust, John, was a goldsmith of Mentz, and one of the three artists to whom the valuable invention of printing has been usually ascribed. The names of the other two were Guttemberg and Schœffer. It seems impossible, however, to determine with certainty, whether Fust had any other merit in the business than that of supplying Guttemberg with money, who had been making some attempts with carved blocks at Strasburgh, before he visited Mentz. To Schœffer, the son-in-law of Fust, we are indebted for the invention of punches and matrices, by means of which this noble art was afterwards carried to perfection. That work which may be regarded as the origin of the true typographic art, was the "Durandi Rationale Divinorum Officiorum," published in 1459, by Fust and Schœffer, which was soon followed by a copy of the Bible, both executed in a very masterly manner.

We are informed that Fust went to Paris in 1462, in order to dispose of a part of the second edition of his bible, which he was enabled to sell considerably lower than bibles in manuscript, yet some reckoned themselves overcharged by him, and some pretend that he was even accused of magic, but for the belief of this there appears to be no rational foundation. It seems certain that Fust was never in Paris after the year 1466; but that he was in that metropolis then, is proved by a note at the end of a copy of Cicero's Offices, intimating that the first possessor received it from John Fust at Paris, in 1466. It is extremely probable that he died that year of the plague, to which 40,000 of the inhabitanrs fell a sacrifice in the months of August and September. This opinion is farther corroborated by this circumstance, that the name of Schœffer alone was prefixed to the books which were published at Mentz after that period.

This man has been frequently confounded with John Faust, better known by the name of Dr Faustus, a pretender to the art of magic, who was first a theologian, then a student of medicine, and last of all sold himself to the devil for 24 years, at the expiration of which period it seems the devil came to carry off his purchase, and dashed out the doctor's brains against the wall about midnight. This wretched romance has no doubt been invented by the monks, to blacken the reputation of the great Fust, whose art deprived them of the emoluments arising from the copying of manuscripts. See (History of) Printing.

Fust, in *Architecture*, the shaft of a column, or the part comprehended between the base and the capital, called also the naked.

FUSTIAN, in *Commerce*, a kind of cotton stuff, which seems as it were whaled on one side.

Right fustians should be altogether made of cotton-yarn, both woof and warp; but a great many are made, the warp of which is flax, or even hemp.

There are fustians made of several kinds, wide, narrow, fine, coarse; with shag or nap, and without it.

FUSTIAN is also used for a bombast style, or a high swelling kind of writing, made up of heterogeneous parts.

FUSTICK, or FUSTOCK, a yellow wood, that grows in all the Caribbee islands, and is used in dyeing yellow. It is a species of MORUS. See BOTANY *Index*. And for its properties, see CHEMISTRY and DYEING *Index*.

FUSTIGATIO, in the Roman customs, a punishment inflicted by beating with a cudgel. This punishment was peculiar to freemen; for the slaves were scourged or lashed with whips.

FUTTOCKS, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

FUTURE, something to come hereafter. We say, a *future* state, a *future* contingency: there is none but God to whom *future* things are present.

FUTURE, or FUTURE *Tense*, in *Grammar*, denotes an inflection of verbs, whereby they denote, that a thing will be in some time yet to come. See GRAMMAR.

FUZES, or FUSEES, in artillery. See FUSEE.

FUZILEERS. See FUSILEERS.

G.

G, THE seventh letter and fifth consonant of our alphabet; though in the alphabets of all the oriental languages, the Hebrew, Phenician, Chaldee, Syriac, Samaritan, Arabic, and even Greek, *G* is the third letter. The Hebrews call it *ghimel* or *gimel*, q. d. "camel;" by reason it resembles the neck of that animal; and the same appellation it bears in the Samaritan, Phenician, and the Chaldee; in the Syriac it is called *gamel*, in Arabic *giim*, and in Greek *gamma*.

The gamma (Γ) of the Greeks is manifestly the gimel (ג) of the Hebrews or Samaritans. All the difference between the gamma and gimel consists in this, that the one is turned to the right, and the other to the left, according to the different manners of writing and reading which obtained among those different nations; so that all the pains Salmasius has taken on Solinus, to prove that the G was derived from the Greek kappa, is lost.

From the Greeks the Latins borrowed their form of this letter; the Latin G being certainly a corruption of the Greek gamma Γ, as might easily be shown had our printers all the characters and forms of this letter which we meet with in the Greek and Latin MSS. through which the letter passed from Γ to G.

Diomed, lib. ii. cap. *De Litera*, calls G a new letter. His reason is, that the Romans had not introduced it before the first Punic war; as appears from the rostral column erected by C. Duilius, on which we everywhere find a C in lieu of G. It was Sp. Carvilius who first distinguished between those two letters, and invented the figure of the G; as we are assured by Terentius Scaurus. The C served very well for G; it being the third letter of the Latin alphabet, as the Γ or γ was of the Greek.

The G is found instead of C on several medals: *Vaillant. Num. Imperat.* tom. i. p. 39.

M. Beger produces a medal of the *Familia Ogulnia*, where GAR is read instead of CAR, which is on those of M. Patin. But the C is more frequently seen on medals in lieu of G; as, AUCUSTALIS CALLAECIA CARTACINENSIS, &c. for AUGUSTALIS, &c. Not that the pronunciation of those words was altered, but only that the G was unartfully or negligently cut by the workmen; as is the case in divers inscriptions of the eastern empire; where AVC, AUCC, AUCCC, are frequently found for AUG, &c.

The northern people frequently change the G into V or W; as in *Gallus*, *Wallus*; *Gallia*, *Wallia*, *Vallia*, &c. For, in this instance, it must not be said that the French have changed the W into G; because they wrote *Gallus* long before *Wallus* or *Wallia* was known, as appears from all the ancient Roman and Greek writers. And yet it is equally true, that the French change the W of the northern nations, and V consonant, into G; as, *Willielmus*, "William," into *Guillaume*; *Wulphilas* into *Gulphilas*; *Vascon* into *Gascon*, &c.

The letter G is of the mute kind, and cannot be any way sounded without the help of a vowel. It is formed by the reflection of the air against the palate, made by the tongue as the air passes out of the throat; which Martianus Capella expresses thus, G *spiritus cum palato*; so that G is a palatal letter.

The modern G takes its form from that of the Latins. In English it has two sounds, one from the Greek Γ and the Latin, which is called that of the hard G, because it is formed by a pressure somewhat hard on the fore part of the tongue against the upper gum; which sound it retains before *a*, *o*, *u*, *l*, *r*; as *gate*, *go*, *gull*. At the end of a word it is always hard, as *ring*, *sing*, &c. The other sound, called that of the soft G, resembles that of *j*; and is commonly, though not always, found before *e* and *i*, as in *gesture*, *giant*, &c. To this rule, however, there are many exceptions; G is often hard before *i*, as *give*, &c. and sometimes before *e*, as *get*, &c. It is also hard in derivatives from words ending in *g*, as *singing*, *stronger*, &c. and generally before *er*, at the ends of words, as *finger*. G is mute before *n*, as *gnash*, *sign*. *Gh* has the sound of the hard *G* in the beginning of a word, as *ghostly*; in the middle, and sometimes at the end, it is quite silent, as *right*, *though*. At the end of a word *Gh* has often the sound of *f*, as *laugh*, *rough*, *tough*.

As a numeral, G was anciently used to denote 400; and with a dash over it thus $\bar{G}$, 40,000.

As an abbreviature, G. stands for *Gaius*, *Gellius*, *gens*,

gens, *genius*, &c. G. G. for *gemina*, *gessit*, *gesserunt*, &c. G. C. for *genio civitatis* or *Cæsaris*. G. L. for *Gaius libertus*, or *genio loci*. G. V. S. for *genio urbis sacrum*. G. B. for *genio bono*. And G. T. for *genio tutelari*.

In music, G is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name of *gamut*.

GABALE, in *Mythology*, a deity worshipped at Heliopolis under the figure of a lion, with a radiant head; and it is thus represented on many medals of Caracalla.

GABARDINE, from the Italian *gavardina*, has been sometimes used to denote a coarse frock, or mean dress. In this sense it is used by Shakespeare in his Tempest and Merchant of Venice, and by Butler in his Hudibras, book i.

GABARA, or GABBARA, in antiquity, the dead bodies which the Egyptians embalmed, and kept in their houses, especially those of such of their friends as died with the reputation of great piety and holiness, or as martyrs. See EMBALMING, and MUMMY.

GABEL, (*Gabella*, *Gablum*, *Gablagium*), in French *Gabelle*, i.e. *Vectigal*, hath the same signification among the ancient English writers that *gabelle* hath in France. It is a tax; but hath been variously used, as for a rent, custom, service, &c. And where it was a payment of rent, those who paid it were termed *gablatores*. When the word *gabel* was formerly mentioned without any addition to it, it signified the tax on salt, though afterwards it was applied to all other taxes.

In the French customs, the gabel, or tax on salt, computed to make one-fourth of the whole revenue of the kingdom, is said to have had its rise in France in 1286, under Philip the Fair. Philip the Long took a double per livre on salt, by an edict in 1318, which he promised to remit when he was delivered from his enemies; which was renewed by Philip de Valois in 1345; and the duty was raised to four deniers per livre; King John resumed it in 1355, and it was granted to the dauphin in 1358, to ransom King John. It was continued by Charles V. in 1366; after his decease it was suppressed, but revived again by Charles VI. in 1381. Louis XI. raised it to 12 deniers per livre; and Francis I. in 1542 to 24 livres per muid: and it has been considerably augmented since that time; so that a minot of salt latterly paid a duty of 52 livres 8 sols and 6 deniers. Philip de Valois first established granaries and officers of the gabelles, and prohibited any other persons from selling salt: from which time the whole commerce of salt for the inland consumption continued wholly in the king's hands, every grain thereof being sold and distributed by his farmers and officers created for the purpose.—This oppressive tax was abolished by the National Assembly.

GABII, in *Ancient Geography*, a town of Latium, midway almost between Rome and Preneste to the east, often mentioned in the history of Tarquin the Proud. *Cinctus Gabinus* denoted a particular way of tucking the gown, by drawing it forwards on the breast, and tying it into a knot; as the people of Gabii did at a solemn sacrifice, on the sudden attack of an enemy, in order to be fitter for action. In this manner the consul used to declare war, to sacrifice, and burn the spoils of the enemy; and then he was said to be *præcinctus*. The place now extinct.

GABINIAN LAWS, in Roman antiquities; laws instituted upon several occasions by persons of the name of *Gabinius*. The first was the *Gabinia lex de Comitiis*, by A. Gabinius the tribune, in the year of Rome 614. It required, that in the public assemblies for electing magistrates, the votes should be given by tablets, and not *viva voce*.—Another *de Comitiis*, which made it a capital punishment to convene any clandestine assembly, agreeable to the old law of the 12 tables. Another *de Militia*, by A. Gabinius the tribune, year of Rome 685. It granted Pompey the power of carrying on the war against the pirates, during three years, and of obliging all kings, governors, and states, to supply him with all the necessaries he wanted, over all the Mediterranean sea, and in the maritime provinces as far as 400 *stadia* from the sea.—Another *de Usura*, by Aul. Gabinius the tribune, year of Rome 685. It ordained that no action should be granted for the recovery of any money borrowed upon small interest to be lent upon larger. This was an usual practice at Rome, which obtained the name of *versuram facere*.—Another against fornication.

GABIONS, in *Fortification*, baskets made of ozier twigs, of a cylindrical form, six feet high and four wide; which, being filled with earth, serve as a shelter from the enemy's fire.

GABLE or GABEL *End*, of a house (from *gaval*, Welsh), is the upright triangular end from the cornice or eaves to the top of the house.

GABRES, or GAVRES, a religious sect in Persia and India; called also *Gebres*, *Guebres*, *Gevres*, *Gaurs*, &c. Sea MAGI.

The Turks call the Christians *Gabres*, q. d. Infidels, or people of a false religion; or rather as Leunclavius observes, Heathens or Gentiles: the word *Gabre*, among the Turks, having the same signification as *Pagan* or *Infidel* among the Christians, and denoting any thing not Mahometan.

In Persia the word has a more peculiar signification; wherein it is applied to a sect dispersed through the country, and said to be the remains of the ancient Persians or followers of Zoroaster, being worshippers of fire. They have a suburb at Ispahan, which is called *Gaurabad*, or "the town of the *Gaurs*," where they are employed in the meanest and vilest drudgery; some of them are dispersed through other parts of Persia; but they principally abound in Kerman, the most barren province in the whole country, where the Mahometans allow them liberty and the exercise of their religion. Several of them fled many ages ago into India, and settled about Surat, where their posterity remain to this day. There is also a colony of them at Bombay. They are a poor, ignorant, inoffensive people, extremely superstitious, and zealous for their rights, rigorous in their morals, and honest in their dealings. They profess to believe a resurrection and a future judgment, and to worship only one God. And though they perform their worship before fire, and direct their devotion towards the rising sun, for which they have an extraordinary veneration, yet they strenuously maintain that they worship neither; but that these are the most expressive symbols of the Deity, and that for this reason they turn towards them in their devotional services.—However, some have supposed, that these are Persians converted to Christianity, who, being afterwards left to themselves, mingled their ancient superstitions with the truths and practices of Christianity, and so formed for themselves a religion apart: and they allege, that throughout the whole of their system of doctrine and practice, we may discern the marks and traces of Christianity, though grievously defaced; the annunciation, the magi, the massacre of the infants, our Saviour's miracles, his persecutions, ascension, &c.

GABRIEL, the name of one of the principal angels in heaven. It signifies *the strength of God.* There are a few events, in which this exalted being was concerned, recorded in Scripture. He was sent to the prophet Daniel, to explain to him the vision of the ram and goat, and the mystery of the seventy weeks, which had been revealed to him. He was sent to Zecharias, to declare to him the future birth of John the Baptist. Six months after, he was sent to Nazareth to the Virgin Mary, to warn her of the birth of Jesus Christ.

The Orientalists add several particulars to what the Scriptures inform us concerning the angel Gabriel. The Mahometans call him the *faithful spirit;* and the Persians, by way of metaphor, the *peacock of heaven.* We read, in the second chapter of the Koran, that *whosoever is an enemy to Gabriel shall be confounded.* It was Gabriel, they believe, who brought to Mahomet their false prophet the revelations which he published; and it was he who conducted him to heaven mounted upon the animal Borak.

GABRIEL, *St*, an island lying in the great river La Plata, South America, which was discovered by the celebrated navigator Sebastian Cabot, in the year 1526.

GABRIELITES, in ecclesiastical history, a sect of Anabaptists that appeared in Pomerania in 1530. They derive their name from Gabriel Scherling; who, after having been for some time tolerated in that country, was obliged to remove, and died in Poland.

GAD, a Jewish prophet, the seer or domestic prophet of King David, and his adviser in all matters of importance. When the displeasure of the Almighty was roused against David and the children of Israel for numbering the people, Gad received a commission to wait upon the king, and make him an offer of three evils as a punishment for his offence. These were famine, war, or pestilence, the last of which was chosen by David, the ravages of which were terrible beyond description, and produced genuine repentance in the hearts of survivors. To perpetuate the memory of this event, Gad ordered an altar to be erected in the threshing floor of Ornan the Jebusite, around which place, it is said, the temple was afterwards built. We learn from the Old Testament that Gad was an author, who wrote a history of his own times, of which much use appears to have been made by the compilers of the books of Samuel and Chronicles. Gad was also the name of one of the twelve patriarchs, or sons of Jacob.

GAD, in *Ancient Geography*, a district of the Transjordan Palestine, situated between Gilead and the kingdom of Bashan to the north, and the kingdom of the Amorites, to the south; having the Jordan to the west, and bounded by various people on the east; so called from a tribe of that name.

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge hammer.

GAD-Bee, or *Gad-Fly*. See OESTRUS, ENTOMOLOGY *Index*,

GADARA, in *Ancient Geography*, a town of the Peræa, or Transjordan, in the Decapolis, a very strong place. Restored by Pompey after its demolition by the Jews (Josephus). After Herod's death, it was joined to the province of Syria by Augustus.

GADARENORUM AGER, in *Ancient Geography*, the country of the Gadarenes, called by Matthew the country of the Gergesenes, because it was a district that lay between Gadara and Gergesa, otherwise called *Gerasa*, both which lay within the Decapolis on the other side Jordan.

GADES, or GADIRA, in *Ancient Geography*, a small island in the Atlantic, on the Spanish coast, 25 miles from the Columns of Hercules. It was sometimes called *Tartessus* and *Erythia* according to Pliny. Geryon, whom Hercules killed, fixed his residence there. Hercules, surnamed Gaditanus, had there a celebrated temple, in which all his labours were engraved with excellent workmanship. The inhabitants are called Gaditani.

GADUS, a genus of fishes belonging to the order of jugulares. This genus includes the cod, the whiting, the torsk, &c. See ICHTHYOLOGY *Index*.

GAELIC LANGUAGE. See HIGHLANDS.

GÆTULIA, in *Ancient Geography*, a country of Africa, lying to the south of Mauritania, called *Gætulia Propria*, and *Vetus*. *Gætuli*, the people, were distinguished by different epithets; as *Nigri*, *Autololes*, *Daræ* and *Baniuræ*, (Pliny. The *Gætuli* were among the first inhabitants of Africa: a rough, unpolished people, living on venison and the spontaneous productions of the earth; a roving, wandering people, who took up with the first place in which night surprised them, (Sallust).

GAFF, a sort of boom or pole, frequently used in small ships, to extend the upper edge of the mizen; and always employed for the same purpose on those sails whose foremost edges are joined to the mast by hoops or lacings, and which are usually extended by a boom below. Such are the main sails of all sloops, brigs, and schooners.

GAFFAREL, JAMES, a French divine, and very learned writer, born about 1601. He acquired great skill in the oriental and several other languages; and was particularly versant in the cabbalistic and occult sciences, which he learned, exposed, and refuted. Cardinal Richelieu made choice of him for his library keeper, and sent him into Italy to collect the best manuscripts and books. He published a book entitled *Curiositez Innouies*, i.e. Unheard-of Curiosities. It is said the cardinal designed to employ him in his grand project for the reunion of religions. He died in 1681, aged 80. He had been labouring for many years, and had almost finished a history of the subterranean world; containing an account of the caves, grottoes, vaults, catacombs,

catacombs, and mines, he had met with in 30 years travels.

GAGATES, or JET. See JET, MINERALOGY *Index*.

GAGE, in our ancient customs, signifies a pledge or pawn, given by way of security. The word is only properly used in speaking of moveables; for immoveables, *hypotheca* is used.

If the gage perish, the person who received it is not to answer for it, but only for extreme negligence, &c.

GAGE is also used for a challenge to combat: (See CARTEL). In which sense, it was a pledge, which the accuser or challenger cast on the ground, and the other took up as accepting the challenge; it was usually a glove, gauntlet, chaperoon, or the like. See COMBAT, and DUEL.

GAGE, is only now retained as a substantive. As a verb, the *G* is changed into *W*, and of *gage* is formed *wage*: as to wage law, to wage deliverance, q. d. to give security a thing shall be delivered. See WAGE.

If a person who has distrained be sued for not having delivered what he had taken by distress, he should wage, or gage, or gager, deliverance; that is, put in surety that he will deliver them.

Mort-GAGE, is that which is left in the hands of the proprietor, so that he reaps the fruits thereof.

In opposition to *vis-gage*, where the fruits or revenues are reaped by the creditor, and reckoned on the foot of the debt, which diminishes in proportion thereto. The second acquits or discharges itself; the first does not.

GAGE, in the sea language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's *gage*; this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water is the ship's gage.

GAGE, among letter founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. See FOUNDERY.

GAGE, in joinery, is an instrument made to strike a line truly parallel to the straight side of any board or piece of stuff. Its chief use is for gaging of tenons true, to fit into mortises; and for gaging stuff of an equal thickness. It is made of an oval piece of wood, fitted upon a square stick, to slide up and down stiffly thereon, and with a tooth at the end of a staff, to score, to strike a line upon the staff at any distance, according to the distance of the oval from it.

Sliding GAGE, a tool used by the mathematical instrument makers for measuring and setting off the distances.

Sea GAGE, an instrument invented by Dr Hales and Dr Desaguliers for finding the depth of the sea; the description whereof is this. AB (fig. 1.) is the gage bottle, in which is cemented the gage tube *Ff* in the brass cape at G. The upper end of tube F is hermetically sealed, and the open lower end *f* is immersed in mercury, marked C, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass HG, pierced with several holes to admit the water into the bottle AB. The body K is a weight hanging by its shank L, in a socket N, with a notch on one side at *m*, in which is fixed the catch *l* of the spring S, and passing through the hole, L, in the shank of the weight K, prevents its falling out when once hung on. On the top, in the upper part of the brass tube at H, is fixed a large empty ball, or full blown bladder I, which must not be so large, but that the weight K may be able to sink the whole under water.

The instrument thus constructed is used in the following manner. The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom: the socket N is somewhat longer than the shank L; and therefore, after the weight K comes to the bottom, the gage will continue to descend till the lower part of the socket strikes against the weight; this gives liberty to the catch to fly out of the hole L, and let go the weight K: when this is done, the ball or bladder I instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube F*f*, and the height to which it has been forced by the greatest pressure, viz. that at the bottom, will be shown by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shows into what space the whole air in the tube F*f* is compressed; and consequently the height or depth of the water which by its weight produced that compression, which is the thing required.

If the gage tube F*f* be of glass, a scale might be drawn on it with the point of a diamond, showing, by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is more than 634 feet, which is not half a quarter of a mile.

If, to remedy this, we make use of a tube 50 inches long, which for strength may be a musket barrel, and suppose the air compressed into the hundredth part of half an inch; then by saying, as 1 : 99 :: 400 : 39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore, to explore such great depths, the Doctor contrived a new form for the sea gage, or rather for the gage tube in it, as follows. BCDF (fig. 2.) is a hollow metalline globe, communicating on the top with a long tube AB, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot there be seen through the tube: therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube AB, will receive the mark of the treacle, and show it when taken out.

If the tube AB be 50 inches long, and of such a bore

Gage.

bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then when the air is compressed within an hundredth part of the whole, it is evident the treacle will not approach nearer than five inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, viz. $2\frac{1}{2}$ inches, which correspond to 6600, which is a mile and a quarter. Again, half that space, or $1\frac{1}{4}$ inch, will show double the former depth, viz. 13200 feet, or $2\frac{1}{2}$ miles; which is probably very nearly the greatest depth of the sea.

Bucket Sea GAGE, an instrument contrived by Dr Hales to find the different degrees of coolness and saltness of the sea, at different depths: it consists of a common household pail or bucket, with two heads: These heads have each a round hole in the middle, about four inches in diameter, covered with square valves opening upward; and that they may both open and shut together, there is a small iron rod fixed to the upper part of the lower valve, and the other end to the lower side of the upper valve. So that as the bucket descends with its sinking weight into the sea, both the valves may open by the force of the water, which by that means has a free passage through the bucket. But when the bucket is drawn up, then both the valves shut by the force of the water at the upper part of the bucket; so that the bucket is drawn up full of the lowest sea water to which it has descended. When the bucket is drawn up, the mercurial thermometer fixed in it is examined; but great care must be taken to observe the degree at which the mercury stands, before the lower part of the thermometer is taken out of the water in the bucket, lest it be affected by the different temperature of the air. In order to keep the bucket in a right position, there are four cords fixed to it, reaching about three feet below it; to which the sinking weight is fixed. The result of several trials with this gage was, that when it was let down to different depths, from 360 feet to 5346 feet, in lat. 25. 13. N. and long. 25. 12. W. it was discovered by the thermometer, that the cold increased gradually in proportion to the depths, till it descended to 3900 feet, viz. near $\frac{3}{4}$ths of a mile, whence the mercury in the thermometer came up at 53°; and though it was afterwards sunk to 5346 feet, i. e. a mile and 66 feet, it came up no lower: the warmth of the water upon the surface, and that of the air, was all that time 84°. When the water in the bucket was become of the same temperature with that on the surface of the sea, equal quantities of both were weighed and tried by the hydrometer; that from below was found to be the heaviest, and consequently the saltest.

Dr Hales was probably led to the construction of this sea gage from an instrument invented by Dr Hook, and designed for the same purpose. This consists of a square wooden bucket C, (fig. 3.) whose bottoms are so contrived, that as the weight of A sinks the iron B, to which the bucket C is fastened by two handles D, D, on the end of which are the moveable bottoms or valves EE, and thereby draws down the bucket, the resistance of the water keeps up the bucket in the posture C, whereby the water, whilst the bucket was descending, hath a free passage through it; whereas, as soon as the bucket is pulled upwards by the line F, the resistance of the water to that motion beats the bucket downwards, and keeps it in the posture G, whereby the included water is kept from getting out, and the ambient water kept from getting in. Phil. Trans. N° ix. p. 149. and N° xxiv. p. 447. or Abr. vol. ii. p. 260.

Fig. 3.

Aqueo-mercurial GAGE, is the name of an apparatus contrived by Dr Hales, and applied in various forms to the branches of trees, in order to determine the force with which they imbibe moisture. Let *e r*, (fig. 4.) be a cylindric glass, e. gr. of an inch diameter within, and eight inches long. Into this glass is introduced the branch of a young thriving apple tree *b*, about three feet long, with lateral branches; the diameter of the transverse cut *i* being $\frac{3}{4}$ths of an inch. Having fitted the joint *r* to the tube at *r*, by folding a piece of sheep's skin round the stem, it is cemented with a mixture of bees wax and turpentine melted together, in such proportion as to make a very stiff clammy paste when cold, and over the cement folds of wet bladders are bound firmly with pack thread. To the lower end *e* of the large tube, a smaller tube *z e* is cemented, being about $\frac{1}{4}$ of an inch diameter, and 18 inches long, and in substance full $\frac{1}{6}$ of an inch thick. These tubes are cemented together at *e* with common hard brick dust or powdered chalk cement, and the joint is farther secured with the cement of bees wax and turpentine, over which a wet bladder is bound. The apparatus being thus prepared, the branch is turned downwards, and the glass tube upwards, and then both tubes are filled with water; with the finger applied to the open end of the small tube, it is inverted and immersed in the glass cistern *x*, full of mercury and water. In this situation the lower end of the branch was immersed six inches in water, viz. from *r* to *i*; the water was imbibed by the branch at its transverse cut *i*; and during its ascent into the sap vessels of the branch, the mercury rose in the tube *e z* from the cistern *x*, so that in half an hour it was risen $5\frac{1}{4}$ inches high, as far as *z*. The height of the mercury indicated, in some measure, the force with which the sap was imbibed, though not the whole force; because while the water was imbibed by the branch, its transverse cut was covered with innumerable little hemispheres of air, and many air bubbles issued out of the sap vessels, which partly filled the tube *e r*, as the water was drawn out of it; and therefore the height of the mercury could only be proportionable to the excess of the quantity of water drawn off above the quantity of the air which issued out of the wood. If the quantity of air issuing from the wood had been equal to the quantity of water imbibed, it is plain that the mercury could not rise at all, because there would be no room for it in the tube: but if nine parts in twelve of the water be imbibed by the branch, and only three such parts of air issue into the tube in the same time the mercury must rise near six inches, and so proportionably in other cases. Dr Hales observed, that the mercury rose highest, in most cases, when the sun was clear and warm, and that it subsided three or four inches towards evening, but rose again the next day as it grew warm, though seldom so high as at first. Dr Hales adapted the size and shape of the glass apparatus to a great variety of branches of several sizes and of different kinds of trees, and repeated the experiment above

Gage.

above described, *mutatis mutandis*, in a variety of instances. See his Vegetable Statics, vol. i. chap. ii. p. 84, &c.

Tide GAGE, the name of an instrument used for determining the height of the tides by Mr Bayly, in the course of a voyage towards the south pole, &c. in the Resolution and Adventure, in 1772, 1773, 1774, and 1775. This instrument consists of a glass tube, whose internal diameter was seven-tenths of an inch, lashed fast to a ten-feet fir rod, divided into feet, inches, and quarters: this rod was fastened to a strong post fixed upright and firm in the water. At the lower end of the tube was an exceeding small aperture, through which the water was admitted. In consequence of this construction, the surface of the water in the tube was so little affected by the agitation of the sea, that its height was not altered one-tenth of an inch, when the swell of the sea was two feet; and Mr Bayly was certain, that with this instrument he could discern a difference of one-tenth of an inch in the height of the tide.

Wind GAGE, an instrument for measuring the force of the wind upon any given surface. It was invented by Dr Lind, who gives the following description of it, Phil. Trans. vol. lxv.

This instrument consists of two glass tubes AB, CD, (fig. 5.) of five or six inches in length. Their bores, which are so much the better for being equal, are about four-tenths of an inch in diameter. They are connected together like a siphon, by a small bent glass tube *a b*, the bore of which is about one-tenth of an inch in diameter. On the upper part of the leg AB there is a tube of latten brass, which is kneed, or bent perpendicularly outwards, and has its mouth open towards F. On the other leg CD, is a cover with a round hole G in the upper part of it two-tenths of an inch in diameter. This cover and the kneed tube are connected together by a slip of brass *e d*, which not only gives strength to the whole instrument, but also serves to hold the scale HI. The kneed tube and cover are fixed on with hard cement or sealing wax. To the same tube is soldered a piece of brass *e*, with a round hole in it to receive the steel spindle KL; and at *f* there is just such another piece of brass soldered to the brass hoop *g h*, which surrounds both legs of the instrument. There is a small shoulder on the spindle at *f*, upon which the instrument rests, and a small nut at *i*, to prevent it from being blown off the spindle by the wind. The whole instrument is easily turned round upon the spindle by the wind, so as always to present the mouth of the kneed tube towards it. The end of the spindle has a screw on it; by which it may be screwed into the top of a post or a stand made on purpose. It has also a hole at L, to admit a small lever for screwing it into wood with more readiness and facility. A thin plate of brass *k* is soldered to the kneed tube about half an inch above the round hole G, so as to prevent rain from falling into it. There is likewise a crooked tube AB (fig. 6.) to be put occasionally upon the mouth of the kneed tube F, in order to prevent rain from being blown into the mouth of the wind gage when it is left out all night, or exposed in the time of rain.

The force or momentum of the wind may be ascertained by the assistance of this instrument, by filling the tubes half full of water, and pushing the scale a little up or down till the o of the scale, when the instrument is held up perpendicularly, be on the line with the surface of the water in both legs of the wind-gage. The instrument being thus adjusted, hold it up perpendicularly, and turning the mouth of the kneed tube towards the wind, observe how much the water is depressed by it in the one leg, and raised in the other. The sum of the two is the height of a column of water which the wind is capable of sustaining at that time; and every body that is opposed to that wind will be pressed upon by a force equal to the weight of a column of water, having its base equal to the altitude of the column of water sustained by the wind in the wind gage. Hence the force of the wind upon any body where the surface opposed to it is known may be easily found; and a ready comparison may be made betwixt the strength of one gale of wind and that of another.

The force of the wind may be likewise measured with this instrument, by filling it until the water runs out of the hole G. For if we then hold it up to the wind as before, a quantity of water will be blown out; and if both legs of the instrument are of the same bore, the height of the column sustained will be equal to double the column of water in either leg, or the sum of what is wanting in both legs. But if the legs are of unequal bores, neither of these will give the true height of the column of water which the wind sustained. But the true height may be obtained by the following formulæ.

Suppose that after a gale of wind which had blown the water from A to B (fig. 7.) forcing it at the same time through the other tube out at E, the surface of the water should be found standing at some level DG, and it were required to know what was the height of the column EF or AB, which the wind sustained. In order to obtain this, it is only necessary to find the height of the columns DB or GF, which are constantly equal to one another; for either of these added to one of the equal columns AD, EG, will give the true height of the column of water which the wind sustained.

1. Let the diameters, AC, EH, of the tubes be respectively represented by $c\,d$; and let $a=$AD, or EG, and $x=$DB, or FG: Then it is evident, that the column DB is to the column EG as c^2x to d^2a. But these columns are equal. Therefore $c^2x=d^2a$; and consequently $x=\frac{d^2a}{c^2}$.

2. But if at any instant of time whilst the wind was blowing, it was observed, that, when the water stood at E, the top of the tube out of which it is forced, it was depressed in the other to some given level BF, the altitude at which it would have stood in each, had it immediately subsided, may be found in the following manner: Let $b=$AB or EF.—Then it is evident that the column DB is equal to the difference of columns EF, FG. But the difference of these columns is as d^2b-d^2x; and consequently $x=\frac{d^2b}{c^2+d^2}$.

For the cases when the wind blows in at the narrow leg of the instrument: Let AB$=$EF$=b$, EG or AD$=a$, GF$=$DB$=x$, and the diameters EH, GA, respectively

respectively $=d, c$, as before. Then it is evident, that the column AD is to the column GF as ac^2 to d^2x. But these columns are equal; therefore $d^2x=ac^2$; and consequently $x=\frac{ac^2}{d^2}$. It is also evident that the column AD is equal to the difference of the columns AB, DB; but the difference of these columns is as $bc^2—c^2x$. Therefore $d^2x=bc^2—c^2x$. Whence we get $x=\frac{bc^2}{d^2+c}$.

The use of the small tube of communication ab (fig. 5.) is to check the undulation of the water, so that the height of it may be read off from the scale with ease and certainty. But it is particularly designed to prevent the water from being thrown up to a much greater or less altitude than the true height of the column which the wind is able at that time to sustain, from its receiving a sudden impulse whilst it is vibrating either in its ascent or descent. As in some cases the water in this instrument might be liable to freeze, and thus break the tubes, Dr Lind recommends a saturated solution of sea salt to be used instead of it, which does not freeze till Fahrenheit's thermometer falls to 0.

GAHNIA, a genus of plants belonging to the hexandria class. See BOTANY *Index*.

GAIETA, an ancient, handsome, and strong town of Italy, in the kingdom of Naples, and in the Terra di Lavoro, with a fort, citadel, harbour, and bishop's see. It was taken by the Austrians in 1707, and by the Spaniards in 1734. It is seated at the foot of a mountain near the sea, in E. Long. 13. 37. N. Lat. 41. 30.

GAIN, the profit or lucre a person reaps from his trade, employment, or industry. Some derive the word from the German *gewin:* whereof the Italians had made *guadagno;* the French and English *gain*.

There are legal and reputable gains, as well as sordid and infamous ones. What is gained by gaming is of the latter description. Such gains are not acknowledged by law, so that the payment is not legally binding on the loser.

GAIN, in *Architecture*, is the workman's term for the bevelling shoulder of a joist or other timber. It is used also for the lapping of the end of the joist, &c. upon a trimmer or girder; and then the thickness of the shoulder is cut into the trimmer; also bevelling upwards, that it may just receive the gain; and so the joist and trimmer lie even and level with the surface. This way of working is used in floors and hearths.

To GAIN the Wind, in sea language, is to arrive on the weather side or to windward of some other vessel in sight, when both are plying to windward, or sailing as near the wind as possible.

GAINAGE, GAINAGIUM, in our ancient writers, signifies the draught oxen, horses, wain, plough, and furniture, for carrying on the work of tillage by the baser sort of sokemen and villains.

Gainage is the same with what is otherwise called *wainage*. Bracton, lib. i. cap. 9. speaking of lords and servants, says, *Ut si eos destruant, quod salvum non possit eis esse wainagium suum*. And again, lib. iii. tract. 2. cap. 1. *Villanus non amerciabitur, nisi salvo wainagio suo:* For anciently, as it appears both by Magna Charta, and other books, the villain, when amerced, had his gainage or wainage free, to the end his plough might not stand still; and the law, for the same reason, does still allow a like privilege to the husbandman; that is, his draught horses are not in many cases distrainable.

GAINAGE is also used for the land itself, or the profit raised by cultivating it.

GAINSBOROUGH, a town of Lincolnshire in England, 148 miles from London, seated on the east bank of the Trent, which brings tolerably sized vessels with the tide up to the town, about 40 miles from the Humber. It is a large well built town, with a pretty good trade, is noted for its ale, and has the title of an earldom. W. Long. 1. 45. N. Lat 53. 26. The north marsh in its neighbourhood is noted for horse races. The Danes who invaded the kingdom brought their ships up to this place; and it was here that Sweno the Dane was murdered by one of the English, while revelling with his companions. In the year 1643 a battle was fought here between the royalists and the parliament forces under Cromwell. The number of inhabitants in 1811 amounted to 5172, of whom nearly 600 were employed in trade and manufactures.

GALACTOPHAGI, and GALACTOPOTÆ, in antiquity, persons who lived wholly on milk, without corn or the use of any other food. The words are compounded of γαλα, γαλακτος, *milk;* φαγειν, *to eat;* and ποτης *of* πινω, *I drink*.

Certain nations in Scythia Asiatica, as the Getæ, Nomades, &c. are famous, in ancient history, in quality of *galactophagi*, or milk-eaters. Homer makes their eloge, Iliad, lib. iii.

Ptolemy, in his geography, places the Galactophagi between the Riphæan mountains on one side, and the Hyrcanian sea on the other.

GALANGALS, in the *Materia Medica*. See KÆMPFERIA.

GALANTHUS, the SNOW-DROP, a genus of plants belonging to the hexandria class, and in the natural method ranking under the ninth order, *Spathaceæ*. See BOTANY *Index*.

GALASHIELS, a small town in Selkirkshire in Scotland, situated on the stream called Gala Water, at the place where it joins the Tweed. Galashiels and its neighbourhood have been long famous for the manufacture of coarse woollen cloth, known by the name of *Galashiels grey*. The improved state of the agriculture of this vicinity is much commended. Galashiels is 30 miles S. E. from Edinburgh, and had 986 inhabitants in 1811.

GALATA, a great suburb belonging to Constantinople, opposite to the seraglio, on the other side of the harbour. It is here the Greeks, Armenians, Franks, Christians, and Jews inhabit, and are allowed the exercise of their respective worships.

GALATÆA, or GALATHÆA, in fabulous history, a sea nymph, daughter of Nereus and Doris. She was passionately loved by the Cyclops Polyphemus, whom she treated with coldness and disdain; while Acis, a shepherd of Sicily, enjoyed her unbounded affection. The happiness of these two lovers was disturbed by the jealousy of the Cyclops, who crushed his rival to pieces with a piece of a broken rock while he reposed on the bosom of Galatæa. The nymph was inconsolable for the loss of Acis; and as she could not restore him to life, she changed him into a fountain.

GALATIA, the ancient name of a province of Asia Minor, now called *Amasia*. It was bounded on the

the east by Cappadocia, on the west by Bithynia, on the south by Pamphylia, and on the north by the Euxine sea. It was the north part of Phrygia Magna; but upon being occupied by the Gauls was called *Galatia;* and because situated amidst Greek colonies, and itself mixed with Greeks, *Gallogræcia.* Strabo calls it *Galatia* and *Gallogræcia;* hence a twofold name of the people; *Galatæ* and *Gallogræci.* The Greeks called it *Gallia Parva;* to distinguish it from the *Transalpina*, both which they called *Galatia.* It was reduced under the subjection of the Romans in the time of Augustus, and is now in the hands of the Turks. Here St Paul founded a church, to which he directed that epistle which is still known by the name of the *Epistle to the Galatians*, and was written to reclaim them from the observation of Jewish ordinances, into which they had been seduced by some false teachers.

GALAX, a genus of plants belonging to the pentandria class, and in the natural method ranking with those of which the order is doubtful. See BOTANY.

GALAXY, in *Astronomy*, that long, white, luminous track, which seems to encompass the heavens like a swath, scarf, or girdle: and which is easily perceivable in a clear night, especially when the moon does not appear. The Greeks call it Γαλαξιας, *Galaxy*, of Γαλα, γαλακτος, *Milk;* on account of its colour and appearance: the Latins, for the same reason, call it *via lactea;* or *milky way.* It passes between Sagittarius and Gemini, and divides the sphere into two parts; it is unequally broad; and in some parts is single, in others double.

The ancient poets, and even philosophers, speak of the Galaxy as the road or way by which the heroes went to heaven.

Aristotle makes it a kind of meteor, formed of a crowd of vapours, drawn into that part by certain large stars disposed in the regions of the heavens answering hereto.

Others, finding that the Galaxy was seen all over the globe, that it always corresponded to the same fixed stars, and that it transcended the height of the highest planets, set aside Aristotle's opinion, and placed the Galaxy in the firmament, or region of the fixed stars, and concluded it to be nothing but an assemblage of an infinite number of minute stars.

Since the invention of the telescope, this opinion has been abundantly confirmed. By directing a good telescope to any part of the milky way; where before we only saw a confused whiteness, we now descry an innumerable multitude of little stars, so remote, that a naked eye confounds them. See ASTRONOMY, N° 211.

GALBA, SERGIUS SULPICIUS, a Roman emperor, born the 24th of December, five years before the Christian era. He was gradually raised to the greatest offices of the state, and exercised his power in the provinces with the greatest equity and unremitted diligence. He dedicated the greatest part of his time to solitary pursuits, chiefly to avoid the suspicions of Nero. His disapprobation of the emperor's oppressive command in the provinces was the cause of new disturbances. Nero ordered him to be put to death; but he escaped from the hand of the executioner, and was publicly saluted emperor. When he was seated on the throne, he suffered himself to be governed by favourites, who exposed the goods of the citizens to sale to gratify their avarice. Exemptions were sold at a high price; and the crime of murder was blotted out, and impunity purchased, with a large sum of money. Such irregularities in the emperor's ministers greatly displeased the people; and when Galba refused to pay the soldiers the money which he had promised them when he was raised to the throne, they assassinated him in the 73d year of his age, and the eighth month of his reign. The virtues which had shone so bright in Galba when a private man, totally disappeared when he ascended the throne; and he who showed himself the most impartial judge, forgot the duties of an emperor and of a father of his people.

GALBANUM, in *Pharmacy*, a gum issuing from the stem of an umbelliferous plant growing in Persia and many parts of Africa. See BUBON, BOTANY *Index.*

The juice, as brought to us, is semipellucid, soft, tenacious; of a strong, and to some unpleasant, smell; and a bitterish warm taste: the better sort is in pale coloured masses, which, on being opened, appear composed of clear white tears. Geoffroy relates, that a dark greenish oil is to be obtained from this simple by distillation, which, upon repeated rectifications, becomes of an elegant sky blue colour. The purer sorts of galbanum are said by some to dissolve entirely in wine, vinegar, or water; but these liquors are only partial menstrua with regard to this drug; nor do spirit of wine or oils prove more effectual in this respect: the best dissolvent is a mixture of two parts spirit of wine and one of water. Galbanum agrees in virtue with gum ammoniacum; but is generally accounted less efficacious in asthmas, and more so in hysterical complaints. It is an ingredient in various officinal compositions. See MATERIA MEDICA *Index.*

GALE, in the sea language, a term of various import. When the wind blows not so hard but that a ship may carry her top sails a-trip (that is, hoisted up to the highest), then they say it is a loom gale. When it blows very strong, they say it is a stiff, strong, or fresh gale. When two ships are near one another at sea, and, there being but little wind blowing, one of them finds more of it than the other, they say that the one ship gales away from the other.

GALE, *Dr John*, an eminent and learned minister among the Baptists, was born at London in 1680. He studied at Leyden, where he distinguished himself very early, and afterwards at Amsterdam, under Dr Limborch. He was chosen minister of the Baptist congregation at Barbican; where his preaching, being chiefly practical, was greatly resorted to by people of all persuasions. Four volumes of his sermons were published after his death, which happened in 1721. His Reflections on Dr Wall's History of Infant Baptism is the best defence of the Baptists ever published, and the reading of that performance induced the learned Mr William Whiston and Dr Foster to become Baptists.

GALE, *Theophilus*, an eminent nonconformist minister, born in 1628. He was invited to Winchester in 1657; and continued a stated preacher there until the re-establishment of the church by Charles II. when he rather chose to suffer the penalties of the act of conformity, than to submit to it contrary to his conscience. He was afterwards engaged by Philip Lord Wharton as tutor to his sons, whom he attended to an academy at Caen in Normandy; and when this duty was

was fulfilled, he became pastor over a congregation of private conventiclers in Holborn. He died in 1678; and is principally known by an elaborate work, intitled, the *Court of the Gentiles*, calculated to show that the Pagan philosophers derived their most sublime sentiments from the Scriptures.

GALE, *Dr Thomas*, a learned divine, born at Scruton in Yorkshire, in the year 1636, was educated at Cambridge, and at length became professor of the Greek language in that university. He was afterwards chosen head master of St Paul's school, London; and was employed by the city in writing those elegant inscriptions on the monument erected in memory of the conflagration in 1666. In 1676 he was collated to a prebend in the cathedral of St Paul's; and was likewise elected a fellow of the Royal Society to which he presented a Roman urn with its ashes. About the year 1697, he gave to the new library of Trinity college, in Cambridge, a great number of Arabian manuscripts; and in the same year he was admitted dean of York. He died in that city in 1702; and was interred in the cathedral, where a monument, with a Latin inscription, was erected to his memory. He was a learned divine, a great historian, one of the best Greek scholars of his age, and maintained a correspondence with the most learned men abroad as well as at home. He published, 1. *Historiæ Poeticæ Antiqui Scriptores*, octavo. 2. *Opuscula Mythologica, Ethica, et Physica*, in Greek and Latin, octavo. 3. *Herodoti Historia*, folio. 4. *Historiæ Anglicanæ Scriptores quinque*, in folio. 5. *Historiæ Britannicæ, Saxonicæ, Anglo-Danicæ, Scriptores quindecim*, in folio. 6. *Rhetores Selecti*, &c.

GALEA, in antiquity, a light casque, head piece, or morrion, coming down to the shoulders, and commonly of brass; though Camillus, according to Plutarch, ordered those of his army to be of iron, as being the stronger metal. The lower part of it was called *buccula*, and on the top was a crest. The velites wore a light galea, made of the skin of some wild beast to make it more terrible.

GALEASSE, a large low-built vessel, in which both sails and oars are used, and the largest of all the vessels that make use of the latter. It may carry twenty guns, and has a stern capable of lodging a great number of marines. It has three masts, which are never to be lowered or taken down. It has also thirty-two benches of rowers; and to each bench six or seven slaves, who sit under cover. This vessel is at present used only by the Venetians.

GALEGA, a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

GALEN, CLAUDIUS, in Latin *Galenus*, prince of the Greek physicians after Hippocrates, was born at Pergamus in the Lesser Asia, about the year 131. His father was possessed of a considerable fortune; was well versed in polite literature, philosophy, astronomy, and geometry; and was also well skilled in architecture. He himself instructed his son in the first rudiments of learning, and afterwards procured him the greatest masters of the age in philosophy and eloquence. Galen having finished his studies under their care, chose physic for his profession, and chiefly studied the works of Hippocrates. Having at length exhausted all the sources of literature that were to be found at home, he resolved to travel, in order to converse with the most able physicians in all parts, intending at the same time to take every opportunity of inspecting on the spot the plants and drugs of the countries through which he passed. With this view he went to Alexandria, and staid some years in that metropolis of Egypt; from thence he travelled through Cilicia; passed through Palestine; visited the isles of Crete and Cyprus; and made two voyages to Lemnos, in order to examine the Lemnian earth, which was then esteemed an admirable medicine. With the same view he went into the Lower Syria, in order to obtain a thorough insight into the nature of the opobalsamum, or balm of Gilead; and having completed his design, returned home by the way of Alexandria.

Galen had been four years at Pergamus, where his practice was attended with extraordinary applause, when some seditious commotions induced him to go to Rome, where he resolved to settle: but the proofs he gave of his superior skill, added to the respect shown him by several persons of very high rank, created him so many enemies among his brethren of the faculty, that he was obliged to quit the city, after having resided there four or five years. But he had not long returned to Pergamus, when he was recalled by the emperors Aurelius and Verus. After their death, he retired to his native country; where he died about the year 200. He wrote in Greek; and is said to have composed two hundred volumes, which were unhappily burnt in the temple of Peace. The best editions of those that remain, are, that printed at Basil in 1538, in five volumes, and that of Venice in 1625, in seven volumes. Galen was of a weak and delicate constitution, as he himself asserts; but he nevertheless, by his temperance and skill in physic, arrived at a great age; for it was his maxim, always to rise from table with some degree of appetite. He is justly considered as the greatest physician of antiquity, next to Hippocrates; and he performed such surprising cures, that he was accused of magic.

GALEN, a military township in the state of New-York, situated on the creek of Cauadaque, about 12 miles north-west of Cayuga lake, and 13 south by east of Great Sodus.

GALENA, a name given by mineralogists to a species of lead ore. See LEAD-*Mine*, and MINERALOGY *Index*. It was also the original name given by Andromachus to the theriaca, from its effect in bringing on a pleasing calm over the blood and spirits on taking it.

GALENIA, a genus of plants belonging to the octandria class; and in the natural method ranking under the 13th order, *Succulentæ*. See BOTANY *Index*.

GALENIC, or GALENICAL, in *Medicine*, is that manner of considering and treating diseases, founded on the principle of Galen, or introduced by GALEN. This author, collecting and digesting what the physicians before him had done, and explaining every thing according to the strictest doctrine of the Peripatetics, set physic on a new footing: he introduced the doctrine of the four elements; the cardinal qualities and their degrees; and the four humours or temperaments.

GALENIC is more frequently used as contradistinguished from *chemical*.

The distinction of *galenical* and *chemical* was occasioned

sioned by a division of the practitioners of medicine into two sects, which happened on the introduction of chemistry into medicine. Then the chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice. And though this division into the two sects of galenists and chemists has long since ceased, yet the distinction of medicines which resulted from it is still sometimes observed.

Galenical medicines are those which are formed by the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and by combining and multiplying ingredients; while those of chemistry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digestion, fermentation, &c.

GALENISTS, a denomination given to such physicians as practise, prescribe, or write, on the galenical principles; and stand opposed to the *chemists*. See GALENICAL. At present the galenists and chemists are pretty well accommodated; and most of our physicians use the preparations and remedies of both.

GALENISTS, or *Galenites*, in church history, a branch of Mennonites or Anabaptists, who take in several of the opinions of the Socinians, or rather Arians, touching the divinity of our Saviour. In 1664 the Waterlandians were divided into two parties, of which the one were called *Galenists*, and the other *Apostolians*. They are thus called from their leader Abr. Galenus, a learned and eloquent physician of Amsterdam, who considered the Christian religion as a system that laid much less stress on faith than practice; and who was for taking into the communion of the Mennonites all those who acknowledged the divine origin of the books of the Old and New Testament, and led holy and virtuous lives.

GALEON. See GALLEON.

GALEOPSIS, a genus of plants belonging to the didynamia class; and in the natural method ranking under the 42d order, *Verticillatæ*. See BOTANY *Index*.

GALERICULUM, was a cap worn both by men and women amongst the ancient Romans. It consisted of skin, which was so neatly dressed with human hair, that the artificial covering could scarcely be distinguished from the natural. It was used by those whose hair was thin; and by wrestlers, to keep their own hair from receiving any injury from the nasty oils with which they were rubbed all over before they exercised. It seems to have resembled our wigs.

GALIANI, FERDINAND, an eminent Italian writer. See SUPPLEMENT.

GALIC or *GAELIC Language*. See HIGHLANDS.

GALICIA, a province of Spain, bounded on the north and west by the ocean, on the south by Portugal, and on the east by Asturias and the kingdom of Leon. The air is temperate along the coast; but, in other places, it is cold and moist. It is but thinly peopled; and the produce is wine, flax, and citrons: the soil is unequal, but affords good pasture. St Jago di Compostella is the capital town.

GALILEE, once a province of Judea, now of Turkey in Asia, was bounded by Mount Lebanon on the north, by the river Jordan and the sea of Galilee on the east, by the Chison on the south, and by the Mediterranean on the west. It was the scene of many of our Saviour's miracles; but the bounds of the country are not now well known, nor yet the places where many of the towns stood.

GALILEANS, a sect of the Jews. Their founder was one Judas a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of the emperor Augustus, which had ordered a taxation or enrolment of all the subjects of the Roman empire.

They pretended that God alone should be owned as Master and Lord, and in other respects were of the opinion of the Pharisees; but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

As our Saviour and his apostles were of Galilee, they were suspected to be of the sect of Galileans; and it was on this principle, as St Jerome observes, that the Pharisees laid a snare for him; asking, Whether it was lawful to give tribute to Cæsar; that in case he denied it, they might have an occasion of accusing him.

GALILEO GALILEI, the famous mathematician and astronomer, was the son of a Florentine nobleman, and born in the year 1564. He had from his infancy a strong inclination to philosophy and the mathematics; and made prodigious progress in these sciences. In 1592, he was chosen professor of mathematics at Padua; and during his abode there he *invented*, it is said, the telescope; or, according to others, improved that instrument, so as to make it fit for astronomical observations: (See ASTRONOMY, N° 27.). In 1611, Cosmo II. grand duke of Tuscany, sent for him to Pisa, where he made him professor of mathematics with a handsome salary, and soon after inviting him to Florence, gave him the office and title of *principal philosopher and mathematician to his highness*.

He had been but a few years at Florence, before he was convinced by sad experience, that Aristotle's doctrine, however ill grounded, was held too sacred to be called in question. Having observed some solar spots in 1612, he printed that discovery the following year at Rome; in which, and in some other pieces, he ventured to assert the truth of the Copernican system, and brought several new arguments to confirm it. For these he was cited before the inquisition; and after some months imprisonment, was released upon a simple promise, that he would renounce his heretical opinions, and not defend them by word or writing. But having afterwards, in 1632, published at Florence his "Dialogues of the two greatest systems of the world, the Ptolemaic and Copernican," he was again cited before the inquisition, and committed to the prison of that ecclesiastical court at Rome. In June 22d N. S. that year, the congregation convened: and in his presence pronounced sentence against him and his books, obliging him to abjure his errors in the most solemn manner; committed him to the prison of their office during pleasure; and enjoined him, as a saving penance, for three years to come, to repeat once a-week the seven penitential psalms: reserving to themselves, however, the power of moderating, changing, or taking away altogether or in part, the above-mentioned punish-

 ment

Galileo ‖ Gall.

ment and penance. On this sentence, he was detained a prisoner till 1634; and his "Dialogues of the system of the World" were burnt at Rome.

He lived ten years after this, seven of which were employed in making still further discoveries with his telescope. But by the continual application to that instrument, added to the damage he received in his sight from the nocturnal air, his eyes grew gradually weaker, till he became totally blind in 1639. He bore this calamity with patience and resignation, worthy of a great philosopher. The loss neither broke his spirit, nor hindered the course of his studies. He supplied the defect by constant meditation: whereby he prepared a large quantity of materials, and began to dictate his own conceptions; when, by a distemper of three months continuance, wasting away by degrees, he expired at Arcetti near Florence, in January 1642, N. S. in the 78th year of his age.

Among various useful inventions of which Galileo was the author, is that of the simple pendulum, which he had made use of in his astronomical experiments. He had thought of applying it to clocks; but did not execute it: the glory of that invention was reserved for Vicenzio his son, who made the experiment at Venice in 1649; and M. Huygens afterwards carried this invention to perfection. He wrote a great number of treatises, several of which were published in a collection by Signior Mendessi, under the title of *L'opera di Galileo Galilei Lynceo*. Some of these, with others of his pieces, were translated into English and published by Thomas Salisbury, Esq. in his mathematical collections, &c. in two volumes folio. A volume also of his letters to several learned men, and solutions of several problems, were printed at Bologna in quarto. Besides these, he wrote many others, which were unfortunately lost through his wife's devotion; who, solicited by her confessor, gave him leave to peruse her husband's manuscripts; of which he tore and took away as many as he said were not fit to be published.

GALINACEUS LAPIS. See GALLINACEUS.

GALIUM, a genus of plants belonging to the tetrandia class; and in the natural method ranking under the 47th order, *Stellatæ*. See BOTANY *Index*.

GALL, in the animal economy. See BILE.

Gall was generally given amongst the Jews to persons suffering death under the execution of the law, to make them less sensible of their pain; but gall and myrrh are supposed to have been the same thing; because at our Saviour's crucifixion, St Matthew says, they gave him vinegar to drink mingled with gall; whereas St Mark calls it wine mingled with myrrh. The truth of the matter perhaps is, that they distinguished every thing bitter by the name of gall. The Greeks and Romans also gave such a mixture to persons suffering a death of torture.

A great number of experiments have been made upon the gall of different animals, but few conclusions can be drawn from them with any certainty. Dr Percival, however, hath shown, that putrid bile may be perfectly corrected and sweetened by an admixture of the vegetable acids, vinegar, and juice of lemons. These, he observes, have this effect much more completely than the mineral ones: and hence, he thinks, arises the great usefulness of the vegetable acids in autumnal diseases; which are always attended with a putrescent disposition of the bile, owing to the heat of the preceding summer. On this occasion he takes notice of a common mistake among physicians, who frequently prescribe elixir of vitriol in those diseases where vinegar or lemon juice would be much more effectual.

From this effect of acids on the gall, he also thinks, we may see why the immoderate use of acids is so pernicious to digestion. It is necessary to health that the gall should be in some degree acrid and alkalescent: but as acids have the property of rendering it perfectly mild and sweet, they must be proportionably pernicious to the due concoction and assimilation of the food; which without an acrid bile cannot be accomplished. Hence the body is deprived of its proper nourishment and support, the blood becomes vapid and watery, and a fatal cachexy unavoidably ensues. This hath been the case with many unfortunate persons, who, in order to reduce their excessive corpulency, have indulged themselves in the too free use of vinegar. From the mild state of the gall in young children, Dr Percival also thinks it is, that they are so much troubled with acidities.

GALL-Bladder. See ANATOMY, N° 97.

GALL, in *Natural History*, denotes any protuberance or tumour produced by the puncture of insects on plants and trees of different kinds.

These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed *gall nuts*, and the latter *berry galls*, or *apple galls*.

The general history of the gall is this. An insect of the fly kind (the cynips) is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: she for this purpose wounds the leaves or tender branches of a tree; and the lacerated vessels, discharging their contents, soon form tumours about the holes thus made. The external coat of this excrescence is dried by the air; and grows into a figure which bears some resemblance to the bow of an arch, or the roundness of a kernel. This little ball receives its nutriment, growth, and vegetation, as the other parts of the tree, by slow degrees, and is what we call the *gall nut*. The worm that is hatched under this spacious vault, finds in the substance of the ball, which is as yet very tender, a subsistence suitable to its nature; gnaws and digests it till the time comes for its transformation to a nymph, and from that state of existence changes into a fly. After this, the insect, perceiving itself duly provided with all things requisite, disengages itself soon from its confinement, and takes its flight into the open air. The case, however, is not similar with respect to the gall nut that grows in autumn. The cold weather frequently comes on before the worm is transformed into a fly, or before the fly can pierce through its enclosure. The nut falls with the leaves; and although you may imagine that the fly which lies within is lost, yet in reality it is not so; on the contrary, its being covered up so close, is the means of its preservation. Thus it spends the winter in a warm house, where every crack and cranny of the nut is well stopped up; and lies buried as it it were under a heap of leaves, which preserves it from the injuries of the weather. This apartment, however, though so commodious a retreat in the winter, is a perfect prison in the spring. The fly, roused from its lethargy by the first heats, breaks its way through, and ranges where it pleases. A very small aperture is sufficient, since at this time the fly is but a diminutive creature. Besides, the ringlets whereof its body is composed dilate and become pliant in the passage.

Oak galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or violet colour: which, as it grows stronger, becomes black; and on this property depends the art of making our writing ink, as also the arts of dyeing and dressing leather, and other manufactures. See INK, CHEMISTRY *Index*.

The best galls come from Aleppo: these are not quite round and smooth like the other sorts, but have several tubercles on the surface. Galls have a very austere styptic taste, without any smell: they are very strong astringents, and as such have been sometimes made use of both internally and externally, but are not much taken notice of by the present practice. Some recommend an ointment of powdered galls and hogs lard as very effectual in certain painful states of hæmorrhois; and it is alleged, that the internal use of galls has cured intermittents after the Peruvian bark has failed. A mixture of galls with a bitter and aromatic has been proposed as a substitute for the bark.

GALL, *St*, a considerable town in Swisserland, and in the Upper Thurgow, with a rich and celebrated abbey, whose abbot is a prince of the empire. This place has for some time been a republic, in alliance with the cantons. It is not very large; but well built, neat, and populous. It contains about 10,000 inhabitants, who are chiefly employed in the linen manufacture; and make annually, it is said, 40,000 pieces of linen, of 200 ells each; which renders it one of the richest towns in Swisserland. The inhabitants are Protestants; for which reason there are often great contests between them and the abbey about religious affairs. It is seated in a narrow barren valley, between two mountains, and upon two small streams. E. Long. 2. 59. N. Lat. 47. 38.

Gall-Fly. See CYNIPS, ENTOMOLOGY *Index*.

GALLA, an Abyssinian nation, originally dwelling, as Mr Bruce supposes, under the line, and exercising the profession of shepherds, which they still continue to do. For a number of years, our author tells us, they have been constantly migrating northwards, though the cause of this migration is not known. At first they had no horses; the reason of which was, that the country they came from did not allow these animals to breed: but as they proceeded northward and conquered some of the Abyssinian provinces, they soon furnished themselves with such numbers, that they are now almost entirely cavalry, making little account of infantry in their armies. On advancing to the frontiers of Abyssinia, the multitude divided, and part directed their course towards the Indian ocean; after which, having made a settlement in the eastern part of the continent, they turned southward into the countries of Bali and Dawaw, which they entirely conquered, and settled there in the year 1537. Another division having taken a westerly course, spread themselves in a semicircle along the banks of the Nile; surrounding the country of Gojam, and passing eastward behind the country of the Agows, extended their possessions as far as the territories of the Gongas and Gafats. Since that time the Nile has been the boundary of their possessions; though they have very frequently plundered, and sometimes conquered, the Abyssinian provinces on the other side of the river, but have never made any permanent settlement in these parts. A third division has settled to the southward of the low country of Shoa, which the governor of that province has permitted, in order to form a barrier betwixt him and the territories of the emperor, on whom he scarcely acknowledges any dependence.

The Galla are of a brown complexion, and have long black hair; but some of them who live in the valleys are entirely black. At first their common food was milk and butter; but since their intercourse with the Abyssinians, they have learned to plough and sow their land, and to make bread. They seem to have predilection for the number seven, and each of the three divisions already mentioned is subdivided into seven tribes. In behaviour they are extremely barbarous; and live in continual war with the Abyssinians, whom they murder without mercy as often as they fall into their hands. They cut off the privities of the men, and hang them up in their houses by way of trophies; and are so cruel as to rip up women with child, in hopes of thus destroying a male. Yet notwithstanding their excessive cruelty abroad, they live under the strictest discipline at home; and every broil or quarrel is instantly punished according to the nature of the offence. Each of the three divisions of the Galla above mentioned has a king of its own; and they also have a kind of nobility, from among whom the sovereign can only be chosen: however, the commonalty are not excluded from rising to the rank of nobles if they distinguish themselves very much in battle. None of the nobility can be elected till upwards of 40 years of age, unless he has with his own hand killed a number of enemies which added to his own age makes up 40. There is a council of each of the seven tribes, which meets separately in its own district, to settle how many are to be left behind for the governing and cultivating of the territory, and other matters of importance. These nations have all a great veneration for a tree which grows plentifully in their country, called *wanzey*, and which these superstitious people are even said to adore as a god. Their assemblies for the choice of a king are all held under one of these trees; and when the sovereign is chosen, they put a bludgeon of this wood in his hand by way of sceptre, and a garland of the flowers upon his head.

The Galla are reported to be very good soldiers, especially in cases of surprise; but, like most other barbarians, have no constancy nor perseverance after the first attack. They will, however, perform extraordinary marches, swimming rivers holding by the horse's tail, and thus being enabled to do very great mischief by reason of the rapidity of their movements. They are excellent light horse for a regular army in a hostile country; but are very indifferently armed, on account of the scarcity of iron among them. Their principal arms are lances made of wood sharpened at the end and hardened in the fire; and their shields are composed only of one single fold of bull's hide; so that they are extremely apt to warp by heat, or become too soft

soft in wet weather. They are exceedingly cruel; and make a shrill horrid noise at the beginning of every engagement, which greatly terrifies the horses, and very often the barbarous riders which oppose them.

The Galla, according to Mr Bruce's account, are somewhat below the middle size, but extremely light and nimble. The women are fruitful; and suffer so little in childbearing, that they do not even confine themselves for a single day after delivery. They plough, sow, and reap the corn, which is trodden out by the cattle; but the men have all the charge of the cattle in the fields. In their customs they are filthy to the last degree; plaiting their hair with the guts of oxen, which they likewise twist round their middle, and which by the quick putrefaction occasion an abominable stench. They anoint their heads and whole bodies with butter or grease; in which, as well as in other respects, they greatly resemble the Hottentots. It has been supposed that they have no religion whatever; but Mr Bruce is of opinion that this is a mistake. The wanzey, he says, is undoubtedly worshipped by all the nations as a god; and they have likewise certain stones which are worshipped as gods: besides these, they worship the moon, and some stars, when in certain positions, and at some particular seasons of the year. They all believe in a resurrection; and have some faint notions of a state of happiness, but no idea of future punishment. Some of them to the southward profess the Mahometan religion, but those to the east and west are generally Pagans. All of them intermarry with each other; but will not allow strangers to live among them, though the Moors have at last found out a method of trading safely with them. The commodities they deal in are blue Surat cloths, myrrh, and salt; the last being the most valuable article.

The marriages among the Galla are celebrated with some of the disgusting customs of the Hottentots; and after these ceremonies the bridegroom promises to give the bride meat and drink while she lives, and to bury her when dead. Polygamy is allowed among them; but it is singular, that among these people the women solicit their husbands to take others to their embraces. The reason of this custom is, that the men may have numerous families of children, who may be capable of defending them against their enemies; as the Galla, according to our author, always fight in families, whether against foreign enemies or with one another.

GALLAND, Anthony, a learned antiquarian, member of the Academy of Inscriptions, and professor of Arabic in the Royal College of Paris, was born of poor parents at Rollo, a village in Picardy. Having studied at the Sorbonne and other universities, he travelled into the east; where he acquired great skill in the Arabic tongue, and in the manners of the Mahometans. He wrote several works; the principal of which are, 1. An account of the Death of the Sultan Osman, and the Coronation of the Sultan Mustapha. 2. A Collection of Maxims, drawn from the works of the Orientals. 3. A Treatise on the Origin of Coffee. 4. The Arabian Nights Entertainments, &c.

GALLANT, or Galant, a French term adopted into our language, and signifying polite, civil, and well bred, with a disposition to please, particularly the ladies. It also signifies brave or courageous.

GALLE, the name of several engravers, of whom the principal was Cornelius, who flourished about the 1600. He learned the art of engraving from his father, and imitated his stiff stile, till he went to Rome, where he resided a considerable time, and there acquired that freedom, taste, and correctness of drawing, which are found in his best works. He settled at Antwerp upon his return from Italy, where he carried on a considerable commerce in prints. His best prints are those done after Rubens.

GALLEON, in naval affairs, a sort of ships employed in the commerce of the West Indies. The Spaniards send annually two fleets; the one for Mexico, which they call the *flota*; and the other for Peru, which they call the *galleons*. See Flota.

By a general regulation made in Spain, it has been established, that there should be twelve men of war and five tenders annually fitted out for the armada or galleons; eight ships of 600 tons burden each, and three tenders, one of 100 tons, for the island Margarita, and two of 80 each, to follow the armada; for the New Spain fleet, two ships of 600 tons each, and two tenders of 80 each; and for the Honduras fleet, two ships of 500 tons each: and in case no fleet happened to sail any year, three galleons and a tender should be sent to New Spain for the plate.

They are appointed to sail from Cadiz in January, that they may arrive at Porto Bello about the middle of April; where, the fair being over, they may take aboard the plate, and be at Havannah with it about the middle of June; where they are joined by the flota that they may return to Spain with the greater safety.

GALLEOT, a small galley designed only for chase, carrying but one mast and two pattereroes; it can both sail and row, and has 16 or 20 oars. All the seamen on board are soldiers, and each has a musket by him on quitting his oar.

GALLERIES, in *Gardening*, are certain ornaments made with trees of different kinds; which are very common in all the French gardens, but are seldom introduced into the British ones, especially since the taste for clipped trees has been exploded. For those, however, who may still choose to have them, Mr Miller gives the following directions.

In order to make a gallery in a garden with porticoes and arches, a line must first be drawn of the length you design the gallery to be; which being done, it is to be planted with hornbeam, as the foundation of the gallery. The management of galleries is not difficult. They require only to be digged round about; and sheered a little when there is occasion. The chief curiosity required is in the ordering the fore part of the gallery, and in forming the arches. Each pillar of the porticoes or arches ought to be four feet distant from another, and the gallery 12 feet high and 10 feet wide, that there may be room for two or three persons to walk abreast. When the hornbeams are grown to the height of three feet, the distance of the pillars well regulated, and the ground work of the gallery finished, the next thing to be done is to form the frontispiece; to perform which, you must stop the hornbeam between two pillars for that purpose, which forms the arch. As it grows, you must with your sheers cut off those boughs which outshoot the others. In time they will grow strong, and may be kept in form by the sheers. Portico galleries may be covered with lime trees.

GALLERY, in *Architecture*, a covered place in a house, much longer than broad, and usually in the wings of a building, its use being chiefly to walk in.

GALLERY, in *Fortification*, a covered walk across the ditch of a town, made of strong beams covered over with planks, and loaded with earth: sometimes it is covered with raw hides, to defend it from the artificial fires of the besieged.

GALLERY of a Mine, is a narrow passage or branch of a mine carried on under ground to a work designed to be blown up. See MINE.

GALLERY, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

GALLEY, a kind of low flat-built vessel, furnished with one deck, and navigated with sails and oars, particularly in the Mediterranean. By the Greek authors under the eastern empire, this kind of vessel was called γαλαια and γαλεια; and by the Latin authors of the same time, *galea;* whence, according to some, the modern denomination. Some say it was called *galea*, on account of a casque or helmet which is carried on its prow, as Ovid attests, *de Tristibus*. The French call it *galere;* by reason, they say, that the top of the mast is usually cut in the form of a hat, which the Italians call *galero*. Others derive both *galea*, and *galere*, from a fish by the Greeks called γαλεωτης or ξιφιας, and by us the *sword-fish*, which this vessel resembles. Lastly, Others derive the *galley*, *galea*, *galere*, *galeasse*, &c. from the Syriac and Chaldee *gaul*, and *galin*, a man exposed on the water in a vessel of wood.

The largest sort of these vessels is employed only by the Venetians. They are commonly 162 feet long above, and 133 feet by the keel; 32 feet wide, with 23 feet length of stern post. They are furnished with three masts, and 32 banks of oars; every bank containing two oars, and every oar being managed by six or seven slaves, who are usually chained thereto. In the fore part they have three little batteries of cannon, of which the lowest is of two 36 pounders, the second of two 24 pounders, and the uppermost of two 2 pounders: three 18 pounders are also planted on each quarter. The complement of men for one of these galleys is 1000 or 1200. They are esteemed extremely convenient for bombarding or making a descent upon an enemy's coast, as drawing but little water; and having by their oars frequently the advantage of a ship of war, in light winds or calms, by cannonading the latter near the surface of the water; by scouring her whole length with their shot, and at the same time keeping on her quarter or bow, so as to be out of the direction of her cannon.

The galleys next in size to these, which are also called *half galleys*, are from 120 to 130 feet long, 18 feet broad, and nine or ten feet deep. They have two masts which may be struck at pleasure; and are furnished with two large lateen sails, and five pieces of cannon. They have commonly 25 banks of oars, as described above. A size still less than these are called *quarter galleys*, carrying from 12 to 16 banks of oars. There are very few galleys now besides those in the Mediterranean, which are found by experience to be of little utility except in fine weather; a circumstance which renders their service extremely precarious. They generally keep close under the shore, but sometimes venture out to sea to perform a summer cruise.

GALLEY-Worm, in *Zoology*. See IULUS, ENTOMOLOGY *Index*.

GALLI, in antiquity, a name given to the priests of Cybele, from the river Gallus in Phrygia; but of the etymology of the name we have no certain account. All that we learn with certainty about them is, that they were eunuchs and Phrygians, and that in their solemn processions they danced, bawled, drummed, cut and slashed themselves, played upon timbrels, pipes, cymbals, &c. and driving about an ass loaded with the sacred rites and trumpery of their goddess. When a young man was to be initiated, he was to throw off his clothes, run crying aloud into the midst of their troop, and there draw a sword and castrate himself; after this he was to run into the street with the parts cut off, in his hand, throw them into some house, and in the same house put on a woman's dress.

These priests had the names also of *Curetes*, *Corybantes*, and *Dactyli*. The chief priest was called *Archi-Gallus*. This order of priesthood is found both amongst the Greeks and Romans. See an account of them in *Lucret.* lib. ii. and *Juv.* Sat. vi.

GALLI, the *Gauls*. See GALLIA and GAULS.

GALLI, five small desolate islands on the coast of the Principato Citra of Naples. They are supposed to be the Syrenusæ, or islands once inhabited by the Sirens, which Ulysses passed with so much caution and hazard. Great revolutions, however, have been occasioned in their shape, size, and number, by the effects of subterranean fire; and some learned persons go so far as to assert, that these rocks have risen from the bottom of the sea since Homer sang his rhapsodies; consequently, that those monsters dwelt on some other spot, probably Sicily or Capri. The tradition of Sirens residing hereabouts is very ancient and universally admitted; but what they really were, divested of their fabulous and poetical disguise, it is not easy to discover. See SIREN.

The Sirenusæ were only three in number; and therefore if these and the Galli be the same, two more must have since risen, or the three have been split into five by a subterraneous convulsion. On the largest is a watch-tower, and the next has a deserted hermitage. The principal island is only a narrow semicircular ridge covered with a shallow coat of soil; two other little islands and some jagged rocks just peeping above the waves, correspond with this one so as to trace the outline of a volcanical crater. The composition of them all is at top a calcareous rock, extremely shaken, tumbled, and confused, mixed with masses of breccia, disposed in a most irregular manner; below these is lava, and the deeper the eye follows it the stronger are the marks of fire: below the surface of the water, and in some places above it, the layers are complete blocks of basaltes. Hence it is presumed by some that central fires have heaved up to light the torrefied substances that originally lay near their focus, with all the intermediate strata that covered them from the sea. The layers incline downwards from east to west; the air seems to have forced its way into part of the mass while in fusion, and by checking its workings caused many large caverns.

caverns to be left in it. These islands are uncultivated and uninhabited since the old hermit of St Antonio died. Myrtle covers most of the surface.

GALLIA, a large country of Europe, called *Galatia* by the Greeks. The inhabitants were called *Galli*, *Celtæ*, *Celtiberi*, and *Celtoscythæ*. Ancient Gaul was divided into four different parts by the Romans, called *Gallia Belgica*, *Narbonensis*, *Aquitania*, and *Celtica*. Gallia Belgica was the largest province, bounded by Germany, Gallia Narbonensis, and the German ocean; and containing the modern county of Alsace, Lorraine, Picardy, with part of the Low Countries, and of Champagne, and of the Isle of France. Gallia Narbonensis, which contained the provinces now called *Languedoc*, *Provence*, *Dauphiné*, *Savoy*, was bounded by the Alps and Pyrenean mountains, by Aquitania, Belgium, and the Mediterranean. Aquitania Gallia, now called the *provinces of Poitou*, *Santonge*, *Guienne*, *Berry*, *Limosin*, *Gascogny*, *Auvergne*, &c. was situated between the Garumna, the Pyrenean mountains, and the ocean. Gallia Celtica, or Lugdunensis, was bounded by Belgium, Gallia Narbonensis, the Alps, and the ocean. It contained the country at present known by the names of *Lyonnois*, *Touraine*, *Franche Compté*, *Senenois*, *Switzerland*, and part of *Normandy*. Besides these grand divisions, there is often mention made of Gallia Cisalpina or Citerior, Transalpina or Ulterior, which refers to that part of Italy which was conquered by some of the Gauls who crossed the Alps. By Gallia Cisalpina, the Romans understood that part of Gaul which lies in Italy, and by Transalpina, that which lies beyond the Alps, in regard only to the inhabitants of Rome. Gallia Cispadana, and Transpadana, is applied to a part of Italy conquered by some of the Gauls; and then it means the country on this side of the Po, or beyond the Po, with respect to Rome. By Gallia Togata, the Romans understood Cisalpine Gaul, where the Roman gowns, *togæ*, were usually worn. Gallia Narbonensis was called *Braccata*, on account of the peculiar covering of the inhabitants for their thighs. The epithet of *Comata* is applied to Gallia Celtica, because the people suffered their hair to grow to an uncommon length. The inhabitants were great warriors, and their valour overcame the Roman armies, took the city of Rome, and invaded Greece in different ages. They spread themselves over the greatest part of the world. They were very superstitious in their religious ceremonies, and revered the sacerdotal order as if they had been gods. They long maintained a bloody war against the Romans, and Cæsar resided ten years in their country before he could totally subdue them. See GAUL.

GALLIARD, or GAGLIARDA, a sort of dance anciently in great request; consisting of very different motions and actions, sometimes proceeding *terra à terra* or smoothly along; sometimes capering; sometimes along the room, and sometimes across. The word is French, *galliarde*, or rather Italian; and literally signifies, gay, merry, sprightly." This dance was also called *Romanesque*, because brought from Rome.

Thoinot Arbeau, in his Orchesography, describes it as consisting of five steps, and five positions of the feet, which the dancers performed before each other, and whereof he gives us the score or tablature, which is of six minims, and two triple times.

GALLIARDA, in the Italian music, the name of a tune that belongs to a dance called a *Galliard*. The air of it is lively and in triple time.

GALLIC ACID. See CHEMISTRY *Index*.

GALLICAN, any thing belonging to France; thus the term *Gallican church* denotes the church of France, or the assembly of the clergy of that kingdom.

GALLICISM, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages. With us it is used to denote such phrases or modes of speech in English as are formed after the French idiom.

GALLINACEUS LAPIS, a glossy mineral substance supposed by some to be produced by the operation of volcanic fires; and is thought to be the *lapis obsidianus* of the ancients. See OBSIDIAN, MINERALOGY *Index*.

GALLINÆ, an order of birds. See ORNITHOLOGY *Index*.

GALLINACEOUS, an appellation given to the birds of the order of the gallinæ.

GALLING, or EXCORIATION, in *Medicine*. See EXCORIATION.

GALLING *of a Horse's Back*, a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well garnished with hair, and fit it neatly under the pannel of the saddle, so that the hairy side may be next the horse.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel: anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it with salt butter, or, for want of that with grease: wash the swelling, or hurt, every evening with cold water and soap; and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLINULE. See FULICA, ORNITHOLOGY *Index*.

GALLIPOLI, a sea-port town of Italy, in the kingdom of Naples, and in the Terra-di-Otranto, with a bishop's see. It stands on a rocky island, joined to the continent by a bridge. From the remotest antiquity this was a station so favourable to commerce, that every maritime power wished to secure it; and it is a reproach to government, that nothing has been done to improve its natural advantages: at present, Mr Swinburne informs us, it has neither harbour nor shelter for shipping. Charles II. demolished Gallipoli for its adherence to Frederick of Arragon. The Venetians treated it with great cruelty in the 15th century: and in 1481 it was pillaged by the Turks. To preserve it from future calamities, Charles V. repaired and strengthened its fortifications; and, since that period, it has enjoyed the benefits of peace and trade, which have rendered it the most opulent and gayest town upon the coast, though its inhabitants do not exceed 9000 in number. Consumptions and spitting of blood are rather frequent here, occasioned by the great subtility of the air, which is ventilated from every quarter. The buildings are tolerable, and some of of the churches have good paintings. The cotton trade brings in about 30,000 ducats a-year. Good muslins, cotton stockings, and other parts of apparel, are manufactured here, and purchased by the Provençals; for Gallipoli has no direct trade with the metropolis. Silk and saffron were formerly objects of traffic; but heavy duties and oppression have caused them to be abandoned. The wine of this territory is good; but from dryness of climate, and shallowness of soil, the vintage frequently fails in quantity; and then the Gallipolitans have recourse to Sicily for a supply. Oil is the great support of the place: two thirds of the produce of its olive plantations are exported to France, and the north of Italy; the remainder is sent to Naples, and other ports of the kingdom. Neapolitan merchants, by means of agents settled at Gallipoli, buy up the oils, from year to year, long before an olive appears upon the tree; and the price is afterwards settled by public authority. The Neapolitans sell their oil to the merchants of Leghorn; and, if faithfully served by their factors in Terra di Otranto, ought to double their capital in two years. But, to balance this advantage, they run great risks, pay exorbitant interest, and have frequent bankruptcies to guard against. E. Long. 15. 28. N. Lat. 40. 29.

GALLIPOLI, a sea-port town of Turkey in Europe, in the province of Romania, seated at the mouth of the sea of Marmora, with a good harbour and a bishop's see. It contains about 10,000 Turks, and 7000 Greeks and Jews. The bazar or bezestein, the place where merchandises are sold, is a handsome structure, with domes covered with lead. It is an open place, and has no other defence than a paltry square castle. The houses of the Greeks and Jews have doors not above three feet and a half high, to prevent the Turks riding into their houses. E. Long. 26. 44. N. Lat. 40. 24.

GALLIUM. See GALIUM, BOTANY *Index*.

GALLO, an island of the South sea, near the sea-coast of Peru, in South America, which was the first place possessed by the Spaniards when they attempted the conquest of Peru; it is also the place where the bucaniers used to come for wood and water, and to refit their vessels when they were in these parts. W. Long. 88. 0. N. Lat. 2. 30.

GALLO-Græcia, a country of Asia Minor, near Bithynia and Cappadocia. It was inhabited by a colony of Gauls, who assumed the name of *Gallogræci* because a number of Greeks had accompanied them in their emigration. See GALATIA.

GALLOIS, JOHN, born at Paris in 1632, was an universal scholar, but chiefly noted for having been, in conjunction with M. de Sallo who formed the plan, the first publisher of the *Journal des Sçavans*. The first journal was published January 5. 1665; but these gentlemen criticised new works so rigorously, that the whole tribe of authors united and cried it down. De Sallo declined entirely after the publication of the third number: but Gallois ventured to send out a fourth, on January 4. 1666; though not without a most humble advertisement at the beginning, wherein it was declared, that the author "would not presume to criticise, but simply give an account of the books." This, with the protection of M. Colbert, who was greatly taken with the work, gradually reconciled the public to it: and thus began literary journals, which have been continued from that time to this, under various titles, and by various writers. Gallois continued his journal to the year 1674, when more important occupations obliged him to turn it over to other hands. M. Colbert had taken him into his house to teach him Latin; and when he lost his patron in 1683, he was first made librarian to the king, and then Greek professor in the royal college. He died in 1707.

GALLON, a measure of capacity both for dry and liquid things, containing four quarts. But these quarts, and consequently the gallon itself, are different, according to the quality of the things measured: For instance, the wine gallon contains 231 cubic inches, and holds eight pounds avoirdupois of pure water; the beer and ale gallon contains 282 solid inches, and holds ten pounds three ounces and a quarter avoirdupois of water; and the gallon for corn, meal, &c. 272$\frac{1}{4}$ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOP, in the manege, is the swiftest natural pace of a horse, performed by reaches or leaps; the two fore feet being raised almost at the same time; and when these are in the air, and just ready to touch the ground again, the two hind feet are lifted almost at once. The word is borrowed from the barbarous Latin *calupare*, or *calparc*, "to run." Some derive it from *caballicare*; others from the Greek καλπαζειν, *to spur a horse.*

GALLOPER, in artillery, is the name of a carriage which serves for a pound and a half gun. This carriage has shafts so as to be drawn without a limber, and is thought by some to be more convenient and preferable to other field carriages; and it may likewise serve for our light three and six pounders.

GALLOWAY, a county of Scotland, which gives the title of Earl to a branch of the noble family of Stuart. It is divided into two districts; the western, called *Upper Galloway*, being the same with Wigtonshire; and the eastern, or stewartry of Kirkcudbright, called *Lower Galloway*. See KIRKCUDBRIGHT and WIGTONSHIRE.

MULL of Galloway, the most southerly cape or promontory of Scotland, in the county of Galloway, and on the Irish sea.

GALLOWAYS is the name of a peculiar sort of horses, so called from the county of Galloway in Scotland, where they are bred. Tradition reports that this kind of horses sprang from some Spanish stallions, which swam on shore from some of the ships of the famous Spanish armada, wrecked on the coast; and coupling with the mares of the country, furnished the kingdom with their posterity. They were much esteemed, and of a middling size, strong, active, nervous, and hardy.

GALLOWS, an instrument of punishment, whereon persons convicted capitally of felony, &c. are executed by hanging.

Among our ancestors it was called *furca*, "fork;" a name by which it is still denominated abroad, particularly in France and Italy. In this latter country, the reason of the name still subsists; the gallows being a real fork driven into the ground, across the legs whereof

whereof is laid a beam, to which the rope is tied. See FURCA.

GALLUS, CORNELIUS, an ancient Roman poet, born at Forum Julium, now called *Frejus* in France. He was a particular favourite with Augustus Cæsar, who made him governor of Egypt: but his maladministration there occasioned his banishment, and the loss of his estate; for grief of which he put an end to his own life. He wrote four books of love elegies; and Virgil has complimented him in many places.

GALLUS, or *Cock*. See PHASIANUS, ORNITHOLOGY *Index*.

GALLY, in printing, a frame into which the compositor empties the lines out of his composing-stick, and in which he ties up the page when it is completed.

The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom called a *gally slice*.

GALVANI, LEWIS, was born at Bologna in Italy, in the year 1737. There many of his relations had arrived at distinguished eminence in jurisprudence and divinity, and he himself had the honour of giving his name to a supposed new principle in nature, which of consequence is called *Galvanism*, although this great man gave it the name of *animal electricity*. From a boy he became enamoured of the greatest austerities of the Catholic religion, and joined himself to a convent, the monks of which were celebrated for their attachment to the solemn duty of visiting the dying. He wished much to become a member of this order, but was prevailed on to relinquish the idea by one of the brotherhood, after which he turned his whole attention to the study of medicine in its various branches. He studied under Beccari, Tacconi, Galli, and in a particular manner Galleazzi, who took him into his own house; and he afterwards became his son-in-law. He acquired great reputation by his inaugural thesis, *De Ossibus*, in 1762, and was soon after chosen public lecturer in the university of Bologna, and reader in anatomy to the institute of that city. So much admired was his talent for lecturing, that vast numbers constantly attended him; and he employed his few leisure hours in making experiments, and in the useful study of comparative anatomy. We find in the Memoirs of the Institute of Bologna, a number of curious observations on the urinary organs, and on the organs of hearing in birds.

Soon after his anatomical and physiological knowledge was fully established throughout the Italian schools, a mere accident led him to that interesting discovery which will transmit his name with honour to the latest posterity. His amiable wife, for whom he cherished the most ardent love, and with whom he had been united for a number of years, was in a declining state of health, and was using a soup of frogs by way of restorative. Some of these animals being skinned for this purpose, were lying on a table in Galvani's laboratory, where also stood an electrical machine. One of those who assisted him in conducting his experiments, unintentionally brought the point of a scapel near the crural nerves of a frog which lay near the conductor, when the muscles of the limb were very strongly convulsed. Madame Galvani, who was a woman of a penetrating understanding, and a lover of science, happened to witness the phenomena, of which she instantly informed her husband. On his arrival he repeated the experiment, and discovered that the convulsions only happened when the scapel was in contact with the nerve, and a spark was drawn from the conductor at the same time. After an almost endless variety of experiments, conducted with great ingenuity, which it would be foreign to the design of this article to enumerate here, he concluded that all animals have within them an electricity of a peculiar nature; that this fluid is contained in most parts, but is most apparent in the nerves and muscles; that it is secreted by the brain, and diffused by the nerves through various parts of the body.

He compared each muscular fibre to a small Leyden phial, and attempted to explain the phenomena of muscular motion by analogies taken from that instrument. He first thought of its pathological influence in regard to rheumatic, convulsive, paralytic, and other nervous affections. His first publication on this grand discovery was entitled *Aloysii Galvani de viribus Electricitatis in Motu Musculari Commentarius*, which made its appearance in 4to, in the year 1791, and was printed for the Institute of Bologna. By this work the attention of philosophers both in Italy and other countries was instantly roused, and it was soon followed by numerous publications, in some of which the sentiments of Galvani were defended, and in others they were opposed. The celebrated Volta turned his attention to the subject, and adduced a number of arguments to prove that Galvani's opinion respecting animal electricity was erroneous, deriving the phenomena from the electric matter of the atmosphere, and allowing the nerves and muscles no higher place than that of the most sensible tests hitherto discovered. The doctrine of Volta received many admirers and advocates; yet there are still numbers to be met with in the learned world who support the sentiments of Galvani, who still adhere to his original theory, in the defence of which he displayed much candour and modesty, as well as ingenuity, by which he may be justly considered as deserving that distinguished place among the experimental philosophers, which the union of his name with the most interesting natural phenomena will probably secure to him for ever. See GALVANISM.

These important inquiries, joined to the duties of his office as a professor, and his extensive practice in the capacity of surgeon and man-midwife (*accoucheur*), in both which he eminently excelled, afforded abundant scope for his indefatigable industry. He composed a variety of memoirs on topics connected with his profession; but these, as far as we know, have never been published. He delighted to converse with men of science, in whose company new publications were read, and their merits investigated, which was certainly a valuable source of intellectual improvement.

The character of Galvani in private life is allowed to have been most amiable; and his sensibility, which was naturally strong, received a violent shock in the death of his amiable wife, in the year 1790. This event brought upon him the most alarming melancholy, which he even delighted to encourage, by visiting her tomb in the nunnery of St Catharine, and pouring forth his unavailing lamentations over her grave. He was ever punctual in the discharge of the duties of his religion, even

Galvani.

even to the minutest rite, as he never lost the pious impressions which were made upon his mind at an early period of life. To this cause we may probably trace back his determination never to take what was called the civic oath of allegiance to the Cisalpine republic, for which he was barbarously deprived of all his offices and dignities. Devoured by melancholy, and nearly reduced to a state of indigence, he took up his residence in the house of his brother James, a man of respectability, where he fell into a state of extenuation and debility. At this time even *republican* governors appear to have been ashamed of their brutal conduct towards such an extraordinary man; in consequence of which a decree was passed for restoring him to his chair in the university, together with its emoluments; but this fit of generosity was too long in seizing them. He departed this life on the 5th of November, 1798, in the 61st year of his age, amidst the tears of his friends, and the regret of the public, in whose death the learned world has been deprived of one of its brightest ornaments.

GALVANISM.

Experiment showing

If two pieces of metal, the one of zinc, and the other of silver, or the one of zinc and the other of copper, or, what answers the purpose equally well, a penny piece and a half crown piece, be so placed that the one shall touch the upper surface of the tongue, and the other shall touch its under surface, while the edges project over the point; as often as the edges of the metals in this situation are brought into contact, a peculiar sensation is produced in the tongue; there is something like a slight shock of electricity, and there is perceived at the same time an austere, astringent, or metallic taste.

If a bit of tin-foil be placed on one of the eyes, and a bit of copper held between the teeth or touching the tongue, and a communication be formed by means of a wire between the piece of metal on the eye and that on the tongue, a flash of light is seen, and this is produced as often as the communication is completed. But, in the above experiments, if metals of the same kind be employed, no perceptible effect whatever is produced.

If a pile composed of 50 or 60 pairs of plates of zinc and silver, or zinc and copper, be arranged in a regular series, with pieces of cloth moistened in a solution of common salt placed between each pair; and if one hand, previously moistened with water, touch the lower pair, and the other hand, also moistened, touch the upper pair of plates, the moment the communication between the bottom and top of the pile is completed, a smart shock is felt; and if 50 or 60 pairs of plates of copper and zinc be arranged in a trough as will be afterwards described, and the spaces between the pairs be filled with water, to which about $\frac{1}{10}$th of pretty strong nitric acid has been added, a similar shock is perceived, when the hands wetted with water touch the plates at the extremities of the trough. If a communication by means of wires and two pieces of well-prepared charcoal be made between the extremities of the trough, a very brilliant combustion is excited every time the two pieces of charcoal are brought into contact. By placing tin-foil, gold leaf, white or yellow Dutch metal or brass leaf, on a wire connected with one end of the trough, and touching the metallic leaves with a plate of copper or zinc connected with a wire from the other end of the trough, a rapid and brilliant deflagration is exhibited every time that the communication is effected.

2
What is understood by galvanism.

The phenomena which are thus produced have received the name of *Galvanism*, from the name of Galvani, who first observed and published an account of some of them, and the power by which these effects are produced has been denominated the *galvanic power* or *fluid*. From its effects on animals being similar to those of the electrical fluid, it was at first called *animal electricity*; but then the knowledge of galvanism was limited to its effects on animals, and it was supposed to depend on something peculiar to animal life.

In the following treatise we propose to give a view of the progress and present state of galvanism; and for this purpose we shall arrange the whole under two great divisions. Under the first, we shall consider the phenomena of galvanism, or detail the facts which have been ascertained with regard to this power. The second part will be occupied in the history, progress, and theories, which have been held with regard to the nature of galvanism.

PART I. OF THE PHENOMENA OF GALVANISM.

Arrangement.

IN treating of the phenomena of galvanism, its progressive history suggests an arrangement sufficiently convenient for taking a view of the effects of the galvanic fluid. Those effects, which are to be regarded as strictly chemical, were altogether unknown, till after its application to animals, and a great mass of facts relative to its effects on animal life had been accumulated. We may therefore first consider the effects produced on animals by the operation of the galvanic fluid, and in the next place those effects which are strictly chemical. But before we proceed to this, it is necessary that the nature and construction of the apparatus, by which these effects were produced, should be understood. These topics, therefore, shall be the subjects of the three following chapters. In the first we shall treat of the construction of the apparatus by which the phenomena of galvanism are produced; the second will be employed in considering the effects of the galvanic fluid on animals; and the third will comprehend a view of its chemical effects.

Construction of Apparatus.

Chap. I. *Of the Construction of the Apparatus for exhibiting the Phenomena of Galvanism.*

4 Apparatus at first simple.

On the first discovery of galvanism, the apparatus for exhibiting its effects was extremely simple. It consisted merely of two pieces of different metals, such as has been described above, by which a peculiar sensation is produced on the tongue. This, it has been stated, is effected by means of a piece of zinc and a piece of copper, the one placed on the upper surface, and the other on the under surface of the tongue, while the projecting edges are brought into contact. In the same way, and with such an apparatus, a great variety of experiments, especially in cold-blooded animals, were exhibited, when the knowledge of this remarkable power was first announced and investigated.

Plate CCXXIX. fig. 1.

For the purpose of exhibiting some of the simpler effects of galvanism, we shall describe the following apparatus, which is of very easy construction. AB, fig. 1. is zinc wire, sharp at the point A, and fixed in the wooden stand C. If the frog prepared in the way which we shall immediately describe, be fixed on the point of the wire at A, and a gold or a silver wire (a silver tea spoon will answer the purpose) be brought into contact with the side of the wire as at the point D; and while in contact with the wire at D, it is brought into contact with the feet of the frog at E or F, the effect of the galvanic power will be immediately perceived. The limbs of the animal will be strongly convulsed, and will exhibit as much motion by the contraction of the muscles as if it were alive, and in full vigour. But if a zinc wire, similar to AB, were substituted for the gold or silver wire, no such effect would be produced.

5 Methods of preparing frogs for experiments.

Frogs, as they are most easily found, and as they are, perhaps, more convenient in other respects, have been oftener the subject of galvanic experiments than any other animal. To prepare them for these experiments, various methods have been followed. Some physiologists propose to remove only the integuments, and lay bare the muscles, while others open the cavities of the thorax and abdomen, remove the viscera which are contained in these cavities, and bring into view the nerves and muscles which are there distributed. Some again, after the above previous preparation, separate all the parts between the origin of the nerve and its insertion in the muscle, so that the latter may be attached by means of the nerves only, to the trunk of the body; while others, after a similar preparation, cut off the animal's head, that the effects produced by galvanism may not be confounded with the voluntary movements of the living animal. By another mode of preparation, each of the parts is separated from the body by dissection, after laying bare the muscles and nerves.

But in general a frog is understood to be prepared when it is divided with a pair of scissars into two portions, through the middle of the body and spine. The viscera are then removed, as well as the integuments of the inferior extremities. As the sciatic nerves of this animal rise very high upon the spine, they are distinctly seen after this treatment. When it is intended, as in some experiments, to arm the nerves, as it is called, a pair of sharp-pointed scissars is introduced beneath them, and the spine is cut through, but without dividing the nerves. A portion of the inferior part of the spine is afterwards to be separated, that room may be left for covering the nerves with a bit of tin-foil. This is what is usually understood by arming or coating the nerves. In some experiments it will be found more convenient to separate the lower extremities from the trunk, and to employ the crural nerve.

Construction of Apparatus.

Phenomena similar to the above may be produced by placing a frog A prepared in the way described above, on a plate of zinc B, fig. 2. and on a plate of silver or copper C. If the communication between the plates A and B be completed by means of the conductor D, the muscles of the frog are immediately thrown into strong convulsions, and these motions are renewed as often as the contact is made by the conducting wire and the two metals. Fig. 2.

6 Single galvanic combination.

The apparatus we have now described affords an example of the simplest galvanic combination, or what is usually denominated a single galvanic combination. Here it may be observed, that this combination must consist of three different conductors. The conductors of electricity have been arranged into two principal classes: to the first belong the metallic substances and charcoal, which have been otherwise called dry and perfect conductors; the second class consists of the imperfect conductors, which are water and other oxidating fluids, and the substances which contain these fluids. But although the conductors of electricity, for the sake of conveniency, are thus arranged, they differ from each other in their conducting power, and this difference is greatest among the substances comprehended under the second class. Now, if the three conductors of the galvanic fluid be all of the first class, or all of the second, the effect is scarcely perceptible. An active, simple galvanic combination, then, must consist of three different bodies, one conductor must belong to one class, and two different conductors must be taken from the other class. In fig. 3. and 4. are exhibited examples of active simple galvanic combinations. In fig. 3. the letters AB mark the bodies belonging to the first class or perfect conductors; and *a* marks the body belonging to the second class, or imperfect conductors; and in fig. 4. A marks one body belonging to the first class, and *a b* two bodies belonging to the second class, or the imperfect conductors. Of the three bodies forming a galvanic combination, if two of them belong to the first class, and one to the second, this combination is said to be of the first order; but if one of the three bodies only belong to the first class, and two to the second, the combination is said to be of the second order. Fig. 3. is a galvanic combination of the first order, and fig. 4. is one of the second. This may be further illustrated by examining fig. 5, 6, 7, which consist of two bodies only, and therefore are not active combinations; and also by examining fig. 8 and 9. which consist of three bodies, but two of them are of the same kind, and therefore act as a single body. In the last five figures, the capital letters denote the bodies belonging to the first class, and the small letters those belonging to the second. Fig. 3 and 4. Fig. 8, 9.

In the single active galvanic combination, or the simple galvanic circle, the two bodies of one class must be in contact with each other in one or more points, while, at the same time, they are connected together at other points

points with the body belonging to the other class. Thus, if a prepared frog is convulsed by the contact of the same piece of metal in two different places, the fluids of those parts, which must be somewhat different from each other, are the two conductors of the second class, and the metal constitutes the third body for the conductor of the first class. But if two metals be employed, the fluids of the prepared animal differing little from each other, are to be considered as one body of the second class.

Here it may be necessary to anticipate a little, by observing, that in a simple galvanic circle, the conductor or conductors of one class must have some chemical action upon the other conductor or conductors, otherwise no galvanic action would be produced, or at least a very feeble one, from the combination of three bodies. This galvanic action, too, seems to be in proportion to the degree of chemical action, from which some have supposed, that this chemical agency is the primary cause of the phenomena.

It is found that the most active galvanic combinations, or galvanic circles belonging to the first order, are those in which two solids possessing different degrees of oxidability, are combined with a fluid which is capable of oxidating at least one of the solids. Gold, silver, and water, do not form an active galvanic combination, because water is incapable of oxidating either of these metals; but if a small quantity of nitric acid, or any other fluid which may be decomposed by the silver, be mixed with water, an active galvanic circle may thus be formed.

If zinc, silver, and water, or zinc, copper, and water, be combined together, an active galvanic circle is formed, and the water will be found to oxidate the zinc, if it hold any portion of atmospherical air in solution, and still more so, if it contain oxygen. But the combination of the same substances forms a much more powerful galvanic circle, if a little nitric acid be added to the water, because then the fluid has a strong action on the zinc, and oxidates it.

Galvanic combinations belonging to the second order are found to be most powerful, when two conductors of the second class have different chemical actions on the conductors of the first class, while at the same time they have an action upon each other. As an example of this, copper, silver, or lead, combined with a solution of an alkaline sulphuret, and diluted nitric acid, constitute a very active galvanic circle.

The following is a list of galvanic circles of the first order, composed of two conductors of the first class, and one of the second.

Zinc with gold, or charcoal, or silver, or copper, or tin, or iron, or mercury; and water containing a small quantity of any of the mineral acids.

Iron, with gold, or charcoal, or silver, or copper, or tin, and a weak solution of any of the mineral acids, as above.

Tin, with gold, or silver, or charcoal, and a weak solution of any of the mineral acids, as above.

Lead, with gold, or silver, and a weak acid solution, as above.

Any of the above metallic combinations, and common water, viz. water containing atmospherical air, or especially water containing oxygen air.

Copper, with gold, or silver, and a solution of nitrate of silver and mercury; or the nitric acid; or the acetous acid.

Construction of Apparatus.

Silver, with gold, and the nitric acid.

9 Of the second order.

The following is a list of galvanic circles of the second order, consisting of one conductor of the first class, and two of the second.

Charcoal, or Copper, or Silver, or Lead, or Tin, or Iron, or Zinc,	with water, or with a solution of any hydrogenated alkaline sulphurets, capable of acting on the first three metals only;	and a solution of nitrous acid, or oxygenated muriatic acid, &c. capable of acting upon all the metals.

But the effects of the galvanic fluid are extremely feeble, when they are limited to the operation of even the most powerful simple combinations. In the progress of the knowledge of galvanism it was soon found, that these effects might be combined and increased to almost any degree. This is done by connecting together a number of active simple combinations, which, it is to be observed, must be so disposed that they may not counteract each other. A number of simple combinations thus connected together have received the name of *batteries;* and these batteries are said to belong to the first and second order, according as the simple combinations of which they are formed, are composed of substances of the first or second order of conducting powers. Thus, for example, if a plate of zinc be laid upon a plate of copper, and a piece of moistened card or leather be laid upon the zinc, and a similar arrangement of three other pieces be laid upon the first, and any number of combinations of the same kind be continued, taking care that they are always arranged in the same order, the whole will form a battery of the first order. But if a plate of copper be connected with a piece of cloth moistened with water, and the latter with another piece of cloth, moistened with a solution of sulphuret of potash, and this be connected with another piece of copper, repeating the same series to any convenient number, a battery of the second order will be formed of the whole.

10 Batteries.

Batteries of the second order have been arranged by Mr Davy into the three following classes. 1. The most feeble battery is composed, when single metallic plates are so arranged that two of their surfaces or opposite extremities are in contact with different fluids, the one of which is capable, and the other is incapable, of oxidating the metal, a regular series of such combinations are formed. 2. When single combinations or elements of the series are each composed of a single plate of a metallic substance, capable of acting upon sulphurated hydrogen, or upon sulphurets dissolved in water, accompanied with portions of a solution of sulphuret of potash on one side, and water on the other. 3. The third class is the most powerful, being formed when metallic substances oxidable in acids, and capable of acting on solutions of sulphurets, are connected as plates with oxidating fluids, and solutions of sulphuret of potash, and so arranged that the opposite sides of every plate may undergo different chemical changes, the mode of alteration being regular.

11 Couronne de tasses.

The first attempt to increase the effects of the galvanic fluid, by combining a series of simple circles, was made by Volta; to this he gave the name *couronne de tasses.*

Construction of Apparatus.

tasses. The following is the construction and mode of applying this apparatus.

Fig. 10.

Take any number of cups or glass tumblers A, B, C, D, E, fig. 10. Fill them about three-fourths full with any of the saline solutions, which will be afterwards described, as that of common salt or sal ammoniac in water. To one extremity of a bent brass wire solder a plate of zinc of about two inches in diameter, and to the other extremity of the same wire, solder in the same manner a plate of copper of the same diameter. These connecting wires are represented in the figure by the letters *a*, *a*, *a*, *a*; and the plates of the different metals are marked with the letters Z and C, viz. zinc and copper. In arranging the plates in the vessels, it ought to be observed, that a plate of zinc and a plate of copper belonging to different wires, must be in the same vessel, and never two plates of the same kind. Thus in the first vessel A, there is a plate of copper; in the second B, connected by the same wire, there is a plate of zinc; in the same vessel B, there is also a plate of copper, which is connected by means of another wire to a plate of zinc in the third vessel C. The same order and arrangement are to be observed to whatever number of plates and vessels the series may extend.

Suppose now that the apparatus has been arranged in the way described above, and the vessels have been filled with a solution of common salt in water; if the number of vessels be not less than ten or twelve, a slight shock will be felt by immersing one hand in the vessel, at one extremity of the series, and the other hand in the vessel at the other extremity; as for instance, by putting the fingers of one hand in the vessel A, fig. 10. and suddenly plunging the fingers of the other hand in the vessel E. The shock will perhaps be more sensibly felt by previously wetting the palms of both hands, and taking a silver or pewter spoon in each hand, immerse the handle of the one into the vessel A, and the handle of the other into the vessel E.

The strength of this apparatus depends on the number of series of plates and vessels employed. But it is obvious that this series, from the nature of the apparatus, could not be greatly extended, so as to afford any great increase of power. This occurred very early to the ingenious discoverer, as an insurmountable objection to the use of this apparatus. The views of this philosopher in investigating the nature of galvanism, seem at this time to have been chiefly directed to the discovery of instruments or apparatus, by means of which he might be enabled to augment its power. In the prosecution of his inquiries, therefore, he contrived another apparatus, which was afterwards known by the name of the galvanic pile, and sometimes, but more rarely, by that of the voltaic pile or pile of Volta, from the name of the discoverer. This apparatus is constructed in the following manner.

12
Pile of Volta.

A pile of moderate strength may be constructed of 60 pairs of plates of zinc and copper, each plate being about two inches diameter; it may be constructed also with similar plates of zinc and silver, or of almost any two other dissimilar metals. Such piles have been very conveniently constructed, with half crown pieces and plates of zinc of the same size, or more conveniently with penny pieces and plates of zinc of the same diameter. But of whatever different metals this kind of apparatus is to be constructed, the same order of arrangement is to be observed throughout the whole series.

Suppose the metals to be employed in the construction of the pile are zinc and copper, (and these from views of economy have been most frequently employed), an equal number of pieces of cloth, pasteboard, or leather, of the same diameter with the metallic plates, is to be prepared. The use of these pieces of cloth is to retain the moisture, by means of which the communication between the plates is formed, and the galvanic combinations are completed; and in proportion to the length of time during which the pieces of cloth or other substances retain the fluid which they have absorbed, the operation of the pile continues. The pile is formed by placing a pair of plates, one of zinc, and one of copper, upon a stand, the one immediately above the other. Upon this pair of plates is then placed a piece of cloth which has been soaked in some saline solution, as that of common salt, or sal ammoniac. Upon this piece of cloth is placed another pair of plates, arranged in the same order as the first pair. It makes no difference which of the metals is placed first in the series, only it is necessary to take care that the same order be observed throughout the whole pile. If the series, for instance, begins with copper, it runs in the following order: copper, zinc, cloth; copper, zinc, cloth, &c. to whatever number of pairs of plates and pieces of cloth the series may extend.

But if the number of series amount to 60 pairs, it will be necessary to have rods to confine the pairs of plates, and to retain them in a perpendicular column; for without this the weight at top would be so considerable that the least inclination to one side (and this could not well be avoided) would derange the whole apparatus. The rods which have been employed for this purpose have been sometimes made of glass, and sometimes of wood. When wood is used, it should be pretty dry, or baked, by which means its conducting power is either greatly diminished or entirely destroyed.

The pile being constructed in this manner, its effects may be observed, by applying the fingers of one hand moistened with water to the lowest pair of plates, and then touching with the fingers of the other hand, moistened in the same manner, the upper pair of plates, thus completing the communication between the extremities of the pile. Every time that this communication is made, a sensation is experienced, similar to a slight shock of electricity. The intensity of this shock is in proportion to the number of the pairs of plates, the nature of the fluid employed, and the care with which the pile has been erected, or the time that it has continued in action. With a pile of 60 pairs of plates, the shock will be perceptible through the fingers, or the whole of the hand, and in some persons, when it is in full activity, it will extend as high as the elbows.

In making experiments with this kind of apparatus, it will be found that 50 or 60 pairs of plates will be a sufficient number to be erected in one pile; but to increase the power of the galvanic fluid, a number of piles may be connected together. This may be done in two ways; either by combining the separate action of the different piles employed; as, for instance, if three piles are constructed, let the pairs of plates be arranged in

Construction of Apparatus.

in each exactly in the same way, and let the conducting substances, as wires, pass from the top and bottom of each to one common conductor. In this case we have the action of three different currents of the galvanic fluid; but whatever number of piles may be employed, their mutual action may be so combined, that the whole effect may be produced by one single current. Suppose the metallic plates of one pile are arranged in the following order; copper, zinc, cloth; copper, zinc, cloth, &c.: then the plates of the second must be arranged in a different order, namely, zinc, copper, cloth; zinc, copper, cloth, &c. and the plates of the third in the same way as the first, viz. copper, zinc, cloth; copper, zinc, cloth, &c. The three piles being thus arranged, let a metallic conductor, as a slip of copper or zinc, be placed between the tops of the first and second pile, and a similar conductor be placed between the bottom of the second and third piles; and when they are thus connected together, let the fingers of one hand, moistened, be placed at the lowest pair of plates of the first pile, and the fingers of the other hand, also moistened, be brought in contact with the upper pair of plates of the third, a violent shock will be felt. The shock will be the same as if the whole number of pairs of plates of which the three piles are composed were formed into a single pile; for the same order of arrangement being observed from the bottom of the first pile to the top, and from the top of the second pile to the bottom, and again from the bottom of the third pile to the top, the current passes uninterruptedly through the whole series, as if it were uniformly arranged in one pile.

The effects of this apparatus may be farther observed in its chemical action. If the circle is completed, or the communication between the extremities of the apparatus by means of charcoal be formed, a spark is produced. This is done by attaching a piece of well prepared charcoal to a wire which communicates with one extremity of the apparatus, and another similar piece of charcoal to another wire communicating with the other extremity; if the two pieces of charcoal be brought into contact, thus completing the circle, a spark will be observed, and this may be repeated as long as the activity of the pile continues. The chemical effects of such an apparatus are also exhibited in the decomposition of water. The apparatus for effecting this decomposition, and the method of using it, will be afterwards described.

But it was soon found that the effects of this pile, although when it is first erected it possesses considerable energy, in a very short time it becomes extremely feeble, and at last altogether imperceptible. This is owing to the pieces of cloth or other substance which is interposed between the pairs of plates being deprived of their moisture, either by evaporation, or by being squeezed out, from the weight of the plates. The latter effect, it is obvious, must be in proportion to the height, and consequently the incumbent pressure of the upper on the lower part of the pile; and besides this, the liquid as it oozes out, trickles down the sides of the pile, so that the different pairs of plates are less perfectly insulated than they otherwise ought to be, to produce the full effect.

Various contrivances were thought of to obviate these inconveniences, and the first which was proposed was announced by the ingenious inventor of the pile himself. Volta inclosed his piles, after they were erected, with wax or pitch. By this contrivance which he put in practice on two columns or piles, each consisting of 20 plates, he succeeded so far in preventing the inconveniences alluded to above, that their effects continued nearly undiminished for several weeks. By other contrivances the plates and pieces of cloth or pasteboard were arranged horizontally, by which means some of the inconveniences of the upright column were avoided; among these the unequal pressure was removed, but still it was found that the evaporation continued, so that it was not long before its operation began to diminish, and at last to be entirely interrupted.

As it was found that the chemical effects of the pile were greatly increased by employing plates of a larger surface, even when the number was greatly diminished, piles were erected both on the continent and in Britain, with plates from 10 to 14 inches square. Twelve or fourteen pairs of plates of the above size, arranged in the same way as those which have been already described, produced very considerable chemical effects, such as burning phosphorus, setting fire to gunpowder, and deflagrating gold and silver leaf. The pieces of thick cloth or pasteboard moistened with water, to which a certain proportion of nitric acid was added, were usually employed in the construction of this pile; but it is unnecessary to mention that it was attended with similar inconveniences to those which accompanied the smaller pile. These inconveniences probably led to another and more effectual contrivance for exhibiting the effects of galvanism. But before we give an account of these, we shall farther illustrate the nature and construction of the pile with an explanation of fig. 11. and 12.

Fig. 11.

Fig. 11. is a representation of a pile composed of copper, zinc, and pieces of pasteboard, soaked in some saline solution. The pile is erected on the stand A, and the different parts of which it is composed are retained in their perpendicular position by means of the three rods made of glass or baked wood, *b*, *b*, *b*. The pieces of metal are marked *c*, *z*, and the pasteboard *p*, in the order in which they are placed. The pile being erected from bottom to top in the same order, let a piece of wire *e* be inserted under the lower pair of plates, and let another wire *f*, be kept in contact with the upper surface of the upper pair of plates; the different parts being thus disposed, if the fingers of one hand moistened be brought in contact with the wire *e*, and the fingers of the other hand, also moistened, be brought in contact with the wire *f*, a shock will be felt, and thus it will be found that the energy of the pile will continue till the moisture of the pieces of pasteboard has evaporated, or the peculiar change which takes place on one of the metals during its action, and which will be taken notice of afterwards, has been effected.

Fig. 12.

Fig. 12. exhibits a view of a combination of three piles, A, B, C. In the column A the arrangement is copper, zinc, pasteboard; copper, zinc, pasteboard, &c.: in the column A, this arrangement is reversed, from the bottom of the column, which is zinc, copper, pasteboard; zinc, copper, pasteboard, &c.; because it must be the same as if the column B were placed upon the top of the column A, the points A and B being brought into

Construction of Apparatus.

into contact, only having a piece of pasteboard interposed. The third column C is arranged in the same manner as the column A, viz. copper, zinc, pasteboard; copper, zinc, pasteboard, &c. Thus, then, the three columns are so arranged, that the different series succeed each other from the bottom of column A to the top, from the top of column B to the bottom, and from the bottom of column C to the top, as if the whole had been disposed in one column A. A communication is then formed between the top of the column A and the top of column B, by a metallic conductor D, and between the bottom of column B, and the bottom of column C, by means of the metallic conductor E. If then the fingers of one hand moistened are brought into contact with the wire F, which communicates with the bottom of column A, and the fingers of the other hand also moistened are brought into contact with the wire G, a smart shock will be felt, from the combined action of the three columns or piles.

The inconveniences of the pile, as we have already hinted, were soon felt by those who were eager in the investigation of galvanism, and who wished their experiments to continue with undiminished energy, that they might be enabled to ascertain with precision the new and curious facts which presented themselves. These inconveniences, it is very probable, suggested the improvements in galvanic apparatus which we are now to describe.

13 Galvanic trough.

By the invention of the trough, for which we are indebted to the ingenuity of Mr Cruikshank of Woolwich, the progress of galvanism became rapid and brilliant; for by this means philosophers were enabled not only to give a longer duration to their experiments, but to command a degree of energy in the galvanic fluid, which, before the discovery of this apparatus, was not even suspected. This apparatus, we believe, is now almost universally employed for galvanic experiments. We shall therefore give a more detailed account of the method of constructing and using it.

Troughs with plates of various sizes have been constructed, from 2 to 6, 8, and even 14 inches square; but, as an example, we shall suppose the following trough to be constructed with plates of about four inches square. A wooden trough AB, fig. 13. is to be made of baked mahogany; the length may be about 30 inches, and, as we shall suppose the number of pairs of plates to be 50, an equal number of grooves is to be cut on the sides and bottom of the inside of the trough. These grooves are to be cut at equal distances from each other, and the width of each groove is to be such, as to correspond nearly to the thickness of each pair of plates, so that the latter may slip easily into the grooves.

Fig. 13.

14 Casting of the zinc plates.

The plates are like those which have been already described in the construction of the pile made of zinc and copper. No difficulty has ever occurred in procuring plates of copper for this purpose; because all that is necessary is to cut them out of sheets of copper of the requisite thickness to any size that is wanted. But the case has been very different with regard to plates of zinc, especially where large plates were required. Attempts have been made to cast them in moulds of sand, such as are used for casting different utensils of other metals; but these attempts, it would appear, have been generally unsuccessful. The method which it is said has succeeded best in forming plates of any considerable size is the following. The zinc of which the plates are to be composed is to be melted in a narrow-mouthed vessel, so that a small surface of fused metal may be exposed. The reason of this is, that the metal when it reaches a certain temperature is very rapidly oxidated in consequence of the strong affinity between this metal and oxygen. The metal in this state is converted into a fine flocculent substance, known by the name of flowers of zinc. This change, therefore, as it is attended with a loss of the metal, is to be as much as possible avoided. A mould of stone of the dimensions of the proposed plates (in this case four inches), and about one-eighth of an inch in thickness, is to be prepared; but one formed of brass is found to answer the purpose still better. When the metal is in perfect fusion, the plates should be cast as quickly as possible, because, as the metal cools rapidly, cavities and imperfections would appear on the surface from its flowing unequally.

The plates of zinc being prepared, plates of copper which need not exceed one-tenth of the thickness of the zinc plates are to be cut out of a sheet of copper to the requisite dimensions, viz. corresponding to the size of the zinc plates. The copper plates must be reduced by hammering to a smooth and plane surface that they may apply exactly to the surface of the zinc plates, and be in contact in as many points as possible.

Soldering the plates.

The plates being thus prepared are to be soldered together; but it must be observed that it is not to be through the whole extent of the plate. It is found quite sufficient to solder them about one-fourth of an inch from the edges. The solder employed for this purpose is soft solder; and great precaution must be observed that the union at the edges be so close as to prevent any of the liquid with which the cells in the trough are to be filled from entering between the plates; for otherwise the power of its action would be greatly interrupted or perhaps entirely destroyed.

The operation of soldering was performed with considerable difficulty by many workmen; at least, it was found that in many cases the plates were either not in contact when the dimensions were large, or the joints were not perfectly secure. We are not certain in what way this operation is generally performed, but we know that this difficulty has been obviated by the following contrivance. The inside angles on the edges of the plates, that is, on the sides of the plates which are to be united together, are filed away, so that, when the plates are brought into close contact, a triangular groove all round the edge of the pair of plates remains. This groove is filled with solder, and the operation is conducted in the usual way. Plates soldered according to this contrivance have been found to answer the purpose extremely well. But this inconvenience is now rendered less embarrassing since the discovery of rendering zinc malleable and flexible was made, for plates of zinc of this description are of a much more equal thickness, are thinner and smoother, so that the copper can be brought into a closer contact. The plates which have been prepared of malleable zinc have the copper folded over the edge of the zinc plates, and in this way they are secured without difficulty, by soldering.

In whatever way the pairs of plates are to be secured, so that they may remain in close contact, they are afterwards

Construction of Apparatus.

wards to be fixed in the grooves of the box prepared for their reception; and here it is to be observed that each individual pair of plates is to be completely insulated. This is done by means of a particular kind of cement, the use of which is not only to retain the pairs of plates in their places, and to render their insulation complete, but also to defend the wood of the box against the action of the fluid which is employed to fill the cells of the trough.

16 Cement for securing the plates.

The cement which is employed for this purpose is composed of rosin, bees-wax, and fine brick dust, or powdered red ochre. Different proportions of these substances, it would appear, have been recommended in the construction of galvanic troughs. According to some, five parts of rosin, four of bees-wax, and two of powdered red ochre, are found to answer this purpose extremely well. The rosin and bees-wax are melted together, that they may be completely incorporated, and the red ochre is afterwards added. According to others, four ounces of bees-wax, eight ounces of rosin, and about an ounce of fine brick dust, melted together in the same way, are also found to answer the same purpose equally well. With this cement, the pairs of plates are secured in the grooves, and the intervening spaces on the inside of the bottom and sides of the trough are also covered with it, to defend the wood from the action of the fluid. It is scarcely necessary to observe, that the plates are to be arranged in the same way throughout the trough as the first pair; that is, if the copper side of the first pair of plates be towards the end of the trough at B, all the other pairs are to be so arranged as to have their copper sides towards the same point B, and the zinc sides towards the other end of the trough A. The plates being arranged in this way, the end of the trough B is called the copper end of the trough or battery, and the end A is called the zinc end.

Superior advantages are derived from arranging the plates in this way, to that of constructing them in the method described for the pile; for in this way the fluid can be applied more equally and with greater facility; the apparatus is more convenient for performing experiments; its action continues for a considerably longer time, and there is little or no trouble in cleaning the plates after the operation. It is otherwise with the pile, for, after it has been once used, the surface of the zinc plates is so much oxydated, that before they can be employed again, they must be scoured or filed, which, it is obvious, must be a troublesome and tedious process; but in the trough the oxydated surface of the plates is cleaned in every successive operation, the fluid which is employed dissolving the oxide which has collected on the surface of the zinc plates.

Liquid to fill the trough.

In treating of the construction and action of the pile, we have already observed that different saline solutions were employed, to moisten the pieces of cloth or pasteboard interposed between the pairs of plates. These solutions were muriate of soda or common salt, muriate of ammonia or sal ammoniac, and sometimes sulphate of potash. Similar solutions will answer the purpose of filling the cells of the trough, but these are found to be weaker than solutions of the acids; and, besides, as they are apt to crystallize on the plates, it becomes extremely troublesome to clean the trough. Acid solutions, therefore, which are more powerful, have been properly preferred; and the acid which seems to answer best, on different accounts, is the nitric; the proportion to be employed, it is obvious, must vary according to the strength of the acid. Of the common acid of the shops, one part with 16 of water will form a pretty active mixture; but when the acid is stronger, it may be necessary to add 20 parts of water. But this mixture is attended with the inconvenience of the evolution of nitrous gas, which, it is well known, is extremely disagreeable, and is injurious to respiration; and, on account of the high price of nitric acid, when a large quantity of this mixture is required, it becomes very expensive. Sulphuric acid mixed with water has also been employed for the same purpose, and it is found to answer very well. The use of this acid, however, is liable to many serious objections. Its action is too rapid; and, by its operation on the zinc, hydrogen gas is disengaged in such quantity as to be inconvenient to the operator. So much heat is evolved during its action, that the cement which is used for securing the plates in the trough, is apt to be rendered soft and loosened. Muriatic acid also has been employed, and this is recommended by some as in different respects the most convenient. One part of muriatic acid and 16 of water form a mixture which answers the purpose extremely well. The action of this mixture is slow and uniform, and the quantity of hydrogen gas which is evolved is so small as to produce little inconvenience. The use of this acid is attended with another advantage, that the plates are kept uniformly clean.

Whatever mixture has been employed, unless the operation has been continued for a very long time, when it is emptied from the trough, it may be bottled up, and reserved for future use; and if the most powerful action of the trough is not required, the same mixture may be employed several times. Here it may be worth while to notice, that the precaution of emptying the trough should be invariably observed, as soon as the experiments for which it was filled and prepared are finished; by this management there will be a considerable saving, both of the fluid and of the surface of the plates, which undergo oxidation. In filling the trough with the fluid, it should be observed that it does not rise higher than about $\frac{1}{4}$ of an inch from the upper edge of the plates; and after the filling of the trough is completed, the upper edges of the plates, as well as the edges of the trough, should be carefully wiped dry, that there may be no communication between the fluid in the cells, but through the metallic substances.

A trough composed of 50 plates of three inches square will be found suitable for a great variety of useful and entertaining experiments; but when it is found necessary to produce a more powerful action of the galvanic fluid, a greater number of pairs of plates, or the same number with a larger surface, according to the nature of the action required, must be employed. We have already observed, that several columns or piles may be so constructed as to have the full effect of their combined action, in the same way as if they formed a single pile. By similar management, different troughs or batteries may be so arranged as to combine together the effects of each, as if they constituted a single trough or battery. And all that is necessary to observe is, that to whatever extent the series may be carried, the surface of each of the

Construction of Apparatus.

the plates must be opposed to the surface of a different plate; as, for instance, the zinc surface of one of the plates must be constantly opposite to the copper surface of the next plate in the series. The different troughs thus uniformly arranged, are to be connected together by means of metallic conductors. A slip of copper, for instance, about half the width of the trough, is inserted by its opposite extremities in the cells of the ends of two of the troughs.

When the plates are of a very large size, their weight, with that of the quantity of fluid required to fill the cells, renders the trough very unmanageable. It is then necessary to fix it in a frame of sufficient strength, to support its weight by means of axles of brass or iron, fixed to the outside of the box. By this contrivance the fluid can be easily poured out into a proper vessel placed under the trough.

We shall afterwards speak more particularly of the effects of plates of different extent of surface: here, however, it may be necessary to observe, that in combining together two or more troughs or batteries, to have the full effect of such a number of plates as may be employed, in proportion to the extent of their surfaces, the surface of the plates in each trough should be the same; otherwise, if troughs of different extent of surfaces be employed, the action of that trough which has the largest surface is diminished, and reduced to that of the action of the trough whose plates have the smallest extent of surface. This circumstance is necessary to be attended to, for, if it be overlooked in the construction or combination of different batteries, the effects will be so feeble as to produce disappointment without the cause being known.

In making experiments with the trough, the communication is to be formed between the two extremities, or the circle is to be completed in the same way as has been already directed in the management of the pile. For this purpose there is a projecting piece of wood fixed to the upper edge of each of the ends of the trough; this is perforated so as to admit a piece of wire which passes through to the fluid in the two last cells at the extremity of the trough. If then the wires are placed in this situation, and the moistened fingers of one hand touch the wire at one extremity, while the moistened fingers of the other hand are brought into contact with the wire at the other extremity of the trough, a shock will be felt; and in this way the circle is completed.

The other parts of the apparatus which are necessary to conduct experiments with a trough of this description, are so simple as scarcely to require any particular description. All that is wanted for deflagrating metals is to have a bent wire fixed at one extremity of the trough, and to have a polished plate of copper or zinc communicating with the other extremity of the trough by means of a flexible wire. The metal to be deflagrated is placed upon the bent wire, and the metallic plate is brought into contact with it.

18 Apparatus for decomposing water.

The apparatus for the decomposition of water is the following. A glass tube, G, H, fig. 11. about three inches long, and $\frac{1}{2}$ inch in diameter, is furnished with a tight cork at the upper end G, through which cork the wire *i* communicating with the upper part of the pile, passes. It may be also furnished with a cork at the other extremity H, but this must have grooves cut on its sides, to allow the water to escape from the tube. The wire K communicating with the bottom of the pile, passes through this cork; or without the cork at this extremity, if the tube is retained in its perpendicular position by any other contrivance, the wire K may be passed within the tube. When this operation is to commence, the tube is to be filled with water, the cork at the upper extremity G being made air-tight, and then it is to be inverted, and the extremity H to be placed in a small cup or bason of water; after which the wire K being introduced, the circle is completed between the wires through the medium of the water in the tube, the decomposition of which will go on as long as the communication and the action of the pile are continued. This process will be observed by bubbles of air escaping from one of the wires, and rising to the top of the tube; or if the wires are of gold or of platina, bubbles of air will be seen passing from the extremity of both wires, and this air collecting at the top of the tube, forces out a quantity of water equal to the space which it occupies. The same experiment may be made by means of a still simpler apparatus. If the wires communicating with the extremities of the pile are introduced into a small glass phial filled with water, and inverted in a bason of water, the same process of decomposition will go on.

But an apparatus which is rather more complicated, but at the same time sufficiently convenient, is usually employed for this purpose. A small brass cup, E, fig. 13. is supported by the wire F, which is fixed in the hole of the projecting piece of wood D, at one end of the trough; from the centre of the cup there arises a pair of brass pincers, which hold a piece of wire of gold or platina G. Over the pincers is placed a glass tube HI, which has at the upper extremity, I, a brass cap, to the inside of which is fixed another piece of wire of gold or platina. The two wires should be at a little distance from each other, as they appear in the figure. The tube is then filled with water, and is inverted over the pincers in the brass cup, which is also filled with water; and thus, by means of the water in the tube, a communication is formed between the two wires. A wire proceeding from the other extremity of the trough C, is connected with the top of the tube I, and, as soon as this comunication is formed, the process of the decomposition of the water in the tube commences; for the galvanic circle, or the communication between the extremities of the trough or battery is completed. The gases, as they are disengaged from the wires in the tube, rise to the top, and the water which occupied the space now filled with air, is forced out into the cup. This process goes on as long as the communication continues, or till the surface of the water is lower than the extremity of the upper wire, when the communication is interrupted, and then the operation ceases.

With these observations we conclude what was intended to be said concerning the construction of galvanic apparatus. We shall notice what may be farther necessary to be explained, in the course of the detail which is to be given of the experiments in galvanism, or of the influence of the galvanic fluid on animals, as well as its chemical effects. We, therefore, now proceed, in the following chapter, to the consideration of some of these phenomena.

Chap.

Effects of Galvanism on Animals.

CHAP. II. *Of the Effects of the Galvanic Fluid on Animals.*

119 Animal electricity.

It has been already observed, that the first effects of galvanism were exhibited on animals; and indeed it was supposed that these effects could only be exhibited by means of animals; and hence, from the coincidence which was observed with the properties of electricity already known, it was denominated *animal electricity*.

The first experiments which were made in investigating the nature and properties of the galvanic fluid, were chiefly performed on cold-blooded animals. It was indeed from observing its effects on them, as we shall find afterwards in tracing its history, that the discovery was first made. This discovery was made on the frog, and since that time the frog has been oftener the subject of galvanic experiments than any other animal. From being found in great numbers, from being conveniently got, as well as from the irritability of the muscular fibre, as it is denominated by physiologists, continuing for a long time, it has perhaps become the devoted victim of those investigations.

We have already mentioned a simple experiment with a prepared frog, in which it forms the communication between two dissimilar metals. When the frog, as in fig. 1. is prepared, that is, skinned, and the lower extremities separated from the spine, and suspended on the zinc wire AB, if the extremities of the frog be touched with a different metallic substance, such as gold or silver, while this metallic substance is in contact with the zinc wire at the point D, the limbs of the frog are thrown into convulsions, and this takes place as often as the communication is formed.

Soon after the discovery of Galvani, and after the result of his experiments and opinions on the subject of this discovery was announced to the world, the attention of philosophers became much occupied in repeating and extending these experiments. Among others, Valli, an Italian physician, instituted a series of experiments, an account of which was communicated to the French philosophers, who soon after repeated them. As these experiments afford us not only a pretty full view of the effects of the galvanic fluid on animals, but also the state of galvanism at the time, we shall here detail them.

120 Experiments of Valli and the French philosophers.

Experiment 1.—When two metallic coatings or slips of metal, the one of lead, and the other of silver, were placed on a frog, fastened to a table, the coating of lead being placed on the belly of the animal, and that of silver on the pelvis, and a communication being formed by means of a slip or wire of copper, strong convulsive motions were produced in the animal.

Exper. 2.—The coating or slip of lead which was employed in the preceding experiment, was removed, and the abdomen was left bare. The copper wire was then applied to the abdomen the same way as before, while its other extremity was in contact with the coating of silver on the pelvis; convulsive motions were still produced, but they were less sensible than in the former experiment, and sometimes did not succeed at all.

Exper. 3.—When two coatings of the same metal were employed, as, for instance, silver or gold, the effects produced by means of copper forming the communication, were found to be much fuller; and when the coatings were of similar metals, such as copper, lead, or tin, and the metal forming the communication was the same, no effect whatever was produced.

Exper. 4.—By placing the coating on the abdomen in a horizontal direction, so that the points of contact became less numerous, the effects were found to be proportionally diminished; but when the coating was brought into full contact with the surface of the abdomen, it was observed that they became equally powerful as before.

Exper. 5.—A frog was skinned and cut transversely through the middle; the nerves of the thighs were laid bare, joined together, and placed on a slip of gold, while the thighs themselves were in contact with a piece of silver. When the metallic conductor of copper was applied, slight contractions were produced. It was found also that contractions took place when both the coatings were of silver; but when coatings of tin, copper, or lead, were substituted for the silver coating which surrounded the nerves, powerful contractions took place. The gradation observed in the action of the metals, is the following. Lead produced the strongest contractions, next the tin, and lastly the copper; but in proportion as the vitality of the animal diminished, the metals were found also to lose their power of producing motion. The metals which retained this property longest were lead, tin, and zinc.

Exper. 6.—When plumbers lead was employed on each side as a coating, and when the metal forming the communication was the same, no effect was produced; but when lead of different qualities, as, for instance, lead of the assayer and plumbers lead, was used, and the metal forming the communication being either the one or the other, very singular effects took place.

While it was found that these two kinds of lead, by changing the different metals, were no longer susceptible of producing any effect in one of the coatings, silver, gold, bismuth, antimony, or zinc, substituted for the lead, produced very powerful contractions; and, what seemed still more singular, when the pieces of lead in the first part of this experiment were re-applied, slight convulsions took place.

Exper. 7.—After a short interruption of the experiments on the same animal, it appeared that it became susceptible of pretty strong convulsive motions, when the same experiments were repeated.

Exper. 8.—When the galvanic power seemed to be nearly exhausted in the frog, it was found that the different metals, when they produced, by their contact, new convulsions, did not, when this effect could be no longer produced, leave to the animal the power of exhibiting anew any contractions with coatings of the different kinds of lead, as in experiment 6.

Exper. 9.—The following is the gradation of the diminution of effect, till it entirely ceased, when the plumbers lead always formed one of the coatings. With the assayers lead forming the other coating, the action became feeble, and it at last ceased. The next in order was tin, the next antimony, and so on in the order in which they are named as follows: zinc, copper, gold, silver. Iron, it was observed, had lost its power of producing any effect before the antimony; but whether it was deprived of this property before lead and tin, was not ascertained.

Effects of Galvanism on Animals.

Exper. 10.—Zinc, on losing the property of exciting convulsions in a frog, on which experiments had been made for an hour, was not found susceptible of any farther action, when the communication was formed by means of lead; but it was observed as a very singular circumstance, that contractions were still produced by this metal the moment that the person engaged in the experiment removed the conductor, and interrupted the circle. This experiment was frequently repeated.

Exper. 11.—The upper part of a frog which was skinned, and divided transversely, had the crural nerves, as in the former experiments, armed with a piece of lead, and placed in a glass filled with water, while the lower part was placed in another glass, also filled with water. Strong contractions were produced when the communication was formed by means of different persons holding each other by the hand, while two of them touched the water in the glasses. One of them held in his hand a piece of metal, which was brought into contact with the coating of lead.

Exper. 12.—When any one individual of the persons who thus formed the chain of communication between the two glasses withdrew himself, so that the communication was interrupted, no effect was perceptible.

Exper. 13.—When the frog was arranged in the same way as in experiment 11. having its parts placed in two glasses, no motion was excited when a communication was established with two fingers; nor was any motion produced, when a person with one hand armed with a piece of metal, touched the body of the frog, while he brought a finger of the other hand in contact with the metallic coating of the crural nerves. But by placing one finger on the inferior part of the frog, he touched with a piece of metal the coatings of the nerves, powerful contractions were produced.

Exper. 14.—When the animal was touched with a metallic substance in an insulated state, no perceptible effect was observed; but when the metals ceased to be insulated, very considerable motions were invariably produced.

Exper. 15.—The fore leg of a rabbit was separated from the body; the brachial nerves were laid bare and armed with a bit of sheet lead. The communication between the lead on the nerve and one of the contiguous muscles was made with a piece of silver, and strong convulsive contractions took place in the limb; but when this experiment was varied, by substituting for the metallic conductors, plumbers and assayers lead, no farther motion was produced. When one of the coatings employed was lead, and the other iron, no perceptible motion was observed. But when lead as one of the coatings, was employed with silver, gold, copper, zinc, or antimony, as the other coating, the motions and contractions of the limb were renewed. The motions were very slight, which were produced by means of a coating of bismuth, along with a coating of lead.

Exper. 16.—This experiment was instituted to ascertain the state of the electricity in the animal which was the subject of it. With this view, the animal was placed in a vessel containing one or two of Coulomb's electrometers, and it was then successively electrified, both positively and negatively; and in both of these cases the balls of the electrometer were so much influenced by the animal, as to shew, not only that its electricity was in a state of perfect rest, both before and during the time of the experiment, but also to exhibit in the system of the body on which the experiment was made, in a very distinct and striking manner, phenomena quite analogous to those of the Leyden phial.

Exper. 17.—The left crural nerve of a living frog was tied with a ligature so strongly, that the animal was deprived of the power of motion in that part of the limb below the point where the ligature was fixed; but when the nerve was armed with a metallic coating, in the way described in the former experiments, and a communication was formed between the part of the nerve above the ligature and the muscle, the motion and contraction of the limb were excited.

Exper. 18.—The ligature was afterwards placed on the left crural nerve, and brought in contact with the muscle. It was also fixed in such a way on the right crural nerve, so that part of it projected: the left part of the animal was then quite paralytic, and without motion, and the convulsive contractions which were produced when the communication was formed, were entirely limited to the right side; but when the same left crural nerve was more completely laid bare, and separated from the muscular substance which surrounded it, its conducting power was restored, and the communication being established, the convulsive motions became pretty strong. When, however, the ligature was again brought into contact with the muscle, the limb was again deprived of its power of motion.

Exper. 19.—One of the crural nerves of a frog being laid bare, was armed with a piece of sheet lead; and a communication having been formed between this nerve and the other crural nerve, which was unarmed, very strong convulsive motions were produced.

Exper. 20.—When one of the crural nerves was armed with two pieces of lead at different places in its course, and a communication formed between the two parts by a metallic conductor, violent agitations followed. It was observed, too, that the same effects took place, when the whole of the nerve was laid bare, and completely separated from the surrounding muscle.

Exper. 21.—A similar experiment was made on a hot-blooded living animal. The animal selected for this purpose was a guinea pig; but when the communication was established in the usual way, no effect followed, from which any thing precise or satisfactory could be deduced.

Length of time that motion can be produced in frogs.

With a view to discover during what length of time frogs, which were made the subjects of these experiments, could resist their effects, and retain the power of having motion excited in them, Valli made a number of experiments. At 10 o'clock at night he prepared two frogs, which on the following morning at seven o'clock he found had become extremely feeble, but not entirely deprived of the power of motion. Slight convulsions were excited in both by means of the galvanic apparatus; but an hour having elapsed, they ceased to afford any farther symptoms of vitality. No effort that could be made succeeded in producing motion. In other cases he prepared frogs, which by the following morning were found to be quite dry, and then no symptoms of motion could be exhibited. He separated several of the muscles from the body of a frog, and after having torn them, he found it impossible to

[Effects of Galvanism on Animals.]

to excite the irritability by any mechanical stimulus whatever; but, after previous preparation, and by means of a metallic conductor, motion was produced.

22 [Effects of narcotics on animals subjected to galvanism.]

The same naturalist made a variety of experiments, to ascertain the effects of galvanism on animals which were destroyed with opium, and other narcotic substances; but the results of his experiments on animals to which opium had been exhibited internally, as well as applied externally, were found to be very different from each other. Four frogs were destroyed by means of powdered tobacco, were rendered completely insensible to any mechanical stimulus, and seemed to be in a state of total stupefaction; but by the application of the galvanic apparatus, symptoms of vitality appeared, and slight motions were produced. A number of lizards being poisoned with tobacco, exhibited, at the time of their death, convulsive motions; but they still continued to afford symptoms of vitality and motion on the application of galvanism.

23 [Of hydrogen gas, &c.]

Animals were destroyed in a variety of ways, with a view of ascertaining what were the effects of galvanism, after the principle of life seemed to be extinguished. A small bird, which was for some time immersed in hydrogen gas, or inflammable air, shewed no symptoms of vitality or motion; but, on the application of galvanism, convulsive contractions of its limbs were produced. Two kittens were killed in azotic gas, and the fore legs were separated and prepared in the usual way. The same effects were produced as in the experiment with the bird.

Some animals were destroyed with the extract of hemlock; but it did not appear that the effects on the application of the galvanic apparatus were at all diminished by means of this poison. In frogs which were exposed to the exhalation of corrupted animal matters, perceptible motions were observed by means of galvanism; but these were very feeble.

Moscati deprived several frogs of life, by placing them in the vacuum of an air pump; and when these were subjected to experiment with the galvanic apparatus, slight motions were produced; but it was observed that these, although they followed each other in rapid succession, were excited with some difficulty. Here it was found that the blood was extravasated in the cellular membrane of the muscles, by which the flesh was tinged with a deep red colour. To this circumstance was ascribed the feeble effects produced in the above experiment, as it was supposed that the blood carried off part of the galvanic fluid, and thus prevented its action on the muscular fibres, through the medium of the nerves. This opinion was supported by another experiment, which was made on prepared frogs, in which there was no extravasation of blood; and in this case the galvanic effects did not seem to be in any degree diminished.

Before proceeding farther with an account of the experiments of the particular effects of galvanism on animals, we shall here relate two of a more general nature, the one with regard to the effects produced by the peculiar application of the metallic conductor, and the other with respect to the velocity of the galvanic fluid being increased, without increasing its intensity.

[Difference in effects of applying the conductor.]

A difference, which appeared to be a very singular fact, was observed in the mode of applying the metallic conductor, to excite motion in animals by means of galvanism. It was found, that the motions produced in the animal by this means were generally more powerful, when the conductor was applied, first to the muscles, and then to the coating, than if the reverse had taken place; that is, by applying first to the coating, and afterwards to the muscles; and indeed when the galvanic power began to be nearly exhausted, no motion whatever could be excited when the application was made, first to the coating and then to the muscles, while at the same time, by the contrary mode of application, motion could be easily produced.

Effects of Galvanism on Animals.

25 Velocity of the galvanic fluid increased without increase of intensity.

The other fact alluded to is, that the velocity of the galvanic fluid may be increased without increasing the degree of its intensity. This was proved by M. Valli in the following experiment. By means of a chain, which was in contact with the nerves of a prepared frog, he completed the galvanic circle. The animal at first exhibited convulsive contractions, but afterwards remained for some time without motion. When the conductor was removed to a very small distance, motion was again excited in the animal; soon after, however, this ceased. But when an insulated conductor was brought to the muscles of the frog, the motions were immediately renewed; and when they again ceased, a communication being formed between the operator himself and the conductor, the contractions were again excited. The conclusion which he deduced from the above experiment was, that the galvanic influence is constantly the same, however various the modes of its application. The same result, however, he observes, would not be obtained, if the experiment were made on an animal in which the principle of life was in full vigour.

From a number of experiments which were made by the same physiologist, it appeared that certain intervals were necessary, in order to obtain the same intensity of action in animals subjected to the influence of the galvanic fluid. Frogs, mice, rats, and tortoises, were the subjects of these experiments; they were destroyed by means of different poisons, or by respiring some of the noxious gases. In applying the galvanic apparatus to these animals, an interval of several minutes was required, when the motions excited became feeble, or had nearly ceased; and then, after this interval had elapsed, the same effects, and almost equally powerful as before, were produced.

26 Conducting power of blood vessels investigated.

With regard to the conducting power of the blood-vessels, two questions were proposed to Valli, by Vicq D'Azyr. 1. Whether the blood-vessels are to be considered as conductors of the galvanic fluid. And, 2. Whether, by coating the blood-vessels instead of the nerves, any motion through their medium could be excited? In the solution of these questions Valli observed, that the blood-vessels are undoubtedly to be considered as conductors of the galvanic fluid; but in whatever way this is effected, it seems to be through the nerves alone, in consequence of the way in which they are disposed, that muscular motion can be excited. The arteries and veins, he farther observes, are to be considered as less powerful conductors than the nerves; for no motion is obtained, if the vessels, without having any communication with the nerves, be distributed directly to the muscles. The tendons also, when the same communication is established, are also conductors as well as the bones, if they have not been deprived of the

Effects of Galvanism on Animals.

the periosteum. The membranes also possess this conducting power; but exhibit no motions when the communication with the nerves is interrupted.

It had been observed, that the nerves, when dry, exhibited, by means of friction, some symptoms of electricity. With a view to ascertain whether, in this dry state, the nerves were conductors of the galvanic fluid, and whether motions could be excited through this medium, Valli made several experiments; but in all these he was unsuccessful, for no motion was produced. In a series of experiments which were made on fowls, he found that ligatures applied to the nerves, did not prevent the contractions of the muscles, provided these ligatures were not applied to the nerves in immediate contact with the muscles.

27 Effects on drowned animals, &c.

In order to ascertain what would be the effects of the galvanic fluid on animals which were drowned or suffocated, Valli made a number of experiments. Several pullets were drowned, and kept so long under water, that no symptoms of life appeared. By the application of the galvanic apparatus, muscular contractions were produced in some, while others, by the same application, exhibited no motion whatever. The same experiment was repeated on six pullets, which were also drowned; and on the application of the apparatus, strong convulsive motions were produced. These continued for nearly the space of an hour. In others which were also drowned, the brain and wings were laid bare; and after this previous preparation, when the galvanic apparatus was applied, strong muscular contractions were excited: none of the animals, however, as was expected, were restored to life. Similar experiments, followed by the same result, were made on rabbits.

Several pullets were exposed to the action of different gases, as hydrogen, nitrous, and azotic gases, and did not afterwards, by any mechanical stimulus whatever that could be applied, exhibit symptoms of life. The galvanic apparatus being applied, very feeble contractions were produced; and these succeeded each other after long intervals. Similar experiments were made with the same view, on frogs, and it appeared that these animals could resist the effects of those gases better than the others. Nitrous gas, he found, was more injurious than hydrogen gas. In some of the frogs on which the experiments were made, the application of the galvanic apparatus produced violent agitations; but having repeated three or four shocks, no farther motion could be excited, not even after some interval had elapsed.

To ascertain what were the effects of different kinds of air on animals subjected to the galvanic apparatus, he separated the hinder extremities of a frog, exposed the one to the action of nitrous gas, and the other to that of atmospherical air. After being subjected for a short time to the action of these airs, the galvanic apparatus was applied. Contractions were produced in both; but those which were induced in the limb exposed to the nitrous air, were feebler than the other; and when the action of the nitrous air was continued beyond a very limited time, no motion whatever could be excited. The same experiment was made on limbs exposed to the action of hydrogen gas; and it appeared that its effects in destroying the irritability of the muscular fibre, or in diminishing its susceptibility of being acted upon by galvanism, were less powerful than the nitrous gas. Azotic gas was also found to produce effects on frogs somewhat similar. The heart was indeed observed to palpitate after the death of the animal; but, in general, the contractions which were induced by galvanism were extremely feeble.

It would lead us too much into detail to mention all the experiments which were made by this naturalist. We shall therefore only add a short account of the general results.

28 Results of Valli's experiments.

1. In frogs newly killed, he found, that a single metallic conductor was sufficient to excite convulsive contractions; and that in producing these motions, it was not found essentially necessary to apply a coating either to the muscle or nerve. Scissars, in which the steel appeared to be of a bad quality, might be successfully employed as a conductor; but gold, silver, copper, lead, and tin, in general, produced no effect.

2. The galvanic fluid was found to pass through glass and sealing wax; but it was necessary that these substances should have their temperature considerably increased.

3. Water in which the temperature was pretty high, or when raised to the boiling point, seemed to prevent the effects of galvanism from taking place, or at least diminish them greatly.

4. Water, the temperature of which was very much reduced, seemed also to be deprived of the property of conducting the galvanic fluid.

5. It was found, that when an individual formed part of the chain, in cases where the galvanic apparatus was applied to the prepared feet of rabbits, cats, and dogs, the latter were unsusceptible of motion.

6. The diaphragm of a dog was immersed in a vessel of water, and so placed in the vessel, that the phrenic nerve, previously armed, projected from it; and on touching the coating with a piece of gold or silver coin, while one of the fingers of the other hand was put into the water, feeble contractions were excited in the muscle. In some other experiments on the same muscle of horses, it was found that no motion could be induced by means of galvanism, while the same power, with the same intensity, constantly excited contractions in that of dogs.

7. A metallic wire, which was entirely covered with sealing wax, produced no motion in frogs, which began to be exhausted when it was employed as a conductor. This was stated by Valli, as a proof that the galvanic fluid passes along the surface of conductors.

8. A ligature on the nerve, when placed near to the muscle, or in contact with it, interrupted or diminished the effects of galvanism: it was found also, that a ligature, applied in the same way, prevented the effects of artificial electricity.

9. A ligature was applied, at a small distance from the muscle, to the crural nerve of a frog, and another was prepared in the same way, but without any ligature; these being subjected to experiment, it appeared that galvanism produced a more perceptible action in the latter than in the former.

10. Weak shocks of artificial electricity produce motion in the muscles of that leg only where no ligature has been applied to the nerve; but in the other, muscular contractions can be excited by means of the galvanic apparatus. From this experiment, it was attempted to deduce a method of subjecting the intensity of galvanism

Effects of Galvanism on Animals.

nism to calculation. If, for example, it is found that the effects of artificial electricity are considered as amounting to five, six, or seven degrees, and this power is insufficient to excite contractions, while they are produced by means of galvanism, it may be said that the latter is five, six, or seven degrees stronger than the former.

11. Valli did not succeed in effecting the muscular contraction of the heart by means of galvanism; nor did he succeed in similar experiments made on the stomach, intestines, or bladder, although he armed or applied metallic coatings to the nerves of all these organs.

12. To produce contractions in the wing of a fowl, the nerves of which were coated and previously steeped in oil, very powerful shocks of artificial electricity were found requisite; but the effects of the galvanic fluid did not, by this process, seem to be at all diminished: it retained its whole energy.

Experiments by Fontana,

Fontana, in his experiments and investigations on this subject, found, that he could accelerate the motions of the heart, when these motions were going on; and when the motions had ceased, could bring it to produce contractions. By placing the heart between two pieces of metal, zinc and antimony, so that it shall be in contact with both, and then forming a communication by means of a metallic conductor between the two metals, its motions are excited, even after it is separated from the body and cut in pieces. According to the experiments of Marsigli, part of the heart of a fowl, placed on a piece of charcoal, and another portion put on a piece of pasteboard, covered with tinfoil, gave repeated contractions, and was strongly convulsed.

by Delametherie

M. Delametherie made a variety of experiments, at a very early period, on this subject. The following are some of the general results of these experiments.

1. He found that the effects of galvanism in a prepared frog were feeble.

2. That it possesses the greatest intensity at the time when the animal has been just deprived of life; from this he infers, that the intensity of the effect must be greater in the living animal; from which he thinks it follows, that it is only by means of good conductors that the galvanic fluid can be conveyed from the nerves to the muscles of a frog; and it is by means of the metals, which may vary in the degree of their conducting power, that this communication is established.

3. Plumbago and charcoal were found to be inferior in their conducting power to metallic substances; but by their means the galvanic fluid could be conveyed from the nerves to the muscles of a frog.

4. He did not find from his experiments that this effect could be produced by forming the communications by means of animal substances; for when a person touched at the same time the nerves and muscles of a frog which had been laid bare, the same effect did not follow.

by Volta.

Volta, whose name has been already mentioned as the inventor and improver of the apparatus by means of which the galvanic power could be greatly increased, was, at the same time, one of the most zealous and the most indefatigable inquirers into its nature and properties. The views which this philosopher entertained with regard to the nature of this fluid, were different from those of Galvani. They are distinguished for their originality, exhibit a train of careful investigation, and have served as an excellent foundation on which the superstructure of galvanism was quickly raised. We shall therefore give a pretty full detail of the experiments and reasonings of this philosopher; and from the importance of his views, which we have stated above, it will not be less acceptable to the reader, if this detail be given, as we propose to do, in his own words. In this, indeed, something of what belongs to the second part of this treatise, will be unavoidably anticipated; but the sacrifice of strict method to perspicuity, will, we are persuaded, be readily admitted as a sufficient apology for this deviation.

To understand clearly the peculiar views which Volta has embraced in the observations which we have now referred to, it will be necessary to anticipate a little farther, by stating, that, according to Galvani, the fluid which bears his name is a peculiar kind of electricity, which resides in the organs of the animal, and is essentially and inseparably connected with them. But, according to the theory of Volta, the whole phenomena of the galvanic fluid depend entirely on artificial electricity, which is excited into action, or put in motion, when conductors of a different nature are brought into contact; and these, he thinks, are to be considered as the primary exciters. The motion of this fluid is induced in three different ways, that is, by means of three conductors at least, which are of a different nature, being so arranged as to form the communication or circle. In the first way, two metals or conductors of the first class, of a dissimilar nature, are employed. These are brought directly into contact by one of their extremities; but the communication between the other extremities is established by means of moist conductors, or conductors belonging to the second class. This fluid is put in motion another way, by a single metallic conductor of the first class, placed between two moist conductors of a dissimilar nature, between the latter of which a communication is established. In the third way of exciting the action of this fluid, or putting it in motion, a communication is formed among three conductors, each of which is of a different nature. To illustrate the variety of action observed in these conducting substances, the following account of the experiments of this naturalist, with his views and reasonings, was communicated by him in letters to Gren.

"If a tin bason, says he, be filled with soap-suds, lime-water, or a strong ley, which is still better, and if you then lay hold of the bason with both your hands, having first moistened them with pure water, and apply the tip of your tongue to the fluid in the bason, you will immediately be sensible of an acid taste upon your tongue, which is in contact with the alkaline liquor. This taste is very perceptible, and, for the moment, pretty strong; but it is changed afterwards into a different one, less acid, but more saline and pungent, until it at last becomes alkaline and sharp in proportion as the fluid acts more upon the tongue, and as the activity of its peculiar taste and its chemical power, more called forth, produce a greater effect in regard to the sensation of acidity occasioned by the stream of the electric fluid, which, by a continued circulation, passes from the tin to the alkaline liquor, thence to the tongue, then through the person to the water, and thence to the tin.

Effects of Galvanism on Animals.

tin again. I explain the phenomenon in this manner according to my principles; and indeed it cannot be explained in any other, as every thing tends to confirm my assertion, and to prove it in various ways. The contact of different conductors, particularly the metallic, including pyrites and other minerals as well as charcoal, which I call *dry conductors*, or of the first class, with moist conductors, or conductors of the second class, agitates or disturbs the electric fluid, or gives it a certain impulse. Do not ask in what manner; it is enough that it is a principle, and a general principle. This impulse, whether produced by attraction or any other force, is different or unlike, both in regard to the different metals and to the different moist conductors, so that the direction, or at least the power with which the electric fluid is impelled or excited, is different when the conductor A is applied to the conductor B, and to another, C. In a perfect circle of conductors, where either one of the second class is placed between two different from each other of the first class, or, contrariwise, one of the first class is placed between two of the second class different from each other, an electric stream is occasioned by the predominating force either to the right or to the left; a circulation of this fluid, which ceases only when the circle is broken, and which is renewed when the circle is again rendered complete. This method of connecting the different conductors will be more readily comprehended by turning to the figures, where the capital letters denote the different conductors or exciters (*moteurs*) of the first class, and the small letters those of the second class. Fig. 3. and 4. express the two cases above mentioned.

"I consider it as almost superfluous to observe, that when the circle consists merely of two kinds of conductors, however different or however numerous the pieces may be of which each consists, two equal powers are opposed to each other; that is, the electric fluid is impelled with equal force in two different directions, and consequently no stream can be formed from right to left, or, contrariwise, capable of exciting convulsive movements.

"There are other cases, however, and other modes of combination, where the powers are equally in equilibrium, and where no current of the electric fluid can take place; or, at least, none of such a force as to make an impression on the tenderest nerves, or to excite any convulsive movement in the best prepared frog that may be placed in the circle, notwithstanding the intervention of two or more different kinds of metals. This is the case when each of these metals is placed between two moist conductors, or of the second class, and which are very nearly of the same kind; or when, in a circle of three pieces, two of them of the same metal, and one of a different metal, are so connected, that the latter is immediately between the other two.

"When one of the ends of a piece of metal, which is a conductor of the first class, is immediately applied to another of the same class, but, instead of immediately touching with the other end, the other piece touches an intermediate conductor of the second class, either great or small, either a drop of water, a piece of raw or boiled flesh, or of sponge not moist, paste of meal, jelly, soap, cheese, or the white of an egg boiled to hardness; in this new combination, where a conductor of the second class is between two of the first class, the powers are no longer opposed to each other; and this is sufficient to determine an electric stream. When, therefore, a prepared frog is placed as the conductor of the second class, it will always be violently agitated as often as this circle is made complete.

"It may be readily perceived that the two last experiments coincide with those announced by M. Humboldt, where a drop of water, a small bit of fresh meat, or a very thin stratum of any fluid, performs the whole wonder. When another drop of water, or any other aqueous conductor, is applied between the other end of the first conductor and the other corresponding piece, each piece of metal is insulated, as I shall express it, between two aqueous conductors; but then the powers from right to left, and from left to right, are again completely opposed to each other; consequently the electric stream is impeded, and the frog remains without any movement. It is, therefore, absolutely necessary that two different metals or conductors of the first class, should be in immediate contact with each other, on the one side, while with their opposite ends they touch conductors of the second class.

"We might consider this mutual contact of two different metals as the immediate cause which puts the electric fluid in motion, instead of ascribing that power to the contact of the two metals with the moist conductors. Thus, for example, in fig. 3. instead of admitting two different actions, at least, in regard to the magnitude of the power, one where B comes in contact with a, and another where A comes in contact with a also, by which an electric current arises in the direction from A to B, we might suppose only one action at the point where B comes in contact with A, which impels the fluid in that direction. In both suppositions the result, as may easily be seen, is the same. But though I have reasons for adopting the first as true rather than the second, yet the latter represents the proposition with more simplicity, and it may be convenient to adhere to it in the explanation, as it affords a readier view of it. We may then say, that in the cases above stated, no effect will be produced, because here there is no mutual contact of different metals; the effect also will be null, when a conductor of the first class, on two opposite sides, is in contact with two others of the same class; for the actions therefore are in equilibrium; and, lastly, that an electric current will be occasioned by the action which arises from the contact of conductors of the first class, and which is counteracted by no other contact of the like kind.

"Having seen the result of employing three pieces of metal, or conductors of the first class, viz. two of one kind and one of a different, when combined sometimes in one way and sometimes in another, with conductors of the second class, we shall now try what will be the result, according to my principles, with four pieces of metal, two of which are of one kind, for example, zinc, when connected with moist conductors of different kinds.

"I shall first observe, that when they are connected in a circle, the powers which endeavour to put the electric fluid in a streaming movement, will be opposed to each other, and in perfect equilibrium, and that consequently no movement can take place in the frog, here supposed to be the moist conductor a, or a part of it, however irritable and well prepared it may be;

Effects of Galvanism on Animals.

be; and if the experiment be made with accuracy and the necessary precaution, so that the metals, in particular, be very clean and dry at the points of contact, it will perfectly confirm what I have above said; the frog will experience no agitation, no convulsive moment.

"These movements, on the other hand, took place, as might be foreseen from my principles, as often as I omitted one of the middle pieces, or changed the order.

"The conductors of the second class, which, in all the figures, are denoted by small letters, may be cups with water, in which the ends of the pieces of metal denoted by the large letters are immersed; or sponges or other bodies which have imbibed aqueous moisture. They may be either large or small, and may consist of one or more pieces, provided they be in proper contact; they may also be persons, if their skin be moistened at the places of contact, &c. By the last method the experiments will be very beautiful and incessant, when the circle consists of three or more persons (I have formed it frequently of ten, and even more), of two or more frogs properly prepared, and of four pieces of metal, two of silver and two of iron, tin, and particularly zinc. The change of effect, when you change the connection, is striking.

Fig. 14.

"Let the position be as represented in fig. 14. where g is the prepared frog, which the two persons p, p, hold in their hands, one on the one side by the feet, and the other on the opposite by the rump. Z, Z, are two plates of zinc, which are held also by these persons, and A, A two pieces of silver, which are held by a third person, denoted also by p. It must not be forgotten that the hands should be very moist, as the dry skin is not a conductor sufficiently strong. As in this chain the actions of the electric exciters are opposed to each other, and in exact equilibrium, as may be readily perceived, no convulsion or agitation in the frog will take place.

"Now, let one of the metallic pieces A, Z, which stand between the two persons, p, p, or between any other moist conductors, be left in combination as it is; and let the position of the two other metallic pieces A, Z, be reversed, by converting fig. 14. into fig. 15. (so that the actions, instead of being contrary, will act together to impel the electric fluid to one side or to produce the same current); or introduce between A and Z another person, or any other conductor of the second class, so that the chain be formed as in fig. 16.; or take away one of the pieces A, Z, in fig. 14. and make the chain like those of fig. 17. and 19.; or, in the last place, remove the whole two pieces A, Z, either in the one or the other side, as represented fig. 19. (by which means it will correspond with fig. 17. as the whole chain p, g, p, p, may be considered as a single moist conductor of the second class). In all these combinations, which are represented by fig. 15. 16. 17. 18. and 19. the actions arising from the metallic contacts are no longer contrary to each other, or in equilibrium, as they were in fig. 14.; consequently an electric stream is produced, and the frog g, which I suppose to be properly prepared, and which forms a part of the chain, will be violently agitated as often as the circle, when broken at any one place, particularly between metal and metal, is again restored.

Fig. 15.

Fig. 16.

Fig. 17.

Fig. 18. & 19.

"In regard to the experiment where a moist conductor, or one of the second class, is to be introduced between the two pieces A, Z (fig. 16.), that is, between two different metals, a drop of water, or a small bit of moistened sponge, or a thin stratum of any fluid, soap, or any other viscous matter, will be quite sufficient, as has been already observed. This surprising experiment I generally make in such a manner, that, instead of the piece of the metal, I employ a cup or spoon filled with water, and then cause the person who holds the perfectly dry and pure stick of tin, to touch with the stick sometimes the perfectly dry sides of the spoon or cup, and sometimes the water contained in them. It is wonderful to see, that, as by the latter method, the violent agitation of the frog never ceases, the first method, which corresponds with fig. 14. does not produce the least irritation; unless by accident there be a small drop of water, or a thin stratum of moisture, at the place of contact, by which the case represented fig. 16. would be restored. This may serve to shew with what care and attention the experiment must be made, in order to guard against error or deception, which might so easily arise; and every where exhibit anomalies.

"When I introduce water or any other moist body, great or small, not merely between one pair of metallic pieces, A, Z, as fig. 16. but between two pairs, as represented fig. 20. each piece of metal is between like moist conductors, and by these means all the actions are again rendered contrary, or brought into equilibrium; or, according to the other mode of viewing the matter, there is no longer any action, for want of the mutual contact of two different metals, which, as we have seen, is certainly necessary to excite an electric current: and it is always found that the frog experiences no agitation.

Fig. 20.

"I shall not enlarge farther on these combinations, which may be varied *ad infinitum* with a greater number of metallic pieces, and by which one may be enabled to foretel the phenomena which, according to my principles, will always be found to take place. It will be sufficient, for the present, to draw this conclusion, that in a circle consisting merely of two conductors, however different they may be, their mutual contact can produce no electric stream sufficient to excite sensibility, or muscular movement; and that, on the contrary, this effect infallibly follows as often as the chain is formed of three conductors, one of one class, and two different from each other of another class, which come into mutual contact with each other, and that this effect will be stronger, the greater the difference is between the latter; that in other cases, where there are more than three different conductors, the effect either is not produced, or will be produced in different degrees, according as the forces called forth by the different combinations, which will be expanded at each heterogeneous contact, and which are often in opposition, and endeavour to impel the electric fluid in opposite directions, are perfectly in equilibrium with each other (which must be a very rare case), or when the sum of those which exert themselves in one direction is more or less exceeded by the sum of those which act in another direction.

"I shall here, however, leave the two complex combinations, and return to the simple cases, those with three different conductors, represented by fig. 3. which are more demonstrative; or, in other words, those with two

Effects of Galvanism on Animals.

two different metals or conductors of the first class, which are in contact with each other, and are applied on the other side to moist conductors, or conductors of the second class. This method has been commonly employed since Galvani's discovery, and is in exact proportion with the diversity of metals, on which I consider the whole phenomena to depend.

"The other method of combination, which is expressed by fig. 4. or that of a metal placed between two different moist conductors, for example, between water on the one side, and an aqueous, saponaceous, or saline fluid on the other, I discovered in the autumn of 1794; and though since that period I have repeated the much varied experiments of different persons, both foreigners and others, among which was that of Humboldt, and though I wrote to several correspondents respecting it, that light has not yet been thrown on this new phenomenon which it seems to deserve.

"The singular circumstance before mentioned, in regard to the acid taste when the tongue is brought into contact with an alkaline liquid, belongs, as you may perceive, to this second method of exciting the electric fluid, and putting it in circulation (if the tin vessel be touched on the outside by the hand moistened with water, and on the inside by the alkaline liquor), and shews that this current is no less strong and active than that excited by the first method, viz. by employing two sufficiently well-chosen metals, such as lead and copper, iron and silver, zinc and tin. I must here observe, that though with tin alone, placed between water and an alkaline liquor, you obtain nearly the effect which is produced by two of the most different metals, as silver and zinc, combined with any conductor whatever of the second class; you can obtain the same, and even in a higher degree, with iron alone or silver alone, when the iron is introduced between water on the one side and nitrous acid on the other, or when the silver is applied between water and a solution of sulphur or pot-ash.

"If you take a frog, the head of which has been cut off, and which has been deprived of all life by thrusting a needle into the spinal marrow, and immerse it, without skinning it, taking out the bowels, or any other preparation, into two glasses of water, the rump into one, and the leg into the other as usual, it will be strongly agitated and violently convulsed when you connect the water in both glasses by a bow formed of two very different metals, such as silver and tin or lead, or, what is better, silver and zinc; but this will by no means be the case when the two metals are less different in regard to their powers, such as gold and silver, silver and copper, copper and iron, tin and lead. But what is more, the effect will be fully produced on this so little prepared frog, when you immerse in one of the two glasses the end of a bow merely of tin or zinc, and into the other glass the other end of this bow, which has been rubbed over with a little alkali. You may perform the experiment still better with an iron bow, one end of which has been covered with a drop or thin coating of nitrous acid; and beyond all expectation, when you take a silver bow having a little sulphur of potash adhering to the end of it.

Fig. 21.

"Fig. 21. represents the form of this experiment, where *g* is the frog; *a*, *a*, the two glasses with water; A, the bow formed of one single metal, and *m* the drop or a thin stratum of a mucous, saline, &c. fluid, with which the bow has been rubbed over, and which on this side is between the metal and the water.

"The very considerable difference in regard to the quantity of effect in the before-mentioned experiments already shews, that if the electric stream excited by contact is strongest towards a certain metal, when that metal is placed between a certain fluid on the one side, and another fluid on the other, there are other fluids which produce a greater effect with another kind of metal; so that it will be necessary to discover by experiment the particular arrangement of conductors suited to each metal, in which the fluids or conductors of the second class must be disposed according to their activity. I have paid great attention to this circumstance, and have formed several tables, which I shall publish as soon as I have brought them to perfection.

"I shall here, however, only observe, that in order to class, in some manner, the innumerable different moist conductors of this kind, I distinguish them into aqueous, spirituous, mucous, and gelatinous, saccharine, saponaceous, saline, acid, alkaline, and sulphurous (livers of sulphur) liquids; that I make subdivisions in the acids down to the best known simple mineral acids, (as I find in this respect great difference between the nitrous and the muriatic acids), comprehending the principal vegetable acids and the acids of galls; and do the same in regard to the saline fluids, according as they are solutions of neutral salts, earthy salts, and particularly metallic salts.

"When it can be determined in what order all these kinds of fluids follow each other, in regard to the power in question, for the metal A, and another for the metal B, &c. we shall then be in a condition to determine what place must be assigned to a great number of other heterogeneous fluids, whether mineral, vegetable, or animal, which belong to several of the above classes. In general, the order for the greater part of the metals hitherto observed is as follows: 1st, pure water; 2d, water mixed with clay or chalk (which shows a pretty different effect when the before-mentioned experiment is made with two glasses, a bow of tin or zinc, and a properly prepared frog, which has a sufficient degree of vitality); 3d, a solution of sugar; 4th, alcohol; 5th, milk; 6th, mucilaginous fluids; 7th, animal gelatinous fluids; 8th, wine; 9th, vinegar, and other vegetable juices and acids; 10th, saliva; 11th, mucus of the nose; 12th, blood; 13th, brains; 14th, solution of salt; 15th, soap-suds; 16th, chalk-water; 17th, concentrated mineral acids; 18th, strong alkaline leys; 19th, alkaline fluids; 20th, livers of sulphur. With some metals there is, however, a considerable deviation from this order, in regard to livers of sulphur, alkaline fluids, and the nitrous and saline acids.

"As to the metals, which in their position between these different fluids are more or less proper for the electric effect in question, I have found in general, that tin exceeds all others, and that silver is the worst; except when one of the fluids betwixt which the silver is placed is water, or any other aqueous conductor, and the other liver of sulphur: in this case silver far exceeds zinc, and even tin. Iron also produces a much greater effect than any other metal, when it is in contact, on the one side, with mere water or an aqueous conductor,

conductor, and on the other with the nitrous acid, were it even only a drop. The excitement occasioned in both cases is wonderful; since it exceeds, as I have already remarked, that produced, according to the usual method, by means of a double metallic bow, even of different metals, as zinc and silver, applied to conductors of the second class of the same kind. It is sufficiently strong and powerful to produce convulsive movements in a half-prepared frog, the bowels of which have not been taken out, when one of the two moist conductors is a concentrated alkaline solution, and the metal placed between them is zinc, or rather tin. With other metals and other fluids you can seldom produce convulsions in a frog, if it be not perfectly prepared, or at least embowelled.

"The reader will readily perceive, that when a bow of one and the same metal touches with both its ends the same kind of saline water, the same acid, the same alkaline fluid, &c. an electric steam will not take place, as happens also when it touches on each side merely water: in that case two opposite actions are opposed to each other, and keep each other in equilibrium. That these contrary powers, however, may be in perfect equilibrium, it is necessary that the fluids applied to both ends of the homogeneous metalline bow be exactly of the same kind and of the same strength. For this reason the most careful attention and a certain dexterity are required, in order to ensure success to the experiment, which I have often performed to the great astonishment of the spectators, and which any one may repeat as was done by my friend Humboldt. That philosopher has already published some of the most striking and decisive of these experiments in his second letter; and I shall here give a more particular account of them.

"Having placed a completely or only half-prepared frog as usual in two glasses of water, take a very clean bow of silver (it will be best when it has been washed with water from the glasses), and immerse both ends of it at once, or the one after the other, in the glasses; no agitation of the frog will be occasioned. Repeat the experiment, after you have daubed over one end of the bow with the white of an egg, liquid glue, saliva, mucus, blood, a solution of tartar, or any other fluid or conducting substance sufficiently different from pure water. First, immerse the pure end, or that moistened merely with water, in the water of one of the glasses; and afterwards the other end, daubed over with the above substances, in the water of the other glass; you will then infallibly produce a convulsive movement in the frog, and several times in succession, if you draw out the bow and again immerse it until nothing more of the above substances is left adhering to the metal, or until the metal, with its ends in both the glasses, touches only pure, or nearly pure, water. Daub both the above substances uniformly over both ends of the bow, and immerse them at the same time in both the glasses of water, and no convulsions will arise. They will often be produced in newly prepared and highly irritable frogs, when the saline fluid, or, in general, the substance with which the two ends of the bow are daubed over, is not perfectly the same, or when the substance at the one end is more diluted than at the other, &c. Wash and clean carefully the one end of the bow, daub over the other more or less, and convulsions will be again produced as soon as the circle is made complete by the double immersion of the bow. Clean both ends completely, and no agitation will arise, as in the first experiment.

"For comparative experiments of this kind, I would recommend viscous fluids or substances rather than saline, because the latter are too soon dissolved in the water. It oft-times happens that the convulsions of the frog, when it is completely prepared and highly irritable, take place, though both ends of the metallic bow are daubed over with the same kind of saline fluid. The cause of this is, that when one end is immersed in the water after the other (and it may be easily seen that it is impossible to do so in a moment with sufficient accuracy), the one end of the bow loses a portion of its saline substance sooner than the other, or at least the adhering part is more diluted by the water, so that the fluid with which both ends have been daubed over is no longer the same.

"For these experiment I would also recommend silver, as a metal that is less liable than others to be attacked and changed by saline and other liquids. Tin, lead, copper, and in particular iron, are more susceptible of lasting variations; so that bows of these metals, and of iron above all, retain for a long time the power of producing convulsions in a newly prepared and highly irritable frog, even when both the ends of the bow are immersed in two glasses of water, although the places of the metal, attacked by any of the saline fluids, have been carefully washed and cleaned. A superficial alteration in the metal is sufficient to produce this change, as may be easily seen. These variations often shew themselves to the eye by a yellow blackish spot, &c. which it is difficult to remove. I do not here speak of lasting variations, that proceed to a greater depth, which can be produced in the end of the metallic bow, and particularly in iron, when its hardness is changed; a process by which such a bow can be rendered capable of producing not only convulsions in frogs, but also a particular sensation on the tongue, and light before the eyes, if both its ends, made perfectly clean, are only brought into contact with pure water. These, and many other experiments of the like kind, form the chief subject of my first letter to the abbe Vassali, professor of natural philosophy at Turin, written in the beginning of the year 1794, and afterwards published with the other in Brugnatelli's Journal.

"If silver be less exposed to be attacked by saline and other fluids (except by liver of sulphur, which instantaneously renders it black); if it be less susceptible of considerable and lasting variations, and has therefore this advantage over other metals, that it is liable to fewer irregularities; tin, on account of its greater activity, that is, the strength of the effects which it produces by being brought into contact with almost all moist conductors, as I have already observed, is to be preferred to silver, and in a certain degree to all other metals. The experiment I have already described with a tin bason filled with an alkaline fluid, and held in the hands moistened with water, by which an acid sensation is excited on the tongue when brought into contact with the above fluid, is a proof of it; for it would be vain to expect a like effect from a bason of lead, iron, or copper, and much more so from one of silver. With the latter it would be obtained only when it contained

Effects of Galvanism on Animals.

tained liquid liver of sulphur; and in that case the acid taste would be pretty strong.

"The electric fluid is excited also with the greatest strength and activity, when the metal is tin, between water and a saline fluid: but it will be excited with still greater energy to produce an acid sensation on the tongue when the tin is between water and an insipid mucilaginous fluid; or when the experiment is made with a tin bason filled with a solution of gum, liquid glue, white of an egg, &c. The other metals, in like circumstances, produce some effect, but much weaker: silver produces the weakest, except with liver of sulphur, as I have already observed.

"A like experiment, which I made three years ago, and exhibited to various persons, not with two different fluids and one metal, as in that above described, but contrariwise, with two metals of a different kind and a fluid, is already known. I took a bason of tin (one of zinc is better), placed it on a silver stand, and filled it with water. When any of the persons in company applied the tip of his tongue to the water, he found it perfectly tasteless as long as he did not touch the silver stand; but as soon as he laid hold of the stand, and grasped it in his hands well moistened, he experienced on the tongue a very perceptible and pretty strong acid taste. This experiment will succeed, though the effect is proportionably weaker, with a chain of several persons who hold each other's hands, after they have been moistened with water, while the first applies the tip of his tongue to the water in the bason, and the last lays hold with his hands of the silver stand.

"If these experiments, in regard to the taste excited on the tongue by the action of two different metals, are striking, the others, in regard to the taste excited, modified and changed by one metal between two different fluids, are no less so, and they are also newer. They are still interesting on this account, that they discover to us the cause of that taste often perceived in water and other liquids, which is more or less considerable or various when drunk from vessels of metal, and particularly of tin. When the outer extremity of the vessel is applied to the under lip, rendered moist by the saliva, and the tongue is extended so as to be in contact with the water, beer, wine, &c. in the vessel, or when the tongue is bent as is done in drinking, is there not then a complete circle, and is not the metal between two more or less different liquids, that is, between the saliva of the under lip and the liquor in the cup or vessel? A stronger or weaker electric stream must thereby be occasioned, according as the fluids are different—a stream which will not fail in its way to affect the sensible organs of the tongue in the said circle.

"Besides the two methods already considered, of producing an electric current, that is, by means of one or more moist conductors, or conductors of the second class, placed between two different metals or conductors of the first class; or contrariwise by means of a conductor of the first class placed between two of the second class, also different; there is still a third method of exciting the electric fluid, though in a degree so much weaker, that it is scarcely capable of causing convulsions in a perfectly prepared frog, in which there is still a strong degree of vitality. This new method consists in forming the circle of three different conductors, all of the second class, without the intervention of one of the first or a metal one. Some think they find in this method a strong objection against my principle.

Fig. 22.

Fig. 22. represents this third method compared with the other two. In the experiments of Professor Valli, respecting which so much noise has been made without any reason, *t* represents the leg of the frog, and particularly the hard tendinous part of the *musculus gastrocnemius*; *m* the rump, or the muscles of the back, or the ischiatic nerves, to which the said tendinous parts are applied; and *a* the blood, or the viscous saponaceous or saline fluid, applied to the point of contact.

"I have fully described this new method, where no metal is used, in my third and fourth letter to Professor Vassali, written in the autumn and winter of the year 1795. I have there shewn, that these new facts, far from altering my ideas and principles, serve rather to establish them; and that they render more general the principle that the conductors, by heterogeneous contact, that is, of two different from each other, become exciters of electricity, and confirm the beautiful law arising from it, that to produce an electric stream, the circle must necessarily be formed of three different conductors. You now see in what the whole secret, the whole magic consists; and that it depends not merely on metals, as might have been believed, but on all the different conductors. As long as we adhere to these principles, it will be easy to explain all the before-mentioned experiments without being reduced to the necessity of having recourse to any imaginary principle, or any peculiar and active electricity of the organs. By their assistance you will be enabled to invent new experiments, and to foretel the result of them, as I have several times done, and still do daily. If you, however, abandon these principles, you will find nothing but uncertainty and contradiction, and the whole will be an inexplicable problem.

"Some new facts, he observes in a farther communication, lately discovered, seem to shew that the immediate cause which excites the electric fluid, and puts it in motion, whether it be an attractive or a repulsive power, is to be ascribed much rather to the mutual contact of two different metals, than to their contact with moist conductors. But, though it cannot be denied, that in the latter case there exists an action, it is proved that it exerts itself in a far more considerable degree when the two metals mutually touch each other. There arises by the mutual contact, for example, of silver and tin, an action or power by which the former communicates the electric fluid, and the latter receives it; or the silver suffers it to escape, and the tin attracts it. This produces, when the circle is rendered complete by moist conductors, a stream, or continual circulation of the fluid. When the circle is complete, there is an accumulation in the tin at the expence of the silver; which indeed is very small, and far under the point necessary to enable it to announce itself by the most delicate electrometer. I have however been able, by the assistance of my condenser, constructed on a new plan, and still better by NICHOLSON's doubler, to render it very perceptible: I shall here communicate the result obtained by my experiments, which I made some time ago with great satisfaction.

"*Experiment* I. The three plates of the doubler are of brass. I took two strong wires, one of silver and the of the other of tin, and brought the former into contact with the moveable plates, and the other with one of the fixed plates; while they both rested on the table, or, what is better, on moist pasteboard, or any other moist conductor, so as to be in communication by the intervention of one or more conductors of the second class. I suffered the apparatus to remain some hours in this state, then removed the two wires, and put the machine in motion. After 20, 30, or 40 revolutions (or more when the atmosphere was not dry, or the insulation imperfect), I brought one of my straw electrometers into contact with the moveable plate, and observed indications of positive electricity (+E), which arose to 4, 6, 10 degrees, and more. If I suffered it to touch the fixed plates, I had the corresponding indications of the opposite kind of electricity (—E).

"The silver, therefore, poured the electric fluid into the brass plate, when it had been some time in contact with it; and the tin attracted it from the other plate, which was also of brass, while in contact with it. This was confirmed by the following experiment, which is a real *experimentum crucis*.

"II. I reversed the experiment, so that the silver was in contact with one of the fixed plates, and the tin with the moveable one. The electricity which I obtained from the latter, after the apparatus had remained a sufficient time in that position was negative (—E); while that of the fixed plate was positive (+E).

"III. I applied only the tin wire to the moveable plate, and insulated the two fixed ones, or brought them into communication with the table or any other moist conductors with which the tin wire was in contact. This simple contact of the tin with the brass of which the moveable plate consists, is sufficient to excite in it a very small degree of negative electricity; only a longer time is required.

"Those acquainted with the action of electric atmospheres, and the construction of the doubler, will need no farther explanation, to enable them to comprehend the mode of action of this very ingenious instrument; how the electricity, once obtained from the moveable plate, must occasion an opposite kind in the fixed plate, and *vice versa;* how the opposite kinds of electricity are increased by each revolution of the machine, &c. In the present experiment, therefore, when the moveable plate is —E, the fixed plate must be +E.

"IV. This is the reverse of the former. The piece of tin was applied to one of the fixed plates, and the metallic one was insulated from all metallic contact. The result was now reversed; that is, the fixed plates were electrified negatively, and the moveable one had positive electricity.

"All these experiments succeed much better, and in a shorter time, if, during the mutual contact of the different metals, the moveable plate be opposite to either of the other two that are fixed; but still better when a piece of thick paper, such as a card, not moist, and of a thickness equal to the intermediate space, is placed between the two plates that stand opposite to each other. It is of advantage to leave the card some time in its place, and not to remove it till the moment when the metals in contact are removed and the machine put in motion. To render the insulation com-

Effects of Galvanism on Animals.

plete, and make the contact of the metals immediate, without the least moisture, which would be highly prejudicial, it will be proper to place the apparatus in the sun. Half an hour, and often less, will then be sufficient to obtain the required electricity, &c.; whereas, in other cases, several hours are necessary before the desired resnlt can be obtained. This experiment is represented in fig. 23. 24. 25. and 26. LLL (fig. 22. and 23.) are the three brass plates of the doubler; A the piece of silver which is in contact with one of these plates; E the piece of tin applied to the other plate, which is opposite to the former; *a a*, the moist conductor, or chain of moist conductors which form a communication with the pieces of metal. When the silver, as in fig. 23. is in contact with the anterior moveable plate, it gives up to it a little of the electric fluid, and the latter accumulates as much of it as possible; consequently the electricity of the plate becomes positive, as the sign + of the plate shews: whereas the tin attracts the electric fluid from the corresponding fixed plate, which by these means has negative electricity, as the sign (—) of the plate indicates; and it even communicates this electricity to the other fixed plate, which therefore has the sign (—) also.

Fig. 23.

"In fig. 24. every thing is reversed: the moveable plate is negatively electrified (—E), while the two fixed plates become positive (+E).

Fig. 24.

"Lastly, in the 25th and 26th figures, it is seen that the tin abstracts the electric fluid from the brass plate with which it is in contact. This plate is therefore negatively electrified, or has — E; and by the action of its atmosphere occasions positive electricity (+E) in the other plate standing opposite, which is in communication, either with the third plate, as fig. 25. or, what is still better, with other conductors, as fig. 26. These opposite electricities increase afterwards with each revolution of the machine; the action of which, according to the theory of electric atmospheres, produces this effect to the degree mentioned, and justifies the appellation of doubler of electricity, which has been given to this instrument.

Fig. 25. & 26.

"I now come to the experiments, which shew that we are to seek for the cause which calls forth the action of the electric fluid; which excites it, of whatever kind it be; determines its transition, &c. much rather in the mutual contact of the metals, than in the contact of the moist conductors with these metals. Though, according to every circumstance, we must admit some action of this kind in the latter contact, it cannot be denied that the former is certainly the most effectual. At present I shall only mention the two following experiments, which I contrived in such a manner that they may serve to explain a question of this kind.

"V. I left the two fixed plates of brass without making any alteration; took off the third moveable plate, and supplied its place by one of tin; and arranged the machine in such a manner, that the latter stood opposite to one of the other two plates. I then applied to this tin plate a bit of brass, and to the opposite fixed plate of brass a piece of tin. After a convenient time, (for example an hour, when the weather was perfectly dry), I took away the two pieces of metal, or only that of brass, and made the moveable plate of tin, which

Effects of Galvanism on Animals.

which was in contact with the piece of brass, to revolve about 30 times. It then gave me very perceptible marks of positive electricity.

"VI. I reversed the former experiment, and made the piece of brass touch the brass plate, and the piece of tin the plate of the same metal. I, however, obtained nothing, or almost nothing; even when the apparatus was left a much longer time in that situation, and when the machine had made twice or three times as many revolutions.

Fig. 27.

"These two experiments are represented by fig. 27. and 28.; where L is the piece of brass, E that of tin, and *a a* the moist conductors which connect the two different pieces of metal.

Fig. 28.

"In the arrangement of fig. 28. the same contact of different metals, viz. brass on the one side, and tin on the other, with the same kind of moist conductor, takes place, as well as in the preceding experiment of fig. 27. The addition of the electric fluid in the one, and the abstraction of it in the other, ought therefore equally to take place, though in an inverted order, when the action on the fluid calls forth the moving power, by this contact of the two metals, L, E, with the moist conductor between them; and yet this is not the case, as no signs of electricity are obtained even after a long time, and when the machine has been caused to make twice or three times as many revolutions. The condition essentially necessary to obtain electricity is, that the different metals must be in contact with each other, which is the case in fig. 27. but not in fig. 28.

"When the machine has been repeatedly turned, something may be obtained. This arises either from small remains of old electricity, which could not be destroyed or dissipated in the time during which the arrangement of fig. 26. was continued; or even from fresh electricity, which the moveable plate may have obtained from the atmosphere or vapours during the pretty considerable time of the machine being in a state of revolution; or some accidental difference, either between the two tin or the two brass pieces, may be the cause of some action on the electric fluid, or of some derangement in regard to the equilibrium. In the last place, the contact of the moist conductor with the tin on the one side, or with the brass on the other, may have a different action, which, in my opinion, must be very small, but yet is not entirely without effect.

"As it is now proved that, according to the arrangement of the sixth experiment, nothing, or almost nothing, is obtained by 40, 60, and even 80 revolutions of the doubler, while a great deal is obtained by that of the fifth with 20 or 30, we must therefore conclude that the contact of two metals of a different kind with moist conductors, without the mutual contact of these metals themselves (which is wanting in the sixth experiment, where brass is in contact with brass, and tin with tin), produces nothing, or almost nothing; and that, on the contrary, the mutual contact of the two metals of a different kind, which takes place in the fifth experiment, produces the whole, or almost the whole effect *."

* Phil. Mag. vi. 59, 163, 506.

32 Experiments of Fowler.

Dr Fowler instituted an elaborate series of experiments on this subject, in which he confirmed and extended many of the results which had been already obtained in the experiments and investigations of other naturalists. He found that metallic substances were the best agents or conductors, and he concluded that the contact of two dissimilar metals is an essential condition in the production of the phenomena of galvanism. It did not indeed escape his observation, that in some cases a single metal produced muscular contraction, but this he ascribed to mechanical stimulus, which excited a painful sensation in the animal, not quite dead, or to the impurity of the metal, containing some portion of alloy, or solder. Future observations, however, proved that these motions could be produced without any metal whatever. He found that the most powerful effects were produced by employing zinc, in combination with gold or silver. By means of these metals he produced contractions twenty-four hours after they had ceased. In the experiment by which this was established, the nerve was coated with tin, and a different metal was employed to complete the circle between the coating and the muscle. The same philosopher also found that the effects were increased in proportion to the bulk of the metals employed, and the extent of surface brought into contact; that a communication might be formed between the metals in contact, and the nerves of the animal which were exposed, by means of water; and that the temperature of the season and the nature of the animal's death seemed to have considerable influence on the duration of the phenomena. In many cases he was able to produce contractions in a frog, after three days had elapsed from the time that the head had been separated from the body. He seems to have directed his attention particularly to the conducting power of the substances employed in galvanic apparatus, and in tracing the analogy between this property and electricity. Although metals were found to be good conductors, this was not the case with the metallic oxides, or with the salts which have these oxides for their basis.

An earth-worm placed on a circular piece of zinc, exhibited contractions similar to those produced in living frogs, when a piece of silver was brought in contact to complete the circle. Worms of the same kind, suspended across a silver rod, and the head and tail being at the same time brought into contact with a piece of zinc, sustained a shock which seemed to pass through the whole body. A similar experiment, followed by the same result, was made on leeches. If an earth-worm or leech be placed on a piece of silver, resting on a plate of zinc, the animal experiences a painful sensation, when any part of its body comes in contact with the zinc. It seems to have the same disagreeable sensation when it is placed on the zinc, and any part of the body is brought into contact with the silver.

The inquiries of the same philosopher were also directed to ascertain whether the nerves in general are all equally subject to the galvanic influence, or whether its effects are limited to those which are subject to the power of the will. With this view the heart of a cow was separated from the body, soon after the animal was killed, and prepared in the way which has been already described, in the preparation of frogs; and while the contractions of the auricles still continued, the intercostal nerve being coated, and the apparatus arranged, the metals were brought into contact, but seemed to have no effect whatever on the contractions while they continued, and after they had ceased, had not the power of renewing them. He failed in many similar attempts on hot-of hot-blooded animals, but succeeded in producing muscular contractions in part of a frog, after an hour had elapsed from the time that the natural motions had ceased. He made a similar experiment on the heart of a cat which had been drowned in warm water, and he found that in this case the motion of the heart could be excited by means of galvanism; but when the animal was drowned in cold water, no effect could be produced.

It was another object of his investigations, to ascertain the effects of galvanism on the organs of the senses. The disagreeable taste which remains on the tongue, when two dissimilar metals, the one placed on the upper surface, and the other touching the under surface, are brought into contact, has been already taken notice of, and the method of applying the metals particularly described. The strongest impression, it was observed, was produced, when gold and zinc were employed. He introduced a metallic substance of a different kind into each ear, and having formed a communication between them, he experienced a shock in the head when these two metals were brought into contact. A bit of tin-foil was placed on the point of the tongue; the rounded end of a silver pencil case was applied to the internal angle of the eye; and when the other extremity of the pencil case and the tin-foil on the tongue were brought into contact, he perceived a flash of pale light, as well as the metallic taste in the tongue which is produced in a preceding experiment. The flash seemed most vivid when gold and zinc were employed. A similar effect is produced by introducing one of the metals between the upper lip and the gum, and the other between the under lip and the gum, and retaining them in this position to bring the edges in contact: or, by inserting one of the metals into the nose, and placing the other on the tongue, to form the communication between them.

3[4] Experiments of Robison.

Similar experiments were made by the late Professor Robison of Edinburgh. He particularly observed, that the effects of the galvanic fluid were more sensibly felt when one of the conducting metals was placed on a wound, or on the nerve of a carious tooth. From the peculiar impression on the tongue on the application of gold or silver trinkets, he could ascertain whether any solder was employed about them.

In another experiment the same philosopher seemed to think that he had proved that the effect was produced even before the metallic conductors were brought into direct contact. A piece of zinc was introduced between the gums and cheek on one side of the head, and a piece of silver was placed in the same way on the other side of the head. A rod of zinc was then applied to the zinc piece, and a rod of silver to the silver piece on the different sides of the head; the extremities of these rods which projected from the mouth were then cautiously brought into contact; and, as soon as this was completed, a strong sensation was produced in the gums. But before the direct contact was made between the extremities of the rods, he perceived a flash of light which was repeated when the rods were again separated to a small distance from each other. It is scarcely necessary to add, that when the arrangement of the rods was reversed, the effects ceased; that is, when the zinc rod was substituted for the silver rod, and the silver one for that of zinc.

Effects of Galvanism on Animals.

35 Aldini's experiments on the body of a malefactor.

To the account of the experiments on animals now given, which were chiefly made on cold-blooded animals, we shall now add those of Aldini, the nephew of Galvani, which were made on the body of a man executed in London for murder. This man, who was executed on the 17th January 1803, was 26 years of age, and seemed to have been of a strong vigorous constitution. The body was exposed for an hour to a temperature two degrees below the freezing point Fahrenheit, at the end of which it was conveyed to a house not far distant, where the apparatus for the experiments had been arranged. The following is the account of these experiments in the author's own words.

" *Experiment* 1.—One arc being applied to the mouth, and another to the ear, wetted with a solution of muriate of soda (common salt), galvanism was communicated by means of three troughs combined together, each of which contained 40 plates of zinc, and as many of copper. On the first application of the arcs the jaw began to quiver, the adjoining muscles were horribly contorted, and the left eye actually opened.

" *Exper.* 2.—On applying the arc to both ears, a motion of the head was manifested, and a convulsive action of all the muscles of the face; the lips and eyelids were also evidently affected, but the action seemed much increased by making one extremity of the arc to communicate with the nostrils, the other continuing in one ear.

" *Exper.* 3.—The conductors being applied to the ear and to the rectum, excited in the muscles contractions much stronger than in the preceding experiments. The action even of those muscles furthest distant from the points of contact with the arc was so much increased as almost to give an appearance of re-animation.

" *Exper.* 4.—In this state, wishing to try the power of ordinary stimulants, I applied volatile alkali to the nostrils and to the mouth, but without the least sensible action; on applying galvanism great action was constantly produced. I then administered the galvanic stimulus and volatile alkali together; the convulsions appeared to be much increased by this combination, and extended from the muscles of the head, face, and neck, as far as the deltoid. The effect in this case surpassed our most sanguine expectations, and vitality might, perhaps, have been restored, if many circumstances had not rendered it impossible.

" *Exper.* 5.—I next extended the arc from one ear to the *biceps flexor cubiti*, the fibres of which had been laid bare by dissection. This produced violent convulsions of all the muscles of the arm, and especially in the *biceps* and the *coraco brachialis*, even without the intervention of salt-water.

" *Exper.* 6.—An incision having been made in the wrist, among the small filaments of the nerves and cellular membrane, on bringing the arc into contact with this part, a very strong action of the muscles of the fore-arm and hand was immediately perceived. In this, as in the last experiment, the animal moisture was sufficient to conduct the galvanic stimulus without the intervention of salt-water.

" *Exper.* 7.—The short muscles of the thumb were dissected,

Effects of Galvanism on Animals.

dissected, and submitted to the action of the galvanic apparatus, which induced a forcible effort to clench the hand.

" *Exper.* 8.—The effects of galvanism in this experiment were compared with those of other stimulants. For this purpose, the point of the scalpel was applied to the fibres, and even introduced into the substance of the *biceps flexor cubiti*, without producing the slightest motion. The same result was obtained from the use of caustic volatile alkali and concentrated sulphuric acid. The latter even corroded the muscle, without inducing it to action.

" *Exper.* 9.—Having opened the thorax and the pericardium, exposing the heart *in situ*, I endeavoured to excite action in the ventricles, but without success. The arc was first applied upon the surface, then in the substance of the fibres, to the *carneæ columneæ*, to the *septum ventriculorum*, and lastly, in the course of the nerves by the coronary arteries, even with salt water interposed, but without the slightest visible action being induced.

" *Exper.* 10.—In this experiment the arc was conveyed to the right auricle, and produced a considerable contraction, without the intervention of salt water, but especially in that part called the *appendix auricularis*; in the left auricle scarcely any action was exhibited.

" *Exper.* 11.—Conductors being applied from the spinal marrow to the fibres of the *biceps flexor cubiti*, the *gluteus maximus*, and the *gastrocnemius*, separately, no considerable action in the muscles of the arm and leg was produced.

" *Exper.* 12.—The sciatic nerve being exposed between the great trochanter of the femur and the tuberosity of the ischium, and the arc being established from the spinal marrow to the nerve divested of its theca, we observed, to our astonishment, that no contraction whatever ensued in the muscles, although salt water was used at both extremities of the arc. But the conductor being made to communicate with the fibres of the muscles and the cellular membrane, as strong an action as before was manifested.

" *Exper.* 13.—By making the arc to communicate with the sciatic nerve and the gastrocnemius muscle, a very feeble action was produced in the latter.

" *Exper.* 14.—Conductors being applied from the sciatic to the peronæal nerve, scarcely any motion was excited in the muscles.

" *Exper.* 15.—The sciatic nerve being divided about the middle of the thigh, on applying the conductors from the biceps flexor cruris to the gastrocnemius, there ensued a powerful contraction of both. I must here observe that the muscles continued excitable for seven hours and a half after the execution. The troughs were frequently renewed, yet towards the close they were very much exhausted. No doubt, with a stronger apparatus we might have observed muscular action much longer; for, after the experiments had been continued for three or four hours, the power of a single trough was not sufficient to excite the action of the muscles: the assistance of a more powerful apparatus was required. This shows that such a long series of experiments could not have been performed by the simple application of metallic coatings. I am of opinion that, in general, these coatings, invented in the first instance by Galvani, are passive. They serve merely to conduct the fluid pre-existent in the animal system; whereas, with the galvanic batteries of Volta, the muscles are excited to action by the influence of the apparatus itself.

Effects of Galvanism on Animals.

" From the above experiments there is reason to conclude,

36 Conclusions from the

" 1. That galvanism, considered by itself, exerts a considerable power over the nervous and muscular systems, and operates universally on the whole of the animal economy.

" 2. That the power of galvanism, as a stimulant, is stronger than any mechanical action whatever.

" 3. That the effects of galvanism on the human frame differ from those produced by electricity communicated with common electrical machines.

" 4. That galvanism, whether administered by means of troughs or piles, differs in its effects from those produced by the simple metallic coatings employed by Galvani.

" 5. That when the surfaces of the nerves and muscles are armed with metallic coatings, the influence of the galvanic batteries is conveyed to a greater number of points, and acts with considerably more force in producing contractions of the muscular fibre.

" 6. That the action of galvanism on the heart is different from that on other muscles. For, when the heart is no longer susceptible of the galvanic influence, the other muscles remain still excitable for a certain time. It is also remarkable that the action produced by galvanism on the auricles is different from that produced on the ventricles of the heart, as is demonstrated in experiment the tenth.

" 7. That galvanism affords very powerful means of resuscitation in cases of suspended animation under common circumstances. The remedies already adopted in asphyxia, drowning, &c. when combined with the influence of galvanism, will produce much greater effect than either of them separately *."

* p. S.

Excepting the experiments of Aldini which we have just detailed, the greater number of those of which an account has been given, it has been already observed, were made on cold-blooded animals, and besides, the apparatus usually employed, was a single galvanic combination. After the construction of the pile was known, and still more so after batteries in the form of troughs were invented and employed, very different effects were exhibited on the animal body, both in the dead and living state.

With batteries composed of 200, 300, or 400 pairs of plates arranged in troughs, very powerful shocks will be felt when the circle is completed between the extremities of the battery by means of the two hands of any person, so that the fluid shall pass through the body. This experiment may be performed by touching with one hand wetted, a wire connected with one extremity of the battery, and with the other hand also moistened a wire proceeding from the other end of the battery. Every time that the contact is made a shock is felt. The effect will be more powerful if round balls of brass having brass rods attached to them after being well wetted, be placed in the palms of the hands also well wetted, and a communication be established between the ends of the battery. The same effect is produced when the circle is completed by means of a number of persons joining hands together; but it must be observed, that each person must take care to have the

Chemical Effects.

the hands well moistened, otherwise the intensity of the shock will be greatly diminished, or its effect entirely obstructed. No experiments have been made, so far as we recollect, to ascertain with any degree of precision, how far the intensity of the shock is diminished by increasing the number of persons composing the circle of communication, or whether, indeed, when the experiment is made with the requisite degree of caution and attention, it suffers any diminution.

7 Galvanic shock compared.

It has been observed by some, (and so far as we can judge from our own feelings in numerous experiments made with a pile composed of 60 pairs of plates, or with a trough of 50 pairs, and sometimes with two and four troughs of 50 pairs each combined, the observation which we have made coincides with that of others), that the shock from the galvanic battery possessed some peculiarity, by which the sensation it excited was much more disagreeable than a shock of artificial electricity which seemed to be of no greater intensity. But it must be allowed, that in the comparison of experiments of such delicacy, the result of which depends on the feelings, great ambiguity must prevail; and therefore, when the comparison is unavoidably so inaccurate, it can afford no precise conclusion.

8 Effect on wounds.

The sensation is extremely unpleasant when the shock of galvanism, even when it is very slight, passes through the fingers, if they have been scratched or wounded.

9 Directed through the head.

A slight shock directed through the head between the temples, produces the sensation of a flash of light before the eyes, and an irresistible contraction of the muscles of the upper eyelids, so that the person who is the subject of the experiment involuntarily winks every time that the circle is completed. This experiment, which should be repeated with caution, is performed in the following manner: Place a bit of tin-foil which will adhere by wetting with water to the part to which it is applied, on each temple. Then having formed the communication between one end of the trough and one temple by means of a metallic conductor, flat like a small button, in that part which touches the tin-foil; this is retained in contact with the tin-foil by an assistant; and by means of another assistant, another similar conductor is applied to the tin-foil on the other temple. Things being thus arranged, the wire connected with the latter, is by the operator brought in contact with the other extremity of the battery, or with that part of it to which the extent or intensity of the shock is to be limited. Every time that this contact is repeated, the sensation of the flash of light, and the other effects, are produced. It has been hinted above, that this experiment should be performed with caution.

Cautions.

Not more than from 12 to 20 pairs of plates should be employed, at least on those on whom the effects of a small number have not been previously tried; and perhaps with that number, at least in the experiments of this kind which we have seen made, there are not many persons who would choose to have them repeated on themselves. But these effects, it may be added, will be more or less powerful in proportion to the period that the battery has continued in action with the same fluid.

Effect on dead animals.

A battery composed of 200 pairs of plates will produce strong contractions in the limbs of a fowl or rabbit, which has been recently killed. These effects may be conveniently exhibited by introducing one of the conducting wires, by means of a hook, into the mouth, or fixing it about the back part of the head of the animal, and fixing a similar hook from another wire connected with the other end of the battery near the rump, so that the current of galvanic fluid shall pass through the body. When the communication between the extremities of the battery is formed, the convulsive motions of the limbs of the animal take place, and are repeated as often as the circle is completed. Similar effects are produced on a dog or sheep; but to induce strong convulsions in the larger animals, a more powerful apparatus must be employed. It will be necessary to put in action a battery consisting of at least 300 or 400 pairs of plates arranged in troughs.

With a battery of such extent and power, the convulsive motions produced on the limbs of horses that were subjected to its action, were so strong that they could scarcely be resisted by the strength of two persons.

The head of an ox, soon after it was separated from the body, and while it was yet warm, was acted on by six batteries, amounting to about 300 pairs of plates. Strong convulsive motions were produced; the eyes opened, and the pupils were greatly dilated; the ears were also put in motion; and the tongue, drawn out and fixed to the table with an iron skewer which entered the wood above half an inch, was retracted with such force as to detach itself from the skewer which was thrown to some height into the air.

It has been said that the motions thus induced on the limbs of animals by means of galvanism, resemble the convulsive motions of epilepsy. Perhaps the motions of animals during the struggles of death may be considered as nearly similar. Whether this be so or not, we have observed that the convulsive contractions of animals subjected to galvanism, greatly resemble the peculiar motions of each animal in the struggles of death. This observation, however, only extends to what has happened to fowls, rabbits, and sheep; but so far as it goes, it has been allowed by those to whom we have remarked the circumstance to be pretty correct.

With these observations we conclude this long detail of the effects of galvanism on animals. This seemed to be necessary in order to give the reader a distinct view of what may be considered as the dawn of this department of science; for as we have already hinted, the experiments and investigations of naturalists were at first limited to its effects on animals; and from their labours an immense body of facts were accumulated before its chemical effects were much known or distinctly ascertained. We now therefore proceed to the consideration of the chemical effects of galvanism. These shall be the subject of the next chapter.

Chap. III. *Of the Chemical Effects of Galvanism.*

In the account we propose to lay before our readers, of those effects of the galvanic fluid which are to be considered as more strictly chemical, we shall first state more generally some of the experiments by means of which these effects are illustrated, and describe the method of performing them, and then enter into a more particular detail of the experiments of different philosophers which tended to improve and enlarge the knowledge of galvanism.

We shall limit the account of the experiments first alluded to above to the combustion of charcoal, the deflagration and combustion of metallic substances, the decomposition of water and some other fluids, and the precipitation of metals from their solution in acids.

42 Combustion of charcoal.

Exper. 1.—With a battery composed of 50 pairs of plates of three or four inches square, with proper management, a brilliant light may be produced from the combustion of charcoal. The charcoal for this experiment should be well prepared from some of the harder woods, such as beech or boxwood. It has been said that it could only be properly prepared by exposing it to a degree of heat equal to that of a glasshouse furnace; but we know from experience that so high a temperature is by no means absolutely necessary. We have prepared charcoal which was found to answer the purpose of the present experiment, with such a heat as can be easily commanded in a small chemical furnace. The wood which is to be converted into charcoal is divided into slips of about one-fourth of an inch square; it is then put into a crucible, which is filled up with sand, and may be covered with another crucible inverted, so as still more effectually to prevent the access of air. The crucible is then placed in the middle of the furnace, which is to be filled up with charcoal, and a strong heat maintained for eight or ten hours. After this the charcoal will be found sufficiently prepared, and this is of some consequence to be attended to, because on the complete conversion of the wood into this state much of the experiment depends.

Slips of charcoal reduced to a fine point are attached to wires, which communicate with the extremities of the battery. The charcoal may be fixed to the conducting wires by means of a bit of thread, or fine iron or brass wire, or they may be fixed in pincers, or an instrument similar to that which is used for holding crayons or black-lead penils; but in whatever way this part of the apparatus is contrived, when the two pieces of charcoal connected by means of metallic conductors with the extremities of the battery are brought into contact, combustion immediately takes place. The rapidity or brilliancy of this combustion is proportioned to the strength and activity of the battery. The light produced by such a battery as that we have described above, will be at times pretty vivid; but with two such batteries whose action is combined, it is still more brilliant. When four batteries, consisting each of 50 pairs of plates of eight inches square, are employed for this experiment, nothing perhaps can exceed the brilliancy of the light which is given out during the combustion of the charcoal. With the smaller battery, the process is occasionally interrupted; but with the larger apparatus the combustion goes on for a short time, giving out a continued and uniform brilliant light. When this is the case, the rays seem to proceed from the point where the combustion is going on, and exhibit all the variety of the prismatic colours. When the pieces of charcoal are immersed in water, and brought into contact under its surface, the combustion also goes on with considerable rapidity.

43 Of metals.

Exper. 2.—The deflagration and combustion of many metallic substances may be also effected with a battery composed of 50 pairs of three inch plates, and this may be done with a very simple apparatus. A bent wire, such as we have already described, is inserted into the perforated projecting piece of wood, at the extremity of the battery. The wire is to be bent at a right angle to that part of it which is fixed perpendicularly into the extremity of the trough, and on the horizontal part of it is placed the metallic substance to be deflagrated. A plate of copper, which must be perfectly clean and free from oxide, is to be connected with the other end of the battery by means of a conducting wire. When the apparatus is thus arranged, if the copper plate be brought into contact with gold or silver leaf, for instance, the combustion of these substances will take place, and this combustion, it is scarcely necessary to add, will be in proportion to the power of the battery and its energy. In the same way tin-foil, white and yellow Dutch metal, as it is called, may be subjected to experiment, and with a battery of moderate power, a brilliant combustion may be produced.

When a battery of greater power is employed, a very brilliant and rapid combustion of steel wire can be effected. This experiment is made by stretching a piece of wire, such as that which is used for the smaller strings of musical instruments, between the two metallic conductors connected with the opposite extremities of the battery; and thus completing the circle, the combustion takes place. When the experiment succeeds, several inches of the wire are almost instantaneously reduced to the state of oxide. In this way the energy of the battery may be in some measure ascertained, as it must be in proportion to the length of the wire which is burnt. When a very powerful battery is in action, 10 or 12 inches of such wire may be completely burnt, that is, not merely made red hot, but having undergone the process of combustion, and having passed from the metallic state to that of oxide.

44 Decomposition of water.

Exper. 3.—We have already described the apparatus for the decomposition of water. To exhibit this experiment, it is only necessary to fill some of the tubes which have been mentioned for this purpose with water, and to complete the circle of communication between the extremities of the battery, the water in the tube to be decomposed forming part of this circle. If the conducting wires terminating in the tube consist of metals which do not readily undergo oxidation, such as gold or platina, the gases which are the constituent parts of water are separated from the wires, the oxygen gas from the one, and the hydrogen gas from the other, and are seen rising in bubbles to the top of the tube, displacing a quantity of water equal to the space occupied by the gases evolved. This process goes on till the surface of the water falls below the conducting wire passing through the top of the tube; and the circle being then interrupted, the process stops. When this is the case, if the two conducting wires within the tube can by any contrivance be brought into contact, a spark is produced, by which the gases are set fire to, and are again converted into the state of water. This combustion is attended with an explosion. Or if the tube be carefully taken from the apparatus under water, while the finger is placed upon the open end, and then inverted, the gas collected will rise through the water; it may then be set fire to by means of a burning body, a similar combustion will take place, attended with an explosion.

But

Chemical Effects.

But if the wires terminating in the tube be of brass or iron, or any metal which is easily oxidated, only one of the gases is collected in the tube; the other (the oxygen) combines with the metal, forming an oxide, which collects on the point of the wire.

By a very simple contrivance the gases may be collected separately. With this view two tubes in which the conducting wires terminate, are employed. These tubes being filled with water, must be inverted in the same bason of water, the latter of which forms the communication between the extremities of the battery.

45 Other liquids decomposed.

Other fluids, as oil, alcohol, ether, and ammonia in solution, may be also decomposed by a similar process. For the decomposition of oil, alcohol, and ether, the pieces of charcoal may be immersed in vessels containing these liquids; and, when they are brought into contact, the decomposition is effected, with the formation and evolution of carbonic acid gas, which is seen rising in bubbles to the surface.

46 Precipitation of metals.

Exper. 4.—By means of galvanism, and with a battery of moderate power, metals may be precipitated from their solutions in acids. The apparatus to be employed for this purpose is similar to that for the decomposition of water, and the tube is filled with a solution of the metallic salt. The communication being then established, the metal is precipitated, and appears in an arborescent form on the point of the wire. In this way the acetate of lead, or sugar of lead, the nitrate of silver, and many other metallic salts, may be revived.

Many other curious and amusing experiments might have been related, but what we have now given will enable the reader to have a distinct notion of the chemical effects of galvanism. Many other of the chemical effects of the galvanic fluid are so closely connected with the peculiar views and theories of those who have discovered and observed them, that we shall not enter into any detail of them till we come to consider that part of the subject. In the mean time we shall occupy the remaining part of the present chapter with an account of some of the experiments on the chemical effects of galvanism which were observed by philosophers in the earlier part of its progress.

Mr Cruickshank, the inventor of the galvanic trough, very early directed his attention to this inquiry, and prosecuted it with great ardour and success. In one of his early communications on this subject we have a comprehensive view of some of the chemical phenomena of galvanism. We shall, therefore, give it in his own words.

47 Experiments of Cruickshank.

"I shall not, says he, give any particular account of the apparatus employed, being a pile, and not differing materially from that in use. I shall only just observe, that it consisted of plates of zinc and silver, of about 1.6 inches square, and that the number of each employed in the following experiments varied from 40 to 100, according to the power required.

"I found that a solution of the muriate of ammonia answered better for moistening the interposed papers than common water.

"When the machine was in full action, sparks which were perfectly visible in the day time, could be taken at pleasure, by making a communication in the usual way between the extremities of the pile, and a small report or snap could be heard; the shock given at that time was very strong, and a gold-leaf electrometer, placed in the circle of communication, was very sensibly affected: these circumstances, some of which, I believe, have been already ascertained by Messrs Nicholson and Carlisle, shew the strong resemblance of this influence to electricity. These gentlemen have likewise discovered that galvanism decomposes water with much greater facility than electricity, but with phenomena somewhat different.

"*Exper.* 1.—A quantity of common water was introduced into a glass tube, being confined at each end by corks, but perfectly at one by a cement of rosin and bees wax: pieces of silver wire were passed through the corks, and brought within an inch of each other in the fluid, their other extremities being at the same time connected with those of the machine or pile, one with the lower zinc plate, and the other with the upper silver plate. In future, to avoid circumlocution, I shall call the wire attached to the silver plate, the silver wire, and the other the zinc wire. The tube was then placed upright in a cup containing water, with the uncemented end downwards. As soon as the communication was made between the extremities of the pile by the wires, a quantity of small air bubbles began to ascend from the end of the wire connected with the silver, as observed by Messrs Nicholson and Carlisle; but a white cloud at the same time made its appearance at the one proceeding from the zinc, or the zinc wire. This cloud gradually increased, and assumed a darker colour, and at last it became purple, or even black. A very few air bubbles were likewise collected upon and ascended from this wire, but when the machine was in full force, a considerable stream could be observed.

"The gas was collected, and found to be a mixture of hydrogen and oxygen, in the proportion of three parts of the former to one of the latter. No great dependence, however, was placed upon this in point of accuracy. The zinc wire was found to be much corroded, and looked as if a considerable portion of it had been dissolved. As the cloud which was formed around this wire became purple on exposure to the light, I suspected it might be luna cornea, or muriate of silver proceeding from the silver, which had been somehow dissolved, and afterwards precipitated in this state, by the muriatic salts in the common water. This led to the following experiments:

"*Exper.* 2.—The glass tube was now filled with distilled water, to which a little tincture of litmus was added; when the communication was made by the wires as in the former experiment, a quantity of gas arose from both wires, but in the greatest quantity from that connected with the silver. In a few minutes a fine red line, extending some way upwards, was perceived at the extremity of the zinc wire; this increased, and in a short time the whole fluid below the point of this wire became red; the fluid, however, above the silver wire, looked of a deeper blue than before, the slight tinge of purple being destroyed.

"*Exper.* 3.—I next filled the tube with distilled water, tinged with the tincture of Brazil wood; it was no sooner placed in the circle of communication, than the fluid surrounding the silver wire, particularly towards its extremity, became purple, and this tinge increased so fast, that the whole fluid surrounding this wire, and occupying the upper part of the tube, soon assumed as deep a colour, as could be produced by ammonia.

"The portion of the fluid in contact with the zinc wire

Chemical Effects.

wire became very pale, and almost colourless, nor could the purple tinge extend below its upper extremity. From these experiments it would appear, that an acid, probably the nitrous, is produced at the wire proceeding from the zinc, and an alkali, probably ammonia, at that in contact with the silver. These facts sufficiently explain the action upon the silver wire, and the nature of the whitish cloud proceeding from it, and afterwards becoming purple. When lime water was employed instead of common or distilled water, the wire was likewise acted upon, but in a less degree, and the cloud had at first an olive colour, exactly resembling the precipitate of silver by lime-water.

"The quantity of silver dissolved or corroded, if I may use the expression, in these experiments, was very considerable, and where common or distilled water had been employed, a small portion of it remained in solution, which was discovered by the addition of the muriatic acid. Indeed a much larger quantity would probably have been suspended, had it not been for the alkali generated at the same time, and which manifestly produced a precipitate at, or near, the upper extremity of the zinc wire, where, after a certain time, a dark zone or stratum was always formed.

"*Exper.* 4.—It is a well known fact, that hydrogen gas when heated, or in its nascent state, reduces the calces of the metals; I expected, therefore, that by filling the glass tube with a metallic solution, I might be enabled to separate the hydrogen from the oxygen gas, and thus procure the latter in its simple or pure state. With this view the tube was filled with a solution of the acetite of lead, to which an excess of acid was added, to counteract the effects of the alkali. When the communication was made in the usual way, no gas could be perceived, but after a minute or two, some fine metallic needles were perceived at the extremity of the wire connected with the silver. These soon increased, and assumed the form of a feather, or rather that of the crystals of the muriate of ammonia. The lead thus precipitated was perfectly in its metallic state, and very brilliant; a little gas escaped from the wire connected with the zinc, and it was considerably corroded as usual.

"A solution of the sulphate of copper was next employed, and with the same result, the copper being precipitated in its metallic form by the wire connected with the silver. In this instance the metal did not crystallize, but formed a kind of button at the end of the wire, which adhered so completely to the silver, that it was found impossible to separate it.

"The most beautiful precipitate, however, was that of silver from its solution in the nitrous acid. In this case, the metal shot into fine needle-like crystals, articulated, or jointed to each other, as in the Arbor Dianæ.

"What became of the oxygen gas usually produced in these experiments?

"*Exper.* 5.—A quantity of pure water mixed with distilled vinegar was introduced into the tube, and placed in the circle of communication; some gas was disengaged from the silver wire, but no cloud appeared at the extremity of the zinc. After some time, however, a quantity of metallic silver was precipitated by the silver wire, and this precipitate at last became very copious; a perfectly similar effect was produced, when the tube was filled with very diluted sulphuric acid; in these cases the precipitated silver had the appearance of shining scales, like that thrown down by copper in the usual way. It may be proper to observe, that in all these precipitations and reductions, nothing but wires of pure silver were employed. The results in this last experiment were exactly what was expected; the vinegar prevented the alkali from precipitating the silver, dissolved by the generated acid; in consequence of which, when a sufficient quantity of the metal was taken up, it was again thrown down by the silver wire in its metallic form.

"*Exper.* 6.—A solution of the muriate of ammonia being introduced into the tube, and exposed to this influence, a little gas was disengaged from the silver wire, while the zinc one was incrusted with a substance which soon became black, and was found to be luna cornea. The liquor which remained in the tube, after the operation had been finished, was highly alkaline, and smelled strongly of ammonia; common salt was decomposed in a similar manner. This experiment accounts for the decomposition of the muriate of soda and ammonia, which always takes place when the papers in the pile are moistened with a solution of these salts.

"A solution of the nitrate of magnesia appeared to be likewise decomposed by this process; for after some time, a white powder resembling magnesia, was precipitated on the surface of the silver wire, very little gas was disengaged.

"*Exper.* 7.—In order to ascertain how far this influence might be carried, provided the circle of communication was complete, two tubes were employed, and connected by a silver wire passing through corks; the tubes were filled with water and secured by corks; two other wires being then passed through these corks, the arc was connected with the silver, and the other with the zinc, at the extremity of the pile. A quantity of gas as usual was disengaged at the extremity of the silver wire, and the portion of the connecting wire in the same tube was partly dissolved, and as mentioned in experiment 1st; but the other portion of the same wire in the other tube gave out gas, while the communicating zinc wire was corroded. And I make no doubt that a similar effect would be produced, if any number of tubes were connected in a similar manner, by which means a large quantity of gas might be procured in a short time.

"Besides silver wires, I likewise employed those of copper or iron, and it did not appear that these were more corroded or acted upon than the silver; indeed, in some of the above experiments, not less than half, or three-quarters of an inch of the wire was entirely consumed. The copper wire connected with the zinc gives out a greenish blue substance resembling the nitrate of copper with excess of the metal, or when part of the acid has been expelled by heat, &c. In examining the gas which was procured at different times, I always found it mixed with a little oxygen gas, but sometimes this did not exceed one-eighth of the whole in bulk; however, I paid but little attention to this part of the process, for as my wires were always corroded, no conclusion with regard to the composition of water could be drawn from it *."

We might have here detailed a great variety of experiments,

History.

periments, which have been made to ascertain the chemical effects of galvanism, and to elucidate the nature and properties of the fluid which is supposed to be concerned in these changes. In particular we might give an account of the later experiments and researches of philosophers, in investigating the formation of muriatic acid, and an alkali which is supposed to be soda, by means of this power. This forms one of the most curious subjects of inquiry which has yet occurred with regard to galvanism; but as some part of the investigations of those who have occupied their attention with this inquiry, is connected with theoretical views, we shall reserve the consideration of the whole to the second part of this treatise, the object of which is, to give a historical detail of the progress of galvanism, with the opinions of philosophers concerning the nature of the galvanic fluid. To this therefore we now proceed.

PART II. OF THE HISTORY AND PROGRESS OF GALVANISM.

IN the first part of this treatise we have given a pretty full view of the method of constructing apparatus for the purpose of exhibiting the phenomena of galvanism, and we have entered at considerable length into a detail of the experiments which have been made, to ascertain the effects of the galvanic fluid on animals, as well as those experiments by which its chemical effects are illustrated, with some of the theoretical views and opinions of those who have been engaged in researches concerning the properties of this fluid. It is now proposed, in the second part, first, to consider the progressive history of galvanism, with the theories by which philosophers have attempted to account for its effects; secondly, we shall endeavour to trace the analogy between artificial electricity and galvanism; and, lastly, give an account of the experiments and inquiries which have been made concerning the formation of muriatic acid and soda by means of this power. These will form the subjects of the three following chapters.

Chap. I. *History of the Discovery and Progress of Galvanism.*

48 First hint of galvanism.

THE first hint which is usually quoted as connected with the phenomena of galvanism, is extracted from a book entitled the General Theory of Pleasures, by Sultzer, which was published in the year 1767. In this work the author particularly describes the experiment with two dissimilar pieces of metal which we have related at the beginning of this treatise, and by which, we have endeavoured to illustrate what is understood by galvanism, in its effects on the living body. The experiment alluded to is that in which a piece of zinc and a piece of silver being placed, the one in contact with the upper, and the other with the under surface of the tongue, and their projecting edges being brought into contact, a taste is produced, which, the author observes, resembles vitriol of iron. This sensation is ascribed to a vibration of the particles of the metals affecting the nerves of the tongue.

Other hints and experiments have been quoted, which seem to be connected with the phenomena of galvanism; but as they were not prosecuted, and as no conclusion, with the view of establishing any particular point, was deduced from them, it would be unnecessary to give an account of them, excepting those of Vassalli, member of the royal academy of Turin, who published, in 1789, a theory on this subject, supported by a series of experiments which he had instituted. Here he throws out a conjecture, that a provision has been made by nature in the system of a living animal, by which the electricity accumulated in any particular part of the body is preserved and retained for some necessary purpose of its existence. It had indeed been supposed by some, that the animation of the blood depended on the electric fluid; but according to others, this fluid and the nervous fluid were to be considered as one and the same.

49 Galvani's discovery.

This subject was particularly investigated and illustrated, when in the year 1791 a remarkable discovery which was made by Dr Galvani, professor of anatomy in the university of Bologna in Italy, was announced to the world. This discovery, like most others, was accidental. Some frogs deprived of the skin were placed upon a table near which the professor happened to be engaged in experiments with an electrifying machine. The crural nerve of one of the frogs was touched by a person present, with the point of a scalpel during the time that the machine was working. The whole animal was thrown into convulsions. The same experiments were afterwards repeated with the same success. Every time that the scalpel was applied to the nerve, while the machine was in motion, violent convulsions were produced. But when the machine ceased to move, on the application of the scalpel to the nerve no effect followed. To this accidental discovery this branch of science owed its origin, and from the name of the discoverer was called *Galvanism*.

Since the period of this discovery, a great many experiments have been made, and many curious phenomena have been observed, which have excited much interest and attention among philosophers. We shall now present our readers with a historical sketch of the progress of these discoveries.

The experiment which has been mentioned was repeated by Galvani in every possible way he could think of. He varied it both by means of artificial and atmospherical electricity, and the result of all these experiments he found to be uniform and consistent. When Galvani first began his researches, he supposed that the phenomena depended on common electricity, passing through the animals on which the experiments were made. He had observed that the same effects were produced, but in a smaller degree, in living frogs and in other animals, as in those which had been newly deprived of life. In the course of some experiments which he made on atmospherical electricity, he suspended some frogs, by means of metallic hooks fixed in the spine, from iron palisades; and he observed that the muscles of these animals were frequently and involuntarily contracted, as if they had received a shock of electricity. At first he ascribed these convulsions to the

History.

the changes in the state of the electricity in the atmosphere; but after a repetition of the experiments he found that he was mistaken. He discovered, however, at last, after many ingenious experiments, that he could at pleasure produce the convulsions, by touching two different parts of the animal, each with a piece of metal, and then bringing these pieces of metal into contact. The experiment may be made in the following manner. Let the crural nerve of a frog be laid bare about an inch in extent; let a piece of zinc be placed in contaet with the nerve, and let a piece of silver be placed on the muscles with which the nerve communicates. Then bring the zinc and silver into contact, and the whole limb will be instantly thrown into convulsions.

After Galvani had published his experiments, the convulsions thus excited were ascribed to the action of some unknown fluid, to which the name *Galvanism* was

50 His theory.

given, or *Animal Electricity*. According to Galvani, a fluid is secreted in the brain, the same with the nervous fluid; but being analogous to common electricity, might with more propriety be termed animal electricity. The conductors of this fluid are the nerves. It is carried off by them as it is secreted, and deposited on the interior surface of the muscular fibres, which being non-conductors of the fluid, do not permit it to pass through them. The state of the muscular fibres exaetly resembled that of a charged Leyden jar. Their inner surface is electrified positively, and the outer surface is electrified negatively. The communication between the exterior and interior surfaces of the muscular fibres is formed by the nerves. They convey the redundant electricity from the internal to the external surface, and, like the effect of the electrical stimulus, every discharge is attended with a muscular contraction.

51 Volta's.

On the other hand Volta, another philosopher who carried his researches far into this subject, and of whose experiments and views we have given a long detail, adopted a different opinion. He thought that the convulsions occasioned by the galvanic apparatus were entirely independent of the action of the nervous fluid, and were to be ascribed to common electricity excited by the metallic conductors which are employed. These different opinions were supported with much ingenuity in a controversy which commenced between Galvani and Volta. The writers on galvanism divided themselves into two parties. While one party maintained with Volta, that the phenomena were owing to the action of common electricity on the muscular fibres, another party thought that they were entirely dependent upon something peculiar to animal matter. By many this seemed to have been considered as the nervous fluid, which was supposed to be the same with, or analogous to, common electricity.

It had been long asserted, that porter, and some other liquors, drank out of a pewter pot, had a different taste from what it has when drank out of glass or earthen ware. Pure mercury, it has been observed, retains its metallic splendour for a long time; but when amalgamated with any other metal, it is soon tarnished or oxidated. The Etruscan inscriptions on pure lead are in good preservation to this day; whereas some medals of lead and tin, of no great antiquity, are much corroded, and works of metal, whose parts are soldered together by the interposition of other metals, soon tarnish about the places where the different metals are joined. When the copper sheeting of ships is fastened on by means of iron nails, the nails, but particularly the copper, are readily corroded about the place of contact. A piece of zinc placed in water for a considerable time scarcely undergoes any change; but if a piece of silver happen to touch the zinc whilst it is in the water, it is soon corroded or oxidated.

In the course of a very few years after the publication of Galvani's discovery, a great number of writers appeared, and presented to the world a great body of facts which they had ascertained by experiments and observations. The following are among the most important: 1. When a piece of metal is placed on the muscle of an animal just dead, and still moist, and another piece of a different metal is placed on the nerve which leads to the muscle, or on another part of the muscle, and if the two pieces of metal be brought into contact, a contraction or convulsion of the muscle takes place. 2. A single piece of metal, or two pieces of the same metal, have no effect in exciting contraction of the muscle. It is necessary to have two perfect conductors of electricity in contact, before any convulsion can be produced. 3. The muscle must be moist. The effect is not prevented by a ligature on a nerve; but the susceptibility of a muscle to be thrown into convulsions is diminished, and at last destroyed, by the application of opium, which destroys irritability. The same change takes place if the muscle be allowed to remain for some time after death. 4. The different muscles of the body are differently affected by the galvanic influence. They are not equally susceptible of the same degree of convulsive effect. 5. If a plate of zinc be placed on the upper surface of the tongue, and a plate of silver or copper be applied to its under surface; and if the two pieces of metal thus placed be brought into contact, a strong metallic taste is immediately perceived. An acid taste is perceived, when the tongue is dipt into an alkaline solution contained in a tin or zinc cup held in the moist hand. 6. If a piece of metal, as a silver spoon, be placed on the ball of the eye, and another piece of a different metal, as a piece of zinc, be placed on the tongue, and if the two pieces of metal be brought into contact, a flash of fire is instantly perceived; and it is perceived, both when the metals are brought into contact, and when they are separated. 7. Another fact, which was ascertained by Aldini, who performed a great many experiments in galvanism during his visit to this country, is, that convulsions may be excited merely by forming a proper chain of muscles and nerves. This is proved by the following experiment. He took a prepared frog, and held it suspended in one hand by the foot. The sciatic nerves were brought into contact with the tongue of an ox, the head of which had been recently separated from the body. He then introduced the other hand moistened with a solution of common salt in water into the ear of the animal, thus completing the circle. Every time that the communication was formed, the muscles of the frog were thrown into convulsions.

Most of the facts which we have now related, were ascertained by the different philosophers, whose researches were directed to the subject of galvanism, between the years 1791 and 1794. Hitherto the connection between galvanism and animal bodies was considered by most

most writers, so close and intimate, that they supposed the one could not exist independent of the other. Some facts, however, which were established by Fabroni and others, seemed to favour the opinion of those who considered galvanism as the action of a peculiar fluid on the animal fibre. This fluid is developed by the mutual action of the metals employed as exciting causes, and it exists in other bodies as well as in those which are endowed with life. We have already mentioned that two pieces of different metals put into water produce changes on the water which neither of them separately could effect. This was observed by Fabroni, from which he concluded that a chemical change was effected by the metals on each other. To this change he supposed part at least of the phenomena of galvanism was owing.

53 Phenomena of galvanism ascribed to chemical action.

Thus he explained the necessity of two different metals and of moisture in the production of these phenomena. Those metals, he also observed, which occasioned the most rapid changes on each other in water, were most powerful in exciting galvanic convulsions.

Metals and charcoal, it was ascertained by Volta, being good conductors of electricity, attract and repel that fluid with different forces. When two different metals in their natural state of electricity are brought into contact, electric matter passes from the one to the other; the one becomes electrified positively, and the other negatively. From this he concluded, that the electricity which occasioned the galvanic phenomena did not reside in the animal fibres, but in the metals employed as exciters, and that the convulsions were produced by the electric matter passing through these fibres.

The seeming inconsistency which appeared in the opinions of Volta and Fabroni was removed by succeeding discoveries, which demonstrated that both electricity and chemistry were concerned in the galvanic phenomena. Galvanism was now no longer considered as something connected with living matter, which was totally inexplicable, but as something developed by the mutual action of inorganized substances on each other, the effect or energy of which might be estimated and measured by its action on the muscular fibres. The discovery of the galvanic pile by Volta put it in the power of philosophers to increase the power or energy of the galvanic influence at pleasure. This pile, and the method of constructing it, have been already described.

A description has also been given of a different apparatus, the invention of Mr Cruickshank of Woolwich, which has been employed in place of Volta's pile. This is called the *galvanic trough*, and it consists of a number of square plates of different metals as in the other, which are soldered together in pairs, and fixed by means of cement in a box of baked wood, at a small distance from each other.

Analogous to that of electricity.

A striking analogy was at once observed between this apparatus and charged electrics. A great deal of discussion took place on the subject; much investigation followed: and philosophers held different opinions concerning the phenomena of galvanism, whether it was to be considered as the same with common electricity, or as something specifically different.

It was at last ascertained by Nicholson and Carlisle, that the zinc end of the pile was in the state of positive electricity, and the silver or copper end in the negative state. The zinc end of the pile, then, according to the commonly received theory of electricity, gives out the electric fluid, which enters at the silver or copper end. And if the circle be completed by means of metallic wires or charcoal, when the pile is sufficiently powerful, sparks similar to what take place by the discharge of common electricity may be perceived. Electric batteries have been charged by means of the pile; metallic wires, tin-foil, gold leaf, are burnt; and mixtures of hydrogen and oxygen gas are exploded in the same way as happens when electric discharges are made to pass through them. From the whole of the phenomena, there seems now to be little doubt of the identity of the two fluids.

Chemistry, however, has a very considerable share in the phenomena of galvanism. The action of the pile is most powerful in oxygen gas: it ceases entirely in the vacuum of an air-pump, or in azotic gas. The electrical machine also, it has been ascertained, cannot be excited in any gas unless it contain oxygen; and it seems probable, that the effect of the amalgam, which is employed in exciting the electrical machine, bears a proportion to the facility or rapidity of its oxidation. But we shall discuss this point more fully in the second chapter.

When the action of the pile has continued for some time, it gradually becomes weaker, till at last its energy is entirely lost. This power can only be renewed by cleaning the plates, the surfaces of which have been very much changed. It was observed that the time in which the action of the pile ceased, was in proportion to the energy which it originally possessed. When it was strongest, the duration of its action was shortest. It was observed also, that one of each pair of plates was covered with a coat of oxide; and when this process of oxidation was finished, and the surface of the plate was entirely covered, the action ceased. Of the two metals employed in the construction of the pile, that which is most easily oxidated, always undergoes this process. When zinc and silver, or zinc and copper, are used, the zinc is always oxidated; and unless this oxidation take place, there is no action of the pile. Its action or energy is proportional to the oxidation of the metal; and thus it appears that this oxidation is essentially necessary to the action of the pile. For, unless the liquid which is employed to moisten the pieces of card or cloth between the pairs of plates, or that which fills the cells in the trough, be capable of oxidating the zinc, no action follows. There is no action at all with silver and zinc, and perfectly pure water. *In vacuo* the action of the pile soon ceases, even with common water; for the oxygen which is held in solution by the water soon combines with the zinc, and then the process stops. The action is increased by oxygen gas, because the oxidation of the zinc is facilitated. Its action is also increased, and goes on even *in vacuo*, when nitric acid, which supplies oxygen for the process of oxidation, is substituted for the water. Thus, by estimating the proportion between the oxidation of the metals and the action of the pile, it may be determined what metals are proper for forming piles, and with what liquids they may be employed. In the choice of the different metals, it must be observed, that one of them must always be more easily oxidated than the other. Two perfect conductors which are unequally oxidable, with an imperfect

History.

perfect conductor which is capable of oxidating the most oxidable of the perfect conductors, constitute the elements of the galvanic battery.

But some of the most important phenomena of galvanism are exhibited in its chemical effects. Most of these were first observed by the chemical philosophers of this country. We have already detailed many of the experiments by which these effects are illustrated; and we shall here only, for the sake of giving a connected view of this subject, merely recapitulate some of them.

55 Recapitulation of the chemical effects.

When water forms part of the circle between the extremities of the battery, and the conducting wires are brought within a small distance of each other, being immersed in a glass of water, the water is decomposed, and it will be recollected that the phenomena are different according to the nature of the wires employed. When the wires are of gold or platina, they undergo no change; oxygen gas is evolved in small bubbles from the positive wire, and hydrogen gas from the negative wire; and if the gases be collected separately by the apparatus formerly described, they are found to be in the proportions of the component parts of water. If one of the wires be immersed into one glass, and another into a separate glass, by completing the circle with a finger plunged into each glass, the process goes on, and the hydrogen gas is extricated in the one vessel, while the oxygen is given out from the wire in the other. This fact was first discovered by Mr Davy. When spring water is used, or water having azotic gas in solution, an acid is formed at the extremity of the positive wire, and an alkali at the extremity of the negative wire. The acid was found to be nitric, and the alkali ammonia. If the wires be plunged in different glasses, and the connection be formed by means of an animal body, the positive wire produces in the water tinged with an infusion of litmus, a red colour, while the negative wire also reddens an infusion of brasil wood.

If other wires besides those of gold or platina be used, it is found that the positive wire undergoes oxidation, but little or no gas is separated from it; while the negative wire, as in the former case, gives out hydrogen gas. When the wires are immersed into metallic solutions, as acetate of lead, nitrate of silver, &c. the silver or lead is revived, and deposited on the negative wire; and if solutions which contain sulphuric, nitric, or oxymuriatic acids, are used for the immersion of the conducting wires, the acids are decomposed, oxygen gas is evolved from the positive wire, and sulphur or hydrogen gas makes its appearance at the negative wire. The decomposition of ammonia has already been mentioned. This was discovered by Mr Henry. The hydrogen is given out by the negative wire, while the azotic gas is evolved by the positive wire. When plumbago or charcoal are employed as conductors in place of metals, it is found that carbonic acid is evolved from the positive end, and hydrogen gas from the negative.

It may be necessary here to describe a galvanic battery, constructed by Mr Davy, on principles somewhat different from that of Volta. In the Voltaic pile there are two perfect conductors, and one imperfect conductor; but this consists of two imperfect, and one perfect conductor: the two imperfect conductors are nitrous acid and liquid sulphuret of potash. A trough is divided into cells with slips of horn and plates of zinc, arranged alternately; nitrous acid is poured into the first cell, and sulphuret of potash into the second; the two liquids being separated by the slip of horn, a communication is formed between them by means of a moist piece of cloth laid over the horn, and in the same way the rest of the cells are filled. In this case the liquids are the imperfect conductors, and the zinc is the perfect one; and the action of the battery continues till the oxidation of one of the surfaces of the zinc takes place, the other surfaces remaining unchanged.

Having finished the short view which we proposed to give of the history and progress of galvanism, we should next proceed to detail some of the later experiments and discoveries which have been made on this subject. What we here chiefly allude to, is the discovery of the formation of muriatic acid and soda by means of the galvanic fluid. But this is proposed to be the subject of a separate chapter. We shall therefore proceed in the next chapter to consider the hypothesis by means of which the phenomena of galvanism have been explained, and to point out the analogy between electricity and galvanism.

Chap. II. *Of the Theory of Galvanism, and the Analogy between the Galvanic Fluid and Electricity.*

We have already observed that the philosophers who were occupied in researches on galvanism, early divided themselves into two parties. According to one party, with Volta at their head, the phenomena of galvanism were ascribed to the action of common electricity on the muscular fibres; while another party maintained the opinion that they depended entirely on something peculiar to animal matter. This was the opinion of Galvani himself, the original discoverer, and it was supported by his nephew Aldini, with certain modifications. The greater number of philosophers have now adopted the opinion of Volta, as being more consistent with the phenomena. We shall therefore now give a more particular account of the hypothesis which has been more generally followed in explaining these phenomena on the principles of electricity.

According to the received principles of electricity, there is a subtile fluid which exists in all bodies; but the existence of this fluid can only be recognised when the proportion which a body contains is greater or less than the quantity which is natural to it. When the quantity is greater than usual, the body is said to be electrified *positively* or *plus*; and when the quantity is less than usual, the body is said to be electrified *negatively* or *minus*. The electric fluid penetrates certain bodies, and passes through them with facility, and these bodies are called *conductors of electricity*; but there are other bodies which it cannot pass through without difficulty, these bodies are called *non-conductors* or *electrics*. Of conductors there are two kinds; one of which is denominated *perfect*, because the electric fluid passes through them with ease; the other is called *imperfect* conductors, because the fluid passes through them with difficulty. The perfect conductors are solid bodies which are susceptible of oxidation; and when they enter into combination with oxygen, they lose their properties as perfect conductors. The metal and charcoal are

Theory. are the only perfect conductors which are known. The imperfect conductors are those bodies which contain oxygen, and when they are deprived of it, they lose the properties of imperfect conductors. They are all liquid bodies, and usually contain water as one of their component parts. See ELECTRICITY.

Affinity of the electric fluid for conductors; There is an affinity between the perfect conductors and the electric fluid, in consequence of which this fluid remains in combination with the perfect conductor, till it is attracted by some body, for which it has a stronger affinity, or is excelled by some body combining with the conductor, for which the conductor has a stronger affinity than it has for the electric fluid. Perfect conductors possess different forces or degrees of affinity for the electric fluid. Thus, if two perfect conductors be brought into contact, the proportion of electric matter in each of them changes. That conductor which has the strongest affinity for the fluid, is electrified positively, or plus; and the conductor which has the weaker affinity is electrified negatively or minus. If a plate of zinc and one of copper, each of which possesses its natural proportion of electric fluid, be brought into contact, the zinc is electrified plus, and the copper minus; or, if iron and silver be brought into contact, the iron is electrified plus, and the silver minus; and if no other circumstances operate to change the state of the electricity, these two states will be permanent.

But, when a perfect conductor in the positive state of electricity, enters into combination with oxygen, it parts with the excess of electric fluid which it contained, and the discharge is made towards the side of the conductor which is combined with oxygen. The affinity of imperfect conductors for the electric fluid is weaker than that of the perfect conductors, so that, if a perfect and imperfect conductor be brought into contact, the perfect conductor becomes plus, and the imperfect minus; and this state is not changed, if the imperfect conductor cannot communicate oxygen to the perfect one.

for hydrogen. Between the electric fluid and hydrogen there is also an affinity, so that the electric fluid combines with hydrogen, provided this latter be present when the fluid is separated from a perfect conductor. The electric fluid is differently conducted through the bodies which are called perfect and imperfect conductors. The fluid passes through the perfect conductors, in its simple and uncombined state; but unless the fluid be combined with hydrogen, it cannot pass through the imperfect conductors, and this compound of electricity and hydrogen is capable of passing invisibly through liquid conductors.

Let us now suppose a plate of copper and another of zinc to be brought into contact, the zinc is immediately electrified plus, and the copper minus; but let us suppose also, that the surface of the zinc farthest from the copper, is brought into contact with a liquid which can communicate oxygen to that surface, so that it becomes oxidated, such, for instance, is water impregnated with common air, or with an acid. As soon, then, as the oxygen of the imperfect conductor combines with the zinc, the excess of its electricity is separated, and passes towards the imperfect conductor; but the zinc is oxidated by the decomposition of the water, the oxygen of which combines with the metal, while the hydrogen is set free. The electricity of the perfect conductor enters into combination with the hydrogen, and in this state it can pass through the imperfect conductor. If then the imperfect conductor be in contact on the other side with a perfect conductor, such as a plate of copper, which cannot, in this case, be oxidated, the electric fluid leaves the imperfect conductor, and enters the perfect one; but it cannot combine with a perfect conductor while it is in union with hydrogen; the hydrogen, therefore, is left behind, and, accordingly, when the electric fluid passes from the perfect to the imperfect conductor, a portion of hydrogen gas is given out at the surface of the perfect conductor; or, if that surface has undergone any degree of oxidation, the hydrogen combines with the oxygen, and thus leaves the conductor in the metallic state. But, farther, if a plate of zinc be in contact with a plate of copper, the fluid having a greater affinity for the zinc, will enter it; and if the zinc be again followed by another imperfect conductor, its surface is oxidated, the electricity is disengaged; it combines with hydrogen, and passes through the imperfect conductor as in the former case. Whatever the number of these sets of bodies may be, if they are arranged in the same order, the same phenomena will be exhibited.

Let us now suppose, that a battery is constructed, either in the form of a pile or trough, of any given number of pairs or plates; and suppose, if this battery is in the form of a pile, that the uppermost plate is zinc, the lowest is therefore of copper; the zinc is electrified plus, and the copper minus. If, then, a communication is established between the upper and lower plates of the pile, by means of conductors, according to the laws of electricity, the excess at the top of the pile immediately passes to the bottom. A current of electricity, therefore, will pass through the pile, and will continue till the surfaces of the zinc next the imperfect conductors are completely oxidated, when the action ceases, because the double decompositions on which this action depends, can no longer take place.

The number of repeated charges which pass through the pile, must be in proportion to the number of plates, so that the intensity of the pile increases with the number of plates of which it is composed. Hence it is, that the effects of galvanism on animals is found to be in proportion to the number of plates employed in the battery; but this depends upon its intensity, or the number of discharges followed by intervals, which pass through the body in a given time. 59 Different effects from the number of plates,

But, on the other hand, the effect of the galvanic fluid on metallic substances depends on the absolute quantity which passes through the metal in a given time. But the absolute quantity of fluid discharged from a single pair of plates, must be proportional to the surface of these plates; and hence it is, that the quantity of electricity discharged from a pile in a given time, depends upon the surface of the plates. When a battery is discharged, the small charge contained in each pair of plates, passes through the discharger; but there must be an interval between each of those separate charges, for they cannot be supposed to pass instantaneously, although the interval being too small to be perceptible, the discharge of the battery seems to be instantaneous. As then the number of small discharges which are apparently instantaneous, when a battery is discharged, is in proportion to the number of plates, the 60 and extent of surface.

Theory.

the intensity of each little discharge is proportional to the places which the pair of plates occupies in the battery; and hence it is, that the shock is increased by the number of plates more rapidly than the effect of the battery on metals is increased; but, on the contrary, the surface of the plates being increased, the effect on metals is also increased, because the quantity discharged at once from the upper pair is increased; and it seems to be in this way that the effect on metallic substances is produced.

61 Chemical effects.

In the same way the chemical changes which are effected by means of galvanism may be explained. Let it be supposed, that a gold wire, connected with the upper plate of the battery, terminates in a glass of water, and another gold wire, from the lower plate of the battery, terminates in the same water. The circle is then completed by the gold wire, which is a perfect conductor. The current of electricity passes through the wire which is connected with the uppermost plate to the base of the battery, and it would pass uninterruptedly, if there were no interval between the wires. This interval is supplied with water, and, when the electric fluid reaches the extremity of the wire, it must pass through the water, but it can only pass through an imperfect conductor when it is in combination with hydrogen. It therefore combines with the hydrogen of the water, which is accordingly decomposed at the point of the wire. The oxygen is disengaged, and the hydrogen in combination with the electricity passes through the water till it reach the point of the other wire; and the affinity between this wire and the electric fluid being greater than the affinity of the latter for water, the electric fluid enters the wire, and passes on to the other end of the battery; but the hydrogen is previously separated from the extremity of this second wire, in the form of gas, because the fluid cannot enter the wire in combination with hydrogen.

If the wires are immersed in ammonia, the hydrogen is derived from that substance of which it forms one of the component parts; the azotic gas, the base of which is its other constituent, is evolved at the extremity of the first wire, and hydrogen gas at the extremity of the second. But, if the wires are plunged in the water which contains common air, and consequently a certain portion of azote, as oxygen gas combines with azote in its nascent state, or at the moment of its evolution, the compound resulting from this combination is nitric acid. Hydrogen gas also, in its nascent state, will combine with azote, and ammonia is the result of this combination. Hence it is, that in some experiments nitric acid is found at the point of the positive wire, and ammonia at the point of the negative wire, when common water is employed.

When liquids holding in solution a metallic salt, the base of which is an oxide of the metal, are employed; as hydrogen gas possesses the property of reducing or reviving metals, if in its nascent state it comes in contact with their oxides, the metallic salts are in this case decomposed, and the metal is revived. It is found deposited on the negative wire. When copper or iron wires are employed to complete the circle, instead of wires of gold or platina, as oxygen has the property of combining with these metals, at the moment of its disengagement, it is deposited on the positive wire, and in this case none is separated from it; but if the circle be completed by means of charcoal or plumbago, and the interval between these conducting substances be water, carbonic acid gas is separated from the positive conductor, because the oxygen in its nascent state is susceptible of combination with carbone; and the hydrogen in the same state combining with carbone, carburetted hydrogen is given out by the negative conductor.

Such is the hypothetical explanation which has been given of the action of galvanism, and the phenomena which it exhibits. A fuller view of the analogy between galvanism and electricity has been given by Dr Wollaston.

"Notwithstanding, he observes, the power of Mr Volta's electric pile is now known to be proportional to the disposition of one of the metals to be oxidated by the fluid interposed, a doubt has been entertained by many persons, whether this power arises from the chemical action of the fluid on the metal, or, on the contrary, whether the oxidation itself may not be occasioned by electricity, set in motion by the contact of metals that have different conducting powers.

Elec[...] evol[...] durin[...] dati[...]

"That the oxidation of the metal is the primary cause of the electric phenomena observed, is, I think, to be inferred from the following experiments, which exhibit the galvanic process reduced to its most simple state.

"*Exper.* 1.—If a piece of zinc and a piece of silver have each one extremity immersed in the same vessel, containing sulphuric or muriatic acid diluted with a large quantity of water, the zinc is dissolved, and yields hydrogen gas, by decomposition of the water; the silver, not being acted upon, has no power of decomposing water; but, whenever the zinc and silver are made to touch, or any metallic communication is made between them, hydrogen gas is also formed at the surface of the silver.

"Any other metal besides zinc, which by assistance of the acid employed is capable of decomposing water, will succeed equally, if the other wire consists of a metal on which the acid has no effect.

"*Exper.* 2.—If zinc, iron, or copper, is employed with gold in diluted nitric acid, nitrous gas is formed; in the same manner, and under the same circumstances, as the hydrogen gas in the former experiment.

"*Exper.* 3.—Experiments analogous to the former, and equally simple, may also be made with many metallic solutions. If, for instance, the solution contains copper, it will be precipitated by a piece of iron, and appear on its surface. Upon silver merely immersed in the same solution, no such effect is produced; but as soon as the two metals are brought into contact, the silver receives a coating of copper.

"In the explanation of these experiments, it is necessary to advert to a point established by means of the electric pile.

"We know that when water is placed in a circuit of conductors of electricity, between the two extremities of a pile, if the power is sufficient to oxidate one of the wires of communication, the wire connected with the opposite extremity affords the hydrogen gas.

"Since the extrication of hydrogen, in this instance, is seen to depend on electricity, it is probable, that in other instances, electricity may be also requisite for its conversion into gas. It would appear, therefore, that in the solution of a metal, electricity is evolved during the

the action of the acid upon it; and that the formation of hydrogen gas, even in that case, depends on a transition of electricity between the fluid and the metal.

"We see, moreover, in the first experiment, that the zinc, without contact of any other metal, has the power of decomposing water; and we can have no reason to suppose that the contact of the silver produces any new power, but that it serves merely as a conductor of electricity, and thereby occasions the formation of hydrogen gas.

"In the third experiment also, the iron by itself has the power of precipitating copper, by means, I presume, of electricity evolved during its solution; and here likewise the silver, by conducting that electricity, acquires the power of precipitating the copper in its metallic state.

"The explanation here given receives additional confirmation from comparative experiments, which I have made with common electricity; for it will be seen that the same transfer of chemical power, and the same apparent reversion of the usual order of chemical affinities in the precipitation of copper by silver, may be effected by a common electrical machine.

"The machine with which the following experiments were conducted, consists of a cylinder seven inches in diameter, with a conductor on each side, 16 inches long, and three and a half inches diameter, each furnished with a sliding electrometer, to regulate the strength of the spark received from them.

"*Exper* 4.—Having a wire of fine silver $\frac{1}{120}$ of an inch in diameter, I coated the middle of it for two or three inches, with sealing wax, and by cutting through in the middle of the wax, exposed a section of the wire. The two coated extremities of the wire, thus divided, were immersed in a solution of sulphate of copper, placed in an electric circle between the two conductors; and sparks, taken at $\frac{1}{10}$ of an inch distance, were passed by means of them through the solution. After 100 turns of the machine, the wire which communicated with (what is called) the negative conductor, had a precipitate formed on its surface, which, upon being burnished, was evidently copper; but the opposite wire had no such coating.

"Upon reversing the direction of the current of electricity, the order of the phenomena was of course reversed; the copper being shortly re-dissolved by assistance of the oxidating power of positive electricity, and a similar precipitate formed on the opposite wire.

"*Exper.* 5.—A similar experiment made with gold wires $\frac{1}{100}$ of an inch diameter, in a solution of corrosive sublimate, had the same success.

"The chemical agency, therefore, of common electricity, is thus proved to be the same with the power excited by chemical means; but, since a difference has been observed in the comparative facility with which the pile of Volta decomposes water, and produces other effects of oxidation and de-oxidation of bodies exposed to its action, I have been at some pains to remove this difficulty, and can at least produce a very close imitation of the galvanic phenomena, by common electricity.

"It has been thought necessary to employ powerful machines, and large Leyden jars, for the decomposition of water; but when I considered that the decomposition must depend on duly proportioning the strength of the charge of electricity to the quantity of water, and that the quantity exposed to its action at the surface of communication depends on the extent of that surface, I hoped that, by reducing the surface of communication, the decomposition of water might be effected by smaller machines, and with less powerful excitation, than have hitherto been used for that purpose; and, in this hope, I have not been disappointed.

"*Exper.* 6.—Having procured a small wire of fine gold, and given it as fine a point as I could, I inserted it into a capillary glass tube; and after heating the tube, so as to make it adhere to the point and cover it in every part, I gradually ground it down, till, with a pocket lens, I could discern that the point of the gold was exposed.

64
in decomposing water,

"The success of this method exceeding my expectations, I coated several wires in the same manner, and found, that when sparks from the conductors before-mentioned were made to pass through water, by means of a point so guarded, a spark passing to the distance of one-eighth of an inch would decompose water, when the point exposed did not exceed $\frac{1}{700}$ of an inch in diameter. With another point, which I estimated at $\frac{1}{1500}$, a succession of sparks $\frac{1}{20}$ of an inch in length, afforded a current of small bubbles of air.

"I have since found, that the same apparatus will decompose water, with a wire $\frac{1}{40}$ of an inch diameter, coated in the manner before described, if the spark from the prime conductor passes to the distance of $\frac{4}{10}$ of an inch of air.

"*Exper.* 7.—In order to try how far the strength of the electric spark might be reduced by proportional diminution of the extremity of the wire, I passed a solution of gold in *aqua regia* through a capillary tube, and, by heating the tube, expelled the acid. There remained a thin film of gold, lining the inner surface of the tube, which, by melting the tube, was converted into a very fine thread of gold, through the substance of the glass.

"When the extremity of this thread was made the medium of communication through water, I found that the mere current of electricity would occasion a stream of very small bubbles to rise from the extremity of the gold, although the wire, by which it communicated with the positive or negative conductor, was placed in absolute contact with them. Hence it appears, that decomposition of water may take place by common electricity, as well as by the electric pile, although no discernible sparks are produced.

"The appearance of two currents of air may also be imitated, by occasioning the electricity to pass by fine points of communication on both sides of the water: but, in fact, the resemblance is not complete; for, in every way in which I have tried it, I observed that each wire gave both oxygen and hydrogen gas, instead of their being formed separately, as by the electric pile.

"I am inclined to attribute the difference in this respect to the greater intensity with which it is necessary to employ common electricity; for, that positive and negative electricity, so excited, have each the same chemical power as they are observed to have in the electric pile, may be ascertained by other means.

"In the precipitation of copper by silver, an instance of de-oxidation (or phlogistication) by negative electricity has been mentioned; the oxidating power of positive

 sitive

Theory.

sitive electricity may be also proved, by its effects on vegetable blue colours.

65 and in changing the blue colour of vegetables.

"*Exper.* 8.—Having coloured a card with a strong infusion of litmus, I passed a current of electric sparks along it, by means of two fine gold points, touching it at the distance of an inch from each other. The effect, as in other cases, depending on the smallness of the quantity of water, was most discernible when the card was nearly dry. In this state a very few turns of the machine were sufficient to occasion a redness at the positive wire, very manifest to the naked eye. The negative wire, being afterwards placed on the same spot, soon restored it to its original blue colour.

"By Mr Volta's apparatus the same effects are produced in much less time.

"Besides the similarity which has thus been traced between the effects of electricity excited by the common machine, and those observed from the electric pile, I think it appears also probable, that they originate from the same source.

"With regard to the latter, its power is known to depend on oxidation; so also does the excitement in the former appear very much to depend on the same process; for,

"*Exper.* 9.—I have found that, by using an amalgam of silver or of platina, which are not liable to be oxidated, I could obtain no electricity. An amalgam of tin, on the contrary, affords a good degree of excitement. Zinc acts still better; but the best amalgam is made with both tin and zinc, a mixture which is more easily oxidated than either metal separately.

"*Exper.* 10.—But, as a farther trial whether oxidation assists in the production of electricity, I mounted a small cylinder, with its cushion and conductor, in a vessel so contrived, that I could at pleasure charge the contained air.

"After trying the degree of excitement in common air, I substituted carbonic acid gas, and found that the excitement was immediately destroyed, but that it returned upon re-admission of atmospheric air.

"In conformity to this hypothesis, we find that the metal oxidated is, in each case, in a similar state of electricity; for the cushion of the machine, by oxidation of the amalgam adhering to it, becomes negative; and in the same manner, zinc, oxidated by the accumulated power of an electric pile, or simply by action of an acid, is also negative.

"This similarity in the means by which both electricity and galvanism appear to be excited, in addition to the resemblance that has been traced between their effects, shews that they are both essentially the same, and confirms an opinion that has already been advanced by others, that all the differences discoverable in the effects of the latter, may be owing to its being less intense, but produced in much larger quantity*."

This analogy was still farther established by the experiments of Van Marum, in which he succeeded in charging an electrical battery, consisting of $137\frac{1}{2}$ square feet, by means of the galvanic pile. On examining the power of the shocks which were given by the battery charged with the pile, it was found that the shock from 100 pairs of plates was about equal to a shock from the battery, when it was charged by means of 200. A pile of 200 pairs of plates seemed to have six times the power of an electrical machine having a plate of 31 inches diameter.

66 Distinguishing property between galvanism and electricity.

The following experiments made by Mr Cuthbertson, with galvanic batteries, are supposed by him to afford a distinguishing property between the galvanic and electric fluids. 1. Charcoal was deflagrated and ignited for above an inch in length. 2. Iron wire $\frac{1}{40}$ of an inch diameter was melted into a ball of $\frac{1}{16}$ inch diameter. 3. Platina wire $\frac{1}{100}$ inch diameter, was melted into a ball $\frac{1}{10}$ inch diameter. 4. Brass wire $\frac{1}{20}$ inch diameter, three-fourths of an inch in length was ignited. 5. Brass wire $\frac{1}{16}$ inch diameter was red hot at the end. 6. Iron wire $\frac{1}{150}$ inch diameter was red hot for 16 inches in length. 7. Iron wire 12 inches deflagrated, and melted into a ball. 8. Iron wire six inches in length was deflagrated. 9. Iron wire eight inches in length was ignited.

The first seven experiments above were made with two troughs, each containing 30 pairs of plates, six inches square, but in the last two experiments, one of these troughs only was used. The conclusion drawn from the four last experiments is, that double quantities of galvanic fluid only burn double lengths of wire, and not the square, as electrical discharges do*.

To discover what quantity of coated glass would be required to take a charge sufficient to ignite the same lengths of wire, the two last experiments were compared with common electrical discharges. Two jars, each containing about 170 square inches of coating, were set to the conductor of a 24 inch single-plate electrical machine, with the author's universal electrometer, loaded with 31 grains. Eight inches of the same kind of wire were laid in the circuit, and with 57 revolutions of the plate the electrometer discharged the jars, and the wire was ignited as perfectly as in experiment 9th. Afterwards six inches of the wire being laid in the circuit, a discharge was produced with the same number of revolutions of the machine, and the wire was deflagrated, and fused into balls, in the same manner as in the 8th experiment. Hence he concluded, that 340 square inches of coated glass, properly constructed, are sufficient to bear a charge equal to a galvanic battery of 1080 square inches of surface. On comparing the above experiments with some others made some time before, the author finds it necessary to modify the conclusion which he had deduced from them. With a pile of 16 pairs of plates, of 10 inches diameter, eight of which were laid upon each other in the usual manner, and cloths moistened with diluted muriatic acid interposed, he burnt half an inch of wire of $\frac{1}{195}$ inch diameter; and when the other eight pairs were added, he burnt four inches of the same wire. This was repeated with the eight in pairs with the same result, with respect to the burning of metals, but it gave strong and loud sparks from metal to metal, which might be heard at the distance of 300 yards. This result, he observes, had not been attained from troughs, to be heard at any distance. In the last experiment the cloths were moistened with a strong solution of muriate of ammonia. Comparing this effect of the pile and the trough, Mr Cuthbertson thinks there is some defect in the arrangement or construction of the latter.

* Phil. Mag. i. 358.

In many experiments which Volta made on piles composed of a single metal, and a single wet stratum, which

which of themselves are inactive, it was found that they became more or less active, after affording a passage for a longer or shorter time to an electric current, which was set in motion by an active pile. According to Ritter, the active pile or common electrometer transmits a real charge to the pile, which is itself inactive, and this he calls the *charged pile*. Volta, however, is of opinion, that no charge is transmitted but by means of the ordinary chemical action; for the electrical current being continued, changes the single wet stratum interposed between two pieces of gold, for example, into two different fluids; one acid, by which the electric current issues out of the metal, and the other alkaline, by which it enters, thus constituting a pile of the second order, composed of one metal, and two fluids of different natures. The action of this pile, however, soon ceases, because the fluids soon mix together *.

* Nichol. Jour. xi. 74.

Formation of Muriatic Acid, &c.

Chap. III. *Of the Formation of Muriatic Acid and Soda, by means of Galvanism.*

Some of the most curious phenomena which have yet been exhibited in galvanism, relate to the formation of muriatic acid by means of this power. In the account which has been given of Mr Cruickshank's experiments, it will be recollected that he made the discovery of the formation of an acid and alkali, during the action of the galvanic battery. This acid, he concluded, was the nitric, and the alkali, ammonia. The theory of the production of these substances in the galvanic pile has been already mentioned, and it corresponds with the explanation of the principles which have been adopted for explaining the phenomena of galvanism; later researches, however, have been conducted with more accurate observation, or have opened a wider field of discovery. The truth of this remark will be fully confirmed, if it be at last finally ascertained, that common salt, the component parts of which are muriatic acid and soda, is produced by the action of galvanism.

Mr Peel's discovery of the formation of muriat of soda.

The first hint of this discovery was given by Mr Peel of Cambridge, in a letter dated April 1805, addressed to the editor of the Philosophical Magazine †, of which the following account is given in his own words. "I took (says he), about a pint of distilled water, and decomposed one half of it by means of galvanism; the other half I evaporated, and I found to remain at the bottom of the glass a small quantity of salt, which upon examination I found to be muriate of soda, or common salt.—What induced me to try the experiment was this; I knew that when water was decomposed by means of galvanism, the water near one of the wires had alkaline, while that near the other had acid properties. This being the case, I inferred, that if an alkali and an acid were really produced, I should, by decomposing a large quantity of water, obtain a small quantity of some kind of neutral salt: as was actually the case on trying the experiment. The salt could not have been contained in the water before I made the experiment, because I used every precaution to have it free from impurities. I even took the trouble to repeat the experiment, though a tedious one, and I again obtained the same result." He adds, that a similar experiment being repeated by a friend of his, afforded a similar result.

† Ib. xxi. p. ...

It having been suggested to Mr Peel, that it might be worth while to vary the experiment, by employing water formed of its elements, he gives the following account of the result of this process, in another letter, dated June 1805.

Formation of Muriatic Acid, &c.

"Having proceeded, he observes, to the formation of water from its elements, with which to repeat my former experiment, I found when the oxygen and hydrogen gases were quite pure, and exactly in due proportion, that no residuum of air was left, and that the water formed was not in the slightest degree acidulous. When the process was not conducted with great accuracy, or any precaution to have it accurate was omitted, I then found the water acidulous, and the acid that caused this acidity to be the nitric acid.

"The acidulous water thus obtained I neutralized with lime, from which I distilled the water, and this water I decomposed by the galvanic process, as in the experiment detailed in my former letter.

"I did not imagine the using water so obtained could make the least difference on the result of the experiment; but as a wish was expressed to have the trial made, I again undertook that interesting but very tedious labour.

"When I came to examine the residuum, to my great astonishment I found that not muriate of soda, but muriate of potash, was produced. I must own I feel myself entirely at a loss how to account for this, nor shall I attempt it; all I can say is, that this, as well as my former experiment, was conducted with the greatest care and accuracy that I could bestow *."

* Phil. Mag. xxii. 153.

168 Pacchiani's, of muriatic acid.

About the same time a discovery of a similar nature was made by Professor Pacchiani of Pisa. This discovery, which relates to the composition of muriatic acid, was first announced in this country in the number of the Edinburgh Medical and Surgical Journal, published the 1st July 1805. The following is an account of his experiments, and the conclusions which he deduces from them in his own words. "The simplicity of the apparatus, (he says), and of the means adopted to attain my views, the care with which I endeavoured to avoid every source of error, have, I hope, sufficiently secured me against those illusions which frequently deceive young men ardent in the pursuit of science, and even those practised in the art of extorting from nature her secrets. Want of time prevents me from relating the series of experiments by which I arrived at the discovery I have mentioned; but you may see it by perusing the manuscript of my memoir, which will be immediately published, to submit my researches and their results to the judgment of the learned. For the present, I shall select from the experiments and facts therein described those which are decisive, and which establish, in an evident manner, the following truths:—

"I. Muriatic acid is an oxyde of hydrogen, and consequently composed of hydrogen and oxygen.

"II. In the oxygenated muriatic acid, and therefore, *à fortiori*, in muriatic acid, there is a much less proportion of oxygen than in water.

"III. Hydrogen is susceptible of very many and different degrees of oxidation, contrary to what is universally believed by pneumatic chemists, who assert that hydrogen is susceptible only of one invariable degree of oxidation, that in which it forms water.

"Having at first examined the phenomenon of the decomposition of water by the galvanic pile, and having, by accurate experiments, ascertained the true theory, Formation of Muriatic Acid, &c.

theory, I readily discovered a very simple and exact apparatus, in which I could distinctly perceive the changes which happen to water, which, from the continued action of the galvanic pile, is continually losing its oxygen at the surface of a wire of very pure gold immersed in it.

"I therefore proceeded to examine these gradual changes of water thus losing its oxygen; and I at last observed a very singular fact, which unequivocally indicated the formation of an acid. In other antecedent experiments I had examined the nature of the air obtained before arriving at this remarkable point, and I always found, by means of the eudiometer of Giobert, that it was very pure oxygen, as the residuum scarcely amounted to one-sixtieth.

"Having thus examined the nature of the air formed in various experiments, from the first moment of decomposition, until there were evident indications of the formation of an acid, I began to endeavour to determine, in a more positive manner, the existence and nature of this acid.

"When the water, or, to speak more accurately, the residual fluid, occupied about half the capacity of the receiver, which at first contained the water, this residual fluid presented the following characters:

"Its colour was an orange yellow, more or less deep, according as the bulk of the residual liquor was greater or less, and it resembled in appearance a true solution of gold.

"From the inferior orifice of the vessel, which was closed with a piece of taffety, and then with double bladder, there escaped a smell which was easily recognized to be that of oxygenated muriatic acid.

"The gold wire had in part lost its metallic lustre, and its surface appeared as if corroded by a solvent.

"The bit of taffety which had been in contact with the coloured fluid, in consequence of its action, was easily torn, as is usual with similar bodies when half burnt (*semi-combusto*).

"Around the edges of the vessel, on the bladder, there was formed a deep purple ring, which surrounded a circular space rendered entirely colourless, or white.

"A drop of this fluid tinged the skin of the hand, after some hours, with a beautiful rose colour.

"Having obtained, in various successive experiments, the same liquid, possessing constantly the same properties, I chose that obtained in the last experiment to subject it to chemical examination. The very able chemist of this university, Signior Giuseppe Branchi, had the goodness to enter zealously into my views; and in his laboratory we easily proved,

"1. The existence of a volatile acid, by the white vapours which were formed by ammonia placed near it.

"2. That this acid was certainly oxygenated muriatic acid, since it formed in nitrate of silver a curdy precipitate, the luna cornea of the ancients, or the muriate of silver of the moderns. From these facts we may draw the following positive and undeniable results:

"1. Muriatic acid is an oxyde of hydrogen, and is therefore composed of hydrogen and oxygen.

"2. Oxygenated muriatic acid, and of course muriatic acid, contains less oxygen than water does.

"3. Hydrogen has not one degree of oxygenation, but many. One of these constitutes water, another below it oxygenated muriatic acid, and, below this, there is another which constitutes muriatic acid."

69 Henry's remarks.

Mr Henry of Manchester, in an account of his investigations on this subject, observes that there is a considerable point of difference between the English and the Italian chemist. The result of Mr Peel's experiment was found to be muriate of soda; but in Professor Pacchiani's, in which an interrupted gold wire was employed, it appeared to be muriate of gold. This ingenious chemist, with the same view, made the following experiment. He took a glass tube $4\frac{1}{2}$ inches long, 35 inches diameter, in which were secured with corks, two slips of platina, having their extremities at a proper distance to effect the decomposition of the water. The quantity of water, at the beginning of the experiment, amounted to two drams. After being exposed to the galvanic action for six days, it was so far diminished, that $\frac{1}{2}$ inch of the tube was unfilled. The water which was employed was carefully purified, by being first distilled, and then, after adding nitrate of silver, by a second distillation. After the experiment was finished, with the addition of nitrate of silver, it became opalescent in a few seconds, and being exposed to the light, exhibited those changes which indicate the presence of muriatic acid. It did not appear that muriate of platina had been produced, for muriate of ammonia being added to one portion, and carbonate of soda to another, produced no precipitation.

In making this experiment, Mr Henry suggests a very useful precaution. The water employed, he observes, should never, on any account, come into contact with the fingers, because there is a constant excretion of muriate of soda from the skin, and in this way the purest water is very soon contaminated. He recommends also, that glass stoppers should be employed in place of corks, for transmitting the conducting wires *.

* Ibid.

70 New experiments of Mr Peel.

In another communication by Mr Peel on the same subject, he relates the following experiments, which were undertaken, he says,

"1st, To determine whether the difference in the result of the before-mentioned experiments was owing in any degree to my having employed lime to neutralize the water employed in my second experiment, before it was distilled.

"2d, To ascertain whether the salts found in the residual water, or any component part of them, came from the galvanic battery by means of the wires.

"To determine the first point, I varied my experiment by employing for decomposition water distilled under different circumstances.

"*Exper.* 1.—The water employed in this experiment was distilled from water containing lime. A portion of it was decomposed in the manner that has before been stated. The remaining water yielded muriate of potash.

"*Exper.* 2.—Water distilled from water containing magnesia was decomposed in the same manner. The result was muriate of soda.

"*Exper.* 3.—In this experiment double distilled snow water was employed. The result was muriate of soda.

"*Exper.*

"*Exper.* 4.—Water distilled from barytes was now used. The result was still muriate of soda.

"The water which I used in the experiment detailed in my first letter was distilled from pump water (the pump is on the premises where I live), which I have not myself analyzed, but a friend has been so good as to take upon him that trouble. He has not been able to detect it in the minutest portion of magnesia. In one of the above experiments, having used water distilled from magnesia, I obtained muriate of soda; but, having obtained the same result from distilled snow water, and from water distilled from barytes, I conclude that the production of the soda has nothing to do with the presence of magnesia.

"But, in the production of potash, the presence of lime seems to be essential, and, as you hinted, a portion of lime must have been carried over with the distilled water, a fact which few would suspect, and which probably may often be the cause of differences in the results of chemical investigations, conducted, to all appearance, in a similar manner.

"To determine the second point which I had in view, namely, whether the salts found in the residual water, or any component part of them, came from the galvanic battery by means of the conducting wires, I made similar experiments to those before stated, employing for the decomposition of the distilled water a powerful electrical machine instead of a galvanic battery, but without obtaining results different from what have been already stated *."

It is stated in the same number of the Philosophical Magazine, that the following result was obtained in an experiment on the same subject. By continuing to pass the galvanic fluid from a trough composed of 40 pairs of square inch plates, through distilled water, contained in a glass tube, the tube being furnished at one end with a wire of gold, and at the other with a wire of platina, it was found that a coating of oxide of gold was deposited on the gold wire, from which it is concluded, that oxymuriatic acid was found in the process †. A more particular account was afterwards given by the author of this experiment, and of the precautions he observed in repeating it. He took a clean glass tube, which was bent as in the former experiment; but, instead of the gold wire, he employed one of platina, so that both wires were of the same metal. One of the wires was only introduced a short way into the tube containing the distilled water; the other wire introduced at the other extremity, passed nearly through its whole length, till it reached beyond the point at which the short wire terminated. After the apparatus had stood for three days, with the zinc end of the trough connected with the short platina wire, the latter assumed the colour of gold, and the long one became black from the lower end to the height of the short wire, and continued so for the space of three weeks. The water being diminished one-third, the short wire was connected with the copper end of the trough, and in one day's time the long wire became bright, and the short one black. After two days had elapsed, that part of the long wire which reached to the height of the short one, assumed a yellowish golden tinge. Both the wires remained so for three days, when they were placed in their first situation. The black powder then left the short wire, and the long one became black. A slip of blue test paper being immersed in the remaining water, its colour was changed, which indicates the production of an acid.

ation / uriatic / , &c. | * [...] xxiii. [...] 71 | [...] others. | † [...] 85.

Formation of Muriatic Acid, &c.

Pacchiani, the discoverer, in another letter on this subject addressed to Fabroni, seems to think that those who have failed in obtaining the same results in the decomposition of water, have either been influenced in conducting their experiments by preconceived opinions, or have deviated from the process which he followed. But for an account of his views and reasonings, see *An. de Chim.* tom. lvi. or Phil. Mag. xxiv. 176. We shall only observe, that he still considers himself warranted to draw the same conclusion with regard to the formation of the acid, by the action of galvanism.

Mr Sylvester of Sheffield made the following experiment on this subject. The water which he employed was not changed by adding nitrate of silver. This water was introduced into a tube which was secured at one end with a bit of bladder. At the other end was a cork, through which a wire of platina was passed, nearly to the bottom of the tube. The tube was then set in a wine glass, containing also pure water, and into this was also introduced another wire of platina, the extremity of which came under the end of the tube, and as near as possible to the bladder. The wire within the tube was connected with the zinc end of the trough, and the wire in the glass, which was in contact with the bladder, proceeded from the copper end. After the process had continued for an hour, the liquid in the tube was put to the test of nitrate of silver, and when a sufficient precipitate was obtained, to ascertain the presence of muriatic acid, the liquid in the glass contained an alkali, which the author suspected was ammonia *.

* *Nichol. Journal*, xiv. 97.

Brugnatelli observes, that, after having galvanised several times, both negatively and positively, a certain quantity of pure water with golden wires, inserted in separate tubes, till he found, by the usual tests, that acid was produced on the one part, and alkali on the other, when the two liquids were mixed to perfect saturation, and evaporated in the air, he always obtained muriate of soda crystallized in cubes. He has therefore no doubt, that water negatively and positively galvanised, by means of gold wires, produces or disengages muriatic acid in the one case, and soda in the other †.

† *Phil. Mag.* xxv. 66.

Such are the authorities for this curious phenomenon which we have hitherto had an opportunity of consulting; but although in general it would appear that the experiments made with a view of ascertaining the truth of the discovery announced by Pacchiani, have most generally succeeded, some other experiments, made with the same view, have failed. For this purpose a series of experiments was instituted by the Galvanic Society of Paris, whose attention was directed to endeavour, as well by means of electricity as of galvanism, to confirm this important discovery; but although they employed a very simple apparatus, and one which seemed least susceptible of any foreign influence, they do not think it possible to produce any thing by the action of the galvanic pile, except the decomposition of a greater or less proportion of the water submitted to its action. The water remaining in the tube being carefully examined, produced no effect on the tinctures of turnsole or brazil wood, or the solution of nitrate of silver.

Formation of Muriatic Acid, &c.

silver. Hence it is concluded that neither muriatic acid nor soda was formed in this experiment.

Some other experiments made with the same view have also failed; but according to De Buch, certain precautions seem to be necessary in conducting this experiment, which, if overlooked, it cannot be expected, he thinks, to be followed with success. For the particulars of these, see Phil. Mag. xxiv. 244. For an account of the analogy between the peculiarity of structure of the torpedo, by which it is enabled to give electric shocks, and the galvanic battery, see TORPEDO; and for a full detail of the chemical effects of Galvanism, see ZINC. See also the article GALVANISM in the SUPPLEMENT.

THE following facts, which seem to extend the analogy of galvanism with electricity on the one hand, and with magnetism on the other, were omitted in the preceding treatise.

Ritter, one of the most indefatigable philosophers, in prosecuting experiments and inquiries on this subject, has succeeded in charging a piece of money with the galvanic fluid, and with this some of the phenomena of galvanism can be exhibited. To effect this, he places a louis d'or between two pieces of pasteboard, thoroughly wetted, and keeps it for six or eight minutes in the chain of circulation connected with the pile. In this way the louis becomes charged, without being immediately in contact with the conducting wires. If this louis be afterwards applied to the crural nerves of a frog, recently prepared, the usual contractions will be produced. It is found that the charge is retained, in proportion to the time that the piece has remained in the circuit of the pile. Some have retained it for five minutes. Ritter has also discovered, that the piece of gold thus galvanised, exerts at once the action of two metals; the half next the negative pole, while in the circle, became positive, and the half towards the positive pole became negative. He also tried the effect of golden needles charged with galvanism, and balanced on a pivot, and he perceived, to his surprise, that these needles had a certain dip and variation;—that the angle of variation was uniformly the same, differing, however, from that of the magnetic needle, and that the positive pole always dips*.

If the facts which the above experiments seem to prove, should be fully ascertained, there is an obvious analogy, not only between electricity and galvanism, but also between the latter and magnetism.

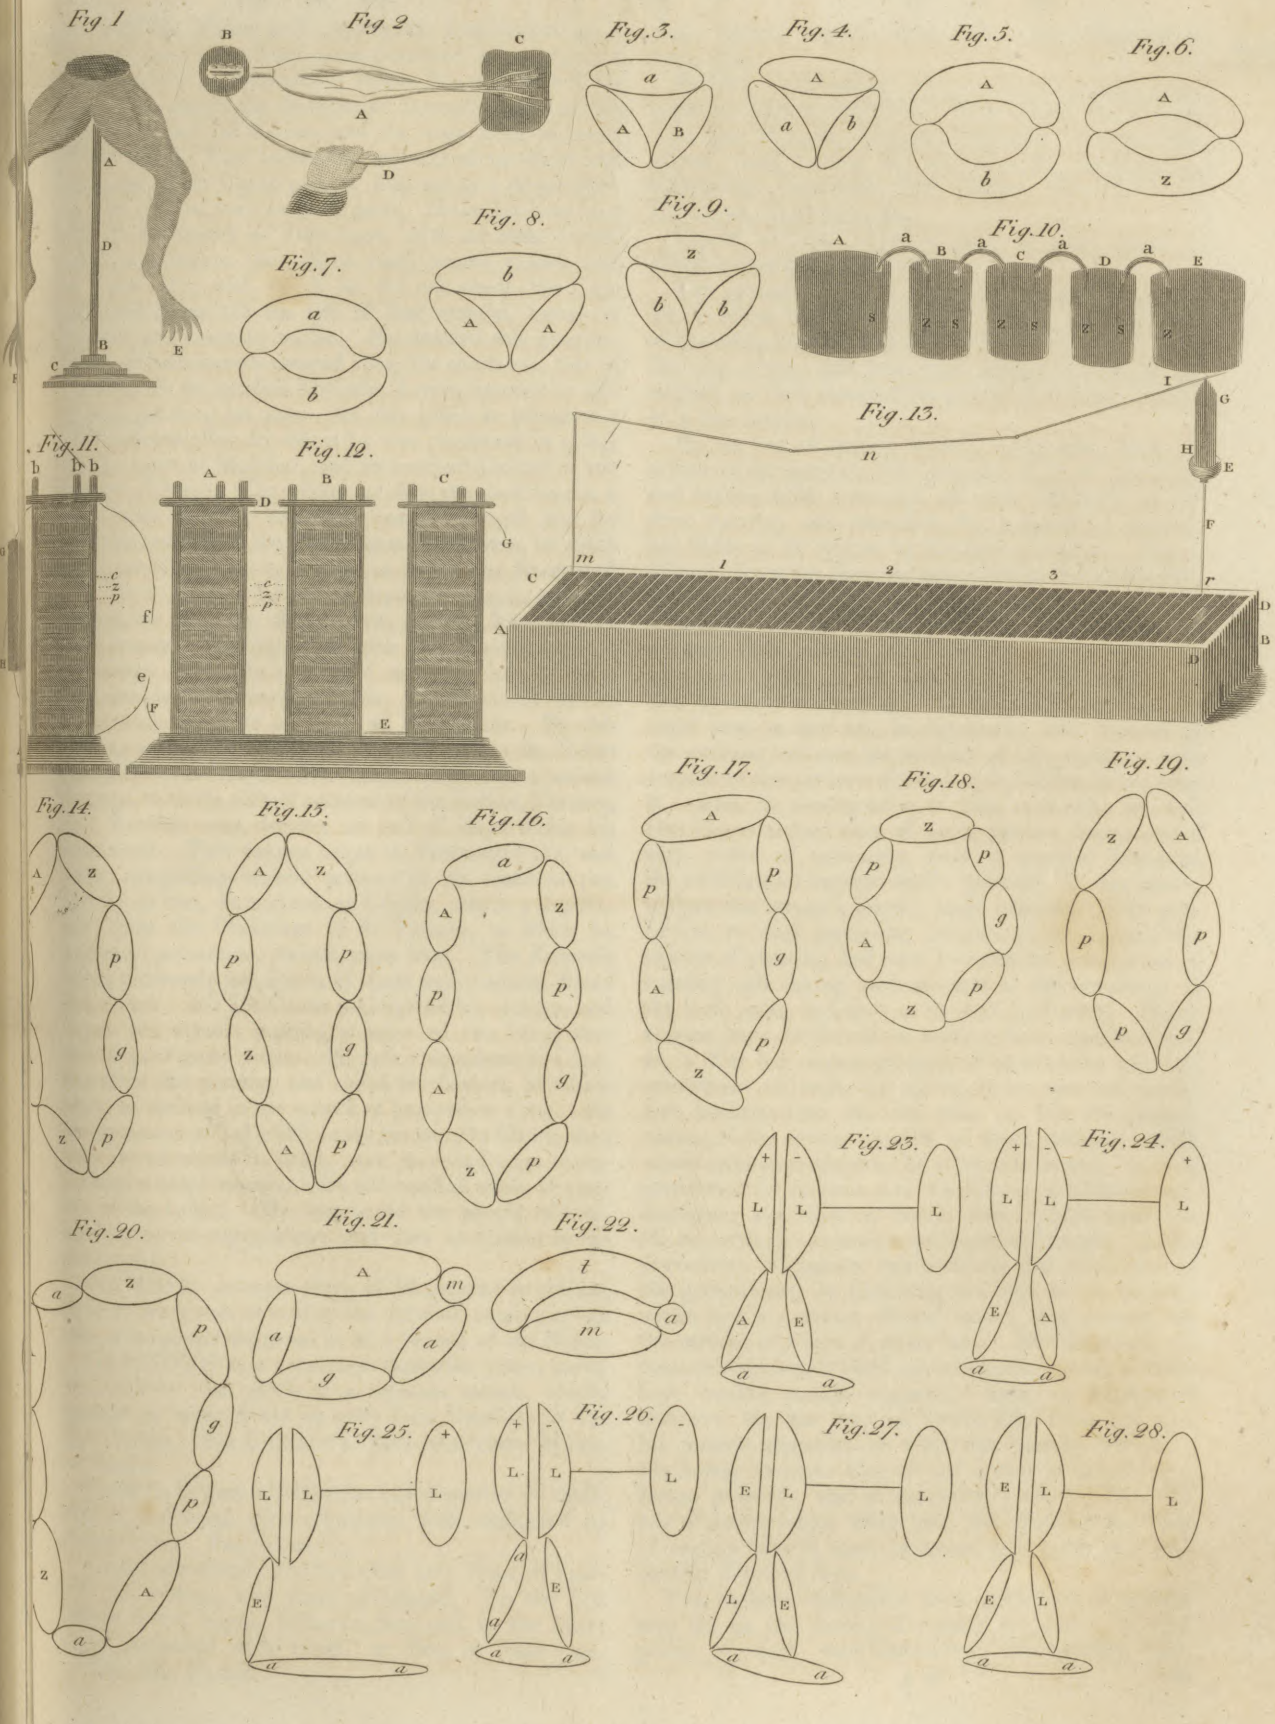
* Nicol. Journ. xii. 99.

A galvanic pile has been constructed by Dr Baronio of Milan, entirely of vegetable matters. For this purpose he cuts discs of horse radish and beet root, of two inches in diameter. He then prepared equal discs of walnut tree wood; the latter discs were raised at their edges, to contain a little solution of acidulous tartrate of potash in vinegar, in which they had been previously boiled to free the wood from rosin. Sixty pairs of discs were employed in the following order; viz. horse radish, beet-root, discs of wood, in each of which the solution was put. The spinal marrow of a prepared frog was connected with the pile, by means of a leaf of *cochlearia*: the muscles of the frog were connected with the top of the pile by means of a double band of gray paper wetted with vinegar, and as often as this circuit was completed, contractions were excited in the animal.

Galway.

GALWAY, or GALLOWAY, a county of Ireland, which is 76 miles in length, and 40 in breadth, bounded by the counties of Clare, Tipperary, King's County, Roscommon, and the sea. The river Shannon washes the frontiers of the east and south-east, and forms a lake several miles in length. This county contained 142,000 inhabitants in 1792. It sends two members to the imperial parliament. See GALWAY, SUPPLEMENT.

GALWAY, a town of Ireland, in the county of the same name, and province of Connaught, of which it is the capital. It is seated on the bay of Galway on the western ocean, 96 miles west of Dublin, and in W. Long. 8. 58. N. Lat. 53. 15. It is surrounded with strong walls; the houses are well built, and the number of inhabitants is about 15,000. It has a good trade into foreign parts, on account of its harbour, which is defended by a fort. It is governed by a mayor, sheriffs, and recorder. It has but one parish church, which is a large and beautiful Gothic structure, an exchange, barracks for 10 companies of foot, a charter school, and an hospital. This was one of the strongest towns in the kingdom; it held out some time against General Ginkle, who invested and took it after the battle of Aughrim. Its fortifications were then repaired. The walls are flanked by bastions, but are mostly gone to decay. The salmon and herring fisheries are carried on here with great spirit, and employ 700 boats; the quantity of kelp manufactured and exported is considerable; and the growth of the linen manufacture, though of late introduction, is become very important. In 1296, Sir William de Burgh founded a monastery here for Franciscan friars, on St Stephen's island, situated without the north gate of the town. In 1381, there being two popes at Rome, and the people of Ireland being doubtful to which they should pay obedience, Pope Urban, to fix them entirely to his interest, empowered the guardian of this monastery to excommunicate every person in the province of Connaught who should adhere to his rival Clement VII. who he assured them was antipope.—Near the west gate of the town, without the walls, was the monastery of St Mary of the Hill: on the nuns forsaking it, the secular clergy entered into and kept possession of it for a considerable time; but on the petition of the inhabitants of the town to Pope Innocent VIII. it was granted to the Dominican friars, by a bull dated the 4th December 1488. There are no remains of this foundation except the cemetery; the whole building having been demolished by the townsmen in the year 1652, in order to prevent Cromwell from turning it into a fortification against themselves: there was also an Augustinian friary, on a hill near this town, founded by Stephen Lynch, and Margaret his wife, in the year 1508, at the earnest solicitation of Richard Nangle, a friar of the same order, who afterwards became bishop of Tuam.



E. Mitchell sculp.t

Gama ‖ Game.

GAMA, Vasco or Vasques de, a celebrated navigator, was born at Sines, a sea-port town in the province of Alentejo, in Portugal. When King Emanuel resolved to extend the discoveries formerly made of the southern parts of Africa, and the seas lying between these and the East Indies, the well-known prudence and courage of De Gama pointed him out as a proper person to conduct such an enterprise. He sailed from Lisbon in the month of July 1497, with no more formidable a squadron than three small armed vessels and a store ship, with which he did not reach the Cape of Good Hope till the end of four months, owing to violent and contrary winds. He doubled this promontory, and afterwards coasted along the south-east side of Africa, till he reached Melinda, having touched at different ports on his way. At this place he procured a Mahometan pilot, by whom he was conducted in safety to the coast of Malabar, and he reached Calicut in the month of May. The prince at first received him in a hospitable manner, but a plot being at length laid for his destruction by the Mahometan merchants, he made the best of his way to Europe as soon as he discovered it. He arrived at Lisbon in September 1499, with the loss of the majority of his crew, arising from fatigue and disease. Having spent some time in devotion at a hermitage, he made a splendid entrance into the city, and besides pecuniary rewards, was honoured by the king with the title of count of Videgueira. By this voyage the practicability of a new passage to the Indies was fully established. De Gama undertook a second voyage, with the title of admiral of the Indian, Persian, and Arabian seas, having 20 sail of ships under his command. This voyage began in February 1502, and after compelling several princes in his route to pay tribute to him, he arrived at Cochin, where a deputation from the Christians of St Thomas, to whom he promised protection, waited upon him. The Zamorin being extremely suspicious of these new visitors, fitted out a fleet; but De Gama anticipated the design, and began the attack, making a prize of two large vessels of prodigious value. He left a squadron at Cananor after this victory, and sailed for Lisbon, at which place he arrived in the month of September 1503. On the accession of John III. to the throne, De Gama, then very far advanced in years, was prevailed upon to undertake a third voyage, with the exalted rank of viceroy of the Indies. He conquered the people of Calicut in a naval engagement, and died at Cochin in the year 1525.

GAMBIA, a large river of Negroland in Africa, running from east to west to the Atlantic ocean; it was once erroneously supposed to be a branch of the Niger.

GAMBOGE is a concreted vegetable juice, partly of a gummy and partly of a resinous nature, chiefly brought in large cakes or rolls from Cambaja in the East Indies. See Chemistry and Materia Medica *Index*.

GAME, in general, signifies any diversion or sport, that is performed with regularity, and conducted by certain rules. See Gaming.

Games are usually distinguished into those of exercise and address, and those of hazard. To the first belong chess, tennis, billiards, &c. and to the latter those performed with cards, or dice, as back-gammon, ombre, piquet, whist, &c. See *Back-Gammon*, &c.

Games, in antiquity, were public diversions, exhibited on solemn occasions. Such among the Greeks were the Olympic, Pythian, Isthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games. See Olympic, Pythian, Funeral, &c.

Game, in *Law*, signifies birds, or prey, taken or killed by fowling or hunting.

The property of such animals *feræ naturæ* as are known under the denomination of *game*, with the right of pursuing, taking, and destroying them, is vested in the king alone, and from him derived to such of his subjects as have received the grants of a chase, a park, or a free warren.

By the law of nature, indeed, every man, from the prince to the peasant, has an equal right of pursuing, and taking to his own use, all such creatures as are *feræ naturæ*, and therefore the property of nobody, but liable to be seized by the first occupant. But it follows, from the very end and constitution of society, that this natural right, as well as many others belonging to man as an individual, may be restrained by positive laws enacted for reasons of state, or for the supposed benefit of the community. This restriction may be either with respect to the *place* in which this right may, or may not, be exercised; with respect to the *animals* that are the subjects of this right; or with respect to the *persons* allowed or forbidden to exercise it. And, in consequence of this authority, we find that the municipal laws of many nations have exerted such power of restraint; have in general forbidden the entering on another man's grounds, for any cause, without the owner's leave; have extended their protection to such particular animals as are usually the objects of pursuit; and have invested the prerogative of hunting and taking such animals in the sovereign of the state only, and such as he shall authorize. Many reasons have concurred for making these constitutions; as, 1. For the encouragement of agriculture and improvement of lands, by giving every man an exclusive dominion over his own soil. 2. For the preservation of the several species of these animals, which would soon be extirpated by a general liberty. 3. For prevention of idleness and dissipation in husbandmen, artificers, and others of lower rank; which would be the unavoidable consequence of universal license. 4. For prevention of popular insurrections and resistance to the government, by disarming the bulk of the people: which last is a reason oftener meant than avowed, by the makers of forest or game laws. Nor certainly, in these prohibitions is there any *natural* injustice, as some have weakly enough supposed: since, as Puffendorf observes, the law does not hereby take from any man his present property, or what was already his own; but barely abridges him of one means of acquiring a future property, that of occupancy; which indeed the law of nature would allow him, but of which the laws of society have in most instances very justly and reasonably deprived him.

Yet, however defensible these provisions in general may be, on the footing of reason, or justice, or civil policy, we must, notwithstanding, acknowledge, that, in

Game.

in their present shape, they owe their immediate original to slavery. It is not till after the irruption of the northern nations into the Roman empire, that we read of any other prohibitions, than that natural one of not sporting on any private grounds without the owner's leave.

With regard to the rise and original of our present civil prohibitions, it will be found, that all forest and game laws were introduced into Europe at the same time, and by the same policy, as gave birth to the feodal system: when those swarms of barbarians issued from their northern hive, and laid the foundation of most of the present kingdoms of Europe, on the ruins of the western empire. For when a conquering general came to settle the economy of a vanquished country, and to part it out among his soldiers or feudatories, who were to render him military service for such donations; it behoved him, in order to secure his new acquisitions, to keep the *rustici* or natives of the country, and all who were not his military tenants, in as low a condition as possible, and especially to prohibit them the use of arms. Nothing could do this more effectually than a prohibition of hunting and sporting: and therefore it was the policy of the conqueror to reserve this right to himself, and such on whom he should bestow it; which were only his capital feudatories, or greater barons. And, accordingly, we find, in the feudal constitutions, one and the same law prohibiting the *rustici* in general from carrying arms, and also proscribing the use of nets, snares, or other engines for destroying the game. This exclusive privilege well suited the martial genius of the conquering troops, who delighted in a sport which in its pursuit and slaughter bore some resemblance to war. *Vita omnis* (says Cæsar, speaking of the ancient Germans) *in venationibus atque in studiis rei militaris consistit.* And Tacitus in like manner observes, that *quoties bella non ineunt, multum venatibus, plus per otium transigunt.* And indeed, like some of their modern successors, they had no other amusement to entertain their vacant hours; for they despised all arts as effeminate, and had no other learning than what was couched in such rude ditties as were sung at the solemn carousals which succeeded these ancient huntings. And it is remarkable, that in those nations where the feodal policy remains the most uncorrupted, the forest or game laws continue in their highest rigour. Formerly in France, all game was properly the king's; and in some parts of Germany it is death for a peasant to be found hunting in the woods of the nobility.

With us, in Britain, also hunting has ever been esteemed a most princely diversion and exercise. The whole island was replenished with all sorts of game in the time of the Britons; who lived in a wild and pastoral manner, without enclosing or improving their grounds; and derived much of their subsistence from the chase, which they all enjoyed in common. But when husbandry took place under the Saxon government, and lands began to be cultivated, improved, and enclosed, the beasts naturally fled into the woody and desert tracts, which were called the *forests;* and, having never been disposed of in the first distribution of lands, were therefore held to belong to the crown. These were filled with great plenty of game, which our royal sportsmen reserved for their own diversion, on pain of a pecuniary forfeiture for such as interfered with their sovereign. But every freeholder had the full liberty of sporting upon his territories, provided he abstained from the king's forests.

However, upon the Norman conquest, a new doctrine took place; and the right of pursuing and taking all beasts of chase or *venary*, and such other animals as were accounted *game*, was then held to belong to the king, or to such only as were authorized under him. And this, as well upon the principles of the feodal law, that the king is the ultimate proprietor of all the lands in the kingdom, they being all held of him as the chief lord, or lord paramount of the fee; and that therefore he has the right of the universal soil, to enter thereon, and to chase and take such creatures at his pleasure: as also upon another maxim of the common law, that these animals are *bona vacantia*, and, having no other owner, belong to the king by his prerogative. As therefore the former reason was held to vest in the king a *right* to pursue and take them anywhere, the latter was supposed to give the king, and such as he should authorise, a *sole* and *exclusive* right.

This right, thus newly vested in the crown, was exerted with the utmost rigour, at and after the time of the Norman establishment; not only in the ancient forests, but in the new ones which the Conqueror made, by laying together vast tracts of country, depopulated for that purpose, and reserved solely for the king's royal diversion; in which were exercised the most horrid tyrannies and oppressions, under colour of forest law, for the sake of preserving the beasts of chase: to kill any of which, within the limits of the forest, was as penal as the death of a man. And, according to the same principle, King John laid a total interdict upon the *winged* as well as the *four-footed* creation; *capturam avium per totam Angliam interdixit**. The cruel and insupportable hardships which these forest laws created to the subject, occasioned our ancestors to be as zealous for their reformation, as for the relaxation of the feodal rigours and the other exactions introduced by the Norman family: and accordingly we find the immunities of *charta de foresta* as warmly contended for, and extorted from the king with as much difficulty, as those of *magna charta* itself. By this charter, confirmed in parliament†, many forests were disafforested, or stripped of their oppressive privileges, and regulations were made in the regimen of such as remained; particularly killing the king's deer was made no longer a capital offence, but only punished by a fine, imprisonment, or abjuration of the realm. And by a variety of subsequent statutes, together with the long acquiescence of the crown without exerting the forest laws, this prerogative is now become no longer a grievance to the subject.

* M. P. 303.

† 9 Hen. III.

But as the king reserved to himself the *forest* for his own exclusive diversion, so he granted out from time to time other tracts of lands to his subjects under the names of *chases* or *parks;* or gave them license to make such in their own grounds; which indeed are smaller forests in the hands of a subject, but not governed by the forest laws; and by the common law no person is at

Game.

at liberty to take or kill any beasts of chase, but such as have an ancient chase or park; unless they be also beasts of prey.

As to all inferior species of game, called *beasts and fowls of warren;* the liberty of taking or killing them is another franchise or royalty, derived likewise from the crown, and called *free warren;* a word which signifies preservation or custody: as the exclusive liberty of taking and killing fish in a public stream or river is called a *free fishery;* of which, however, no new franchise can at present be granted by the express provision of *magna charta*, c. 16. The principal intention of granting a man these franchises or liberties was in order to protect the game, by giving him a sole and exclusive power of killing it himself, provided he prevented other persons. And no man but he who has a chase or free warren, by grant from the crown, or prescription, which supposes one, can justify hunting or sporting upon another man's soil; nor indeed, in thorough strictness of common law, either hunting or sporting at all.

However novel this doctrine may seem, it is a regular consequence from what has been before delivered, that the sole right of taking and destroying game belongs exclusively to the king. This appears, as well from the historical deduction here made, as because he may grant to his subjects an exclusive right of taking them; which he could not do, unless such a right was first inherent in himself. And hence it will follow, that no person whatever, but he who has such derivative right from the crown, is by common law entitled to take or kill any beast of chase, or other game whatsoever. It is true, that by the acquiescence of the crown, the frequent grants of free warren in ancient times, and the introduction of new penalties of late by certain statutes for preserving the game, this exclusive prerogative of the king is little known or considered; every man that is exempted from these modern penalties looking upon himself as at liberty to do what he pleases with the game; whereas the contrary is strictly true, that no man, however well *qualified* he may vulgarly be esteemed, has a right to encroach on the royal prerogative by the killing of game, unless he can shew a particular grant of free warren; or a prescription which presumes a grant; or some authority under an act of parliament. As for the latter; there are but two instances wherein an express permission to kill game was ever given by statute: the one by 1 Jac. I. c. 37. altered by Jac. I. c. 12. and virtually repealed by 22 and 23 Car. II. c. 25. which gave authority, so long as they remained in force, to the owners of free warren, to lords of manors, and to all freeholders having 40l. per annum in lands of inheritance, or 80l. for life or lives, or 400l. personal estate (and their servants), to take partridges and pheasants, upon their own, or their master's free warren, inheritance, or freehold: the other by 5 Ann. c. 14. which empowers lords and ladies of manors to appoint gamekeepers, to kill game for the use of such lord or lady; which with some alteration still subsists, and plainly supposes such power not to have been in them before. The truth of the matter is, that these game laws do indeed *qualify* nobody, except in the instance of a gamekeeper, to kill game: but only to save the trouble and formal process of an action by the person injured, who perhaps too might remit the offence, these statutes inflict *additional* penalties, to be recovered either in a regular or summary way, by any of the king's subjects, from certain persons of inferior rank who may be found offending in this particular. But it does not follow that persons excused from these additional penalties are therefore *authorized* to kill game. The circumstance of having 100l. per annum, and the rest, are not properly qualifications, but exemptions. And these persons so exempted from the penalties of the game statutes, are not only liable to actions of trespass by the owners of the land; but also if they kill game within the limits of any royal franchise, they are liable to the actions of such who may have the right of chase or free warren therein.

Upon the whole it appears, that the king, by his prerogative, and such persons as have, under his authority, the ROYAL FRANCHISE of CHACE, PARK, or *Free WARREN*†, are the *only* persons who may acquire any property, however fugitive and transitory, in these animals *feræ naturæ*, while living; which is said to be vested in them *propter privilegium*. And it must also be observed, that such persons as may thus lawfully hunt, fish, or fowl, *ratione privilegii*, have only a qualified property in these animals; it not being absolute or permanent, but lasting only so long as the creatures remain within the limits of such respective franchise or liberty, and ceasing the instant they voluntarily pass out of it. It is held indeed, that if a man starts any game within his own grounds, and follows it into another's and kills it there, the property remains in himself. And this is grounded on reason and natural justice; for the property consists in the possession; which possession commences by the finding it in his own liberty, and is continued by the immediate pursuit. And so, if a stranger starts game in one man's chase or free warren, and hunts it into another liberty, the property continues in the owner of the chase or warren; this property arising from privilege, and not being changed by the act of a mere stranger. Or if a man starts game on another's private grounds, and kills it there, the property belongs to him in whose ground it was killed, because it was also started there; this property arising *ratione soli*. Whereas if, after being started there, it is killed in the grounds of a third person, the property belongs not to the owner of the first ground, because the property is local; nor yet to the owner of the second, because it was not started in his soil; but it vests in the person who started and killed it; though guilty of a trespass against both the owners. See the article *Game Laws*.

† See those articles.

It will probably be considered by sportsmen who have not an opportunity of seeing the book, as a curious piece of information, to have the following, which we extract from Daniel's Rural Sports, concerning the quantity of game killed in different countries.

"The lists of the game, says he, that has been killed upon particular manors in England by parties, and even by single gentlemen, exhibit such a wanton registry of slaughter, as no sportsman can read without regret; but to prove that *British* are rather more merciful than *French* shooters, the account of the former game establishment at Chantilli is first presented to the reader, in the words of the very ingenious person who recorded it.

Game.

"The game establishment at Chantilli was the most extraordinary establishment of the kind in Europe.

"The following list of the quantity of different kinds of game killed at Chantilli, in a period of 32 years, beginning with the year 1748, and ending with the year 1779, was copied from the household registers there, and what seems unaccountable, never was printed before, not even in France! The copy was taken in 1788, and the statement, as an object in natural history, is no small curiosity, and as such it is philosophically interesting.

Connected with this establishment, there was a park of 21 miles, and a forest of 48 miles in extent, and while the family were at the place, they had 500 horses, as many servants, and from 60 to 80 couple of dogs.

"The Germans too, says Mr Daniel, have a happy knack at a massacre. In 1788 a party of 10 persons at the chateau of Prince Adam Daversperg, in Bohemia, were out five hours on the 9th and 10th of September, allowed that the first day 6168 shots were fired, and 876 hares, 259 pheasants, 362 partridges, beside quails, rabbits, &c. were bagged, or rather waggoned. On the second day 5904 shots were discharged, and 181 hares, 634 pheasants, and 736 partridges were killed, besides some that were picked up in the evening. The number of shots in the two days were 11,972, the game carried home were

Hares	1099
Pheasants	958
Partridges	1201

besides small game. It is added that the birds were all shot on the wing.

"In Germany, during the month of October 1797, Prince Lichtenstein, and eleven other gentlemen, killed in one day, when they were out fourteen hours, 39,000 pieces of game; it was of all sorts, but chiefly hares and partridges. The king of Naples and Sir W. Hamilton killed 800 head of game in the neighbourhood of Casarte, of which 640 were partridges, in a very short space of time.

Game ‖ Gaming.

"Upon Mr Colquhoun's manor in our own country, at Writham in Norfolk, the late duke of Bedford, and six other gentlemen, in 1796, killed 80 cock pheasants, 40 hares, besides partridges, in one day. At Houghton, in the same county, the duke of Bedford, and seven others, killed in the same space, 165 hares, 42 pheasants, 5 rabbits, a couple of woodcocks, and a brace of partridges; and this was done, although the woods had been beat five times before during the season *."

* Vol.

Game Cock, , a fighting cock, or one kept for sport; a barbarous practice, which is a disgrace to any civilized nation. See *Cock-Fighting*.

GAMELIA, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before a marriage; thus called from a custom they had of shaving themselves on this occasion, and presenting their hair to some deity to whom they had particular obligations.

GAMELION, in the ancient chronology, was the eighth month of the Athenian year, containing 29 days, and answering to the latter part of our January and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

GAMING, the art of playing or practising any game, particularly those of hazard; as cards, dice, tables, &c.

Gaming has at all times been looked upon as a thing of pernicious consequence to the commonwealth; and is therefore severely prohibited by law. It is considered as a practice generally intended to supply, or retrieve, the expences occasioned by LUXURY: it being a kind of tacit confession, that the company engaged therein do, in general, exceed the bounds of their respective fortunes; and therefore they cast lots to determine upon whom the ruin shall at present fall, that the rest may be saved a little longer. But taken in any light, it is an offence of the most alarming nature, tending by necessary consequence, to promote public idleness, theft, and debauchery, among those of a lower class; and, among persons of a superior rank, it hath frequently been attended with the sudden ruin and desolation of ancient and opulent families, and abandoned prostitution of every principle of honour and virtue, and too often hath ended in self-murder. To restrain this pernicious vice among the inferior sort of people, the statute 33 Hen. VIII. c. 9. was made; which prohibits to all but gentlemen, the games of tennis, tables, cards, dice, bowls, and other unlawful diversions there specified, unless in the time of Christmas, under pecuniary pains and imprisonment. And the same law, and also the statute 23 Geo. II. c. 24. inflict pecuniary penalties, as well upon the master of any public house wherein servants are permitted to game, as upon the servants themselves, who are found to be gaming there. But this is not the principal ground of modern complaint: it is the gaming in high life that demands the attention of the magistrate; a passion to which every valuable consideration is made a sacrifice, and which we seem to have inherited from our ancestors, the ancient Germans; whom Tacitus describes to have been bewitched with the spirit of play to a most exorbitant

bitant degree. "They addict themselves (says he) to dice (which is wonderful) when sober, and as a serious employment, with such a mad desire of winning or losing, that, when stript of every thing else, they will stake at last their liberty, and their very selves. The loser goes into a voluntary slavery; and, though younger and stronger than his antagonist, suffers himself to be bound and sold. And this perseverance in so bad a cause they call the point of honour: *ea est in re prava pervicacia, ipsi fidem vocant.*" One would almost be tempted to think Tacitus was describing a modern Englishman. When men are thus intoxicated with so frantic a spirit, laws will be of little avail: because the same false sense of honour that prompts a man to sacrifice himself, will deter him from appealing to the magistrate. Yet it is proper that laws should be, and be known publicly, that gentlemen may consider what penalties they wilfully incur, and what a confidence they repose in sharpers; who, if successful in play, are certain to be paid with honour, or if unsuccessful, have it in their power to be still greater gainers by informing. For, by stat. 16 Car. II. c. 7. if any person by playing or betting shall lose more than 100l. at one time, he shall not be compelled to pay the same; and the winner shall forfeit treble the value, one moiety to the king, the other to the informer. The statute 9 Ann. c. 14. enacts, that all bonds and other securities, given for money won at play, or money lent at the time to play withal, shall be utterly void: that all mortgages and encumbrances of lands, made upon the same consideration, shall be and endure to the heir of the mortgager: that, if any person at one time loses 10l. at play, he may sue the winner, and recover it back by action of debt at law; and, in case the loser does not, any other person may sue the winner for treble the sum so lost; and the plaintiff in either case may examine the defendant himself upon oath: and that in any of these suits no privilege of parliament shall be allowed. The statute farther enacts, that if any person cheats at play, and at one time wins more than 10l. or any valuable thing, he may be indicted thereupon, and shall forfeit five times the value, shall be deemed infamous, and suffer such corporal punishment as in case of wilful perjury. By several statutes of the reign of King George II. all private lotteries by tickets, cards, or dice, (and particularly the games of faro, basset, ace of hearts, hazard, passage, rolly polly, and all other games with dice, except backgammon), are prohibited under a penalty of 200l. for him that shall erect such lotteries, and 50l. a-time for the players. Public lotteries, unless by authority of parliament, and all manner of ingenious devices under the denomination of *sales* or otherwise, which in the end are equivalent to lotteries, were before prohibited by a great variety of statutes under heavy pecuniary penalties. But particular descriptions will ever be lame and deficient, unless all games of mere chance are at once prohibited; the invention of sharpers being swifter than the punishment of the law, which only hunts them from one device to another. The stat. 13 Geo. II. c. 19. to prevent the multiplicity of horse races, another fund of gaming, directs, that no plates or matches under 50l. value shall be run, upon penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertise the plate. By statute 18 Geo. I. c. 34. the statute 9 Ann. is farther enforced, and some deficiencies supplied: the forfeitures of that act may now be recovered in a court of equity; and, moreover, if any man be convicted, upon information or indictment, of winning or losing at any sitting 10l. or 20l. within 24 hours, he shall forfeit five times the sum. Thus careful has the legislature been to prevent this destructive vice: which may show that our laws against gaming are not so deficient as ourselves and our magistrates in putting those laws in execution.

Chance, or *Hazard*, in *Gaming*. Hazard, or chance, is a matter of mathematical consideration, because it admits of more and less. Gamesters either set out upon an equality of chance, or are supposed to do so. This equality may be altered in the course of the game, by the greater good fortune or address of one of the gamesters, whereby he comes to have a better chance, so that his share in the stakes is proportionably better than at first. This more and less runs through all the ratios between equality and infinite difference, or from an infinitely little difference till it come to an infinitely great one, whereby the game is determined. The whole game, therefore, with regard to the issue of it, is a chance of the proportion the two shares bear to each other.

The probability of an event is greater or less, according to the number of chances by which it may happen, compared with the number of all the chances by which it may either happen or fail.

M. de Moivre, in a treatise *de Mensura Sortis*, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose p the number of cases in which an event may happen, and q the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as p to q.

If two gamesters, A and B, engage on this footing, that, if the cases p happen, A shall win; but if q happen, B shall win, and the stake be a; the chance of A will be $\frac{pa}{q+p}$, and that of B $\frac{qa}{p+q}$; consequently, if they sell the expectancies, they should have that for them respectively.

If A and B play with a single dice, on this condition, that, if A throw two or more aces at eight throws, he shall win; otherwise B shall win; What is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five wherein it may not, let $a=1$, and $b=5$. And again, since there are eight throws of the die, let $n=8$; and you will have $\overline{a+b}|^n - b^n - nab^{n-1}$, to $b^n + nab^{n-1}$: that is, the chance of A will be to that of B as 663991 to 1015625, or nearly as 2 to 3.

A and B are engaged at single quoits; and, after playing some time, A wants 4 of being up, and B 6; but B is so much the better gamester, that his chance against A upon a single throw would be as 3 to 2; What is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws; therefore, raise $a+b$ to the ninth power, and it will be $a^9+9a^8b+36a^7bb+84a^6b^3+126a^5b^4+126a^4b^5$ to $84a^3b^6+36aab^7+6ab^3+b^9$: call a 3, and b 2, and you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A

A and B play at single quoits, and A is the best gamester, so that he can give B 2 in 3: What is the ratio of their chances at a single throw? Suppose the chances as z to 1, and raise $z+1$ to its cube, which will be z^3+3z^2+3z+1. Now since A could give B 2 out of 3, A might undertake to win three throws running; and consequently the chances in this case will be as z^3 to $3z^2+3z+1$. Hence $z^3=3z^2+3z+1$; or $2z^3=z^3+3z^2—3z+1$. And therefore $z\sqrt[3]{2}=z+1$; and, consequently, $z=\frac{1}{\sqrt[3]{2}-1}$. The chances, therefore, are $\frac{1}{\sqrt[3]{2}-1}$, and 1, respectively.

Again, suppose I have two wagers depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4; What is the probability I win both wagers?

1. The probability of winning the first is $\frac{3}{5}$, that is, the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is $\frac{7}{11}$: therefore, multiplying these two fractions together, the product will be $\frac{21}{55}$, which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is $\frac{34}{55}$, which is the probability I do not win both wagers: therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus; the probability of winning the first is $\frac{3}{5}$, the probability of losing the second is $\frac{4}{11}$: therefore multiplying $\frac{3}{5}$ by $\frac{4}{11}$, the product $\frac{12}{55}$ will be the probability of my winning the first and losing the second; which being subtracted from 1, there will remain $\frac{43}{55}$, which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: The probability of winning the second is $\frac{7}{11}$; the probability of losing the first is $\frac{2}{5}$: therefore, multiplying these two fractions together, the product $\frac{14}{55}$ is the probability I win the second, and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is $\frac{2}{5}$, and the probability of losing the second $\frac{4}{11}$: therefore the probability of losing them both is $\frac{8}{55}$: which, being subtracted from 1, there remains $\frac{47}{55}$: therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration. Thus if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is $\frac{5}{6}$, the second is also $\frac{5}{6}$, the third $\frac{5}{6}$, and the fourth $\frac{5}{6}$; therefore the probability of missing it four times together is $\frac{5}{6}\times\frac{5}{6}\times\frac{5}{6}\times\frac{5}{6}=\frac{625}{1296}$; which being subtracted from 1, there will remain $\frac{671}{1296}$ for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three times, the probability of missing it three times would be $\frac{5}{6}\times\frac{5}{6}\times\frac{5}{6}=\frac{125}{216}$; which being subtracted from 1, there will remain $\frac{91}{216}$ for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more; since the probability of throwing it the first time is $\frac{1}{6}$, and of missing it the other three times, is $\frac{5}{6}\times\frac{5}{6}\times\frac{5}{6}$, it follows, that the probability of throwing it the first time, and missing it the other three successive times, is $\frac{1}{6}\times\frac{5}{6}\times\frac{5}{6}\times\frac{5}{6}=\frac{125}{1296}$; but because it is possible to hit every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing it the other three, is $\frac{4\times125}{1296}=\frac{500}{1296}$; which being subtracted from 1, there will remain $\frac{796}{1296}$ for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has twice as many chances to come up as the other; what is the probability that the event which has the greater number of chances to come up, does not happen twice before the other happens once, which is the case of flinging 7 with two dice before 4 once? Since the number of chances is as 2 to 1, the probability of the first happening before the second is $\frac{2}{3}$, but the probability of its happening twice before it is but $\frac{2}{3}\times\frac{2}{3}$ or $\frac{4}{9}$: therefore it is 5 to 4, seven does not come up twice before four once.

But, if it were demanded, what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once? The answer is, 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is $\frac{12}{17}$, and the probability of throwing it twice is $\frac{12}{17}\times\frac{12}{17}$, or $\frac{144}{289}$; therefore the probability of not doing it is $\frac{145}{289}$; therefore the odds against it are as 145 to 144, which comes very near an equality.

Suppose there is a heap of thirteen cards of one colour, and another heap of thirteen cards of another colour; What is the probability, that, taking one card at a venture out of each head, I shall take out the two aces?

The probability of taking the ace out of the first heap is $\frac{1}{13}$; the probability of taking the ace out of the second heap is $\frac{1}{13}$; therefore the probability of taking out both aces is $\frac{1}{13}\times\frac{1}{13}=\frac{1}{169}$, which being subtracted from 1, there will remain $\frac{168}{169}$: therefore the odds against me are 168 to 1.

In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap of thirteen cards of one colour I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be $\frac{1}{13}$, and the probability of taking out the two be likewise $\frac{1}{13}$: yet, the ace being supposed as taken out already, there will remain only twelve cards in the heap, which will make the probability of taking out the two to be $\frac{1}{12}$; therefore the probability of taking out the ace, and then the two, will be $\frac{1}{13}\times\frac{1}{12}$.

In this last question the two events have a dependence on each other; which consists in this, that one of the events

events being supposed as having happened, the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards.

If the events in question be n in number, and be such as have the same number a of chances by which they may happen, and likewise the same number b of chances by which they may fail, raise $a+b$ to the power n. And if A and B play together, on condition that if either one or more of the events in question happen, A shall win, and B lose, the probability of A's winning will be $\frac{\overline{a+b}|^n - b^n}{\overline{a+b}|^n}$, and that of B's winning will be $\frac{b^n}{\overline{a+b}|}$; for when $a+b$ is actually raised to the power n, the only term in which a does not occur is the last b^n: therefore all the terms but the last are favourable to A.

Thus if $n=3$, raising $a+b$ to the cube $a^3+3a^2b+3ab^2+b^3$, all the terms but b^3 will be favourable to A; and therefore the probability of A's winning will be $\frac{a^3+3a^2b+3ab^2}{\overline{a+b}|}$, or $\frac{\overline{a+b}|^3 - b^3}{\overline{a+b}|^3}$; and the probability of B's winning will be $\frac{b^3}{\overline{a+b}|^3}$. But if A and B play on condition, that if either two or more of the events in question happen, A shall win; the probability of A's winning will be $\frac{\overline{a+b}|^n - nab^{n-1} - {}^n}{\overline{n+b}|^n}$; for the only two terms in which $a\,a$ does not occur are the two last, viz. nab^{n-1} and b^n.

GAMMONING, among seamen, denotes several turns of a rope taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit.

GAMMUT, Gamut, *Gam-ut*, in *Music*, a scale whereon we may learn to sound the musical notes, *ut*, *re*, *mi*, *fa*, *sol*, *la*, in their several orders and dispositions. See Music.

The invention of this scale is owing to Guido Aretin, a monk of Arezzo, in Tuscany, about the year 1009; though it is not so properly an invention, as an improvement on the diagram or scale of the ancients. See Aretin.

Several alterations have been made in the gammut. M. Le Maire, particularly, has added a seventh note; viz. *si*; and the English usually throw out both *ut* and *si*, and make the other five serve for all.

GANDER, in *Ornithology*, the male of the goose kind. See Anas, Ornithology *Index*.

GANG-way, is the several passages or ways from one part of the ship to the other; and whatsoever is laid in any of those passages is said to lie in the gangway.

GANGANELLI. See Clement XIV.

GANGES, a large and celebrated river of India. It has its source in the mountains which border on Little Thibet, in 78 degrees of longitude, and 32 of latitude. It crosses several kingdoms, running from northwest to south-east; and falls into the bay of Bengal by several mouths. The waters are lowest in April and May, and highest before the end of September. It overflows yearly like the Nile; and renders the kingdom of Bengal as fruitful as that of the Delta in Egypt. The people in these parts hold the water of this river in high veneration; and it is visited annually by a prodigious number of pilgrims from all parts of India. The greatest happiness that many of the Indians wish for, is to die in this river. The English have several settlements on this river, which will be taken notice of in their proper places.

GANGLION, in *Anatomy*, denotes a knot frequently found in the course of the nerves, and which is not morbid; for wherever any nerve sends out a branch, or receives one from another, or where two nerves join together, there is generally a ganglion or plexus, as may be seen at the beginning of all the nerves of the medulla spinalis, and in many other places of the body.

Ganglion, in *Surgery*, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part; usually without pain to the patient.

GANGRENE, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. See Medicine, and Surgery.

GANNET, or *Soland Goose*, in *Ornithology*. See Pelicanus, Ornithology *Index*.

GANTLET, or Gauntlet, a large kind of glove made of iron, and the fingers covered with small plates. It was formerly worn by the cavaliers, when armed at all points. The word is derived of the French *guntelet*; and that from *gand*, or *gant*, "glove."

The casque and gauntlets were always borne in the ancient marches in ceremony. Gauntlets were not introduced till about the 13th century.

The gauntlet was frequently thrown like the glove, by way of challenge.

GANTLOPE. See Gauntlope.

GANYMEDE, in mythology, a beautiful youth of Phrygia, son of Tros and brother to Ilus; according to Lucian, he was the son of Dardanus. Jupiter was charmed with him; and carrying him away, made him his cupbearer in the room of Hebe. Some say that he caused him to be carried away by an eagle, and others affirm he was himself the ravisher under the form of that bird. He deified this youth; and to comfort his father made a present to him of some of those very swift horses upon which the gods rode.

GAOL (*Gaola*, Fr. *Geole*, i. e. *Caveola*, "a cage for birds"), is used metaphorically for a prison. It is a strong place or house for keeping of debtors, &c. and wherein a man is restrained of his liberty to answer an offence done against the law: and every county hath two gaols, one for debtors, which may be any house where the sheriff pleases; the other for the peace and matters of the crown, which is the county gaol.

If a gaol be out of repair, or insufficient, &c. justices of peace, in their quarter sessions, may contract with workmen for the rebuilding or repairing it; and by their warrant order the sum agreed on for that purpose to be levied on the several hundreds, and other divisions in the county, by a just rate, 11 and 12 Will. III. c. 19. See Prison.

Gaol Delivery. The administration of justice being originally in the crown, in former times our kings in in person rode through the realm once in seven years, to judge of and determine crimes and offences; afterwards justices in eyre were appointed; and since, justices of assize and goal delivery, &c. A commission of gaol delivery, is a patent in nature of a letter from the king to certain persons, appointing them his justices, or two or three of them, and authorizing them to deliver his gaol, at such a place, of the prisoners in it: for which purpose it commands them to meet at such a place, at the time they themselves shall appoint; and informs them, that, for the same purpose, the king hath commanded his sheriff of the same county to bring all the prisoners of the gaol, and their attachments, before them at the day appointed.

The justices of gaol delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order to execution or reprieve: they may likewise discharge such prisoners, as on their trials are acquitted, and those against whom, on proclamation being made, no evidence has appeared: they have authority to try offenders for treason, and to punish many particular offences, by statute, 2 *Hawk.* 24. 2. *Hale's Hist. Placit. Cor.* 35.

GAOLER, the keeper of a gaol or prison. Sheriffs are to make such gaolers for whom they will be answerable: but if there be any default in the gaoler, an action lies against him for an escape, &c. yet the sheriff is most usually charged; 2d Inst. 592. Where a gaoler kills a prisoner by hard usage, it is felony; 3d Inst. 52. No fee shall be taken by gaolers, but what is allowed by law, and settled by the judges, who may determine petitions against their extortions, &c. 2 Geo. II. c. 22.

GAONS, a certain order of Jewish doctors, who appeared in the East, after the closing of the Talmud. The word *Gaons* signifies "excellent, sublime;" as in the divinity schools we formerly had Irrefragable, Sublime, Resolute, Angelic, and Subtile doctors. The Gaons succeeded the Seburæans or Opiners about the beginning of the sixth century. Chanan Meischtia was the head and first of the excellents. He restored the academy of Pandebita, which had been shut up for 30 years.

GAR FISH, *Horn Fish*, or *Sea Needle*. See Esox, Ichthyology *Index*.

GARAMA, in *Ancient Geography*, the capital of the Garamantes in Libya Interior; near the springs of the Cinyphus, now in ruins. Garamantes the people. It lay to the south of Gætulia, extending from the springs of the Cinyphus, and the adjacency of the river Gir, to the mountains which form at the *Vallis Garamantica* (Pliny): or from the springs of the Bagrades to the lake Nuba (Ptolemy).

GARAMOND, Claude, a very ingenious letter-founder, was born at Paris; where he began, in the year 1510, to found his printing types free from all the remains of the Gothic, or (as it is generally called) the *black letter*, and brought them to such perfection, that he had the glory of surpassing all who went before him, and of being scarcely ever excelled by his successors in that useful art. His types were prodigiously multiplied: both by the great number of matrices he struck, and the types formed in resemblance of his in all parts of Europe. Thus in Italy, Germany, England, and Holland, the booksellers, by way of recommending their books, distinguished the type by his name; and in particular the small Roman was by way of excellence known among the printers of these nations by the name of *Garamond's small Roman*. By the special command of King Francis I. he founded three sizes of Greek types for the use of Robert Stephens, who with them printed all his beautiful editions of the New Testament, and other Greek authors. He died at Paris in 1561.

GARASSE, Francis, a remarkable Jesuitical writer, the first author of that irreconcilable enmity that still subsists between the Jesuits and Jansenists, in the church of Rome, was born at Angoulesme in 1585, and entered the Jesuits college in 1600. As he had a quick imagination, a strong voice, and a peculiar turn to wit, he became a popular preacher in the chief cities of France; but not content with this honour, he distinguished himself still more by his writings, which were bold, licentious, and produced much controversy. The most considerable in its consequences was entitled *La somme theologique des veritez capitales de la religion Cretienne*; which was first attacked by the abbot of St Cyran, who observing in it a prodigious number of falsifications of the Scriptures and of the fathers, besides many heretical and impious opinions, conceived the honour of the church required him to undertake a refutation. Accordingly he published a full answer to it; while Garassé's book was also under examination of the doctors of the Sorbonne, by whom it was afterwards condemned. Garasse replied to St Cyran; but the two parties of Jesuits and Jansenists, of whom these were respectively the champions, grew to an implacable animosity against each other, that is not even now likely to subside. The Jesuits were forced to remove their brother to a distance from Paris; where, probably weary of his inactive obscurity, when the plague raged at Poictiers in 1631, he begged leave of his superior to attend the sick, in which charitable office he caught the disorder, and died.

GARBE, in *Heraldry*, a sheaf of any kind of grain, borne in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

GARBLE, a word used to signify the action of separating the dross and dust from spice, drugs, &c. *Garbling* is the cleansing and purifying the good from the bad; and may come from the Italian *garbo*; i. e. finery or neatness: and hence, probably, we say, when we see a man in a neat habit, that he is in handsome *garb*.

GARCILASSO de la Vega, an eminent Spanish poet, was born at Toledo, in 1503. He was the younger son of a man of rank, who had been employed in negociating business of importance. Garcilasso was distinguished for his wit and bravery, and in a particular manner for his poetical talents. He was chiefly instrumental in giving popularity to an innovation of his friend Boscan, who introduced measures borrowed from the Italians. His works consist chiefly of pastorals, which have a tedious prolixity. He is chiefly noted for tenderness, which is remarkably conspicuous in some of his sonnets. He is freer of bombast than the generality of his countrymen, owing to his familiar acquaintance with the ancients; and it is said that his learning and taste were superior to his genius. He followed the profession of arms, and attended Charles V. in in a number of his expeditions. He lost his life at the attack of a fortress in Provence, when only 33 years of age. Garcilasso is also the name of an author, a native of Cusco in Peru, who composed a history of Florida in Spanish, and another of Peru and its Incas.

GARCINIA, a genus of plants belonging to the dodecandria class; and in the natural method ranking under the 18th order, *Bicornes*. See BOTANY *Index*.

GARCON, or GARSOON, a French term, literally signifying a boy, but also applied to divers inferior officers, amongst us called *groom, garçiones*.

GARD, a department in the south of France. The north part which lies among the Cevennes is rugged and barren; but the south part is fertile and populous. It contains mines of copper, lead, iron, and pit coal. The whole number of inhabitants in 1815 was 322,000, of whom about one half were Protestants. Nismes is the chief town.

GARDANT, or GUARDANT, in *Heraldry*, denotes any beast full faced, and looking right forward.

GARDEN, FRANCIS, better known to the public by the title of *Lord Gardenstone*, was born at Edinburgh June 24th, in the year 1721. His father was Alexander Garden of Troup, an opulent landholder in Aberdeenshire; his mother was Jane, daughter of Sir Francis Grant of Cullen, S. C. I.

After passing through the usual course of liberal education at the school and the university, he betook himself to the study of law for his profession; and in the year 1744 he was admitted a member of the Faculty of Advocates, and called to the Scottish bar.

In his practice as an advocate he soon began to be distinguished, by a strong native rectitude of understanding; by that vivacity of apprehension and imagination which is commonly denominated *genius;* by manly candour in argument, often more persuasive than subtlety and sophistical artifice; by powers which, with diligence, might easily attain to the highest eminence of the profession. But the same strength, openness, and ardour of mind, which distinguished him so advantageously among the pleaders at the bar, tended to give him a fondness for the gay enjoyments of convivial intercourse, which was unfavourable to his progress in juridical erudition. Shining in the social and convivial circle, he became less solicitously ambitious than he might otherwise have been, of the character of an eloquent advocate, or of a profound and learned lawyer. The vivacity of his genius was averse from austere and plodding study, while it was captivated by the fascinations of polite learning, and of the fine arts. Nor did he always escape those excesses in the pursuit of pleasure into which the temptations of opening life are apt, occasionally, to seduce the most liberal and ingenuous youth. But his cheerful conviviality, his wit, humour, taste, good-nature, and benevolence of heart, rendered him the delight of all his acquaintance. He became his majesty's solicitor July 3d, 1764.

At length the worth of his character, and his abilities as a lawyer, recommended him to the office of a judge in the courts of session and justiciary, the supreme judicatures, civil and criminal, for Scotland. His place in the court of session he continued to occupy till his death; but had, some years before, resigned the office of a commissioner of justiciary, and in recompense got a pension of 200l. per annum. Clear discernment, strong good sense, conscientious honesty, and amiable benevolence, remarkably distinguished all his opinions and conduct as a judge.

In the year 1762 he purchased the estate of Johnston, in the county of Kincardine. Within a few years after he began to attempt a plan of the most liberal improvement of the value of this estate, by an extension of the village of Laurencekirk, adjoining. He offered leases of small farms, and of ground for building upon, which were to last for the term of one hundred years; and of which the conditions were extremely inviting to the labourers and tradesmen of the surrounding country. These offers were eagerly listened to. More desirous to make the attempt beneficial to the country than to derive profit from it to himself, he was induced, within a few years, to reduce his groundrents to one-half of the original rate.—Weavers, joiners, shoemakers, and other artisans in a considerable number, resorted to settle in the rising village. His lordship's earnestness for the success of his project, and to promote the prosperity of the good people whom he had received under his protection, led him to engage in several undertakings; by the failure of which he incurred considerable losses. Projects of a printfield, and of manufactures of linen and of stockings, attempted with sanguine hopes in the new village, and chiefly at his lordship's risk and expence, misgave in such a manner as might well have finally disgusted a man of less steady and ardent philanthropy with every such engagement. But the village still continued to advance. It grew up under his lordship's eye, and was the favourite object of his care. In the year 1779, he procured it to be erected into a burgh of barony; having a magistracy, an annual fair, and a weekly market. He provided in it a good inn for the reception of travellers; and with an uncommon attention to the entertainment of the guests who might resort to it, furnished this inn with a library of books for their amusement. He invited an artist for drawing, from the continent, to settle at Laurencekirk. He had the pleasure of seeing a considerable linen-manufacture at length fixed in it. A bleachfield was also established as a natural counterpart to the linen manufacture. Before his lordship's death, he saw the plan of improving the condition of the labourers, by the formation of a new village at Laurencekirk, crowned with success beyond his most sanguine hopes. He has acknowledged, with an amiable frankness, in a memoir concerning this village, "That he had tried, in some measure, a variety of the pleasures which mankind pursue; but never relished any so much as the pleasure arising from the progress of his village."

In the year 1785, upon the death of his elder brother, Alexander Garden of Troup, M. P. for Aberdeenship, Lord Gardenstone succeeded to the possession of the family estates, which were very considerable. Until this time his lordship's income had never been more than adequate to the liberal expence into which his rank, and the generosity of his nature, unavoidably led him. But the addition of a fortune of about three thousand pounds a-year to his former revenue, gave him the power of performing many acts of beneficence with which he could not before gratify his good heart. It was happy, likewise, that his succession to this ample income, at a period when the vigour of

Garden. of his constitution was rapidly yielding to the infirmities of old age, enabled him to seek relief, by a partial cessation from business, by travel, and by other means, which could not have been easily compatible with the previous state of his fortune.

In the month of Sept. 1786, he set out from London for Dover, and passed over into France. After visiting Paris, he proceeded to Provence, and spent the winter months in the genial climate of Hieres. In the spring of 1787 he returned northwards, visiting Geneva, Switzerland, the Netherlands, and the Dutch provinces, and passing through Germany into Italy. With a fond curiosity, attentive alike to the wonders of nature, to the noble monuments of the arts, and to the awful remains of ancient grandeur, with which Italy abounds, he visited all its great cities, and surveyed almost every remarkable and famous scene that it exhibits.

His first object, in these travels, was to obtain the restoration of his declining health by the influence of a milder climate, by gentle, continued, and varied exercise; by that pleasing exhilaration of the temper and spirits, which is the best medicine to health, and is most successfully produced by frequent change of place, and of the objects of attention. But the curiosities of nature and art, in those countries through which he travelled, could not fail to attract, in a powerful manner, the curiosity of a mind cultivated and ingenious as his. He, whose breast glowed with the most ardent philanthropy, could not view the varied works and manners of a diversity of nations of his fellow men, without being deeply interested by all those circumstances which might appear to mark their fortunes as happy or wretched. He eagerly collected specimens of the spars, the shells, the strata of rocks, and the veins of metals, in the several countries through which he passed. He amassed also cameos, medals, and paintings. He enquired into science, literature, and local institutions. He wrote down his observations, from time to time; not indeed with the minute care of a pedant, or the ostentatious labour of a man travelling with a design to publish an account of his travels; but simply to aid memory and imagination in the future remembrance of objects useful or agreeable.

After an absence of about three years, he returned to his native country. The last years were spent in the discharge of the duties of his office as a judge; in social intercourse with his friends, among whom was the venerable Lord Monboddo, and others of the most respectable characters that our country has to boast of; in the performance of a thousand generous offices of benevolence and humanity; in cherishing those fine arts, of which he was an eminent admirer and judge; and above all, in promoting the comfort, and encouraging the industry of his dependants, and in lending his aid to every rational attempt at the improvement of public economy and public virtue.

St Bernard's Well, in the neighbourhood of Edinburgh, had been, long since, distinguished for the medicinal virtues of its waters. But various circumstances had also concurred of late to throw it into neglect. Yet its waters being strongly mineralized by a sulphurated hydrogenous gas, were, by this means, unquestionably qualified to operate, with highly beneficial effects, in the cure of various diseases. The qualities of this mineral water falling under Lord Gardenstone's notice, he was induced to purchase the property of the well, to direct it to be cleared from surrounding obstacles, which contaminated the virtues of the water, or made it inaccessible; to erect a beautiful and commodious edifice over it; and to appoint proper persons to distribute the water, for a very trivial compensation to the public. The well lies at a distance from Edinburgh, which is very convenient for a summer morning's walk. Within the few years which have passed since Lord Gardenstone's benevolent care brought it into notice, it has attracted many of the inhabitants of that city to visit it in the mornings of spring and summer. And, undoubtedly, the agreeable exercise to which they have thus been allured, and the salutary effects of the water, have contributed, in no mean degree, to dispel disease, and to confirm or re-establish health. Such monuments are worthy to preserve the memory of a patriotic and a good man!

As an amusement for the last two or three years of his life, when his increasing infirmities precluded him from more active exercise, and from mingling so frequently in the society of his friends as was agreeable to his social and convivial temper, he bethought himself of revising some of the *jeux d'esprit*, and light fugitive pieces, in which he had indulged the gaiety of his fancy, in his earlier days; and a small volume of poems was published, in which the best pieces are, upon good authority, ascribed to Lord Gardenstone. He revised also the memorandums which he had made upon his travels, and permitted them to be sent to press. The two former volumes were published one after another while his lordship was yet alive; the third after his death. They met with a very favourable reception in the world, and were honoured with the high approbation of the most respectable writers of periodical criticism. They convey much agreeable information, and bespeak an elegant, enlightened, and amiable mind. The last volume is filled chiefly with memorandums of his lordship's travels in Italy; and contains many interesting criticisms upon some of the noblest productions of the fine arts of painting and sculpture.

His lordship's health had long been declining; and he died a bachelor on the 22d of July 1793, lamented by his relations and friends, by his tenants and humble dependents, and by all true patriots and good men to whom his merits and virtues were known.

Garden, a piece of ground properly laid out, cultivated and ornamented with a variety of plants, flowers, fruits, &c. See Gardening.

Gardens are usually distinguished into flower garden, fruit garden, and kitchen garden: the first of which, being designed for pleasure and ornament, is to be placed in the most conspicuous part, that is, next to the back front of the house; and the two latter, being designed for use, should be placed less in sight. But though the fruit and kitchen gardens are here mentioned as two distinct gardens, yet they are now usually in one; and that with good reason, since they both require a good soil and exposure, and equally require to be placed out of the view of the house.

In the choice of a place proper for a garden, the most essential points to be considered are, the situation, the soil, the exposure, water, and prospect.

1st, As to the situation, it ought to be such a one as as is wholesome, and in a place neither too high nor too low; for if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees; and if it be too low, the dampness, the vermine, and the venomous creatures that breed in ponds and marshy places, add much to their insalubrity. The most happy situation is on the side of a hill, especially if the slope be easy, and in a manner imperceptible; if a good deal of level ground be near the house; and if it abounds with springs of water: for, being sheltered from the fury of the winds and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hill, either from springs or rain, will not only supply fountains, canals, and cascades for ornament, but, when it has performed its office, will water the adjacent valleys, and, if it be not suffered to stagnate, will render them fertile and wholesome.

2dly, A good earth or soil is next to be considered; for it is scarce possible to make a fine garden in a bad soil. There are indeed ways to meliorate ground, but they are very expensive; and sometimes, when the expence has been bestowed of laying good earth three feet deep over the whole surface, a whole garden has been ruined, when the roots of the trees have come to reach the natural bottom. To judge of the quality of the soil, observe whether there be any heath, thistles, or such like weeds, growing spontaneously in it; for they are certain signs that the ground is poor. Or if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, and grubby; and whether they are of a faded green, and full of moss, or infested with vermine: if this be the case, the place is to be rejected. But, on the contrary, if it be covered with good grass fit for pasture, you may then be encouraged to try the depth of the soil. To know this, dig holes in several places, six feet wide and four deep; and if you find three feet of good earth it will do very well, but less than two will not be sufficient. The quality of good ground, is neither to be stony nor too hard to work; neither too dry, too moist, nor too sandy and light; nor too strong and clayey, which is the worst of all for gardens.

3dly, The next requisite is water; the want of which is one of the greatest inconveniences that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry situation in summer; besides its usefulness in fine gardens for making fountains, canals, cascades, &c. which are the greatest ornaments of a garden.

4thly, The last thing to be considered is the prospect of a fine country; and though this is not so absolutely necessary as water, yet it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that has no kind of prospect, it will not only be disagreeable but unwholesome.

In the laying out and planting of gardens, the beauties of nature should always be studied; for the nearer a garden approaches to nature, the longer it will please. According to Mr Miller, the area of a handsome garden may take up 30 or 40 acres, but not more; and the following rules should be observed in the disposition of it. There ought always to be a descent of at least three steps from the house to the gardens; this will render the house more dry and wholesome, and the prospect on entering the garden more extensive.—The first thing that ought to present itself to view should be an open lawn of grass, which ought to be considerably broader than the front of the buildings; and if the depth be one half more than the width, it will have a better effect: if on the sides of the lawn there are trees planted irregularly, by way of open groves, the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn should be surrounded with a gravel walk, on the outside of which should be borders three or four feet wide for flowers: and from the back of these the prospect will be agreeably terminated by a slope of evergreen shrubs; which, however, should never be suffered to exclude agreeable prospects, or the view of handsome buildings. These walks may lead through the different plantations, gently winding about in an easy natural manner; which will be more agreeable than either those long straight walks, too frequently seen in gardens, or those serpentine windings that are twisted about into so many short turns as to render it difficult to walk in them; and as no garden can be pleasing where there is a want of shade and shelter, these walks should lead as soon as possible into plantations, where persons may walk in private, and be sheltered from the wind.

Narrow rivulets, if they have a constant stream, and are judiciously led about a garden, have a better effect than many of the large stagnating ponds or canals so frequently made in large gardens. When wildernesses are intended, they should not be cut into stars and other ridiculous figures, nor formed into mazes of labyrinths, which in a great design appear trifling.

In short, the several parts of a garden should be diversified; but in places where the eye takes in the whole at once, the two sides should be always the same. In the business of designs, the aim should be always at what is natural, great, and noble. The general disposition of a garden and of its parts ought to be accommodated to the different situations of the ground, to humour its inequalities, to proportion the number and sorts of trees and shrubs to each part, and to shut out from the view of the garden no objects that may become ornamental. But for a more extended view of this subject, see the article GARDENING.

A practical attention to a garden, is by some esteemed a degrading employment. It is true, indeed, that pastoral and agricultural manners, if we may form a judgment from the dignified descriptions of Virgil, are greatly degenerated. The employments of shepherds and husbandmen are now become mean and sordid. The work of the garden is usually left to a peasant. Nor is it unreasonable to assign the labour, which wearies without amusement, to those who are sufficiently amused by the prospect of their wages. But the operations of grafting, of inoculating, of pruning, of transplanting, are curious experiments in natural philosophy; and that they are pleasing as well as curious, those can testify who remember what they felt on seeing their attempts in the amusement of practical gardening attended with success. Among the employments suitable to old age, Cicero has enumerated the superintendence of a garden.

Garden.

It requires no great exertion of mind or body; and its satisfactions are of that kind which please without violent agitation. Its beneficial influence on health is an additional reason for an attention to it at an age when infirmities abound.

In almost every description of the seats of the blessed, ideas of a garden seem to have predominated. The word Paradise itself is synonymous with garden. The fields of Elysium, that sweet region of poesy, are adorned with all that imagination can conceive to be delightful. Some of the most pleasing passages of Milton, are those in which he represents the happy pair engaged in cultivating their blissful abode. Poets have always been delighted with the beauties of a garden. Lucan is represented by Juvenal as reposing in his garden. Virgil's Georgics prove him to have been captivated with rural scenes; though, to the surprise of his readers, he has not assigned a book to the subject of a garden. Our Shenstone made it his study; but, with all his taste and fondness for it, he was not happy in it. The captivating scenes which he created at the Leasowes, afforded him, it is said, little pleasure in the absence of spectators. The truth is, he made the embellishment of his grounds, which should have been the amusement of his life, the business of it; and involved himself in such troubles, by the expences it occasioned, as necessarily excluded tranquil enjoyment.

It is the lot of few, in comparison, to possess territories like his, extensive, and sufficiently well adapted to constitute an ornamented farm. Still fewer are capable of supporting the expence of preserving it in good condition. But let not the rich suppose they have appropriated the pleasures of a garden. The possessor of an acre, or a smaller portion, may receive a real pleasure, from observing the progress of vegetation, even in a plantation of culinary plants. A very limited tract, properly attended to, will furnish ample employment for an individual. Nor let it be thought a mean care; for the same hand that raised the cedar, formed the hyssop on the wall. Even the orchard, cultivated solely for advantage, exhibits beauties unequalled in the shrubbery; nor can the greenhouse produce an appearance to exceed the blossom of the apple and the almond.

Hanging GARDENS, in antiquity, gardens raised on arches by Nebuchadnezzar king of Babylon, in order to gratify his wife Amyctis, daughter of Astyages king of Media. Quintus Curtius makes them equal in height to the walls of the city, viz. 50 feet. They contained a square of 400 feet on every side, and were carried up into the air in several terraces laid above one another, and the ascent from terrace to terrace was by stairs 10 feet wide. The arches sustaining the whole pile were raised above one another, and it was strengthened by a wall, surrounding it on every side, of 22 feet in thickness. The floors of each of the terraces were laid in the following manner: on the top of the arches were first laid large flat stones 16 feet long and 4 broad, and over them was a layer of reeds mixed with a great quantity of bitumen, over which were two rows of bricks closely cemented together by plaster, and over all were laid thick sheets of lead; and lastly, upon the lead was laid the mould of the garden. The mould or earth was of such a depth as to admit the largest trees to take root and grow; and it was covered with various kinds of trees, plants, and flowers. In the upper terrace there was an aqueduct or engine, whereby water was drawn up out of the river for watering the whole garden.

Floating GARDENS. We are informed by the abbé Clavigero in his History of Mexico, that when the Mexicans were brought under subjection to the Colhuan and Tepanecan nations, and confined to the miserable little islands in the lake of Mexico, they ceased for some years to cultivate the land, because they had none, until necessity and industry together taught them to form moveable fields and gardens, which floated on the waters of the lake. The method which they pursued to make these, and which they still practise, is extremely simple. They plait and twist willows and roots of marsh plants or other materials together, which are light, but capable of supporting the earth of the garden firmly united. Upon this foundation they lay the light bushes which float on the lake; and over all, the mud and dirt which they draw up from the bottom of the same lake. Their regular figure is quadrangular; their length and breadth various: but generally they are about eight perches long, and not more than three in breadth, and have less than a foot of elevation above the surface of the water. These were the first fields which the Mexicans owned after the foundation of Mexico; there they first cultivated the maize, great pepper, and other plants necessary for their support. In progress of time, as those fields grew numerous from the industry of the people, there were among them gardens of flowers and odoriferous plants, which were employed in the worship of their gods, and served for the recreation of the nobles. At present they cultivate flowers and every sort of garden herbs upon them. Every day of the year, at sunrise, innumerable vessels loaded with various kinds of flowers and herbs, which are cultivated in those gardens, are seen arriving by the canals, at the great market place of that capital. All plants thrive there surprisingly; the mud of the lake is an extremely fertile soil, and requires no water from the clouds. In the largest gardens there is commonly a little tree, and even a little hut to shelter the cultivator and defend him from rain or the sun. When the owner of a garden, or the *Chinampa* as he is usually called, wishes to change his situation, to remove from a disagreeable neighbour, or to come nearer to his own family, he gets into his little vessel, and by his own strength alone, if the garden is small, or with the assistance of others if it is large, he tows it after him, and conducts it wherever he pleases with the little tree and hut upon it. That part of the lake where those floating gardens are, is a place of infinite recreation, where the senses receive the highest possible gratification.

GARDENING;

GARDENING;

THE art of planning and cultivating gardens. In its utmost extent, whatever contributes to render the scenes of nature delightful, is among the subjects of gardening; and animate as well as inanimate objects are circumstances of beauty or character. The whole range of nature is open to the gardener, from the parterre to the forest; and whatever is agreeable to the senses or the imagination, he may appropriate to the spot he is to improve: it is a part of his business to collect into one place the delights which are generally dispersed through different species of country.

History of Gardening.

GARDENING, Mr Walpole † observes, was probably one of the first arts that succeeded to that of building houses, and naturally attended property and individual possession. Culinary, and afterwards medicinal herbs, were the objects of every head of a family: it became convenient to have them within reach, without seeking them at random in woods, in meadows, and on mountains, as often as they were wanted. When the earth ceased to furnish spontaneously all those primitive luxuries, and culture became requisite, separate enclosures for rearing herbs grew expedient. Fruits were in the same predicament; and those most in use, or that demand attention, must have entered into and extended the domestic enclosure. The good man Noah, we are told, planted a vineyard, drank of the wine, and was drunken; and every body knows the consequences. Thus we acquired kitchen gardens, orchards, and vineyards. No doubt the prototype of all these sorts was the garden of Eden; but as that Paradise was a good deal larger than any we read of afterwards, being enclosed by the rivers Pison, Gihon, Hiddekel, and Euphrates; as every tree that was pleasant to the sight and good for food grew in it; and as two other trees were likewise found there, of which not a slip or sucker remains; it does not belong to the present discussion. After the fall no man living was suffered to enter into the garden; and the poverty and necessities of our first ancestors hardly allowed them time to make improvements in their estates in imitation of it, supposing any plan had been preserved. A cottage and a slip of ground for a cabbage and a gooseberry bush, such as we see by the side of a common, were in all probability the earliest seats and gardens: a well and bucket succeeded to the Pison and Euphrates. As settlements increased, the orchard and the vineyard followed; and the earliest princes of tribes possessed just the necessaries of a modern farmer.

† Hist. of Mod. Gardening, subjoined to the 4th vol. of Anecdotes of Painting.

Matters, we may well believe, remained long in this situation; and we have reason to think that for many centuries the term *garden* implied no more than a kitchen garden or orchard.

The garden of Alcinous, in the Odyssey, is the most renowned in the heroic times. Is there an admirer of Homer who can read his description without rapture? or who does not form to his imagination a scene of delights more picturesque than the landscapes of Tinian or Juan Fernandez? "Yet (continues our author) what was that boasted Paradise with which

> the gods ordain'd
> To grace Alcinous and his happy land?

Why, divested of harmonious Greek and bewitching poetry, it was a small orchard and vineyard, with some beds of herbs and two fountains that watered them, enclosed within a quickset hedge. The whole compass of this pompous garden enclosed—four acres:

> Four acres was th' allotted space of ground,
> Fenc'd with a green enclosure all around.

The trees were apples, figs, pomegranates, pears, olives, and vines.

> Tall thriving trees confess'd the fruitful mold;
> The red'ning apple ripens into gold.
> Here the blue fig with luscious juice o'erflows,
> With deeper red the full pomegranate glows;
> The branch here bends beneath the weighty pear,
> And verdant olives flourish round the year.
> * * * * * *
> Beds of all various herbs, for ever green,
> In beauteous order terminate the scene.

Alcinous's garden was planted by the poet, enriched by him with the fairy gift of eternal summer, and no doubt an effort of imagination surpassing any thing he had ever seen. As he has bestowed on the same happy prince a palace with brazen walls and columns of silver, he certainly intended that the garden should be proportionably magnificent. We are sure, therefore, that, as late as Homer's age, an enclosure of four acres, comprehending orchard, vineyard, and kitchen garden, was a stretch of luxury the world at that time had never beheld."

Previous to this, however, we have in the sacred writings hints of a garden still more luxuriously furnished. We allude to the Song of Solomon, part of the scene of which is undoubtedly laid in a garden *. Flowers and fruits are particularly spoken of as the ornaments and the produce of it; and besides these, aromatic vegetables formed a considerable part of the gratification it afforded. The camphor and the cinnamon tree, with all trees of frankincense, and all the chief spices, flourished there †. Solomon tells us in another place ‡, That he made him great works;—gardens and orchards, and planted in them trees of every kind. Indeed we must suppose his gardens to have been both amply and curiously furnished, seeing the kinds, nature, and properties of the vegetable tribes, seem to have been a favourite study with the royal philosopher, and to have been deemed a subject worthy of his pen: for we are told, that he wrote of plants, from the great cedar of Lebanon down to the hyssop of the wall §. Fountains and streams of water appear also to have had a share in the composition, and probably for ornament as well as use.

* Chap. ii. 1.

† Cant. iv. 12.

‡ Eccl. ii. 4, 5.

§ Kings iv. 33.

The hanging gardens of Babylon, mentioned in a preceding

preceding article, were a still greater prodigy. But as they are supposed to have been formed on terraces and the walls of the palace, whither soil was conveyed on purpose, Mr Walpole concludes, "they were what sumptuous gardens have been in all ages till the present, unnatural, enriched by art, possibly with fountains, statues, balustrades, and summer houses, and were any thing but verdant and rural."

Others, however, have allowed them greater praise. They seem, in many respects, to have been laid out with good taste. Their elevation not only produced a variety and extent of view, but was also useful in moderating the heat. Such a situation would likewise suit a greater variety of trees and plants than a plain surface, and would contain a larger as well as a more diversified extent.

The suiting of the situation to the nature of the tree seems, from the account given by Josephus, to have been one view ‡ in the erecting the building in such a manner. And the success seems to have been answerable, as the trees are said to have flourished extremely well †, and to have grown as tall as in their native situations. On the whole, then, however different these may appear from modern gardens, they seem to have been formed with judgment and taste, and well adapted to the situation and circumstances.

‡ *Contra Apion*, lib. i. § 19.

† *Q. Curt.* lib. v.

It seems probable, from several circumstances, that the eastern gardens were adjoining to the house or palace to which they belonged. Thus, King Ahasuerus goes immediately from the banquet of wine to walk in the garden of the palace §. The garden of Cyrus, at Sardis, mentioned by Xenophon *, was probably contiguous to the palace: as was that of Attalus, mentioned by Justin ‖. The hanging gardens at Babylon, were not so much adjacent to the palace, as a part of the palace itself, since several of the royal apartments were beneath them ‡.

§ Esther vii. 7.

* *Oecon.*

‖ Lib. xxxvi. c. 4.

‡ *Diod.* lib. ii.

It is not clear what the taste for gardening was among the Greeks. The Academus, we know, was a wooded shady place; and the trees appear to have been of the olive species. It was situated beyond the limits of the walls, and adjacent to the tombs of the heroes; and though we are nowhere informed of the particular manner in which this grove was disposed or laid out, it may be gathered from Pausanias, in his Attica, that it was an elegant ornamented place. At the entrance was an altar dedicated to Love, which was said to be the first erected to that deity. Within the Academus, were the altars of Prometheus, of the Muses, of Mercury, of Minerva, and Hercules; and at a small distance was the tomb of Plato. So that in all probability, it was highly adapted by art, as well as nature, to philosophic reflection and contemplation.

We are told by Plutarch, that before the time of Cimon, the Academus was a rude and uncultivated spot: but that it was planted by that general, and had water conveyed to it; whether this water was brought merely for use to refresh the trees, or for ornament, does not appear. It was divided into gymnasia, or places of exercise, and philosophic walks shaded with trees. These are said to have flourished very well, until destroyed by Sylla (when he besieged Athens), as well as those in the Lyceum.

Near the academy were the gardens of the philosophers, of Plato and of Epicurus; which, however, were probably but small. The scene of Plato's Dialogue concerning Beauty is elegantly described as being on the banks of the river Ilissus, and under the shade of the plantain; but no artificial arrangement of objects is mentioned, nor any thing which will lead us to imagine the prospect to be any other than merely natural.

Among the Romans, a taste of gardening, any otherwise than as a matter of utility, seems not to have prevailed till a very late period; at least the writers on husbandry, Cato, Varro, Columella, and Palladius, make not the least mention of a garden as an object of pleasure, but solely with respect to its productions of herbs and fruits. The Lucullan gardens are the first we find mentioned of remarkable magnificence; though probably from the extravagance to which these were arrived, they were not the first. Plutarch speaks of them as incredibly expensive, and equal to the magnificence of kings. They contained artificial elevations of ground to a surprising height, of buildings projected into the sea, and vast pieces of water made upon land. In short, his extravagance and expence were so great, that he acquired thence the appellation of the Roman Xerxes. It is not improbable, from the above account, and from the consideration of Lucullus having spent much time in Asia, in a situation wherein he had an opportunity of observing the most splendid constructions of this kind, that these gardens might be laid out in the Asiatic style. The vast masses of building said to have been erected, might have borne some resemblance, in the arrangement and style, to the Babylonian gardens; and the epithet of the Roman Xerxes might be applicable to the taste, as well as to the size and expence of his works.

The Tusculan villa of Cicero, though often mentioned, is not anywhere described in his works, so as to give an adequate idea of the style in which his gardens or grounds were disposed.

There is but little to be traced in Virgil relative to this subject. Pines †, it seems probable, were a favourite ornament in gardens; and flowers §, roses especially, were much esteemed, perfumes indeed having been always highly valued in warm climates. Virgil places Anchises in Elysium, in a grove of bays: and is careful to remark, that they were of the sweet-scented kind. The Pæstan roses were chiefly valued for their excellent odour; and the same quality appears to be the cause why they were placed by Tibullus as ornaments to the Elysian fields. There appears also to have prevailed among the Romans a piece of luxury relative to gardens, which is equally prevalent at present among us, namely the forcing of flowers at seasons of the year not suited to their natural blowing: and roses were then, as at present, the principal flowers upon which these experiments were tried, as appears from Martial ‡ and others.

† *Ecl*[og.] ii. 65. & § *Geo*[rg.] i[v.] 118.

When Roman authors (Mr Walpole remarks), whose climate instilled a wish for cool retreats, speak of their enjoyments in that kind, they sigh for grottoes, caves, and the refreshing hollows of mountains, near irriguous and shady founts; or boast of their porticoes, walks of planes, canals, baths, and breezes from the sea. Their gardens are never mentioned as affording shade and shelter from the rage of the dog star. Pliny has left us descriptions of two of his villas. As he used his Laurentine villa for his winter retreat, it is not surprising

‡ *Vi*[de] *Epi*[g.] vi. e[t] lib. 127. *Lam*[pri]*dius* *Eleg*[ab.]

surprising that the garden makes no considerable part of the account. All he says of it is, that the gestatio or place of exercise, which surrounded the garden (the latter consequently not being very large), was bounded by a hedge of box, and, where that was perished, with rosemary; that there was a walk of vines; and that most of the trees were fig and mulberry, the soil not being proper for any other sorts. On his Tuscan villa he is more diffuse; the garden makes a considerable part of the description:—and what was the principal beauty of that pleasure ground? Exactly what was the admiration of this country about threescore years ago; box trees cut into monsters, animals, letters, and the names of the master and the artifice. In an age when architecture displayed all its grandeur, all its purity, and all its taste; when arose Vespasian's amphitheatre, the temple of Peace, Trajan's forum, Domitian's baths, and Adrian's villa, the ruins and vestiges of which still excite our astonishment and curiosity; a Roman consul, a polished emperor's friend, and a man of elegant literature and taste, delighted in what the mob now scarce admire in a college garden. All the ingredients of Pliny's corresponded exactly with those laid out by London and Wise on Dutch principles. He talks of slopes, terraces, a wilderness, shrubs methodically trimmed, a marble bason, pipes spouting water, a cascade falling into the bason, bay trees alternately planted with planes, and a straight walk from whence issued others parted off by hedges of box and apple trees, with obelisks placed between every two. There wants nothing but the embroidery of a parterre, to make a garden in the time of Trajan serve for a description of one in that of King William. In one passage above, Pliny seems to have conceived that natural irregularity might be a beauty; *in opere urbanissimo*, says he, *subita velut illati ruris imitatio*. Something like a rural view was contrived amidst so much polished composition. But the idea soon vanished, lineal walks immediately enveloped the slight scene, and names and inscriptions in box again succeeded to compensate for the daring introduction of nature.

In the paintings found at Herculaneum are a few traces of gardens, as may be seen in the second volume of the prints. They are small square enclosures, formed by trellis-work and espaliers, and regularly ornamented with vases, fountains, and careatides, elegantly symmetrical, and proper for the narrow spaces allotted to the garden of a house in a capital city.

From what has been said, it appears how naturally and insensibly the idea of a kitchen garden slid into that which has for so many ages been peculiarly termed a *garden*, and by our ancestors in this country distinguished by the name of a *pleasure garden*. A square piece of ground was originally parted off in early ages for the use of the family:—to exclude cattle, and ascertain the property, it was separated from the fields by a hedge. As pride and desire of privacy increased, the enclosure was dignified by walls; and in climes where fruits were not lavished by the ripening glow of nature and soil, fruit trees were assisted and sheltered from surrounding winds by the like expedient: for the inundation of luxuries, which have swelled into general necessities, have almost all taken their source from the simple fountain of reason.

When the custom of making square gardens enclosed with walls was thus established to the exclusion of nature and prospect, pomp and solitude combined to call for something that might enrich and enliven the insipid and unanimated partition. Fountains, first invented for use, which grandeur loves to disguise and throw out of the question, received embellishments from costly marbles, and at last, to contradict utility, tossed their waste of waters into the air in spouting columns. Art, in the hands of rude man, had at first been made a succedaneum to nature; in the hands of ostentatious wealth, it became the means of opposing nature; and the more it traversed the march of the latter, the more nobility thought its power was demonstrated. Canals measured by the line were introduced in lieu of meandering streams, and terraces were hoisted aloft in opposition to the facile slopes that imperceptibly unite the valley to the hill. Balustrades defended these precipitate and dangerous elevations, and flights of steps rejoined them to the subjacent flat from which the terrace had been dug. Vases and sculpture were added to these unnecessary balconies, and statues furnished the lifeless spot with mimic representations of the excluded sons of men. Thus difficulty and expence were the constituent parts of those sumptuous and selfish solitudes; and every improvement that was made, was but a step farther from nature. The tricks of waterworks to wet the unwary, not to refresh the panting spectator; and parterres embroidered in patterns like a petticoat, were but the childish endeavours of fashion and novelty to reconcile greatness to what it had surfeited on. To crown these impotent displays of false taste, the sheers were applied to the lovely wildness of form with which nature has distinguished each various species of tree and shrub. The venerable oak, the romantic beech, the useful elm, even the aspiring circuit of the lime, the regular round of the chesnut, and the almost moulded orange tree, were corrected by such fantastic admirers of symmetry. The compass and square were of more use in plantations than the nurseryman. The measured walk, the quincunx, and the etoile, imposed their unsatisfying sameness on every royal and noble garden. Trees were headed, and their sides pared away; many French groves seem green chests set upon poles. Seats of marble, arbours, and summer houses, terminate every vista; and symmetry, even where the space was too large to permit its being remarked at one view, was so essential that, as Pope observed,

> ——— each alley has a brother,
> And half the garden just reflects the other.

Knots of flowers were more defensibly subjected to the same regularity. Leisure, as Milton expressed it,

> —— in trim gardens took his pleasure.

In the garden of Marshal de Biron at Paris, consisting of 14 acres, every walk is buttoned on each side by lines of flower pots, which succeed in their seasons.

It does not precisely appear what our ancestors meant by a bower: it was probably an arbour; sometimes it meant the whole frittered enclosure, and in one instance it certainly included a labyrinth. Rosamond's bower was indisputably of that kind; though whether composed of walls or hedges, we cannot determine. A square and a round labyrinth were so capital ingredients of of a garden formerly, that in Du Cercean's architecture, who lived in the time of Charles IX. and Henry III. there is scarce a ground plot without one of each.

In Kip's Views of the Seats of our Nobility and Gentry, we see the same tiresome and returning uniformity. Every house is approached by two or three gardens, consisting perhaps of a gravel walk and two grass plats or borders of flowers. Each rises above the other by two or three steps, and as many walls and terraces, and so many iron gates, that we recollect those ancient romances in which every entrance was guarded by nymphs or dragons. Yet though these and such preposterous inconveniences prevailed from age to age, good sense in this country had perceived the want of something at once more grand and more natural. These reflections, and the bounds set to the waste made by royal spoilers, gave origin to Parks. They were contracted forests, and extended gardens. Hentzner says, that, according to Rous of Warwick, the first park was that at Woodstock. If so, it might be the foundation of a legend that Henry II. secured his mistress in a labyrinth: it was no doubt more difficult to find her in a park than in a palace, where the intricacy of the woods and various lodges buried in covert might conceal her actual habitation.

It is more extraordinary that, having so long ago stumbled on the principle of modern gardening, we should have persisted in retaining its reverse, symmetrical and unnatural gardens. That parks were rare in other countries, Hentzner, who travelled over great part of Europe, leads us to suppose, by observing that they were common in England. In France they retain the name, but nothing is more different both in compass and disposition. Their parks are usually square or oblong enclosures, regularly planted with walks of chesnuts or limes, and generally every large town has one for its public recreation.

"One man, one great man, we had (continues Mr Walpole), on whom nor education nor custom could impose their prejudices; who, 'on evil days though fallen, and with darkness and solitude compassed round,' judged that the mistaken and fantastic ornaments he had seen in gardens, were unworthy of the Almighty hand that planted the delights of Paradise. He seems with the prophetic eye of taste to have conceived, to have foreseen modern gardening; as Lord Bacon announced the discoveries since made by experimental philosophy. The description of Eden is a warmer and more just picture of the present style than Claud Lorraine could have painted from Hagley or Stourhead. The first lines we shall quote exhibit Stourhead on a more magnificent scale:

> Thro' Eden went a river large,
> Nor chang'd his course, but thro' the shaggy hill,
> Pass'd underneath ingulphed: for God had thrown
> That mountain as his garden mound, high rais'd
> Upon the rapid current——

Hagley seems pictured in what follows:

> Which thro' veins
> Of porous earth with kindly thirst updrawn,
> Rose a fresh fountain, and with many a rill
> Watered the garden——

What colouring, what freedom of pencil, what landscape in these lines!

> ——from that sapphire fount the crisped brooks,
> Rolling on orient pearl and sands of gold,
> With mazy error under pendant shades,
> Ran nectar, visiting each plant, and fed
> Flow'rs worthy of Paradise, which not *nice art*
> In beds and curious knots, but *nature boon*,
> Pour'd forth profuse on hill, and dale, and plain,
> Both where the morning sun first warmly smote
> The *open field*, and where the unpierc'd shade
> Imbrown'd the noontide bow'rs—*Thus was this place*
> *A happy rural seat of various view.*

Read this transporting description, paint to your mind the scenes that follow, contrast them with the savage but respectable terror with which the poet guards the bounds of his paradise, fenced

> ——with the champaign head
> Of a steep wilderness, whose hairy sides
> With thicket overgrown, grotesque and wild,
> Access denied; and over head up grew
> Insuperable height of loftiest shade,
> Cedar and pine, and fir, and branching palm,
> A sylvan scene, and, as the ranks ascend,
> Shade above shade, a woody theatre,
> Of stateliest view——

and then recollect, that the author of this sublime vision had never seen a glimpse of any thing like what he has imagined; that his favourite ancients had dropped not a hint of such divine scenery; and that the conceits in Italian gardens, and Theobalds and Nonsuch, were the brightest originals that his memory could furnish. His intellectual eye saw a nobler plan, so little did he suffer by the loss of sight. It sufficed him to have seen the materials with which he could work. The vigour of a boundless imagination told him how a plan might be disposed, that would embellish nature, and restore art to its proper office, the just improvement or imitation of it.

"Now let us return to an admired writer, posterior to Milton, and see how cold, how insipid, how tasteless, is his account of what he pronounced a perfect garden. We speak not of his style, which it was not necessary for him to animate with the colouring and glow of poetry. It is his want of ideas, of imagination, of taste, that deserve censure, when he dictated on a subject which is capable of all the graces that a knowledge of beautiful nature can bestow. Sir William Temple was an excellent man; Milton, a genius of the first order.

"We cannot wonder that Sir William declares in favour of parterres, fountains, and statues, as necessary to break the sameness of large grass plots, which he thinks have an ill effect upon the eye, when he acknowledges that he discovers fancy in the gardens of Alcinous. Milton studied the ancients with equal enthusiasm, but no bigotry; and had judgment to distinguish between the want of invention and the beauties of poetry. Compare his paradise with Homer's garden, both ascribed to a celestial design. For Sir William, it is just to observe, that his ideas centered in a fruit garden. He had the honour of giving to his country many delicate fruits,

fruits, and he thought of little else than disposing them to the best advantage.

"The best figure of a garden (says he) is either a square or an oblong, and either upon a flat or a descent: they have all their beauties, but the best I esteem an oblong upon a descent. The beauty, the air, the view, make amends for the expence, which is very great in finishing and supporting the terrace walks, in levelling the parterres, and in the stone stairs that are necessary from one to the other. The perfectest figure of a garden I ever saw, either at home or abroad, was that of Moor Park in Hertfordshire, when I knew it about 30 years ago. It was made by the countess of Bedford, esteemed among the greatest wits of her time, and celebrated by Dr Donne; and with very great care, excellent contrivance, and much cost; but greater sums may be thrown away without effect or honour, if there want sense in proportion to money, or 'if nature be not followed;' which I take to be the great rule in this, and perhaps in every thing else, as far as the conduct not only of our lives but our governments.' [We shall see how natural that admired garden was]. 'Because I take the garden I have named to have been in all kinds the most beautiful and perfect, at least in the figure and disposition, that I ever have seen, I will describe it for a model to those that meet with such a situation, and are above the regards of common expence. It lies on the side of a hill, upon which the house stands, but not very steep. The length of the house, where the best rooms and of most use or pleasure are, lies upon the breadth of the garden; the great parlour opens into the middle of a terrace gravel walk that lies even with it, and which may be, as I remember, about 300 paces long, and broad in proportion; the border set with standard laurels and at large distances, which have the beauty of orange trees out of flower and fruit. From this walk are three descents by many stone steps, in the middle and at each end, into a very large parterre. This is divided into quarters by gravel walks, and adorned with two fountains and eight statues in the several quarters. At the end of the terrace walk are two summer houses, and the sides of the parterre are ranged with two large cloisters open to the garden, upon arches of stone, and ending with two other summer houses even with the cloisters, which are paved with stone, and designed for walks of shade, there being none other in the whole parterre. Over these two cloisters are two terraces covered with lead and fenced with balusters; and the passage into these airy walks is out of the two summer houses at the end of the first terrace walk. The cloister facing the south is covered with vines, and would have been proper for an orange house, and the other for myrtles or other more common greens, and had, I doubt not, been cast for that purpose, if this piece of gardening had been then in as much vogue as it is now. From the middle of this parterre is a descent by many steps flying on each side of a grotto, that lies between them, covered with lead and flat, into the lower garden, which is all fruit trees ranged about the several quarters of a wilderness, which is very shady; the walks here are all green, the grotto embellished with figures of shell rock-work, fountains, and water works. If the hill had not ended with the lower garden, and the wall were not bounded by a common way that goes through the park, they might have added a third quarter of all greens; but this want is supplied by a garden on the other side the house, which is all of that sort, very wild, shady, and adorned with rough rock-work and fountains. This was Moor Park when I was acquainted with it, and the sweetest place, I think, that I have seen in my life, either before or since, at home or abroad.'

"It is unnecessary to add any remarks on this description. Any man might design and build as sweet a garden, who had been born in and never stirred out of Holborn. It was not, however, peculiar to Sir William Temple to think in that manner. How many Frenchmen are there who have seen our gardens, and still prefer natural flights of steps and shady cloisters covered with lead! Le Nautre, the architect of the groves and grottoes at Versailles, came hither on a mission to improve our taste. He planted St James's and Greenwich Parks—no great monuments of his invention.

"To do farther justice to Sir William Temple, we must not omit what he adds. 'What I have said of the best forms of gardens is meant only of such as are in some sort regular; for there may be other forms wholly irregular, that may, for ought I know, have more beauty than any of the others: but they must owe it to some extraordinary dispositions of nature in the seat, or some great race of fancy or judgment in the contrivance, which may reduce many disagreeing parts into some figure, which shall yet, upon the whole, be very agreeable. Something of this I have seen in some places, but heard more of it from others who have lived much among the Chineses, a people whose way of thinking seems to lie as wide of ours in Europe as their country does. Their greatest reach of imagination is employed in contriving figures, where the beauty shall be great and strike the eye, but without any order or disposition of parts, that shall be commonly or easily observed. And though we have hardly any notion of this sort of beauty, yet they have a particular word to express it: and when they find it hit their eye at first sight, they say the Sharawadgi is fine or is admirable, or any such expression of esteem: but I should hardly advise any of these attempts in the figure of gardens among us; they are adventures of too hard achievement for any common hands; and though there may be more honour if they succeed well, yet there is more dishonour if they fail, and it is twenty to one they will; whereas in regular figures it is hard to make any great and remarkable faults.'

"Fortunately Kent and a few others were not quite so timid, or we might still be going up and down stairs in the open air. It is true, we have heard much lately, as Sir William Temple did, of irregularity and imitations of nature in the gardens or grounds of the Chinese. The former is certainly true: they are as whimsically irregular, as European gardens are formally uniform and unvaried:—but with regard to nature, it seems as much avoided, as in the squares and oblongs and straight lines of our ancestors. An artificial perpendicular rock starting out of a flat plain, and connected with nothing, often pierced through in various places with oval hollows, has no more pretension to be deemed natural than a lineal terrace or a parterre. The late Mr Joseph Spence, who had both taste and zeal for

for the present style, was so persuaded of the Chinese emperor's pleasure ground being laid out on principles resembling ours, that he translated and published, under the name of Sir Harry Beaumont, a particular account of that enclosure, from the collection of the letters of the Jesuits. But except a determined irregularity, one can find nothing in it that gives any idea of attention being paid to nature. It is of vast circumference, and contains 200 palaces, besides as many contiguous for the eunuchs, all gilt, painted, and varnished. There are raised hills from 20 to 60 feet high, streams and lakes, and one of the latter five miles round. These waters are passed by bridges:—but even their bridges must not be straight—they serpentize as much as the rivulets, and are sometimes so long as to be furnished with resting places, and begin and end with triumphal arches. The colonnades undulate in the same manner. In short, this pretty gaudy scene is the work of caprice and whim, and, when we reflect on their buildings, presents no image but that of unsubstantial tawdriness. Nor is this all. Within this fantastic paradise is a square town, each side a mile long. Here the eunuchs of the court, to entertain his imperial majesty with the bustle and business of the capital in which he resides, but which it is not of his dignity ever to see, act merchants and all sorts of trades, and even designedly exercise for his royal amusement every art of knavery that is practised under his auspicious government. Methinks this is the childish solace and repose of grandeur, not a retirement from affairs to the delights of rural life. Here too his majesty plays at agriculture: there is a quarter set apart for that purpose; the eunuchs sow, reap and carry in their harvest, in the imperial presence; and his majesty returns to Pekin, persuaded that he has been in the country.

"Having thus cleared our way by ascertaining what have been the ideas on gardening in all ages as far as we have materials to judge by, it remains to show to what degree Mr Kent invented the new style, and what hints he had received to suggest and conduct his undertaking.

"We have seen what Moor Park was, when pronounced a standard. But as no succeeding generation in an opulent and luxurious country contents itself with the perfection established by its ancestors, more perfect perfection was still sought; and improvements had gone on, till London and Wise had stocked all our gardens with giants, animals, monsters, coats of arms, and mottoes, in yew, box, and holly. Absurdity could go no farther, and the tide turned. Bridgman, the next fashionable designer of gardens, was far more chaste; and whether from good sense, or that the nation had been struck and reformed by the admirable paper in the Guardian, N° 173. he banished verdant sculpture, and did not even revert to the square precision of the foregoing age. He enlarged his plans, disdained to make every division tally to its opposite; and though he still adhered much to straight walks with high clipped hedges, they were only his great lines; the rest he diversified by wilderness, and with loose groves of oak, though still within surrounding hedges. As his reformation gained footing, he ventured, in the royal garden at Richmond, to introduce cultivated fields, and even morsels of a forest appearance, by the sides of those endless and tiresome walks that stretched out of one into another without intermission. But this was not till other innovators had broke loose too from rigid symmetry.

"But the capital stroke, the leading step to all that has followed, was the destruction of walls for boundaries, and the invention of fosses—an attempt then deemed so astonishing, that the common people called them Ha! Ha's! to express their surprise at finding a sudden and unperceived check to their walk.

"A sunk fence may be called the *leading step*, for these reasons. No sooner was this simple enchantment made, than levelling, mowing, and rolling, followed. The contiguous ground of the park without the sunk fence was to be harmonized with the lawn within; and the garden in its turn was to be set free from its prime regularity, that it might assort with the wilder country without. The sunk fence ascertained the specific garden; but that it might not draw too obvious a line of distinction between the neat and the rude, the contiguous out-lying parts came to be included in a kind of general design; and when nature was taken into the plan, under improvements, every step that was made pointed out new beauties, and inspired new ideas. At that moment appeared Kent, painter enough to taste the charms of landscape, bold, and opinionative enough to dare and to dictate, and born with a genius to strike out a great system from the twilight of imperfect essays. He leaped the fence, and saw that all nature was a garden. He felt the delicious contrast of hill and valley changing imperceptibly into each other, tasted the beauty of the gentle swell or concave scoop, and remarked how loose grooves crowned an easy eminence with happy ornament; and while they called in the distant view between their graceful stems, removed and extended the perspective by delusive comparison.

"Thus the pencil of his imagination bestowed all the arts of landscape on the scenes he handled. The great principles on which he worked were perspective, and light and shade. Groups of trees broke too uniform or too extensive a lawn; evergreens and woods were opposed to the glare of the champaign; and where the view was less fortunate, or so much exposed as to be beheld at once, he blotted out some parts by thick shades, to divide it into variety, or to make the richest scene more enchanting by reserving it to a farther advance of the spectator's step. Thus, selecting favourite objects, and veiling deformities by screens of plantation; sometimes allowing the rudest waste to add its foil to the richest theatre; he realized the compositions of the greatest masters in painting. Where objects were wanting to animate his horizon, his taste as an architect could bestow immediate termination. His buildings, his seats, his temples, were more the works of his pencil than of his compasses. We owe the restoration of Greece and the diffusion of architecture to his skill in landscape.

"But of all the beauties he added to the face of this beautiful country, none surpassed his management of water. Adieu to canals, circular basons and cascades tumbling down marble steps, that last absurd magnificence of Italian and French villas. The forced elevation of cataracts was no more. The gentle stream was taught to serpentize seemingly at its pleasure; and where

where discontinued by different levels, its course appeared to be concealed by thickets properly interspersed, and glittered again at a distance, where it might be supposed naturally to arrive. Its borders were smoothed, but preserved their waving irregularity. A few trees scattered here and there on its edges sprinkled the tame bank that accompanied its meanders; and when it disappeared among the hills, shades descending from the heights leaned towards its progress, and framed the distant point of light under which it was lost, as it turned aside to either hand of the blue horizon.

"Thus, dealing in none but the colours of nature, and catching its most favourable features, men saw a new creation opening before their eyes. The living landscape was chastened or polished, not transformed. Freedom was given to the forms of trees: they extended their branches unrestricted; and where any eminent oak, or master beech, had escaped maiming and survived the forest, bush and bramble was removed, and all its honours were restored to distinguish and shade the plain. Where the united plumage of an ancient wood extended wide its undulating canopy, and stood venerable in its darkness, Kent thinned the foremost ranks, and left but so many detached and scattered trees, as softened the approach of gloom, and blended a chequered light with the thus lengthened shadows of the remaining columns.

"Succeeding artists have added new master strokes to these touches; perhaps improved or brought to perfection some that have been named. The introduction of foreign trees and plants, which we owe principally to Archibald duke of Argyle, contributed essentially to the richness of colouring so peculiar to our modern landscape. The mixture of various greens, the contrast of forms between our forest trees and the northern and West Indian firs and pines, are improvements more recent than Kent, or but little known to him. The weeping willow, and every florid shrub, each tree of delicate or bold leaf, are new tints in the composition of our gardens.

"But just as the encomiums are that have been bestowed on Kent's discoveries, he was neither without assistance or faults. Mr Pope undoubtedly contributed to form his taste. The design of the prince of Wales's garden at Carlton house was evidently borrowed from the poet's at Twickenham. There was a little of affected modesty in the latter, when he said, of all his works he was most proud of his garden. And yet it was a singular effort of art and taste to impress so much variety and scenery on a spot of five acres. The passing through the gloom from the grotto to the opening day, the retiring and again assembling shades, the dusky groves, the larger lawn, and the solemnity of the termination at the cypresses that lead up to his mother's tomb, are managed with exquisite judgment; and though Lord Peterborough assisted him

> To form his quincunx and to rank his vines,

those were not the most pleasing ingredients of his little perspective.

"Having routed professed art (for the modern gardener exerts his talents to conceal his art), Kent, like other reformers, knew not how to stop at the just limits. He had followed Nature, and imitated her so happily, that he began to think all her works were equally proper for imitation. In Kensington garden he planted dead trees to give a greater air of truth to the scene—but he was soon laughed out of this excess. His ruling principle was, that nature abhors a straight line. His mimics (for every genius has his apes), seemed to think that she could love nothing but what was crooked. Yet so many men of taste of all ranks devoted themselves to the new improvements, that it is surprising how much beauty has been struck out, with how few absurdities. Still in some lights the reformation seems to have been pushed too far. Though an avenue crossing a park or separating a lawn, and intercepting views from the seat to which it leads, are capital faults; yet a great avenue cut through woods, perhaps before entering a park, has a noble air, and,

> Like footmen running before coaches
> To tell the inn what lord approaches,

announces the habitation of some man of distinction. In other places the total banishment of all particular neatness immediately about a house, which is frequently left gazing by itself in the middle of a park, is a defect. Sheltered and even close walks, in so very uncertain a climate as ours, are comforts ill exchanged for the few picturesque days that we enjoy; and whenever a family can purloin a warm and even something of an old-fashioned garden from the landscape designed for them by the undertaker in fashion, without interfering with the picture, they will find satisfactions in those days that do not invite strangers to come and see their improvements."

PART I. PRINCIPLES OF GARDENING.

GARDENING, in the perfection to which it has been lately brought in Britain, is entitled to a place of considerable rank among the liberal arts. It is (says Ms Wheatley) as superior to landscape painting as a reality to a representation: it is an exertion of fancy; a subject for taste; and being released now from the restraints of regularity, and enlarged beyond the purposes of domestic convenience, the most beautiful, the most simple, the most noble scenes of nature, are all within its province. For it is no longer confined to the spots from which it takes its name; but as already observed, regulates also the disposition and embellishment of a park, a farm, a forest, &c.: and the business of a gardener is to select and apply whatever is great, elegant, or characteristic in any of them; to discover, and to show all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and to improve its beauties.

Ground, Wood.

Sect. I. *Materials of Gardening.*

These may be divided into two general classes; *Natural* and *Factitious.*

§ 1. *Of the* Natural Materials.

These, according to Mr Wheatley's enumeration, are—Ground, Wood, Water, and Rocks.

I. GROUND. By this is meant that portion of naked surface which is included within the place to be improved; whether that surface be swamp, lawn, roughet, or broken ground; and whether it be a height, a valley, a plain, or a composition of swells, dips, and levels.

The following passage has been quoted from Mr Gilpin's observations on the Wye*, as affording a sublime idea of what ground ought to be.—"Nothing (says he) gives so just an idea of the beautiful swellings of ground as those of water, where it has sufficient room to undulate and expand. In ground which is composed of very refractory materials, you are presented often with harsh lines, angular insertions, and disagreeable abruptnesses. In water, whether in gentle or in agitated motion, all is easy, all is softened into itself; and the hills and valleys play into each other in a variety of the most beautiful forms. In agitated water, abruptnesses indeed there are, but yet they are such abruptnesses as in some part or other unite properly with the surface around them; and are on the whole peculiarly harmonious. Now, if the ocean in any of these swellings and agitations could be arrested and fixed, it would produce that pleasing variety which we admire in ground. Hence it is common to fetch our images from water, and apply them to land: we talk of an undulating line, a playing lawn, and a billowy surface; and give a much stronger and more adequate idea by such imagery, than plain language could possibly present."

* Page 62.

The exertions of art, however, are here inadequate; and the artist ought not to attempt to create a mountain, a valley, or a plain: he should but rarely meddle even with the smaller inequalities of grounds. Roughets and broken ground may generally be reduced to lawn, or hid with wood; and a swamp may be drained or covered with water; whilst lawn may be variegated at pleasure by wood, and sometimes by water.

II. WOOD, as a general term, comprehends all trees and shrubs in whatever disposition; but it is specifically applied in a more limited sense, and in that sense we shall now use it.

Every plantation must be either a *wood*, a *grove*, or *clump*. A wood is composed both of trees and underwood, covering a considerable space. A grove consists of trees without underwood. A clump differs from either only in extent: it may be either close or open; when close, it is sometimes called a *thicket*; when open, a *group of trees*; but both are equally clumps, whatever may be the shape or situation.

1 Of the surface of a wood.

1. One of the noblest objects in nature (Mr Wheatley observes) is the *surface of a large thick wood*, commanded from an eminence, or seen from below hanging on the side of a hill. The latter is generally the more interesting object. Its aspiring situation gives it an air of greatness; its termination is commonly the horizon; and, indeed, if it is deprived of that splendid boundary, if the brow appears above it (unless some very peculiar effect characterises that brow), it loses much of its magnificence: it is inferior to a wood which covers a less hill from the top to the bottom; for a whole space filled is seldom little. But a wood commanded from an eminence is generally no more than a part of the scene below; and its boundary is often inadequate to its greatness. To continue it, therefore, till it winds out of sight, or loses itself in the horizon, is generally desirable: but then the varieties of its surface grow confused as it retires; while those of a hanging wood are all distinct, the furthest parts are held up to the eye, and none are at a distance though the whole be extensive.

The varieties of a surface are essential to the beauty of it: a continued smooth shaven level of foliage is neither agreeable nor natural; the different growths of trees commonly break it in reality, and their shadows still more in appearance. These shades are so many tints, which, undulating about the surface, are its greatest embellishment; and such tints may be produced with more effect, and more certainty, by a judicious mixture of greens; at the same time an additional variety may be introduced, by grouping and contrasting trees very different in shape from each other; and whether variety in the greens or in the forms be the design, the execution is often easy, and seldom to a certain degree impossible. In raising a young wood, it may be perfect. In old woods, there are many spots which may be either thinned or thickened: and there the characteristic distinctions should determine what to plant, or which to leave; at the least will often point out those which, as blemishes, ought to be taken away; and the removal of two or three trees will sometimes accomplish the design. The number of beautiful forms and agreeable masses, which may decorate the surface, is so great, that where the place will not admit of one, another is always ready; and as no delicacy of finishing is required, no minute exactness is worth regarding; great effects will not be disconcerted by small obstructions and little disappointments.

The contrasts, however, of masses and of groups must not be too strong, where *greatness* is the character of the wood; for unity is essential to greatness: and if direct opposites be placed close together, the wood is no longer one object; it is only a confused collection of several separate plantations. But if the progress be gradual from the one to the other, shapes and tints widely different may assemble on the same surface; and each should occupy a considerable space: a single tree, or a small cluster of trees, in the midst of an extensive wood, is in size but a speck, and in colour but a spot; the groups and the masses must be large to produce any sensible variety.

When, in a romantic situation, very broken ground is overspread with wood, it may be proper on the surface of the wood to mark the inequalities of the ground. *Rudeness*, not greatness, is the prevailing idea; and a choice directly the reverse of that which is productive of unity will produce it. Strong contrasts, even oppositions,

sitions, may be eligible; the aim is rather to disjoin than to connect: a deep hollow may sink into dark greens; an abrupt bank may be shewn by a rising stage of aspiring trees, a sharp ridge by a narrow line of conical shapes: firs are of great use upon such occasions; their tint, their form, their singularity, recommend them.

A hanging *wood of thin forest trees*, and seen from below is seldom pleasing: these few trees are by the perspective brought nearer together; it loses the beauty of a thin wood, and is defective as a thick one: the most obvious improvement, therefore is to thicken it. But, when seen from an eminence, a thin wood is often a lively and elegant circumstance in a view; it is full of objects; and every separate tree shows its beauty. To increase that vivacity which is the peculiar excellence of a thin wood, the trees should be characteristically distinguished both in their tints and their shapes; and such as for their airiness have been proscribed in a thick wood, are frequently the most eligible here. Differences also in their growths are a farther source of variety; each should be considered as a distinct object, unless where a small number are grouped together; and then all that compose the little cluster must agree: but the groups themselves, for the same reason as the separate trees, should be strongly contrasted; the continued underwood is their only connexion, and that is not affected by their variety.

Of the outline of a wood.

Though the surface of a wood, when commanded, deserves all these attentions, yet the *outline* more frequently calls for our regard: it is also more in our power; it may sometimes be great, and may always be beautiful. The first requisite is irregularity. That a mixture of trees and underwood should form a long straight line, can never be natural; and a succession of easy sweeps and gentle rounds, each a portion of a greater or less circle, composing all together a line literally serpentine, is, if possible, worse. It is but a number of regularities put together in a disorderly manner, and equally distant from the beautiful both of art and of nature. The true beauty of an outline consists more in breaks than in sweeps; rather in angles than in rounds; in variety, not in succession.

Every variety in the outline of a wood must be a *prominence* or a *recess*. Breadth in either is not so important as length to the one and depth to the other. If the former ends in an angle, the latter diminishes to a point; they have more force than a shallow dent, or a dwarf excrescence, how wide so ever. They are greater deviations from the continued line which they are intended to break; and their effect is to enlarge the wood itself, which seems to stretch from the most advanced point, back beyond the most distant to which it retires. The extent of a large wood on a flat, not commanded, can by no circumstance be so manifestly shewn as by a deep recess; especially if that recess wind so as to conceal the extremity, and leave the imagination to pursue it. On the other hand, the poverty of a shallow wood might sometimes be relieved by here and there a prominence, or clumps which by their apparent junction should seem to be prominences from it. A deeper wood with a continued outline, except when commanded, would not appear so considerable.

An inlet into a wood seems to have been cut, if the opposite points of the entrance tally; and that show of art depreciates its merit: but a difference only in the situation of those points, by bringing one more forward than the other, prevents the appearance, though their forms be similar. Other points, which distinguish the great parts, should in general be strongly marked: a short turn has more spirit in it than a tedious circuity; and a line broken by angles has a precision and firmness, which in an undulated line are wanting; the angles should indeed commonly be a little softened; the rotundity of the plant which forms them is sometimes sufficient for the purpose; but if they are mellowed down too much, they lose all meaning. Three or four large parts thus boldly distinguished, will break a very long outline. When two woods are opposed on the sides of a narrow glade, neither has so much occasion for variety in itself as if it were single; if they are very different from each other, the contrast supplies the deficiency to each, and the interval between them is full of variety. The form of that interval is indeed of as much consequence as their own: though the outlines of both the woods be separately beautiful, yet if together they do not cast the open space into an agreeable figure, the whole scene is not pleasing; and a figure is never agreeable, when the sides too closely correspond: whether they are exactly the same, or exactly the reverse of each other, they equally appear artificial.

Wood. Wheatley's Observat. on Modern Gardening.

Every variety of outline hitherto mentioned may be traced by the underwood alone; but frequently the same effects may be produced with more ease, and with much more beauty, by a few trees standing out from the thicket, and belonging, or seeming to belong, to the wood, so as to make a part of its figure. Even where they are not wanted for that purpose, detached trees are such agreeable objects, so distinct, so light, when compared to the covert about them, that skirting along it in some parts, and breaking it in others, they give an unaffected grace, which can no otherwise be given to the outline. They have a still further effect, when they stretch across the whole breadth of an inlet, or before part of a recess into the wood; they are themselves shown to advantage by the space behind them; and that space, seen between their stems, they in return throw into an agreeable perspective.

2. The prevailing character of a wood is generally grandeur: the principal attention therefore which it requires, is to prevent the excesses of that character, to diversify the uniformity of its extent, to lighten the unwieldiness of its bulk, and to blend graces with greatness. The character of a *grove* is beauty. Fine trees are lovely objects: a grove is an assemblage of them; in which every individual retains much of its own peculiar elegance, and whatever it loses is transferred to the superior beauty of the whole. To a grove, therefore, which admits of endless variety in the disposition of the trees, differences in their shapes and their greens are seldom very important, and sometimes they are detrimental. Strong contracts scatter trees which are thinly planted, and which have not the connection of underwood; they no longer form one plantation; they are a number of single trees. A thick grove is not indeed exposed to this mischief, and certain situations may recommend different shapes and different greens for their effects upon the surface; but in the outline they are seldom much regarded. The eye attracted into the depth of

3 Of a grove.

Wood. ibid.

of the grove, passes by little circumstances at the entrance; even varieties in the form of the line do not always engage the attention; they are not so apparent as in a continued thicket, and are scarcely seen if they are not considerable.

But the surface and the outline are not the only circumstances to be attended to. Though a grove be beautiful as an object, it is besides delightful as a spot to walk or to sit in; and the choice and the disposition of the trees for effects within, are therefore a principal consideration. Mere irregularity alone will not please: strict order is there more agreeable than absolute confusion; and some meaning better than none. A regular plantation has a degree of beauty; but it gives no satisfaction, because we know that the same number of trees might be more beautifully arranged. A disposition, however, in which the lines only are broken, without varying the distances, is equally improper. The trees should gather into groups, or stand in various irregular lines, and describe various figures: the intervals between them should be contrasted both in shape and in dimensions: a large space should in some places be quite open; in others the trees should be so close together, as hardly to leave a passage between them; and in others as far apart as the connexion will allow. In the forms and the varieties of these groups, these lines, and these openings, principally consists the interior beauty of a grove.

The force of them is most strongly illustrated at Claremont †, where the walk to the cottage, though destitute of many natural advantages, and eminent for none; though it commands no prospect; though the water below it is a trifling pond; though it has nothing, in short, but inequality of ground to recommend it; is yet the finest part of the garden: for a grove is there planted in a gently curved direction, all along the side of a hill, and on the edge of a wood, which rises above it. Large recesses break it into several clumps, which hang down the declivity: some of them approaching, but none reaching quite to the bottom. These recesses are so deep as to form great openings in the midst of the grove; they penetrate almost to the covert: but the clumps being all equally suspended from the wood; and a line of open plantation, though sometimes narrow, running constantly along the top; a continuation of grove is preserved, and the connexion between the parts is never broken. Even a group, which near one of the extremities stands out quite detached, is still in style so similar to the rest as not to lose all relation. Each of these clumps is composed of several others still more intimately united; each is full of groups, sometimes of no more than two trees, sometimes of four or five, and now and then in larger clusters; an irregular waving line, issuing from some little crowd, loses itself in the next; or a few scattered trees drop in a more distant succession from the one to the other. The intervals, winding here like a glade, and widening there into broader openings, differ in extent, in figure, and direction; but all the groups, the lines, and the intervals, are collected together into large general clumps, each of which is at the same time both compact and free, identical and various. The whole is a place wherein to tarry with secure delight, or saunter with perpetual amusement.

† New Esher in Surry.

The grove at Esher place was planted by the same masterly hand; but the necessity of accommodating the young plantation to some large trees which grew there before, has confined its variety. The groups are few and small: there was not room for larger or for more; there were no opportunities to form continued narrow glades between opposite lines; the vacant spaces are therefore chiefly irregular openings, spreading every way, and great differences of distance between the trees are the principal variety; but the grove winds along the bank of a large river, on the side and at the foot of a very sudden ascent, the upper part of which is covered with wood. In one place, it presses close to the covert; retires from it in another; and stretches in a third across a bold recess, which runs up high into the thicket. The trees sometimes overspread the flat below; sometimes leave an open space to the river; at other times crown the brow of a large knoll, climb up a steep, or hang on a gentle declivity. These varieties in the situation more than compensate for the want of variety in the disposition of the trees; and the many happy circumstances which concur,

——————In Esher's peaceful grove,
Where Kent and nature vie for Pelham's love,

render this little spot more agreeable than any at Claremont. But though it was right to preserve the trees already standing, and not to sacrifice great present beauties to still greater in futurity; yet this attention has been a restraint; and the grove at Claremont, considered merely as a plantation, is in delicacy of taste, and fertility of invention, superior to that at Esher.

It is, however, possible to secure both a present and a future effect, by fixing first on a disposition which will be beautiful when the trees are large, and then intermingling another which is agreeable while they are small. These occasional trees are hereafter to be taken away; and must be removed in time, before they become prejudicial to the others.

The consequence of variety in the disposition, is variety in the light and shade of the grove; which may be improved by the choice of the trees. Some are impenetrable to the fiercest sunbeam; others let in here and there a ray between the large masses of their foliage; and others, thin both of boughs and of leaves, only chequer the around. Every degree of light and shade, from a glare to obscurity, may be managed, partly by the number, and partly by the texture, of the trees. Differences only in the manner of their growths have also corresponding effects: there is a closeness under those whose branches descend low, and spread wide; a space and liberty where the arch above is high; and frequent transitions from the one to the other are very pleasing. These still are not all the varieties of which the interior of a grove is capable; trees, indeed, whose branches nearly reach the ground, being each a sort of thicket, are inconsistent with an open plantation: but though some of the characteristic distinctions are thereby excluded, other varieties more minute succeed in their place; for the freedom of passage throughout brings every tree in its turn near to the eye, and subjects even differences in foliage to observation. These, slight as they may seem, are agreeable when they occur; it is true, they are not regretted when wanting; but a defect of ornament is not necessarily a blemish.

3. It has been already observed, that *clumps* differ only

only in extent from woods, if they are close; or from groves, if they are open: they are small woods, and small groves, governed by the same principles as the larger, after allowances made for their dimensions. But besides the properties they may have in common with woods or with groves, they have others peculiar to themselves which require examination.

They are either *independent* or *relative*: when independent, their beauty, as single objects, is solely to be attended to; when relative, the beauty of the individuals must be sacrificed to the effect of the whole, which is the greater consideration.

The *occasions* on which independent clumps may be applied, are many. They are often desirable as beautiful objects in themselves; they are sometimes necessary to break an extent of lawn, or a continued line whether of ground or of plantation; but on all occasions a jealousy of art constantly attends them, which irregularity in their figure will not always alone remove. Though elevations show them to advantage, yet a hillock evidently thrown up on purpose to be crowned with a clump, is artificial to a degree of disgust: some of the trees should therefore be planted on the sides, to take off that appearance. The same expedient may be applied to clumps placed on the brow of a hill, to interrupt its sameness: they will have less ostentation of design, if they are in part carried down either declivity. The objection already made to planting many along such a brow, is on the same principle: a single clump is less suspected of art; if it be an open one, there can be no finer situation for it, than just at the point of an abrupt hill, or on a promontory into a lake or a river. It is in either a beautiful termination, distinct by its position, and enlivened by an expanse of sky or of water about and beyond it. Such advantages may balance little defects in its form: but they are lost if other clumps are planted near it; art then intrudes, and the whole is displeasing.

But though a multiplicity of clumps, when each is an independent object, seldom seems natural; yet a number of them may, without any appearance of art, be admitted into the same scene, if they bear a *relation* to each other: if by their succession they diversify a continued outline of wood, if between them they form beautiful glades, if altogether, they cast an extensive lawn into an agreeable shape, the *effect* prevents any scrutiny into the means of producing it. But when the reliance on that effect is so great, every other consideration must give way to the beauty of the whole. The figure of the glade, of the lawn, or of the wood, are principally to be attended to: the finest clumps, if they do not fall easily into the great lines, are blemishes; their connexions, their contrasts, are more important than their forms.

5

III. WATER. All inland water is either *running* or *stagnated*. When stagnated, it forms a *lake* or a *pool*, which differ only in extent; and a *pool* and a *pond* are the same. Running waters are either a *rivulet*, a *river*, or a *rill;* and these differ only in breadth: a *rivulet* and a *brook* are synonymous terms; a *stream* and a *current* are general names for all.

1. Space or expansion is essential to a *lake*. It cannot be too large as a subject of description or of contemplation; but the eye receives little satisfaction when it has not a form on which to rest: the ocean itself hardly atones by all its grandeur for its infinity; and a prospect of it is, therefore, always most agreeable, when in some part, at no great distance, a reach of shore, a promontory, or an island, reduces the immensity into shape. An artificial lake, again, may be comparatively extravagant in its dimensions. It may be so out of proportion to its appendages, as to seem a waste of water; for all size is in some respects relative: if this exceeds its due dimensions, and if a flatness of shore beyond it adds still to the dreariness of the scene; wood to raise the banks, and objects to distinguish them, are the remedies to be employed. If the length of a piece of water be too great for its breadth, so as to destroy all idea of circuity, the extremities should be considered as too far off, and made important to give them proximity; while at the same time the breadth may be favoured, by keeping down the banks on the sides. On the same principle, if the lake be too small, a low shore will, in appearance, increase the extent.

Water.

But it is not necessary that the whole scene be bounded: if form be impressed on a considerable part, the eye can, without disgust, permit a large reach to stretch beyond its ken; it can even be pleased to observe a tremulous motion in the horizon, which shows that the water has not there yet attained its termination. Still short of this, the extent may be kept in uncertainty; a hill or a wood may conceal one of the extremities, and the country beyond it, in such a manner as to leave room for the supposed continuation of so large a body of water. Opportunities to choose this shape are frequent, and it is the most perfect of any: the scene is closed, but the extent of the lake is undetermined; a complete form is exhibited to the eye, while a boundless range is left open to the imagination.

But mere form will only give content, not delight: that depends upon the outline, which is capable of exquisite beauty; and the *bays*, the *creeks*, and the *promontories*, which are ordinary parts of that outline, together with the accidents of *islands*, of *inlets*, and of *outlets* to rivers, are in their shapes and their combinations an inexhaustible fund of variety.

Bays, creeks, and promontories, however, though extremely beautiful, should not be very numerous: for a shore broken into little points and hollows has no certainty of outline; it is only ragged, not diversified; and the distinctness and simplicity of the great parts are hurt by the multiplicity of subdivisions. But islands, though the channels between them be narrow, do not so often derogate from greatness: they intimate a space beyond them whose boundaries do not appear; and remove to a distance the shore which is seen in perspective between them. Such partial interruptions of the sight suggest ideas of extent to the imagination.

2. Though the windings of a *river* are proverbially descriptive of its course; yet without being perpetually wreathed, it may be natural. Nor is the character expressed only by the turnings. On the contrary, if they are too frequent and sudden, the current is reduced into a number of separate pools, and the idea of progress is obscured by the difficulty of tracing it. Length is the strongest symptom of continuation: 6 Of a River.

long

Water. Ibid.

long reaches are therefore characteristic of a river, and they conduce much to its beauty; each is a considerable piece of water, and variety of beautiful forms may be given to their outlines.

A river requires a number of *accompaniments*. The changes in its course furnish a variety of situations; while the fertility, convenience, and amenity, which attend it, account for all appearances of inhabitants and improvement. Profusion of ornament on a fictitious river, is a just imitation of cultivated nature. Every species of building, every style of plantation, may abound on the banks; and whatever be their characters, their proximity to the water is commonly the happiest circumstance in their situation. A lustre is from thence diffused on all around; each derives an importance from its relation to this capital feature; those which are near enough to be reflected, immediately belong to it; those at a greater distance still share in the animation of the scene; and objects totally detached from each other, being all attracted towards the same interesting connexion, are united into one composition.

In the front of Blenheim was a deep broad valley, which abruptly separated the castle from the lawn and the plantations before it; even a direct approach could not be made without building a monstrous bridge over the vast hollow; but this forced communication was only a subject of raillery; and the scene continued broken into two parts, absolutely distinct from each other. This valley has been lately flooded: it is not filled; the bottom only is covered with water; the sides are still very high; but they are no longer the steeps of a chasm, they are the bold shores of a noble river. The same bridge is standing without alteration: but no extravagance remains; the water gives it propriety. Above it the river first appears, winding from behind a small thick wood in the valley; and soon taking a determined course, it is then broad enough to admit an island filled with the finest trees; others corresponding to them in growth and disposition, stand in groups on the banks, intermixed with younger plantations. Immediately below the bridge, the river spreads into a large expanse: the sides are open lawn. On that furthest from the house formerly stood the palace of Henry II. celebrated in many an ancient ditty by the name of Fair Rosamond's Bower. A little clear spring, which rises there, is by the country people still called Fair Rosamond's Well. The spot is now marked by a single willow. Near it is a fine collateral stream, of a beautiful form, retaining its breadth as far as it is seen, and retiring at last behind a hill from the view. The main river, having received this accession, makes a gentle bend: then continues for a considerable length in one wide direct reach; and, just as it disappears, throws itself down a high cascade, which is the present termination. On one of the banks of this reach is the garden: the steeps are there diversified with thickets and with glades; but the covert prevails, and the top is crowned with lofty trees. On the other side is a noble hanging wood in the park: it was depreciated when it sunk into a hollow, and was poorly lost in the bottom; but it is now a rich appendage to the river, falling down an easy slope quite to the water's edge, where, with overshadowing, it is reflected on the surface. Another face of the same wood borders the collateral stream, with an outline more indented and various: while a very large irregular clump adorns the opposite declivity. This clump is at a considerable distance from the principal river: but the stream it belongs to brings it down to connect with the rest; and the other objects, which were before dispersed, are now, by the interest of each in a relation, which is common to all, collected into one illustrious scene. The castle itself is a prodigious pile of building; which, with all the faults of the architecture, will never seem less than a truly princely habitation; and the confined spot where it was placed, on the edge of an abyss, is converted into a proud situation, commanding a beautiful prospect of water, and open to an extensive lawn, adequate to the mansion, and an emblem of its domain. In the midst of this lawn stands a column, a stately trophy, recording the exploits of the duke of Marlborough and the gratitude of Britain. Between this pillar and the castle is the bridge, which now, applied to a subject worthy of it, is established in all the importance due to its greatness. The middle arch is wider than the Rialto, but not too wide for the occasion; and yet that is the narrowest part of the river; but the length of the reaches is everywhere proportioned to their breadth. Each of them is alone a noble piece of water; and the last, the finest of all, loses itself gradually in a wood, which on that side is also the boundary of the lawn, and rises into the horizon. All is great in the front of Blenheim: but in that vast space no void appears; so important are the parts, so magnificent the object. The plain is extensive, the valley is broad, the wood is deep. Though the intervals between the building are large, they are filled with the grandeur which buildings of such dimensions and so much pomp diffuse all around them; and the river in its long varied course, approaching to every object, and touching upon every part, spreads its influence over the whole.

In the composition of this scene, the river, both as a part itself, and as uniting the other parts, has a principal share. But water is not lost though it be in so confined or so concealed a spot as to enter into no view; it may render that spot delightful. It is capable of the most exquisite beauty in its form; and though not in space, may yet in disposition have pretensions to greatness; for it may be divided into several branches, which will form a cluster of islands all connected together, make the whole place irriguous, and, in the stead of extent, supply a quantity of water. Such a sequestered scene usually owes its retirement to the trees and the thickets with which it abounds; but, in the disposition of them, one distinction should be constantly attended to. A river flowing through a wood which overspreads one continued surface of ground, and a river between two woods, are in very different circumstances. In the latter case, the woods are separate; they may be contrasted in their forms and their characters, and the outline of each should be forcibly marked. In the former no outline ought to be discernible; for the river passes between trees, not between boundaries; and though in the progress of its course, the style of the plantations may be often changed, yet on the opposite banks a similarity should constantly prevail, that the identity of the wood may never be doubtful.

A

Water.

A river between two woods may enter into a view; and then it must be governed by the principles which regulate the conduct and the accompaniments of a river in an open exposure. But when it runs through a wood, it is never to be seen in a prospect; the place is naturally full of obstructions; and a continued opening, large enough to receive a long reach, would seem an artificial cut. The river must therefore necessarily wind more than in crossing a lawn where the passage is entirely free. But its influence will never extend so far on the sides: the buildings must be near the banks: and, if numerous, will seem crowded, being all in one track, and in situations nearly alike. The scene, however, does not want variety; on the contrary, none is capable of more. The objects are not indeed so different from each other as in an open view; but they are very different, and in much greater abundance; for this is the interior of a wood, where every tree is an object, every combination of trees a variety, and no large intervals are requisite to distinguish the several dispositions; the grove, the thicket, or the groups, may prevail, and their forms and their relations may be constantly changed, without restraint of fancy, or limitation of number.

Water is so universally and so deservedly admired in a prospect, that the most obvious thought in the management of it, is to lay it as open as possible; and purposely to conceal it would generally seem a severe self-denial: yet so many beauties may attend its passage through a wood, that larger portions of it might be allowed to snch retired scenes than are commonly spared from the view, and the different parts in different styles would be fine contrasts to each other. If the water at Wotton * were all exposed, a walk of near two miles along the banks would be of a tedious length, from the want of those changes of the scene which now supply through the whole extent a succession of perpetual variety. The extent is so large as to admit of a division into four principal parts, all of them great in style and in dimensions, and differing from each other both in character and situation. The two first are the least. The one is a reach of river, about the third of a mile in length, and of a competent breadth, flowing through a lovely mead, open in some places to views of beautiful hills in the country, and adorned in others with clumps of trees, so large, that their branches stretch quite across, and form a high arch over the water. The next seems to have been once a formal basin encompassed with plantations, and the appendages on either side still retain some traces of regularity: but the shape of the water is free from them; the size is about 14 acres; and out of it issue two broad collateral streams, winding towards a large river, which they are seen to approach, and supposed to join. A real junction is however impossible, from the difference of the levels; but the terminations are so artfully concealed, that the deception is never suspected, and when known is not easily explained. The river is the third great division of the water; a lake into which it falls, is the fourth. These two do actually join; but their characters are directly opposite; the scenes they belong to are totally distinct; and the transition from the one to the other is very gradual; for an island near the conflux, dividing the breadth, and concealing the end of the lake, moderates for some way the space; and permitting it to expand but by degrees, raises an idea of greatness, from uncertainty accompanied with increase. The reality does not disappoint the expectation; and the island, which is the point of view, is itself equal to the scene: it is large, and high above the lake; the ground is irregularly broken; thickets hang on the sides; and towards the top is placed an Ionic portico, which commands a noble extent of water, not less than a mile in circumference, bounded on one side with wood, and open on the other to two sloping lawns, the least of an hundred acres, diversified with clumps, and bordered by plantations. Yet this lake, when full in view, and with all the importance which space, form, and situation can give, is not more interesting than the sequestered river, which has been mentioned as the third great division of the water. It is just within the verge of a wood, three quarters of a mile long, everywhere broad, and its course is such as to admit of infinite variety without any confusion. The banks are cleared of underwood; but a few thickets still remain, and on one side an impenetrable covert soon begins: the interval is a beautiful grove of oaks, scattered over a green sward of extraordinary verdure. Between these trees and these thickets the river seems to glide gently along, constantly winding, without one short turn or one extended reach in the whole length of the way. This even temper in the stream suits the scenes through which it passes; they are in general of a very sober cast, not melancholy, but grave; never exposed to a glare; never darkened with gloom; nor, by strong contrasts of light and shade, exhibiting the excess of either. Undisturbed by an extent of prospect without, or a multiplicity of objects within, they retain at all times a mildness of character; which is still more forcibly felt when the shadows grow faint as they lengthen, when a little rustling of birds in the spray, the leaping of the fish, and the fragrancy of the woodbine, denote the approach of evening; while the setting sun shoots its last gleams on a Tuscan portico, which is close to the great basin, but which from a seat near this river is seen at a distance, through all the obscurity of the wood, glowing on the banks, and reflected on the surface of the water. In another still more distinguished spot is built an elegant bridge, with a colonnade upon it, which not only adorns the place where it stands, but is also a picturesque object to an octagon building near the lake, where it is shewn in a singular situation, overarched, encompassed, and backed with wood, without any appearance of the water beneath. This building in return is also an object from the bridge; and a Chinese room, in a little island just by, is another: neither of them are considerable, and the others which are visible are at a distance; but more or greater adventitious ornaments are not required in a spot so rich as this in beauties peculiar to its character. A profusion of water pours in from all sides round upon the view; the opening of the lake appears; a glimpse is caught of the large basin: one of the collateral streams is full in sight, and the bridge itself is in the midst of the finest part of the river: all seem to communicate the one with the other. Though thickets often intercept, and groups perplex the view, yet they never break the connexion between the several pieces of water; each may still be traced along

* Vale of Aylesbury, Buckinghamshire.

along

Water. Ibid. along large branches or little catches; which in some places are overshadowed and dim; in others glisten through a glade, or glimmer between the boles of trees in a distant perspective; and in one, where they are quite lost to the view, some arches of the stone bridge, but partially seen among the wood, preserve their connexion.

7 Of a Rill and a Rivulet. 3. If a large river may sometimes, a smaller current undoubtedly may often, be conducted through a wood: it seldom adorns, it frequently disfigures, a prospect, where its course is marked, not by any appearance of water, but by a confined line of clotted grass, which disagrees with the general verdure. A *Rivulet* may, indeed, have consideration enough for a home scene, though it be open; but a *Rill* is always most agreeable when most retired from public view. Its characteristic excellencies are vivacity and variety, which require attention, leisure, and silence, that the eye may pore upon the little beauties, and the ear listen to the low murmurs of the stream without interruption. To such indulgence a confined spot only is favourable; a close copse is therefore often more acceptable than a high wood, and a sequestered valley at all times preferable to any open exposure: a single rill at a very little distance is a mere water course; it loses all its charms; it has no importance in itself, and bears no proportion to the scene. A number of little streams have indeed an effect in any situation, but not as objects; they are interesting only on account of the character they express, the irriguous appearance which they give to the whole.

The full tide of a large river has more force than activity, and seems too unwieldy to allow of very quick transitions. But in a rill, the agility of its motions accounts for every caprice; frequent windings disguise its insignificance; short turnings show its vivacity; sudden changes in the breadth are a species of its variety; and however fantastically the channel may be wreathed, contracted, and widened, it still appears to be natural. We find an amusement in tracing the little stream through all the intricacies of its course, and in seeing it force a passage through a narrow strait, expatiate on every opportunity, struggle with obstructions, and puzzle out its way. A rivulet, which is the mean betwixt a river and a rill, partakes of the character of both: it is not licensed to the extravagance of the one, nor under the same restraints as the other: it may have more frequent bends than the river, longer reaches than a rill: the breadth of a stream determines whether the principal beauty results from extent or from variety.

The murmurs of a rill are amongst the most pleasing circumstances which attend it. If the bed of the stream be rough, mere declivity will occasion a constant rippling noise: when the current drops down a descent, though but of a few inches, or forcibly bubbles up from a little hollow, it has a deep gurgling tone, not uniformly continued, but incessantly repeated, and therefore more engaging than any. The flattest of all, is that sound rather of the splashing than the fall of water, which an even gentle slope, or a tame obstruction, will produce: this is less pleasing than the others; but none should be entirely excluded: all in their turns are agreeable; and the choice of them is much in our power. By observing their causes, we may often find the means to strengthen, to weaken, or to change them; and the addition or removal of a single stone, or a few pebbles, will sometimes be sufficient for the purpose.

8 Of Cascades. A rill cannot pretend to any sound beyond that of a little water fall: the roar of a cascade belongs only to a larger stream; but it may be produced by a rivulet to a considerable degree, and attempts to do more have generally been unsuccessful. A vain ambition to imitate nature in her great extravagancies betrays the weakness of art. Though a noble river, throwing itself headlong down a precipice, be an object truly magnificent, it must however be confessed, that in a single sheet of water there is a formality which its vastness alone can cure. But the height, not the breadth, is the wonder: when it falls not more than a few feet, the regularity prevails; and its extent only serves to expose the vanity of affecting the style of a cataract in an artificial cascade. It is less exceptionable if divided into several parts: for then each separate part may be wide enough for its depth; and in the whole, variety, not greatness, will be the predominant character. But a structure of rough, large, detached stones, cannot easily be contrived of strength sufficient to support a great weight of water: it is sometimes from necessity almost smooth and uniform, and then it loses much of its effects. Several little falls in succession are preferable to one great cascade which in figure or in motion approaches to regularity.

When greatness is thus reduced to number, and length becomes of more importance than breadth, a rivulet vies with a river: and it more frequently runs in a continued declivity, which is very favourable to such a succession of falls. Half the expence and labour which are sometimes bestowed on a river, to give it at the best a forced precipitancy in one spot only, would animate a rivulet through the whole of its course. And, after all, the most interesting circumstance in falling waters is their animation. A great cascade fills us with surprise: but all surprise must cease; and the motion, the agitation, the rage, the froth, and the variety of the water, are finally the objects which engage the attention: for these a rivulet is sufficient; and they may there be produced without that appearance of effort which raises a suspicion of art.

To obviate such a suspicion, it may be sometimes expedient to begin the descent out of sight; for the beginning is the difficulty: if that be concealed, the subsequent falls seem but a consequence of the agitation which characterises the water at its first appearance; and the imagination is, at the same time, let loose to give ideal extent to the cascades. When a stream issues from a wood, such management will have a great effect: the bend of its course in an open exposure may afford frequent opportunities for it; and sometimes a low broad bridge may furnish the occasion: a little fall hid under the arch will create a disorder; in consequence of which, a greater cascade below will appear very natural.

Of Rocks. IV. ROCKS. Rocks are themselves too vast and too stubborn to submit to our controul; by the addition or removal of appendages which we can command, parts may be shown or concealed, and the characters with their impressions may be weakened or enforced:

forced: to adopt the accompaniments accordingly, is the utmost ambition of art when rocks are the subject.

Their most distinguished characters are, *dignity*, *terror*, and *fancy*: the expressions of all are constantly wild: and sometimes a rocky scene is only wild, without pretensions to any particular character.

Rills, rivulets, and cascades, abound among rocks: they are natural to the scene; and such scenes commonly require every accompaniment which can be procured for them. Mere rocks, unless they are particularly adapted to certain impressions, though they may surprise, cannot be long engaging, if the rigour of their character be not softened by circumstances which may belong either to these or to more cultivated spots: and when the dreariness is extreme, little streams and waterfalls are of themselvess insufficient for the purpose; an intermixture of vegetation is also necessary, and on some occasions even marks of inhabitants are proper.

Large clefts, sloping or precipitous, with a dale at bottom, furnish scenes of the wildest nature. In such spots, verdure alone will give some relief to the dreariness of the scene; and shrubs or bushes, without trees, are a sufficiency of wood: the thickets may also be extended by the creeping plants, such as pyracantha, vines, and ivy, to wind up the sides or cluster on the tops of the rocks. And to this vegetation may be added some symptoms of inhabitants, but they must be slight and few; the use of them is only to cheer, not to destroy, the solitude of the place; and such therefore should be chosen as are sometimes found in situations retired from public resort; a cottage may be lonely, but it must not here seem ruinous and neglected; it should be tight and warm, with every mark of comfort about it, to which its position in some sheltered recess may greatly contribute. A cavity also in the rocks, rendered easy of access, improved to a degree of convenience, and maintained in a certain state of preservation, will suggest similar ideas of protection from the bitterest inclemencies of the sky, and even of occasional refreshment and repose. But we may venture still further; a mill is of necessity often built at some distance from the town which it supplies; and here it would at the same time apply the water to a use, and increase its agitation. The dale may besides be made the haunt of those animals, such as goats, which are sometimes wild, and sometimes domestic; and which accidentally appearing, will divert the mind from the sensations natural to the scene, but not agreeable if continued long without interruption. These and such other expedients will approximate the severest retreat to the habitations of men, and convert the appearance of a perpetual banishment into that of a temporary retirement from society.

But too strong a force on the nature of the place alway fails. A winding path, which appears to be worn, not cut, has more effect than a high road, all artificial and level, which is too weak to overbear, and yet contradicts the general idea. The objects therefore to be introduced must be those which hold a mean between solitude and population; and the inclination of that choice towards either extreme, should be directed by the degree of wildness which prevails; for though that runs sometimes to an excess which requires correction, at other times it wants encouragement, and at all times it ought to be preserved: it is the predominant character of rocks, which mixes with every other and to which all the appendages must be accommodated; and they may be applied so as greatly to increase it: a licentious irregularity of wood and of ground, and a fantastic conduct of the streams, neither of which would be tolerated in the midst of cultivation, become and improve romantic rocky spots; even buildings, partly by their style, but still more by their position, in strange, difficult, or dangerous situations, distinguish and aggravate the native extravagancies of the scene.

Greatness is a chief ingredient in the character of *dignity*, with less of wildness than in any other. The effect here depends more upon amplitude of surface, than variety of forms. The parts, therefore, must be large: if the rocks are only high, they are but stupendous, not majestic: breadth is equally essential to their greatness; and every slender, every grotesque shape, is excluded. Art may interpose to show these large parts to the eye, and magnify them to the imagination, by taking away thickets which stretch quite across the rocks, so as to disguise their dimensions; or by filling with wood the small intervals between them, and thus, by concealing the want, preserving the appearance of continuation. When rocks retire from the eye down a gradual declivity, we can, by raising the upper ground, deepen the fall, lengthen the perspective, and give both height and extent to those at a distance: this effect may be still increased by covering that upper ground with a thicket, which shall cease or be lowered, as it descends. A thicket, on other occasions, makes the rocks which rise out of it seem larger than they are. If they stand upon a bank overspread with shrubs, their beginning is at the least uncertain; and the presumption is, that they start from the bottom. Another use of this brushy underwood is to conceal the fragments and rubbish which have fallen from the sides and the brow, and which are often unsightly. Rocks are seldom remarkable for the elegance of their forms; they are too vast, and too rude, to pretend to delicacy: but their shapes are often agreeable; and we can affect those shapes to a certain degree, at least we can cover many blemishes in them, by conducting the growth of shrubby and creeping plants about them.

For all these purposes mere underwood suffices: but for greater effects larger trees are requisite: they are worthy of the scene; and not only improvements, but accessions to its grandeur: we are used to rank them among the noblest objects of nature; and when we see that they cannot aspire to the midway of the heights around them, the rocks are raised by the comparison. A single tree is, therefore, often preferable to a clump: the size, though really less, is more remarkable: and clumps are besides generally exceptionable in a very wild spot, from the suspicions of art which attends them; but a wood is free from that suspicion, and its own character of greatness recommends it to every scene of magnificence.

On the same principle all possible consideration should be given to the streams. No number of little rills are equal to one broad river; and in the principal current, some varieties may be sacrificed to importance: but a degree of strength should always be preserved: the water, though it needs not be furious, should not be dull;

Rocks. Ibid.

dull; for dignity, when most serene, is not languid; and space will hardly atone for want of animation.

This character does not exclude marks of inhabitants, though it never requires them to tame its wildness: and without inviting, it occasionally admits an intermixture of vegetation. It even allows of buildings intended only to decorate the scene: but they must be adequate to it, both in size and in character. And if cultivation is introduced, that too should be conformable to the rest; not a single narrow patch cribbed out of the waste; but the confines of a country shelving into the vale, and suggesting the idea of extent: nothing trivial ought to find admittance. But, on the other hand, no extravagance is required to support it; strange shapes in extraordinary positions, enormous weights unaccountably sustained, trees rooted in the sides, and torrents raging at the foot of the rocks, are at the best needless excesses. There is a temperance in dignity, which is rather hurt by a wanton violence on the common order of nature.

The terrors of a scene in nature are like those of a dramatic representation: they give an alarm; but the sensations are agreeable, so long as they are kept to such as are allied only to terror, unmixed with any that are horrible and disgusting. Art may therefore be used to heighten them, to display the objects which are distinguished by greatness, to improve the circumstances which denote force, to mark those which intimate danger, and to blend withal here and there a cast of melancholy.

Greatness is as essential to the character of *terror* as to that of dignity: vast efforts in little objects are but ridiculous; nor can force be supposed upon trifles incapable of resistance. On the other hand, it must be allowed, that exertion and violence supply some want of space. A rock wonderfully supported, or threatening to fall, acquires a greatness from its situation, which it has not in dimensions; so circumstanced, the size appears to be monstrous: a torrent has a consequence which a placid river of equal breadth cannot pretend to; and a tree, which would be inconsiderable in the natural soil, becomes important when it bursts forth from a rock.

Such circumstances should be always industriously sought for. It may be worth while to cut down several trees, in order to exhibit one apparently rooted in the stone. By the removal perhaps of only a little brushwood, the alarming disposition of a rock, strangely undermined, rivetted, or suspended, may be shown; and if there be any soil above its brow, some trees planted there, and impending over it, will make the object still more extraordinary. As to the streams, great alterations may generally be made in them: and therefore it is of use to ascertain the species proper to each scene, because it is in our power to enlarge or contract their dimensions; to accelerate or retard their rapidity; to form, increase, or take away obstructions; and always to improve, often to change, their characters.

Inhabitants furnish frequent opportunities to strengthen the appearances of force, by giving intimations of danger. A house placed at the edge of a precipice, any building on the pinnacle of a crag, makes that situation seem formidable, which might otherwise have been unnoticed: a steep, in itself not very remarkable, becomes alarming, when a path is carried aslant up the side: a rail on the brow of a perpendicular fall, shows that the height is frequented and dangerous: and a common foot bridge thrown over a cleft between rocks has a still stronger effect. In all these instances, the imagination immediately transports the spectator to the spot, and suggests the idea of looking down such a depth; in the last, that depth is a chasm, and the situation is directly over it.

Rocks.

In other instances, exertion and danger seem to attend the occupations of the inhabitants:

> ————Half way down
> Hangs one that gathers samphire; dreadful trade!

is a circumstance chosen by the great poet of nature, to aggravate the terror of the scene he describes.

The different species of rocks often meet in the same place, and compose a noble scene, which is not distinguished by any particular character; it is only when one eminently prevails, that it deserves such a preference as to exclude every other. Sometimes a spot, remarkable for nothing but its wildness, is highly romantic: and when this wildness rises to *fancy*; when the most singular, the most opposite forms and combinations are thrown together; then a mixture also of several characters adds to the number of instances which there concur to display the inexhaustible variety of nature.

So much variety, so much fancy, are seldom found within the same extent as in Dovedale †. It is about two miles in length, a deep, narrow, hollow valley; both the sides are of rock; and the Dove in its passage between them is perpetually changing its course, its motion, and appearance. It is never less than ten, nor so much as twenty, yards wide, and generally about four feet deep; but transparent to the bottom, except when it is covered with a foam of the purest white, under waterfalls, which are perfectly lucid. These are very numerous, but very different. In some places they stretch straight across, or aslant the stream: in others, they are only partial; and the water either dashes against the stones, and leaps over them, or, pouring along a steep, rebounds upon those below: sometimes it rushes through the several openings between them; sometimes it drops gently down; and at other times it is driven back by the obstruction, and turns into an eddy. In one particular spot, the valley, almost closing, leaves hardly a passage for the river, which, pent up, and struggling for a vent, rages, and roars, and foams, till it has extricated itself from the confinement. In other parts, the stream, though never languid, is often gentle; flows round a little desert island, glides between bits of bulrushes, disperses itself among tufts of grass or of moss, bubbles about a water dock, or plays with the slender threads of aquatic plants which float upon the surface. The rocks all along the dale vary as often in their structure as the stream in its motion. In one place, an extended surface gradually diminishes from a broad base almost to an edge: in another, a heavy top hanging forwards, overshadows all beneath: sometimes many different shapes are confusedly tumbled together; and sometimes they are broken into slender sharp pinnacles, which are upright, often two or three together, and often in more numerous clusters. On this side of the dale,

† Near Ashbourn in Derbyshire.

dale, they are universally bare; on the other, they are intermixed with wood; and the vast height of both the sides, with the narrowness of the interval between them, produces a further variety: for whenever the sun shines from behind the one, the form of it is distinctly and completely cast upon the other; the rugged surface on which it falls diversifies the tints; and a strong reflected light often glares on the edge of the deepest shadow. The rocks never continue long in the same figure or situation, and are very much separated from each other: sometimes they form the sides of the valley, in precipices, in steeps, or in stages; sometimes they seem to rise in the bottom, and lean back against the hill; and sometimes they stand out quite detached, heaving up in cumbrous piles, or starting into conical shapes, like vast spars, 100 feet high; some are firm and solid throughout; some are cracked; and some, split and undermined, are wonderfully upheld by fragments apparently unequal to the weight they sustain. One is placed before, one over another, and one fills at some distance behind an interval between two. The changes in their disposition are infinite; every step produces some new combination; they are continually crossing, advancing, and retiring; the breadth of the valley is never the same 40 yards together: at the narrow pass which has been mentioned, the rocks almost meet at the top, and the sky is seen as through a chink between them: just by this gloomy abyss, is a wider opening, more light, more verdure, more cheerfulness than anywhere else in the dale. Nor are the forms and the situations of the rocks their only variety: many of them are perforated by large natural cavities, some of which open to the sky, some terminate in dark recesses, and through some are to be seen several more uncouth arches, and rude pillars, all detached, and retiring beyond each other, with the light shining in between them, till a rock far behind them closes the perspective: the noise of the cascades in the river echoes amongst them; the water may often be heard at the same time gurgling near, and roaring at a distance; but no other sounds disturb the silence of the spot: the only trace of men is a blind path, but lightly and but seldom trodden, by those whom curiosity leads to see the wonders they have been told of Dovedale. It seems indeed a fitter haunt for mere ideal beings: the whole has the air of enchantment. The perpetual shifting of the scenes; the quick transitions, the total changes, then the forms all around, grotesque as chance can cast, wild as nature can produce, and various as imagination can invent; the force which seems to have been exerted to place some of the rocks where they are now fixed immoveable, the magic by which others appear still to be suspended; the dark caverns, the illuminated recesses, the fleeting shadows, and the gleams of light glancing on the sides, or trembling on the stream; and the loneliness and the stillness of the place, all crowding together on the mind, almost realize the ideas which naturally present themselves in this region of romance and of fancy.

The solitude of such a scene is agreeable, on account of the endless entertainment which its variety affords, and in the contemplation of which both the eye and the mind are delighted to indulge: marks of inhabitants and cultivation would disturb that solitude; and ornamental buildings are too artificial in a place so absolutely free from restraint. The only accompaniments proper for it are wood and water; and by these sometimes improvements may be made. When two rocks similar in shape and position are near together, by skirting one of them with wood, while the other is left bare, a material distinction is established between them: if the streams be throughout of one character, it is in our power, and should be our aim, to introduce another. Variety is the peculiar property of the spot, and every accession to it is a valuable acquisition. On the same principle, endeavours should be used not only to multiply, but to aggravate differences, and to increase distinctions into contrasts: but the subject will impose a caution against attempting too much. Art must almost despair of improving a scene, where nature seems to have exerted her invention.

§ 2. *Of Factitious Accompaniments.*

Fence, &c.

These consist of Fences, Walks, Roads, Bridges, Seats, and Buildings.

Practical Treatise on Planting and Gardening, p. 593, &c.

"I. The FENCE, where the place is large, becomes necessary; yet the eye dislikes constraint. Our ideas of liberty carry us beyond our own species: the imagination feels a dislike in seeing even the brute creation in a state of confinement. The birds wafting themselves from wood to grove are objects of delight; and the hare appears to enjoy a degree of happiness unknown to the barriered flock. Besides, a tall fence frequently hides from the sight objects the most pleasing; not only the flocks and herds themselves, but the surface they graze upon. These considerations have brought the unseen fence into general use.

This species of barrier it must be allowed incurs a degree of deception, which can scarcely be warranted upon any other occasion. In this instance, however, it is a species of fraud which we observe in nature's practice: how often have we seen two distinct herds feeding to appearance in the same extended meadow; until coming abruptly upon a deep sunk rivulet, or an unfordable river, we discover the deception.

Besides the sunk fence, another sort of unseen barrier may be made, though by no means equal to that, especially if near the eye. This is constructed of paling, painted of the invisible green. If the colour of the back ground were permanent, and that of the paint made exactly to correspond with it, the deception would at a distance be complete; but back grounds in general changing with the season, this kind of fence is the less eligible.

Clumps and patches of woodiness scattered promiscuously on either side of an unseen winding fence, assist very much in doing away the idea of constraint. For by this means

> The wand'ring flocks that browse between the shades,
> Seem oft to pass their bounds; the dubious eye
> Decides not if they crop the mead or lawn.
>
> MASON.

"II. The WALK, in extensive grounds, is as necessary as the fence. The beauties of the place are disclosed that they may be seen; and it is the office of the walk

Bridge, &c.

Ibid.

walk to lead the eye from view to view; in order that whilst the tone of health is preserved by the favourite exercise of nature, the mind may be thrown into unison by the harmony of the surrounding objects.

The direction of the walk must be guided by the points of view to which it leads, and the nature of the ground it passes over: it ought to be made subservient to the natural impediments (the ground, wood, and water) which fall in its way, without appearing to have any direction of its own. It can seldom run with propriety any distance in a straight line; a thing which rarely occurs in a natural walk. The paths of the Negroes and the Indians are always crooked; and those of the brute creation are very similar. Mr Mason's description of this path of nature is happily conceived.

> The peasant driving through each shadowy lane
> His team, that bends beneath th' incumbent weight
> Of laughing Ceres, marks it with his wheel;
> At night and morn, the milkmaid's careless step
> Has through yon pasture green, from stile to stile
> Imprest a kindred curve: the scudding hare
> Draws to her dew-sprent seat, o'er thymy heaths,
> A path as gently waving————
>
> *Eng. Gard.* v. 60.

"III. The **ROAD** may be a thing of necessity, as an approach to the mansion; or a matter of amusement only, as a drive or a ride, from which the grounds and the surrounding country may be seen to advantage. It should be the study of the artist to make the same road answer, as far as may be, the twofold purpose.

The road and the walk are subject to the same rule of nature and use. The direction ought to be natural and easy, and adapted to the purpose intended. A road of necessity ought to be straighter than one of mere conveniency: in this, recreation is the predominant idea; in that, utility. But even in this the direct line may be dispensed with. The natural roads upon heaths and open downs, and the grassy glades and green roads across forests and extensive wastes, are proper subjects to be studied.

"IV. The **BRIDGE** should never be seen where it is not wanted: a useless bridge is a deception; deceptions are frauds; and fraud is always hateful, unless when practised to avert some greater evil. A bridge without water is an absurdity; and half a one stuck up as an eye-trap is a paltry trick, which, though it may strike the stranger, cannot fail of disgusting when the fraud is found out.

In low situations, and wherever water abounds, bridges become useful, and are therefore pleasing objects; they are looked for; and ought to appear not as objects of ornament only, but likewise as matters of utility. The walk or the road therefore ought to be directed in such a manner as to cross the water at the point in which the bridge will appear to the greatest advantage.

In the construction of bridges also, regard must be had to ornament and utility. A bridge is an artificial production, and as such it ought to appear. It ranks among the noblest of human inventions; the ship and the fortress alone excel it. Simplicity and firmness are the leading principles in its construction. Mr Wheatley's observation is just when he says, "The single wooden arch, now much in fashion, seems to me generally misapplied. Elevated without occasion so much above, it is totally detached from the river; it is often seen straddling in the air, without a glimpse of water to account for it; and the ostentation of it as an ornamental object, diverts all that train of ideas which its use as a communication might suggest." But we beg leave to differ from this ingenious writer when he tells us, "that it is spoiled if adorned; it is disfigured if only painted of any other than a dusky colour." In a rustic scene, where nature wears her own coarse garb, "the vulgar foot bridge of planks only guarded on one hand by a common rail, and supported by a few ordinary piles," may be in character; but amidst a display of ornamented nature, a contrivance of that kind would appear mean and paltry; and would be an affectation of simplicity rather than the lovely attribute itself. In cultivated scenes, the bridge ought to receive the ornaments which the laws of architectural taste allow; and the more polished the situation, the higher should be the style and finishings.

Buildings.

Ibid.

"V. **SEATS** have a twofold use; they are useful as places of rest and conversation, and as guides to the points of view in which the beauties of the surrounding scene are disclosed. Every point of view should be marked with a seat; and, speaking generally, no seat ought to appear but in some favourable point of view. This rule may not be invariable, but it ought seldom to be deviated from.

In the ruder scenes of neglected nature, the simple trunk, rough from the woodman's hands, and the butts or stools of rooted trees, without any other marks of tools upon them than those of the saw which severed them from their stems, are seats in character; and in romantic or recluse situations, the cave or the grotto are admissible. But wherever human design has been executed upon the natural objects of the place, the seat and every other artificial accompaniment ought to be in unison; and whether the bench or the alcove be chosen, it ought to be formed and finished in such a manner as to unite with the wood, the lawn, and the walk, which lie around it.

The colour of seats should likewise be suited to situations: where uncultivated nature prevails, the natural brown of the wood itself ought not to be altered; but where the rural art presides, white or stone colour has a much better effect.

Mr ...ley's ...vati... sum...

"VI. **BUILDINGS** probably were first introduced into gardens merely for convenience, to afford refuge from a sudden shower, and shelter against the wind; or, at the most, to be seats for a party; or for retirement. They have since been converted into objects, and now the original *use* is too often forgotten in the greater purposes to which they are applied: they are considered as objects only; the inside is totally neglected, and a pompous edifice frequently wants a room barely comfortable. Sometimes the pride of making a lavish display to a visitor without any regard to the owner's enjoyments, and sometimes too scrupulous an attention to the style of the structure, occasions a poverty and dulness within, which deprive the buildings of part of their utility. But in a garden they ought to be considered both as beautiful objects and as agreeable

greeable retreats: if a character becomes them, it is that of the scene they belong to; not that of their primitive application. A Grecian temple or Gothic church may adorn spots where it would be affectation to preserve that solemnity within which is proper for places of devotion: they are not to be exact models, subjects only of curiosity or study: they are also seats: and such seats will be little frequented by the proprietor; his mind must generally be indisposed to so much simplicity, and so much gloom, in the midst of gaiety, richness, and variety.

But though the interior of buildings should not be disregarded, it is by their exterior that they become *objects;* and sometimes by the one, sometimes by the other, and sometimes by both, they are entitled to be considered as *characters.*

1. As objects, they are designed either to *distinguish,* or to *break,* or to *adorn,* the scenes to which they are applied.

The differences between one wood, one lawn, one piece of water, and another, are not always very apparent: the several parts of a garden would, therefore, often seem similar, if they were not distinguished by buildings; but these are so observable, so obvious at a glance, so easily retained in the memory, they mark the spots where they are placed with so much strength, they attract the relation of all around with so much power, that parts thus distinguished can never be confounded together. Yet it by no means follows, that therefore every scene must have its edifice: the want of one is sometimes a variety; and other circumstances are often sufficiently characteristic: it is only when these too nearly agree, that we must have recourse to buildings for differences: we can introduce, exhibit, or contrast them as we please: the most striking object is thereby made a mark of distinction; and the force of this first impression prevents our observing the points of resemblance.

The uniformity of a view may be broken by similar means, and on the same principle: when a wide heath, a dreary moor, or a continual plain, is in prospect, objects which catch the eye supplant the want of variety: none are so effectual for this purpose as buildings. Plantations or water can have no very sensible effect, unless they are large and numerous, and almost change the character of the scene: but a small single building diverts the attention at once from the sameness of the extent; which it breaks, but does not divide; and diversifies, without altering its nature. The design, however, must not be apparent. The merit of a cottage applied to this purpose, consists in its being free from the suspicion: and a few trees near it will both enlarge the object, and account for its position. Ruins are a hackneyed device immediately detected, unless their style be singular, or their dimensions extraordinary. The semblance of an ancient British monument might be adapted to the same end, with little trouble, and great success. The materials might be brick, or even timber plastered over, if stone could not easily be procured: whatever they were, the fallacy would not be discernible; it is an object to be seen at a distance, rude, and large, and in character agreeable to a wild open view. But no building ought to be introduced, which may not in reality belong to such a situation: no Grecian temples, no Turkish mosques, no Egyptian obelisks or pyramids; none imported from foreign countries, and unusual here. The apparent artifice would destroy an effect, which is so nice as to be weakened, if objects proper to produce it are displayed with too much ostentation; if they seem to be contrivances, not accidents; and the advantage of their position appear to be more laboured than natural.

But in a garden, where objects are intended only to adorn, every species of architecture may be admitted, from the Grecian down to the Chinese; and the choice is so free, that the mischief most to be apprehended is an abuse of this latitude in the multiplicity of buildings. Few scenes can bear more than two or three: in some, a single one has a greater effect than any number: and a careless glimpse, here and there, of such as belong immediately to different parts, frequently enlivens the landscape with more spirit than those which are industriously shown. If the effect of a partial sight, or a distant view, were more attended to, many scenes might be filled, without being crowded; a greater number of buildings would be tolerated, when they seemed to be casual, not forced; and the animation, and the richness of the objects, might be had without pretence or display.

Too fond an ostentation of buildings, even of these which are principal, is a common error; and when all is done, they are not always shown to the greatest advantage. Though their symmetry and their beauties ought in general to be distinctly and fully seen, yet an oblique is sometimes better than a direct view: and they are often less agreeable objects when entire, than when a part is covered, or their extent is interrupted; when they are bosomed in wood, as well as backed by it; or appear between the stems of trees which rise before or above them; thus thrown into perspective, thus grouped and accompanied, they may be as important as if they were quite exposed, and are frequently more picturesque and beautiful.

But a still greater advantage arises from this management, in connecting them with the scene: they are considerable, and different from all around them; inclined therefore to separate from the rest; and yet they are sometimes still more detached by the pains taken to exhibit them: that very importance which is the cause of the distinction ought to be a reason for guarding against the independence to which it is naturally prone, and by which an object, which ought to be a part of the whole, is reduced to a mere individual. An elevated is generally a noble situation. When it is a point or pinnacle, the structure may be a continuation of the ascent; and on many occasions, some parts of the building may descend lower than others, and multiply the appearances of connexion: but an edifice in the midst of an extended ridge, commonly seems naked alone, and imposed upon the brow, not joined to it. If wood, to accompany it, will not grow there, it had better be brought a little way down the declivity; and then all behind, above, and about it, are so many points of contact, by which it is incorporated into landscape.

Accompaniments are important to a building; but they lose much of their effect when they do not appear to be casual. A little mount just large enough for it; a small piece of water below, of no other use than

Buildings.

than to reflect it; and a plantation close behind, evidently placed there only to give it relief; are as artificial as the structure itself, and alienate it from the scene of nature into which it is introduced, and to which it ought to be reconciled. These appendages therefore should be so disposed, and so connected with the adjacent parts, as to answer other purposes, though applicable to this: that they may be bonds of union, not marks of difference; and that the situation may appear to have been chosen at the most, not made, for the building.

In the choice of a situation, that which shows the building best ought generally to be preferred: eminence, relief, and every other advantage which can be, ought to be given to an object of so much consideration: they are for the most part desirable; sometimes necessary; and exceptionable only when, instead of rising out of the scene, they are forced into it, and a contrivance to procure them at any rate is avowed without any disguise. There are, however, occasions, in which the most tempting advantages of situation must be waved; the general composition may forbid a building in one spot, or require it in another; at other times, the interest of the particular group it belongs to may exact a sacrifice of the opportunities to exhibit its beauties and importance; and at all times, the pretensions of every individual object must give way to the greater effect of the whole.

11 Of those expressive of character.

2. The same structure which adorns as an object, may also be expressive as a *character*. Where the former is not wanted, the latter may be desirable: or it may be weak for one purpose, and strong for the other; it may be grave, or gay; magnificent, or simple: and according to its style, may or may not be agreeable to the place it is applied to. But mere consistency is not all the merit which buildings can claim: their characters are sometimes strong enough to *determine*, *improve*, or *correct*, that of the scene: and they are so conspicuous, and so distinguished, that whatever force they have is immediately and sensibly felt. They are fit therefore to make a first impression; and when a scene is but faintly characterized, they give at once a cast which spreads over the whole, and which the weaker parts concur to support, though perhaps they were not able to produce it.

Nor do they stop at fixing an uncertainty, or removing a doubt; they raise and enforce a character already marked: a temple adds dignity to the noblest, a cottage simplicity to the most rural, scenes; the lightness of a spire, the airiness of an open rotunda, the splendour of a continued colonnade, are less ornamental than expressive; others improve cheerfulness into gaiety, gloom into solemnity, and richness into profusion: a retired spot, which might have been passed unobserved, is noticed for its tranquillity, as soon as it is appropriated by some structure to retreat; and the most unfrequented place seems less solitary than one which appears to have been the haunt of a single individual, or even of a sequestered family, and is marked by a lonely dwelling, or the remains of a deserted habitation.

The means are the same, the application of them only is different, when buildings are used to correct the character of the scene; to enliven its dulness, mitigate its gloom, or to check its extravagance; and, on a variety of occasions, to soften, to aggravate, or to counteract, particular circumstances attending it. But care must be taken that they do not contradict too strongly the prevailing idea: they may lessen the dreariness of a waste, but they cannot give it amenity; they may abate horrors, but they will never convert them into graces; they may make a tame scene agreeable, and even interesting, not romantic; or turn solemnity into cheerfulness, but not into gaiety. In these, and in many other instances, they correct the character, by giving it an inclination towards a better which is not very different; but they can hardly alter it entirely: when they are totally inconsistent with it, they are at the best nugatory.

The great effects which have been ascribed to buildings do not depend upon those trivial ornaments and appendages which are often too much relied on; such as the furniture of a hermitage, painted glass in a Gothic church, and sculpture about a Grecian temple; grotesque or bacchanalian figures to denote gaiety, and death's heads to signify melancholy. Such devices are only descriptive, not expressive, of character; and must not be substituted in the stead of those superior properties, the want of which they acknowledge, but do not supply. They besides often require time to trace their meaning, and to see their application; but the peculiar excellence of buildings is, that their effects are instantaneous, and therefore the impressions they make are forcible. In order to produce such effects, the general style of the structure, and its position, are the principal considerations: either of them will sometimes be strongly characteristic alone; united, their powers are very great; and both are so important, that if they do not concur, at least they must not contradict one another.

Species and situations of buildings.

Every branch of architecture furnishes, on different occasions, objects proper for a garden; and there is no restraint on our selection, provided it be conformable to the style of the scene, proportioned to its extent, and agreeable to its character.

The choice of situations is also very free. A hermitage, indeed, must not be close to a road; but whether it be exposed to view on the side of a mountain, or concealed in the depth of a wood, is almost a matter of indifference; that it is at a distance from public resort is sufficient. A castle must not be sunk in a bottom; but that it should stand on the utmost pinnacle of a hill, is not necessary; on a lower knoll, and backed by the rise, it may appear to greater advantage as an object, and be much more important to the general composition. Many buildings, which from their splendour best become an open exposure, will yet be sometimes not ill bestowed on a more sequestered spot, either to characterize or adorn it; and others, for which a solitary would in general be preferred to an eminent situation, may occasionally be objects in very conspicuous positions. A Grecian temple, from its peculiar taste and dignity, deserves every distinction; it may, however, in the depth of a wood, be so circumstanced, that the want of those advantages to which it seems entitled will not be regretted. A happier situation cannot be devised, than that of the temple of Pan on the south lodge on Enfield Chase. It is of the usual oblong form, encompassed by a colonnade; in dimensions, and in style, it is equal to a most extensive landscape: and yet by the antique

Buildings.

antique and rustic air of its Doric columns without bases; by the chastity of its little ornaments, a crook, a pipe, and a scrip, and those only over the doors; and by the simplicity of the whole both within and without; it is adapted with so much propriety to the thickets which conceal it from the view, that no one can wish it to be brought forward, who is sensible to the charms of the Arcadian scene which this building alone has created. On the other hand, a very spacious field, or sheep walk, will not be disgraced by a farm house, a cottage, or a Dutch barn; nor will they, though small and familiar, appear to be inconsiderable or insignificant objects. Numberless other instances might be adduced to prove the impossibility of restraining particular buildings to particular situations, upon any general principles: the variety in their forms is hardly greater than in their application. Only let not their uses be disguised, as is often absurdly attempted with the humbler kinds. "A barn ‡ dressed up in the habit of a country church, or a farm house figuring away in the fierceness of a castle, are ridiculous deceptions. A landscape daubed upon a board, and a wooden steeple stuck up in a wood, are beneath contempt."

‡ Painting and Gardening, p. 3.

Temples, those favourite and most costly objects in gardens, too generally merit censure for their inutility, their profusion, or the impropriety of their purpose. "Whether they be dedicated to Bacchus, Venus, Priapus, or any other demon of debauchery, they are in this age, enlightened with regard to theological and scientific knowledge, equally absurd. Architecture, in this part of its sphere, may more nobly, and with greater beauty and effect, be exercised upon a chapel, a mausoleum, a monument, judiciously disposed among the natural ornaments. The late Sir William Harbord has given us a model, of the first kind, at Gunton, in Norfolk; the parish church standing in his park, and being an old unsightly building, he had it taken down, and a beautiful temple, under the direction of the Adams erected upon its site for the same sacred purpose:—The mausoleum at Castle-Howard, in Yorkshire, the seat of the earl of Carlisle, is a noble structure:—And as an instance of the last sort, may be mentioned the Temple of Concord and Victory at Stowe, erected to the memory of the great Lord Chatham and his glorious war; a beautiful monumental building, suited to the greatness of the occasion."

Ibid. 599

To the great variety above mentioned must be added, Mr Wheatley observes, the many changes which may be made by the means of ruins. They are a class by themselves, beautiful as objects, expressive as characters, and peculiarly calculated to connect with appendages into elegant groups. They may be accommodated with ease to irregularity of ground, and their disorder is improved by it. They may be intimately blended with trees and thickets; and the interruption is an advantage: for imperfection and obscurity are their properties, and to carry the imagination to something greater than is seen, is their effect. They may for any of these purposes be separated into detached pieces: contiguity is not necessary, nor even the appearance of it, if the relation be preserved; but straggling ruins have a bad effect, when the several parts are equally considerable. There should be one large mass to raise an idea of greatness, to attract the others about it, and to be a common centre of union to all: the smaller pieces then mark the original dimensions of one extensive structure; and no longer appear to be the remains of several little buildings.

Observations on Modern Gardening.

All remains excite an inquiry into the former state of the edifice, and fix the mind in a contemplation of the use it was applied to; besides the characters expressed by their style and position, they suggest ideas which would not arise from the buildings if entire. The purposes of many have ceased: an abbey, or a castle, if complete, can now be no more than a dwelling; the memory of the times, and of the manners to which they are adapted, is preserved only in history, and in ruins; and certain sensations of regret, of veneration, or compassion, attend the recollection. Nor are these confined to the remains of buildings which are in disuse; those of an old mansion raise reflections on the domestic comforts once enjoyed, and the ancient hospitality which reigned there. Whatever building we see in decay, we naturally contrast its present with its former state, and delight to ruminate on the comparison. It is true that such effects properly belong to real ruins: they are, however, produced in a certain degree by those which are fictitious: the impressions are not so strong, but they are exactly similar; and the representation, though it does not present facts to the memory, yet suggests subjects to the imagination. But, in order to affect the fancy, the supposed original design should be clear, the use obvious, and the form easy to be traced: no fragments should be hazarded without precise meaning, and an evident connexion; none should be perplexed in their construction, or uncertain as to their application. Conjectures about the form raise doubts about the existence of the ancient structure: the mind must not be allowed to hesitate; it must be hurried away from examining into the reality by the exactness and the force of the resemblance.

In the ruins of Tintern abbey ‖ the original construction of the church is perfectly marked; and it is principally from this circumstance that they are celebrated as a subject of curiosity and contemplation. The walls are almost entire; the roof only is fallen in, but most of the columns which divided the aisles are still standing: of those which have dropped down, the bases remain, every one exactly in its place; and in the middle of the nave four lofty arches, which once supported the steeple, rise high in the air above all the rest, each reduced now to a narrow rim of stone, but completely preserving its form. The shapes even of the windows are little altered; but some of them are quite obscured, others partially shaded, by tufts of ivy; and those which are most clear are edged with its slender tendrils, and lighter foliage, wreathing about the sides and the divisions: it winds round the pillars; it clings to the walls; and in one of the aisles clusters at the top in branches, so thick and so large as to darken the space below. The other aisles, and the great nave, are exposed to the sky: the floor is entirely overspread with turf; and to keep it clear from weeds and bushes, is now its highest preservation. Monkish tomb stones and the monuments of benefactors long since forgotten, appear above the green sward: the bases of the pillars which have fallen, rise out of it; and maimed effigies, and sculpture worn with age and weather, Gothic capitals, carved

‖ Between Chepstow and Monmouth.

cornices,

Art.

cornices and various fragments, are scattered about, or lie in heaps piled up together. Other shattered pieces, though disjointed and mouldering, still occupy their original places; and a staircase much impaired, which led to a tower now no more, is suspended at a great height, uncovered and inaccessible: nothing is perfect; but memorials of every part still subsist; all certain, but all in decay; and suggesting at once every idea which can occur in a seat of devotion, solitude, and desolation. Upon such models fictitious ruins should be formed; and if any parts are entirely lost, they should be such as the imagination can easily supply from those which are still remaining. Distinct traces of the building, which is supposed to have existed, are less liable to the suspicion of artifice, than an unmeaning heap of confusion. Precision is always satisfactory, but in the reality it is only agreeable; in the copy it is essential to the imitation.

A material circumstance to the truth of the imitation is, that the ruins appear to be very old. The idea is besides interesting in itself: a monument of antiquity is never seen with indifference; and a semblance of age may be given to the representation by the hue of the materials, the growth of ivy and other plants, and cracks and fragments seemingly occasioned rather by decay than by destruction. An appendage evidently more modern than the principal structure will sometimes corroborate the effect: the shed of a cottager amidst the remains of a temple, is a contrast both to the former and to the present state of the building; and a tree flourishing among ruins, shows the length of time they have lain neglected. No circumstance so forcibly marks the desolation of a spot once inhabited, as the prevalence of nature over it:

Campos ubi Troja fuit,

is a sentence which conveys a stronger idea of a city totally overthrown, than a description of its remains; but in a representation to the eye, some remains must appear; and then the perversion of them to an ordinary use, or an intermixture of a vigorous vegetation, intimates a settled despair of their restoration.

Sect. II. *Principles of Selection and Arrangement in the Subjects of Gardening.*

Planting and Gardening, p. 602.

I. Of ART. In the lower classes of rural improvements, art should be seen as little as may be; and in the more negligent scenes of nature, every thing ought to appear as if it had been done by the general laws of nature, or had grown out of a series of fortuitous circumstances. But in the higher departments, art cannot be hid; and the *appearance* of design ought not to be excluded. A human production cannot be made perfectly natural; and held out as such it becomes an imposition. Our art lies in endeavouring to adapt the productions of nature to human taste and perceptions; and if much art be used, do not *attempt* to hide it. Art seldom fails to please when executed in a masterly manner: nay, it is frequently the design and execution, more than the production itself, that strikes us. It is the artifice, not the design, which ought to be avoided. It is the labour and not the art which ought to be concealed. The rural artist ought, therefore, upon every occasion, to endeavour to avoid labour; or, if indispensably necessary, to conceal it. No trace should be left to lead back the mind to the expensive toil. A mound raised, a mountain levelled, or a useless temple built, convey to the mind feelings equally disgusting.

Picturesque Beauty & ...

II. PICTURESQUE BEAUTY. Though the aids of art are as essential to gardening, as education is to manners; yet art may do too much: she ought to be considered as the handmaid, not as the mistress, of nature; and whether she be employed in carving a tree into the figure of an animal, or in shaping a view into the form of a picture, she is equally culpable. The nature of the place is sacred. Should this tend to landscape, from some principal point of view, assist nature and perfect it; provided this can be done without injuring the views from other points. But do not disfigure the natural features of the place:—do not sacrifice its native beauties, to the arbitrary laws of landscape painting.

> Great Nature scorns controul; she will not bear
> One beauty foreign to the spot or soil
> She gives thee to adorn: 'Tis thine alone
> To mend, not change, her features. Mason.

Nature scarcely knows the thing mankind call a *landscape*. The landscape painter seldom, if ever, finds it perfected to his hands; some addition or alteration is almost always wanted. Every man who has made his observations upon natural scenery, knows that the misletoe of the oak occurs almost as often as a perfect natural landscape; and to attempt to make up artificial landscape upon every occasion is unnatural and absurd.

If, indeed, the eye were fixed in one point, the trees could be raised to their full height at command, and the sun be made to stand still, the rural artist might work by the rules of light and shade, and compose his landscape by the painter's law. But, whilst the sun continues to pour forth its light impartially, and the trees to rise with slow progression, it would be ridiculous to attempt it. Let him rather seek out, imitate, and associate, such striking passages in nature as are immediately applicable to the place to be improved, with regard to rules of landscape, merely human:—and let him,

> ————————in this and all
> Be various, wild, and free, as Nature's self. Mason.

Instead of sacrificing the natural beauties of the place to one formal landscape, let every step disclose fresh charms unsought for.

III. Of CHARACTER. Character is very reconcilable with beauty; and, even when independent of it, has attracted so much regard, as to occasion several frivolous attempts to produce it: statues, inscriptions, and even paintings, history and mythology, and a variety of devices, have been introduced for this purpose. The heathen deities and heroes have therefore had their several places assigned to them in the woods and lawns of a garden; natural cascades have been disfigured with river gods, and columns erected only to receive quotations; the compartiments of a summer

Character. mer house have been filled with pictures of gambols and revels, as significant of gaiety; the cypress, because it was once used in funerals, has been thought peculiarly adapted to melancholy; and the decorations, the furniture, and the environs of a building, have been crowded with puerilities under pretence of propriety. All these devices are rather *emblematical* than expressive: they may be ingenious contrivances, and recal absent ideas to the recollection; but they make no immediate impression: for they must be examined, compared, perhaps explained, before the whole design of them is well understood. And though an allusion to a favourite or well known subject of history, of poetry, or of tradition, may now and then animate or dignify a scene; yet as the subject does not naturally belong to a garden, the allusion should not be principal: it should seem to have been suggested by the scene; a transitory image, which irresistibly occurred; not sought for, not laboured; and have the force of a metaphor, free from the detail of an allegory.

Of imitative characters. Another species of character arises from direct *imitation;* when a scene or an object, which has been celebrated in description, or is familiar in idea, is represented in a garden. Artificial ruins, lakes, and rivers, fall under this denomination. The air of a seat extended to a distance, and scenes calculated to raise ideas of Arcadian elegance or of rural simplicity, with many more which have been occasionally mentioned, or will obviously occur, may be ranked in this class. They are all representations. But the materials, the dimensions, and other circumstances, being the same in the copy and the original, their effects are similar in both: and if not equally strong, the defect is not in the resemblance; but the consciousness of an imitation checks that train of thought which the appearance naturally suggests. Yet an over anxious solicitude to disguise the fallacy is often the means of exposing it: too many points of likeness sometimes hurt the deception; they seem studied and forced; and the affectation of resemblance destroys the supposition of a reality. A hermitage is the habitation of a recluse; it should be distinguished by its solitude, and its simplicity: but if it is filled with crucifixes, hour glasses, beads, and every other trinket which can be thought of, the attention is diverted from enjoying the retreat to examining the particulars: all the collateral circumstances which agree with a character seldom meet in one subject; and when they are industriously brought together, though each be natural, the collection is artificial.

Of original characters. But the art of gardening aspires to more than imitation: it can create *original* characters, and give expressions to the several scenes superior to any they can receive from allusions. Certain properties, and certain dispositions, of the objects of nature, are adapted to excite particular ideas and sensations; many of them have been occasionally mentioned, and all are very well known. They require no discernment, examination, or discussion; but are obvious at a glance, and instantaneously distinguished by our feelings. Beauty alone is not so engaging as this species of character: the impressions it makes are more transient and less interesting; for it aims only at delighting the eye, but the other affects our sensibility. An assemblage of the most elegant forms in the happiest situations is to a degree indiscriminate, if they have not been selected and arranged with a design to produce certain expressions; an air of magnificence, or of simplicity, of cheerfulness, tranquillity, or some other general character, ought to pervade the whole; and objects pleasing in themselves, if they contradict that character, should therefore be excluded: those which are only indifferent must sometimes make room for such as more significant; many will often be introduced for no other merit than their expression; and some, which are in general rather disagreeable, may occasionally be recommended by it. Barrenness itself may be an acceptable circumstance in a spot dedicated to solitude and melancholy.

The power of such characters is not confined to the ideas which the objects immediately suggest; for these are connected with others, which insensibly lead to subjects far distant perhaps from the original thought, and related to it only by a similitude in the sensations they excite. In a prospect enriched and enlivened with inhabitants and cultivation, the attention is caught at first by the circumstances which are gayest in their season, the bloom of an orchard, the festivity of a hay field, and the carols of harvest home; but the cheerfulness which these infuse into the mind, expands afterwards to other objects than those immediately presented to the eye; and we are thereby disposed to receive, and delighted to pursue, a variety of pleasing ideas, and every benevolent feeling. At the sight of a ruin, reflections on the change, the decay and the desolation before us, naturally occur; and they introduce a long succession of others all tinctured with that melancholy which these have inspired; or if the monument revive the memory of former times, we do not stop at the simple fact which it records, but recollect many more coeval circumstances, which we see, not perhaps as they were, but as they are come down to us, venerable with age, and magnified by fame. Even without the assistance of buildings or other adventitious circumstances, nature alone furnishes materials for scenes which may be adapted to almost every kind of expression: their operation is general, and their consequences are infinite: the mind is elevated, depressed, or composed, as gaiety, gloom, or tranquillity, prevails in the scene; and we soon lose sight of the means by which the character is formed; we forget the particular objects it presents; and giving way to their effects, without recurring to the cause, we follow the track they have begun, to any extent which the disposition they accord with will allow. It suffices that the scenes of nature have a power to affect our imagination and our sensibility; for such is the constitution of the human mind, that if once it is agitated, the emotion spreads far beyond the occasion: when the passions are roused, their course is unrestrained; when the fancy is on the wing, its flight is unbounded; and, quitting the inanimate objects which first gave them their spring, we may be led by thought above thought, widely differing in degree, but still corresponding in character, till we rise from familiar subjects up to the sublimest conceptions, and are wrapt in the contemplation of whatever is great or beautiful, which we see in nature, feel in man, or attribute to divinity.

General Arrangement.

IV. GENERAL ARRANGEMENT. Notwithstanding the nature of the place, as already observed, ought

Hunting-Box.

Practical Treatise on Planting and Gardening.

ought not to be sacrificed to the mansion;—the house must ever be allowed to be a principal in the composition. It ought to be considered as the centre of the system; and the rays of art, like those of the sun, should grow fainter as they recede from the centre. The house itself being entirely a work of art, its immediate environs should be highly finished; but as the distance increases, the appearance of design should gradually diminish, until nature and fortuitousness have full possession of the scene.

In general, the approach should be to the back front, which, in suitable situations, ought to lie open to the pasture grounds. On the sides more highly ornamented, a well kept gravel walk may embrace the walls; to this the shaven lawn and shrubbery succeed: next, the grounds closely pastured; and lastly, the surrounding country, which ought not to be considered as out of the artist's reach: for his art consists not more in decorating particular spots, than in endeavouring to render the whole face of nature delightful.

Another reason for this mode of arrangement is, objects immediately under the eye are seen more distinctly than those at a distance, and ought to be such as are pleasing in the detail. The beauties of a flower can be discerned on a near view only; whilst at a distance a roughet of coppice wood, and the most elegant arrangement of flowering shrubs, have the same effect. The most rational entertainment the human mind is capable of receiving, is that of observing the operations of nature. The foliation of a leaf, the blowing of flowers, and the maturation of fruits, are among the most delightful subjects that a contemplative mind can be employed in. These processes of nature are slow; and except the object fall spontaneously under the eye of the observer, the inconveniences of visiting it in a remote part, so far interfere with the more important employments of life, as to blunt, if not destroy, the enjoyment. This is a strong argument in favour of shrubs and flowers being planted under or near our windows, especially those from whence they may be viewed during the hours of leisure and tranquillity.

Ibid. p. 606.

Ornamented Cottage.

Further, the vegetable creation being subject to the animal, the shrub may be cropt, or the flower trodden down in its day of beauty. If therefore we wish to converse with nature in private, intruders must be kept off,—the shrubbery be severed from the ground;—yet not in such a manner as to drive away the pasturing stock from our sight. For this reason, the shaven lawn ought not to be too extensive, and the fence which incloses it should be such as will not interrupt the view: but whether it be seen or unseen, suspected or unsuspected, is a matter of no great import: its utility in protecting the shrubs and flowers,—in keeping the horns of the cattle from the window, and the feet of the sheep from the gravel and broken ground,—in preserving that neatness on the outside, which ought to correspond with the finishings and furniture within,—render it of sufficient importance to become even a part of the ornament.

PART II. EXECUTION OF THE GENERAL SUBJECTS.

IMPROVEMENTS in general may be classed under the following heads: The *Hunting-Box*, the *Ornamented Cottage*, the *Villa*, and the *Principal Residence*.

But before any step can be taken towards the execution of the design, be it large or small, a map or plan of the place, exactly as it lies in its unimproved state, should be made; with a corresponding sketch to mark the intended improvements upon. Not a hovel nor a twig should be touched, until the artist has studied maturely the natural abilities of the place, and has decidedly fixed in his mind, and finally settled on his plan, the proposed alterations: and even then, let him "dare with caution."

1. *Of Improvements adapted to a* Hunting-Box.

Here art has little to do. Hunting may be called the amusement of nature; and the place appropriated to it ought to be no farther altered from its natural state than decency and conveniency require:—With men who live in the present age of refinement, "a want of decency is a want of sense."

Ibid. p. 610, &c.

The style throughout should be *masculine*. If shrubs be required, they should be of the hardier sorts: the box, the holly, the laurustinus. The trees should be the oak and the beech, which give in autumn an agreeable variety of foliage, and anticipate as it were the season of diversion. A suite of paddocks should be seen from the house; and if a view of distant covers can be caught, the back-ground will be complete. The stable, the kennel, and the leaping-bar, are the factitious accompaniments; in the construction of which simplicity, substantialness, and conveniency, should prevail.

2. *Of the Style of an* Ornamented Cottage.

Neatness and simplicity ought to mark the style of this rational retreat. Ostentation and show should be cautiously avoided; even elegance should not be attempted; though it may not be hid, if it offer itself spontaneously.

Nothing, however, should appear vulgar, nor should simplicity be pared down to baldness; every thing whimsical or expensive ought to be studiously avoided;—chasteness and frugality should appear in every part.

Near the house a studied neatness may take place; but at a distance, negligence should rather be the characteristic.

If a taste for botany lead to a collection of native shrubs and flowers, a shrubbery will be requisite; but in this every thing should be native. A gaudy exotic ought not to be admitted; nor should the lawn be kept close shaven; its flowers should be permitted to blow; and the herbage, when mown, ought to be carried off, and applied to some useful purpose.

In the artificial accompanyments, ornament must be subordinate; utility must preside. The buildings, if any appear, should be those in actual use in rural economics. If the hovel be wanted, let it appear; and as a side-screen, the barn and rick-yard are admissible; whilst the

the dove-house and poultry-yard may enter more freely into the composition.

In fine, the ornamented cottage ought to exhibit cultivated nature in the first stage of refinement. It ranks next above the farm-house. The plain garb of rusticity may be set off to advantage; but the studied dress of the artist ought not to appear. That becoming neatness, and those domestic conveniences, which render the rural life agreeable to a cultivated mind, are all that should be aimed at.

3. *Of the Embellishment of a* Villa.

This demands a style very different from the preceding. It ought to be elegant, rich, or grand, according to the style of the house itself, and the state of the surrounding country; the principal business of the artist being to connect these two in such a manner, that the one shall not appear naked or flaring, nor the other desolate and inhospitable.

If the house be stately, and the adjacent country rich and highly cultivated, a shrubbery may intervene, in which art may show her utmost skill. Here the artist may even be permitted to play at landscape: for a place of this kind being supposed to be small, the purpose principally ornamental, and the point of view probably confined simply to the house, side-screens may be formed, and a fore-ground laid out suitable to the best distance that can be caught.

If buildings or other artificial ornaments abound in the offscope, so as to mark it strongly, they ought also to appear more or less in the fore-ground: if the distance abound with wood, the fore-ground should be thickened, lest baldness should offend; if open and naked, elegance rather than richness ought to be studied, lest heaviness should appear.

It is far from being any part of our plan to cavil unnecessarily at artists, whether living or dead; we cannot, however, refrain from expressing a concern for the almost total neglect of the principles here in ornamenting the vicinages of villas. It is to be regretted, that in the present practice these principles seem to be generally lost sight of. Without any regard to uniting the house with the adjacent country, and, indeed, seemingly without any regard whatever to the offscape, one invariable plan of embellishment prevails; namely, that of stripping the fore-ground entirely naked, or nearly so, and surrounding it with a wavy border of shrubs and a gravel walk; leaving the area, whether large or small, one naked sheet of green sward.

In small confined spots, this plan may be eligible. But a simple border round a large unbroken lawn only serves to show what more is wanted. Simplicity in general is pleasing; but even simplicity may be carried to an extreme, so as to convey no other idea than that of poverty and baldness. Besides, how often do we see in natural scenery, the holly and the fox-glove flourishing at the foot of an oak, and the primrose and the campion adding charms to the hawthorn scattered over the pastured lawn? And we conceive that single trees footed with evergreens and native flowers, and clumps as well as borders of shrubs, are admissible in ornamental as well as in natural scenery.

The species of shrub will vary with the purpose. If the principal intention be a winter retreat, evergreens and the early-blowing shrubs should predominate; but in a place to be frequented in summer and autumn, the deciduous tribes ought chiefly to be planted.

Principal Residence.

4. *Of the* Principal Residence.

Here the whole art centres. The artist has here full scope for a display of taste and genius. He has an extent of country under his eye, and will endeavour to make the most of what nature and accident have spread before him.

Round a principal residence, a gentleman may be supposed to have some considerable estate, and it is not a shrubbery and a ground only which fall under the consideration of the artist: he ought to endeavour to disclose to the view, either from the house or some other point, as much as he conveniently can of the adjacent estate. The love of possession is deeply planted in every man's breast: and places should bow to the gratification of their owners. To curtail the view by an artificial side-screen, or any other unnatural machinery, so as to deprive a man of the satisfaction of overlooking his own estate, is an absurdity which no artist ought to be permitted to be guilty of. It is very different, however, where the property of another intrudes upon the eye: Here the view may, with some colour of propriety, be bounded by a woody screen.

The grounds, however, by a proper management, may be made independent of whatever is external; and though prospects are nowhere more delightful than from a point of view which is also a beautiful spot, yet if in the environs of such a garden they should be wanting, the elegant, picturesque, and various scenes within itself, almost supply the deficiency.

Mr Wheatley's description of Stowe gardens.

"This (says Mr Wheatley) is the character of the gardens at Stowe: for there the views in the country are only circumstances subordinate to the scenes; and the principal advantage of the situation is the variety of the ground within the inclosure. The house stands on the brow of a gentle ascent: part of the gardens lie on the declivity, and spread over the bottom beyond it: this eminence is separated by a broad winding valley from another which is higher and steeper; and the descents of both are broken by large dips and hollows, sloping down the sides of the hills. The whole space is divided into a number of scenes, each distinguished with taste and fancy; and the changes are so frequent, so sudden, and complete, the transitions so artfully conducted, that the same ideas are never continued or repeated to satiety.

These gardens were begun when regularity was in fashion; and the original boundary is still preserved, on account of its magnificence: for round the whole circuit, of between three and four miles, is carried a very broad gravel walk, planted with rows of trees, and open either to the park or the country; a deep sunk fence attends it all the way, and comprehends a space of near 400 acres. But in the interior scenes of the garden, few traces of regularity appear; where it yet remains in the plantations, it is generally disguised: every symptom, almost, of formality, is obliterated from the ground; and an octagon bason in the bottom is now converted into an irregular piece of water, which receives on one hand two beautiful streams, and falls on the other down a cascade into a lake.

In the front of the house is a considerable lawn, open to

Principal Residence.

to the water: beyond which are two elegant Doric pavilions, placed in the boundary of the garden, but not marking it, though they correspond to each other; for still further back, on the brow of some rising grounds without the inclosure, stands a noble Corinthian arch, by which the principal approach is conducted, and from which all the gardens are seen, reclining back against their hills; they are rich with plantations; full of objects; and lying on both sides of the house almost equally, every part is within a moderate distance, notwithstanding the extent of the whole.

On the right of the lawn, but concealed from the house, is a perfect garden scene, called the *queen's amphitheatre*, where art is avowed, though formality is avoided. The fore-ground is scooped into a gentle hollow. The plantations on the sides, though but just rescued from regularity, yet in style are contrasted to each other: they are, on one hand, chiefly thickets, standing out from a wood; on the other, they are open groves, through which a glimpse of the water is visible. At the end of the hollow on a little knoll, quite detached from all appendages, is placed an open Ionic rotunda: beyond it, a large lawn slopes across the view; a pyramid stands on the brow; the queen's pillar, in a recess on the descent; and all the three buildings, being evidently intended for ornament alone, are peculiarly adapted to a garden-scene. Yet their number does not render it gay: the dusky hue of the pyramid, the retired situation of the queen's pillar, and the solitary appearance of the rotunda, give it an air of gravity; it is encompassed with wood; and all the external views are excluded; even the opening into the lawn is but an opening into an inclosure.

At the king's pillar, very near to this, is another lovely spot; which is small, but not confined; for no termination appears; the ground one way, the water another, retire under the trees out of sight, but nowhere meet with a boundary. The view is first over some very broken ground, thinly and irregularly planted; then between two beautiful clumps, which feather down to the bottom; and afterwards across a glade, and through a little grove beyond it, to that part of the lake where the thickets close upon the brink, spread a tranquillity over the surface, in which their shadows are reflected. Nothing is admitted to disturb that quiet: no building obtrudes; for objects to fix the eye are needless in a scene which may be comprehended at a glance; and none would suit the pastoral idea it inspires, of elegance too refined for a cottage, and of simplicity too pure for any other edifice.

The situation of the rotunda promises a prospect more enlarged; and in fact most of the objects on this side of the garden are there visible: but they want both connexion and contrast; each belongs peculiarly to some other spot: they are all blended together in this, without meaning; and are rather shown on a map, than formed into a picture. The water only is capital; a broad expanse of it is so near as to be seen under the little groups on the bank without interruption. Beyond it is a wood, which in one place leaves the lake, to run up behind a beautiful building, of three pavilions joined by arcades, all of the Ionic order: it is called *Kent's Building*. And never was a design more happily conceived: it seems to be characteristically proper for a garden; it is so elegant, so varied, and so purely ornamental: it directly fronts the rotunda, and a narrow rim of the country appears above the trees beyond it. But the effect even of this noble object is fainter here than at other points: its position is not the most advantageous; and it is but one among many other buildings, none of which are principal.

The scene at the temple of Bacchus is in character directly the reverse of that about the rotunda, though the space and the objects are nearly the same in both: but in this, all the parts concur to form one whole. The ground from every side shelves gradually towards the lake; the plantations on the further bank open to show Kent's building, rise from the water's edge towards the knoll on which it stands, and close again behind it. That elegant structure, inclined a little from a front view, becomes more beautiful by being thrown into perspective; and though at a greater distance, is more important than before, because it is alone in the view: for the queen's pillar and the rotunda are removed far aside; and every other circumstance refers to this interesting object: the water attracts, the ground and the plantations direct, the eye thither: and the country does not just glimmer in the offscape, but is close and eminent above the wood, and connected by clumps with the garden. The scene altogether is a most animated landscape; and the splendor of the building; the reflection in the lake; the transparency of the water, and picturesque beauty of its form, diversified by little groups on the brink, while on the broadest expanse no more trees cast their shadows than are sufficient to vary the tints of the surface; all these circumstances, vying in lustre with each other, and uniting in the point to which every part of the scene is related, diffuse a peculiar brilliancy over the whole composition.

The view from Kent's building is very different from those which have been hitherto described. They are all directed down the declivity of the lawn. This rises up the ascent: the eminence being crowned with lofty wood, becomes thereby more considerable; and the hillocks into which the general fall is broken, sloping further out this way than any other, they also acquire an importance which they had not before; that, particularly, on which the rotunda is placed, seems here to be a profound situation; and the structure appears to be properly adapted to so open an exposure. The temple of Bacchus, on the contrary, which commands such an illustrious view, is itself a retired object, close under the covert. The wood rising on the brow, and descending down one side of the hill, is shown to be deep; is high, and seems to be higher than it is. The lawn too is extensive; and part of the boundary being concealed, it suggests the idea of a still greater extent. A small portion only of the lake indeed is visible; but it is not here an object: it is a part of the spot; and neither termination being in sight, it has no diminutive appearance: if more water had been admitted, it might have hurt the character of the place, which is sober and temperate; neither solemn nor gay; great and simple, but elegant; above rusticity, yet free from ostentation.

These are the principal scenes on one side of the gardens. On the other, close to the lawn before the house, is

Principal Residence.

is the winding valley above mentioned: the lower part of it is assigned to the Elysian fields. These are watered by a lovely rivulet; are very lightsome, and very airy, so thinly are the trees scattered about them; are open at one end to more water and a larger glade; and the rest of the boundary is frequently broken to let in objects afar off, which appear still more distant from the manner of showing them. The entrance is under a Doric arch, which coincides with an opening among the trees, and forms a kind of vista, through which a Pembroke bridge just below, and a lodge built like a castle in the park, are seen in a beautiful perspective. That bridge is at one extremity of the gardens; the queen's pillar is at another; yet both are visible from the same station in the Elysian fields: and all these external objects are unaffectedly introduced, divested of their own appurtenances, and combined with others which belong to the spot. The temple of Friendship is also in sight, just without the place; and within it are the temples of ancient Virtue, and of the British worthies; the one in an elevated situation, the other low down in the valley, and near to the water: both are decorated with the effigies of those who have been most distinguised for military, civil, or literary merit; and near to the former stands a rostral column, sacred to the memory of Captain Grenville, who fell in an action at sea: by placing here the meed of valour, and by filling these fields with the representations of those who have deserved best of mankind, the character intended to be given to the spot is justly and poetically expressed; and the number of the images which are presented or excited, perfectly corresponds with it. Solitude was never reckoned among the charms of Elysium; it has been always pictured as the mansion of delight and of joy: and in this imitation, every circumstance accords with that established idea. The vivacity of the stream which flows through the vale; the glimpses of another approaching to join it; the sprightly verdure of the green sward, and every bust of the British worthies reflected in the water; the variety of the trees; the lightness of the greens; their disposition; all of them distinct objects, and dispersed over gentle inequalities of the ground; together with the multiplicity of objects both within and without, which embellish and enliven the scene; give it a gaiety, which the imagination can hardly conceive, or the heart wish to be exceeded.

Close by this spot, and a perfect contrast to it, is the alder grove; a deep recess in the midst of a shade, which the blaze of noon cannot brighten. The water seems to be a stagnated pool, eating into its banks; and of a peculiar colour, not dirty but clouded, and dimly reflecting the dun hue of the horse-chesnuts and alders which press upon the brink: the stems of the latter, rising in clusters from the same root, bear one another down, and slant over the water. Mishapen elms and ragged firs are frequent in the wood which encompasses the hollow; the trunks of dead trees are left standing amongst them: and the uncouth sumach, and the yew, with elder, nut, and holly, compose the underwood: some limes and laurels are intermixed; but they are not many; the wood is in general of the darkest greens; and the foliage is thickened with ivy, which not only twines up the trees, but creeps also over the falls of the ground: these are steep and abrupt: the gravel-walk is covered with moss; and a grotto at the end, faced with broken flints and pebbles, preserves, in the simplicity of its materials, and the duskiness of its colour, all the character of its situation: two little rotundas near it were better away; one building is sufficient for such a scene of solitude as this, in which more circumstances of gloom concur than were perhaps ever collected together.

Immediately above the alder-grove is the principal eminence in the gardens. It is divided by a great dip into two pinnacles; upon one of which is a large Gothic building. The space before this structure is an extensive lawn: the ground on one side falls immediately into the dip; and the trees which border the lawn, sinking with the ground, the house rises above them, and fills the interval: the vast pile seems to be still larger than it is; for it is thrown into perspective, and between and above the heads of the trees, the upper story, the porticoes, the turrets, and ballustrades, and all the slated roofs, appear in a noble confusion. On the other side of the Gothic building, the ground slopes down a long continued declivity into a bottom, which seems to be perfectly irriguous. Divers streams wander about it in several directions: the conflux of that which runs from the Elysian fields with another below it, is full in sight; and a plain wooden bridge thrown over the latter, and evidently designed for a passage, imposes an air of reality on the river. Beyond it is one of the Doric porticoes which front the house; but now it is alone; it stands on a little bank above the water, and is seen under some trees at a distance before it; thus grouped, and thus accompanied, it is a happy incident, concurring with many other circumstances to distinguish this landscape by a character of cheerfulness and amenity.

From the Gothic building a broad walk leads to the Grecian valley, which is a scene of more grandeur than any in the gardens. It enters them from the park, spreading at first to a considerable breadth; then winds; grows narrower, but deeper; and loses itself at last in a thicket, behind some lofty elms, which interrupt the sight of the termination. Lovely woods and groves hang all the way on the declivities: and the open space is broken by detached trees; which, near the park, are cautiously and sparingly introduced, lest the breadth should be contracted by them; but as the valley sinks, they advance more boldly down the sides, stretch across or along the bottom, and cluster at times into groups and forms, which multiply the varieties of the larger plantations. Those are sometimes close coverts, and sometimes open groves: the trees rise in one upon high stems, and feather down to the bottom in another; and between them are short openings into the park or the gardens. In the midst of the scene, just at the bend of the valley, and commanding it on both sides, upon a large, easy, natural rise, is placed the temple of Concord and Victory: at one place its majestic front of six Ionic columns, supporting a pediment filled with bas relief, and the points of it crowned with statues, faces the view; at another, the beautiful colonnade, on the side, of 10 lofty pillars, retires in perspective. It is seen from every part; and impressing its own character of dignity on all around, in spreads an awe over the whole: but no gloom, no melancholy, attends it: the sensations it excites are rather

Principal Residence.

ther placid; but full of respect, admiration, and solemnity: no water appears to enliven, no distant prospect to enrich the view; the parts of the scene are large, the idea of it sublime, and the execution happy; it is independent of all adventitious circumstances, and relies on itself for its greatness.

The scenes which have been described are such as are most remarkable for beauty or character; but the gardens contain many more; and even the objects in these, by their several combinations, produce very different effects, within the distance sometimes of a few paces, from the unevenness of the ground, the variety of the plantations, and the number of the buildings. The multiplicity of the last has indeed been often urged as an objection to Stowe; and certainly, when all are seen by a stranger in two or three hours, twenty or thirty capital structures, mixed with others of inferior note, do seem too many. But the growth of the wood every day weakens the objection, by concealing them one from the other: each belongs to a distinct scene; and if they are considered separately, at different times, and at leisure, it may be difficult to determine which to take away. Yet still it must be acknowledged that their frequency destroys all ideas of silence and retirement. Magnificence and splendor are the characteristics of Stowe: it is like one of those places celebrated in antiquity, which were devoted to the purposes of religion, and filled with sacred groves, hallowed fountains, and temples dedicated to several deities; the resort of distant nations, and the object of veneration to half the heathen world: this pomp is, at Stowe, blended with beauty; and the place is equally distinguished by its amenity and its grandeur.

In the midst of so much embellishment as may be introduced into this species of garden, a plain field, or a sheep-walk, is sometimes an agreeable relief, and even wilder scenes may occasionally be admitted. These indeed are not properly parts of a garden, but they may be comprehended within the verge of it; and the proximity to the more ornamented scenes is at least a convenience, that the transition from the one to the other may be easy, and the change always in our option. For though a spot in the highest state of improvement be a necessary appendage to a seat; yet, in a place which is perfect, other characters will not be wanting: if they cannot be had on a large scale, they are acceptable on a smaller; and so many circumstances are common to all, that they might often be intermixed; they may always border on each other."

Practical Treatise on Planting and Gardening, p. 615.

But on this head it would be in vain to attempt to lay down particular rules: different places are marked by sets of features as different from each other as are those in men's faces. Much must be left to the skill and taste of the artist; and let those be what they may, nothing but mature study of the natural abilities of the particular place to be improved can render him equal to the execution, so as to make the most of the materials that are placed before him.

Some few general rules may nevertheless be laid down. The approach ought to be conducted in such a manner, that the striking features of the place shall burst upon the view at once: no trick however should be made use of: all should appear to fall in naturally. In leading towards the house, its direction should not be fully in front, not exactly at an angle, but should pass obliquely upon the house and its accompaniments; so that their position with respect to each other, as well as the perspective appearance of the house itself, may vary at every step: and having shown the front and the principal wing, or other accompaniment, to advantage, the approach should wind to the back front, which, as has been already observed, ought to lie open to the park or pastured grounds.

The improvements and the rooms from which they are to be seen should be in unison. Thus, the view from the drawing-room should be highly embellished, to correspond with the beauty and elegance within: every thing here should be feminine, elegant, beautiful, such as attunes the mind to politeness and lively conversation. The breakfasting room should have more masculine objects in view: wood, water, and an extended country for the eye to roam over; such as allures us imperceptibly to the ride or the chase. The eating and banqueting rooms need no exterior allurements.

There is a harmony in taste as in music: variety, and even wildness upon some occasions, may be admitted; but discord cannot be allowed. If, therefore, a place be so circumstanced as to consist of properties totally irreconcileable, the parts ought, if possible, to be separated in such a manner, that, like the air and the recitative, the adagio and the allegro, in music, they may set off each other's charms by the contrast.—These observations, in the elegant performance whence they are extracted, the author illustrates by the following description and proposed improvement of Persefield, the seat of Mr Morris, near Chepstow in Monmouthshire; a place upon which nature has been peculiarly lavish of her favours, and which has been spoken of by Mr Wheatley, Mr Gilpin, and other writers, in the most flattering terms.

Description of Persefield, ib. p. 61[illegible].

"Persefield is situated upon the banks of the river Wye, which divides Gloucestershire and Monmouthshire, and which was formerly the boundary between England and Wales. The general tendency of the river is from north to south; but about Persefield it describes by its winding course the letter S, somewhat compressed, so as to reduce it in length and increase its width. The grounds of Persefield are lifted high above the bed of the river, shelving, and form the brink of a lofty and steep precipice, towards the southwest.

"The lower limb of the letter is filled with Persewood, which makes a part of Persefield; but it is at present an impenetrable thicket of coppice-wood. This dips to the south-east down to the water's edge; and, seen from the top of the opposite rock, has a good effect.

"The upper limb receives the farms of Llancot, rich and highly cultivated, broken into inclosures, and scattered with groups and single trees; two well-looking farm-houses in the centre, and a neat white chapel on one side: altogether a lovely little paradisaical spot. The lowliness of its situation stamps it with an air of meekness and humility; and the natural barriers which surround it add that of peacefulness and security. The picturesque farms do not form a low flat bottom, subject to be overflowed by the river; but take the form of a gorget, rising fullest in the middle, and falling on every side gently to the brink of the Wye; except

Principal Residence.

except on the east side, where the top of the gorget leans in an easy manner against a range of perpendicular rock; as if to show its disk with advantage to the walks of Persefield.

"This rock stretches across what may be called the *Isthmus*, leaving only a narrow pass down into the fields of Llancot, and joins the principal range of rocks at the lower bend of the river.

"To the north, at the head of the latter, stands an immense rock (or rather a pile of immense rocks heaped one above another) called *Windcliff;* the top of which is elevated as much above the grounds of Persefield as those are above the fields of Llancot.

"These several rocks, with the wooded precipices on the side of Persefield, form a circular inclosure, about a mile in diameter, including Perse-wood, Llancot, the Wye, and a small meadow lying at the foot of Windcliff.

"The grounds are divided into the upper and lower lawn, by the approach to the house: a small irregular building, standing near the brink of the precipice, but facing down the lower lawn, a beautiful ground, falling 'precipitately every way into a valley which shelves down in the middle,' and is scattered with groups and single trees in an excellent style.

"The view from the house is soft, rich, and beautifully picturesque; the lawn and woods of Persefield and the opposite banks of the river; the Wye, near its mouth, winding through 'meadows green as emerald,' in a manner peculiarly graceful; the Severn, here very broad, backed by the wooded and highly cultivated hills of Gloucestershire, Wiltshire, and Somersetshire. Not one rock enters into the composition. The whole view consists of an elegant arrangement of lawn, wood, and water.

"The upper lawn is a less beautiful ground, and the view from it, though it command the 'cultivated hills and rich valleys of Monmouthshire,' bounded by the Severn and backed by the Mendip-hills, is much inferior to that from the house.

"To give variety to the views from Persefield, to disclose the native grandeur, which surrounds it, and to set off its more striking features to advantage, walks have been cut through the woods and on the face of the precipice which border the grounds to the south and east. The viewer enters these walks at the lower corner of the lower lawn.

"The first point of view is marked by an alcove, from which are seen the bridge and the town of Chepstow, with its castle situated in a remarkable manner on the very brink of a perpendicular rock, washed by the Wye; and beyond these the Severn shows a small portion of its silvery surface.

"Proceeding a little farther along the walk, a view is caught which the painter might call a complete landscape: The castle, with the serpentine part of the Wye below Chepstow, intermixed in a peculiar manner with the broad waters of the Severn, forms the fore-ground; which is backed by distant hills: the rocks, crowned with wood, lying between the alcove and the castle, to the right, and Castlehill farm, elevated upon the opposite banks of the river, to the left, form the two side-screens. This point is not marked, and must frequently be lost to the stranger.

"The grotto, situated at the head of Perse-wood, commands a near view of the opposite rocks; magnificent beyond description! The littleness of human art was never placed in a more humiliating point of view; the castle of Chepstow, a noble fortress, is, compared with the natural bulwarks, a mere house of cards.

"Above the grotto, upon the isthmus of the Persefield side, is a shrubbery; strangely misplaced! an unpardonable intrusion upon the native grandeur of this scene. Mr Gilpin's observations upon this, as upon every other occasion, are very just. He says, 'It is a pity the ingenious embellisher of these scenes could not have been satisfied with the great beauties of nature which he commanded. The shrubberies he has introduced in this part of his improvements I fear will rather be esteemed paltry.'——'It is not the shrub which offends; it is the formal introduction of it. Wild underwood may be an appendage of the grandest scene; it is a beautiful appendage. A bed of violets or of lilies may enamel the ground with propriety at the foot of an oak; but if you introduce them artificially in a border, you introduce a trifling formality, and disgrace the noble object you wish to adorn.'

"The walk now leaves the wood, and opens upon the lower lawn, until coming near the house it enters the alarming precipice facing Llancot; winding along the face of it in a manner which does great honour to the artist. Sometimes the fragments of rock which fall in its way are avoided, at other times partially removed, so as to conduct the path along a ledge carved out of the rock; and in one instance, a huge fragment, of a somewhat conical shape and many yards high, is perforated; the path leading through its base. This is a thought which will hand down to future times the greatness of Mr Morris's taste; the design and the execution are equally great; not a mark of a tool to be seen; all appears perfectly natural. The arch-way is made winding, so that on the approach it appears to be the mouth of a cave; and, on a nearer view, the idea is strengthened by an allowable deception; a black dark hole on the side next the cliff, which, seen from the entrance before the perforation is discovered, appears to be the darksome inlet into the body of the cave.

From this point, that vast inclosure of rocks and precipices which marks the peculiar magnificence of Persefield is seen to advantage. The area, containing in this point of view the fields of Llancot and the lower margin of Perse-wood, is broken in a manner peculiarly picturesque by the graceful winding of the Wye; here washing a low grassy shore, and there sweeping at the feet of the rocks which rise in some places perpendicular from the water; but in general they have a wooded offset at the base; above which they rise to one, two, or perhaps three or four hundred feet high; exposing one full face, silvered by age, and bearded with ivy, growing out of the wrinkle-like seams and fissures. If one might be allowed to compare the paltry performances of art with the magnificent works of nature, we should say, that this inclosure resembles a prodigious fortress which has long lain in ruins. It is in reality one of nature's strong-holds; and as such has probably been frequently made use of. Across the isthmus on the Gloucestershire side there are the remains of a deep intrenchment, called to this day the *Bulwark;*

Principal Residence.

Bulwark; and tradition still teems with the extraordinary warlike feats that have been performed among this romantic scenery.

"From the perforated rock, the walk leads down to the cold-bath (a complete place), seated about the mid-way of the precipice, in this part less steep; and from the cold-bath a rough path winds down to the meadow, by the side of the Wye, from whence the precipice on the Persefield side is seen with every advantage; the giant fragments, hung with shrubs and ivy, rise in a ghastly manner from amongst the underwood, and show themselves in all their native savageness.

"From the cold-bath upward, a coach-road (very steep and difficult) leads to the top of the cliff, at the upper corner of the upper lawn. Near the top of the road is a point which commands one of the most pleasing views of Persefield: The Wye sweeping through a grassy vale which opens to the left:—Llancot backed by its rocks, with the Severn immediately behind them; and, seen in this point of view, seems to be divided from the Wye by only a sharp ridge of rock, with a precipice on either side; and behind the Severn, the vale and wooded hills of Gloucestershire.

"From this place a road leads to the top of Windcliff—astonishing sight! The face of nature probably affords not a more magnificent scene! Llancot in all its grandeur, the ground of Persefield, the castle and town of Chepstow, the graceful windings of the Wye below, and its conflux with the Severn; to the left the forest of Dean; to the right, the rich marshes and picturesque mountains of South Wales; a broad view of the Severn, opening its sea-like mouth; the conflux of the Avon, with merchant ships at anchor in King-road, and vessels of different descriptions under sail; Aust-Cliff, and the whole vale of Berkeley, backed by the wooded swells of Gloucestershire, the view terminating in clouds of distant hills, rising one behind another, until the eye becomes unable to distinguish the earth's billowy surface from the clouds themselves."

The leading principle of the improvement proposed by our author is, to, "separate the sublime from the beautiful; so that in viewing the one, the eye might not so much as suspect that the other was near.

"Let the hanging walk be conducted entirely along the precipices, or through the thickets, so as to disclose the natural scenery, without once discovering the lawn or any other acquired softness. Let the path be as rude as if trodden only by wild beasts and savages, and the resting places, if any, as rustic as possible.

"Erase entirely the present shrubbery, and lay out another as elegant as nature and art could render it before the house, swelling it out into the lawn towards the stables; between which and the kitchen-garden make a narrow winding entrance.

"Convert the upper lawn into a deer-paddock, suffering it to run as wild, rough, and forest-like, as total negligence would render it.

"The viewer would then be thus conducted: He would enter the hanging-walk by a sequestrated path at the lower corner of the lawn, pursuing it through the wood to beneath the grotto, and round the head-land, or winding through Perse-wood, to the perforated rock and the cold-bath, without once conceiving an idea (if possible) that art, or at least that much art, had been made use of in disclosing the natural grandeur of the surrounding objects; which ought to appear as if they presented themselves to his view, or at most as if nothing was wanted but his own penetration and judgement to find them out. The walk should therefore be conducted in such a manner, that the breaks might be quite natural; yet the points of view obvious, or requiring nothing but a block or stone to mark them. A stranger at least wants no seat here; he is too eager in the early part of his walk, to think of lounging upon a bench.

"From the cold bath he would ascend the steep, near the top of which a commodious bench or benches might be placed: the fatigue of ascending the hill would require a resting place; and there are few points which afford a more pleasing view than this; it is grand, without being too broad and glaring.

"From these branches he would enter the forest part. Here the idea of Nature in her primitive state would be strengthened: the roughnesses and deer to the right, and the rocks in all their native wilduess to the left. Even Llancot might be shut out from the view by the natural shrubbery of the cliff. The Lover's Leap, however (a tremendous peep), might remain; but no benches, nor other work of art, should here be seen. A natural path, deviating near the brink of the precipice, would bring the viewer down to the lower corner of the park; where benches should be placed in a happy point, so as to give a full view of the rocks and native wildnesses, and at the same time hide the farm houses, fields, and other acquired beauties of Llancot.

"Having satiated himself with this savage scene, he would be led, by a still rustic path, through the labyrinth—when the shrubbery, the lawn, with all its appendages, the graceful Wye, and the broad silver Severn, would break upon the eye with every advantage of ornamental nature: the transition could not fail to strike.

"From this soft scene he would be shown to the top of Windcliff, where in one vast view he would unite the sublime and beautiful of Persefield."

Only one particular remains now to be noticed. A place which is the residence of a family all the year is very defective, if some portion of it be not set apart for the enjoyment of a fine day, for air, and exercise, in winter. To such a spot shelter is absolutely essential; and evergreens being the thickest covert, are therefore the best; their verdure also is then agreeable to the eye; and they may be arrauged so as to produce beautiful mixture of greens, with more certainty than deciduous trees, and with almost equal variety: they may be collected into a wood; and through that wood gravel-walks may be led along openings of a considerable breadth, free from large trees which would intercept the rays of the sun, and winding in such a manner as to avoid any draft of wind, from whatever quarter it may blow. But when a retreat at all times is thus secured, other spots may be adapted only to occasional purposes; and be sheltered towards the north or the east on one hand, while they are open to the sun on the other. The few hours of cheerfulness and warmth which its beams afford are so valuable as to justify the sacrifice even of the principles of beauty to the enjoyment of them; and therefore no objections

Principal Residence. objections of sameness or formality can prevail against the pleasantness of a straight walk, under a thick hedge or a south wall. The eye may, however, be distorted from the skreen by a border before it, where the aconite and the snowdrop, the crocus and hepatica, brought forward by the warmth of the situation, will be welcome harbingers of spring; and on the opposite side of the walk little tufts of laurustines, and of variegated evergreens, may be planted. The spot thus enlivened by a variety of colours, and even a degree of bloom, may be still further improved by a green-house. The entertainment which exotics afford peculiarly belongs to this part of the year; and if amongst them be interspersed some of our earliest flowers, they will there blow before their time, and anticipate the gaiety of the season which is advancing. The walk may also lead to the stoves, where the climate and the plants are always the same. And the kitchen-garden should not be far off; for that is never quite destitute of produce, and always an active scene: the appearance of business is alone engaging; and the occupations there are an earnest of the happier seasons to which they are preparative. By these expedients even the winter may be rendered cheerful in a place where shelter is provided against all but the bitterest inclemencies of the sky, and agreeable objects and interesting amusements are contrived for every hour of tolerable weather.

PART III. PRACTICAL GARDENING.

WE now proceed to treat of horticulture or practical gardening. And although it may not appear to be the most perfect arrangement; yet as it is probably the most convenient and useful in the directions to be given for the practical management of the garden, we shall consider the work to be done for each month of the year in the kitchen garden, the fruit garden, the flower garden and the nursery, under so many separate sections.

JANUARY.

SECT. I. *Kitchen Garden.*

Sowing radishes. IN the beginning, or any time in the course of this month, when the weather is open, sow some short-top'd radishes on a border exposed to the south, and protected by a wall or other fence; and about the middle or latter end of the month, you may sow some more of the same sort, and also some salmon radishes to succeed the short-top'd. The seed should be sown pretty thick at this season, because vegetation being slow at this period they will be longer exposed to the depredation of birds, and if the weather prove severe, many of them will be cut off after they have appeared above ground. Sow the seed evenly over the surface, and rake it in with a large wide-toothed rake, or if sown in beds, cover it with earth to the depth of half an inch from the alleys. A covering of straw about two inches thick would greatly promote their growth, and protect them from frost and birds. After the plants have come above ground, the covering of straw should be drawn off with a light rake in the early part of the day, and replaced in the evening.

Garden mats are frequently used to cover radishes, a number of small pins being previously stuck into the ground to support them an inch or two from the surface, and prevent them from pressing down the young plants. The covering ought to be continued for a longer or shorter time, according to the severity of the weather; but when the plants have pushed out their rough leaves it may safely be discontinued. Radishes sown under common hot-bed frames, without the assistance of warm dung, will succeed very well, and come on much earlier than those sown in the open air: due attention, however, must be paid to give them air whenever the weather is mild, by raising the glasses, or removing them altogether during warm days. If wanted very early, recourse must be had to a slight hot-bed.

At any time in this month, when the weather is mild and dry, let a spot of ground in a warm situation be prepared for sowing a few early carrots, by digging the ground a full spade deep, and breaking the earth well; and when the seed is sown, let it be raked in. When carrots are wanted very early, they may be reared in a slight hot-bed. 18 Carrots.

About the beginning, or any time in the month, when the weather is mild, you may sow some spinach; but if the weather will permit, some ought to be sown, both in the beginning and towards the end of the month. The smooth-seeded or round-leaved spinach should chiefly be sown now. It is preferred, on account of its leaves being thicker, larger, and more succulent than the prickly-seeded; though some of the latter ought also to be sown, because it is hardier, and better able to sustain the severity of the weather. They may be sown either broadcast and raked in, or in shallow drills about an inch deep, and nine or ten inches asunder. It is a frequent practice to sow spinach in drills between the rows of early beans and cabbages. 19 Spinach.

You may sow some seed of cress, mustard, radish, rape, &c. and likewise some lap lettuce in a warm situation exposed to the sun. They form an agreeable salad when cut young. The ground on which they are to be sown ought to be sloped to the south, and covered with a common hot-bed frame, which should be sunk in the ground, so far as to allow the glasses to approach to within six or eight inches of the sown surface. 20 Small salad.

But small salad will succeed best in a slight hot-bed of warm dung formed to the depth of 18 or 20 inches; air must be admitted freely, whenever the weather will permit, by raising or removing the glasses.

About the middle, or towards the latter end of the month, sow parsley seed in any dry situation, in shallow drills nine inches asunder, and cover it in with earth to the depth of a quarter of an inch, or in single rows along the borders of the kitchen garden. There are two sorts, the plain-leaved and curled-leaved; the latter is preferred as garnishing on account of its large bushy leaves, 21 Parsley.

January. Kitchen Garden.

leaves, but both are equally good as pot herbs. This seed lies very long in the ground before it vegetates.

22 Peas. Sow some early peas in a warm situation, to succeed those sown in November and December. The principal early peas are the Charlton hotspur, golden hotspur, Reading hotspur, Masters hotspur, &c. the two first of which are reckoned the earliest. Sow them in rows two feet and a half asunder, but when they are to be supported by sticks they ought to be three feet asunder. Some marrowfat peas should likewise be sown at this season for a first crop of late peas: the dwarf marrowfat is the most proper, but any other late pea will succeed very well, such as the Spanish moratto, tall marrowfat, Prussian prolific, sugar pea, dwarf sugar, egg pea, pearl pea, &c. These should be sown in rows three feet asunder; but when it is intended that they should be supported by sticks, the rows should be three feet and a half apart.

23 Beans. Any time in the course of the month, if the weather be mild, a main crop of beans may be sown. The Sandwich bean, toker, Windsor, broad Spanish, broad long-pod, &c. are the kinds most commonly used. After the ground has been well dug, put in the beans to the depth of about two inches, with a dibble, in rows three feet apart, and at the distance of four or five inches from each other in the rows: or they may be sown in drills to the same depth and distance. If no early beans were sown in November or December, they ought to be sown the earliest opportunity this month: the early Mazagan and Lisbon beans are the best. They ought to be planted in a warm border; if at the foot of a south wall, they will come on earlier. These may be planted closer than the larger beans, two feet, or two feet and a half, between the rows, being sufficient. When peas or beans are wanted very early, they may be sown in hot-beds or stoves, and when somewhat advanced, they may either be planted out into other hot-beds, into peach and vine-houses, or into any warm situation in the open air.

24 Lettuce. In the beginning, and again towards the end of the month, you may sow some lettuce. The kinds commonly used are the green and white cos, brown Dutch, Cilicia, and common cabbage lettuce. Prepare a piece of ground in a warm situation; sow the seeds moderately thick, and rake them in as evenly as possible. They may also be sown under hand glasses or in common hot-bed frames, to be occasionally covered with glasses or mats: but in either case, air must be freely admitted, whenever the weather will permit. When wished for very early, they may be sown in a slight hot-bed, and planted out in the open air in March or April.

Take care of lettuce plants which have stood the winter.—If you have lettuce plants in frames or under hoops, covered with mats, give them plenty of air when the weather is moderate. Remove all decayed leaves, and destroy snails which frequently infest them; and when the frost is severe, take care to protect them well with mats.

25 Examine cauliflower plants. The cauliflower plants raised last autumn, which have stood during the winter in frames, should be looked over in open weather. If any decayed leaves appear, pick them off; stir up the earth between the plants, and remove all weeds. In mild weather, give them plenty of air during the day, by pushing down, or removing the glasses altogether: but cover them during the night, unless when the weather is particularly mild: when it is frosty, or rains much, they ought to be covered during the day. But if the frost is very severe, the frames should be protected at night with a covering of mats, and even during the day, should the frost be intense, without sunshine; and some straw, dried leaves, or something of that nature, should likewise be laid all round the outside of the frame, to prevent the frost from penetrating its sides.

Cauliflowers under bell and hand glasses require the same attention: during mild weather, the covers should either be taken off altogether, or raised (or tilted) on the south side, so as to admit the air freely during the day, and shut again at night, unless the weather should be very mild, in which case they may remain a little tilted on one side; but should intense frost prevail, they should be kept shut, and covered with straw or something of that nature. The free admission of the air will prevent the plants from becoming weak, and make them less apt to run up to flower before they have acquired sufficient size. In mild winters, slugs very frequently injure cauliflower plants; they ought, therefore, to be carefully looked for and destroyed.

26 Plant cabbages. About the end of the month, if the weather is mild, plant out a few early cabbages, on a spot of ground well dug and manured with rotten dung, at the distance of a foot and a half from each other, or even closer, as they are to be cut early, and before they acquire a great size. The early York, Battersea, and sugar-loaf, are the kinds which should be planted at this season.

27 Transplant cabbages, &c. for seed. Transplant some full grown cabbages and savoys, for seed, about the beginning of the month; though the early part of winter is the most proper time for doing so. See NOVEMBER.

28 Earth celery. In open dry weather, earth up such celery as has advanced much above ground; let the earth be well broken, and laid up almost to the tops of the plants, but care must be taken not to bruise them. This will afford them protection against frost, which might prove very injurious to them at this season.

Where celery is wanted daily, a quantity of straw or something of that nature, should be laid over the rows on the approach of frost, which will prevent the frost from penetrating the ground, and on the removal of the covering, the celery may be dug up: or when severe weather threatens to set in, a quantity of celery may be taken up, placed in some situation sheltered from the weather, and covered as far as the blanched part extends with sand.

29 Blanch endive. In open dry weather prepare some full grown endive for blanching. When the plants are perfectly dry tie up their leaves close together, and they will be completely blanched in about a fortnight. As endive is very apt to rot in wet weather at this season, when blanched in the open air, a quantity of it ought to be transplanted into a ridge of dry earth, in some situation where it may be sheltered from rain.

30 Earth peas and beans. In open dry weather, the earth should be drawn up about such peas and beans as may have advanced an inch or two above ground, which will both strengthen them and protect them against frost.

If

January. Kitchen Garden.

Artichokes. Management of mushroom beds.

If artichokes have not been earthed up before this, that work should now be done the first opportunity. See NOVEMBER.

Mushroom beds ought to be well covered at this season, and protected both from rain and frost. The covering of straw should at least be a foot thick, and if the rain should at any time have penetrated nearly through it, it ought to be removed, and a covering of dry straw put in its place; for if the bed should get wet, the spawn would be injured, and the future crop destroyed.

Sometimes it is desirable to have some of the ordinary kitchen garden crops, at an earlier period, than that at which they are produced in the open air. For this purpose recourse is had to hot-beds; there are likewise some things reared in the kitchen garden, such as cucumbers and melons, which cannot be obtained in this country without their aid. The principal crops, besides cucumbers and melons, for which hot-beds may be prepared in this month, are asparagus, small salad, mint, tansey, peas and beans for transplanting, radishes, early carrots, early potatoes, and kidney beans. Hot-beds are formed either of fresh horse dung, or of tanners bark; the hot-beds used this month, as seed beds for early cucumbers and melons, are almost always formed of horse dung. Procure a sufficient quantity of fresh horse dung, according to the size and number of the hot-beds you mean to form, lay it up in a heap to ferment for ten or twelve days, longer or shorter according to the condition of the dung or the state of the weather, during which time it ought to be turned over once or twice with a fork, that it may be thoroughly mixed and equally fermented. After the violent fermentation is over, and the rank steam has escaped, it will be in proper condition to form a hot-bed. Dung that is very much mixed with straw, or is too dry, ought to be rejected. About a cart-load may be sufficient for a common hot-bed frame of one light, and so on in proportion for one of two or three lights. Hot-beds should be formed in a situation sheltered from the wind, and exposed to the morning or mid-day sun. Some dig a trench about a foot deep, and a few inches longer and wider than the frame with which they mean to cover the bed; others form hot-beds on the surface of the ground. At this season of the year the last mode is to be preferred, because it affords an opportunity of lining the bed with fresh hot dung quite down to the bottom, to augment the heat when it declines; in this way water is likewise prevented from settling about the bottom of the bed, which is often the case, when the bed is formed in a trench, which would inevitably check the fermentation, and consequently destroy the heat of the bed. Mark out a space on the ground, a few inches longer and wider than the frame which you intend to put on the bed. Spread the dung when in proper condition, regularly with a fork, beating it down gently from time to time with the fork; when the dung is trodden down, it is apt to heat too violently, and does not succeed so well as when the dung is allowed to settle gradually. The dung ought to be raised to three feet and a half or thereabouts. In this way hot beds may be formed, which will preserve their heat for a considerable time: When slighter hot-beds are required, the dung may be raised to one foot and a half, or two feet: those slight hot-beds answer very well for raising early crops.

33 Sow cucumber and melon seeds.

Having prepared a hot-bed according to the directions just given for a larger or smaller frame, in proportion to the quantity of seed you intend to sow, such a one as may be covered with a frame of one light will be sufficient to raise plants for an ordinary crop. Let the frame and lights be put on, and kept close, till the heat begin to rise, then raise the glass, that the steam may pass off. Three or four days after the bed has been formed, it may be covered with earth prepared for that purpose, to the depth of about three inches; before the earth is put on, if the dung shall have settled unequally, the surface of the bed ought to be made perfectly level. Rich light dry earth is best adapted to this purpose: that it may be dry enough, it ought to have been protected from the rain by some shade during the winter; for, should it be wet, it is apt to prevent the seeds from germinating, or to injure the young plants. Fill two or three small flower-pots with some of the same earth, and place them in the hot-bed till the earth in them be warmed, and then sow the seeds.

Sow the seeds, and cover them about half an inch deep; the bottom of the pots ought to be plunged a little way into the earth with which the bed is covered, some of which ought to be drawn up round the pots. A few days after sowing the seeds in the pots, some seeds may be sown in the earth of the bed. By sowing in pots, if the bed should overheat (which is sometimes the case) you have it in your power to withdraw and remove the pots out of danger.

After sowing the seeds, put on the lights; when the steam rises copiously, give the hot-bed air by raising the glasses a little. The hot-bed ought to be covered every evening about sunset with mats, which should be taken off again in the morning about nine o'clock, sooner or later according to the state of the weather. A single mat will be sufficient at first, as the warmth of the bed will be strong. The ends of the mats ought not to hang down over the sides of the frame, because the rank steam proceeding from the bed would be confined, and might injure the plants. The plants will appear, in two or three days after the seeds have been sown, when care must be taken to raise the glasses a little to admit fresh air, and to allow the steam of the bed to escape; if this be not properly attended to, and if the beds be kept too close, the plants will either be destroyed altogether, or become weak and yellowish. About the time the first sown seeds appear above ground, a few more ought to be sown in the earth of the bed. As those tender plants are liable to suffer from various causes at this season, it would be proper to sow a little seed at three different periods, at short intervals, that if one sowing should miscarry, another may succeed. Three or four days after the plants have come up, they ought to be planted out into small pots.

The day before the plants are to be transplanted, pots filled with light rich dry earth should be put into the bed, that the earth which they contain may be brought to a proper temperature. Take the plants carefully up, raising them with your finger and thumb, with all the roots as entire as possible, and with as much of the earth as will readily adhere about the fibres. Plant three cucumbers and two melons in each pot, and draw the earth well up about the stems. If the earth in the pots be very dry, a little water should be given

January. Kitchen Garden.

given after the transplanting has been finished. The pots ought to be plunged close to one another in the earth of the bed, and all the spaces between them ought to be carefully filled with earth, to prevent the rank steam of the dung from rising up, which would certainly kill the plants. The bed ought to be carefully examined every day, to see that the roots of the plants do not receive too much heat. If any thing like that appear, draw up the pots a little, taking care to replunge them to the rim after the danger is over. When the plants are fairly rooted, if the earth appears dry, give them a little water in the warmest time of the day; let the watering be occasionally repeated very moderately, according as the earth in the pots becomes dry. All the water given to the plants at this season ought to stand for a few hours within the bed, that it may acquire the same temperature with the earth in which the plants grow, as very cold water would chill the plants too much. In order to preserve a proper heat in the bed as long as possible, the sides of it ought to be covered with straw or dry leaves, which will defend the bed from cold piercing winds, heavy rains, and snow. Should the bed be unprotected when any of these prevail, the heat would be diminished, and the plants receive a check. If a lively heat be kept up, you may admit air to the plants every day, by raising the glasses in proportion to the heat of the bed and temperature of the external air. If the air be very cold, it will be necessary to fix a piece of mat or some such thing to the edge of the sash, which may hang down over the opening, and prevent the cold air from rushing too freely into the bed. About a fortnight after the bed has been formed, it ought to be examined carefully, to discover whether the heat of the bed still continues strong enough; if not, the dry leaves and straw ought to be removed from the front and back of the bed if any had been placed there, and a quantity of fresh horse dung should be supplied. The lining thus applied should not exceed 15 or 18 inches in thickness, and should be raised a few inches higher than the bed. When too thick a lining is applied, it is apt to throw in too great a heat, and injure the plants. A quantity of earth should be laid on the top of the dung thus applied to the depth of two inches, to keep down the rank steam. The lining will soon increase the heat of the bed, and maintain it for ten days or a fortnight longer. At the expiration of that time, when the heat begins to fail, the two sides of the bed should receive a lining of the same thickness, which will again augment the heat of the bed, and preserve it in good condition for upwards of a fortnight longer. By lining first the one side and then the other at the interval of about a week or ten days, the heat of the bed may be made to last longer than when both linings are applied at the same time. Either method may be followed, according to the degree of external cold which may prevail, or according to the degree of warmth required to be maintained in the bed. After performing the lining, if very cold, wet, or snowy weather prevail, it may be proper to lay a quantity of long dry litter all round the general lining, which will protect the whole of the bed, and keep it in a proper temperature. By the proper management of this seed-bed, and by the due application of linings, the growth of young plants may be promoted till they are fit to be planted out into other hot-beds, where they are to remain and produce fruit. Where there is plenty of hot dung and every other convenience, a second bed may be prepared, into which the young plants may be transferred and nursed till they become perfectly fit for final transplantation. Due attention must be paid to have this second nursery-bed in proper condition for the reception of the pots containing the young plants. It is to be formed, earthed over, and taken care of, according to the directions given for the management of the seed-bed. When the plants have got their two first rough leaves, two or three inches broad, and have pushed out their two first running buds, they are in a proper state for planting out into larger hot-beds. For the farther management of cucumbers and melons, see FEBRUARY.

It is proper that none but such seeds, both of cucumbers and melons, as have been kept for some time, should be sown; those which have been kept for two or three years are to be preferred, because the plants which proceed from them are thought to be, not only more fruitful, but to produce their fruit sooner. Plants which are produced from recent seeds commonly push vigorously, and their shoots grow to a great length before they show a single fruit. The best sorts of cucumbers for producing an early crop, are the early short prickly and long green prickly; the former of these is the earlier, the other produces the best crop and the largest fruit. There are several sorts of melons sown for an early crop, viz. the romana, cantaloupe, polignac, &c. The romana is a very good bearer, and produces early, and is a very well-flavoured, though small fruit. The cantaloupe is a very well-flavoured melon, acquires a good size, and ripens early. The polignac is also a very good melon. It is better, however, to sow two or three kinds, if they are easily to be had, for the sake of gaining greater variety.

Hot-beds may be formed any time this month for forcing asparagus: they are to be formed in the same way as hot-beds for cucumbers and melons; the dung, however, need not be raised to the same height, from two and a half to three feet will be sufficient. After a bed has been formed, it should be covered with earth to the depth of six or seven inches, and the asparagus plants immediately put in; but the frame and glasses are not to be put on till after the violent heat of the bed shall have subsided, and the rank steam escaped. A sufficient quantity of asparagus plants, proper for forcing, must be provided; viz. such as have been raised from seed and planted out in the open ground for two or three years, as directed elsewhere; six hundred will be sufficient for a frame of three lights, and so on in proportion, for a larger or smaller frame. The strongest and most vigorous plants ought to be chosen, and should be planted very close together, that the quantity produced may repay the trouble and expence of forcing. Having marked the size of the frame on the surface of the bed, raise a ridge of earth a few inches high, against which place the first row of plants, and draw a little earth over the roots of each; next to them another row may be planted as close as possible, and so on till the whole space is covered, some moist earth should be applied all round the outside of the space, occupied by the plants, and raised an inch or two above their tops. Then the whole should be covered with a quantity

quantity of rich light earth, to the depth of about two inches, and left in that situation till the buds begin to appear above ground. They should then receive an additional covering of rich light earth to the depth of three or four inches. A wreath of strong straw band is previously fixed by some round the bed, which both supports the last covering of earth and the frame. The straw ropes should be about four inches thick, and fixed down all round the edge of the bed, exactly in that place where the frame is to be put. Should there be no reason to suspect overheating or burning, the frame may be immediately put on; care should be taken to raise up or shove down the glasses to allow the rank steam to escape, particularly about the time the buds begin to appear. If much rain or snow should fall after the bed has been formed, and before the frame is put on, it will be necessary to cover the bed with mats or with straw. The heat of the bed likewise during that time should be carefully examined; with that view, two or three sticks, called *watch sticks*, should be stuck in the dung, to be pulled out occasionally, and examined by applying the hand to their extremities; or the heat may be better regulated by the agricultural thermometer, invented and constructed by Mrs Lovi of Edinburgh. If there be danger of burning, it is moderated by boring several wide holes in the dung on each side of the bed, and in the earth immediately under the roots of the plants, to admit air, and let the rank steam pass off: these holes should be shut after the heat of the bed is become moderate. The outside of the bed should be protected in wet, or cold windy weather, and when its heat decays, it is revived by means of lining, as directed in cucumber and melon beds. After the asparagus begins to appear above ground, due attention should be paid to the regular admission of air, whenever the weather is at all moderate; and care must be taken to cover the beds with mats during severe weather, and constantly during the night. In four or five weeks after the formation of the bed, the asparagus will be fit for cutting, and will continue to produce abundantly for two or three weeks longer. During that time three or four hundred may be collected every week from a three light frame. They must not be cut, as is the case when asparagus is collected in the open air, the fingers must be introduced into the earth, and the buds are to be broken off close to the roots.

3 Sow roots. When carrots are required early, make a hot-bed about two feet thick of dung, and cover it to the depth of six inches with light rich earth. Sow the seed thin, and cover it to the depth of a quarter of an inch. Admit air freely in mild weather through the day, and cover them during the night. When about an inch or two high, thin them to about three inches asunder, they will be fit for drawing in April or May.

Sow rape, cresses, mustard, and radish, in a slight hot-bed. The dung should not exceed the thickness of eighteen inches or two feet, and should be covered with five or six inches of light dry earth. The seeds may be sown very thick, either in drills or all over the surface of the bed, and covered slightly. The bed should be covered with a frame and glasses, and protected during the night and severe weather, with mats. Whenever the weather will permit, air must be admitted, otherwise the plants will be apt to die as fast as they come up.

Where mint, tansey, and terragon, are required very early, a slight hot-bed may be prepared and covered with earth to the depth of five or six inches, in which the roots of mint, tansey, and terragon, may be planted and covered with a frame and glasses.

About the beginning of this month, some peas and beans may be sown in a hot-bed, either for transplanting into a warm border in the open air, or into other hot-beds where they are to remain, and produce a crop; the early framing pea is best for this purpose. 35 Early peas and beans.

A hot-bed may be formed, in which some early dwarf potatoes may be planted, either to be planted out afterwards, or to remain to produce a crop. 36 Early potatoes.

Sow some early kidney beans in a hot-bed, or in pots to be placed in a hot-house. Fill moderate sized pots (24s) with rich light earth, and sow three or four beans in each pot. When the plants have come up, give them a moderate quantity of water; they will produce a crop in March and April. 37 Early kidney beans.

Sect. II. *Fruit Garden.*

January. Fruit Garden.

If any apple or pear trees remain unpruned on walls or espaliers, that work may be performed any time this month, even though the weather should be frosty; some people indeed think it improper to prune trees during frost, lest the trees should receive injury by having their cut surfaces exposed to the action of the frost; but their apprehensions are chimerical. 38 Apple and pear trees to be pruned.

Apple and pear trees produce their flower buds on short branches, (or spurs as they are termed), which proceed from the sides of the branches of one or more years standing, and which every year increase in number, while the branches from which they proceed continue vigorous: if these branches, which throw out spurs, be shortened or cut at their extremities, they commonly push out a number of smaller branches, which acquire considerable length, but form no flower buds; it is therefore proper in pruning these trees, to take care never to shorten a leading branch where there is room on the wall or espalier to allow it to be extended, unless when a supply of new wood is wanted to fill up a vacancy. In young trees which have not yet formed a sufficient head, select the most vigorous and best placed shoots, and train them to the wall or espalier, at the distance of from four to six inches from one another; any branches that intervene between them are to be removed close to their origin, and all those branches which do not apply well to the wall or espaliers may likewise be removed. When the branches are too thin, and a supply of wood is wanted, one or more of the last year's shoots may be cut down to within a few inches of its origin; four or five buds are commonly left. These branches, so shortened, commonly push out three or four shoots the ensuing season. The young branches that have been laid in at full length, will in two or three years produce a good many spurs or short branches along their sides, from which a crop of fruit may be expected. In old trees, that have been already trained, all the vigorous bearing branches are to be retained, unless where they may happen to be too crowded, then the branch intended to be removed should be cut out close to its insertion. When any of the old bearing branches seem to be worn out, or decayed, they should be pruned out near

January. Fruit Garden.

near to their insertion; from the stump that is left some shoots will be pushed out the following season, the best of which may be retained, to supply the place of the branch removed. All the leading branches ought to be looked over, and the superfluous fore-right and misplaced shoots of last year's growth which will not easily apply to the wall, ought to be cut off close to their insertion into the main branch; the most vigorous and best placed shoots should be trained at full length to the wall or espalier at the distance of from four to six inches from one another. When there happens to be any vacant space on the wall or espalier, some of the last year's shoots may be shortened, as directed in the pruning of young trees.

In looking over the leading branches, all the spurs which produce flower buds ought to be carefully retained; and any stumps which may have been left, after former prunings, ought to be cut away quite close to the branch from which they proceed, for they constantly produce a redundancy of branches which create confusion, shade the fruit from the sun, and rob it of its proper nourishment.

39 Plum and cherry.

This is a proper season to prune plum and cherry trees either on walls or espaliers: the same directions which have been given for pruning apples and pears will apply to the pruning of plums and cherries, as they likewise produce their fruit on spurs, pushed out from nearly the extremity of the shoots, which are two or three years old It is improper in pruning to shorten the branches, because the very part would be removed from which the fruit buds should proceed next or subsequent season.

40 Peach, nectarine, &c.

These trees produce their fruit on the young branches of last year. A plentiful supply of last year's shoots must therefore be retained to be nailed to the wall, at the distance of from three inches to half a foot from one another; the most vigorous and best placed shoots are to be selected for this purpose, and all fore-right, weakly or superfluous shoots are to be removed, likewise some of the last year's bearers. That the pruning knife may be used more freely, it would be proper not only to unnail the shoots which had been laid in last year, but even some of the principal branches. In selecting the branches, attention must be paid not only to their position and proper distance, but likewise to the quantity of flower buds they contain. These buds are distinguishable from those which produce branches by their roundness; and towards spring when the buds begin to swell, by their size: those which produce branches being generally small, flat, and pointed. It frequently happens that one of each is prodnced at the same eye (as it is termed), or sometimes two flower buds, with a branch bud between them. All very strong thick branches are to be rejected, as well as those that are long, small, and feeble, because the very vigorous branches are much more apt to run to wood, than to produce fruit. Those branches which are selected as the fittest to be retained, ought to be shortened (due regard being paid to their vigour, and to the number and situation of the flower buds they contain), which will make them push out two or three branches the ensuing summer, the best of which may be retained for next year's bearers.

In weak trees that are not disposed to push vigorously, the smaller shoots may be shortened to the length of six or eight inches; the more vigorous shoots may be left from ten to fifteen inches long, or thereby. In trees of moderate growth the branches ought to be left proportionally longer, the smaller ones from half a foot to ten inches, the more vigorous from one foot to a foot and a half. In very vigorous trees, the branches ought to be shortened but little, and some of them not at all, the smaller shoots may be shortened to the length of a foot or fifteen inches; the more vigorous shoots should have only about a third or fourth part of their length cut off; and the most vigorous should not be shortened at all, for the more they are shortened, the more they are disposed to push vigorously and run to wood, and on that account produce few fruit. As the flower buds are sometimes situated near the extremity, at other times near the bottom of the branch, this circumstance in a certain degree must regulate the shortening the branch, as care must be taken to leave a sufficient quantity of flower buds, where fruit is the object. Care must likewise be taken to have a bud which is expected to produce a branch, at the eye which is next the cut extremity; it is of no moment whether it be alone or in company with one or two flower buds, but it is absolutely necessary to have one to produce a leading branch, without which the fruit will not thrive. When three or four last year's shoots are found on a branch of the preceding year, the one at the upper and lower extremities is frequently preserved; in that case the intermediate ones ought to be cut away close to the branch: but should any of the intermediate ones be selected as the most proper to be retained, the branch of the preceding year should be cut off close by the uppermost of the shoots which has been fixed on, and all these shoots which are to be removed should be cut away close to the branch from which they proceed. After each tree has been gone over, it ought to be carefully nailed to the wall or fixed to the espalier.

Vine and fig.

Vines if cut when in a growing state are apt to bleed very copiously. This bleeding is detrimental to them, and is stopt with great difficulty. If vines are pruned a short time before the rise of the sap, they are likewise liable to bleed at the recently cut extremities; it would therefore be improper any time this month to prune vines which grow in the hot-house or in a vinery which is to be early forced; but such as grow on open walls or in vineyards may be safely cut any time this month. Though it would certainly be adviseable to prune as soon after the fall of the leaf as may be, as in that case the cut extremities would have sufficient time to heal, and all danger of bleeding would be removed.

Fig trees may be pruned any time this month, though perhaps it would be as well to defer it till next or following month. For the method, see FEBRUARY.

Gooseberries and currants may still be pruned. See NOVEMBER.

Plant gooseberries and currants.

Gooseberries and currants may be planted if the severity of the frost does not render the ground too hard; indeed they may be planted any time from the fall of the leaf in autumn till the pushing out of their buds in spring. It is usual to plant them in rows along the borders, or to divide the plots in the kitchen garden; in which case they ought to be planted two or three yards apart, and the distance between the rows must depend on the size of the plots they are to separate (10, 15 or 18 yards). They ought to be trained up with a single

January. Fruit Garden.

single stalk to the height of 10 or 15 inches, which will allow the kitchen crops that may be planted near them to grow freely, and will render the operations of hoeing, weeding, and raking under the bushes easy. They are frequently planted out in compartments by themselves, in which case the bushes ought to stand at the distance of from five to eight feet in the rows, and the rows ought to be eight or nine feet apart.

When plenty of room is allowed between the bushes, they grow freely, and produce larger fruit; free admission is likewise afforded to the sun and air, without which, the fruit would not acquire its proper flavour: hoeing, and digging between the bushes, is more easily performed, and crops of different kinds of kitchen garden productions may be reared in the intervals. Currants are very frequently planted against walls and rails, to which they are regularly trained. Gooseberries also are sometimes planted against walls and rails; those against walls yield early and well-flavoured fruit. The variety of gooseberries is very great, and every season adds new varieties to those already known. The principal kinds are the early rough green, small early red, smooth green, large Dutch red, common hairy red, smooth black, rough white, white crystal, large yellow, rough yellow, large amber, large tawney, &c.

The different kinds of currants are the black, common white, large Dutch white or grape currant, common red, and champaigne.

Rasberries.

Raspberries may be pruned or planted during this or any of the winter months; they produce their fruit on small branches which proceed from the shoots of the former year. Every year they push up a number of shoots from the root, which bear fruit the subsequent summer, and then die. In dressing raspberries, all the old dead stalks must be cut away close by the ground, and all the young ones except four or five of the strongest, which should be shortened a little. All these shoots become small towards their extremity and bend a little; it is the common practice to cut off the bent part, but some shorten them one-third, others one-fourth. After the shoots have been shortened, they ought to be intertwined or surrounded by a bandage of some kind to keep them together, for the sake of mutual support, because when they are allowed to stand single they are apt to be weighed down in summer by the weight of their own leaves and fruit, particularly when loaded with rain, or to be beaten down by the wind; in which case they may frequently lie one over the other, create confusion, and exclude the sun and air from those that are undermost, or may lie so close to the ground as to have their fruit destroyed. After the plants are pruned, the ground between them ought to be dug, and all straggling shoots which advance to a distance from the main plants ought to be taken up.

Raspberries may be planted any time this month when the weather is moderate: when new plantations of them are wanted, they ought to be formed in open situations, if high-flavoured fruit be wished for; but rasps will thrive very well and produce good crops in shadowy situations. The ground in which they are to be planted ought to be well dug, and if a little rotten dung be added, the plants will succeed the better. They ought to be planted at the distance of three feet from each other, in rows four or five feet apart. The offsets which are dug up from between the rows of old plantations of raspberries are commonly made use of for this purpose. Any of the last years shoots that are well rooted and tolerably vigorous will answer perfectly well. Those which have two or three buds, formed on the roots, from which young shoots are to proceed the following summer, are generally to be preferred to those which have fewer though equally vigorous. They ought to be taken up carefully with all their roots, and after the stem has been shortened a little (about one-third) they may be planted at the distances already mentioned. Plantations formed now will yield some fruit the ensuing summer, and a plentiful crop the following season. The kinds of raspberries commonly used are the white, double bearing, (which bears two crops, one in summer the other in autumn), the smooth stalk, the Antwerp (very large).

44 Prepare for planting fruit trees.

If the weather be mild, all kind of fruit trees may be planted any time this month; but if it should be deemed more adviseable to defer planting till next month, the ground may be prepared for their reception any time during open weather. The borders on which fruit trees are to be planted, which are to be trained against walls or espaliers, should be trenched or dug two spades deep. For planting and preparing ground for fruit trees, see OCTOBER.

45 Protect the roots, &c.

The roots of the more tender sorts of fruit trees, viz. peaches, nectarines, apricots, and indeed of all sorts of stoned fruit, which may have been planted any time in the course of the winter, will require to be protected during frost by a covering of straw, or litter mixed with dung, or something of that nature, applied to a considerable distance round the stem, so as to cover the ground completely, and prevent the frost from penetrating.

Protect fig-trees during frosty weather with a covering of mats, or something of that nature, because their shoots being succulent, particularly towards their extremities, are apt to be destroyed by the frost. This is of the more consequence as the fruit is produced from the young shoots only, and chiefly from their extremities, the parts most liable to suffer.

46 Force fruit trees

Where there are vineries, peach, cherry-houses, &c. the glasses ought to be put on about the beginning of the month when it is intended to force early, and fires ought to be applied about the middle or towards the end of it. See *Forcing*, FEBRUARY.

47 and strawberries.

Towards the beginning, middle, or end of the month, hot-beds may be made for forcing strawberries, which, if properly managed, will produce ripe fruit in March or April. The hot-beds are to be formed according to the directions given under the article *Melon*, and *Cucumber*. See *Kitchen Garden*, JANUARY. The dung should be raised at least to the height of three feet, and the frame and glasses put on as soon as the bed is made, which will both protect it from rain or snow, and draw up the steam sooner. As soon as the violent heat is over, the surface of the bed should be covered to the depth of four or five inches with dry earth, or with a quantity of decayed tanners bark taken from an old tan-bed. The pots containing the plants should be plunged up to the rims into the earth or tan with which the bed is covered. They should be placed as close together as possible, and care taken to fill up all the interstices with earth or tan. When all the pots are plunged, put on the glasses and keep them close till the

January. Flower Garden. the steam rise in the bed, when it will be necessary to raise them a little behind, to allow the steam to pass off. The alpine and scarlet strawberry are commonly made use of for this purpose.

The plants should be two years old, and if potted the preceding autumn, they will succeed the better; but if a quantity of plants were not put into pots last autumn for this purpose, that work may be done any time this month during open weather. For the method, see SEPTEMBER. Or the plants may be taken up now with balls of earth, and placed in the beds without being put into pots. When the plants begin to push, let them have plenty of air during favourable weather, for should they be kept too close they will become weakly, and either produce no flowers at all, or their flowers will drop off without yielding fruit. They should likewise be frequently watered and protected during the night in severe weather with a covering of mats. When the heat of the bed begins to decay, it should be renewed by proper linings of fresh dung, applied as directed for melon-beds. As to the size of hot-beds nothing need be said, as that must be regulated by the number of plants intended to be forced. Hot-beds formed of tanners bark, particularly where there are pits constructed on purpose, will answer better than those of horse-dung, because they afford a more equable heat. Where there are pine-houses, or hot-houses of any kind, plenty of strawberries may be obtained early, without much trouble, by placing pots filled with the plants in them any where near the glass.

SECT. III. *The Flower Garden or Pleasure Ground.*

48 Protect flowers in pots. DOUBLE flowers, as sweetwilliams, wallflowers, stocks, rose campion, and auriculas, carnations, &c. kept in pots, ought to be protected in severe weather, either by common garden frames, or by coverings of mats supported on hoops. Due attention must be paid to give them air whenever the weather is mild. Where there are no conveniences of the above description, the pots may be plunged up to their rims in well-sheltered borders close to a south wall. The pots containing hardy plants should likewise be plunged in the earth in some dry situation up to the rims, to protect the roots from frost.

49 Bulbous roots in beds. During severe frosty weather the beds in which the finer sorts of hyacinths, tulips, ranunculuses, anemones, &c. have been planted, should be protected by a covering of mats or straw; but if the plants have begun to make their appearance above ground, the beds should be arched over with low hoops and covered with mats, which ought to be fixed down to prevent their being blown off by the wind; and they should be removed occasionally during mild weather.

50 Plant bulbous roots. If any hyacinth, tulip, narcissus, crown imperial, crocus, or snowdrop roots remain unplanted, they ought now to be put into the ground. For the method of planting them, see OCTOBER.

51 Sow hardy annuals. About the latter end of the month, if the weather is mild, sow a few sweet peas in any warm sheltered situation for flowering early, also some seeds of candytuft, larkspur, adonis, dwarf sunflower, persicaria, venus navel-wort, venus looking-glass, lobel's-catchfly, and pansy violet.

52 Force flowers in the hot-house. Pots of pinks, carnations, roses, Persian or common lilach, hyacinth, polyanthus, narcissus, Italian narcissus, dwarf tulip, jonquil, lily of the valley, &c. may be placed in the hot-house, where they will flower early. As soon as they come into blow they should be removed into a green-house, or the apartments of a dwelling-house, where they will continue longer in flower than they would do if left in the stove, where the great heat would accelerate their decay. All those should have been put into pots the preceding autumn, or at least some time previous to their being introduced into the hot-house. The roses in particular require to be well rooted in the pots before they are forced.

Management of shrubs. Shrubs may now be pruned, which should be performed with a knife and not with garden sheers. All irregular shoots which extend far beyond the rest of the branches should be cut off. A few branches should also be cut out wherever they are too much crowded together, likewise all dead and decayed ones. After the pruning has been finished, the ground in the shrubbery ought to be dug over, and all suckers removed. Where the shrubs are too much crowded together, some of them ought to be taken out; and where any of them have died, or if they stand too distant, some young ones may now be planted to fill up the vacancies.

Of grass walks and lawns. Grass walks and lawns should be kept neat by frequent poling and rolling. Poling may be performed in open dry weather, with a long taper ash pole about twelve or fifteen feet long, which breaks and scatters the worm casts. After this, in moderately dry weather, roll with a wooden roller, to which all the loose worm-casts will adhere. Walks or lawns may also be made this month during open weather. Good turf may be obtained from commons or downs where sheep feed, or from fields which have been long under pasture. Each turf should be marked out a yard long and a foot in breadth, and cut to the thickness of an inch with a turfing iron. As the cutting proceeds, they should be rolled up compactly with the grass side in. If they are not closely rolled up they will be apt to break in carrying. They must be laid on the walk or lawn close to one another after the surface has been rendered level and compact by proper treading, that it may not settle unequally. When they have been put on they must be beat down with a wooden rammer, and afterwards rolled with a large iron or wooden roller.

Of gravel walks. Gravel walks should be cleared of weeds and all decayed leaves, and kept clean; and in dry weather they should be occasionally rolled. New walks may likewise be formed now. For the method, see MARCH.

Edgings. Edgings of boxwood, thrift, &c. may be planted any time this month in open weather. See OCTOBER.

Planting &c. hedges. Hedges of hawthorn, barberry, privet, hazel, holm, yew, birch, elm, elder, &c. may be planted during this month. See NOVEMBER. Old hedges which have become open below should be plashed. See DECEMBER.

Of forest trees. Forest trees for ornamental plantations, coppices, or woods, may be planted either now, or at any time from the fall of the leaf till the rise of the sap in spring. See OCTOBER.

SECT. IV. *Nursery.*

Management of shrubs, trees. PRUNE and transplant shrubs, fruit and forest trees. Trim the stems of forest trees, and cut off all irregular uary. een- and House.

regular rambling shoots of shrubs, and reduce them to a regular neat form. This work may be executed any time this month, even during frost, when little else can be done. All kinds of hardy deciduous shrubs, fruit, and forest trees, may be transplanted during open weather.

Dig ground in open weather, and wheel out dung in frost.

Vacant compartments of ground may be dug any time during open weather; and likewise after the necessary pruning has been given to the trees and shrubs, the ground between the rows may be dug, and all weeds carefully buried.

Of seed-lin

The young plants of many of the tenderer kinds of trees and shrubs, such as cedar of Lebanon, and some other species of pine, cypress, chinese arbor vitæ, strawberry-tree, &c. require to be protected during frost. If they have been raised in boxes or pots, they may be placed in garden frames and occasionally covered with the glasses; but care must be taken always to remove the glasses in mild open weather. If the plants stand in beds in the open ground, they may be covered with mats supported on hoops, which must be removed during favourable weather, or a covering of pease straw, or something of that nature may answer the purpose.

Propagate trees &c. by layers.

Layers of many kinds of trees and shrubs may be made any time this month during open weather; many of them which are laid now will be well rooted and fit for removing by October; for the method, see NOVEMBER.

By cuttings.

Put in cuttings of honeysuckles, gooseberries, currants, &c. indeed most kinds of trees and shrubs may be propagated by cuttings. For this purpose select the straight shoots of last year's growth; take them off by a clean cut with a sharp knife, and reduce them to the length of ten, twelve, or fifteen inches, by cutting off part of their smaller extremities. Plant them in rows a foot apart, and at the distance of four or five inches from one another in the rows, taking care to insert one-third or one half of their length into the ground. Though cuttings will grow when their smaller extremities are put into the ground, they never succeed so well in this inverted position, therefore in planting, attention should be paid to place them in their natural position. Older and longer branches of some trees and shrubs, viz. willow, elder, &c. may be employed as cuttings.

By suckers.

Gooseberries, currants, roses, lilachs, and many other shrubs and trees, may be propagated by suckers or offsets from the roots; these may be taken off any time this month, and planted in rows. Previous to their being planted it would be proper to trim off part of their extremities.

SECT. V. *Green-House and Hot-House.*

The air to be cautiously admitted.

DURING frost, keep the glasses shut; but whenever the weather is mild, give the green-house air by opening the glasses more or less according to the state of the weather: even in the brightest mild days during this month the glasses should not be opened until about ten o'clock in the morning, and ought to be shut again about three in the afternoon. In dull foggy days, even though the weather be mild, they should be opened but little, and that for a short time, and in very damp weather, not at all. When very severe frost prevails, fires must be put on, and the flues gently warmed; but the temperature of the air should not be raised higher than merely to keep off the effects of the external frost. A little fire should likewise be put on during very wet weather to banish the damps. Water should be given to such plants as require it, but sparingly. Succulent plants, such as aloes, &c. require little or no water at this season. All dead and decayed leaves should be carefully picked off, and the green-house kept clean.

January. Green-house.

65 Pine apple plants require attention.

Particular attention must be paid to the pine apple plants which are to produce fruit the ensuing summer, as many of them in the course of this month begin to shew flowers. If due attention be not now paid to keep up a proper heat, both in the tanned bed and in the air of the hot-house, the plants may receive such a check as will considerably affect the size of the future fruit. The bark bed must be carefully examined; and if the bark be much decayed and the heat found on the decline, a quantity of fresh tanners bark should be prepared to be added as a refreshment to the old. The pots containing the pine apple plants should then be taken out of the tan pits, and a quantity of the decayed tan removed from the surface and sides of the pits, to make room for the fresh tan which is to be added. The old tan must likewise be turned up from the bottom, and well mixed with the new, after which the pots must be again plunged into the tan. But if, on examination, the heat of the tan pit be found good, and the tan not much decayed, it will be sufficient to turn the old tan, and to mix it well together without making any addition of new. This operation will revive the heat of the bed, and preserve it in good condition for some time to come. The heat of the air in the house must likewise be attended to, and regulated by the thermometer and by due attention to the fires. Moderate watering must be given once a week or ten days, according as the pine apple plants may seem to require it; and care must be taken not to pour any of the water into their hearts or among their leaves.

The other plants in the hot-house must be regularly watered; but those of a succulent nature, such as the different species of aloe, euphorbia, mesembryanthemum, &c. require very little water at a time, and that but seldom.

66 Kidney beans.

Kidney beans, sown in pots or in narrow boxes of about two or three feet long, may be reared in the hot-house. Those sown this month will produce fruit in April or March. When sown in pots, two or three may be put into each, and covered about an inch deep: When in boxes they may be planted to the depth of an inch along the middle, at the distance of two or three inches from one another. The pots or boxes may be placed on the crib of the bark bed, on shelves, or any convenient situation, within the house, where they may not encumber the other plants. After the plants have come up, they should be regularly and frequently watered. The kinds commonly used for this purpose are the early speckled dwarf, negro dwarf, and dun-coloured dwarf.

67 Cucumbers.

Cucumbers may be raised with tolerable success in the hot-house, which will produce fruit early in spring. If the plants have been raised in small pots, plunged in the tan of the bark bed, or in hot-beds made of horse dung, they should be transplanted into larger pots or boxes, in which they may remain and produce fruit; or

February. Kitchen Garden.

or the seeds may be sown at once in the pots where they are to remain. In this case six or eight seeds may be sown in each pot, or patches containing that number may be sown at proper intervals in long narrow boxes. When the plants have come up, only two or three of the strongest should be left in each pot or patch. The pots or boxes may be placed in any convenient situation in the hot-house, but will succeed best on a shelf fixed near the top of the house, within a short distance of the glass. The plants must be frequently watered, and have some small rods fixed near them, to which the runners may be fastened.

FEBRUARY.

Sect. I. *Kitchen Garden.*

68 Admit air to cauliflower plants. The cauliflower plants, which are under frames, should have plenty of air. Indeed, whenever the weather will permit, the glasses ought to be taken off entirely.

About the end of the month, if the weather be mild, some of the strongest plants may be transplanted into the situations where they are to remain. They ought to be planted in good well-manured ground, in a warm situation, at the distance of two feet and a half each way from one another. The same attention must be paid to cauliflowers under bell or hand-glasses. When more than two plants happen to be under one glass, the weakest of them should be planted out about the end of the month, if the weather be mild, and only one or two should be left under each glass: but if the weather is unsettled or severe, transplanting ought to be deferred till next month.

69 Sow cauliflowers. Some cauliflower seed may be sown any time this month to produce plants to succeed those that have been preserved during winter under frames or hand-glasses, or to supply the place of those which may have been cut off by the severity of the weather.

For this purpose make a slight hot-bed of horse dung, to the height of 20 inches or two feet; cover it with a light rich earth to the depth of four or five inches, on the surface of which sow the seeds, and cover them to the depth of a quarter of an inch with earth of the same description. After the seed has been sown, a frame and glasses should be put on, if one can be spared for this purpose; and when the plants begin to appear above ground, they should have plenty of air, whenever the weather will permit, otherwise they will be drawn up and become weak. The glasses, therefore, (unless in very severe weather) should be raised every day, and in mild ones taken off entirely. When there are no glasses to spare, the bed may be covered during the night, and in severe weather, with mats properly fixed over it. The plants should be sprinkled with water from time to time, if moderate showers should not render this unnecessary.

70 Transplant cabbages. Cabbage plants, if tolerably strong, should be transplanted in the course of this month. See *Planting out cabbages*, January.

71 Sow cabbages. About the middle, or towards the end of the month, sow some cabbage and savoy seed to raise plants for late crops in summer and autumn. Both the early and late kinds of cabbage may be sown now, but it is better to sow them in August; but if none were sown in autumn, or if the plants raised then have been cut off by the severity of the winter, a quantity of both early and late should be sown the first opportunity this month. That the plants may sooner acquire sufficient strength for planting out, it would be proper to sow them in a slight hot-bed.

72 Small salad. Where small salad is required, let some seeds of mustard, cress, radish, rape, &c. be sown regularly every eight or ten days during the course of the month. See January.

73 Celery. Earth up celery in open dry weather if the plants have advanced much above ground. Sow some upright celery seed for an early crop about the middle or towards the end of the month, in a small bed of rich light earth in a warm situation. There are three ways in which this may be performed. 1st, The earth of the bed should be well broken with the spade; the seed sown on the rough surface and raked in. 2dly, The surface of the bed may be made smooth; the seed sown and covered to the depth of a quarter of an inch with light rich earth. 3dly, A quantity of earth, to the depth of about half an inch, should be removed with the back of a rake from the surface of the bed into the alleys, which, after the seed has been sown, should be gently replaced with the rake. Those who are very anxious to have early celery, should sow some in a slight hot-bed. The plants raised now will be fit for use in June or July; but it would be adviseable to sow few at this season, as they will be very apt to pipe or run up to seed before they acquire sufficient size: there are two kinds of celery, the Italian, and turnip-rooted or celeriac.

74 Radish. About the beginning of this month sow some short-topped radishes to succeed those sown last month, and some salmon and Italian radishes at any time during the month. See January.

75 Spinach. Some round-leaved spinach may be sown any time in the course of the month, to succeed that which was sown last month. See January.

76 Peas. Some early peas may be sown this month. This is likewise a proper season for sowing a full crop of late peas, such as marrowfats, rouncivals, Carolina, and sugar pea, &c. For the distances at which they are to be sown, see January.

77 Beans. This is the proper time to plant beans. For the method and distances, see January.

78 Earth peas and beans. Such peas and beans as are sufficiently advanced in growth should now be earthed up.

79 Sow and transplant lettuce. In mild open weather sow some seeds of green and white cos lettuce, likewise some Sicilian, imperial, brown Dutch, and common cabbage lettuce. See January.

If young lettuce plants are wanted for transplanting early, they should be sown in a slight hot-bed or in some warm sheltered situation; and when they have advanced to the height of about two inches, they may be planted out in the open ground. Lettuces that have stood the winter in frames, under hand-glasses, or in warm borders, should be thinned and left standing at the distance of one foot from each other, and those that are drawn out should be planted in some proper situation.

80 Sow carrots and parsnips. About the middle or end of this month sow some carrots and parsnips. They succeed best in light deep soil, and in an open situation. The ground should be dug, at least one spade deep or two, if the depth of the soil will

will admit, and the clods ought to be well broken. They may be sown either broadcast, in narrow beds, or in drills. See MARCH.

Sow some seeds of red, white, and green beet, likewise of mangel wurzel or German beet. The fine red root of the first is used as a pickle, &c.; the leaves of the white and green are made use of in soups, &c.; and the large leaves of the mangel wurzel are boiled and used as spinach. The footstalks of its leaves are likewise used as asparagus. Each kind should be sown separately, either broadcast or in drills, an inch deep, and about a foot apart; but the mangel wurzel requires more room than the other kinds, because it is of larger growth. After the plants have come up, they should be thinned out, to the distance of six or eight inches from each other. The seed may likewise be dibbled in rows, about a foot apart, and at the distance of six or eight inches from each other in the rows. Two or more seeds may be put into each hole; and when the plants appear above ground, one of the strongest only should be left.

Some of last year's carrots, parsnips, and beets, should be planted out in rows, two feet apart, and one foot distant from each other in the row, to stand and produce seed.

Some onions and leeks may be sown in mild dry weather, any time after the middle of this month. The ground should be well dug, and the seeds sown when the surface is dry, and then raked in. The best mode is to divide the ground into beds of about four feet wide, for the convenience of thinning, weeding, &c.; but they may also be sown in plots, without being divided into beds, in which case, if the soil be light, the seed may be gently trodden in, before the surface is raked. The leeks will be fit for transplanting in June and July, and the onions for drawing in August. Sometimes a small quantity of leek-seed is sown along with the onion; and when the onions are drawn in August, the leeks are allowed to remain to acquire a proper size; but it is better to sow each separately. The principal kinds of onion are Strasburg, Deptford, Spanish, Portugal, long keeping, and red.

The Hamburgh parsley and scorzonera are cultivated for their roots; the salsafy for its roots and tops. The roots of all of them, if sown now or any time in spring, will be fit for using in autumn, and continue good all winter. The Hamburgh parsley roots are not only used for culinary purposes, but recommended in medicine. They are said to be useful in the gravel. The seeds may be sown in drills, six inches apart, and covered with earth to the depth of half an inch. The plants should be thinned in May or June, and left standing at the distance of six inches from each other in the rows.

About the middle of the month you may sow seeds of burnet, lovage, angelica, marigold, fennel, dill, sorrel, chervil, and clary. Each kind should be sown separately, either in the place where they are to remain, or they may be transplanted in summer. See JUNE.

About the middle or end of the month sow marjoram, thyme, savory, and hyssop. The plants may either remain where sown, or be planted out in the beginning of summer. See JUNE.

Towards the end of the month plant shalot, garlic, and rokambole. Having procured a quantity of their roots, divide and plant them in rows nine inches apart and six inches distant from each other in the row. They may be put in to the depth of two inches with the dibble, or placed in drills, two inches deep, drawn with a hoe. February. Kitchen Garden.

This is a proper time to raise a full crop of parsley. See JANUARY. 87 Parsley.

A few potatoes may be planted about the middle or end of this month for an early crop; but if wanted very early, some early dwarf potatoes should be planted in a slight hot-bed. For the method of planting, see MARCH. 88 Potatoes.

Horse radish is propagated by offsets or cuttings of the roots, about three inches long, which may be planted either with the dibble or spade, at the distance of six or eight inches from each other, in rows two feet apart. When they are planted with the dibble, the holes ought to be made 10 or 12 inches deep; when with the spade a trench should be made a full spade deep, in the bottom of which the offsets or cuttings should be placed erect, and covered with earth from the next trench. As they will not appear above ground till the month of May, a crop of spinach, radishes, or small salad, may be got from the ground, and cleared off before the horse radish appears. After the plants have come above ground, they ought to be kept clear of weeds. 89 Horse radish.

About the middle or towards the end of the month, sow some seed of the early Dutch turnip in a border of light earth, in a warm situation. See MARCH. 90 Sow turnip.

If no preparations were made last month for raising early cucumbers and melons, they may be commenced, any time this month, with better prospect of success. For the method of forming and managing the seed-bed, see JANUARY.—If the cucumbers and melons, sown last month and transplanted into small pots, be fit for ridging out, a hot-bed for one or more frames should be got ready for their reception, which should be raised to the height of three feet and a half, and covered with a frame and glasses. About a week afterwards, if the hot-bed has settled unevenly, the frame and glasses should be removed; and after the surface of the bed has been made perfectly level, replaced. As soon as the violent heat has subsided, the rank steam escaped, and all danger of burning apparently over, cover the bed to the depth of two inches with dry light rich earth, and raise a conical heap of the same earth, to the height of about 10 inches, immediately under the centre of each light. By the following day the earth will have acquired a proper warmth, and the bed will be fit for the reception of the young plants. The earth, laid over the surface of the bed, to the depth of two inches, will prevent the rank steam of the dung, on the one hand, from rising up freely, and yet not keep it down altogether: were much of the surface of the dung exposed, and the steam allowed to escape freely, the young plants would be destroyed; and, on the other hand, were it prevented from escaping altogether, by laying on earth to a sufficient depth at once, the bed would become overheated, and the roots of the plants might be burnt. 91 Cucumbers and melons.

The pots containing the young cucumber and melon plants, which were transplanted last month (see JANUARY), should be well watered the day previous to their being ridged out, to make the ball of earth adhere, and come out of the pot entire. After the tops of the hillocks of earth, which had been raised to the height 92 Management of the former crop.

February. Kitchen Garden.

height of 10 inches under each light, have been flattened by reducing their height about two inches, make a hole in the centre of each, capable of containing one of the balls of earth, which is to be turned out of the pots. Select some pots containing the strongest plants; place your hand on the surface of the pot, allowing the plants to pass between your fingers; invert it, and strike the edge of it gently against the frame till the ball of earth comes out, which should be put into one of the holes in the hillock just mentioned; close the earth round the ball, and make it rise about an inch over its surface. After they have been thus ridged out, they should receive a gentle watering, and be covered with the glasses till the steam begin to rise much, when air should be given by raising the glasses. These hot-beds, into which the cucumbers and melons have been finally transplanted, must be managed in the same manner as the nursery beds, mentioned last month. A covering of straw, or something of that nature, should be laid all round the dung; linings of fresh dung should be applied to the sides of the bed when the heat begins to decline, air admitted under the same circumstances and with the same precautions as there stated. If three cucumbers or two melons have been planted in the pots, as before directed, one of the weakest of either should be removed immediately before, or after they are ridged out. Should any symptoms of burning appear soon after the plants have been ridged out, part of the earth, close to the bottom of the hillocks, must be removed; and as soon as the violent heat has subsided, be replaced with fresh earth. When the heat of the bed begins to decline a little, especially if any of the roots of the plants shew themselves through the sides of the hillocks, a quantity of fresh earth should be applied all round them, which should be kept within the frame for one night previously, that it may acquire a proper temperature, for should it be applied cold, it might injure the young roots. Two or three days after this an additional quantity of fresh earth should be applied to the sides of the hills; and in two or three more the whole surface of the bed may be earthed over as high as the tops of the hills.

93 Topping.

When the plants have got two rough leaves, and when the second is about an inch broad, the bud, which is situated at the axilla (or base) of the second rough leaf, must be removed either with the finger, a pair of scissars, or a pen-knife, or, when the bud is very small, with a needle or pin, being careful not to injure the joint. After the plants are thus topped or stopped, they soon acquire strength; and in about 10 or 12 days, each of them will throw out two or three runners, which will shew flowers sometimes at the second or third joint. Were the plants not to be topped, the principal shoots would probably advance to the length of about two feet, without sending off any runners to fill up the frame, and without shewing a single flower. If none of the runners, which are pushed out after the first topping, shew flowers at the third or fourth joint, they should be topped likewise, which will cause each of them to push out two or three runners, all of which may perhaps prove fruitful. As these runners advance in growth they ought to be trained regularly along the surface of the beds, and all very weak or redundant shoots removed. The cucumbers, if well managed, will be fit for the table about the end of this or beginning of next month; but the melons will not be ripe before May or June.

Impregnation of the flowers.

Cucumbers and melons have male and female flowers on the same plant, which are easily distinguished from one another. The male flowers, in the centre of which the antheræ are situated that contain the farina (or fecundating powder), have stalks of an equal thickness, without any swell immediately under the flowers; whereas a swelling is perceptible immediately under the female flowers which contain the female organ of generation, as soon as they are pushed out from the stalks of the plant, which is the germen or future fruit. If none of the farina of the male be conveyed into the female flower, the germen decays, becomes yellowish, and drops off. It becomes therefore necessary, particularly at this early period, to impregnate the female flowers by suspending male flowers over them, and shaking some of the farina into the pistillum (or female organ); for after the plants have continued some time in flower, the air of the hot-bed in which they grow becomes loaded with the farina, by which means it is wafted into the female flowers. Insects likewise, particularly bees, at a more advanced period of the year, serve to convey it from flower to flower. As soon as the female flowers have opened, pinch off a newly blown male flower, together with a portion of its foot stalk, remove the greatest part of its corolla or flower leaf, introduce it into the female flower, and either touch the pistillum of the female gently with the antheræ of the male so as to make some of the farina adhere, or shake the male flower over the pistillum of the female in order to make some of the farina fall on it. In a day or two after impregnation the germen or future fruit begins to swell, and in about a fortnight, if the weather be favourable and the heat of the bed good, the young cucumbers may be brought to table. This operation may be employed to produce new varieties, not only of cucumbers and melons, but of many other vegetables. Were the female of one variety of melon to be impregnated with the farina of another, a kind would be produced partaking somewhat of the properties of both; thus a large melon, not possessed of much flavour, might be improved by intermixture with one superior in flavour but inferior in size. In hermaphrodite flowers this operation of impregnating, or crossing, as it is called by cattle breeders, is performed by removing the antheræ from a flower of one species, and impregnating it with the farina of another of the same natural family. The plants proceeding from such a commixture partake more of the properties of the male than the female parent. We have seen a hybrid produced from the *papaver somniferum* impregnated with the farina of the *papaver orientale*, so like the male parent as with difficulty to be distinguished from it.

The *papaver orientale* produces only one flower on a stalk; some of this hybrid however carried more than one, and in this particular alone it resembled the *papaver somniferum*, which branches very much. Mr Knight has made some curious and interesting experiments on this subject, which he has detailed in the following letter to Sir Joseph Banks, published in the Transactions of the Royal Society. "The result of some experiments which I have amused myself with making on plants, appearing to me to be interesting to the naturalist, by proving the existence of superfœtation in in the vegetable world, and being likely to conduce to some improvements in agriculture, I have taken the liberty to communicate them to you. The breeders of animals have very long entertained an opinion that considerable advantages are obtained by breeding from males and females not related to each other. Though this opinion has lately been controverted, the number of its opposers has gradually diminished, and I can speak from my own observation and experience, that animals degenerate in size, at least on the same pasture, and in other respects under the same management, when this process of crossing the breed is neglected. The close analogy between the animal and vegetable world, and the sexual system equally pervading both, induced me to suppose that similar means might be productive of similar effects in each; and the event has, I think, fully justified this opinion. The principal object I had in view, was to obtain new and improved varieties of the apple, to supply the place of those which have become diseased and unproductive by having been cultivated beyond the period which nature appears to have assigned to their existence. But as I saw that several years must elapse before the success or failure of this process could possibly be ascertained, I wished in the interval to see what would be its effects in annual plants. Amongst these none appear so well calculated to answer my purpose as the common pea, not only because I could obtain many varieties of this plant, of different forms, sizes, and colours, but also because the structure of its blossom, by preventing the ingress of insects and adventitious farina, has rendered its varieties remarkably permanent. I had a kind growing in my garden, which, having been long cultivated in the same soil, had ceased to be productive, and did not appear to recover the whole of its former vigour when removed to a soil of a somewhat different quality: on this my first experiment in 1787 was made. Having opened a dozen of its immature blossoms, I destroyed the male parts, taking great care not to injure the female ones; and a few days afterwards, when the blossoms appeared mature, I introduced the farina of a very large and luxuriant gray pea into one half of the blossoms, leaving the other half as they were. The pods of each grew equally well, but I soon perceived that in these into whose blossoms the farina had not been introduced, the seeds remained nearly as they were before the blossoms expanded, and in that state they withered. Those in the other pods attained maturity, but were not in any sensible degree different from those afforded by other plants of the same variety; owing, I imagine, to the external covering of the seed (as I have found in other plants) being furnished entirely by the female. In the succeeding spring the differenee however became extremely obvious, for the plants from them rose with excessive luxuriance, and the colour of their leaves and stems clearly indicated that they had all exchanged their whiteness for the colour of the male parent. The seeds produced in autumn were dark gray.

"By introducing the farina of another white variety, (or in some instances by simple culture), I found this colour was easily discharged, and a numerous variety of new kinds produced, many of which were in point of size and in every other respect much superior to the original white kind, and grew with excessive luxuriance, some of them attaining the height of more than twelve feet. I had frequent occasion to observe in this plant a stronger tendency to produce purple blossoms and coloured seeds than white ones; for when I introduced the farina of a purple blossom into a white one, the whole seeds in the succeeding year became colonred; but when I endeavoured to discharge this colour by reversing the process, a part only of them afforded plants with white blossoms; this part sometimes occupying one end of the pod, and being at other times irregularly intermixed with these which, when sown, retained their colour. It might perhaps be supposed that something might depend on the quantity of farina employed; but I never could discover, in this or any other experiment in which superfœtation did not take place, that the largest or smallest quantity of farina afforded any difference in the effect produced.

"The dissimilarity I observed in the offspring afforded by different kinds of farina in these experiments, pointed out to me an easy method of ascertaining whether superfœtation, (the existence of which has been admitted amongst animals), could also take place in the vegetable world. For as the offspring of a white pea is always white, unless the farina of a coloured kind be introduced into the blossom; and as the colour of the gray one is always transferred to its offspring though the female be white, it readily occurred to me, that if the farina of both were mingled or applied at the same moment, the offspring of each could be easily distinguished.

"My first experiment was not altogether successful, for the offspring of five pods (the whole which escaped the birds) received their colour from the coloured male. There was, however, a strong resemblance to the other male in the growth and character of more than one of the plants, and the seeds of several in the autumn very closely resembled it in every thing but colour. In this experiment, I used the farina of a white pea, which possessed the remarkable property of shrivelling excessively when ripe, and in the second year I obtained white seeds from the gray ones above mentioned, perfectly similar to it. I am strongly disposed to believe, that the seeds were here of common parentage; but I do not conceive myself to be in possession of facts sufficient to enable me to speak with decision on this question.

"If, however, the female afford the first organized atom, and the farina act only as a stimulus, it appears to me by no means impossible, that the explosion of two vesicles of farina at the same moment (taken from different plants) may afford seeds (as I have supposed) of common parentage, and as I am unable to discover any source of inaccuracy in this experiment, I must believe this to have happened.

"Another species of superfœtation, (if I have justly applied the term to a process in which one seed appears to have been the offspring of two males), has occurred to me so often as to remove all possibility of doubt as to its existence. In 1797, that year after I had seen the result of the last-mentioned experiment, having prepared a great many white blossoms, I introduced the farina of a white pea, and that of a gray pea, nearly at the same moment into each, and as in the last year, the character of the coloured male had prevailed, I used its farina more sparingly than that of the white one, and now almost every pod afforded plants of different

February. Kitchen Garden.

ferent colours. The majority however were white, but the characters of the two kinds were not sufficiently distinct to allow me to judge with precision whether any of the seeds produced were of common parentage or not. In the last year I was more fortunate, having prepared blossoms of the little early frame pea, I introduced its own farina, and immediately afterwards, that of a very large and late gray kind; and I sowed the seeds thus obtained in the end of the last summer. Many of them retained the colour and character of the small early pea not in the slightest degree altered, and blossomed before they were 18 inches high, whilst others (taken from the same pods) whose colour was changed, grew to the height of more than four feet, and were killed by the frost before any blossoms appeared.

"It is evident that in those instances, superfœtation took place, and it is equally evident that the seeds were not all of common parentage. Should subsequent experience evince that a single plant may be the offspring of two males, the analogy between animal and vegetable nature may induce some curious conjectures relative to the process of generation in the animal world.

"In the course of the preceding experiments, I could never observe that the character either of the male or female in this plant at all preponderated in the offspring, but as this point appeared interesting, I made a few trials to ascertain it. And as the foregoing observations had occurred in experiments made principally to obtain new and improved varieties of the pea for garden culture; I chose for a similar purpose the more hardy varieties usually sown in the fields. By introducing the farina of the largest and most luxuriant kinds into the blossoms of the most diminutive, and by reversing this process, I found that the powers of the male and female in their effects on the offspring are exactly equal. The vigour of the growth, the size of the seeds produced, and the season of maturity, were the same, though the one was a very early, and the other a late variety. I had in this experiment a striking instance of the stimulative effects of crossing the breeds; for the smallest variety, whose height rarely exceeded two feet, was increased to six feet, whilst the height of the large and luxuriant kind was very little diminished. By this process, it is evident that any number of new varieties may be obtained; and it is highly probable, that many of these will be found better calculated to correct the defects of different soils and situations, than any we have at present; for I imagine that all we now possess have in a great measure been the produce of accident, and it will rarely happen, in this or any other case, that accident has done all that art will be found able to accomplish.

"The success of my endeavours to produce improved varieties of the pea, induced me to try some experiments on wheat, but those did not succeed to my expectations. I readily obtained as many varieties as I wished, by merely sowing the different kinds together, for the structure of the blossoms of this plant, (unlike that of pea), freely admits the ingress of adventitious farina, and is thence very liable to sport in varieties. Some of these I obtained were excellent, others very bad; and none of them permanent. By separating the best varieties, a most abundant crop was produced, but its quality was not quite equal to the quantity, and all the discarded varieties again made their appearance. It appeared to me an extraordinary circumstance, that in the years 1795 and 1796, when almost the whole crop of corn in this island was blighted, the varieties thus obtained, and these only, escaped in this neighbourhood, though sown in several different soils and situations.

"My success in the apple (as far as long experience and attention have enabled me to judge from the cultivated appearance of trees which have not yet borne fruit) has been fully equal to my hopes. But as the improvement of this fruit was the first object of my attention, no probable means of improvement either from soil or aspect were neglected. The plants, however, which I obtained from my efforts to unite the good qualities of two kinds of apple seem to possess the greatest health and luxuriance of growth, as well as the most promising appearance in other respects. In some of these, the character of the male appears to prevail; in others, that of the female; and in others both appear blended, or neither is distinguishable. These variations, which were often observable in the seeds taken from the single apple, evidently arise from the want of permanence in the characters of this fruit when raised from seed.

"The results of similar experiments on another fruit, the grape, were nearly the same as of those on the apple, except that by mingling the farina of a black and a white grape, just as the blossoms of the latter were expanding, I sometimes obtained plants from the same berry so dissimilar that I had good reason to believe them the produce of superfœtation. By taking off the cups and destroying the immature male parts (as in the pea), I perfectly succeeded in combining the characters of different varieties of this fruit, as far as the changes of form and autumnal tints in the leaves of the offspring will allow me to judge.

Many experiments of the same kind were tried on other plants; but it is sufficient to say that all tended to evince, that improved varieties of every fruit and esculent plant may be obtained by this process, and that nature intended that a sexual intercourse should take place between neighbouring plants of the same species. The probability of this will, I think, be apparent, when we take a view of the variety of methods which nature has taken to disperse the farina, even of these plants in which it has placed the male and female parts within the same empalement. It is often scattered by an elastic exertion of the filaments which support it in the first opening of the blossom, and its excessive lightness renders it capable of being carried to a great distance by the wind. Its position within the blossom is generally well adapted to place it on the bodies of insects, and the villous coat of the numerous family of bees is not less well calculated to carry it. I have frequently observed with great pleasure the dispersion of the farina of some of the grasses, when the sun had just risen in a dewy morning. It seemed to be impelled from the plant with considerable force, and being blue was easily visible, and very strongly resembled in appearance the explosion of a grain of gunpowder. An examination of the structure of the blossoms of many plants, will immediately point out that nature has something more in view than that its own proper males should fecundate each blossom, for the means it employs are always best calculated to answer the intended purpose.

pose. But the farina is often so placed that it can never reach the summit of the pointal, unless by adventitious means; and many trials have convinced me that it has no action on any other part of it. In promoting this sexual intercourse between neighbouring plants of the same species, nature appears to me to have an important purpose in view; for independent of its stimulative power, this intercourse certainly tends to confine within more narrow limits those variations which accidental richness or poverty of soil usually produces. It may be objected by those who admit the existence of vegetable mules, that under this extensive intercourse these must have been more numerous; but my total want of success in many endeavours to produce a single mule plant, makes me much disposed to believe that hybrid plants have been mistaken for mules, and to doubt (with all the deference I feel for the opinions of Linnæus and his illustrious followers) whether nature ever did or ever will permit the production of such a monster. The existence of numerous mules in the animal world between kindred species is allowed, but nature has here guarded against their production, by impelling every animal to seek its proper mate; and amongst the feathered tribe, when, from perversion of appetite, sexual intercourse takes place between those of distinct genera (A), it has in some instances at least rendered the death of the female the inevitable consequence. But in the vegetable world there is not any thing to direct the male to its proper female, its farina is carried by winds and insects to plants of every different genus and species, and it therefore appears to me (as vegetable mules certainly are not common) that nature has not permitted them to exist at all.

"I cannot dismiss this subject, without expressing my regret, that those who have made the science of botany their study should have considered the improvement of those vegetables, which in their cultivated state afford the largest portion of subsistence to mankind and other animals, as little connected with the object of their pursuit. Hence it has happened, that whilst much attention has been paid to the improvement of every species of useful animal, the most valuable esculent plants have been almost wholly neglected. But when the extent of the benefit which would arise to the agriculture of the country, from the possession of varieties of plants, which with the same extent of soil and labour would afford even a small increase of produce, is considered, this subject appears of no inconsiderable importance. The improvement of animals is attended with much expence, and the improved kinds necessarily extend themselves slowly; but a single bushel of improved wheat or peas may in ten years be made to afford seed enough to supply the whole island, and a single apple or other fruit tree may within the same time be extended to every garden in it. These considerations have been the cause of my addressing the foregoing observations to you at this time; for it was much my wish to have ascertained before I wrote to you, whether in any instance a single plant can be the offspring of two male parents. The decision of that question must of necessity have occupied two years, and must therefore be left to the test of future experiment."

February. Fruit Garden.

The opinion Mr Knight endeavours to establish towards the end of his letter, is certainly incorrect, if he means to assert that hybrids can only be produced by a commixture of different varieties of the same species, and that none can be produced by the union of plants of different species. The fact already stated relative to the hybrid produced between the *papav. oriental.* and *somnif.* (two species as different, in every respect, from each other as the horse and ass).

Sect. II. *Fruit Garden.*

96 Pruning of fruit-trees.

Where peaches, nectarines, and apricots, have not been pruned before this, that work ought to be done without delay, because the flower buds after they have begun to swell (which they do at this season) are easily rubbed off. Plums, cherries, apples, pears, gooseberries, currants, and raspberries, &c. may likewise be pruned during this month, if neglected till now.

97 Figs.

About the end of the month you may prune fig trees, as by that time all danger of the young shoots being killed by the frost will be over. As the young shoots of last season alone produce figs the ensuing, a sufficient supply of them must be left to nail on to the wall; and superfluous, ill-placed, very strong long-jointed shoots, and small weak ones, ought to be cut away close to the branch of the former year's growth. The branches which are retained ought to be laid in and nailed to the wall at full length, at the distance of about half a foot from each other. They ought not to be shortened, because the figs are generally produced from that part of the branch near to the extremity: on this account likewise care must be taken, in choosing those which are to be retained, not only to prefer the shoots of moderately vigorous growth, but likewise those which have had least of their extremities killed by the frost, for it frequently happens that the frost kills the succulent extremities of branches, and sometimes even the whole shoot.

Shortening the branches has another bad effect besides removing the part from which the fruit is to proceed, it makes them throw out a crowd of lateral shoots, which create confusion and shade the fruit. All worn-out old branches which are not furnished with a sufficient number of young lateral shoots, ought to be cut away, either close to the main branch from which they proceed, or close to some shoot placed near their lower end. Young fig trees may be planted also any time this month. See October.

98 Plant, &c. strawberries.

Strawberry beds should now receive a dressing. Last year's runners should be cut away, weeds and decayed leaves removed, the ground between the rows dug or loosened with the hoe, and some earth drawn up about the roots of the plants. Strawberries may be planted towards the end of the month: for the method, see June and September.

99 Force early fruit.

Any time this month you may begin to force the trees on hot walls, in vine, peach, and cherry houses, &c.

(A) This is said to be the case with the drake and the hen.

February. Pleasure or Flower Garden.

&c. They ought to be covered with the glasses, some time previous to the application of fire-heat, and if the houses have been constructed with pits for containing hot-beds of tanners bark or horse dung, a quantity of either should be got ready. If tanners bark is to be used, it ought to be spread out and exposed to the air, that it may dry, for if it be put in too wet it will either not heat at all, or heat violently and soon rot, but if properly dried, the heat will be moderate and last for a long time. When horse dung is to be used, it ought to be forked up into a heap and allowed to remain for a few days, during which time it should be turned two or three times with a fork that it may be thoroughly mixed. Slight fires should be applied for two or three days at first, which may be gradually increased. They ought to be kindled about sunset, and supplied with fuel from time to time till about ten o'clock, which will keep the house in a proper heat until morning, when the fires should again be set a going, if the heat has declined, but it will seldom be necessary at this season to keep the fires burning all day. The fuel employed may be either coal, wood, peat, or turf: of these coal is best, because it makes the strongest, the most durable, and most easily managed fire. The heat of each house should be regulated by a thermometer. The degree of warmth kept up at this season, should not much exceed the 60° of Fahrenheit. When the sun shines bright, the heat must be regulated by opening the glasses more or less, and admitting the external air. Besides the trees that may be trained to the wall or front of the house, pots or boxes containing cherry or peach trees may be introduced; likewise pots of kidney beans, strawberries, &c. roses, and a variety of other flowers. The trees and plants within the house must be duly watered, and have plenty of air admitted to them whenever the weather will permit. When the fruit approach to maturity a greater heat should be maintained within the house, which may be effected during the day by the rays of the sun, and sparing admission of the external air, and during the night (if the weather be cold) by fire.

SECT. III. *The Pleasure* or *Flower Garden.*

100 Sow tender annuals.

TOWARDS the end of the month, you may sow some tender annuals, such as balsams, cockscombs, globe amaranthus, ice plants, egg plants, &c. They must be sown in a hot-bed, which is to be formed and earthed over in the same way as seed beds for cucumbers and melons. See JANUARY. The seeds may either be sown in the earth of the bed, or in pots plunged into the earth. Or a few may be sown in pots, and introduced into a cucumber or melon bed. When the plants have acquired sufficient strength to admit of being transplanted, they should be put into separate pots and transferred to other hot-beds. See APRIL.

101 Hardy annuals.

About the end of the month, you may sow some seed of mignionet, ten weeks stock, larkspur, flos Adonis, convolvulus, lupines, scarlet, sweet-scented, and Tangier pea, candytuft, dwarf lychnis, Venus's looking glass, Lobel's catchfly, Venus's navel wort, dwarf poppy, annual sunflower, oriental mallow, lavatera, hawkweed, and many others. They must be sown in places where they are to remain, for none of these plants succeed so well when they are transplanted.

Dig small patches with a trowel in the flower borders, break the earth well, remove part of it from the surface with the edge of the trowel, and sow the seeds, which should be covered with the earth which had been moved aside from the surface of the patches. The smaller seeds, such as mignionet, ten weeks stock, larkspur, &c. should be covered to the depth of about a quarter of an inch; the larger ones, such as lupines, painted and sweet peas, annual sunflower, &c. may be covered to the depth of an inch. After the plants have advanced a little in growth, they should be thinned out in proportion to their size, viz. one sunflower should be left in a place, two plants of lavatera and oriental mallow, four or five of the larger, and six or eight of the smaller lupines, and so on in proportion.

Most kinds of hardy perennials and biennials may be planted out this month, viz. polyanthuses, primroses, London pride, violets, double daisies, double chamomile, saxifrage, rose campion, rockets, campanula, catchfly, scarlet lychnis, double feverfew, bachelor's button, carnations, pinks, sweetwilliam, columbines, monkshood, tree primrose, foxglove, goldenrod, perennial asters, perennial sun-flower, holyhocks, French honeysuckles, wallflowers, and many others.

Where auricula plants are much valued, and where there are many of the finer varieties, they are commonly kept in pots. During mild weather any time this month, it would be proper to give them some fresh earth. Clear away all dead leaves from the plants, remove some of the old earth from the sides of the pot all around, so far as you can do it without injuring the roots, and fill the pots with fresh earth prepared for the purpose. See SEPTEMBER.

Auricula and polyanthus seed may be sown any time this month, either in the open grounds or in pots. When sown in pots or boxes they are more easily moved to proper situations during different seasons. Sow them in light rich earth, and cover them to the depth of about a quarter of an inch. The pots or boxes should be placed in a situation sheltered from the north, and exposed to the morning and mid-day sun, from which they ought to be removed in April to a more shady place. They will be fit for transplanting in the month of June. See JUNE.

About the end of the month plant out the carnations which were raised last year by cuttings or layers, into pots or borders where they are to remain to produce flowers in the ensuing summer.

Any time this month you may transplant evergreen trees, and shrubs; such as pines, firs, evergreen oaks, hollies, yews, cypresses, cedars, phillyreas, arbutuses, laurels, laurustinus, &c.

The finer sorts of tulips, hyacinths, anemones, ranunculuses, &c. should be protected during severe weather, as they begin to appear above ground. For the method of sheltering them, see JANUARY.

Grass walks and lawns ought to be kept clean, poled and rolled at least once a week if the weather permit it. After being rolled with a wooden roller to take off the worm-casts, a heavy stone or iron one should be passed over them to render them firm. Their edges ought likewise to be cut with an edging iron about the end

end of the month, which will give them a neat appearance.

[1]7 W[alk]s and [e]dgings.

Gravel and grass walks may be made during this month: for the latter, see JANUARY, and the former MARCH.

Edgings of boxwood, thrift, daisies, thyme, hyssop, &c. may be planted this month. Boxwood forms the neatest, most durable, and most easily kept edging, and if planted now it will succeed very well. For the method, see OCTOBER. Where any of the old boxwood edgings have become irregular, they ought to be taken up and replanted.

Thrift is frequently employed as an edging, and well kept makes a very neat one. The plants may be either put in with the dibble so close as to touch, or at the distance of two or three inches from each other, or planted as boxwood, see OCTOBER. Daisies are sometimes used, and form a very pretty edging; they may be planted in the same manner as the thrift.

[1]8 Ea[rly] flow[ers] for[ced].

A great variety of flowers, such as hyacinths, jonquils, and roses, &c. may be placed in the hot-house, vinery, or peach-house; and when they have come into flower they may be placed in a green-house, or in apartments of a dwelling house.

SECT. IV. *Nursery.*

MANY things mentioned under the article work to be done in the *nursery* for *January* may likewise be done this month; such as pruning young trees and shrubs, digging between the rows, propagating by cuttings, suckers, and layers, &c. See JANUARY.

La[yers] tra[ns]plan[ted].

Such layers of last year, as appear well rooted, should be removed from the parent plant (or stool), and planted in rows of from one to two feet asunder, according to the size of the plant, and at the distance of a foot or foot and a half from each other in the row.

See[ds] of shru[bs] &c. sow[n].

If seeds or stones of apples, pears, cherries, and plums, were not sown last autumn to raise stocks for budding and ingrafting, they should be sown about the beginning of this month. They should be sown in light soil, and covered to about the depth of an inch. The plants raised from this sowing will be fit for transplanting in the beginning of next winter or spring. The seeds of berries and nuts of shrubs and forest trees may likewise be sown any time this month in narrow beds, and covered in proportion to their size, viz. the small seeds to the depth of about half an inch, the larger to the depth of an inch or an inch and a half, and some of the nuts even to a greater depth.

1[21] and [tran]s-plan[ted].

Trees and shrubs may be removed from the seed-bed or from where they stand too thick, and planted out in rows at proper distances, or transplanted into the places where they are to remain.

1[22] Stock[s] heade[d].

Young trees that were budded successfully last summer should be cut down to within about four inches of the bud. See JUNE and JULY.

1[23] Fruit [tr]ees engra[fte]d.

Pears, plums, and cherries may be ingrafted towards the end of the month, if the weather is mild: apples likewise may be ingrafted at the same time, or in the course of the following month.

Grafting or engrafting, in gardening, is the taking a shoot from one tree, and inserting it into another, in such a manner, that both may unite closely and become one tree.

February. Nursery.

By the ancient writers on husbandry and gardening this operation is called *incision*, to distinguish it from inoculation or budding, which they call *insertion*. Grafting has been practised from the most remote antiquity, but its origin and invention are differently related by naturalists. Theophrastus tells us, that a bird having swallowed a fruit whole, cast it forth into a cleft or cavity of a rotten tree, where, mixing with some of the putrefied parts of the tree, and being washed with the rains, it germinated, and produced within this tree a tree of a different kind. This led the husbandman to certain reflections, from which afterwards arose the art of engrafting.

114 History of engrafting.

Pliny gives a different account of the origin of grafting: he says, a husbandman wishing to make a pallisade in his ground, that it might endure the longer, and with a view to fill up and strengthen the bottom of the pallisade, wattled it with the twigs of ivy. The effect of this was, that the stakes of the pallisades taking root, became engrafted into the twigs, and produced large trees, which suggested to the husbandman the art of engrafting.

The use of grafting is to propagate any desirable sorts of fruit so as to be certain of the variety: for as all good varieties of fruit have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as is not worth cultivating; but when grafts are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock or tree on which they are grafted. Many have supposed that fruit undergoes a change, by being engrafted; but this is not the case. M. Du Hamel tried it on different trees, and for fear of error repeated every experiment several times. He grafted the peach on the almond, the plum on the apricot, the pear upon the apple, the quince on the white thorn, one species of plum on another, and the almond and apricot on the peach. All these succeeded alike; the fruit was never altered; the leaves, the wood, the flowers, were perfectly the same with those of the tree from which the grafts were taken.

Some authors have made mention of engrafting trees of distinct genera on one another; such as the apple on the oak, the elm, the maple, and the plum. M. Du Hamel tried a number of these experiments, none of which proved successful. Engrafting seems never to succeed but when trees of the same natural family are grafted on one another. Some trees are supposed to live longer, and grow more vigorously when engrafted than when growing in a natural state. It is said, that this is the case with the peach, when engrafted on the plum. But it is commonly alleged, that engrafted trees do not live so long as they would have done in their natural state. The reason why engrafted trees are short lived, perhaps proceeds from another cause than merely from the circumstance of being grafted, viz. the age of the tree from which the scions were originally taken.

115 Method of performing it.

The proper tools and other materials used in grafting, are, 1. A strong knife for cutting off the heads of the stocks previous to the insertion of the graft; also a small hand saw for occasional use in cutting off the heads of large stocks. 2. A common grafting knife or sharp pen knife for cutting and shaping the grafts ready for insertion; also to slope and form the stocks for the

February. Nursery.

the reception of the grafts. 3. A flat grafting chisel and small mallet for cleaving large stocks, in cleft grafting, for the reception of the graft. 4. A quantity of new bass strings for bandages for tying the grafted parts close together, to secure the grafts, and promote their speedy union with the stock. And, 5. A quantity of grafting clay for claying closely round the grafts after their insertion and binding, to defend the parts from being dried by the sun and winds, for these parts ought to be closely surrounded with a coat of clay in such a manner as effectually to guard them from all weathers, which would prove injurious to the young grafts, and prevent their junction with the stock.

For this purpose some argillaceous loam or pure clay must be procured, to which should be added one-fourth part of fresh horse dung and a small portion of cut hay. The whole must be well moistened with water, and thoroughly beat with a stick after the manner of mortar.

The scions or grafts (which should be shoots of last year) ought to be selected and cut off some time about the beginning or middle of the mouth. Each kind ought to be put up separately in little bundles, which should be inserted into the earth of a dry border, and should be protected during severe weather by a covering of straw or something of that nature. The reason for taking them off at the time mentioned, is that their growth may be checked, and that they may be preserved in a condition for grafting; for were they to remain on the trees, their buds would begin to swell, and would soon advance so far as to be unfit for using with any prospect of success. The stock intended to be grafted, must, previous to the insertion of the graft, be cut down; those intended for dwarf trees, to be trained on walls or espaliers, must be cut over five or six inches above the ground; those intended for standards should be cut over at the height of five or six feet.

The stocks must vary according to the kinds of fruit to be grafted on them, and to the size of the tree to be produced. Apples are grafted on apple stocks raised from seed, cuttings, or layers; for dwarfs, paradise pippin or Siberian crab stocks are used; for half dwarfs, codlin stocks raised from suckers, cuttings or layers; and for full standards, stocks raised by sowing the seed of crabs or any common apple. Pears are engrafted upon pear stocks obtained from seed or suckers, on quinces, and on white thorn. When they are engrafted on quince stocks, they become dwarf, and are fit for espaliers, &c.

Cherries are engrafted upon cherry stocks obtained by sowing the stones of red or black cherries, and plums are engrafted upon plum stocks raised from seed or suckers (B).

There are different methods of grafting, termed whip-grafting, cleft-grafting, crown-grafting, cheek-grafting, side-grafting, root-grafting, and grafting by approach or inarching; but whip-grafting and cleft-grafting are the most commonly used, and whip-grafting most of all.

February. Nursery. Whip-grafting.

Whip-grafting being the most expeditious and successful method of grafting, is the most commonly practised in all the nurseries; it is always performed upon small stocks, from about the size of a goose-quill to half an inch or a little more or less in diameter, but the nearer the stock and graft approach in size, the better; and is called whip-grafting, because the grafts and stock being nearly of a size, are sloped on one side so as to fit each other, and tied together in the manner of whips or joints of angling rods. &c.; and the method is as follows. Having the scions or grafts, knife, bandages, and clay ready, begin the work by cutting off the head of the stock at some smooth part; this done, cut one side sloping upwards, about an inch and a half or near two inches in length, and making a notch or small slit near the upper part of the slope downwards, about half an inch long, to receive the tongue of the scion; then prepare the scion, cutting it to five or six inches in length, forming the lower end also in a sloping manner, so as exactly to fit the sloped part of the stock, as if cut from the same place, that the bark of both may join evenly in every part, and make a slit so as to form a tongue to fit the slit made in the slope of the stock; then place the graft, inserting the tongue of it into the slit of the stock, applying the parts as evenly and close as possible, and immediately tie the parts close together with a string of bass, passing closely several times round the stock and graft; then clay the whole over near an inch thick all round, from about half an inch or more below the bottom of the graft, to an inch above the top of the stock, finishing the whole coat of clay in a kind of oval form, closing it effectually about the scion, so that neither air nor water may penetrate. The clay must be examined from time to time, for should it crack much, or fall off, a quantity of fresh clay ought to be applied immediately. This sort of grafting may also be performed upon the young shoots of any bearing tree, if you wish to alter the kind of fruit or to have more kinds than one on the same tree. By the middle or latter end of May the graft will be well united with the stock, as will be evident from the shooting of the buds of the graft, when the clay should be removed; but the bass bandage should remain until the united parts seem to swell, and be too much confined, then the bandage should be taken off entirely.

Cleft-grafting.

Cleft-grating is so called because the stock being too large for whip-grafting, is cleft or slit down the middle for the reception of the graft, and is performed in stocks from one to two inches diameter or upwards. First, with a strong knife take off the head of the stock with a sloping cut about an inch and a half long, then cleave the stock with a strong knife or chisel and mallet across the slope to the depth of about two inches, or long enough to admit the graft, leaving the instrument in to keep the cleft open. Prepare the scion by cutting it to such length as to leave four or five eyes, sloping the lower part of it on each side, wedge fashion, to the length of an inch and a half or two inches, making one edge very thin, and leaving the other much thicker with the bark on; then place it in the cleft at the back part

(B) Stocks which are raised from seed, generally grow more freely and vigorously than those raised from cuttings or layers, and on that account are called free stocks.

part of the stock, with the thickest edge outwards to the whole depth of the slope, taking care that the bark of the stock and graft join exactly; when the knife or chisel is removed, each side of the cleft will press on the graft and hold it fast. It must then be bound with a bass bandage and clayed over as in whip-grafting, leaving three or four of the eyes of the scion uncovered.

If large stocks or branches are to be grafted in this way, they must be cut horizontally and smoothed, and may be cleft quite across, and a graft inserted on each side. More clefts indeed than one may be made, and two grafts put in each. This method of grafting may be performed on the branches or stems of old trees, with a view to produce vigorous branches or change the kind of fruit.

Towards the latter end of May or beginning of June the junction of the graft with the stock will be effectually formed, when the clay may be removed, and in a fortnight afterwards the bass bandage may also be taken away.

Crown-grafting.

Crown-grafting is commonly practised upon such stocks as are too large to cleave, and is often performed upon the large branches of apple and pear trees, &c. that already bear fruit, when it is intended to change the sorts, or supply the tree with a number of new vigorous branches. It is termed crown-grafting, because, after the stock or branch has been cut over, several grafts are inserted all around betwixt the wood and bark, so as to produce a crown-like appearance; this kind of grafting should not be performed until March or early in April, for then the sap being in motion renders the bark and wood of the stock much easier to be separated for the admission of the graft. The manner of performing this sort of grafting is as follows: first cut off the head of the stock horizontally, and pare the top smooth; then having the grafts, cut one side of each flat, and somewhat sloping, an inch and a half, forming a sort of shoulder at the top of the slope to rest upon the crown of the stock; after the bark of the stock has been raised by means of a wedge, so as to admit the scion between the bark and the wood, let the scion be thrust down to the shoulder with its cut side next the wood of the stock: in this manner three, four, or more grafts may be inserted into one stock or branch. After the grafts have been inserted, let them be tied tight, and let the clay be applied so as to rise an inch above the top of the stock, taking care to form it so as to prevent the admission of water, which would injure the grafts. Crown-grafting may also be performed by making several clefts in the crown of the stock, and inserting the grafts into the clefts. The grafts will be pretty well united with the stock by the end of May or beginning of June, when the clay and bandage may be taken away. The trees grafted by this method will succeed very well; but for the first two or three years the grafts are liable to be blown out of the stock by violent winds, to prevent which, long sticks must be tied to the stock or branch, to which they may be fixed.

119 Cheek-grafting.

Cheek-grafting is thus executed. Cut the head of the stock off horizontally, and pare the top smooth: then cut one side sloping an inch and a half or two inches deep, and cut the lower part of the graft sloping the same length, making a sort of shoulder at the top of the sloped part; it is then to be placed upon the sloped part of the stock, resting the shoulder upon the crown of it; bind it with bass, and finish it with a covering of clay as in whip-grafting.

120 Side-grafting.

Side-grafting is done by inserting grafts into the sides of the branches without cutting them over, and may be practised upon trees to fill up any vacancy, orfor the purpose of variety, to have several sorts of apples, pears, plums, &c. upon the same tree. It is performed thus. Fix upon such parts of the branches where wood is wanted to furnish the head or part of the tree; there slope off the bark and a little of the wood, and cut the lower end of the grafts to fit the part as near as possible; then join them to the branch and tie them with bass, and clay them over.

121 Root-grafting.

Root-grafting. This is done by whip-grafting scions upon pieces of the root of any tree of the same genus, and planting the root where it is to remain; it will take root, draw nourishment, and feed the graft.

122 Inarching.

Grafting by approach, or inarching, is preferred when the stocks designed to be grafted, and the tree from which the graft is intended to be taken, either grow so near, or can be placed so near together, that the branch or graft may be made to approach the stock, without separating it from the tree till after its union or junction with the stock, so that the branch or graft being bent to the stock they together form a sort of arch, whence it is called grafting by approach, or inarching. It is commonly practised upon such trees as are with difficulty made to succeed by any of the former ways of grafting. When intended to propagate any kind of tree or shrub by this method of grafting; if the tree be hardy enough to grow in the open ground, a proper quantity of young plants for stocks must be set round it, and when grown of a proper height, the work of inarching must be performed; if the branches of the tree you intend to take grafts from be too high for the stocks, in that case the stocks planted in pots, must be placed on a slight stage or some support of that nature, of such a height as to make them reach the branches. Inarching is sometimes performed with the head of the stock cut off, sometimes it is allowed to remain; when the head of the stock is cut off, the work is more easily performed, and is generally more successful, because the stock having no top of its own to support, will transmit all the nourishment taken up by its roots into the graft; when the stocks are properly placed, make the branches approach to them, and mark on the branches the places where they will most easily join to the stock, and in those parts of each branch, pare away the bark and part of the wood two or three inches in length, and in the same manner pare the stock at the proper place; then make a slit upwards in the branch so as to form a sort of tongue, and make a slit downwards in the stock to admit it; let the parts be then joined, sloping the tongue of the graft into the slit of the stock so as to make the whole join in an exact manner; then tie them close together with bass, and afterwards cover the whole with a proper quantity of clay, as before directed in the other methods. After this, let a stout stake be fixed for the support of each graft, to which the stock and graft may be fixed, to prevent their being disjoined by the wind. If this operation be performed in spring, the graft and stock will be united in four months, when the branch may be separated from the parent plant; this should be done cautiously and with a sharp knife, lest the graft should be

February. Nursery.

be shaken and loosened from the stock. If the head of the stock were not removed previous to inarching, it should now be cut off close to the insertion of the graft, and all the old clay and bandages should be taken away and replaced with new, which should be allowed to remain a few weeks longer. If the graft and stock do not seem perfectly united the first autumn after they have been inarched, they should be allowed to stand till next autumn: for were the branch to be cut off from the parent plant before a complete union was formed between it and the stock, the operation would prove abortive.

123 A new method.

An anonymous author has given, in a treatise published at Hamburgh under the title *Amœnitates Hortenses Novæ*, a new method of grafting trees, so as to have very beautiful pyramids of fruit upon them, which will exceed in flavour, beauty, and quantity, all that can otherwise be produced. This he says he had long experienced, and gives the following method of doing it. The trees are to be transplanted in autumn, and all their branches cut off: early in the following summer the young shoots are to be pulled off, and the buds are then to be engrafted into them in an inverted position. This he says, not only adds to the beauty of the pyramids, but also makes the branches more fruitful. These are to be closely connected to the trunk, and are to be fastened with the common ligature; they are to be placed circularly round the tree, three buds in each circle, and these circles at six inches distance from each other. The old trees may be grafted in this manner, the success having been found very good in those of twenty years standing; but the most eligible trees are those which are young, vigorous, and full of juice, and are not above an inch or two thick. When these young trees are transplanted, they must be fenced round with pales to defend them from the violence of the wind. The buds engrafted must be small, that the wounds made in the bark to receive them, not being very large, may heal the sooner; and if the buds do not succeed, which will be perceived in a fortnight, there must be others put in their place. The wound made to receive these buds must be a straight cut, parallel to the horizon, and the piece of bark taken out, must be downwards that the rain may not get in at the wound. In the autumn of the same year this will be a green flourishing pyramid, and the next summer it will flower, and ripen its fruit in autumn.

124 Extreme branch-grafting.

Mr Fairman, of Kent, gives an account of a method of renewing decayed trees, by what he calls extreme branch-grafting, which has been published in the Memoirs of the Society of Arts for 1802. It is addressed to the Secretary.

"Sir,

"From much conversation with Mr Bucknall, on the idea of improving standard fruit trees, we could not but remark that in apple orchards, even in such as are most valuable, some were to be seen that were stinted and barren, which not only occasioned a loss in the production, but made a break in the rows, and spoiled the beauty and uniformity of the plantation.

"To bring these trees into an equal state of bearing, size, and appearance, in a short time, is an object of the greatest importance in the system of orcharding, and also for the recovery of old barren trees, which are fallen into decay, not so much from age as from the sorts of their fruits being of the worn out, and deemed nearly lost, varieties.

"Having long entertained these thoughts, and been by no means inattentive to the accomplishment of the design, I attempted to change their fruits by a new mode of engrafting, and am bold enough to assert that I have most fortunately succeeded in my experiments; working, if I am to be allowed to say it, from the errors of other practitioners, as also from those of my own habits.

"My name having several times appeared in the Transactions of the Society for the Encouragement of Arts, &c.; and having the honour of being a member of that Society, I thought no pains or expence would be too much for the completion of so desirable an improvement. Under these impressions, and having many trees of this description, I made an experiment on three of them in March 1798, each being nearly a hundred years old. They were not decayed in their bodies, and but little in their branches. Two of these were golden pippins, and the other was a golden rennet: each had likewise been past a bearing state for several years. I also followed up the practice on many more the succeeding spring, and that of the last year, to the number of forty at least, in my different plantations (c).

"The attempt has gone so far beyond my utmost expectation, that I beg of you, Sir, to introduce the system to the society for their approbation; and I hope it will deserve the honour of a place in their valuable Transactions.

"I directed the process to be conducted as follows: cut out all the spray wood, and make the tree a perfect skeleton, leaving all the healthy limbs; then clean the branches, and cut the top of each branch off, where it would measure from an inch to two inches in diameter. Some of the branches must of course be taken off, where it is a little larger, and some smaller, to preserve a head or canopy of the tree; and it will be necessary to take out the branches which cross others, and observe the arms are left to fork off; so that no considerable opening is to be perceived when you stand under the tree, but that they may represent a uniform head. I must here remark to the practitioner, when he is preparing the tree as I directed, that he should leave the branches sufficiently long to allow of two or three inches to be taken off by the saw, that all the splintered parts may be removed.

"The trees being thus prepared, put in one or two grafts at the extremity of each branch: and from this circumstance I wish to have the method called *extreme branch grafting*. A cement, hereafter described, must be used instead of clay, and the grafts tied with bass or soft string. As there was a considerable quantity of moss on the bodies and branches of the trees, I ordered my gardener to scrape it off, which is effectually done when they are wet, by a stubbed birch broom. I then ordered

(c) The average expence I calculated at 2s. 6d. each tree.

ordered him to brush them over with coarse oil, which invigorated the growth of the tree, acted as a manure to the bark, and made it expand very evidently; the old cracks were soon, by this operation, rendered invisible.

"All wounds should be perfectly cleaned out, and the medication applied, as described in the Orchardist, p. 14. By the beginning of July the bandages were cut, and the shoots from the grafts shortened, to prevent them from blowing out. I must here, too, observe, that all the shoots, or suckers from the tree, must enjoy the full liberty of growth till the succeeding spring, when the greater part must be taken out, and few but the grafts suffered to remain, except on a branch where the grafts have not taken; in that case leave one or two of the suckers, which will take a graft the second year, and make good the deficiency. This was the whole of the process (D).

"By observing what is here stated, it will appear that the tree remains nearly as large when the operation is finished, as it was before the business began; and this is a most essential circumstance, as no part of the former vegetation is lost, which is in health fit to continue for forming the new tree. It is worthy of notice, that when the vivifying rays of the sun have caused the sap to flow, these grafts, inducing the fluid through the pores to every part of the tree, will occasion innumerable suckers or scions to start through the bark, which, together with the grafts, give such energy to vegetation, that, in the course of the summer, the tree will be actually covered over by a thick foliage, which enforces and quickens the due circulation of sap. These, when combined, fully compel the roots to work for the general benefit of the tree.

"In these experiments, I judged it proper to make choice of grafts from the sorts of fruits which were the most luxuriant in their growth, or any new variety, as described in the 17th and 18th volumes of the Society's Transactions, by which means a greater vigour was excited; and if this observation is attended to, the practitioner will clearly perceive, from the first year's growth, that the grafts would soon starve the suckers which shoot forth below them, if they were suffered to remain. With a view to accomplish this grand object of improvement, I gave much attention, as I have observed before, to the general practice of invigorating old trees; and I happily discovered the error of the common mode of engrafting but a short distance from the trunk or body. There the circumference of the wounds is as large as to require several grafts, which cannot firmly unite and clasp over the stumps, and consequently these wounds lay a foundation for after decay. If that were not the case, yet it so reduces the size of the tree, that it could not recover its former state in many years, and it is dubious if it ever would; whereas, by the method of extreme grafting, the tree will be larger in three or four years, than before the operation was performed. For all the large branches remaining, the tree has nothing to make but fruit-bearing wood; and from the very beautiful verdure it soon acquires, and the symmetry of the tree, no argument is necessary to enforce the practice. Some of the trees, done in this way, yielded each two bushels of apples from the third year's wood.

Cement for Engrafting.

One pound of pitch,
One pound of rosin,
Half a pound of bees-wax,
A quarter of a pound of hog's lard,
A quarter of a pound of turpentine;

to be boiled up together, but not to be used till you can bear your finger in it."

February. Green-house and Hot-house.

Sect. V. *Green-house and Hot-house.*

THE same care of the green-house is required during this month which was recommended in January. If severe frost, or very wet weather prevails, the glasses must be kept close during the day to exclude the frost and damp, or slight fires may be had recourse to for this purpose.

125 Air to be admitted.

In mild weather the glasses must be opened during the day to admit air, and water must be given to the plants regularly, though sparingly. Towards the end of the month it will be proper to remove a little of the earth from the surface and sides of the boxes or pots, and to replace it with some fresh compost. If any of the orange trees, myrtles, or plants of that nature, have irregular heads, they may be cut so as to cause them to throw out a number of new branches to fill up any vacant places, or form an entirely new head. If they require to be much pruned, or to be cut over altogether, it would be proper to shift them at the same time, i. e. to remove them from the box or pot in which they have stood with the ball of earth about their roots, part of which, together with any matted roots, should be pared off from the sides and bottom, and replaced in the boxes and pots, with a proper addition of fresh earth. Any of the plants which are to undergo this operation, that are very sickly, should have almost the whole of the earth removed from their roots, and ought, for some time after shifting, to stand in a bark-bed.

126 Pine stove.

If the bark-bed in the pine stove received no fresh tan or turning last month, it should be examined as early as convenient; and if the heat should have at all declined, it ought immediately to be turned or have an addition of fresh tan, as directed last month. See JANUARY.

If a lively heat be not kept up in the bark-bed now, when the plants shew flower, the size of the future fruit will be considerably affected. A proper degree of warmth, applied to the roots of the plants, will make them grow vigorously and produce large fruit. The heat of the air of the house must be kept at a proper temperature, by due attention to the fires every night and morning, and even during the day in frosty weather, or when cold winds prevail. The bark-bed, in which the succession pine-apple plants grow, should be examined; and if the heat in it begins to decline, it ought

(D) The system succeeds equally well on pear, as also on cherry trees, provided the medication is used to prevent the cherry tree from gumming.

March. Kitchen Garden.

ought to be turned or receive an addition of fresh tan. When the sun shines bright, and the weather is moderate, air must be given by opening some of the glasses. Water should be given regularly both to the pine apple and other plants in the hot-house, bnt much should not be given at a time.

127 Kidney beans to be watered. The kidney beans that were sown last month should receive water frequently. If none were sown last month, some of the early dwarf kinds may be sown now.

128 Cucumbers sown. If no cucumbers were sown last month in the hot-house, some may be sown now; or, plants raised in hot-beds may be introduced, and placed in any convenient situation near the glass.

MARCH.

Sect. I. *Kitchen Garden.*

We need not here give a detailed account of the methods of performing many of the things mentioned under this head, in the two preceding months, though most of them might be performed now with better prospect of success, as this is the principal month in the year for

129 Sow full crops. sowing and planting full crops of the greater part of kitchen-garden vegetables. We shall, therefore, merely enumerate them. Make hot-beds. Sow cucumbers and melons. Transplant and sow cauliflower. Transplant and sow cabbage. Transplant and sow lettuce. Sow spinach, onions, leeks, radishes, carrots, parsnips, beets, beans, peas, turnips, celery, small salad, parsley, salsafy, and Hamburgh parsley. Plant shallot, garlic, scorzonera, and rockambole.

130 Brocoli. Some seed of the early purple and cauliflower brocoli should be sown, both about the beginning and towards the end of the month, in a bed of rich earth, in an open situation, to raise plants to be fit for the table the following autumn. For the subsequent management, see April, May, June, and July.

131 Sea cabbage. The seeds of the sea cabbage (*crambe maritima*) may be sown any time this month, in narrow beds of light earth, about four feet wide, for the convenience of weeding. They may either be sown all over the surface of the bed, tolerably thick, when they are to be transplanted, or in drills a foot and a half or two feet apart, where they are to remain. Those plants are perennial, and every year push up thick succulent shoots. They should be covered some time during the course of the winter, with dry earth, to the depth of a few inches, by which the young shoots, as they come up in spring, are blanched and become fit for use. They should be cut as soon as they appear above ground, or very soon after, in the manner of asparagus.

132 Coleworts. Sow brown and green cole, or bore cole.

Any time in the course of the month some seeds of brown and green cole (kale) may be sown in an open situation, for when they are shaded they are apt to grow up tall and weak. The plants raised now will be fit for planting out in summer, and may be cut for use any time from autumn to spring.

133 Asparagus. About the beginning of this month asparagus seed may be sown in narrow beds of good earth in an open situation. The seed may be scattered regularly all over the surface of the bed, raked in, and then receive a slight covering of earth from the alleys, or in drills, about an inch deep, at the distance of six inches from one another. The plants will appear above ground in four or five weeks, when they ought to be kept clear of weeds and watered occasionally during dry weather. The plants raised now will be fit for transplanting next spring into beds, where they are to remain and produce crops, or into plots, to remain for a year or two till they be fit for forcing.

This a proper season for making plantations of asparagus, for which purpose young plants of one or two years old are commonly used. They succeed best in a deep light soil, and in an exposed situation. The ground should be well manured, dug to the depth of 12 or 15 inches, and divided into beds of the breadth of four feet and a half, in which the asparagus may be planted in rows, 10 or 12 inches apart, and about the same distance from each other in the rows. The usual mode of planting them is to stretch a garden line along the bed, and to form a drill with a spade, to the depth of about six inches, in which the asparagus roots are placed with their crowns or buds uppermost.

A crop of onions may be sown in beds when it is an object to make the most of the ground.

The surface of asparagus beds should be loosened or turned over with a fork, in the course of this month. The instrument commonly made use of for this purpose, is a fork with three flat blunt prongs. Care must be taken not to dig too deep, lest the tops of the asparagus roots should receive injury. Immediately after the surfaces of the beds have been loosened, they should be raked over; for if the raking were to be deferred for some time till the buds of the asparagus approach the surface of the ground, they might be broken by the teeth of the rake. Asparagus beds still continue to produce good crops for 10 or 12 years, if properly managed. They ought not to be cut till the third or fourth year after they have been planted in rich soils; however, a few of the strongest shoots may be cut even in the second, but it should be done sparingly. When asparagus has advanced to the height of three or four inches above ground, it should be collected for the table; but as the shoots are commonly cut about three inches under the surface of the ground, care must be taken not to injure the rising buds (for several buds rise in succession from the same root), for this reason, it is commonly cut with an instrument made on purpose, called an *asparagus knife*, which should be introduced close by the shoot to the requisite depth, and directed so as to cut it off obliquely.

Artichoke plants, that were earthed up during winter to protect them from frost, should now be examined; and if their stems appear to push up vigorously, the earth ought to be removed and levelled. The soil should likewise be loosened from the plants, and if many shoots proceed from the same root, they should all be taken away except three of the strongest. The redundant shoots, if carefully detached from the main roots may be employed to form new plantations; the earth, therefore, should be so far removed as to allow the hand to be introduced to slip them close to their insertion.

Plantations of young artichokes are made towards the end of this or in the course of next month, as soon, indeed, as the offsets (the only way in which this plant is propagated) can be procured. For this purpose choose a plot of good ground, dig in a good quantity of of rotten dung, and plant the offsets with a dibble after their tops and roots have been trimmed a little (if it appear necessary), in rows about four feet and a half asunder, and at the distance of from two to three feet in the rows. A crop of spinach, lettuce, radishes, &c. may be got from the ground the first year, without injuring the artichokes. This plantation will produce heads in September and October, and will continue to produce plentiful crops for six or seven years. Whenever artichokes are required late in the season, young plantations ought to be formed every year, as it is from them alone that heads may be expected late in autumn; for the old plantations generally produce them in June, July, and August. There are two sorts, the large globe, and the French or green oval artichoke; the former is commonly preferred, on account of the size of the head and the quantity of eatable matter they afford.

3 Pot-herbs propagated. Slips or cuttings of sage, rue, rosemary, hyssop, thyme, and savory, may be planted any time this month. They should be planted about six inches apart, and to the depth of nearly two-thirds of their length. By next autumn they will be fit for transplanting.

Sow skirrets. Some seeds of skirrets may be sown in narrow beds, in an open situation, either in drills six inches asunder, or regularly over the surface of the bed. After the plants have come above ground, they should be thinned out to the distance of about six inches from one another, and allowed to remain in the place where sown. This plant is frequently propagated by offsets taken from old roots, which should be planted at the distance of six or eight inches from one another.

Kidney beans. About the end of the month, if the weather be mild and dry, a few early kidney-beans may be sown in a well sheltered situation, at the foot of a wall, having a south exposure. See April. But as these plants are tender, they are liable to be injured by cold weather, therefore a small quantity only should be sown now.

and cardoons. About the middle or latter end of the month some cardoons may be sown for transplanting. For this purpose a piece of light ground should be well dug, the seed sown thinly, and raked in evenly; a few weeks after the plants have come up, they should be thinned out to the distance of about six inches from one another, to allow them room to grow till they are strong enough to be planted out, which will be in June. See June. They may be sown likewise in rows five feet asunder, and at the distance of four feet from each other in the row, and allowed to remain where sown. They are biennial, grow to the height of three or four feet, and are cultivated for the sake of the footstalks of their leaves, which are blanched by being earthed up somewhat in the manner of celery, on which account they require a good deal of room.

14[illegible] Plant chives. This is a proper time to plant chives, a small species of onion, which is used in spring as a substitute for young onions. They grow in large tufts, which are propagated by parting the roots into small tufts containing eight or ten bulbs, which may be planted with the dibble in beds or rows at the distance of six or eight inches from one another.

143 Jerusalem artichokes. You may now plant Jerusalem artichokes, a species of sunflower (*helianthus tuberosa*) the roots of which somewhat resemble the potato, and are to be planted much in the same manner, to the depth of about four inches, in rows three feet apart, and about half that distance from each other in the row. They are fit for the table in October, and continue good all winter and spring.

A full crop of potatoes may be planted any time towards the end of this or in the course of next month. 144 potatoes, Cuttings of moderate-sized potatoes (of the variety intended to be planted), each containing one or two eyes, at least, may be put in with a blunt dibble, to the depth of about four inches, in rows two feet apart, and at the distance of about a foot from each other in the row, or in trenches or holes made with the spade. In the fields they are planted either with the dibble or in furrows made by the plough. See Agriculture. They succeed best in light soil, which should be well manured. After they have come above ground, they ought to be kept clear of weeds, and have a quantity of earth drawn up about their stems. There are many varieties of this vegetable, which are obtained from seed; the principal are, early dwarf, champion, large round white, oblong red and white kidney, common kidney, small white kidney, round red, large round dark red, &c.

Any time in the course of this month new plantations of mint may be formed. 145 and mint, This plant is propagated by parting the roots or by cuttings of the young stalks; the former is practised this month, the latter in next and following month. Procure a quantity of the roots from an old plantation of mint; part and plant them in rows six inches asunder, and about the same distance from each other in the row, either with the dibble, or in drills about an inch deep, drawn by the hoe. These plants succeed very well in any soil, but prefer a moist one. The kinds commonly cultivated are spearmint, peppermint, orangemint, &c.

The leaves and flowers of Indian cresses are frequently used for salads, and their seeds for pickling. 146 Sow Indian cresses. The seeds may be sown about the beginning of the month, at the distance of two or three inches from each other, in drills, about an inch deep. If they are not sown along side of a hedge or other support, they may have sticks placed beside them like peas after they have come above ground. There are two kinds, the large, and dwarf; the former is generally preferred.

Seeds of basil, love apple (or *tomatoes*), and capsicum, 147 basil, &c. may be sown any time this month. They are tender annuals, and must be sown in a hot-bed, to be afterwards planted out in the open ground in May; they must be managed like other tender annuals. See *Flower Garden*. Basil is used in soups and salads, and must be sown in very dry earth, otherwise the seeds will rot. Love apples are used in soups and for pickling. The capsicum, of which there is great variety, is used as a pickle, and for seasoning. The principal kinds are the long-podded, heart-shaped, bell-shaped, angular-podded, round short-podded, cherry-shaped, &c.

Sow cucumbers and melons, to be planted out under hand or bell-glasses. 148 cucumbers and melons.

Some cucumber and melon seed may be sown towards the end of this month, in any of the beds already employed; or one may be formed on purpose to raise plants to be reared under bell or hand-glasses. Those sown now will be fit for ridging out in the beginning of May. See May.

March. Fruit Garden, &c.

Sect. II. *Fruit Garden.*

149 Trees pruned, All kinds of fruit trees mentioned under this head last month may be pruned now, though it ought to be performed as near the beginning of the month as possible; for if the weather has been mild during the preceding month, many of the trees will have advanced too far to be in a state proper for pruning. Figs, however, on account of the late period at which they begin to push, may be safely pruned; indeed this is the best season for pruning them.

150 planted, Fruit trees may still be planted, though the earlier in the month the better; for if mild weather prevails, the buds of the trees will have advanced so far before the end of the month, as to render transplanting less safe. For the method, see October. The duration of the planting season depends more on the mildness and severity of the weather than the time of the year.

151 protected in flower, When apricot, nectarine, and peach trees are in flower, they should be protected during frost with large garden-mats fixed to the top of the walls by hooks, and fastened at the bottom to prevent them from being agitated by the wind so as to dash off the blossoms. These mats must be removed during the mildest part of the day, unless when the weather is very severe, and without sunshine. Instead of mats, old fish-nets doubled may be used for this purpose, and need not be removed during the day; a number of small branches of evergreens (well clad with leaves) fixed amongst the branches of the trees in flower, will also afford shelter to the blossom and setting fruit.

Dress strawberry beds, if not done last month. See February.

152 and forced. Fruit trees on hot walls, in peach, cherry, and vine-houses, must be duly attended to, must receive air and water regularly, and have the fires put on every evening and cold morning.

Sect. III. *Flower Garden and Pleasure Ground.*

153 Transplant early annuals. If any early annuals, such as balsams, cockscombs, &c. were sown last month, they will be fit for planting out into small pots or a hot-bed prepared for the purpose. This hot-bed should be raised to the height of two feet; and when the violent heat has subsided, covered over to the depth of six inches with rich dry earth. The plants may be put in at the distance of three or four inches from one another, or rather in small pots, because from these they can be more easily removed into larger ones at a subsequent period. Due attention must be paid to give them water and air when requisite; and linings of fresh dung must be applied to the bed whenever the heat begins to decline. If properly taken care of, they will be fit for final transplantation in May or June.

If no tender annuals were sown in February, some may be sown any time this month.

Sow less tender or half-hardy annuals, such as China aster, Indian pink, capsicum, French and African marigold, chrysanthemum, tree and purple amaranthus, and Chinese hollyhocks.

154 Sow tender and hardy annuals. Form a slight hot-bed any time this month, which need not be raised higher than two feet, and earth it over to the depth of about six inches. The seed may be sown in narrow drills, at the distance of two or three inches from one another, and each kind, separately or in pots, plunged in the earth of the bed. After the plants have come up, they will require plenty of free air and moderate watering; and when they have acquired the height of two or three inches, they must be gradually hardened to bear the open air, by taking the lights entirely off in mild warm days. Instead of hot-bed frames and lights, oil-paper frames, or hand-glasses, may be made use of. The plants raised now will be fit for transplanting into the flower border in May. If hardy annuals were not sown last month, they may be sown any time during the present.

Cuttings of double chrysanthemums which were planted last autumn in pots or boxes, should be planted out into pots or flower borders if mild weather prevails. Auricula plants in pots should be protected from rain and frost, and should still be kept covered with hooped arches, over which mats may be occasionally thrown, for should they be exposed to much rain or severe weather now when their flower-stalks begin to advance, the future bloom might be injured. Keep the pots clear of weeds, and give them a little water in dry weather, or expose them to a gentle shower. If the pots received no fresh earth last month, let them receive some now. 15[illegible] Management of chrysanthemums and auriculas,

Let the hoops mentioned the two preceding months still continue over the beds of tulips, hyacinths, ranunculus, &c. for if severe weather occurs, the beds must be protected by a covering of mats, as already mentioned. See January. When the stalks of hyacinths, particularly double ones, have advanced almost to their full height, they are apt to be borne down by the weight of their own flowers, therefore a neat small stick ought to be fixed in the ground close to every plant, to which the flowerstalks should be fastened by a piece of brass or other soft ligature. 15[illegible] hyacinths, &c.

Ranunculuses and anemones may still be planted; they will succeed the early ones, and flower in June and July. 15[illegible] ranunculuses and anemones.

Towards the end of the month, seeds of biennial and perennial flowers may be sown, such as carnations, pinks, sweetwilliams, wallflowers, and stock julyflowers of all sorts, also rose campion, catchfly, scarlet lychnis, columbines, Greek valerian, polyanthus, auriculas, scabiouses, and Canterbury bells; likewise hollyhocks, French honeysuckles, rockets, honesty or satin flower, tree primrose, shrubby mallow, broad-leaved campanula, foxglove, snapdragon or frogsmouth, &c. 15[illegible] Sow biennials, &c.

Biennial and perennial plants may likewise be transplanted at this season.

Trees and shrubs, both deciduous and evergreen, may still be planted; but that work should be finished before the end of the month. 15[illegible] Plant trees and shrubs.

Sect. IV. *Nursery.*

Fruit trees, elms, &c. may be engrafted; and the shoots of trees engrafted last year should be so shortened about the time their buds begin to swell, as to leave four or five buds, which will push out branches to form a head. The shoots of last year's growth of trees budded the preceding summer should likewise be shortened, and the heads of trees budded last summer should be cut off about four inches above the bud, which will cause 16[illegible] Ingrafting and treatment of trees budded last year.

ch. ery. cause it to push out vigorously. The part of the stock which is left will serve as a support, to which the young branch may be fixed in the course of the summer, to prevent it from being blown out by the wind.

Sow seeds of trees, &c. Seeds of hardy trees and shrubs may be sown any time this month, in beds three or four feet wide, which should be well dug, and thoroughly pulverized. The seed may be sown either regularly over the surface of the bed or in drills, and covered in proportion to their size; the acorns and other large seeds to the depth of from an inch and a half to two inches, and the smaller ones from about half an inch to an inch. Some of the more delicate shrubs, such as the arbutus, &c. may be sown in pots or boxes, by which means they will be more easily protected from the severity of the weather in winter.

Propagate by cuttings. Most kinds of trees and shrubs may be propagated by cuttings this month, particularly vines.

The vine cuttings must be shoots of last year's growth, about ten or twelve inches long, and each furnished with three buds. If cut from the vines during the winter, before the sap begins to rise, and preserved in dry earth, they will succeed the better. Some leave about an inch of the former year's wood attached to each cutting, but this is unnecessary. They may be planted in rows a foot and a half asunder, and at the distance of eight or ten inches from each other in rows, and so deep as to leave only their uppermost bud above ground; they should afterwards be occasionally watered, and kept clear of weeds. Though cuttings of vines may be raised in the open air, much better plants may be obtained by striking them in a hot-bed or tan-pit in a hot-house. At pruning season select some well-ripened shoots, cut them into pieces of a convenient length, and insert them a little way into pots filled with dry earth, where they may remain till wanted for planting. Protect them in severe, but in mild weather, expose them to the free air. About the beginning of this month, if there is no room in the hot-beds already made, prepare one on purpose, which may be formed and earthed over exactly like a seed-bed for melons. See January. Fill a number of pots, about four inches deep, corresponding to the cuttings you mean to plant, with light rich earth. Take the cuttings you have preserved during the winter; select the roundest and fullest buds; cut the branch about a quarter of an inch above, and about three inches below the bud, with a sharp knife, so as to make a smooth cut; and insert each close by the side of the pot, so deep that the bud may be covered about a quarter of an inch by the earth of the pot; for it is alleged, that a cutting strikes with greater freedom when placed close to the side than in the middle of the pot. When plants are raised in this manner from a single bud, they seem as if reared from seed. As soon as the cuttings are planted, plunge the pots into the earth of the bed, give them a gentle watering, and put on the glasses. Attention must be paid to the bed, to see that the heat be not too strong, for a moderate bottom heat is all that is necessary. Air should be freely admitted during the day, and even during the night, in mild weather; but when the weather is cold, the beds should be covered with mats during the night to protect them from frost. The cuttings should likewise be shaded when the sun shines very bright, with mats, and should receive occasional watering. When the plants are about six or eight inches high they will require to be shifted into larger pots, which must be done cautiously for fear of injuring their roots. Take pots of about six inches deep, and about the same width; put a little good earth into the bottom of each, and turn the cutting out of the small pot into it with the ball of earth as entire as possible, and fill it up with earth. The frames of the beds should be raised in proportion as the plants increase in height, and the heat of the bed renewed by linings of fresh dung when on the decline. Support the shoots when they are about ten or twelve inches high, and pinch off the tendrils and lateral shoots as soon as they appear. They will be fit for planting out in the end of June or beginning of July.

When dry weather prevails, give gentle waterings to seedling trees and shrubs, and keep them free from weeds. 163 Water seedlings.

Sect V. *Green-house and Hot-house.*

The plants in the green-house should receive air freely, unless during wet or frosty weather, and more frequent and plentiful waterings than in the two former months. Dead branches or decayed leaves should be removed, and any of the larger leaved plants that appear foul should have their leaves cleaned with a wet sponge. Those also which require shifting or pruning may be managed as directed last month. Sow seeds and plant cuttings of green-house plants; for which purpose a hot-bed or tan-pit of a hot-house will be necessary at this season. 164 Air to be freely admitted.

Pine apple plants will require a good deal of warmth, particularly in the tan-pit; as their fruit will now be considerably advanced, they must therefore be kept in a vigorous state of growth, to secure large fruit. If the heat of the tan-bed be not very great, at least one-third of new tan ought to be added. After the tan has been procured, it ought to be spread out and dried a little, and then laid up in a heap, in some shed adjacent to the hot-house, till it begin to ferment. The plants should then be taken from the tan-bed, and a quantity of the decayed tan removed from its surface and sides, to make room for the new, which must be thoroughly mixed with the old; and as this operation ought to be completed in the course of one day, a sufficient number of hands should be employed to effect it. Both pine apples and other plants in the hot-house should be regularly watered, and have fresh air admitted in bright calm days, from about two hours before till two or three after noon. 165 Treatment of pine apples.

APRIL.

Sect. I. *Kitchen Garden.*

If the heat begin to decline in the cucumber and melon beds, they should receive linings as directed in the former months; for these plants will not yield fine fruit, or a plentiful crop, if the beds are destitute of a proper heat. Air must be admitted every day, and a moderate watering given ever four or five days, particularly to cucumbers; but melons should receive it sparingly, especially when their fruits are setting, as much water at that time would prove injurious, and make the fruit drop off. Keep the plants clear of all decayed leaves 166 Management of cucumbers and melons.

April. Fruit Garden.

leaves and decayed male flowers. When the sun shines so bright as to cause the leaves of cucumbers and melons to flag, it will be proper to shade them for two or three hours, during its greatest heat, with a thin mat or a little loose hay, strewed thinly over the glasses.

Make hot-beds on which to ridge out cucumbers or melons under hand glasses or oiled paper frames. See May.

167 Plant lettuce, Sow some cabbage, Cilicia, imperial, and large admirable cabbage lettuces any time this month; indeed, some ought to be sown about the beginning, middle, and towards the end of the month, to secure a regular succession. Should the lettuces that were sown last month or in February stand too thick, they may be thinned out and transplanted at the distance of about ten inches from each other, and watered occasionally till they take root.

168 kidney beans. Some early kidney beans, viz. the Battersea, speckled, dun-coloured, and Canterbury dwarfs, may be planted towards the end of the month, in a well-sheltered situation, exposed to the south, in drills two feet or two feet and a half asunder, and about two inches from each other in the drills. The tall running kinds should not be planted till next month.

169 Transplant cabbages, &c. Some of the cabbage and savoy plants, which were sown in February and March, should be thinned and transplanted, when their leaves are about two inches broad, into beds, to gain strength before their final transplantation; and those which have stood the winter may be planted out for good.

170 cauliflowers, Cauliflower plants under bell or hand glasses should have some earth drawn up about their stems, and should be exposed to the open air during the day in good weather. Those sown last month should be planted out into beds in the open air or into slight hot-beds, to forward their growth. Some of the strongest of the plants raised in the early part of spring may be planted out at the end of the month, at the distance of two or two feet and a half each way from one another, and should be occasionally watered till they are well rooted.

171 brocoli, Young plants of brocoli, which were sown last month, may be planted out at the distance of two or three inches from one another, to acquire strength for final transplantation; and some seed of the early purple, late purple, and cauliflower brocoli, may be sown to raise plants for transplanting in June. Some plants of last year's sowing, which produced heads this spring, should be allowed to remain for seed, which will ripen in August.

Sect. II. *Fruit Garden.*

172 Transplant and prune, In late seasons, pear, plum, and cherry trees may still be planted, and even apricot, peach, and nectarine; but it should be done as early in the month as possible, for if any of these have advanced much in growth before they are transplanted, they will not push freely in the course of the summer, and will be liable to be injured by drought. Where pruning has been neglected, it may still be done, but the sooner the better, for many fruit trees will now be in flower.

173 and protect fruit trees, Fruit trees in flower should still be protected in cold weather. See March. All ill-placed shoots should be rubbed off, and the young fruit on apricot trees where set too thick should be thinned.

17[illegible] Dress vines, Look over the vines trained on walls about the end of the month, and rub off the young shoots which proceed from the old wood, unless they happen to be situated where a supply of young wood is wanted; likewise where two shoots proceed from the same eye on branches of last year's growth, let the weakest be rubbed off. Stakes should be placed beside the vines in the vineyard, to which they should be tied, and the ground between the rows should be kept perfectly free from weeds.

17[illegible] History of the vine. The vine was introduced by the Romans into Britain, and appears formerly to have been very common. From the name of vineyard yet adhering to the ruinous sites of our castles and monasteries, there seem to have been few in the country but what had a vineyard. The county of Gloucester is particularly commended by Malmsbury in the twelfth century, as exceeding all the rest of the kingdom in the number and goodness of its vineyards. In the earlier periods of our history the isle of Ely was expressly denominated the *Isle of Vines* by the Normans. Vineyards are frequently noticed in the descriptive accounts of Doomsday; and those of England are even mentioned by Bede as early as the commencement of the eighth century.

Doomsday book exhibits to us a particular proof that wine was made in England during the period preceding the Conquest. And after the Conquest, the bishop of Ely appears to have received at least three or four tuns annually, as tithes from the produce of the vineyards in his diocese, and to have made frequent reservations in his leases of a certain quantity of wine for rent. Dr Thomas, the late dean of Ely, gives the following extracts from the archives of that church.

	L.	*s.*	*d.*
Exitus vineti - - -	2	15	$3\frac{1}{4}$
Ditto vineæ - - -	10	12	$2\frac{1}{2}$
Ten bushels of grapes from the vineyard	0	7	6
Seven dolia musti from the vineyard, 12th Edward II. - - -	15	1	0
Wine sold for - -	1	12	0
Verjuice - - -	1	7	0
One dolium and one pipe filled with new wine, and supposed at Ely. For wine out of this vineyard - -	1	2	2
For verjuice from thence. - -	0	16	0
No wine but verjuice made, 9th Edward IV.			

From these extracts it appears that Ely grapes would sometimes ripen, and the convent made wine of them; and sometimes not, and then they converted them into verjuice. Maddocks in his history of the Exchequer, i. 464. says that the sheriffs of Northamptonshire and Leicestershire, were allowed their account, for the livery of the king's vinedresser at Rockingham, and for necessaries for the vineyard. A piece of land in London, now forming East Smithfield and some adjoining streets, was withheld from the religious house within Aldgate by four successive constables of the Tower in the reigns of Rufus, Henry, and Stephen, and made by them into a vineyard, to their great emolument. In the old accounts of rectorial and vicarial revenues, and in the old registers of ecclesiastical suits concerning them, the

the tithe of wine is an article that frequently occurs in Kent, Surry, and other counties. And the wines of Gloucestershire within a century after the Conquest were little inferior to the French in sweetness. It is alleged that a black grape very similar to the black muscadine was introduced from Gaul into Britain, about the middle of the third century. To these proofs of the antiquity of vineyards in Britain, we shall add the following account of the vineyard at Pains-hill, Surry, (the most extensive one at present in England), given by the original proprietor, the honourable Charles Hamilton, to Sir Edward Barry, and published in his Treatise on Wines, p. 468.

"The vineyard at Pains-hill is situated on the south side of a gentle hill, the soil a gravelly sand: it is planted entirely with two kinds of Burgundy grapes, the Auvernat, which is the most delicate, but the tenderest; and the Miller grape, commonly called the black cluster, which is more hardy. The first year I attempted to make red wine in the usual way, by treading the grapes, then letting them ferment in a vat, till all the husks and impurities formed a thick crust at the top: the boiling ceased, and clear wine was drawn off from the bottom. This essay did not answer; the wine was so very harsh and austere, that I despaired of ever making red wine fit to drink; but through that harshness I perceived a flavour something like that of some small French white wines, which made me hope I should succeed better with white wine. That experiment succeeded far beyond my most sanguine expectation; for the very first year I made white wine, it nearly resembled the flavour of Champagne; and in two or three years more, as the vines grew stronger, to my great amazement my wine had a finer flavour than the best Champagne I ever tasted. The first running was as clear as spirits; the second was œil de perdrix; and both of them sparkled and creamed in the glass like Champagne. It would be endless to mention how many great judges of wine were deceived by my wine, and thought it superior to any Champagne they ever drank; but such is the prejudice of most people against any thing of English growth, I generally found it most prudent not to declare where it grew, till after they had passed their verdict upon it. The surest proof I can give of its excellence is, that I have sold it to wine merchants for fifty guineas a hogshead; and one wine merchant to whom I sold five hundred pounds worth at one time assured me, he sold some of the best of it from 7s. 6d. to 10s. 6d. per bottle. After many years experience, the best method I found of making and managing it was this: I let the grapes hang till they had got all the maturity the season would give them; then they were carefully cut off with scissars, and brought home to the wine barn, in small quantities, to prevent their heating, or pressing one another; then they were all picked off the stalks, and all the mouldy or green ones were discarded, before they were put upon the press; where they were all pressed in a few hours after they were gathered: much would run from them, before the press squeezed them, from their own weight one upon another. This running was as clear as water, and sweet as syrup; and all this of the first pressing, and part of the second continued white; the other pressings grew reddish, and were not mixed with the best. As fast as the wine run from the press into a large receiver, it was put into the hogsheads, and closely bunged up. In a few hours one would hear the fermentation begin, which would soon burst the casks, if not guarded against, by hooping them strongly with iron, and securing them in strong wooden frames, and the heads with wedges. In the height of fermentation, I have frequently seen the wine oozing through the pores of the staves. The hogsheads were left all the depth of winter in the cold barn, to reap the benefit of the frosts. When the fermentation was over, which was easily discovered by the cessation of noise and oozing, but to be more certain, by pegging the cask, when it would be quite clear, then it was racked off into clean hogsheads, and carried to the vaults, before any warmth of weather could raise a second fermentation. In March, the hogsheads were examined; if any were not quite fine, they were fined down with common fish glue in the usual manner; those that were fine of themselves were not fined down, and all were bottled about the end of March; and in about six weeks more would be in perfect order for drinking, and would be in their prime for about one year; but the second year the flavour and sweetness would abate, and would gradually decline, till at last it lost all flavour and sweetness; and some that I kept sixteen years became so like old hock, that it might pass for such to one who was not a perfect connoisseur. The only art I ever used to it, was putting three pounds of white sugarcandy to some of the hogsheads, when the fine was first tunned from the press, in order to conform to a rage that prevailed, to drink none but very sweet Champagne. I am convinced much good wine might be made in many parts of the south of England. Many parts are south of Pains-hill; many soils may be yet fitter for it; and many situations must be so; for mine was much exposed to the south-west wind (the worst of all for vines), and the declivity was rather too steep; yet with these disadvantages it succeeded many years. Indeed the uncertainty of our climate is against it, and many fine crops have been spoiled by May frosts and wet summers; but one good year balances many disappointments."

In a dissertation on the growth of wine in England by F. X. Visper, printed at Bath 1786, there is a method of training vines along the surface of the ground proposed, which seems well adapted to the northerly climate of Britain, for which the Rev. M. L. Broeg obtained a patent. Mr Visper acknowledges that he took the first hint from the following passage, from Lord Chancellor Bacon: "The lowness of the fruit boughs makes the fruit greater, and causes it to ripen better; for we always see in apricots, peaches, and mello-cottons; upon a wall, the largest fruit is towards the bottom; and in France, the grapes that make the wine grow upon low vines bound to small stakes, while the raised vines in arbours make verjuice." He adds "It is reported, that in some places vines are suffered to grow like herbs, spreading upon the ground, and the grapes of these vines are very large; it were proper to try whether plants usually sustained by props, will not bear large leaves and fruit if laid along the ground."

Sect.

April. Flower Garden, or Pleasure Ground, &c.

Sect. III. *The Flower Garden, or Pleasure Ground.*

176 Sow and transplant annuals. Sow and transplant tender annuals. See February and March. Protect hyacinths, ranunculuses, and anemones, planted in beds, from heavy rain and frost, as directed in January and February; likewise, when they are in flower, from very bright sunshine, from about two hours before till two or three after noon; but in this case the covering should be raised to a considerable height, to admit air, and allow them to be viewed.

Plant tuberoses in a hot-bed or hot-house, and give them but little water till they have come above ground.

177 Plant evergreens. Evergreen shrubs and trees may still be planted, but the earlier in the month the better.

178 Walks dressed. Grass walks and lawns should be poled, rolled, and mown. Gravel walks may be broken up and turned.

Sect. IV. *Nursery.*

179 Examine newly engrafted trees. Look over newly engrafted trees, and see if the clay keeps close about the grafts, as it is apt to crack and fall off; when you find it any way defective so as to admit the air and rain to the graft, then remove it and apply fresh clay in its stead. All shoots which rise from the stalk below the graft must be taken off whenever they are produced; for if permitted to remain, they would rob the graft of nourishment, and prevent it shooting freely.

180 Those budded last year. Trees that were budded last year, will now begin to push out their first shoots. Should they be infested with insects, so as to cause any of their leaves to curl, these should be picked off, and pains taken to destroy the vermin. Shoots that proceed from the stock under the bud must be rubbed off as soon as they appear.

181 And transplant young ones. The sowing and transplanting of young trees and shrubs from the seed-bed, or where they stand too thick, should be finished early in the month, and if very dry weather prevail, water should be given to seed-beds, cuttings, and lately transplanted trees and shrubs.

Sect. V. *Green-house and Hot-house.*

Air may be admitted, and water given more freely than in the former months, because the plants will begin now to advance in growth; but in general the management must be nearly the same as recommended last month.

182 Requisite heat for pine apples. A proper degree of warmth, both in the bark bed and in the air of the hot-house, is requisite for fruiting pine apple plants. Water may be more frequently given, and air admitted more freely, because the weather will be milder; and in other respects they must be managed as directed in March. The succession pine apple plants, or such as are to fruit next year, should be shifted into larger pots, (viz. 24s.) the size commonly made use of. When the plants are healthy, they should be turned out of the pots with the ball of earth about their roots as entire as possible, and put them into larger ones with an additional quantity of fresh earth; but should the plants be sickly, infested with insects, or appear to have bad roots, the whole of the earth should be shaken off, and the roots trimmed, a few of the under leaves stripped off the stem, and the plants then put into pots filled entirely with fresh earth.

After the plants have been thus shifted, they should have a moderate quantity of water given them frequently, which will promote their growth. The young pine apple plants which were raised from suckers or crowns last season should likewise be shifted into larger pots, if their roots appear to have filled those in which they have stood during the winter: if healthy, they should be turned out of the pots with the ball of earth entire; if otherwise, they must be treated like the succession plants as above.

1[illegible] Propa[gate] hot-h[ouse] plant[s]. This is a proper season for propagating hot-house plants by cuttings, layers, &c. or for sowing their seeds. Cuttings of green-house plants may likewise be struck in the bark bed of the hot-house, and kept there till fit for transplanting.

MAY.

M[ay.] Kit[chen] Gar[den.]

Sect. I. *Kitchen Garden.*

1[illegible] Treat[ment] of me[lons] &c. Melons require attention, particularly when their fruit are setting. The heat of the hot-beds must be kept up by proper linings; water must be given moderately, and air admitted regularly. In warm weather when the sun shines bright, the plants should be shaded from its rays for an hour or two about midday, by a covering of mats or something of that nature. A piece of tile or slate should be placed under each fruit after it is set, to prevent it from coming into contact with the moist earth of the bed, which would injure it, and cause it to drop off. Ridges may be formed for the reception of the melon and cucumber plants, which were sown last or preceding month, to be raised under hand or bell glasses. These ridges should be about four feet wide, and are to be constructed in the same manner as hot-beds. See January. The dung should be raised to the height of two feet and a half, and covered with six or eight inches of rich light earth, and may be made either in trenches about a foot deep or on the surface of the ground. When more than one ridge is to be constructed, they should be placed parallel to one another at the distance of about four feet, which interval should afterwards be filled up with fresh horse dung when the heat in the ridges begins to decline; this will both revive the heat, and when earthed over, will afford room to extend the advancing runners of the plants. As soon as the ridges are earthed over, the hand or bell glasses may be put on along the middle of the bed, at the distance of four feet, when intended for melons, and three feet when for cucumbers; and the following day, or as soon after as the earth under the glasses has become warm, a hole should be made under each, into which two melon or three cucumber plants are to be put with the ball of earth about their roots; the earth should then be well closed about the ball and stem of the plant, a little water given, and the glasses put on. Shade them for a day or two, and give air during the day by raising the glasses. When the plants have filled the glasses, the runners must be trained out from under them, but this should not take place till the end of the month, or some time in June. Oil paper frames are sometimes used for covering the ridges. These frames

frames are made of thin slips of wood covered with paper, rendered transparent and water proof by means of oil. Melons reared in this way will produce plentifully in August and September, and cucumbers from the middle of June, till the cold weather in autumn set in. If no cucumber plants were raised in March or April for this purpose, some seeds may be sown in the ridges. Some may likewise be sown about the end of the month in the open ground, to produce a crop for pickling; but should cold weather prevail at that time, it should be deferred till June. Gourds and pumpkins may be sown in the open ground in a warm situation, or in a hot-bed, to be afterwards transplanted.

A full crop of kidney beans may be planted both of the dwarf and tall running sorts: the former, viz. black speckled, Battersey and Canterbury white, should be planted in drills about an inch deep, and two feet and a half asunder, at the distance of two or three inches from each other; the latter, viz. the scarlet and large Dutch white, should be sown in drills, about an inch and a half deep, and three feet and a half or four asunder. These running kinds must have tall sticks, or some support of that nature.

The capsicum and love apples which were raised last or the preceding month in hot-beds, may be planted out into well sheltered situations exposed to the south.

Some spinach plants, both of the smooth and prickly seeded, should be allowed to run up for seed; and some of the different kinds of radishes should be transplanted for the same purpose.

The different crops should be kept clear of weeds, and thinned with the hoe. Turnips may be left at the distance of seven or eight inches from each other; carrots, six or eight; parsnips, eight to ten or twelve; onions, four or five; Hamburgh parsley, scorzonera, and salsafy, six or seven; and cardoons, five or six; that they may acquire strength for final transplantation.

Plant out cabbages, savoys, cauliflower, brocoli, and bore-cole.

Sect. II. *Fruit Garden.*

As wall trees will now have made vigorous shoots, a sufficient quantity of the best placed lateral, and all the terminal ones, should be trained to the wall, and all foreright, ill placed, superfluous, and very luxuriant shoots, should be removed. None of the young branches should be shortened, unless where a supply of new wood is wanted to fill up some vacant space. When the fruit stands too thick on wall trees, they should be thinned. When wall trees are infested with insects, means should be made use of to destroy them; the curled leaves should be picked off with a view to check their propagation: tobacco dust may be sometimes employed with advantage; but water sprinkled plentifully over the branches with an engine constructed on purpose, is the most efficacious remedy.

Let vines both on walls and in vineyards be looked over; and let all superfluous branches, which proceed from the old wood or lateral shoots, which are pushed out by the young branches, be rubbed off; indeed this must be done constantly during the summer.

Sect. III. *The Flower Garden, or Pleasure Ground.* June. Kitchen Garden.

Tender annuals should be transplanted into newly formed hot-beds, when they are wished to flower early and in full perfection, particularly balsams and cockscombs. 192 Transplant tender annuals into hot-beds.

Let the auricula plants in pots, which are past flower, be placed in some situation where they may enjoy some free air and the sun till about ten o'clock in the morning. 193 Treatment of auriculas.

Some wallflower and stock gilliflower seed may be sown about the beginning of the month; cuttings also of double wall-flowers and stocks may be planted under bell and hand glasses, or in a shady border. 194 Sow wall-flower, &c.

Perennial and biennial plants that were sown last March, will be fit for transplanting about the end of the month into beds, where they may remain to acquire strength. 195 Transplant biennials, &c.

Sect. IV. *Nursery.*

Towards the end of the month, the clay should be removed from newly grafted trees, and the bandages loosened, because they might check the growth of the grafts, which will now shoot freely; and all buds under the graft should be carefully removed. 196 Newly grafted trees.

Sect. V. *Green-house and Hot-house.*

About the end of the month, if the weather should be favourable, the greater part of the plants may be removed from the green-house, and placed in some well-sheltered situation in the open air. The plants in the hot-house should receive water and air freely, particularly in bright weather. 197 Plants to be removed into open air.

JUNE.

Sect. I. *Kitchen Garden.*

The same care of cucumbers and melons which was recommended for last month, is necessary now; the cucumbers sown in the open ground last month should be thinned, when they begin to push out their first rough leaves, and a few more seeds may be sown for the same purpose, but the earlier in the month the better. 198 Melons, &c.

Transplant celery for blanching. For this purpose, form trenches, about a spade deep and three feet apart; lay the earth which comes out of the trenches regularly along each side; lay into each trench some well rotten dung, and dig it in: put the plants in a row along the middle of the trench at the distance of four or five inches from one another. About a month or six weeks after they have been planted, when they have acquired the height of six or eight inches, a quantity of earth should be laid about their stems, to blanch them and prepare them for the table; this should be done during dry weather, and repeated once a fortnight, or according as the plants advance in growth, till they are blanched to the height of a foot or fifteen inches. The earlier sown celery will be fit for transplanting about the beginning of the month; the later sown, about the end.

About the latter end of the month transplant endive for

June. Fruit Garden, &c.

for blanching; which should be planted out in rows, a foot apart, and at the same distance from one another in the row. Some endive seed should be sown for a principal crop; the green curled is commonly sown for this purpose, because it is least apt to be injured by rain or cold.

199 Endive blanched.

200 Cauliflowers, &c. planted out.

The cauliflower, brocoli, and bore-cole plants which were sown last month, should be planted out at the distance of about three inches from one another, into beds where they may remain, to acquire strength to fit them for final transplantation in July. Some of the early cauliflower plants, which have formed good heads, should be allowed to stand for seed, which will ripen in September.

201 Sow turnips.

About the middle of this month is the best season for sowing a principal crop of turnips; the different kinds commonly sown, are the yellow, white Dutch, round white, stone-turnip, Swedish, black Russian, small French round. The large white Norfolk, green topped, and red-topped, are chiefly used for field culture.

202 Plant out leeks,

Plant out leeks in rows nine inches asunder, and about six inches from one another in the row; it is an usual practice to trim off the extremities of their leaves and of their roots before they are planted.

203 and pot-herbs,

Plant out pot-herbs, such as thyme, savory, sweet-marjoram and hyssop; likewise angelica, marygolds, clary, &c. A rainy or dull day should be chosen, and the plants put in at the distance of six inches from one another; occasional watering will be necessary, till they have taken root. Cuttings or slips of sage, hyssop, rue, rosemary, lavender, &c. may be planted in a shady situation, and occasionally watered.

Sect. II. *Fruit Garden.*

204 Strawberry plants prepared.

Wall trees, and vines in the vineyard, require the same attention this month that was recommended last. When plantations of strawberries are wanted, the young plants that are produced at the joints of the runners, that are furnished with good roots, should be taken up about the end of this month, and planted in a shady border at the distance of about six inches from one another; by September they will be fit to be planted out at the distance of a foot or fifteen inches from each other.

Sect. III. *Flower Garden, or Pleasure Ground.*

205 Bulbous roots, &c. taken up.

The roots of hyacinths, jonquils, ranunculuses, &c. should be taken up after their stalks begin to decay, dried and preserved till planting season; the roots of narcissus, crocus, snow-drop, &c. may likewise be taken up and separated, and either planted again immediately or kept till autumn.

Take up also autumnal flowering bulbs, such as colchicum, autumnal crocuses and narcissus, Guernsey and belladona lilies, cyclamens, &c.; take off the offsets, and plant them again immediately, or keep them till next month.

206 Propagate perennial plants.

Perennial plants, such as double scarlet lychnis, double rocket, &c. may be propagated by cuttings of their stalks; each cutting should consist of three or four joints, two of which, (or more than one half the length of the cutting), should be inserted into the ground; they may be either planted into a shady border, three or four inches apart, or more closely together, and covered with bell or hand glasses.

Propagate carnations, pinks, and double sweet-williams, by layers. Select young shoots about five or six inches long for this purpose; strip off the leaves from the lower part of the stalks, and trim off the tops of those placed at its extremity; make a slanting cut with a sharp knife on the under part of the stalk, which should commence at a joint near the middle of the shoot, and extend upwards almost half way to the next; make a hole in the earth about an inch or an inch and a half deep, immediately under the shoot, for its reception; fix it down with a small hooked stick, and cover it with earth, except an inch or two at its extremity. A little water should be given in dry weather, which will make the layers strike root more readily. Pinks and carnations may likewise be propagated by cuttings or pipings. These pipings are formed of the extremities of the young shoots, taken off immediately under the third joint, which should be inserted into light earth almost to their tops, (the extremities of their leaves being previously trimmed off). They should receive a little water to make the earth settle closely about them, and should be covered with a bell or hand glass. The earth is sometimes rendered quite wet, and reduced to a state resembling mortar, before the pipings are introduced.

About the end of the month hedges should receive their first clipping.

Sect. IV. *Nursery.*

About the end of the month you may inoculate peaches, nectarines, apricots, and roses: for the method, see July.

If any of the trees that were budded last summer, or engrafted last spring, have made very vigorous shoots, stakes should be fixed into the ground close to the stocks, to which both the stocks and shoots must be fixed.

Propagate both deciduous and evergreen shrubs by layers, particularly such as do not push out roots freely except from the new wood.

Sect. V. *Green-house and Hot-house.*

If the green-house plants were not placed in the open air last month, on account of the coldness of the weather, they may be safely trusted out now. These plants may be propagated this month by cuttings, layers, inarching, &c.

Hot-house plants may likewise be propagated now, and should receive a plentiful allowance of air and water; pine apple plants which are approaching to maturity should be sparingly watered, because too much water would injure the flavour of the fruit.

JULY.

Sect. I. *Kitchen Garden.*

Plant out cabbages, savoys, brocoli, bore-cole, endive and celery; for the methods see the former months. Sow some brocali seed about the beginning of the month. Sow some endive seed for a winter crop; the green curled endive is the best for this purpose, but some

some white and Batavian may likewise be sown. Some kidney-beans, of the dwarf kind, should be sown for a late crop. Some turnip-rooted or Spanish radish may be sown, and managed exactly like turnip: there are two kinds, the black and the white; both of which are very hardy, and stand the winter well.

1 Late crops of p[eas]. Some peas and beans may be sown when a late crop is wanted.

As artichokes now advance to maturity, those who prefer one large head to two or three smaller ones, ought to cut off all the lateral heads from the stalks, before they exceed the size of a hen's egg; which will promote the growth of the principal head. It is a common practice to break down the stalks of artichokes near the ground, as soon as their heads have been cut for the table, to make them push more vigorously from the root.

If the stalks of onions, garlick, and shallot, begin to decay, which is sometimes the case about the end of this month, they should be pulled up and dried. See AUGUST.

SECT. II. *Fruit Garden.*

2 Fruit protected. As fruits advance to maturity, wall trees should be protected from birds by nets; and means should be taken to destroy snails, wasps, and other insects.

SECT. III. *Flower Garden, or Pleasure Ground.*

2 Plant out annuals. SOME tender annuals may be planted out into the flower borders in the open air.

2 And auriculas, &c. Seedling auriculas and polyanthuses may be planted out, into a border not exposed to the mid-day sun, at the distance of two inches from one another, and watered occasionally.

SECT. IV. *Nursery.*

INOCULATE apricots, peaches, nectarines, plums, and pears; the first four are commonly inoculated on plum stocks, the last on pear or quince stocks. Inoculating or budding, as it is termed, may be performed on many other trees, and shrubs; the method of performing it is as follows.

21 Method of inoculation. With a budding knife, which resembles a penknife with a flat handle, make a horizontal cut at some smooth part quite through the bark of the stock, from the middle of which make a perpendicular cut downwards, about two inches in length, so as to form a figure resembling the letter T. Take a young shoot of the tree, with which you intend to inoculate, cut off the leaves from its lower extremity, leaving a small part of the footstalk of each; then, about an inch under the lowest bud, make a cross cut in the shoot almost halfway through, with the knife slanting upwards, and with a clean cut, bring it out about half an inch above the bud, detaching part both of the wood and bark containing the bud. Separate the small piece of the wood which was taken off along with the bud, from the bark, which is readily done with your knife, placing the point of it between the bark and wood at one end; then examine the inside of the bark, to see if the internal end of the bud be left; for if there appears a small hole, the eye is gone with the wood, and the bud becomes useless; but if no hole appears, the bud is good, and may be inserted into the stock, by raising the bark with the hand of the budding knife on each side of the perpendicular cut, immediately under the cross cut. If the piece of bark which contains the bud be too long for the incision made in the stock, it should be reduced to a proper length with the knife, and introduced between the bark and wood of the stock, and placed so as to make the bud project through the perpendicular cut. Having fixed the bud, and placed the bark of the stock closely above it, put a bandage of mat, which should be previously steeped in water to increase its tenacity, round the stock, which should extend from a little below to a little above the incision; taking care that none of the folds of the bandage cover the bud.

July. Green-House and Hot-House.

In three weeks or a month after the inoculation has been performed, the buds will have united with the stock, which is discoverable by the bud appearing plump; the bandages should then be removed: were they to remain, they would cramp the buds and injure them. The incisions should be made in the stocks about six inches above ground, when dwarf trees are wanted; and at the height of six feet, when standards are to be inoculated: the buds remain dormant, and require no further attention till next spring; when they begin to push out, the heads of the stalks should be cut off.

Seedling pines, where they stand too thick in the seed-bed, may be transplanted; but great care must be taken to water them and shade them from the sun. 216 Seedling pines transplanted.

SECT. V. *Green-House and Hot-House.*

GREEN-HOUSE plants require a plentiful supply of water at this season. If the fruit have set too thick on orange or lemon trees, they should be thinned, otherwise they will not acquire a proper size. 217 Thin the fruit of oranges.

As many of the pines will ripen their fruit in the course of this month, it is a proper time to begin to propagate these plants, which is done by planting the crowns that are produced at the top of the fruit, and the suckers which proceed from the root of the plants, about the time the fruit is ripe, or soon after they are cut. 218 Propagate pine apples.

These suckers or crowns, if properly managed, will produce fruit in two years, and then decay. Each fruit is surmounted by at least one crown, which frequently has a number of offsets at its base; and each plant, after it has produced fruit, throws out from its root one or more suckers before it decays. The crowns, when they are separated from the fruit, must lie five or six days in some dry place, till the part which was attached to the fruit is completely dried, before they are fit for planting. The suckers which proceed from the root of the plant should be taken off, when they have acquired the length of five or six inches, and when their lower extremity has become brown; they must likewise lie in some dry situation for a few days, till the part by which they were connected with the root of the parent plant be thoroughly dried. Put each crown or sucker into a small pot, filled with light rich earth, and plunge them in the bark-bed of a hot-house, or in a hot-bed made on purpose.

A method of raising pine apples in water is given by William Bastard, Esq. of Devonshire, in the 67th volume 219 Method of raising pines in water.

July. Green-house and Hot-house.

lume of the Philosophical Transactions. His account of this method is as follows:

"In the front part of the house, and indeed anywhere in the lowest parts of it, the pine-apple plants will not thrive well in water. The way in which I treat them is as follows:—I place a shelf near the highest part of the back wall, so that the pine apples may stand without absolutely touching, but as near it as can be; on this shelf I place pans full of water, about seven or eight inches deep; and in these pans I put the pine-apple plants, growing in the same pots of earth as they are generally planted in, to be plunged into the bark-bed in the common way; that is, I put the pot of earth, with the pine plant in it, in the pan full of water, and as the water decreases I constantly fill up the pan. I place either plants in fruit, or young plants, as soon as they are well rooted, in these pans of water, and find they thrive equally well: the fruit reared this way is always much larger, as well as better flavoured, than when ripened in the bark-bed. I have more than once put only the plants themselves without any earth, I mean after they had roots, into these pans of water, with only water sufficient to keep the roots always covered, and found them flourish beyond expectation. In my house the shelf I mention is supported by irons from the top; and there is an intervening space of about 10 inches between the back wall and the shelf. A neighbour of mine has placed a leaden cistern upon the top of the back flue, in which, as it is in contact with the flue, the water is always warm when there is fire in the house, and finds his fruit excellent and large. My shelf does not touch the back flue, but is about a foot above it; and, consequently, the water is only warmed by the air in the house. Both these methods do well. The way I account for this success is, that the warm air, always ascending to the part where the shelf is placed, as being the highest part of the house, keeps it much hotter than in any other part. The temperature at that place is, I believe, seldom less than what is indicated by the 73° of Fahrenheit's thermometer, and when the sun shines it is often above 100°: the water the plants grow in seems to enable them to bear the greatest heat, if sufficient air be allowed; and I often see the roots of plants growing out of the holes in the bottom of the pot of earth, and shooting vigorously in the water.

"My hot-house, the dimensions of which it may be proper to know, is 60 feet long, and 11 feet wide, the flues included; six feet high in the front, and 11 feet at the back of the inside of the house. It is warmed by two fires. A leaden trough or cistern on the top of the back flue is preferable to my shelf; as in it the pine plants grow much faster in the winter, the water being always warmed by the flue. Of this I have seen great benefits these last two months in my neighbourhood.

"It is not foreign to this purpose to mention, that as a person was moving a large pine plant from the hot-bed in my house last summer, which plant was just shewing fruit, by some accident he broke off the plant just above the earth in which it grew, and there was no root whatever left to it. By way of experiment, I took the plant, and fixed it upright in a pan of water, without any earth whatever, in the shelf; it there soon threw out roots, and bore a pine apple that weighed upwards of two pounds."

1. The *bromelia ananas*, of which there are six varieties: 1. *Ovatus*, or oval-shaped pine apple. 2. *Pyramidalis* (pyramidal), or sugar-loaf pine. 3. *Glaber*, with smooth leaves. 4. *Lucidus*, with shining green leaves. 5. *Serotinus*, with a yellowish-coloured flesh. 6. *Viridis*, or green pine apple.

Varieties of the pine apple.

The first sort of ananas is the most common in Europe; but the second sort is much preferable to it, the fruit of this being larger and much better flavoured: the juice of this sort is not so astringent as that of the first; so that this fruit may be eaten in greater quantity, with less danger. This sort frequently produces suckers immediately under the fruit, whereby it may be increased much better than the common sort; so that in a few years it may be the best common sort in Britain.

The third sort is preserved for curiosity by way of variety; but the fruit is not worth any thing.

The sort with very smooth green leaves, was raised from seeds taken out of a rotten fruit, which came from the West Indies to the late Henry Heathcote, Esq. from whom Mr Miller received one plant, which produced large fruit: this is what the people of America call the *king pine*.

AUGUST.

Sect. I. *Kitchen Garden.*

Sow some prickly-seeded, or triangular-leaved spinach, for a winter and spring crop; for though the round-seeded produces larger and more succulent leaves, the prickly-seeded is to be preferred now, because it is by much the hardier of the two. After the plants have got their first leaves about an inch broad, they should be thinned to the distance of four inches from one another, and kept free from weeds.

Sow winter crops of spinach.

Sow some cabbage seed, both of the early and late kinds, to produce plants for next year.

Cabbages.

Sow some onions, to be used when young in winter or spring, or to produce a crop of early onions this summer. The Strasburgh or any other kind may be sown now, but the Welsh onion is very hardy, and stands the winter well; for though their tops should be destroyed by the severity of the weather, they will push up again from the root in the spring: this onion, however, does not produce bulbs.

Onions.

Towards the end of the month sow some cauliflower seed to produce plants for an early crop next summer, which may be protected during the winter, either under hot-bed frames, bell or hand-glasses, or in a well-sheltered border exposed to the south. Between the 18th and 24th of this month is, perhaps, the best time to sow these seeds. The London gardeners, who sow great quantities, are accustomed to sow them on a particular day, viz. the 21st of this month. If they be sown too early, they are apt to button, as the gardeners term it, i. e. run up to seed without producing heads of a proper size; and if they be sown too late, the plants do not acquire sufficient strength, before winter, to enable them to support the severity of the weather.

Cauliflowers.

Sow some lettuce seed about the middle of the month, both to supply the table late in the autumn, or beginning of winter, and to plant out into well-sheltered borders, or under hot-bed frames, to stand during winter.

Lettuce.

Plant out brocoli, savoys, bore-cole, and celery, for the use of winter and spring.

The cardoons which were planted in June should have some earth laid up to their stems, to blanch them and render them fit for the table. That this may be accomplished the more easily, tie up the leaves of each plant, with a piece of bass mat or small straw rope, and apply some earth close round the stem, which earthing must be repeated at intervals, till it rise to the height of two feet.

The principal crops of onions will be fit for taking up in the course of this month. Choose a dry day for taking them up; take off the stalks within two or three inches of the bulb; spread them in some dry place, exposed to the sunshine, for 10 or 12 days, that they may be thoroughly dried.

Sect. II. *Fruit Garden.*

Look over vines, figs, and other wall trees; remove all foreright and superfluous branches, and nail the others close into the wall, that the rays of the sun may have free access to the fruit.

Vines in the vineyard likewise should be fixed to the stakes, and cleared of all superfluous shoots.

Sect. III. *Flower Garden*, or *Pleasure Ground.*

About the end of the month, you may propagate by slips, fibrous-rooted perennial plants, such as double rose campion, catchfly, double scarlet lychnis, double rocket, double ragged robin, bachelors button, gentianella, polyanthuses, auriculas, double daisies, &c. As these plants frequently grow in tufts, they may be taken up and divided, taking care that every slip be provided with some roots.

Auricula plants in pots should receive fresh earth.

Auricula and polyanthus seed may be sown any time this month, but will not come up till spring.

Layers of carnations, double sweetwilliams, and pinks, that are properly rooted, may be separated from the parent plant, and planted into borders or pots. Cuttings and pipings of pinks and carnations, may be planted out into beds or borders.

Towards the end of the month the seeds of bulbous-rooted flowers, such as tulips, hyacinths, narcissus, iris, crocus, fritillaria, crown imperial, lilies, and snowdrops; likewise, the seeds of anemone, ranunculus, and cyclamen, may be sown in beds or boxes, to obtain new varieties. They must be protected during winter from frost; and when they appear above ground in spring, they must be kept clear of weeds.

Plant out seedling biennials and perennials.

About the end of this month hedges should receive their second clipping.

Sect. IV. *Nursery.*

234 Budding may still be performed about the beginning of the month, and those trees which were budded three weeks or a month ago, should be examined. If the buds remain plump and fresh, there is reason to believe that they have succeeded; in that case the bandages must be loosened.

Sect. V. *Green-house and Hot-house.*

Green-house plants, in the open air, must be managed as already directed.

The plants in the hot-house must receive a plentiful allowance of air and water.

Succession pine-apple plants, that are to produce fruit next year, should be shifted into larger pots, viz. twenty-fours or sixteens, about the beginning of the month. The plants should be turned out of the old pots and placed in the new ones, a quantity of light rich earth being previously put into the bottom of each. Each pot should then be filled with some of the same earth, watered, and plunged into the tan, which, at the same time, should be turned over and receive an addition of about one-third of fresh tan.

SEPTEMBER.

Sect. I. *Kitchen Garden.*

Plant some brown Dutch, cos, and common cabbage lettuce, in a well-sheltered situation, exposed to the mid-day sun, to be covered with hot-bed frames and glasses, which should not be put over them till some time next month. 235 Plant out lettuce.

Plant out from the seed-bed the cauliflowers that were sown last month, into well-sheltered borders, at the distance of three or four inches from one another, taking care not to plant them so deep as to cover their hearts with earth. These plants may be either planted out again next month under garden frames, bell or hand-glasses to stand during the winter, or may remain where planted. 236 Cauliflowers.

Plant brocoli, savoys, bore-cole, celery, and endive. 237 Brocoli, &c.

Earth up celery and cardoons.

Tie up the leaves of endive with a piece of bass mat, or something of that nature, to blanch them, and prepare them for the table.

Mushroom beds may be formed any time this month, as spawn will very easily be procured during August, September, or October. The spawn has the appearance of a white mould shooting out in strings, which, when bruised, smells like mushrooms. It may be obtained either from old mushroom beds, old hot-beds, or dung hills that are principally composed of horse dung, and from pasture fields, indeed in any place where horse or sheep's dung has lain for some time undisturbed and not exposed to much moisture; and may be preserved for a considerable length of time, in a proper state for using. If spawn is not otherwise to be procured, some may be produced by laying a quantity of horse-dung and rich earth in alternate layers, and covered with straw to exclude the rain and air; for the more these are excluded, the sooner the spawn will appear, which commonly happens in about two months after the dung and earth have been laid together. Mushroom beds should be formed of dung that has been spread out for some time, without having been fermented, and may be made two or three feet broad, and of any length. A stratum of dung about a foot thick, should be laid first, which should be covered with rich earth to the depth of about four inches, then another 238 Preparation of mushroom beds.

September. Fruit Garden.

ther stratum of dung about ten inches thick, which should be covered like the former; a third stratum of dung may be laid and covered with earth like the two former. The whole should be made to grow narrower as it advances in height, and formed into a ridge resembling the roof of a house. When the bed is finished it should be covered with straw, to exclude the rain, and to prevent the bed from being dried by the sun or wind, in which situation it should remain eight or ten days, when the bed will be in a proper temperature of warmth to receive the spawn. The spawn should be placed in lumps four or five inches asunder, in the sloping sides of the bed, and covered with a little rich earth; the whole must then be covered with a thick coat of straw. When these beds are made in spring or autumn, as the weather in those months is temperate, the spawn will take soon, and the mushrooms will appear in about a month after the bed has been made; but when these are made in winter, when the weather is cold, or even in summer when the weather is very hot, a much longer time will elapse. The principal thing to be attended to, in the management of these beds, is to preserve them in a proper degree of moisture and warmth. Therefore, when the weather is very cold or very wet, care must be taken to apply a thick covering of dry straw, and when the bed appears dry, a gentle watering must be given.

Sect. II. *Fruit Garden.*

239 *Fruit to be exposed to the sun.*

Where any fruit, particularly grapes, are shaded with leaves, pains should be taken to expose them to the rays of the sun, that they may acquire proper flavour, likewise when the clusters are entangled, they should be disengaged, that each may have the benefit of the sun and air.

240 *Plant strawberries.*

Strawberries may be planted any time this month when the weather is showery. If rain should not fall towards the beginning of the month, the transplanting should be deferred, otherwise they must be watered occasionally, for some time after they are planted. If any were planted into beds in June, they will be in excellent condition for planting out now; but if none were planted out then, the best rooted plants produced at the joints of the runners, or offsets from the old plants, should be chosen, and planted at the distance of a foot or 15 inches from one another, either in beds, about four feet wide, or in rows along the borders. Most kinds of strawberries succeed best in an open situation, but the wood strawberry may be planted under the shade of trees or bushes.

241 *Different kinds of strawberries.*

The principal kinds of strawberries, are, the scarlet or Virginian, white wood, green wood, red wood, large white wood, hautboy strawberry, large globe hautboy, oblong hautboy, royal hautboy, green hautboy, Chili strawberry, globe Chili, sugar-loaf Chili, pine apple Chili, Bath Chili, Carolina Chili, white Carolina Chili, Devonshire Chili, Royal Chili, Dutch Chili, Alpine or prolific, which produces fruit from June to November, red Alpine, white Alpine, scarlet Alpine, pine-apple strawberry, red, white, and green.

About the end of the month, most of the late pears and apples will be fit for taking down, to be laid up for keeping. See October.

Sect. III. *Flower Garden, or Pleasure Ground.*

Transplant and propagate fibrous-rooted perennial plants by slips.

Towards the end of the month, hyacinths, tulips, and other bulbs, may be planted. See October.

Sect. IV. *Nursery.*

Transplant evergreens towards the end of the month, such as Portugal laurels, laurustinus, arbutus, &c.

Both evergreens and deciduous trees and shrubs may be propagated by layers or cuttings about the end of the month.

Sect. V. *Green-house and Hot-house.*

About the end of the month, if the weather be cold, orange and lemon trees, and many of the tenderer kinds of green-house plants, should be removed into the house.

About the end of this month or beginning of next, the tan-bed in the hot-house should be refreshed with a quantity of new tan, one half or two-thirds according as the old tan may be more or less decayed.

OCTOBER.

Sect. I. *Kitchen Garden.*

Plant out some of the lettuces that were raised in August, into a well-sheltered border, or into a hot-bed frame, to supply the table during winter and spring. Cauliflowers that were planted out last month from the seed-bed, may now be planted under hot bed frames, at the distance of about four inches from one another, or under bell or hand glasses. Four or five plants may be put under each hand glass, all of which (should they survive the winter) may again be planted out in the spring, except one, or at most two, of the strongest, which should be allowed to remain and produce heads. See February.

Propagate aromatic vegetables by slips, such as thyme, mint, balm, sage, &c.

Asparagus beds should receive their winter dressing, i. e. their stalks should be cut down, and the alleys between the beds should be dug, and a little of the earth from the alleys spread over the surface of each bed. Asparagus beds require some dung once every two years, which should be applied at this season. Before the alleys are dug, a little well rotten dung should be spread over the surface of the beds, dug in with a fork, and covered with a little of the earth from the alleys. Where forced asparagus is required early in winter, a hot-bed may be made any time this month. See January.

Plant some early Mazagan beans, and hotspur peas, about the end of the month, to stand the winter, and produce a crop early in summer.

Sect. II. *Fruit Garden.*

Winter pears and apples should in general be gathered this month. Some will be fit to take down the beginning

October. Fruit Garden. beginning of the month, others will not be ready before the middle or towards the end. To know when the fruits have had their full growth, some of them should be tried in different parts of the tree, by turning them gently upwards; if they quit the tree easily, it is a sign of maturity, and time to gather them. But none of the more delicate eating pears should be permitted to hang longer on the trees than the middle of the month, especially if the nights prove frosty; for if they are once touched with the frost, it will occasion many of them to rot before they are fit for the table: and therefore, in general, let neither apples nor pears remain longer on the trees than the middle or the end of this month, for they will not improve by hanging on the trees after that time. The best apples and pears which are intended for long keeping, should be taken down one by one, on a dry day, and carefully put into baskets, to be carried to the fruitery, or place where they are to be stored up. The fruit themselves should be dry when taken down from the trees, therefore should not be gathered too early in the morning, before the dew on their surface has evaporated. They should be laid in a heap for ten days or a fortnight, that their watery juices may transpire; each should then be thoroughly dried with a cloth, and laid on the shelves of the fruitery, or in boxes or hampers well covered with dry straw or hay.

Prune and plant fruit trees. About the end of the month, apricots, peaches, and nectarines may be pruned. See JANUARY.

All sorts of fruit trees may be planted, such as apricots, peaches, nectarines, plums, cherries, apples, pears, quinces, vines, figs, mulberries, medlars, services, filberts, &c. The ground for this purpose should be trenched to the depth of one or two spades, and should be well manured. If the borders on which the fruit trees are to be planted have not a sufficient depth of soil, a quantity of good earth may be added. Peaches, nectarines, apricots, plums, and cherries, are commonly planted at the distance of about fifteen feet from one another. Pears and apples when engrafted on dwarf stocks may be planted about the same distance, but those which are on free stocks, about eighteen or twenty feet. Cherries and plums for standards should be planted at the distance of twenty or twenty-five feet from one another. Apples and pears, on free stocks, should be planted in rows, thirty or forty feet asunder, and at the distance of twenty-five or thirty feet from one another in the row. Dwarf apples and pears, however, may be planted at less than half that distance.

The principal kinds of apricots are, the early muscadine, Turkey, Brussels, Roman, Breda, orange, Algiers, royal, Moor-park, alberget, transparent, Dunmore, or apricot peach, and Portugal.

The principal sorts of peaches are, the red magdalen, white magdalen, red nutmeg, white nutmeg, nobless, early Newington, old Newington, great French mignone, small mignone, admirable chancellor, Millet's mignone, incomparable, violet native, purple native, Royal George, Montauban, teton de Venus, round transparent, Catharine, and bloody peach.

The principal kinds of nectarines are, early nutmeg, Newington, red, Roman, violet, musk, golden, scarlet, Elruge, Temple, Murray, Brugnion, white Italian.

The principal sorts of plums are, the Primordan or early white, Precoce or early black, early Morocco, Orleans, green gage, la royale, damas de Tour, damas violette, white bonum magnum or egg plum, red bonum magnum or Imperial, Perdrigron white, Perdrigron violet, Monsieur plum, drap d'or, royal dauphin, Fotheringham, azure native, or early blue gage, queen mother, myrobalan, apricot plum, red, white, diaprée, Monsieur native, Roche carbon, Jaune native, grosse queen Claude, petite queen Claude, imperiale violette or blue imperial, petite mirabille, damas musque, diaprée noire, diaprée violette, imperitrice blanche or white empress, imperitrice noire or late black, Spanish damas, damas of September, St Catharine, common damson, Bullace.

The principal kinds of cherries are, the early May, May-duke, arch-duke, Harrison's duke, white heart, black heart, bleeding heart, Adams's crown heart, Hertfordshire heart, ox heart, Turkey, carnation, amber, Kentish or Flemish, Portugal, morella, white crossian, black coroun, small black guigne or geen, small red guigne, smallest wild black of the woods and hedges, ditto red.

251 Apples. The principal kinds of apples are, the common codlin, Kentish codlin, Dutch codlin, Margaret, golden pippin, gold rennet, Holland pippin, Kentish pippin, nonpareil, royal russet, Wheeler's russet, golden russet, gray russet, winter pearmain, scarlet pearmain, Loan's pearmain, aromatic russet, pomme d'Appis, Newton pippin, English rennet, autumn rennet, winter queening, margille, nonesuch, gray Leadington, Marget, tender rennet, kitchen rennet, large white, Italian, Spanish rennet, Canada rennet, grosse rennet de Normandie, Fearns pippin, white French rennet, cluster pearmain, lemon pippin, French pippin, winter greening, winter pippin, Flanders pippin, white costin, Kirton pippin, stone pippin, courpendu or hanging body, courpendu red, rambour summer, rambour winter, rennet grise, French rennet, cat's head, leather-coat, russet of winter, pomme de gelée, Siberian crab, American cherry crab, two years apple, hanging on the trees, if permitted, till the second year.

252 Pears. The principal kinds of pears are, the green missal, Catharine, jargonelle, cuisse madame, Windsor chamontelle, cressane, echasserie, grasse blanquette, beuré de roi, white beuré, winter beuré, colmar, St Germain, lent St Germain, Martinsee, grasse muscat, autumn muscat, orange bergamot, Hambden's, bergamot, red beuré, golden beuré, brown beuré, great rousselet, petit rousselet, Holland bergamot, verte longue, winter bonchretien, summer ditto, Spanish ditto, Messieur Jean, Green sugar, la marquis, swan egg, virgleuse, Portugal, gray goodwife, citron de carmes, ambrette, royal d'hiver, St Michael, Louise bonne, summer orange, winter orange, Swiss bergamot, devionett.

Baking pears. Large black pear of Worcester, Parkinson's warden, Uvedale St Germain, cadillac. The principal kinds of quinces are the Portugal, apple quince, pear quince. The principal kinds of mulberries are the common black, white, red, medlars, Dutch, Nottingham or English. Services. Common wild service, bervey, sweet service or serb, apple-shaped, pear-shaped berry-shaped.

253 Figs. The principal sorts of figs are, the common blue, early long blue, early white, large white, large Genoa, Brunswick, Marseilles, Cyprian, brown Ischia, brown Malta.

November. Kitchen Garden.

Malta. Filberts. Large red skinned filbert, white skinned, common hazel nut, Barcelona nut, cob nut, cluster nut, Byzantine nut.

Gooseberries, currants, and raspberries, may likewise be planted about the end of this month. See JANUARY.

SECT. III. *Flower Garden*, or *Pleasure Ground.*

254 Bulbous roots planted.

BULBOUS-rooted plants, such as tulips, hyacinths, narcissus, jonquils, crocus, dens-canis, crown imperial, sword lily, ixia, Persian and English iris, ranunculus, and anemone, may be planted any time this month, either in beds by themselves, or in flower borders, together with other flowers; but the finer sorts of tulip, hyacinths, ranunculus, and anemone, are commonly planted in beds, six or eight inches distant, and two or three deep.

Plant out deciduous and evergreen trees and shrubs. The method of planting all these is to open a circular hole, wide enough to receive the roots, and about a spade deep, more or less, according to the length of the roots.

Thorn and other hedges may be planted towards the end of this month, or any time in the course of the next.

SECT. IV. *Nursery.*

255 Sow stone fruit, &c.

SOW haws, hollyberries, hips, barberries, yew-berries, acorns, beech-masts, maple and ash-seed, cherry and plum stones, in a bed about four feet wide. It is a common practice to keep haws and hips, in heaps covered over with earth for twelve months; for those which are sown without this preparation frequently lie a whole year in the seed-bed without coming above ground. Plant cuttings of laurels and evergreens.

SECT. V. *Green-house and Hot-house.*

THE hardier kinds of green-house plants should be all removed into the green-house, when they should have plenty of air, except in very cold or wet weather.

The succession pine-apple plants should be removed into the fruiting house, which should previously receive a quantity of new tan, as directed last month. The younger succession plants likewise should be moved into the place of those that have been transferred into the fruiting house, air should be given freely in mild weather, and water very moderately.

NOVEMBER.

SECT. I. *Kitchen Garden.*

256 Blanch endive, &c.

TIE up endive for blanching, continue to earth-up cardoons, and dress the plantations of artichokes, i. e. cut down their larger leaves, and lay some earth about the plants, to protect them during winter.

Carrots and parsneps may be taken up, and preserved in sand during the winter.

Some more peas and beans may be sown to succeed those that were sown last month, or to supply their place if they should be cut off by the severity of the weather.

November. Fruit Garden.

SECT. II. *Fruit Garden.*

THE best time for pruning vines is immediately after the fall of the leaf, because the greatest possible time in that way is allowed for healing the wounds. Vines that are cut about the time of the rise of the sap in the spring, are apt to bleed profusely; this happens sometimes even to those that are pruned in the course of the winter. It is a common error, in pruning vines, to allow the branches to grow too close together, particularly in those varieties which grow vigorously, and have very large leaves; for, in summer, when the leaves are fully expanded, they are so much crowded together as to exclude the rays of the sun from the fruit. When pruning is properly performed, the young branches should be left at the distance of from one foot or two feet, and even upwards, from one another; but this in a great measure must be regulated by the size of their leaves. The Syrian grape has leaves about a foot and a half broad, with foot-stalks six inches long. The black Hamburgh has leaves twelve or thirteen inches broad, with foot-stalks seven inches long. The black cluster on the contrary has leaves five inches broad, with foot-stalks three inches long. Blue frontignac and claret grape have leaves six inches broad, with foot-stalks about four inches long. When vines are weakly, each shoot should be shortened so as to leave only three or four eyes; when they are moderately vigorous, each should be left about a foot long. When very vigorous, some of the shoots may be left three or four feet long or more; the shoots of vines, however, that are trained to the rafters of a vinery or pine-stove may be left eighteen or twenty feet long. It has been observed, that both the largest grapes and finest clusters are produced on shoots of a considerable length. When vines have been allowed to run into confusion, much time and pains are requisite to reduce them to regularity; but when they have been trained regularly from the beginning, pruning is easily and expeditiously performed.

If the following directions for training vines in a vinery be observed, they will easily be kept in order, and plentiful crops of good fruit may be expected.

Vines may be planted both on the back wall and front of a vinery; those on the back wall should be planted from six to twelve feet asunder, according to the vigour of growth of the particular sort, and in such a position that the two uppermost buds may point east and west; those on the front should be planted so as one may be trained to each rafter. When the vines begin to grow, all the buds except the two uppermost must be rubbed off from those on the back wall, and all except the uppermost from those on the front wall. If any of the plants shew fruit the first year, the clusters should be rubbed off, as well as the tendrils and lateral shoots, and the principal shoots should be trained regularly to the trellis as they advance in growth. Fires should be put in the vinery during the spring, to encourage an early growth in the vines, that they may have full time to ripen their wood. In the month of June the glasses may be taken off altogether, but should be put on again in September, and continued till the fall of the leaf, when the vines should be pruned. The two shoots which each vine on the back wall was permitted to push, should be cut down to their third or fourth bud, according

November. Fruit Garden.

according as either of them appears fullest and strongest, and then bent down as near as possible to a horizontal position, forming a figure resembling the letter T. Plants in front that are trained to the rafters, should be cut down almost to the bottom, and no more left than is merely sufficient to train them to the rafter. Only two shoots should again be permitted to grow on each plant on the back wall, and one on those of the front, and these may be allowed to run the whole height of the house before they are stopped. After the vine shoots are stopped (which is done by pinching off their tops), they will in general push out laterals at three or four eyes, on the upper part of the shoot. These laterals should not entirely be taken off, as it would cause more eyes lower upon the shoots to push out. It would therefore be prudent to permit the first laterals to grow twelve or fourteen inches, and then to pinch off their tops. These laterals, in their turn, will push out secondary laterals, which should be pinched off at the second or third joint, and in that way the sap may be diverted till the end of the season.

The shoots of the plants on the back wall must be brought down to a horizontal position, and cut so that the branches of each plant may reach within a foot of the other. If all the vines on the rafters have pushed vigorously, it will be proper to prune every other plant down to three or four eyes, and the rest to from twenty to twenty-five eyes each, the latter being intended to produce fruit, and the former to make bearing wood against another year. When the vines begin to push in the spring of the third year, the shoots of those on the back wall should not be allowed to stand nearer one another than a foot or fifteen inches, all the intermediate buds being carefully rubbed off. The shoots ought to be trained up perpendicularly, and however vigorous they may be, no more than one cluster should be allowed to remain on any of them: all of them may run up to the height of five or six feet before they are stopped. The shoots on the rafters, that were pruned to twenty or twenty-five eyes each, will probably push at all of them; but not more than five or seven shoots should be permitted to remain, even on the strongest; viz. a leading shoot, and two or three on each side. Care being taken to leave one shoot as near the bottom as possible, as the whole branch will require to be pruned down to this shoot next winter. Only one shoot should be left upon those vines that were pruned down to three or four eyes, at every other rafter; and this must be trained up the rafter as in the preceding year. At next pruning season all the shoots proceeding from the horizontal branches of the vines in the back wall should be pruned down to three or four eyes. The vines on the front which produced fruit should be pruned to their lowest shoot, which should be shortened, so as to leave four or five eyes. Those at every other rafter which were shortened the preceding year, and which were allowed to push one shoot, should now be pruned like the bearers of the former year; i. e. twenty or twenty-five eyes should be left on each. In the following and all succeeding seasons, these vines on the front will require a similar management, with this difference, that, as they acquire more strength, they may be permitted to push more shoots, and more clusters may be allowed to remain on each shoot; for, as the vines advance in age, they will certainly be enabled to produce every year for a certain period, a larger crop of fruit. The spurs of the vines on the back-wall, i. e. the shoots that were shortened to three or four eyes, should be allowed to push up one shoot: these shoots at next pruning season must be cut so as to leave a long one, viz. about four feet, and a short one, alternately. The long ones should be allowed to push five shoots (all the other buds being rubbed off), the four lateral of which should be cut down to two or three eyes each, at next pruning season, and the terminal one should be left about a foot and a half long. The short shoots between the long ones must constantly be pruned down to two or three eyes each, in order to keep up a proper succession of bottom wood. The pruning following season must be the same, with this difference, that the upright shoots, as they have acquired a foot and a half additional length, may be allowed to push seven shoots instead of five.

259 Different kinds of grapes.

The principal kinds of vines (E) are, * the white muscat of Alexandria, * black damascus, * golden gallician, *†white frontinac, *†grisly frontinac, *†black or purple frontinac, †‡ blue or violet frontinac, †‡ red frontinac, *† white sweet water, *† black Hamburgh, *† red Hamburgh or Gibraltar grape, * white Hamburgh, *† malvoise or blue tokay, *† genuine tokay, *† flame-coloured tokay, †‡ brick grape, *† white muscadine or chasselas, *† royal muscadine or d'arboyce, *† Malmsey grape, *† claret grape, * Syrian, †‡ Burgundy or Munier grape, †‡ small black cluster, † large black cluster, †‡ early black July grape or morillon, noir natif, † white parsley-leaved.

260 Prune gooseberries and currants.

Gooseberries and currants may be pruned any time from the fall of the leaf, till their buds begin to grow in the spring. If these bushes be not well pruned, the fruit will neither be large nor well-flavoured. The principal thing to be attended to is, to keep them open; for they are very apt to become over-crowded with branches: all suckers therefore which arise from the root, or shoots which proceed from the main stem, should be removed, because they would only create confusion, by growing up into the heart of the bush. When last summer's shoots stand too thick, on the main branches, which is frequently the case, particularly with gooseberries, they should be thinned, and few either of them or of the main branches should be shortened, because the more they are shortened the more liable they are to run to wood. They who make use of garden-shears, for sake of expedition, which is too frequently the case, may save time, and make neat-looking bushes, but will be disappointed with respect to the quantity and quality of their fruit.

Sect. III. *Flower Garden*, or *Pleasure Ground*.

November. Flower Garden or Pleasure Ground.

Fibrous-rooted perennial plants may still be planted; likewise bulbous-rooted plants, such as tulips, hyacinths, &c.

Shrubs and ornamental or forest trees may be transplanted

(E) Those marked * are for a hot-house; those marked † are for a vinery; and those marked ‡ are for a common wall.

December. Kitchen Garden.

planted now or any time during the winter when the weather is open.

Sect. IV. *The Nursery.*

Transplant young trees and shrubs, and protect tender seedlings during severe weather.

Sect. V. *Green-House and Hot-House.*

The plants in the green-house should have air during the day, whenever the weather will permit, and should receive but little water. The plants in the hot-house should likewise receive air during the day in favourable weather, and fires must be put on every evening, but seldom need to be continued during the day, except the weather is very severe.

DECEMBER.

Sect. I. *Kitchen Garden.*

The cauliflower plants and lettuces planted under hot-bed frames, or under bell or hand-glasses, should be exposed to the air during the mild days, and protected during severe weather with a covering of mats or straw. In dry weather celery and cardoons should be earthed up, and endive tied up for blanching.

In this month there is nothing to be done either in the fruit garden, nursery, green-house, or hot-house, that has not already been taken notice of in the preceding months.

261 Construction of green-houses.

Here we shall add some observations on the construction of green-houses and hot-houses.

A green-house constructed for the protection of such vegetables as cannot stand in the open air during winter, may vary in form and dimensions according to the fancy of the proprietor, and the number of plants it is intended to contain. When the front only is of glass, which formerly was the only, and even still is the prevalent, mode of constructing green-houses, the pillars between the sashes ought to be as narrow as the weight they have to support will admit of, and formed so as to give the least possible obstruction to the light; they may be either of stone, brick, wood, or cast iron. The height of the sashes should equal if not exceed the width of the house, that a sufficient quantity of light may be thrown on the plants which stand near the back wall, otherwise they will lose colour, become unhealthy and deformed; for not only the colour, but the vigour, and even the form of vegetables, depends on the light. When one half or the whole of the roof is of glass, which ought to be the case, there is no necessity for attending to the proportion the height ought to bear to the width of the house. The ends of the house should also be of glass, unless when it is connected with a series of other buildings. The pots containing the plants are commonly set on benches, which gradually increase in height as they recede from the front; however, when the roof is of glass, the arrangement may be different. Every green-house ought to be furnished with flues; for though many winters may occur in which the application of fire heat may not be necessary, yet such intense frosts at times prevail as would infallibly kill a great many of the plants: external coverings, it is true, are frequently made use of as a protection against the severity of the weather, but they do not answer the purpose equally well, for when the frost continues long they cannot be applied day and night without doing injury, by excluding air and light; the application of fire-heat is likewise necessary for banishing the damp, which very much injures and frequently destroys the plants, during long-continued, dull, rainy weather. The flues in green-houses are frequently confined to the back wall, but they ought to pass in front of the house likewise, because the plants situated there are most liable to be injured by the severity of the weather.

Construction of Green-houses.

As fires are seldom required, and those but very slight ones, merely to banish frost and damp, it will not be necessary from economical motives to construct the flues so as to throw off the greatest possible quantity of heat; they may therefore be concealed, that they may not affect the appearance of the house.

Hot-houses for rearing plants which grow in warmer climates, or for forcing at an early period such vegetables as grow in the open air, vary considerably according to the different purposes for which they are intended. 1st, Conservatories, or dry stoves, so called because they are constructed without pits for containing tanners bark, oak leaves, or other fermentable substances, and in which the plants grow in the earth which forms the floor of the house, and not in pots. These are commonly of a considerable width and height, and are either covered entirely, or at least on the front, roof, and ends, with glass. 2dly, Hot-houses for rearing exotic plants, furnished with a pit containing tanners bark, oak leaves, heated sand, &c. in which pots containing the plants are plunged: these likewise are of considerable breadth and height, and have their front, roof, and ends, covered with glass. 3dly, Pine-houses, which are furnished with a pit, as above: these are low, the roof being within a few feet of the surface of the pit, that the pine plants may be as near the light as possible, and the roof and part of the front only need be of glass.

Vine-houses are commonly constructed without pits, and are generally about 12 or 14 feet high, sometimes very narrow, at other times of considerable breadth; the former answer best for forcing at a very early period, and in both houses the vines are commonly trained both to the back and front.

Peach houses are almost always constructed without pits, are of a moderate height, and vary in breadth. The peaches are trained either to the front or back, or to both; and sometimes they are planted in the middle of the house, and allowed to grow like standard fruit trees, in which case the house should be capacious.

Cherry and fig-houses are constructed nearly in the same way as peach-houses. The flues for warming all these ought to pass round the front as well as the back of the house, and ought to have as much of their surface exposed as possible; for the more of the surface of the flue comes in contact with the air of the house, the more readily the house will be warmed: therefore they ought not to be built in contact with the front or back walls when that can be avoided, but ought to be supported on pillars of brick to keep them from resting on the ground.

The furnaces for containing the fuel are placed sometimes

Construction of Green-houses, &c.

times in front, sometimes at the end, but most frequently behind the house. They ought to be situated so far below the level of the flue, as is necessary to cause a sufficient draught; if this be not attended to, the smoke will not pass through the flues to warm the houses, but escape some other way. When the furnaces are about 18 inches high (a common size), they ought to be placed about two feet below the level of the flue, that the heated air may have an ascent of about six or eight inches, which will be sufficient to give the requisite draught.

When the hot-house is of considerable extent, it is better to employ several moderate, than a smaller number of strong fires, for violent fires are apt to crack the flues, in which case the smoke escapes into the house, and injures the plants. Some are partial to large fires, from an idea that they consume less fuel in proportion; but this is a mistake, for two moderate fires are found to heat the same extent of hot-house to an equal degree, and more equably, with a less expenditure of fuel than one large one. One moderate fire will be sufficient for an extent of 500 or 600 square feet of glass, but if the house is protected with coverings during the night, it will be sufficient for 700 or 800: thus the number of square feet of glass being known, the requisite number of fires may be easily ascertained. The fires employed for warming hot-houses may at the same time be converted to other useful purposes. At Billing in Northamptonshire, the seat of Lord John Cavendish, the furnaces are constructed to burn lime at the same time that they heat the hot-house. One furnace can burn four bushels of lime, and consume about three-fourths of a hundred weight of coal, when lighted only at night and in the morning.

Construction of Green-houses, &c.

Hot-houses are sometimes protected during the winter nights by external coverings of wood or canvas, &c. This renders less fire necessary; but the saving in point of fuel is more than overbalanced by the original expence of the covering, by the trouble of taking it off and putting it on morning and evening, and by the quantity of glass broken, particularly when the covering is made of canvas, which is apt to be dashed against the glass by the wind. When light coverings of cloth are applied internally they are not liable to the last-mentioned objection, but there are few hot-houses where they can be so applied.

INDEX TO PART III.

GARDINER, Stephen, bishop of Winchester, and lord chancellor of England, born at Bury St Edmunds in Suffolk, was natural son to Richard Woodville, brother to Queen Elizabeth wife to Edward IV. was learned in the canon and civil laws, and in divinity. He signed the divorce of Henry VIII. from Katharine of Spain; abjured the pope's supremacy; and wrote *De vera et falsa obedientia*, in behalf of the king; yet in Edward's reign he opposed the reformation, and was punished with imprisonment; but Queen Mary coming to the throne, she enlarged him. He drew up the articles of marriage between the queen and Philip of Spain, which were very advantageous to England. He was violent against the reformers; but on his death-bed was dissatisfied with his life, and often repeated these words: *Erravi cum Petro, sed non flevi cum Petro.* He died in 1555.

GARGARISM (from γαργαριζω, "to wash the mouth;") a gargle. Its use is for washing the mouth and throat with, when inflammations, ulcerations, &c. are there. A small quantity may be taken into the mouth, and moved briskly about, and then spit out; or if the patient cannot do this to any advantage, the liquor may be injected by a syringe. When gargles are required, their use should be more frequently repeated than is done in common practice.

GARGET, a disease of cattle, consisting in a swelling of the throat and the neighbouring parts; to prevent which bleeding in the spring is recommended.

GARGIL, a distemper in geese, which by stopping the head frequently proves mortal. Three or four cloves of garlic, beaten in a mortar with sweet butter, and made into little balls, and given the creature fasting, are the ordinary cure.

GARIDELLA, a genus of plants belonging to the decandria class, and in the natural method ranking under the 26th order, *Multisiliquæ*. See Botany *Index*.

GARIZIM, Gerizim, or *Gerisim*, in *Ancient Geography*, a mountain of Samaria, at the foot of which stood Sichem; so near, that Jotham could be heard by the Sichemites from its top, (Judges, ix. 7.). Famous for the temple built on it by Sanballet, in favour of his son-in-law Manasseh, by the permission of Alexander the Great, and 200 years after destroyed by John Hyrcanus, son of Simon, the fourth in succession of the Asmoneans (Josephus).

GARLAND, a sort of chaplet made of flowers, feathers, and sometimes precious stones, worn on the head in manner of a crown.—The word is formed of the French *guirlande*, and that of the barbarous Latin *garlanda*, or Italian *ghirlanda*. Menage traces its origin from *gyrus* through *gyrulus*, to *gyrulare*, *gyrlandum*, *ghirlandum*; and at length *ghirlanda* and *guirlande*; so that *guirlande* and *garland* are descended in the sixth or seventh degree from *gyrus*.—Hick rejects this derivation, and brings the word from *gardel handa*, which in the northern languages signify a *nosegay artfully wrought with the hand.*

Garland also denotes ornaments of flowers, fruits, and leaves, intermixed; anciently much used at the gates of temples, where feasts and solemn rejoicings were held; or at any other place where marks of public joy or gaiety were required, as at triumphal arches, tournaments, &c.

GARLIC. See Allium, Botany *Index*.

GARMENT, that wherewith any person is clothed. See Dress and Habit.

GARNET, in *Natural History*, a very beautiful gem, of a red colour, with an admixture of blue. See Mineralogy *Index*.

When pure and free from blemishes, it is little inferior in appearance to the oriental ruby, though only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among lapidaries and jewellers, genuine garnets are known by different names according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red with a faint admixture of blue. 2. The rock-ruby; a name very improperly given to the garnet when it is of a very strong but not deep red, and has a fairer cast of the blue; this is a very beautiful gem. 3. The sorane or serain garnet; that of a yet brighter red, approaching to the colour of native cinnabar, Garnet Garrick.

cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the *rock-ruby*.

Garnet-Colour. See *Colouring of Glass*.

To imitate Garnets. The making the counterfeit garnet in paste is done as follows.—Take prepared crystal two ounces, common red-lead six ounces, manganese 16 grains, zaffre three grains; mix all well, put them into a crucible, cover it with lute, and set it in a potter's kiln for 24 hours. Or take crystal two ounces, minium five ounces and a half, manganese 15 grains, zaffre four grains: mix them well together; and let all be baked, in a pot well luted, in a kiln, 24 hours.

GARONNE, a large river of France, which has its source in the Pyrenean mountains, and falls into the sea 60 miles below Bourdeaux.

Garonne, *Upper*, a department in the south of France. The south part extends to the Pyrenees, and is rugged and mountainous: the north part has a hilly or undulating surface. It produces corn, wine, olives, silk, figs, almonds, and abounds in pasturage. The mountains contain mines of copper, lead, iron, and coal. The population in 1815 was 367,000. Thoulouse is the chief town.

GARRICK, David, Esq. the great Roscius of his age and country, who for nearly 40 years shone the brightest luminary in the hemisphere of the stage, was born at the Angel Inn at Hereford, in the year 1716. His father, Captain Peter Garrick, was a French refugee, and had a troop of horse which were then quartered in that city. This rank he maintained in the army for several years, and had a majority at the time of his death; that event, however, prevented him from ever enjoining it. Mr Garrick received the first rudiments of his education at the free-school at Litchfield; which he afterwards completed at Rochester, under the celebrated Mr Colson, since mathematical professor at Cambridge. Dr Johnson and he were fellow-students at the same school; and it is a curious fact, that these two celebrated geniuses came up to London in the same coach, with the intention of pushing themselves into active life. On the 9th of March 1736, he was entered at the honourable society of Lincoln's Inn. The study of the law, however, he soon quitted; and followed for some time the employment of a wine merchant: but that too disgusting him, he gave way at last to the irresistible bias of his mind, and joined a travelling company of comedians at Ipswich in Suffolk, where he went by the name of *Lyddle*. Having in this poor school of Apollo got some acquaintance with the theatric art, he burst at once upon the world, in the year 1740-1, in all the lustre of perfection, at the little theatre in Goodman's Fields, then under the direction of Henry Giffard.

The character he first performed was Richard III. in which, like the sun bursting from behind a cloud, he displayed in the earliest dawn even more than meridian brightness. His excellence dazzled and astonished every one; and the seeing a young man, in no more than his 24th year, and a novice in reality to the stage, reaching at one single step to that height of perfection which maturity of years and long practical experience had not been able to bestow on the most capital performers of the English stage, was a phenomenon that could not but become the object of universal speculation and of as universal admiration. The theatres at the west end of the town were deserted; Goodman's Fields, from being the rendezvous of citizens and citizens wives alone, became the resort of all ranks of men; and Mr Garrick continued to act till the close of the season.

Having very advantageous terms offered him for the performing in Dublin during some part of the summer (1741), he went over thither, where he found the same just homage paid to his merit which he had received from his own countrymen. To the service of the latter, however, he esteemed himself more immediately bound; and therefore in the ensuing winter, engaged himself to Mr Fleetwood, then manager of Drury Lane; in which theatre he continued till the year 1745, when he again went over to Ireland, and continued there the whole season, joint manager with Mr Sheridan in the direction and profits of the theatre royal in Smock Alley. From thence he returned to England, and was engaged for the season of 1746 with Mr Rich at Covent Garden. This was his last performance as a hired actor: for in the close of that season, Mr Fleetwood's patent for the management of Drury Lane being expired, and that gentleman having no inclination further to pursue a design by which, from his want of acquaintance with the proper conduct of it, or some other cause, he had considerably impaired his fortune; Mr Garrick, in conjunction with Mr Lacy, purchased the property of that theatre, together with the renovation of the patent; and in the winter of 1747, opened it with the greatest part of Mr Fleetwood's company, and with the great additional strength of Mr Barry, Mrs Pritchard, and Mrs Cibber, from Covent Garden.

Were we to trace Mr Garrick through the several occurrences of his life,—a life so active, so busy, and so full of occurrences as his, we should swell this account to many pages. Suffice it to say, he continued in the unmolested enjoyment of his fame and unrivalled excellence to the moment of his retirement. His universality of excellence was never once attacked by competition. Tragedy, comedy, and farce, the lover and the hero, the jealous husband who suspects his wife without cause, and the thoughtless lively rake who attacks her without design, were all alike his own. Rage and ridicule, doubt and despair, transport and tenderness, compassion and contempt; love, jealousy, fear, fury, and simplicity; all took in turn possession of his features, while each of them in turn appeared to be the sole possessor of his heart. In the several characters of Lear and Hamlet, Richard, Dorilas, Romeo, and Lusignane; in his Ranger, Bayes, Drugger, Kitely, Brute, and Benedict, you saw the muscular conformations that your ideas attached to them all. In short, Nature, the mistress from whom alone this great performer borrowed all his lessons, being in herself inexhaustible, this her darling son, marked out for her truest representative, found an unlimited scope for change and diversity in his manner of copying from her various productions. There is one part of theatrical conduct which ought unquestionably to be recorded to Mr Garrick's honour, since the cause of virtue and morality, and the formation of public manners, are considerably dependent upon it; and that is, the zeal with which he aimed to banish from the stage all those plays which carry with them an immoral tendency, and

Garrick.

and to prune from those which do not absolutely, on the whole, promote the interests of vice, such scenes of licentiousness and liberty, as a redundancy of wit and too great liveliness of imagination have induced some of our comic writers to indulge themselves in, and to which the sympathetic disposition of our age of gallantry and intrigue has given sanction. The purity of the English stage has certainly been much more fully established during the administration of this theatrical minister, than it had ever been during preceding managements. He seems to have carried his modest, moral, chaste, and pious principles with him into the very management of the theatre itself, and rescued performers from that obloquy which had attached to the profession. Of those who were accounted blackguards, unworthy the association of the world, he made gentlemen, united them with society, and introduced them to all the domestic comforts of life. The theatre was no longer esteemed the receptacle of all vice; and the moral, the serious, the religious part of mankind, did not hesitate to partake of the rational entertainment of a play, and pass a cheerful evening undisgusted with the licentiousness, and uncorrupted by the immorality, of the exhibition.

Notwithstanding the numberless and laborious avocations attendant on his professsion as an actor, and his station as a manager; yet still his active genius was perpetually bursting forth in various little productions in the dramatic and poetical way, whose merit cannot but make us regret his want of time for the pursuance of more extensive and important works. It is certain that his merit as an author is not of the first magnitude: but his great knowledge of men and manners, of stage effect, and his happy turn for lively and striking satire, made him generally successful; and his prologues and epilogues in particular, which are almost innumerable, possess such a degree of happiness, both in the conception and execution, as to stand unequalled. His ode on the death of Mr Pelham ran through four editions in less than six weeks. His Ode on Shakespeare is a masterly piece of poetry; and when delivered by himself, was a most capital exhibition. His alterations of Shakespeare and other authors have been at times successful, and at times exploded. The exclusion of the gravediggers scene from Hamlet will never be forgotten to him by the inhabitants of the gallery at Drury. Though necessary to the chasteness of the scene, they cannot bear to lose so much true sterling wit and humour; and it must be owned, that exuberances of that kind, though they hurt the uniformity, yet increase the luxuriance of the tree. Among his alterations the following are part; Every Man in his Humour, altered from Ben Johnson; Romeo and Juliet, Winter's Tale, Catherine and Petruchio, Cymbeline, Hamlet, &c. altered and made up from Shakespeare; Gamesters, a comedy, from Shirley; Isabella, from Southerne. To these we add, as original productions, The Farmer's Return, and Linco's Travels, interludes; Guardian, Lethe, Lying Valet, Miss in her Teens, Male Coquet, Irish Widow, and other comedies in two acts; Enchanter, a musical entertainment; Lilliput: the Christmas Tale is ascribed to him, and many others.

We now bring him to the period of his retirement in the spring of 1776; when, full of fame, with the acquirement of a splendid fortune, and growing into years, he thought proper to seek the vale of life, to enjoy that dignified and honourable ease which was compatible with his public situation, and which he had so well earned by the activity and the merits of his dramatic reign. But very short indeed was the period allotted to him for this precious enjoyment: for on the 20th of January 1779, he departed this life; leaving no one rival in excellence upon earth to compensate for his loss, or a hope of our ever meeting with his like again.

Garrison. Garstang.

GARRISON, in the art of war, a body of forces, disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection: or even to be subsisted during the winter season: hence *garrison* and *winter quarters* are sometimes used indifferently for the same thing; and sometimes they denote different things. In the latter case, a garrison is a place wherein forces are maintained to secure it, and where they keep regular guard, as a frontier town, a citadel, castle, tower, &c. The garrison should be always stronger than the townsmen.

Du Cange derives the word from the corrupt Latin *garnisio*, which the latter writers use to signify all manner of munition, arms, victuals, &c. necessary for the defence of a place, and sustaining of a siege.

Winter quarters signify a place where a number of forces are laid up in the winter season, without keeping the regular guard.

GARSTANG, a town in Lancashire, 227 miles from London, It is near a mile in length, but built in a very irregular manner, with dirty streets, and very indifferent houses. The population amounts to 790 persons. The church is a stately Gothic structnre. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends above 500 miles, in the counties of Lincoln, Nottingham, York, Westmoreland, Chester, &c. W. Long. 2. 42. N. Lat. 53. 52.

GARTER, a ligatnre for tying up the stocking; but particularly used for the badge of a noble order of knights, hence denominated the

Order of the GARTER, a military order of knighthood, the most noble and ancient of any lay order in the world, instituted by Edward III. The knights companions are generally princes and peers; and the king of England is the sovereign or chief of the order. The number of knights was originally 26: but six were added in 1786, on account of the increase of the royal family. They are a college or corporation, having a great and little seal.

Their officers are a prelate, chancellor, register, king-at-arms, and usher of the black rod. They have also a dean, and 12 canons and petty canons, vergers, and 26 pensioners or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next to the prelate is the chancellor; which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order, with all fidelity: The dean of Windsor is always register *ex officio*. The fourth officer is Garter and king-at-arms, being two distinct offices united in one person.

Garter

Garter carries the rod and sceptre at the feast of St George, the protector of this order, when the sovereign is present. He notifies the election of new knights, attends the solemnity of their installation, carries the garter to foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See *King-at-Arms*.

All these officers except the prelate have fees and pensions. The college of the order is seated in the castle of Windsor, within the chapel of St George, and the charter house, erected by the founder for that purpose. The habit and ensign of the order, are, a garter, mantle, cape, george, and collar. The three first were assigned the knights companions by the founder; and the george and collar by Henry VIII.

The garter challenges pre-eminence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes and absent knights, who, and all other knights-elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, HONI SOIT QUI MAL Y PENSE; i. e. *Shame to him that thinks evil hereof:* The meaning of which is, that King Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprise he had undertaken, for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order, was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle is the chief of these vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights companions. To the collar of the mantle is fixed a pair of long strings, anciently woven with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robes, with knobs or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device HONI SOIT, &c. Within this is the cross of the order, which was ordained to be worn at all times by King Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver.

The collar is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold.

When the knights wear not their robes, they are to have a silver star on the left side; and they commonly bear the picture of St George, enamelled on gold, and beset with diamonds, at the end of a blue ribbon, crossing the body from the left shoulder. They are not to appear abroad without the garter, on penalty of 6s. 8d. paid to the register.

The manner of electing a knight companion into this most noble order, and the ceremonies of investiture, are as follow. When the sovereign designs to elect a companion of the Garter, the chancellor belonging to this order draws up the letters, which, passing both under the sovereign's sign manual and signet of the order, are sent to the person by Garter principal king at arms; and are in this manner, or to the same effect: "We, with the companions of our most noble order of the Garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shown, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c. have elected or chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation upon the — day of this present month, &c."

The garter, which is of blue velvet bordered with fine gold wire, having commonly the letters of the motto of the same, is, at the time of election, buckled upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion, by Garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous; and having undertaken a just war, in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successfully conquer." The princely garter being then buckled on, and the word of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a dark blue ribbon, whereunto is appendant, wrought in gold within the garter, the image of St George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St George, by whose imitation provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory." Then the knight elected kisses the sovereign's hand; thanks his majesty for the great honour done him; rises up and salutes all the companions severally, who return their congratulations. See a representation of the above insignia, among others, on the plate belonging to *Orders of* KNIGHTHOOD.

Since the institution of this order, there have been eight emperors and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related. The common account is, that the countess of Salisbury at a ball happening to drop her garter, the king took it up and presented it to her with these words, '*Honi soit qui mal y pense;* i. e. Evil to him that evil thinks. This accident, it is said, gave rise to the order and the motto; it being the spirit of the times to mix love and war together: but as in the original statutes of this order there is not the least conjecture to countenance such a feminine institution, credit cannot be given to this tradition. Camden, Fern, &c. take it

to

Garter, Garth.

to have been instituted on occasion of the victory obtained by Edward over the French at the battle of Cressy; that prince, say some historians, ordered his garter to be displayed, as a signal of battle: in commemoration whereof, he made a garter the principal ornament of the order, erected in memory of this signal victory, and a symbol of the indissoluble union of the knights.

It appears from Rastel's Chronicle, lib. vi. quoted by Granger in the supplement to his Biographical History, that this order was devised by Richard I. at the siege of the city of Acre, when he caused twenty-six knights, who firmly stood by him, to wear thongs of blue leather about their legs, and that it was perfected in the nineteenth year of Edward III.

In 1551, Edward VI. made some alterations in the ritual of this order: that prince composed it in Latin, the original whereof is still extant in his own hand writing. He there ordained, that the order should no longer be called the order of St George, but that of the Garter; and, instead of the george, hung at the collar, he substituted a cavalier, bearing a book on the point of his sword, with the word *protectio* graven on the sword, and *verbum Dei* on the book: with a buckle in the left hand, and the word *fides* thereon. Larrey.

Garter, *principal King at Arms.* This office was instituted by Henry V.

Garter, and principal king at arms, are two distinct offices united in one person: Garter's employment is to attend the service of the order of the Garter; for which he is allowed a mantle and badge, a house in Windsor castle, and pensions both from the sovereign and knights, and lastly, fees. He also carries the rod and sceptre at every feast of St George, when the sovereign is present, and notifies the election of such as are new chosen; attends the solemnity of their installations, takes care of placing their arms over their seats; and carries the garter to foreign kings and princes, for which services it has been usual to join him in commission with some peer, or other person of distinction.

Garter's oath relates only to services being performed within the order, and is taken in chapter before the sovereign knights. His oath, as king at arms, is taken before the earl marshal.

Garter is also a term in heraldry, signifying the moiety or half of a bend.

GARTH is used in some parts of England for a little backside or close. It is an ancient British word. Gardd, in that language, signifies *garden*, and is pronounced and written *garth*. This word is also used for a dam or wear, &c.

Garth *Men*, is used in our statutes for those who catch fish by means of fish garths, or wears. By statute it is ordained, that no fisher, nor garth men, shall use any nets or engines to destroy the fry of fish, &c. 17 Ric. II. cap. 9. The word is supposed by some to be derived from the Scotch word *gart*, which signifies *forced* or *compelled*; because fish are forced by the wear to pass in a loop, where they are taken.

Garth, *Sir Samuel*, an excellent English poet and physician, was descended from a good family in Yorkshire. He was admitted into the college of physicians at London in 1663. He at that time zealously promoted and encouraged the erecting of the dispensary for the relief of the sick poor, by giving them advice gratis, and medicines at low rates. This work of charity having exposed him and many other physicians to the envy and resentment of several persons of the same faculty as well as apothecaries, he ridiculed them, with a peculiar spirit and vivacity, in a poem called the *Dispensary*, in six cantos, highly esteemed. He was one of the most eminent members of the famous society called the *Kit Kat Club*, which consisted of noblemen and gentlemen distinguished by their excellent parts and affection to the house of Hanover. Upon the accession of George I. he was knighted, and made physician in ordinary to his majesty, and physician general to the army. Nor were these more than just rewards even of his physical merit. He had gone through the office of censor of the college in 1702; and had practised always with great reputation, and a strict regard to the honour and interest of the faculty, never stooping to prostitute the dignity of his profession, through mean and sordid views of self-interest, to any, even the most popular and wealthy characters. In a steady adherence to this noble principle, he concurred with the much celebrated Dr Radcliffe, with whom he was also often joined in physical consultations. He had a very extensive practice, but was very moderate in his views of advancing his own fortune; his humanity and good nature inclining him more to make use of the great interest he had with persons in power, for the support and encouragement of other men of letters. He chose to live with the great in that degree of independency and freedom which became a man possessed of a superior genius, whereof he was daily giving fresh proofs to the public. One of his last performances in polite letters, was his translation of the whole fourteenth book, and the story of Cinnus in the fifteenth book, of Ovid's Metamorphoses. These, together with an English version of the rest, were published in 1717; and he has prefixed an excellent preface to the whole, wherein he not only gives an idea of the work, and points out its principal beauties, but shows the uses of the poem, and how it may be read to most profit. The distemper which seized him the ensuing year, and ended not but with his life, caused a general concern; which was particularly testified by Lord Lansdowne, a brother poet. He died, after a short illness, which he bore with great patience, in January 1719.

Garve, Garumna.

GARVE, Christian, an eminent German philosopher. See Supplement.

GARUMNA, or *Garonne*, a noble and navigable river of Gaul, which, rising from the Pyrenees, formerly bounded Aquitain on the north (Cæsar); but by the new regulation of Augustus divided it in the middle, emptying itself to the north of Burdegala, in the Aquitanic ocean. Mela observes concerning it, that unless it is swelled by winter rains, or the melting of the snow, it is for a great part of the year shoaly and scarcely navigable; but when increased by the meeting tide, whereby its waters are impelled, it is somewhat fuller; and the farther the river advances, it is broader, till at length it resembles a large frith or arm of the sea, not only bearing large vessels, but also so swelling like a raging sea, tosses them extremely, especially if the direction of the wind be one way and that of the current another.

GAS, in *Chemistry*, a general name for all permanently elastic fluids, which are obtained by chemical processes, as *azotic gas*, *muriatic acid gas*, *nitrous gas*. See CHEMISTRY *Index*. It is derived from the German *gascht* or *gast*, signifying the ebullition attending the expulsion of elastic fluids from substances in a state of effervescence. It was first employed by Van Helmont.

GAS LIGHTS. See SUPPLEMENT.

GASCOIGNE, SIR WILLIAM, chief justice of the court of king's bench under Henry IV. A most learned and upright judge: who being insulted on the bench by the prince of Wales, afterwards Henry V. with equal intrepidity and coolness committed the prince to prison; and by this seasonable fortitude laid the foundation of the future glory of that great monarch, who from this event dated his reformation from the licentiousness of his youth. It is not well authenticated that the prince struck Sir William, as recorded by Shakespeare; but all authors agree, that he interrupted the course of justice to screen a lewd servant. Sir William died in 1413.

GASCOIGNE, *George*, an English poet of some fame in the early part of the reign of Queen Elizabeth, was born at Walthamstow in Essex, of an ancient family, and educated at both universities, but principally at Cambridge. From thence he removed to Gray's Inn, and commenced student of the law; but having a genius too volatile for that study, he travelled abroad, and for some time served in the army in the Low Countries. He afterwards went to France; where he became enamoured of a Scottish lady, and married her. Being at length, says Wood, *weary of those vanities*, he returned to England: and settled once more in Gray's Inn, where he wrote most of his dramatic and other poems. The latter part of his life he spent in his native village of Walthamstow, where he died in the year 1578. He had the character of a polite gentleman, an eloquent and witty companion, *et vir inter poetas sui seculi præstantissimus*. His plays, first printed separately, were afterwards, with several other poems, &c. reprinted into two volumes 4to; the first volume in 1577, the second in 1587.

GASCOIN, or GASCOIGN, denotes the hinder thigh of a horse, which begins at the stifle, and reaches to the ply or bending of the ham.

GASCONADE, a boast or vaunt of something very improbable. The term has its rise from the Gascons, or people of Gascony in France, who it seems have been distinguished for bragging and rhodomontade.

GASCONY, the most south-west province of France, is bounded by Guienne on the north, by Languedoc on the east, by the Pyrenees which separate it from Spain on the south, and by the bay of Biscay on the west. It had its name from the ancient inhabitants, called *Gascones* or *Vascones*; by the moderns *Basques*, or *Vasques*. After these were subdued by the Franks, they had for some time dukes of their own, who were subject to the dukes of Aquitaine; but both were at last dispossessed by the kings of France. The country produces corn, wine, fruits, &c. The inhabitants are noted for a corrupt pronunciation: and their tendency to exaggerate their own exploits, has rendered *Gasconade* a proverbial expression.

GASSENDI, PETER, one of the most celebrated philosophers France has produced, was born at Chantersier, about three miles from Digne in Provence, in 1592. When a child, he took particular delight in gazing at the moon and stars as often as they appeared in clear unclouded weather. This pleasure frequently drew him into bye places, in order to feast his eye freely and undisturbed; by which means his parents had him often to seek, not without many anxious fears and apprehensions. They therefore put him to school at Digne; where, in a short time, he made such an extraordinary progress in learning, that some persons, who had seen specimens of his genius, resolved to have him removed to Aix, in order to study philosophy under Fesay, a learned minor friar. This proposal was so disagreeable to his father, who intended to breed him up in his own way to country business, as being more profitable than that of a scholar, that he would consent to it only upon condition that he should return home in two years at farthest. Accordingly young Gassendi, at the end of the appointed time, repaired to Chantersier; but he had not been long there when he was invited to be professor of rhetoric at Digne, before he was quite 16 years of age; and he had been engaged in that office but three years, when his master Fesay dying, he was made professor in his room at Aix. When he had been there a few years, he composed his Paradoxical Exercitations; which, coming to the hands of Nicholas Peiresc, that great patron of learning joined with Joseph Walter prior of Valette in promoting him; and he having entered into holy orders, was first made canon of the church of Digne and doctor of divinity, and then obtained the wardenship or rectorship of that church. Gassendi's fondness for astronomy grew up with his years; and his reputation daily increasing, he was in 1645 appointed royal professor of mathematics at Paris. This institution being chiefly designed for astronomy, our author read lectures on that science to a crowded audience. However, he did not hold this place long; for a dangerous cough and inflammation of the lungs obliged him, in 1647, to return to Digne for the benefit of his native air.—Gassendi wrote against the metaphysical meditations of Descartes; and divided with that great man the philosophers of his time, almost all of whom were Cartesians or Gassendians. He joined to his knowledge of philosophy and the mathematics an acquaintance with the languages and a profound erudition. He wrote, 1. Three volumes on Epicurus's Philosophy; and six others, which contain his own philosophy. 2. Astronomical Works. 3. The Lives of Nicholas de Peiresc, Epicurus, Copernicus, Tycho Brahe, Puerbachius, and Regiomontanus. 4. Epistles, and other treatises. All his works were collected together, and printed at Lyons in 1658, in six volumes folio. He died at Paris in 1658, aged 63.

GASTEROSTEUS, the STICKLEBACK, a genus of fishes belonging to the order of thoracici. See ICHTHYOLOGY *Index*.

GAST-HOUND. See *GAZE Hound*.

GASTRIC, in general, something belonging to the stomach.

GASTRIC Juice, a thin pellucid liquor, which distils from

from certain glands in the stomach, for the dilution, &c. of the food. See ANATOMY.

GASTROCNEMIUS, in *Anatomy*. See ANATOMY, *Table of the Muscles*.

GASTROMANCY, or GASTROMANTIA, a kind of divination practised among the ancients by means of words coming or seeming to come out of the belly.

The word is Greek, γαςρομανλια, composed of γαςηρ, *belly*, and μανλια, *divination*.

There is another kind of divination, called by the same name *gastromancy*, which is performed by means of glasses or other round transparent vessels, within which certain figures appear by magic art. It is thus called, because the figures appear as in the belly of the vessels.

GASTRORAPHY, in *Surgery*, the operation of sewing up wounds of the abdomen. See SURGERY.

GASTROTOMY (of γαςηρ, and τεμνω, *I cut*), the operation of cutting open the belly; otherwise called the *Cæsarean section*. See MIDWIFERY.

GATAKER, THOMAS, a learned critic and divine, was born at London in 1574, and studied at St John's college, Cambridge. He was afterwards chosen preacher at Lincoln's Inn; which he quitted in 1611, for the rectory of Rotherhithe in Surry. In 1620, he made a tour through the Low Countries; and in 1624, published at London a book, entitled, Transubstantiation declared by the confession of the Popish Writers to have no necessary foundation in God's Word: he wrote likewise a defence of this discourse. In 1642, he was appointed one of the assembly of divines, and was engaged with them in writing annotations upon the Bible. He died in July 1654, in the 80th year of his age. Besides the above works, he published, 1. A Dissertation upon the Style of the New Testament. 2. *De Nomine Tetragrammata*. 3. *De Diphthongis, sive Bivocalibus*. 4. An Edition and Translation of the Emperor Marcus Antoninus's Meditations. 5. A Collection of Sermons, in folio; and many other works. His piety and charity were very exemplary; and his modesty so great, that he declined all ecclesiastical dignity and court preferments. His extensive learning was admired by Salmasius and other great men abroad; his house was a private seminary for young gentlemen of this nation, and many foreigners resorted to him to receive advice in their studies.

GATE, in *Architecture*, a large door, leading or giving entrance into a city, town, castle, palace, or other considerable building. See ARCHITECTURE.

Thebes, in Egypt, was anciently known by the appellation *with a hundred gates*. In ancient Rome there was a triumphal gate, *porta triumphalis*. In modern Rome there is the *jubilee gate*, which is only opened in the year of a grand jubilee.

The gates of London were many of them converted into gaols or prisons, as Ludgate, Newgate, &c. but they are now removed. The lesser or by-gates are called *posterns*. Gates, through which coaches, &c. are to pass, should not be less than 7 feet broad, nor more than 12; the height to be $1\frac{1}{2}$ the breadth.

GATE, or GAIT, in the manege, called in French *train*, is used for the going or pace of a horse.

GATE, in a military sense, is made of strong planks, with iron bars, to oppose an enemy. They are generally made in the middle of the curtain, from whence they are seen, and defended by the two flanks of the bastions. They should be covered with a good ravelin, that they may not be seen or enfiladed by the enemy. These gates, belonging to a fortified place, are passages through the rampart, which may be shut and opened by means of doors and a portcullis. They are either private or public.

Private gates are those passages by which the troops can go out of the town unseen by the enemy, when they pass to and from the relief of the duty in the outworks, or from any other occasion which is to be concealed from the besiegers.

Public gates are those passages through the middle of such curtains, to which the great roads of public ways lead. The dimensions of these are usually about 13 or 14 feet high, and 9 or 10 feet wide, continued through the rampart, with proper recesses for foot passengers to stand in out of the way of wheel carriages.

GATES of Hell. This expression is used in Scripture, to denote figuratively either the *grave* or the *powers of darkness*, i. e. the devil and his angels.

The Mahometans use the expression literally, and suppose that hell has seven gates. The first is that where Mussulmans, who incur the guilt of sin, will be tormented. The second is for the Christians. The third is for the Jews. The fourth is for the Sabians. The fifth for the Magians or worshippers of fire. The sixth for Pagans and idolaters. And the seventh for hypocrites, who make an outward show of religion, but have none.

GATESHEAD, in the county of Durham, is as it were the suburbs of Newcastle, though it lies in another county, being divided by the river Tyne; over which there is a fine stone bridge, with an iron gate in the middle, having the arms of Durham on one side, and those of Newcastle on the other, which is the boundary between the bishopric and Northumberland. The church is a fine building, with a very high tower, which is seen at a great distance; and in the church-yard are several ancient monuments. Few traces of its ancient monastery remain, except a stone gateway. The population in 1811 amounted to 8782.

GATH, or GETH, in *Ancient Geography*, a celebrated city of the Philistines, and one of their five principalities. It is famous for having given birth to Goliath. David made a conquest of it in the beginning of his reign over all Israel; and it continued subject to the kings his successors till the declension and decay of the kingdom of Judah. Rehoboam rebuilt or fortified it; King Uzziah retook it, and Hezekiah once more reduced it under his subjection.

Gath stood about five or six miles from Jamnia, about 14 south of Joppa, and 32 west of Jerusalem. Hence some authors (among whom is F. Calmet) have committed an egregious mistake in making Gath the most southern, and Ekron the most northern, of the Philistine cities; as if these two had been the two boundaries of their dominions, whereas these two cities are not above five miles asunder; and Gaza is the last of the five satrapies south. And Josephus (in the place already quoted) expresses himself plainly enough, when he says, that Hezekiah took all the Philistine cities

cities from Gaza to Gath; there being many more cities of that name, which signifies in the Hebrew a *wine press*. Several other cities of the name of Geth or Gath are mentioned in Eusebius and St Jerome, whose situation, according to those authors, plainly shows them to have been different places from this, and from each other; besides those which had an adjunct to distinguish them.

This city recovered its liberty and lustre in the time of the prophets Amos and Micah; but was afterwards demolished by Hazael king of Syria, after which it became of but little consideration till the time of the holy war, when Fulk king of Jerusalem built a castle on its ruins.

Gath *Opher*, Gath *Epher*, or *Gath*, in the canton of Opher, in Galilee, was the birth-place of the prophet Jonah. Joshua makes this city to be part of the tribe of Zebulun; and St Jerome, in his preface upon Jonah, says, that it was two miles from Sephoris, otherwise called *Diocæsarea*.

Gath *Rimmon*, a city belonging to the tribe of Dan. St Jerome places it ten miles from Diospolis on the way from Eleutheropolis. It was given to the Levites of Kohath's family.

Gath *Rimmon*, was also a city in the half tribe of Manasseh, on this side Jordan, and was also given for a place of abode to the Levites of Kohath's family.

Gath *Rimmon*, was likewise a city in the tribe of Ephraim, given to the Kohathites.

GATTON, a village in the county of Surry, 19 miles south from London. It lies under the side of a hill going to Reygate; and is supposed to have been known to the Romans, by reason of their coins and other antiquities that have been found here. It is a borough by prescription; and has sent members to parliament ever since the 29th of Henry VI. It was formerly a large town; but is now a mean village, with a small church, and without either fair or market. It sends two members to parliament. The population in 1801 amounted to 112.

Gaubius.

GAUBIUS, Jerome-David, M. D. professor of medicine at Leyden, and afterwards fellow of the Royal Society of London, was born at Heidelberg in the year 1705. From the Jesuits he received the rudiments of his education, and was much esteemed by them on account of his abilities; but his father afterwards sent him to the orphan house of Halle, lest he should be obliged to abjure his religion. The nature of the discipline, however, he here found to be much too severe, which induced him to request his father to remove him from it, which was accordingly complied with. His teacher at this hospital attributing the dislike of young Gaubius to the want of genius, urged him to give his son some mechanical employment; but the father thought proper to indulge his ardent desire after knowledge, and accordingly sent him to Amsterdam to study under his uncle John, who was an eminent physician. After prosecuting his medical studies for some time at Hordwyk, he resolved to visit Leyden, where the immortal Boerhaave was an eminent professor, and whose penetrating eye soon discovered that Gaubius was possessed of talents above mediocrity. He honoured him with unlimited access to his house, delighted in imparting instruction to him, and gradually forwarded the cultivation of his mind. He took the degree of doctor at the age of 20, after a disputation on the nature of solids, containing an abstract of the system which he himself followed through life.

He travelled through various parts of Europe, and when he returned to Heidelberg by the way of Strasburgh, he was appointed city-physician at Deventer in the province of Overyssel; but he soon after removed to Amsterdam. Boerhaave never lost sight of his favourite pupil; for when the infirmities of old age and indefatigable labour made him anxious to resign his chair, Gaubius on his recommendation was appointed to succeed him. He published his Instructions for writing Recipes in the year 1738, by which he acquired great and justly merited approbation, as he reduced the art from a mere mechanical to a scientific form. His Principles of Nosology is perhaps his most masterly performance, as it evinced that he was highly worthy of such a preceptor. His next publication, which appeared in 1771, was his "Adversaria varii Argumenti," a work which was particularly interesting to chemists; and his oration on the 200th anniversary of the academy of Leyden attracted considerable notice, as in it he traced out, with his accustomed acumen, the chief epochs of the arts and sciences in Holland.

He was likewise the author of numerous and valuable papers in the Transactions of the Society of Haerlem, and was editor of many excellent performances, among which we may rank Cramer's *Elementa artis docimasticæ; Albinus de presagienda vita et morte*, and Swammerdam's Book of Nature, which he partly translated. His literary merit spread his fame so far beyond the bounds of his native country, that pupils repaired to Leyden from every quarter of Europe. In addition to his widely extended reputation, he was blessed with the enjoyment of good health till he was 70 years of age, and died on the 29th of November 1780, in his seventy-fifth year.

One work of his, entitled "Institutiones Pathologiæ Medicinalis," was deemed so valuable by Professor Ackerman, and of such singular advantage in academical lectures, that he gave the world a fourth edition of it, published at Nuremberg in 1787.

Gauden.

GAUDEN, Dr Joseph, son of John Gauden vicar of Mayfield in Essex, was born there in 1605. At the commencement of the civil war, he was chaplain to Robert earl of Warwick; who taking part with the parliament against the king, was followed by his chaplain. Upon the establishment of the Presbyterian model of church government, he complied with the ruling powers, and was nominated one of the assembly of divines who met at Westminster in 1643, and took the covenant; yet having offered some scruples and objections to it, his name was afterwards struck out of the list. Nor did he espouse the parliament cause any longer than they adhered to their first avowed principles of reforming only, instead of destroying, monarchy and episcopacy. In this spirit he was one of those divines who signed a protestation to the army against the violent proceedings that affected the life of the king: and a few days after his execution published the famous Εικων Βασιλικη, *A Portraiture of his Sacred Majesty in his Solitude and Sufferings;* which ran through 50 editions in the course of a year. Upon the return of Charles II. he was promoted to the see of Exeter; aud in 1662 was removed to Worcester, much to his regret,

regret, having flattered himself with the hopes of a translation to Winchester; and his death happened the same year. He wrote many controversial pieces suited to the circumstances of the times, and to his own views from them. The *Eikon Basilike* above mentioned he published as the king's private meditations: though on this point there has been a long controversy. After the bishop's death, his widow, in a letter to one of her sons, calls it *The Jewel;* and said, her husband had hoped to make a fortune by it; and that she had a letter of a very great man's, which would clear up that he writ it. This assertion, as the earl of Clarendon had predicted, was eagerly espoused by the anti-royalists, in the view of disparaging Charles I. But it has been observed, that Gauden had too luxuriant an imagination, which betrayed him into a rankness of style in the Asiatic way; and from thence, as Bishop Burnet argues with others, it may be certainly concluded, that not he, but the king himself, was the true author of the Εικων Βασιλικη; in which there is a nobleness and justness of thought, with a greatness of style, that made it be looked on as the best written book in the English language.

GAVEL or Gabel, among builders. See Gabel.

Gavel, in *Law*, tribute, toll, custom, or yearly revenue; of which we had in old time several kinds. See Gabel.

Gavel Kind, a tenure or custom belonging to lands in the county of Kent. The word is said by Lambard to be compounded of three Saxon words, *gyfe*, *eal*, *kyn*, "*omnibus cognatione proximis data.*" Verstegan calls it *gavelkind*, quasi "give all kind," that is, to each child his part: and Taylor, in his history of *gavelkind*, derives it from the British *gavel*, that is, a hold or tenure, and *cenned*, "*generatio* aut *familia*;" and so *gavel cenned* might signify *tenura generationis*.—It is universally known what struggles the Kentish men made to preserve their ancient liberties, and with how much success those struggles were attended. And as it is principally here that we meet with the custom of gavelkind (though it was and is to be found in some other parts of the kingdom), we may fairly conclude, that this was a part of these liberties: agreeable to Mr Selden's opinion, that gavelkind, before the Norman conquest, was the general custom of the realm. The distinguished properties of this tenure are various: some of the principal are these: 1. The tenant is of age sufficient to alienate his estate by feoffment, at the age of 15. 2. The estate does not escheat in case of an attainder and execution for felony; their maxim being, "the father to the bough, the son to the plough." 3. In most places he had the power of devising lands by will, before the statute for that purpose was made. 4. The lands descend, not to the eldest, youngest, or any one son only, but to all the sons together; which was indeed anciently the most usual course of descent, all over England, though in particular places particular customs prevailed.

GAVELET, in *Law*, an ancient and special cessavit used in Kent, where the custom of gavelkind continues, by which the tenant, if he withdraws his rent and services due to the lord, forfeits his land and tenements.

The process of the gavelet is thus. The lord is first to seek by the steward of his court, from three weeks to three weeks, to find some distress upon the tenement, till the fourth court; and if at that time he find none, at this fourth court it is awarded, that he take the tenement in his hand in name of a distress, and keep it a year and a day without manuring; within which time, if the tenant pay his arrears, and make reasonable amends for the withholding, he shall have and enjoy his tenement as before: if he come not before the year and day be past, the lord is to go to the next county court with witnesses of what had passed at his own court, and pronounce there his process, to have further witnesses; and then by the award of his own court, he shall enter and manure the tenement as his own: so that if the tenant desired afterwards to have and hold it as before, he must agree with the lord; according to this old saying: "Has he not since any thing given, or any thing paid, then let him pay five pound for his were, e'er he become healder again." Other copies have the first part with some variation; "Let him nine times pay, and nine times repay."

Gavelet, in London, is a writ used in the hustings, given to lords of rents in the city of London. Here the parties, tenant and demandant, appear by *scire facias*, to show cause why the one should not have his tenement again on payment of his rent, of the other recover the lands on default thereof.

GAUGAMELA, in *Ancient Geography*, a village of Aturia, lying between the rivers Lycus and Tigris; famous for Alexander's victory over Darius. It is said to have been allowed to Darius Hystaspes for the maintenance of a camel; and hence the name. It was not far from a more considerable place called *Arbela;* whence the latter gave the name to the victory. See Arbela.

GAUGE-point of a solid measure, the diameter of a circle whose area is equal to the solid content of the same measure.

GAUGER, a king's officer, who is appointed to examine all tons, pipes, hogsheads, and barrels, of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

GAUGING. See Geometry.

Gauging-Rod, an instrument used in gauging or measuring the contents of any vessel. That usually employed is the four-foot gauging rod. It is commonly made of box, and consists of four rules, each a foot long and about three-eighths of an inch square, joined together by three brass joints; by which means the rod is rendered four feet long when the four rules are quite opened, and but one foot when they are all folded together. On the first face of this rod, marked 4, are placed two diagonal lines: one for beer and the other for wine: by means of which the content of any common vessel in beer or wine gallons may be readily found, by putting the rod in at the bung hole of the vessel till it meets the intersection of the head of the vessel with the staves opposite to the bung hole. For distinction of this line, there is written thereon, *beer* and *wine gallons*. On the second face, 5, are a line of inches and the gauge-line; which is a line expressing the areas of circles, whose diameters are the correspondent inches in ale gallons. At the beginning is written, *ale area*. On the third face, 6, are three scales of lines; the first, at the end of which is written *hogshead*, is for finding how many gallons there are in a

Gauging-Rod.

a hogshead when it is not full, lying with its axis parallel to the horizon. The second line, at the end of which is written *B. L.* signifying a *butt lying* is for the same use as that for the hogshead. The third line is to find how much liquor is wanting to fill up a butt when it is standing: at the end of it is written *B. S.* signifying a *butt standing*. In the half of the fourth face of the gauging rod, 7, there are the three scales of lines, to find the wants in a firkin, kilderkin, and barrel, lying with their areas parallel to the horizon. They are distinguished by letters *F. K. B.* signifying a *firkin, kilderkin*, and *barrel*.

Use of the diagonal lines on this rod. To find the content of a vessel in beer or wine gallons, put the brased end of the gauging rod into the bung hole of the cask, with the diagonal lines upwards, and thrust this brased end to the meeting of the head and staves; then with chalk make a mark at the middle of the bung hole of the vessel, and also on the diagonal lines of the rod, right against, over one another, when the brased end is thrust home to the head and staves: then turn the gauging rod to the other end of the vessel, and thrust the brased end home to the end, as before. Lastly, See if the mark made on the gauging rod come even with the mark made on the bung hole, when the rod was thrust to the other end; which if it be, the mark made on the diagonal lines will, on the same lines, show the whole content of the cask in beer or wine gallons.

If the mark made on the bung hole be not right against that made on the rod when you put it the other way, then right against the mark made on the bung hole make another on the diagonal line; and the division on the diagonal line between the two chalks will show the vessel's whole contents in beer or wine gallons. Thus, *e. gr.* if the diagonal line of the vessel be 28 inches four-tenths, its contents in beer gallons will be near 51, and in wine gallons 62.

If a vessel be open, as a half barrel, tun, or copper, and the measure from the middle of one side to the head and staves be 38 inches, the diagonal line gives 122 beer gallons; half of which, viz. 61, is the content of the open half tub.

If you have a large vessel, as a tun or copper, and the diagonal line taken by a long rule proves 70 inches; the content of that vessel may be found thus: Every inch at the beginning end of the diagonal line call ten inches. Thus ten inches becomes 100 inches; and every tenth of a gallon call 100 gallons; and every whole gallon call 1000 gallons.

Example. At 44.8 inches on the diagonal beer line is 200 gallons; so that 4 inches 48 parts, now called 44 inches 8-tenths, is just two-tenths of a gallon, now called 200 gallons; so also if the diagonal line be 76 inches and 7-tenths, a close cask of such diagonal will hold 1000 beer gallons: but an open cask but half so much, viz. 500 beer gallons.

Use of the GAUGE LINE. To find the content of any cylindrical vessel in ale gallons; seek the diameter of the vessel in inches, and just against it on the gauge line is the quantity of ale gallons contained in one inch deep: this multiplied by the length of the cylinder will give its content in ale gallons.

For example, suppose the length of the vessel 32.06, and the diameter of its base 25 inches; to find what is the content in ale gallons? Right against 25 inches on the gauge line is one gallon and .745 of a gallon; which multiplied by 32.06, the length, gives 55.9447 gallons for the content of the vessel.

Gauging-Rod, Gaul.

The bung diameter of a hogshead being 25 inches, the head diameter 22 inches, and the length 32.06 inches; to find the quantity of ale gallons contained in it?—Seek 25, the bung diameter, on the line of inches, and right against it on the gauge line you will find 1.745: take one-third of it which is .580, and set it down twice; seek 22 inches in the head diameter, and against it you will find on the gauge line 1.356; one-third of which added to twice .580 gives 1.6096; which multiplied by the length 32.06, the product will be 51.603776, the content in ale gallons. Note, this operation supposes, that the aforesaid hogshead is in the figure of the middle frustum of a spheroid.

The use of the lines on the two other faces of the rod is very easy; you need only put it downright into the bung hole (if the vessel you desire to know the quantity of ale gallons contained therein be lying) to the opposite staves; and then where the surface of the liquor cuts any one of the lines appropriated to that vessel, will be the number of gallons contained in that vessel.

GAUL, the name given by the Romans to the country that now forms the kingdom of France.—The original inhabitants were descended from the Celtes or Gomerians, by whom the greatest part of Europe was peopled; the name of *Galli*, or *Gauls*, being probably given them long after their settlement in that country. See GALLIA.

The ancient history of the Gauls is entirely wrapped up in obscurity and darkness; all we know concerning them for a long time is, that they multiplied so fast, that their country being unable to contain them, they poured forth in vast multitudes into other countries, which they generally subdued, and settled themselves in. It often happened, however, that these colonies were so molested by their neighbours, that they were obliged to send for assistance to their native country. This was always very easily obtained. The Gauls were upon every occasion, ready to send forth great numbers of new adventurers; and as these spread desolation wherever they came, the very name of *Gauls* proved terrible to most of the neighbouring nations.—The earliest excursion of these people, of which we have any distinct account, was into Italy, under a famed leader named *Bellovesus*, about 622 years before Christ. He crossed the Rhone and the Alps, till then unattempted; defeated the Hetrurians; and seized upon that part of their country, since known by the names of *Lombardy* and *Piedmont*.—The second grand expedition was made by the Cœnomani, a people dwelling between the rivers Seine and Loire, under a general named *Elitonis*. They settled in those parts of Italy, now known by the names of *Bresciano*, the *Cremonese*, the *Mantuan*, *Carniola*, and the *Venetian*.—In a third excursion, two other Gaulish nations settled on both sides of the river Po; and in a fourth, the Boii and Lingones settled in the country between Ravenna and Bologna. The time of these three last expeditions is uncertain.

1 Account of the Gaulish incursions into Italy.

The third expedition of the Gauls was more remarkable than any of the former, and happened about 200 years after that of Bellovesus. The Senones settled between

Gaul.

between Paris and Meaux, were invited into Italy by a Hetrurian lord, and settled themselves in Umbria. Brennus their king laid siege to Clusium, a city in alliance with Rome; and this produced a war with the Romans, in which the latter were at first defeated, and their city taken and burnt; but at length the whole army was cut off by Camillus, insomuch, that not a single person escaped.

Some other expeditions the Gauls undertook against the Romans: in which, though they always proved unsuccessful, by reason of their want of military discipline; yet their fierceness and courage made them so formidable to the republic, that, on the first news of their march, extraordinary levies of troops were made, sacrifices and public supplications offered to the gods, and the law which granted an immunity from military service to priests and old men, was, for the time, abolished.

2 Expedition against the Greeks.

Against the Greeks, the expeditions of the Gauls were very little more successful than against the Romans. The first of these we hear of was about 279 years before Christ, in the year after Pyrrhus had invaded Italy. At this time, the Gauls finding themselves greatly overstocked at home, sent out three great colonies to conquer new countries for themselves. One of these armies was commanded by *Brennus*, another by *Cerethrius*, and the third by *Belgius*. The first entered Pannonia or Hungary; the second Thrace; and the third marched into Illyricum and Macedonia. Here Belgius at first met with great success; and enriched himself by plunder to such a degree, that Brennus envying him, resolved to enter the same countries, in order to share the spoil. In a short time, however, Belgius met with such a total defeat, that his army was almost entirely destroyed; upon which Brennus hastened to the same place. His army at first consisted of 150,000 foot and 15,000 horse: but two of his principal officers revolted, and carried off 20,000 men, with whom they marched into Thrace; where, having joined Cerethrius, they seized on Byzantium and the western coast of the Propontis, making the adjacent parts tributary to them.—To retrieve this loss, Brennus sent for fresh supplies from Gaul; and having increased his army to 150,000 foot, and upwards of 60,000 horse, he entered Macedonia, defeated the general who opposed him, and ravaged the whole country. He next marched towards the straits of Thermopylæ, with a design to invade Greece; but was stopped by the forces sent to defend that pass against him. He passed the mountains, however, as Xerxes had formerly done; upon which the guards retired, to avoid being surrounded. Brennus then having ordered Acichorius, the next to him in command, to follow at a distance with part of his army, marched with the bulk of the forces to Delphi, in order to plunder the rich temple there. This enterprise proved exceedingly unfortunate: a great number of his men were destroyed by a dreadful storm of hail, thunder, and lightning; another part of his army was destroyed by an earthquake; and the remainder, somehow or other, imagining themselves attacked by the enemy, fought against each other the whole night, so that in the morning scarcely one half of them remained. The Greek forces then poured in upon them from all parts; and that in such numbers, that though Acichorius came up in due time with his forces, Brennus found himself unable to make head against the Greeks, and was defeated with great slaughter. He himself was desperately wounded; and so disheartened by his misfortune, that, having assembled all his chiefs, he advised them to kill all the wounded and disabled, and to make the best retreat they could: after which he put an end to his own life. On this occasion, it is said that 20,000 of these unhappy people were executed by their own countrymen. Acichorius then set out with the remainder for Gaul; but, by being obliged to march through the country of their enemies, the calamities they met with by the way were so grievous, that not one of them reached their own country. A just judgment, say the Greek and Roman authors, for their sacrilegious intentions against Delphi.

3 Miserable fate of the army.

The Romans having often felt the effects of the Gaulish ferocity and courage, thought proper at last, in order to humble them, to invade their country. Their first successful attempt was about 118 years before Christ, under the command of Quintus Marcius, surnamed *Rex*. He opened a way betwixt the Alps and the Pyrenees, which laid the foundation for conquering the whole country. This was a work of immense labour of itself, and rendered still more difficult by the opposition of the Gauls, especially those called the Stæni, who lived at the foot of the Alps. These people, finding themselves overpowered by the consular army, set fire to their houses, killed their wives and children, and then threw themselves into the flames. After this Marcius built the city of Narbonne, which became the capital of a province. His successor Scaurus also conquered some Gaulish nations; and in order to facilitate the sending troops from Italy into that country, he made several excellent roads between them, which before were almost impassable. These successes gave rise to the invasion of the Cimbri and Teutones; an account of whose unfortunate expedition is given under the articles CIMBRI, ROME, TEUTONES, &c.

Gau[ls in]vaded the R[o]mans

From this time, the Gauls seemed to be formidable to the Romans, and even seem to have been for some time on good terms with them. At last, however, the Helvetii kindled a war with the republic, which brought Cæsar over the Alps, and ended in the total subjection of the country. Orgetorix was the first cause of it; who had engaged a vast number of his countrymen to burn their towns and villages, and to go in search of new conquests. Julius Cæsar, to whose lot the whole country of Gaul had fallen, made such haste to come and suppress them, that he was got to the Rhone in eight days; broke down the bridge of Geneva, and, in a few days more, finished the famed wall between that city and Mount Jura, now St Claude, which extended seventeen miles in length, was sixteen feet high, fortified with towers and castles at proper distances, and a ditch that ran the whole length of it. If his own account of it may be relied upon, he did not set out till the beginning of April; and yet this huge work was finished by the ides or 13th of the month; so that, subtracting the eight days he was a-coming, it must have been all done in about five days; a prodigious work, considering he had but one legion there, or even though the whole country had given him assistance. Whilst this was doing, and the reinforcements he wanted were coming, he amused the Helvetii,

Surpri[sing] succe[ss of] Julius [Cæ]sar.

Helvetii, who had sent to demand a passage through the country of the Allobroges, till he had got his reinforcements; and then flatly refused it to them: whereupon a dreadful battle ensued; in which they lost one hundred and thirty thousand men, in spite of all their valour; besides a number of prisoners, among whom were the wife and daughter of Orgetorix, the leader of this unfortunate expedition. The rest submitted, and begged they might be permitted to go and settle among the Edui, from whom they originally sprung; and at the request of these last, were permitted to go.

The Gauls were constantly in a state of variance with one another; and Cæsar, who knew how to make the most of these intestine broils, soon became the protector of the oppressed, a terror to the oppressor, and the umpire of all their contentions. Among those who applied to him for help, were his allies the Edui; against whom Ariovistus, king of the Germans, had joined with the Arverni, who inhabited the banks of the Loire, had taken the country of the Sequani from them, and obliged them to send hostages to him. Cæsar forthwith sent to demand the restitution of both, and, in an interview which he soon after obtained of that haughty and treacherous prince, was like to have fallen a sacrifice to his perfidy: upon which he bent his whole power against him, forced him out of his strong intrenchments, and gave him a total overthrow. Ariovistus escaped, with difficulty, over the Rhine; but his two wives, and a daughter, with a great number of Germans of distinction, fell into the conqueror's hand. Cæsar, after this signal victory, put his army into winter quarters, whilst he went over the Alps to make the necessary preparations for the next campaign. By this time all the Belgæ in general were so terrified at his success, that they entered into a confederacy against the Romans as their common enemy. Of this, Labienus, who had been left in Gaul, sent Cæsar notice; upon which he immediately left Rome, and made such dispatch, that he arrived upon their confines in about fifteen days. On his arrival, the Rhemi submitted to him; but the rest appointing Galba king of the Suessiones general of all their forces, which amounted to one hundred and fifty thousand men, marched directly against him. Cæsar, who had seized on the bridge of the Axona, now Aisne, led his light horse and infantry over it: and whilst the others were encumbered in crossing that river, made such a terrible slaughter of them, that the river was filled with their dead, insomuch that their bodies served for a bridge to those who escaped. This new victory struck such terror into the rest, that they dispersed themselves; immediately after which, the Suessiones, Bellovaci, Ambiones, and some others, submitted to him. The Nervii, indeed, joined with the Atrebates and Veromandui against them; and having first secured their wives and children, made a vigorous resistance for some time; but were at length defeated, and the greatest part of them slain. The rest, with their wives and old men, surrendered themselves, and were allowed to live in their own cities and towns as formerly. The Aduatici were next subdued; and, for their treachery to the conqueror, were sold for slaves, to the number of 50,000. Young Crassus, the son of the triumvir, subdued likewise seven other nations, and took possession of their cities; which not only completed the conquest of the Belgæ, but brought several nations from beyond the Rhine to submit to the conqueror. The Veneti, or ancient inhabitants of Vannes in Brittany, who had been likewise obliged to send hostages to the conqueror, were, in the mean time, making great preparations by sea and land to recover their liberty. Cæsar, then in Illyricum, was forced to equip a fleet on the Loire; and having given the command of it to Brutus, went and defeated them by land, as Brutus did by sea; and having put their chief men to death, sold the rest for slaves. The Unelli, with Veridorix their chief, together with the Lexovii and Aulerci, were about the same time subdued by Sabinus, and the Aquitani by Crassus, with the loss of 30,000 men. There remained nothing but the countries of the Morini and Menapii to be conquered of all Gaul. Cæsar marched himself against them; but he found them so well intrenched in their inaccessible fortresses, that he contented himself with burning and ravaging their country; and having put his troops into winter quarters, again passed over the Alps, to have a more watchful eye on some of his rivals there. He was, however, soon after obliged to come to defend his Gaulish conquests against some nations of the Germans, who were coming to settle there, to the number of 400,000. These he totally defeated, and then resolved to carry his conquering arms into Germany; but for an account of his exploits there, see the article GERMANY.

6 A general confederacy against him.

7 The Gauls defeated with great slaughter.

8 The Gauls revolt, but are subdued.

Upon his return into Gaul, he found it labouring under a great famine, which had caused a kind of universal revolt. Cotta and Sabinus, who were left in the country of the Eburones, now Liege, were betrayed into an ambush by Ambiorix, one of the Gaulish chiefs, and had most of their men cut off. The Aduatici had fallen upon Q. Cicero, who was left there with one legion, and had reduced him to great straits: at the same time Labienus, with his legion, was attacked by Indutiomarus, at the head of the Rhemi and Senones; but had better luck than the rest, and by one bold sally upon them, put them to flight, and killed their general. Cæsar acquired no small credit by quelling all these revolts; but each victory cost the lives of so many of his troops, that he was forced to have recourse to Pompey for a fresh supply, who readily granted him two of his own legions to secure his Gaulish conquests.

9 A second revolt.

But it was not long before the Gauls, ever restless under a foreign yoke, raised up a new revolt, and obliged him to return thither. His fear lest Pompey should gain the affections of the Roman people, had obliged him to strip the Gauls of their gold and silver, to bribe them over to his interest; and this gave no small handle to those frequent revolts which happened during his absence. He quickly, however, reduced the Nervii, Aduatici, Menapii, and Treviri; the last of whom had raised the revolt, under the command of Ambiorix: but he found the flame spread much farther, even to the greatest part of the Gauls, who had chosen Vercingetorix their generalissimo. Cæsar was forced to leave Insubria, whither he had retired to watch the motions of Pompey, and, in the midst of winter and snow, to repass the Alps into the province of Narbonne. Here he gathered his scattered troops with all possible speed; and, in spite of the hard weather, besieged and took Noviodunum, now Noyons; and defeated Vercingetorix, who was come to the relief of that place. He next

Gaul. next took the city of Avaricum, now Bourges, one of the strongest in Gaul, and which had a garrison of 40,000 men; of whom he made such a dreadful slaughter, that hardly 800 escaped. Whilst he was besieging Gergovia, the capital of the Arverni, he was informed that the Nitiobriges, or Agenois, were in arms; and that the Ædui were sending to Vercingetorix 10,000 men, which they were to have sent to reinforce Cæsar. Upon this news, he left Fabius to carry on the siege, and marched against the Ædui. These, upon his approach, submitted, in appearance, and were pardoned; but soon after that whole nation rose up in arms, and murdered all the Italian troops in their capital. Cæsar, at this, was in great straits what measures to take; but resolved at length to raise the siege of Gergovia, and at once attack the enemy's camp, which he did with some success; but when he thought to have gone to Noviodunum, or Noyons, where his baggage, military chest, &c. were left, he heard that the Ædui had carried it off, and burnt the place. Labienus, justly thinking that Cæsar would want his assistance in the condition he now was, went to join him, and in his way defeated a Gaulish general named *Camulogenus*, who came to oppose his march; but this did not hinder the revolt from spreading itself all over Celtic Gaul, whither Vercingetorix had sent for fresh supplies, and, in the mean time, attacked Cæsar; but was defeated, and forced to retire to Alesia, a strong place, now Alise in Burgundy, as is supposed. Hither Cæsar hastened, and besieged him; and having drawn a double circumvallation, with a design to starve him in it, as he was likely to have done, upon that account refused all offers of a surrender from him. At length, the long expected reinforcement came, consisting of 160,000 men, under four generals: these made several fruitless attacts on Cæsar's trenches, but were defeated in three several battles, which at length obliged Vercingetorix to surrender at discretion. Cæsar used all his prisoners with great severity, except the Ædui and Arverni, by whose means he hoped to gain their nations, which were the most potent of Celtic Gaul: nor was he disappointed; for both of them submitted to him, and the former received him into the capital, where he spent the winter, after he put his army into winter quarters. This campaign, as it proved one of the hardest he ever had, so he gained more glory by it than any Roman general had done before: yet could not at all by this procure from the servile senate, now wholly dedicated to his rival, a prolongation of his proconsulship; upon which he is reported to have laid his hand upon his sword, and said, that that should do it.

10 They are again subdued.

He was as good as his word; and the Gauls, upon their former ill success, resolving to have as many separate armies as provinces, in order to embarrass him the more, Cæsar, and his generals Labienus and Fabius, were forced to fight them one after another; which they did, however, with such success, that, notwithstanding the hardness of the season, they subdued the Bituriges, Carnutes, Rhemi, and Bellovaci, with their general Correus, by which he at once quieted all the Belgic provinces bordering on Celtic Gaul. The next who followed were the Treviri, the Eburones, and the Andes, under their general Dumnacus. The last place which held out against him was Uxellodunum; which was defended by the two last acting generals of the Gauls, Drapes the Senonian, and Luterius the Cadurcean. The place being strong and well garrisoned, Cæsar was obliged to march thither from the farthest part of Belgic Gaul; and soon after reduced it, for want of water. Here again he caused the right hands of all that were fit to bear arms to be cut off, to deter the rest from revolting afresh. Thus was the conquest of Gaul finished from the Alps and Pyrenees to the Rhine, all which vast tract was now reduced to a Roman province under the government of a prætor. During his several expeditions into Gaul, Cæsar is said to have taken 800 cities; to have subdued 300 different nations; and to have defeated, in several battles, three millions of men, of whom one million were killed, and another taken prisoners.—The history of the country, from the time of its conquest by the Romans to the present, is given under the articles ROME and FRANCE.

11 Gaul reduced to a Roman province.

The Gauls were anciently divided into a great number of different nations, which were continually at war with one another, and at variance among themselves. Cæsar tells us, that not only all their cities, cantons, and districts, but even almost all families, were divided and torn by factions; and this undoubtedly facilitated the conquest of the whole. The general character of all these people was an excessive ferocity and love of liberty. This last they carried to such an extreme, that either on the appearance of servitude, or incapacity of action through old age, wounds, or chronic diseases, they put an end to their own lives, or prevailed upon their friends to kill them. In cities, when they found themselves so straitly besieged that they could hold out no longer, instead of thinking how to obtain honourable terms of capitulation, their chief care very often was to put their wives and children to death, and then to kill one another, to avoid being led into slavery. Their excessive love of liberty and contempt of death, according to Strabo, very much facilitated their conquest by Cæsar; for pouring their numerous forces upon such an experienced enemy as Cæsar, their want of conduct very soon proved the ruin of the whole.

Character, &c. of the ancient Gauls.

The chief diversion of the Gauls was hunting; and indeed, considering the vast forests with which their country abounded, and the multitude of wild beasts which lodged in them, they were under an absolute necessity to hunt and destroy them, to prevent the country from being rendered totally uninhabitable. Besides this, however, they had also their hippodromes, horse and chariot races, tilts and tournaments; at all of which the bards assisted with their poems, songs, and musical instruments.—For an account of their religion, see the article DRUID.

The Gauls were excessively fond of feasting, in which they were very profuse; as, like all other northern nations, they were great lovers of good eating and drinking. Their chief liquors were beer and wine. Their tables were very low They ate but little bread, which was baked flat and hard, and easily broken in pieces; but devoured a great deal of flesh, boiled, roasted, or broiled; and this they did in a very slovenly manner, holding the piece in their hands, and tearing it with their teeth. What they could not part by this way, they cut with a little knife which hung at their girdle. When the company was numerous, the *Coryphee*,

phee, or chief of the feast, who was either one of the richest, or noblest, or bravest, sat in the middle, with the master of the house by his side; the rest took their places next according to their rank, having their servants holding their shields behind them. These feasts seldom ended without bloodshed; but if by chance the feast proved a peaceable one, it was generally accompanied not only with music and songs, but likewise with dances, in which the dancers were armed cap-a-pee, and beat time with their swords upon their shields. On certain festivals they were wont to dress themselves in the skins of beasts, and in that accompany the processions in honour of their deities or heroes. Others dressed themselves in masquerade habits, some of them very indecent, and played several antic and immodest tricks. This last custom continued long after their conversion to Christianity.

GAULANITIS, or Gaulonitis (Josephus); in *Ancient Geography*, according to the different manner of writing the capital, *Gaulan* or *Gaulon*; the extreme part of Bashan to the south, and bordering on the tribe of Gad. It was divided into the Superior, which to the east extended to Arabia; and into the Inferior, which lay on the lake of Genesareth, (Josephus).

GAULON, or Golan, the capital of the Gaulanitis Superior; a Levitical city and place of refuge, (Moses, Joshua).

GAULOS, in *Ancient Geography*, a small island of Sicily, in the African sea, adjoining to Melite or Malta; with commodious harbours; a colony of Phœnicians, with a cognominal town. Gaulonitæ, the people, (Inscription). Now called *Gozo*, five miles to the west of Malta.

GAULTHERIA, a genus of plants belonging to the decandria class; and in the natural method ranking under the 18th order, *Bicornes*. See Botany *Index*.

GAUNT-Bellied, in the manege, is said of a horse whose belly shrinks up towards his flanks.

GAUNTLET. See Gantlet.

GAUNTLOPE, pronounced *Gauntlet*, a military punishment for felony, or some other heinous offence.

In vessels of war, it is executed in the following manner. The whole ship's crew is disposed in two rows, standing face to face on both sides of the deck, so as to form a line whereby to go *forward* on one side, and return *aft* on the other; each person being furnished with a small twisted cord, called a *knittle*, having two or three knots upon it. The delinquent is then stripped naked above the waist, and ordered to pass forward between the two rows of men, and aft on the other side, a certain number of times, rarely exceeding three; during which every person gives him a stripe as he runs along. In his passage through this painful ordeal, he is sometimes tripped up, and very severely handled while incapable of proceeding. This punishment, which is called *running the gauntlet*, is seldom inflicted, except for such crimes as naturally excite a general antipathy among the seamen: as, on some occasions, the culprit would pass without receiving a single blow, particularly in cases of mutiny and sedition. But this mode of punishment is now, we believe, rarely or never resorted to, either in the army or navy.

In the land service, when a soldier is sentenced to run the gauntlope, the regiment is drawn out in two ranks facing each other; each soldier, having a switch in his hand, lashes the criminal as he runs along naked from the waist upwards. While he runs, the drums beat at each end of the ranks. Sometimes he runs three, five, or seven times, according to the nature of the offence. The major is on horseback, and takes care that each soldier does his duty.

GAVIES, or Gaurs. See Gabres.

GAVOTTA, or Gavotte, is a kind of dance, the air of which has two brisk and lively strains in common time, each of which strains is twice played over. The first has usually four or eight bars; and the second contains eight, twelve, or more. The first begins with a minim, or two crotchets, or notes of equal value, and the hand rising; and ends with the fall of the hand upon the dominant or mediant of the mode, but never upon the final, unless it be a rondeau: and the last begins with the rise of the hand, and ends with the fall upon the final of the mode.

Tempi di Gavotta, is when only the time or movement of a gavotte is imitated, without any regard to the measures or number of bars or strains.—Little airs are often found in sonatas, which have this phrase to regulate their motions.

GAURA, a genus of plants belonging to the octandria class; and in the natural method ranking under the 17th order, *Calycanthemæ*. See Botany *Index*.

GAUSE, or Gawse, in *Commerce*, a very thin, slight, transparent kind of stuff, woven sometimes of silk, and sometimes only of thread.—To warp the silk for making of gause, they use a peculiar kind of mill, upon which the silk is wound: this mill is a wooden machine, about six feet high, having an axis perpendicularly placed in the middle thereof, with six large wings, on which the silk is wound from off the bobbins by the axis turning round. When all the silk is on the mill, they use another instrument to wind it off again on two beams: this done, the silk is passed through as many little beads as there are threads of silk; and thus rolled on another beam to supply the loom.

The gause loom is much like that of the common weavers, though it has several appendages peculiar to itself. See Loom.

There are figured gauses; some with flowers of gold and silver, on a silk ground: these last are chiefly brought from China.

GAY, John, a celebrated English poet, descended from an ancient family in Devonshire, was born at Exeter, and received his education at the free school of Barnstaple in that county, under the care of Mr William Rayner.—He was bred a mercer in the Strand; but having a small fortune, independent of business, and considering the attendance on a shop as a degradation of those talents which he found himself possessed of, he quitted that occupation, and applied himself to other views, and to the indulgence of his inclination for the Muses. In 1712 we find him secretary, or rather domestic steward, to the duchess of Monmouth, in which station he continued till the beginning of the year 1714; at which time he accompanied the earl of Clarendon to Hanover, whither that nobleman was despatched by Queen Anne. In the latter end of the same year, in consequence of the queen's death, he returned to England, where he lived in the highest estimation and intimacy of friendship with many

Gay.

many persons of the first distinction both in rank and abilities.—He was even particularly taken notice of by Queen Caroline, then princess of Wales, to whom he had the honour of reading in manuscript his tragedy of the *Captives*; and in 1726 dedicated his *Fables*, by permission, to the duke of Cumberland.—From this countenance shown to him, and numberless promises made him of preferment, it was reasonable to suppose, that he would have been genteelly provided for in some office suitable to his inclination and abilities. Instead of which, in 1727, he was offered the place of gentleman usher to one of the young princesses; an office which, as he looked on it as rather an indignity to a man whose talents might have been so much better employed, he thought proper to refuse; and some pretty warm remonstrances were made on the occasion by his sincere friends and zealous patrons the duke and duchess of Queensberry, which terminated in those two noble personages withdrawing from court in disgust. Mr Gay's dependencies on the promises of the great, and the disappointments he met with, he has figuratively described in his fable of the *Hare with many friends*. However, the very extraordinary success he met with from public encouragement made an ample amends, both with respect to satisfaction and emolument, for those private disappointments.—For, in the season of 1727-8, appeared his *Beggar's Opera*; the vast success of which was not only unprecedented, but almost incredible.—It had an uninterrupted run in London of 63 nights in the first season, and was renewed in the ensuing one with equal approbation. It spread into all the great towns of England; was played in many places to the 30th and 40th time, and at Bath and Bristol 50; made its progress into Wales, Scotland, and Ireland, in which last place it was acted for 24 successive nights; and last of all it was performed at Minorca. Nor was the fame of it confined to the reading and representation alone, for the card table and drawing room shared with the theatre and closet in this respect; the ladies carried about the favourite songs of it engraven upon their fan mounts; and screens, and other pieces of furniture were decorated with the same. In short, the satire of this piece was so striking, so apparent, and so perfectly adapted to the taste of all degrees of people, that it overthrew the Italian opera, that Dagon of the nobility and gentry, which had so long seduced them to idolatry, and which Dennis, by the labours and outcries of a whole life, and many other writers by the force of reason and reflection, had in vain endeavoured to drive from the throne of public taste. The profits of this piece were so very great, both to the author and Mr Rich the manager, that it gave rise to a quibble, which became frequent in the mouths of many, viz. *That it had made* Rich gay, *and* Gay rich; and it has been asserted, that the author's own emoluments from it were not less than 2000l. In consequence of this success, Mr Gay was induced to write a second part to it, which he entitled *Polly*. But the disgust subsisting between him and the court, together with the misrepresentations made of him as having been the author of some diaffected libels and seditious pamphlets, occasioned a prohibition and suppression of it to be sent from the lord chamberlain, at the very time when every thing was in readiness for the rehearsal of it. A very considerable sum, however, accrued to him from the publication of it afterwards in quarto.—Mr Gay wrote several other pieces in the dramatic way, and many very valuable ones in verse. Among the latter, his *Trivia*, or the *Art of Walking the Streets of London*, though his first poetical attempt, is far from being the least considerable, and is what recommended him to the esteem and friendship of Mr Pope: but as, among his dramatic works, his *Beggar's Opera* did at first, and perhaps ever will, stand as an unrivalled masterpiece, so, among his poetical works, his *Fables* hold the same rank of estimation; the latter having been almost as universally read as the former was represented, and both equally admired. Mr Gay's disposition was sweet and affable, his temper generous, and his conversation agreeable and entertaining. But he had one foible, too frequently incident to men of great literary abilities, and which subjected him at times to inconveniences which otherwise he needed not to have experienced, viz. an excess of indolence, without any knowledge of economy. So that, though his emoluments were, at some periods of his life, very considerable, he was at others greatly straitened in his circumstances; nor could he prevail on himself to follow the advice of his friend Dean Swift, whom we find in many of his letters endeavouring to persuade him to the purchasing of an annuity, as a reserve for the exigencies that might attend on old age.—Mr Gay chose rather to throw himself on patronage, than secure to himself an independent competency by the means pointed out to him; so that, after having undergone many vicissitudes of fortune, and being for some time chiefly supported by the liberality of the duke and duchess of Queensberry, he died at their house in Burlington gardens, in December 1732. He was interred in Westminster Abbey, and a monument erected to his memory, at the expence of his aforementioned noble benefactors, with an inscription expressive of their regards and his own deserts, and an epitaph in verse by Mr Pope.

GAZA, Theodore, a famous Greek in the 15th century, was born in 1398. His country being invaded by the Turks, he retired into Italy; where he at first supported himself by transcribing ancient authors, an employment the learned had frequent recourse to before the invention of printing. His uncommon parts and learning soon recommended him to public notice; and particularly to Cardinal Bessarion, who procured him a benefice in Calabria. He was one of those to whom the revival of polite literature in Italy was principally owing. He translated from the Greek into Latin, Aristotle's History of Animals, Theophrastus on Plants, and Hippocrates's Aphorisms; and from the Latin into Greek, Scipio's Dream, and Cicero's Treatise on Old Age. He wrote several other works in Greek and Latin; and died at Rome in 1475.

Gaza, in *Ancient Geography*, a principal city and one of the five satrapies of the Philistines. It was situated about 100 stadia from the Mediterranean, on an artificial mount, and strongly walled round. It was destroyed by Alexander the Great, and afterwards by Antiochus. In the time of the Maccabees it was a strong and flourishing city; but was destroyed a third time by Alexander Jannæus. At present it has a miserable appearance. The buildings are mean, both as to the form and matter. Some remains of its ancient grandeur

grandeur appear in the handsome pillars of Parian marble which support some of the roofs; while others are disposed of here and there, in different parts of almost every beggarly cottage. On the top of the hill, at the north-east corner of the town, are the ruins of large arches sunk low into the earth, and other foundations of a stately building, from whence some of the bashaws have carried off marble pillars of an incredible size. The castle is a contemptible structure, and the port is ruined. E. Long. 34. 55. N. Lat. 31. 28.

GAZE-HOUND, or *Gast-hound*, one that makes more use of his sight than of his nose. Such dogs are much used in the north of England: they are fitter in an open champaign country than in bushy and woody places. If at any time a well-taught gaze-hound takes a wrong way, he will return upon a signal, and begin the chase afresh. He is also excellent at spying out the fattest of a herd; and having separated it from the rest, will never give over the pursuit till he has worried it to death.

GAZEL, in *Zoology*, a species of CAPRA. See MAMMALIA *Index*.

GAZETTE, a newspaper, or printed account of the transactions of all the countries in the known world, in a loose sheet or half sheet. This name is with us confined to that paper of news published by authority. The word is derived from *gazetta*, a Venetian coin, which was the usual price of the first newspaper printed there, and which was afterwards given to the paper itself.

The first gazette in England was published at Oxford, the court being there, in a folio half sheet, November 7. 1665. On the removal of the court to London, the title was changed to the *London Gazette*. The Oxford gazette was published on Tuesdays, the London on Saturdays: and these have continued to be the days of publication ever since.

GAZNA, a city of Asia, once much celebrated, and the capital of a very extensive empire; but which is now either entirely ruined, or become of so little consideration, that it is not taken notice of in our books of geography. The city was anciently an empory and fortress of Sablestan, not far from the confines of India. During the vast and rapid conquests of the Arabs, all this country had been reduced under their subjection. On the decline of the power of the caliphs, however, the vast empire established by Mahomet and his successors was divided into a number of independent principalities, most of which were but of short duration. In the year of the Hegira 384, answering to the 994th of the Christian era, the city of Gazna, with some part of the adjacent country, was governed by Mahmud Gazni; who became a great conqueror, and reduced under his subjection a considerable part of India and most of Persia.

This empire continued in the family of Mahmud Gazni for upwards of 200 years. None of his successors, however, were possessed of his abilities; and therefore the extent of the empire, instead of increasing, was very considerably diminished soon after Mahmud's death. The Seljuks made themselves masters of Khorasan, and could not be driven out; the greatest part of the Persian dominions also fell off; and in the 547th year of the Hegira, the race of Gazni sultans was entirely set aside by one Gauri, who conquered Khosru Shah the reigning prince, and bestowed his dominions on his own nephew Gayathoddin Mohammed. These new sultans proved greater conquerors than the former, and extended their dominions farther than even Mahmud Gazni himself had done. They did not, however, long enjoy the sovereignty of Gazna; for in 1218, Jenghiz Khan having conquered the greatest part of China and almost all Tartary, began to turn his arms westward; and set out against the sultan of Gazna at the head of 700,000 men.

To oppose this formidable army, Mohammed, the reigning sultan, could muster only 400,000 men; and, in the first battle, 160,000 of his troops are said to have perished. After this victory, Jenghiz Khan advanced; Mohammed not daring to risk a second battle, the loss of which would have been attended with the entire ruin of his kingdom. He therefore distributed his army amongst the strongest fortified towns he had in his dominions; all of which Jenghiz Khan took one after another. The rapid progress of his conquests, indeed, almost exceeds belief. In 1219 and 1220, he had reduced Zarnuk, Nur, Bokhara, Otrar, Saganak, Uzkant, Alshash, Jund, Tonkat, Khojend, and Samarcand. Mohammed, in the mean time, fled first to Bokhara; but on the approach of Jenghiz Khan's army, quitted that place, and fled to Samarcand. When this last city was also in danger of being invested, the sultan did not think proper to trust himself in it more than in the other, though it was garrisoned by 110,000 of his bravest troops; and therefore fled through byways into the province of Ghilan in Persia, where he took refuge in a strong fortress called *Estabad*. But being also found out in this retreat, he fled to an island in the Caspian sea called *Abiskun;* where he ended his days, leaving his empire, such as it was, to his son Jaloloddin.

The new sultan was a man of great bravery and experience in war; but nothing was able to stop the progress of the Moguls. In 1220 and 1221, they made themselves masters of all the kingdoms of Kàrazim and Khorasan, committing everywhere such massacres as were never heard of before or since that time. In the mean time Jaloloddin assembled his forces with the utmost diligence, and defeated two detachments of the Mogul army. This happened while Jenghiz Khan was besieging Bamiyan; but answered little other purpose, than serving to bring upon that city the terrible destruction of which an account is given under the article BAMIYAN. Immediately after the reduction of that city, Jenghiz Khan marched towards Gazna; which was very strongly fortified, and where he expected to have found Jaloloddin. But he had left the place 15 days before; and, as Jenghiz Khan's army was much reduced, he might perhaps have stood his ground, had it not been for an accident. He had been lately joined by three Turkish commanders, each of whom had a body of 10,000 men under his command. After his victories over the Moguls, these officers demanded the greatest share of the spoils; which being refused, they separated themselves from the sultan. He used his utmost endeavours to make them hearken to reason; and sent several messages and letters to them, representing the inevitable ruin which must attend their separation, as Jenghiz Khan was

Gazna. was advancing against them with his whole army. At last they were persuaded to lay aside their animosities; but it was now too late; for Jenghiz Khan, being informed of what passed, detached 60,000 horse to prevent their joining the sultan's army; who, finding himself deprived of this powerful aid, retired towards the river Indus. When he was arrived there, he stopped in a place where the stream was most rapid and the place confined, with a view both to prevent his soldiers from placing any hopes of safety in flight, and to hinder the whole Mogul army from attacking him at once. Ever since his departure from Gazna he had been tormented with a colic: yet, at a time when he suffered most, hearing that the enemy's vanguard was arrived at a place in that neighbourhood called *Herder*, he quitted his litter, and, mounting a horse, marched with some of his chosen soldiers in the night; surprised the Moguls in their camp; and having cut them almost all in pieces, without the loss of a single man on his side, returned with a considerable booty.

Jenghiz Khan, finding by this that he had a vigilant enemy to deal with, proceeded with great circumspection. When he came near the Indus, he drew out his army in battalia: to Jagatay, one of his sons, he gave the command of the right wing; to Otkay, another son, he gave the command of the left: and put himself in the centre, with 6000 of his guards. On the other side, Jaloloddin prepared for battle like one who had no resource but in victory. He first sent the boats on the Indus farther off; reserving only one to carry over his mother, wife, and children: but unluckily the boat split when they were going to embark, so that they were forced to remain in the camp. The sultan took to himself the command of the main body of the army. His left wing, drawn up under shelter of a mountain which hindered the whole right wing of the Moguls from engaging at once, was commanded by his vizir; and his right by a lord named *Amin Malek*. This lord began the fight; and forced the enemy's left wing, notwithstanding the great disparity of numbers, to give ground. The right wing of the Moguls likewise wanting room to extend itself, the sultan made use of his left as a body of reserve, detaching from thence some squadrons to the assistance of the troops who stood in need of them. He also took one part of them with him when he went at the head of his main body to charge that of Jenghiz Khan; which he did with so much resolution and vigour, that he not only put it in disorder, but penetrated into the place where Jenghiz Khan had originally taken his station: but that prince having had a horse killed under him, was retired from thence, to give orders for all the troops to engage.

This disadvantage had like to have lost the Moguls the battle; for a report being immediately spread that the enemy had broken through the main body, the troops were so much discouraged, that they would certainly have fled, had not Jenghiz Khan encouraged them by riding from place to place in order to show himself. At last, however, Jaloloddin's men, who were in all but 30,000, having fought a whole day with ten times their number, were seized with fear and fled. One part of them retired to the rocks which were on the shore of the Indus, where the enemy's horse could not follow them; others threw themselves into the river, where many were drowned, though some had the good fortune to cross over in safety; while the rest surrounding their prince, continued the fight through despair. The sultan, however, considering that he had scarce 7000 men left, began to think of providing for his own safety: therefore, having bidden a final adieu to his mother, wife, and children, he mounted a fresh horse, and spurred him into the river, which he crossed in safety, and even stopped in the middle of it to insult Jenghiz Khan, who was now arrived at the bank. His family fell into the hands of the Moguls; who killed all the males, and carried the women into captivity.

Jaloloddin being now securely landed in India, got up into a tree in order to preserve himself from wild beasts. Next day, as he walked melancholy among the rocks, he perceived a troop of his soldiers, with some officers, three of whom proved to be his particular friends. These, at the beginning of the defeat, had found a boat in which they had sailed all night, with much danger from the rocks, shelves, and rapid current of the river. Soon after, he saw 500 horse coming towards him; who informed him of 4000 more that had escaped by swimming over the river; and these also soon after joined the rest. In the mean time an officer of his household, named *Jamalarrazad*, knowing that his master and many of his people were escaped, ventured to load a very large boat with arms, provisions, money, and stuff to clothe the soldiers; with which he crossed the river. For this important service Jaloloddin made him steward of his household, and surnamed him the *Chosen* or the *Glory of the Faith*. For some time after, the sultan's affairs seemed to go on prosperously: he gained some battles in India; but the princes of that country, envying his prosperity, conspired against him, and obliged him to repass the Indus. Here he again attempted to make head against the Moguls; but was at last defeated and killed by them, and a final end put to the once mighty empire of Gazna.

The metropolis was reduced by Otkay; who no sooner entered the country in which it was situated, than he committed the most horrid cruelties. The city was well provided with all things necessary for sustaining a siege; had a strong garrison, and a brave and resolute governor. The inhabitants, expecting no mercy from Jenghiz Khan, who they knew had sworn their ruin, were resolved to make a desperate defence. They made frequent sallies on the besiegers, several times overthrew their works, and broke above 100 of their battering rams. But one night, after an obstinate fight, part of the city walls fell down; and a great number of Moguls having filled up the ditch, entered the city sword in hand. The governor perceiving all was lost, at the head of his bravest soldiers rushed into the thickest of his enemies, where he and his followers were all slain. However, Gazna was not entirely destroyed, nor were the people all killed; for after the massacre had continued for four or five hours, Otkay ordered it to cease, and taxed those who were left alive at a certain rate, in order to redeem themselves and the city. It does not, however, appear that after this time the city of Gazna ever made any considerable figure.—It was taken by the Moguls in the year 1222.

GEBRES.

GEBRES. See GABRES.

GECCO, in *Natural History*, a name given by the Indians to their terrible poison, which kills when mixed with the blood even in the smallest quantity. They say that this gecco is a venomous froth or humour vomited out of the mouths of their most poisonous serpents; which they procure in this fatal strength, by hanging up the creatures by the tails, and whipping them to enrage them: they collect this in proper vessels as it falls; and when they use it, they either poison a weapon with it, or wounding any part of the flesh introduce the smallest quantity imaginable into it; and this is said to be immediate death.

GECKO. See LACERTA, ERPETOLOGY *Index*.

GED, WILLIAM, an ingenious though unsuccessful artist, who was a goldsmith in Edinburgh, deserves to be recorded for his attempt to introduce an improvement in the art of printing. The invention, first practised by Ged in 1725, was simply this. From any types of Greek or Roman, or any other character, he formed a plate for every page, or sheet, of a book, from which he printed, instead of using a type for every letter, as is done in the common way. This was first practised, but on blocks of wood, by the Chinese and Japanese, and pursued in the first essays of Coster the European inventor of the present art. "This improvement (says James Ged the inventor's son) is principally considerable in three most important articles, viz. expence, correctness, beauty and uniformity."

In July 1729, William Ged entered into partnership with William Fenner, a London stationer, who was to have half the profits, in consideration of his advancing all the money requisite. To supply this, Mr John James, then an architect at Greenwich (who built Sir Gregory Page's house, Bloomsbury church, &c.) was taken into the scheme, and afterwards his brother Mr Thomas James, a letter founder, and James Ged the inventor's son. In 1730, these partners applied to the university of Cambridge for printing Bibles and common prayer books by blocks instead of single types; and, in consequence, a lease was sealed to them, April 23. 1731. In their attempt they sunk a large sum of money, and finished only two prayer books; so that it was forced to be relinquished, and the lease was afterwards given up. Ged imputed his disappointment to the villany of the pressmen, and the ill treatment of his partners (which he specifies at large), particularly Fenner, whom John James and he were advised to prosecute, but declined it. He returned to Scotland in 1736, where he gave his friends a specimen of his performance, by an edition of Sallust. But being still unsuccessful, and having failed in obtaining redress from Fenner, who died insolvent, he was preparing again to set out for London, in order to join with his son James as a printer there, when he died October 19. 1749. Ged's son attempted unsuccessfully, in 1751, to revive this invention; Messrs Tilloch and Foulis about the year 1782 practised it on a small scale at Glasgow; and of late years many beautiful editions of the classics have been printed in this way by Didot of Paris, and Wilson and Company of London †.

† See Proc. and Phil. Mag. 267.

GEDDES, ALEXANDER, a learned Scots Catholic divine and eminent bible critic, was born in the parish of Ruthven in Banffshire, in the year 1737. His parents were respectable, although not opulent. His father was a farmer, who deemed no trouble too great, in order to procure for his children as liberal an education as possible. Both father and mother were of the Catholic persuasion, and the only book of consequence which the former had in his library was an English translation of the bible, in which young Geddes was instructed with such care and attention, that he was able to give an account of the history of it before he had reached the eleventh year of his age. The first instructions he received, after those of his parents, were communicated by a school-mistress in the vicinity, by whom he was so much distinguished, that it became the first mental gratification which, in his own opinion, he ever felt. He was next put under the tuition of a young man from the city of Aberdeen, who had been engaged by the *laird* for the education of his own children; and afterwards went to a place called Scalan, in the Highlands, where those were to be trained up who designed to devote themselves to the Catholic priesthood, and to finish their education at some foreign university. Here it was, in this obscure retreat, that Geddes laid the foundation of that intimate acquaintance with the learned languages, by which he was so eminently distinguished in the subsequent part of his life. He went to the Scots university at Paris in the year 1758, and soon after began the study of rhetoric in the college of Navarre. By the strength of his genius and his indefatigable attention, he was soon at the head of this class, although he had to contend with two veterans, and became the favourite of Vicaire the professor, whose friendship lasted to the close of life.

Instead of entering into the philosophical class at the usual time, he studied that subject at home, in order to facilitate his theological studies, on which he entered under M. M. Buré and de Sauvent, at the college of Navarre, and Lavocat at the Sorbonne was his Hebrew preceptor. So great, or rather astonishing, was his progress, that Professor Lavocat urged him strongly to continue at Paris; but his friends prevailed with him to return to his native country in 1764. His first charge as a priest was in a Catholic chapel in the county of Angus, from which he removed to Traquair in 1765, and became chaplain to the earl of that name, where he remained for about three years. This situation was most agreeable to his literary pursuits, as he had unlimited access to a very extensive library, which greatly assisted him in the prosecution of his darling studies. He left the earl's house in the year 1768, and returned to Paris, where he devoted his time during the following winter to the perusal of books and manuscripts in the king's libraries, making large extracts from scarce copies, particularly such as were in the Hebrew tongue.

In the spring of 1769, he returned to his native country, and became pastor of a congregation at Auchinhalrig in Banffshire, where he was for some time involved in pecuniary difficulties, out of which he was extricated by the liberality of the then duke of Norfolk. These were occasioned by the debts he incurred in building a new chapel for his flock, and in making the parson's house one of the neatest and most convenient in Scotland. With the view of bettering his circumstances he commenced farmer; but as he had to borrow money to stock his farm, and as the crops failed for three successive seasons, he was under the necessity of abandoning this scheme in a much poorer state than when he

 first

Geddes.

first projected it. But his unwearied exertions, joined to the assistance of friends, again relieved him, and he was enabled to discharge every claim against him of a pecuniary nature in an honourable manner.

In the year 1779 he resigned his pastoral charge at Auchinhalrig, which was a heavy stroke to the members of his congregation, as the zeal and diligence with which he discharged the duties of his ministerial function had endeared him to all. He was also justly esteemed for his attention to the instruction of youth. Next year the university of Aberdeen conferred on him the degree of LL. D. a literary honour which was never bestowed on any Roman Catholic by that body since the Reformation. He afterwards went to London, that he might prosecute his favourite studies with greater facility, and give the world his English translation of the Old and New Testament, to which he had turned his attention for a number of years. He officiated for some months after his arrival at the imperial ambassador's chapel in Duke-street, till the term of Easter 1782, at which time it was suppressed by order of the emperor Joseph II. after which Dr Geddes seems to have declined entirely the exercise of his clerical functions.

No sooner had the design of Mr Geddes, relative to a new translation of the Bible been made public, than he met with formidable opposition from his Catholic brethren; an event which the doctor with good reason seems to have anticipated. His own words on this occasion were: "I expect not excessive profits from excessive exertion. I trust I shall never want *meat*, and *clothes*, and *fire*; to a philosophical and contented mind, what more is necessary?" He was many years employed in preparing this important work for the press, before he had any prospect of adequate success. In addressing the English Catholics on the subject of his translation, he has these memorable words: "At any rate, I do what I think it my duty to do, and do it fairly and openly. In the following pages ye will find neither palliation nor disguise. I pour out my sentiments with the same sincerity as if I were before the tribunal of Him who is to judge the living and the dead. Mistake I may, but prevaricate I never will." He discovered this noble spirit in every action of his life, and in all his transactions and intercourse with mankind, although he did not conciliate the regard of those who could have bestowed upon him the most effectual assistance.

After spending much of his life in biblical studies, he met with a long and cruel interruption, of which he thus speaks: "I had but little hope of ever living in a situation to resume them, when Providence threw me into the arms of such a patron as Origen himself might have been proud to boast of—a patron, who, for these ten years past, has, with a dignity peculiar to himself, afforded me every convenience that my heart could desire towards the carrying on and completing of my arduous work."

It is needless to inform the public, that the patron to whom the learned doctor here alludes was Lord Petre. For this munificence, continued through the whole of his life, and even beyond it by his latter will, Christians of every denomination will feel sentiments of gratitude, when they are qualified to make a true estimate of the advantages of free and impartial enquiry.

In the year 1792, the first volume of his translation was published, dedicated to his patron Lord Petre, containing the first six books of the Old Testament. Soon after this volume made its appearance, three apostolic vicars, calling themselves the bishops of Rama, Acanthos, and Centuriæ, issued a pastoral letter, addressed to their respective flocks over which they presided, warning them against the reception of Dr Geddes's translation. In his reply to the bishop of Centuriæ we find these words: "Perhaps, my lord, you wish to have another occasion of exercising your episcopal authority, and of playing with censures as children do with a new ball.—I wish your lordship much joy of the bauble; but however, my lord, beware of playing too often with it. Read St Chrysostom on Ecclesiastical Censures, and learn from him a little more moderation. Permit an old priest to tell you, that it is a very great ornament in a *young bishop*. As to myself, my lord, I am not afraid of your threats, and shall laugh at your censures as long as I am conscious that I deserve them not.—You cannot hinder me from praying at home; and at home I will pray, in defiance of your censure, as often as I please. The chief Bishop of our souls is always accessible; and through him I can, at all times, have free access to the Father, who will not reject me, but for voluntary unrepented crimes. In the panoply of conscious innocence, the whole thunder of the Vatican would in vain be levelled at my head."

The second volume of his translation, owing to a variety of interruptions, did not make its appearance till the year 1797, to which was prefixed a dedication to her royal highness the duchess of Gloucester, as an "early, spontaneous, and liberal encourager of the work." In this volume the doctor gives up, and boldly combats, the absolute inspiration of scripture, believing that the Hebrew, like all other historians, wrote from such human documents as they could find, and were of consequence liable to similar mistakes. This latitude of thinking naturally led the doctor to give up as fabulous, and wholly unworthy of the divine philanthropy, every command, precept, and injunction, which appeared unworthy even of human authority. He denied of consequence, that the command given to destroy the Canaanites could have God for its author. This volume of Critical Remarks was published in 1800, in which he enters into an able vindication of his own theory, which rather increased than diminished the number of enemies, for as he wrote to please no party, he foresaw that he would have enemies in every party, and so it happened.

Dr Geddes was a man of extensive literature, uncommon liberality of thinking, the friend of all mankind; a man of integrity, honour, and benevolence; in the strictest sense of the word, a truly genuine Catholic, and whose love of truth was so invincible, that neither hopes nor fears could induce him to conceal it.

His prospectus of a new translation of the Bible in 4to was published in 1786, and a letter to the bishop of London on the same subject in 1787. His proposals were printed in 1788. As a controversial writer, Dr Geddes was eminently distinguished by his letter to Dr Priestley, in defence of the divinity of Jesus Christ, and by one to a member of parliament, on the expediency of a general repeal of the penal statutes

tutes which have a respect to religious opinions. In the spring of the year 1800, he published an apology for the Roman Catholics of Great Britain, in which he zealously defended his peculiar tenets, but displayed a commendable moderation, when he mentioned the injuries to which he himself and brethren were subjected by the continuance of persecuting laws; and, when he argued in behalf of abolishing all legal disabilities, he discovered the soundest logical understanding.

We shall close our short account of this great man in the words of one who was well acquainted with him, and fully qualified to appreciate his merits. "It must be lamented, that, in the death of Dr Geddes, the world has lost the services of a man, who by his acute and penetrating genius—his various, profound, and extensive erudition—his deep research—his indefatigable application—and his independent, dignified, and unfettered spirit, rising superior to the prejudices of education; nobly disdaining the shackles of system; spurning the petty temporizing arts of unmanly accommodation; and setting at defiance all the terrors of malignity, bigotry, and intolerance, was supereminently qualified for the great, laborious, and important work in which he had, for a long series of years, been engaged, of giving an English version of the venerable literary remains of sacred antiquity, the scriptures of the Old and New Testament. During his life, this work did not meet with encouragement adequate to the magnitude of the design; or, it may be added, to the merit of the execution. In this last respect, it will be matter of surprise to all who are competent to judge of the nature of such an enterprise, how much has been done, and with what uncommon ability and success. It everywhere displays the skilful hand of a master."

He had corrected and prepared his translation for the press up to the hundredth and eighteenth psalm, when he was seized with a most painful and excruciating distemper, which put a period to his inestimable life on the 26th of February 1802. The learned world will unquestionably have cause to lament, that Dr Geddes was arrested by the hand of death in the midst of his career, unless that unexpected phenomenon, another Geddes, should make his appearance, and happily finish what his extraordinary predecessor conducted so far with such astonishing abilities; but *rara avis in terris*.

GEHENNA, a scripture term which has given some pain to the critics. It occurs in St Matthew, v. 22. 29. 30. x. 28. xviii. 9. xxiii. 15. 33. Mark ix. 43. 45. 47. Luke xii. 5. James iii. 6.

The authors of the Louvain and Geneva versions retain the word *gehenna* as it stands in the Greek; the like does M. Simon: the English translators render it by *hell* and *hell fire*, and so do the translators of Mons and Father Bohours.

The word is formed from the Hebrew *gehinnom*, i. e. "valley of Hinnom." In that valley, which was near Jerusalem, there was a place named *Tophet*, where some Jews sacrificed their children to Moloch, by making them pass through the fire. King Josias, to render this place for ever abominable, made a cloaca or common sewer thereof, where all the filth and carcases in the city were cast.

The Jews observed farther, that there was a continual fire kept up there, to burn and consume those carcases; for which reason, as they had no proper term in their language to signify *hell*, they made use of that of *gehenna* or *gehinnom*, to denote a fire unextinguishable.

GELA, in *Ancient Geography*, a city of great extent on the south of Sicily, taking its name from the river Gelas, which washes it. It was built by colonists from Rhodes and Crete, 45 years after the building of Syracuse, or in the third year of the 22d Olympiad, 690 before Christ; originally called *Lindii*, from the colonists of *Lindus*, a city of Rhodes, who settled there first. Now *Terra Nuova*, and the river called *Fiume di Terra Nuova*. The people were called *Geloi*, *Gelenses*, and *Gelani*. The city of Gela, after having stood 408 years, was destroyed by Phintias, tyrant of Agrigentum; and the inhabitants were removed to a new city, called *Phintias* after his name.

GELATINA, Jelly. See Jelly.

GELATINOUS, among the physicians, is applied to any thing approaching to the glutinous consistence of a jelly.

GELD, in the English old customs, a Saxon word signifying *money*, or *tribute*. It also denoted a compensation for some crimes committed: Hence *wergeld*, in their ancient laws, was used for the value of a man slain; and *orfgeld*, of a beast.

GELDENHAUR, Gerard, in Latin *Geldenharius*, an historian and Protestant divine in the 16th century. He was a native of Nimeguen, and studied classical learning at Deventer. He went through his course of philosophy at Louvain, where he contracted a very strict friendship with several learned men, and particularly with Erasmus. He became reader and historian to Charles of Austria, and afterwards to Maximilian of Burgundy. At length he embraced the Protestant religion, taught history at Marpurg, and afterwards divinity till his death, in 1542. He wrote, 1. History of Holland. 2. History of Low Countries. 3. History of the bishops of Utrecht; and other works.

GELDERLAND. See Guelderland.

GELDERS. See Guelders.

GELDING, the operation of castrating any animal. See Castration, Farriery *Index*.

GELE'E, Claude. See Claude.

GELENHAUSEN, a small imperial town of Wetteravia in Germany, with a castle built by the emperor Frederic I. E. Long. 8. 13. N. Lat. 50. 20.

GELLENIUS, Sigismund, a learned and excellent man, born of a good family at Prague, about the year 1498. Erasmus conceiving an esteem for him at Basil, recommended him to John Frobenius as a corrector for his printing-house; which laborious charge he accepted, and had a great number of Hebrew, Greek, and Latin books to correct: he also translated many works himself from the Greek and Latin; and published a dictionary in four languages, Greek, Latin, German, and Sclavonian. Profitable and honourable employments were offered him in other places; but nothing could tempt him to quit his peaceful situation at Basil. He died in 1555. All his translations are highly esteemed.

GELINOTTE, or Grus. See Tetrao, Ornithology *Index*.

GELLERT, Christian Furghtegolt, was born at Haynichen, in July 1715, near Freyberg, where his

his father was a clergyman. He was extraordinary professor of philosophy at Leipsic, and a distinguished writer among the Germans. When but 13 years of age he discovered a poetical genius; but having none to guide his taste for this kind of composition, he was led to imitate Gunther, Neukerch, and Hanke, men of indifferent abilities. He studied theology at Leipsic in 1734, and returned home at the expiration of four years, when he commenced public speaker; but his timid disposition prevented him from shining as an orator in the pulpit. The delicacy of his constitution forbidding him to aspire after extensive learning, he confined himself to the acquisition of that which might render him useful. He was much respected for his first attempts in poetry, called Amusements of Reason and Wit, which appeared in 1742.

The labour which he found requisite for the composition of sermons, inclined him to lay aside the clerical profession, and devote himself wholly to the instruction of youth, in which he not only diffused knowledge through the minds of his pupils, but also inspired them with the love of religion and virtue. He was made A. M. in 1744, and published the first volume of his fables in the ensuing year. His "Swedish Countess" was the first German romance deserving of notice. He gave the world the second part of his fables in 1748, although two years before this period he was much afflicted with hypochondriacal affections. In 1751, he was solicited to accept the office of extraordinary professor of philosophy, together with a decent salary, which was augmented on the termination of the war.

Assailed by unconquerable lowness of spirits and confirmed melancholy, he still exhibited the same patience, resignation, and universal philanthropy as he had ever shewn, and which excited the admiration of the enemy during the war. His sufferings continued to increase in severity, and at last terminated his existence on the 13th of December 1769. He contributed much to the improvement of the taste and morals of his countrymen, and their gratitude for his services made them deeply lament his loss. His praise was resounded by every voice, his likeness was cast in gypsum, and moulded in wax; it was engraved on copper, and represented in sculpture and painting.

It is said of this amiable man and captivating writer, by Kutner, who wrote the lives of German authors, that it will probably be a century before the appearance of another poet, so fully qualified to excite the love and admiration of his cotemporaries, and obtain such a powerful influence over the taste and way of thinking of all descriptions of men. If it would indicate too much partiality to call him a genius of the first class, he certainly was a most agreeable and fertile writer; the poet to whom religion and virtue are deeply indebted; an able reformer of public manners, and fonder of affording consolation, than of plunging into despondency. Kutner gives him a most excellent and enviable character, in these words: "As long as the Germans shall understand their present language, will the works of Gellert be read; and his character will be honoured while virtue is known and respected."

GELLI, John Baptist, an eminent Italian writer, was born of mean parents at Florence, in the year 1498. He was bred a taylor, some say a shoemaker; but had such an extraordinary genius, that he acquired several languages, and made an uncommon progress in the belles lettres: and though he continued always to work at his trade, became acquainted with all the wits and learned men at Florence, and his merit was universally known. He was chosen a member of the academy there, and the city made him a burgess. He acquired the highest reputation by his works, which are, 1. *I. Caprici del Bottaio*, quarto; which contains ten dialogues. 2. *La Circe*, octavo. This, which also contains ten dialogues, and treats of human nature, has been translated into Latin, French, and English. 3. Dissertations in Italian on the poems of Dante and Petrarch. 4. The comedies of *La Sporta* and *La Errore*; and other works. He died in 1563.

GELLIBRAND, Henry, a laborious astronomer of the 17th century, was born in 1597. Though he was not without good views in the church, yet he became so enamoured with mathematical studies, that on the death of his father he became a student at Oxford, contented himself with his private patrimony, and devoted himself solely to them. On the death of Mr Gunter, he was recommended by Mr Briggs to the trustees of Gresham college, for the astronomical professorship there; to which he was elected in 1627. His friend Mr Briggs dying in 1630, before he had finished his *Trigonometria Britannica*, it was finished by Gellibrand at his request. He wrote several other things, chiefly tending to the improvement of navigation; and died in 1636.

GELLIUS, Aulus, a celebrated grammarian who lived in the 2d century under Marcus Aurelius and some succeeding emperors. He wrote a collection of observations on authors, for the use of his children; and called it *Noctes Atticæ*, because composed in the evenings of a winter he spent at Athens. The chief value of it is for preserving many facts and monuments of antiquity not to be found elsewhere. Critics and grammarians have bestowed much pains on this writer.

GELLY. See Jelly.

GELO, or Gelon, a son of Dinomenes who made himself absolute at Syracuse 484 years before the Christian era. He conquered the Carthaginians at Himera, and made his oppression popular by his great equity and moderation. He reigned seven years, and his death was universally lamented at Syracuse. He was called the father of his people, and the patron of liberty, and honoured as a demigod. His brother Hiero succeeded him. See Syracuse.

GEM, in *Natural History*, a common name for all precious stones; of which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, which are found in small detached masses, extremely hard, and of great lustre.

The bodies composing the class of semipellucid gems, are stones naturally compound, not inflammable or soluble in water, found in detached masses, and composed of crystalline matter debased by earth: however, they are but slightly debased; and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

The knowledge of gems depends principally on observing their hardness and colour. Their hardness is commonly allowed to stand in the following order: The diamond the hardest of all; then the ruby, sapphire, jacinth, emerald, amethyst, garnet, carneol, chalcedony, onyx, jasper, agate, porphyry, and marble. This difference, however, is not regular and constant, but frequently varies. Good crystals may be allowed to succeed the onyx; but the whole family of metallic glassy fluors seems to be still softer.—In point of colour, the diamond is valued for its transparency, the ruby for its purple, the sapphire for its blue, the emerald for its green, the jacinth for its orange, the amethyst carneol for its carnation, the onyx for its tawney, the jasper, agate, and porphyry, for their vermilion, green, and variegated colours, and the garnet for its transparent blood red.

All these gems are sometimes found coloured and spotted, and sometimes quite limpid and colourless. In this case the diamond cutter or polisher knows how to distinguish their different species by their different degrees of hardness upon the mill. For the cutting or polishing of gems, the fine powder of the fragments of those that are next in degree of hardness is always required to grind away the softer; but as none of them are harder than the diamond, this can only be polished by its own powder.

Cronstedt observes of gems in general, that the colour of the ruby and emerald are said to remain in the fire, while that of the topaz flies off: hence it is usual to burn the topaz, and thence substitute it for the diamond. "Their colours (says our author) are commonly supposed to depend upon metallic vapours; but may they not more justly be supposed to arise from a phlogiston united with a metallic or some other earth? because we find that metallic earths which are perfectly well calcined give no colour to any glass: and that the manganese, on the other hand, gives more colour than can be ascribed to the small quantity of metal which is to be extracted from it." M. Magellan is of opinion, that their colour is owing chiefly to the mixture of iron which enters their composition; but approves the sentiment of Cronstedt, that phlogiston has a share in their production, it being well known that the calces of iron when dephlogisticated produce the red and yellow colours of marble, and when phlogisticated to a certain degree produce the blue or green colours.

With regard to the texture of gems, M. Magellan observes, that all of them are foliated or laminated, and of various degrees of hardness. Whenever the edges of these laminæ are sensible to the eye, they have a fibrous appearance, and reflect various shades of colour, which change successively according to their angular position to the eye. These are called by the French *chatoyantes;* and what is a blemish in their transparency, often enhances their value on account of their scarcity. But when the substance of a gem is composed of a broken texture, consisting of various sets of laminæ differently inclined to each other, it emits at the same time various irradiations of different colours, which succeed one another according to their angle of position. This kind of gems has obtained the name of *opals*, and are valued in proportion to the brilliancy, beauty, and variety of their colours. Their crystallization, no doubt, depends on the same cause which produces that of salts, earths, and metals, which is treated of under the article CRYSTALLIZATION. The following table shows the component parts of gems according to the analysis of Bergman and M. Achard; the letter B prefixed to each denoting Bergman's analysis, and A that of Achard.

Gem.

		Argil.	Silic.	Calc	Iron.
Red oriental ruby, -	B	40	39	9	10
Ditto, - -	A	37.5	42.5	9	11
Blue oriental sapphire, -	B	58	35	5	2
Ditto, - -	A	58	33	6	3
Yellow topaz from Saxony,	B	46	39	8	6
Green oriental emerald, -	B	60	24	8	6
Ditto, - -	A	60	23	10	7
Yellow brown orient. hyacinth,	B	40	25	20	13
Ditto, - -	A	42	22	20	16
Tourmalin from Ceylon, -	B	39	37	15	9
Ditto from Brasil, -	B	50	34	11	5
Ditto from Tyrol, -	B	42	40	12	6
Garnet from Bohemia, -	A	30	48	11	10

But later analyses shew that the component parts are different from the above, particularly the colouring matters which are here ascribed to iron. See MINERALOGY.

The chrysoprase from Koseinitz in Silesia was likewise analyzed by M. Achard; who found that it contained 456 grains of siliceous earth, 13 of calcareous, six of magnesia, three of copper, and two of iron. "This (says M. Magellan) seems to be the only gem that contains no argillaceous earth."

Imitation or Counterfeiting of GEMS *in Glass.* The art of imitating gems in glass is too considerable to be passed without notice: some of the leading compositions therein we shall mention upon the authority of Neri and others.

These gems are made of pastes; and are noway inferior to the native stones, when carefully made and well polished, in brightness or transparence, but want their hardness.

The general rules to be observed in making the pastes are these: 1. That all the vessels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels be chosen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry stone; not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantity of the several ingredients be nicely observed. 5. That the materials be all well mixed; and, if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot; for if this be not observed, they will be full of blisters and air bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients.

To make paste of extreme hardness, and capable of all the colours of the gems, with great lustre and beauty.—Take of prepared crystal, ten pounds; salt of polverine, six pounds; sulphur of lead, two pounds: mix all these well together into a fine powder; make the whole with common water into a hard paste; and make this paste into small cakes of about three ounces weight each, with a hole made in their middle; dry them in the sun, and afterwards calcine them in the straitest part of a potter's furnace. After this, powder

Gem.

der them, and levigate them to a perfect fineness on a porphyry stone, and set this powder in pots in a glass furnace to purify for three days: then cast the whole into water, and afterwards return it into the furnace, where let it stand 15 days, in which time all foulness and blisters will disappear, and the paste will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined; for a sea green, brass simply calcined to a redness; for a sapphire, add zaffer, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in this, by the same way of working as the making of coloured glasses; and this is so hard, that they very much approach the natural gems.

The colour of all the counterfeit gems made of the several pastes, may be made deeper or lighter according to the work for which the stones are designed; and it is a necessary general rule, that small stones for rings. &c. require a deeper colour, and large ones a paler. Besides the colours made from manganese, verdigris, and zaffer, which are the ingredients commonly used, there are other very fine ones which care and skill may prepare. Very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brass or copper; a sky colour from silver, and a much finer one from the granates of Bohemia.

A very singular and excellent way of making the paste to imitate the coloured gems is this: Take a quantity of saccharum saturni, or sugar of lead, made with vinegar in the common way; set it in sand, in a glass body well luted from the neck downwards; leave the mouth of the glass open, and continue the fire 24 hours; then take out the salt, and if it be not red but yellowish, powder it fine, and return it into the vessel, and keep it in the sand heat 24 hours more, till it becomes as red as cinnabar. The fire must not be made so strong as to melt it, for then all the process is spoiled. Pour distilled vinegar on this calcined salt, and separate the solution from the dregs; let the decanted liquor stand six days in an earthen vessel, to give time for the finer sediment to subside; filter this liquor, and evaporate it in a glass body, and there will remain a most pure salt of lead; dry this well, then dissolve it in fair water; let the solution stand six days in a glazed pan; let it subside, then filter the clear solution, and evaporate it to a yet more pure white and sweet salt; repeat this operation three times; put the now perfectly pure salt into a glass vessel, set it in a sand heat for several days, and it will be calcined to a fine impalpable powder of a lively red. This is called *the sulphur of lead.*

Take all the ingredients as in the common composition of the pastes of the several colours, only instead of red lead, use this powder; and the produce will well reward the trouble of the operation, as experience has often proved.

A paste proper for receiving colours may be readily made by well pounding and mixing six pounds of white sand cleansed, three pounds of red lead, two pounds of purified pearl ashes, and one pound of nitre. A softer paste may be made in the same manner, of six pounds of white sand cleansed; red lead, and purified pearl-ashes, of each three pounds; one pound of nitre, half a pound of borax, and three ounces of arsenic. For common use a pound of common salt may be substituted for the borax. This glass will be very soft, and will not bear much wear if employed for rings, buckles, or such imitations of stones as are exposed to much rubbing; but for ear-rings, ornaments worn on the breast, and those little used, it may last a considerable time.

In order to give paste different colours, the process is as follows: For

Amethyst. Take ten pounds of either of the compositions described under *Colouring of* GLASS, one ounce and a half of manganese, and one drachm of zaffer; powder and fuse them together.

Black. Take ten pounds of either of the compositions just referred to, one ounce of zaffer, six drachms of manganese, and five drachms of iron, highly calcined; and proceed as before.

Blue. Take of the same composition, ten pounds; of zaffer, six drachms; and of manganese, two drachms: and proceed as with the foregoing.

Chrysolite. Take of either of the compositions for paste above described, prepared without saltpetre, ten pounds, and of calcined iron five drachms; and pursue the same process as with the rest.

Red Cornelian. Take of the compositions mentioned under *Colouring of* GLASS, two pounds; of glass of antimony, one pound; of the calcined vitriol called *scarlet ochre*, two ounces; and of manganese, one drachm. Fuse the glass of antimony and manganese with the composition; then powder them, and mix them with the other, by grinding them together, and fuse them with a gentle heat.

White Cornelian. Take of the composition just referred to, two pounds; of yellow ochre well washed, two drachms; and of calcined bones, one ounce. Mix them, and fuse them with a gentle heat.

Diamond. Take of the white sand, six pounds; of red lead, four pounds; of pearl ashes, purified, three pounds; of nitre two pounds; of arsenic five ounces; and of manganese, one scruple. Powder and fuse them.

Aigue-marine. Take ten pounds of the composition under GLASS; three ounces of copper highly calcined with sulphur; and one scruple of zaffer. Proceed as before.

Emerald. Take of the same composition with the last, nine pounds; three ounces of copper precipitated from aquafortis; and two drachms of precipitated iron. See EMERALD, MINERALOGY *Index*.

Garnet. Take two pounds of the composition under GLASS; two pounds of the glass of antimony, and two drachms of manganese. For vinegar garnet, take of the composition for paste, described in this article, two pounds; one pound of glass of antimony, and half an ounce of iron, highly calcined: mix the iron with the uncoloured paste, and fuse them: then add the glass of antimony powdered, and continue them in the heat till the whole is incorporated.

Gold or *full Yellow.* Take of the composition for paste ten pounds; and one ounce and a half of iron strongly calcined; proceeding as with the others.

Deep Purple. Take of either of the compositions for paste, ten pounds; of manganese, one ounce; and of zaffer, half an ounce.

Ruby. Take one pound of either of the compositions

tions for paste, and two drachms precipitate of gold by tin; powder the paste, and grind the calx of gold with it in a glass, flint, or agate mortar, and then fuse them together. A cheaper ruby paste may be made with half a pound of either of the above compositions, half a pound of glass of antimony, and one drachm and a half of the calx of gold; proceeding as before.

Sapphire. Take of the composition for paste, ten pounds; of zaffer, three drachms and one scruple; and of the *calx Cassii*, one drachm. Powder and fuse them. Or the same may be done, by mixing with the paste one-eighth of its weight of smalt.

Topaz. Take of the compositions under GLASS ten pounds, omitting the saltpetre; and an equal quantity of the *Gold-coloured hard* GLASS. Powder and fuse them. See TOPAZ, MINERALOGY *Index*.

Turquoise. Take of the composition for blue paste already described, ten pounds; of calcined bone, horn, or ivory, half a pound. Powder and fuse them.

Opaque white. Take of the composition for paste ten pounds; and one pound of calcined horn, ivory, or bone; and proceed as before.

Semitransparent white, like opal. See OPAL, MINERALOGY *Index*.

To the above we shall add the following receipts and processes, contained in a memoir by M. Fontanieu of the Royal Academy of Sciences at Paris, and said to have met with much approbation.

I. *Of the Bases.* Although the different calces of lead are all adapted to produce the same effect in vitrification; yet M. Fontanieu prefers lead in scales, and next to that minium, as being the most constantly pure. It is necessary to sift through a silk sieve the preparations of lead one wishes to make use of in the vitrification, in order to separate the grosser parts, as also the lead found in a metallic state when white lead in scales is employed.

The base of factitious gems is calx of lead and rock crystal, or any other stone vitrifiable by the calces already mentioned. Pure sand, flint, and the transparent pebbles of rivers, are substances equally fit to make glass: but as it is first necessary to break the masses of crystal, stones, or pebbles, into smaller parts; so by this operation particles of iron or copper are frequently introduced, and to these dust or greasy matters are also apt to adhere. Our author therefore begins by putting the pounded crystal or pebbles into a crucible, which he places in a degree of heat capable of making the mass red hot; he then pours it into a wooden bowl filled with very clear water; and shaking the bowl from time to time, the small portions of coals furnished by the extraneous bodies swim on the surface of the water, and the vitrifiable earth, with the iron, &c. rests on the bottom. He then decants the water; and having dried the mass, he pounds it, and sifts the powder through the finest silk sieve: he then digests the powder during four or five hours with marine acid, shaking the mixture every hour. After having decanted the marine acid from the vitrifiable earth, he washes the latter until the water no longer reddens the tincture of turnsol. The said earth being dried, is passed through a silk sieve, and is then fit for use. Nitre, salt of tartar, and borax, are the three species of salts that enter with quartz and the several calces of lead into M. Fontanieu's vitrifications.

Much of the success in the art of making coloured stones depends on the accurate proportion of the substances made use of to form the crystal which serves as a base to the factitious stones. After having tried a great variety of receipts, our author found they might be reduced to the following.

1. Take two parts and a half of lead in scales, one part and a half of rock crystal or prepared flints, half a part of nitre, as much borax, and a quarter part of glass of arsenic. These being well pulverized and mixed together, are to be put into a Hessian crucible, and submitted to the fire. When the mixture is well melted, pour it into cold water: then melt it again a second and a third time; taking care, after each melting, to throw it into fresh cold water, and to separate from it the lead that may be revived. The same crucible should not be used a second time, because the glass of lead is apt to penetrate it in such a manner as to run the risk of losing the contents. One must also be careful to cover the crucible well, to prevent any coals getting into it, which would reduce the calx of lead, and spoil the composition.

2. Take two parts and a half of white ceruse, one part of prepared flints, half a part of salt of tartar, and a quarter part of calcined borax: melt the mixture in a Hessian crucible, and then pour it into cold water; it is then to be melted again, and washed a second and a third time, the same precautions being observed as for the first base.

3. Take two parts minium, one part rock crystal, half a part of nitre, and as much salt of tartar: this mixture being melted, must be treated as the former.

4. Take three parts of calcined borax, one part of prepared rock crystal, and one part of salt of tartar; these being well mixed and melted together, must be poured into warm water: the water being decanted, and the mass dried, an equal quantity of minium must be added to it; it is then to be melted and washed several times as directed above.

5. That called by our author the *Mayence base*, and which he considers as one of the finest crystalline compositions hitherto known, is thus composed: Take three parts of fixed alkali of tartar, one part of rock crystal or flint pulverized: the mixture to be well baked together, and then left to cool. It is afterwards poured into a crucible of hot water to dissolve the frit; the solution of the frit is then received into a stone-ware pan, and aquafortis added gradually to the solution till it no longer effervesces: this water being decanted, the frit must be washed in warm water till it has no longer any taste: the frit is then dried, and mixed with one part and a half of fine ceruse or white lead in scales; and this mixture must be well levigated with a little distilled water. To one part and a half of this powder dried add an ounce of calcined borax: let the whole be well mixed in a marble mortar, then melted and poured into cold water as the other bases already described. These fusions and lotions having been repeated, and the mixture dried and powdered, a 12th part of nitre must be added to it, and then melted for the last time; when a very fine crystal will be found in the crucible.

6. As a composition for furnishing very fine white stones: Take eight ounces of ceruse, three ounces of

Gem.

rock crystal pulverized, two ounces of borax finely powdered, and half a grain of manganese: having melted and washed this mixture in the manner directed above, it will produce a very fine white crystal.

II. *Of the Colours.* The calces of metals, as already observed, are the substances employed to colour factitious gems; and on the preparation of these calces depends the vividness of their colours.

a, From *Gold.*] To obtain the mineral purple known by the name of *precipitate of Cassius*, M. Fontanieu employs the following different processes.

1. Dissolve some pure gold in aqua regia, prepared with three parts of precipitated nitrous acid and one part of marine acid; and to hasten the dissolution, the matrass should be placed in a sand bath. Into this solution pour a solution of tin in aqua regia. The mixture becomes turbid, and the gold is precipitated with a portion of the tin, in the form of a reddish powder; which after being washed and dried, is called *precipitate of Cassius.*—The aqua regia employed to dissolve the tin is composed of five parts of nitrous acid and one part of marine acid: to eight ounces of this aqua regia, are added sixteen ounces of distilled water. Some leaves of Malacca tin, about the size and thickness of a sixpence, are then put into this diluted aqua regia, till it will dissolve no more of them: which operation our author observes, requires commonly twelve or fourteen days; though it might probably be hastened by beating the tin still thinner, and then rolling it into the form of a hollow cylinder, or turning it round into spiral convolutions, and thus exposing a greater extent of surface to the action of the menstruum. In order to prepare more readily the precipitate of Cassius, M. Fontanieu puts into a large jug eight ounces of solution of tin, to which he adds four pints of distilled water: he afterwards pours into this metallic lye some solution of gold, drop by drop, taking care to stir the whole with a glass tube: when the mixture becomes of a deep purple colour, he ceases dropping the solution of gold; and in order to hasten the precipitation of the mineral purple, pours into the mixture a pint of fresh urine. Six or seven hours after, the precipitate is collected at the bottom of the vessel: the fluid is then decanted; and the precipitate, washed once or twice, is dried till it becomes a brown powder.

2. Pour into a vessel of fine tin with a thick bottom four ounces of the solution of gold; three minutes after add two pints of distilled water. Let this mixture stand in the tin vessel during seven hours, taking care to stir it every hour with a glass tube; afterwards pour it into a conical glass jug, and add to it a pint of new urine: the mineral purple is soon precipitated, and then is to be washed and dried.

3. Distil in a glass retort placed in a bath of ashes, some gold dissolved in aqua regia, made with three parts nitrous and one part marine acid; when the acid is passed over and the gold contained in the retort appears dry, leave the vessel to cool, then pour into it some new aqua regia, and proceed to distil as before. Replace the aqua regia twice upon the gold, and distil the same. After these four operations, pour by little and little into the retort some oil of tartar *per deliquium*, which will occasion a brisk effervescence: when this ceases, distil the mixture till it becomes dry, and then put some warm water into the retort. Shake the whole and pour it into a cucurbit, when a precipitate is deposited, the colour of which is sometimes brown and sometimes yellow: After having washed this precipitate, dry it. Our author says, this mineral purple was much superior to the foregoing, since two grains of it only were sufficient to an ounce of the base, whilst it required of the other two a 20th part of the base. And he adds, that he found a means of exalting the colour of the precipitate of Cassius, by putting to it a sixth part of its weight of glass of antimony finely powdered, and of nitre in the proportion of a drachm to eight ounces of the base.

b, From *Silver.*] The oxide of silver, being vitrified, produces a yellowish gray colour. This oxide enters only into the composition of the yellow artificial diamond and the opal. M. Fontanieu introduces it into the base in the form of luna cornea.

In order to prepare it, he directs to dissolve the silver in precipitated nitrous acid, and afterwards to pour into it a solution of sea salt: a white precipitate is obtained; which, being washed and dried, melts very readily in the fire, and is soon volatilized if not mixed with vitrifiable matters. To make the yellow diamond, 25 grains of this luna cornea are put to an ounce of the fourth base: the dose of silver may be diminished according to the shade of yellow that one wishes to procure.

c, From *Copper.*] The oxide of copper imparts to white glass the finest green colour; but if this metal be not exactly in a state of oxide, it produces a brownish red colour. *Mountain blue verdigris*, and the residue of its distillation, are the different preparations of copper which our author employs to make the artificial emeralds.

d, From *Iron.*] Although it has been asserted that the oxides of iron introduce a very fine transparent red colour into white glass, M. Fontanieu could only obtain from it a pale red a little opake. The oxide of iron that he employed was in the proportion of the 20th part of the base.

There are several ways of preparing the oxide of iron called *crocus Martis*, or *saffron of Mars.* In general, it is necessary that this metal be so far oxidated that the magnet ceases to attract it: thus one may use the scales of iron found upon the bars of the furnaces which serve to distil aquafortis. By digesting filings of steel with distilled vinegar, then evaporating and replacing the vinegar 10 or 12 times upon these filings and drying them alternately, an oxide of iron is obtained, which must be sifted through a silk sieve, and then calcined. The oxide of iron thus obtained by the vinegar, our author says, only introduced into his bases a green colour inclining to a yellow.

By the following process a saffron of Mars of the finest red colour is obtained: Let an ounce of iron filings be dissolved in nitrous acid in a glass retort, and distilled over a sand bath to dryness. After having replaced the acid or the dry oxide, and re-distilled it a second and a third time, it is then edulcorated with spirits of wine, and afterwards washed with distilled water.

e, From the *Magnet.*] It is necessary to calcine the magnet before it be introduced into the vitrifications: Having therefore torrefied the magnet during two hours,

hours, it must be washed and dried. It is only employed in the composition of the opal.

f, From *Cobalt.*] The oxide of cobalt is only proper to introduce a blue colour into glass; but this semi-metal is rarely found free from iron and bismuth, and therefore it is first necessary to separate them from it. This is done by calcining the ore of cobalt in order to disengage the arsenic; afterwards the oxide must be distilled in a retort with sal ammoniac, and the iron and the bismuth are found sublimed with this salt. The distillation must be repeated with the sal ammoniac till this salt is no longer coloured yellow. The cobalt which remains in the cornute is then calcined in a potsherd, and becomes a very pure oxide; which being introduced into the base, in the proportion of a 900dth part, gives it a very fine blue colour, the intensity of which may be increased at discretion by the addition of oxide of cobalt. In order to prepare *black enamel* resembling that which is called *black agate* of Iceland; melt together a pound and a half of one of the bases, two ounces of the oxide of cobalt, two ounces of *crocus Martis* prepared with vinegar, and two ounces of manganese.

g, From *Tin.*] The oxide of tin, which is of a white colour, renders opake the glass with which it is melted, and forms white enamel. For this purpose, calcine the putty of tin; then wash and dry it, and sift it through a silk sieve. Take six pounds of the second base, the same quantity of the calcined putty of tin, and 48 grains of manganese.

h, From *Antimony.*] Antimony is only susceptible of vitrification in a certain state of oxidation, and then it produces a reddish or hyacinth coloured glass; but if the antimony be in a state of absolute calx, such as the diaphoretic antimony, then it is no longer vitrifiable, and may be substituted for oxide of tin to make white enamel. M. Fontanieu introduces the glass of antimony in the composition of artificial topazes. For the *oriental topaz*, he takes 24 ounces of the first base, and five drachms of the glass of antimony. To imitate the *topaz of Saxony*, he adds to each ounce of the base five grains of the glass of antimony. For the *topaz of Brazil*, he takes 24 ounces of the first base, one ounce 24 grains of glass of antimony, and 8 grains of the *precipitate of Cassius.*

i, From *Manganese.*] This mineral employed in a small quantity, renders the glass whiter; a larger quantity produces a very fine violet colour, and a still larger dose of it renders the glass black and opake.

There are two ways of preparing manganese. 1. The most simple consists in exposing it to a red heat, and then quenching it with distilled vinegar; it is afterwards dried and powdered, in order to pass it through a silk sieve. 2. Haudiquer de Blancour describes the second manner of preparing the manganese, proper to furnish a red colour, and names it *fusible manganese.* Take of manganese of Piedmont one pound; torrefy and pulverize it; then mix it with a pound of nitre, and calcine the mixture during 24 hours; afterwards wash it repeatedly in warm water, till the water of the lyes has no longer any taste; dry the manganese, and mix with it an equal weight of sal ammoniac; levigate this mixture on a slab of porphyry with oil of vitriol diluted with water to the strength of vinegar. Dry the mixture, and introduce it into a cornute; distil by a graduated fire; and when the sal ammoniac is sublimed weigh it, and add to the mixture an equal quantity. Then distil and sublime as before, and repeat the operation six times, being careful at each time to mix the sal ammoniac and the manganese upon the porphyry with diluted oil of vitriol.

At Tournhault in Bohemia, there is sold a fusible glass of a yellow colour, very like that of the topaz of Brazil, which, when exposed to a degree of fire in a cupel sufficient to redden it, becomes of a very fine ruby colour, more or less deep according to the degree of fire to which it has been exposed. Our author assayed this glass, and found it to contain a great deal of lead, but was not able to discover any gold in it.

III. *Of the different degrees of fire necessary for Factitious Gems.* Our author observes, that there are three degrees of heat very different in their energy. The fire kept up in the wind furnaces in the laboratories of chemists, is less active than that whose effect is accelerated by the means of bellows; and a fire supported by wood, and kept up during 60 hours without interruption, produces singular effects in vitrification, and renders the glass finer and less alterable.

When recourse is had to the forge, in order to operate a vitrification, it is necessary to turn about the crucible from time to time, that the mass may melt equally. Some coal also should be replaced, in proportion as it consumes towards the nozel of the bellows; for without this precaution, we should run the risk of cooling the crucible opposite to the flame, and probably of cracking it, when all the melted mass running among the coals would be totally lost. Though this is the readiest way of melting, it should not be employed out of choice; for the crucible often breaks, or coals get into it, which may reduce the lead to the metallic state.

The wind furnace is either square or round. A small cake of baked clay or brick, of the thickness of an inch, is placed upon the grate; and upon this cake is placed the crucible, surrounded with coals. The degree of heat produced by this furnace is much less than that of the forge: but in order to succeed in the vitrification, M. Fontanieu recommends the use of a furnace described by Kunckel, of which, the interior part is so disposed, that we may place crucibles at three different heights; and the name of *chambers* is given to those steps upon which the crucibles are placed.

It is obvious, that the degree of heat cannot be equal in the said three chambers. In the first or lowest chamber the heat is greatest, afterwards in the next, and lastly, in the highest. We should begin by placing the crucibles according to their size, in these different chambers; by which means the best effect in vitrification is produced.

In order to conduct the fire well, only three billets of white wood should be put into the furnace at a time for the first 20 hours, four billets at a time for the next 20 hours, and six billets for the last 30 hours; in all 60 hours. The furnace is then left to cool, care being taken to stop the air hole with some lute; and in about 48 hours after, when the kiln is quite cold, the crucible is to be withdrawn.

IV. *The Compositions.* 1. For the white diamond: Take

Gem.

Take the base of Mayence. This crystal is very pure, and has no colours.

2. For the yellow diamond: To an ounce of the fourth base, add for colour 25 grains of luna cornea or 10 grains of glass of antimony.

3. For the emerald: 1. To 15 ounces of either of the bases, add for colour one drachm of mountain blue and six grains of glass of antimony; or, 2. To an ounce of the second base, add for colour 20 grains of glass of antimony, and three grains of calx of cobalt.

4. For the sapphire: To 24 ounces of the Mayence base, add for colour two drachms 46 grains of the calx of cobalt.

5. For the amethyst: To 24 ounces of the Mayence base, add for colour four drachms of prepared manganese and four grains of precipitate of Cassius.

6. For the beryl: To 24 ounces of the third base, add for colour 96 grains of glass of antimony and four grains of calx of cobalt.

7. For the black agate: To 24 ounces of either of the bases, add two ounces of the mixture directed above in par. *f*.

8. For the opal: To an ounce of the third base, add for colour 10 grains of luna cornea, two grains of magnet, and 26 grains of absorbent earth.

9. For the oriental topaz: To 24 ounces of the first or third base, add for colour five drachms of glass of antimony.

10. For the topaz of Saxony: To 24 of the same base, add for colour six drachms of the glass of antimony.

11. For the topaz of Brasil: To 24 ounces of the second or third base, add for colour one ounce 24 grains of the glass of antimony and eight grains of precipitate of Cassius.

12. For the hyacinth: To 24 ounces of the base made with rock crystal, add for colour two drachms 48 grains of glass of antimony.

13. For the oriental ruby: 1. To 16 ounces of the Mayence base, add for colour a mixture of two drachms 48 grains of the precipitate of Cassius, the same quantity of crocus Martis prepared in aquafortis, the same of golden sulphur of antimony and of fusible manganese, with the addition of two ounces of mineral crystal: or, 2. To 20 ounces of the base made with flint, add half an ounce of fusible manganese and two ounces of mineral crystal.

14. For the balass ruby: 1. To 16 ounces of the Mayence base, add the above colouring powder, but diminished a fourth part; or, 2. To 20 ounces of the base made with flints, add the same colouring powder, but with a fourth less of the manganese.

The *factitious* gems are easily distinguished from the *natural*, by their softness and fusibility; by their solubility in acids; by their causing only a single refraction of the rays of light; and in many cases, by their specific gravity, which exceeds 2.76 in all precious gems of the first order, as the diamond, ruby, sapphire, &c.

Imitation of Antique GEMS. There has been at different times a method practised by particular persons of taking the impressions and figures of antique gems, with their engravings, in glass of the colour of the original gem. This has always been esteemed a very valuable method, and greatly preferable to the more ordinary ones of doing it on sealing wax or brimstone; but, to the misfortune of the world, this art being a secret only in the hands of some particular persons who got their bread by it, died with them, and every new artist was obliged to re-invent the method; till at length Mr Homberg having found it in great perfection, gave the whole process to the world to be no more forgotten or lost; and since that time it has been very commonly practised in France, and sometimes in other places.

Mr Homberg was favoured in his attempts with all the engraved gems of the king's cabinet; and took such elegant impressions, and made such exact resemblances of the originals, and that in glasses so artfully tinged to the colour of the gems themselves, that the nicest judges were deceived in them, and often took them for the true antique stones. The counterfeit gems also serve, as well as the original one, to make more copies from afterwards; so that there is no end of the numbers that may be made from one; and there is this farther advantage, that the copy may be easily made perfect, though the original should not be so, but should have sustained some damage from a blow or otherwise.

The great care in the operation is to take the impression of the gem in a very fine earth, and to press down upon this a piece of proper glass, softened or half melted at the fire, so that the figures of the impression made in the earth may be nicely and perfectly expressed upon the glass. In general, the whole process much resembles that of the common founders. But when it is brought to the trial, there is found a number of difficulties which were not to be foreseen, and which would not at all affect the common works of the founder. For this purpose, every earth will serve that is fine enough to receive the impressions, and tough enough not to crack in the drying: these all serve for their use, because the metals which they cast are of a nature incapable of mixing with earth, or receiving it into them, even if both are melted together, so that the metal always easily and perfectly separates itself from the mould; but it is very difficult in these casts of glass. They are composed of a matter which differs in nothing from that of the mould, but that it has been run into this form by the force of fire, and the other has not yet been so run, but is on any occasion ready to be so run, and will mix itself inseparably with the glass in a large fire: consequently, if there be not great care used, as well in the choice of the glass as in the manner of using it, when the whole is finished there will be found great difficulty in the separating the glass from the mould, and often this cannot be done without wholly destroying the impression.

All earths run more or less easily in the fire as they are more or less mixed with saline particles in their natural formation. As all salts make earths run into glass, and as it is necessary to use an earth on this occasion for the making a mould, it being also necessary to the perfection of the experiment that this earth should not melt or run, it is our business to search out for this purpose some earth which naturally contains very little salt. Of all the species of earth which Mr Homberg examined on this occasion, none proved so much

much divested of salts, or so fit for the purpose, as the common tripela, or TRIPOLI, used to polish glass and stones. Of this earth there are two common kinds: the one reddish, and composed of several flakes or strata; the other yellowish, and of a simple structure. These are both to be had in the shops. The latter kind is from the Levant; the former is found in England, France, and many other places. The tripela must be chosen soft and smooth to the touch, and not mixed with sandy or other extraneous matter. The yellowish kind is the best of the two, and is commonly called *Venetian tripoli*. This receives the impressions very beautifully; and never mixes with the glass in the operation, which the red kind sometimes does. Mr Homberg usually employed both kinds at once in the following manner: first powder a quantity of the red tripela in an iron mortar, and sifting it through a fine sieve set it by for use; then scrape with a knife, a quantity of the yellow tripela into a sort of powder, and afterwards rub it till very fine in a glass mortar with a glass pestle. The finer this powder is, the finer will be the impression, and the more accurately perfect the cast. The artificer might naturally suppose, that the best method to obtain a perfect fine powder of this earth would be by washing it in water; but he must be cautioned against this. There is naturally in this yellowish tripoli a sort of unctuosity, which when it is formed into a mould keeps the granules together, and gives the whole an uniform glossy surface: now the washing the powder takes away this unctuosity; and though it renders it much finer, it makes it leave a granulated surface, not this smooth one, in the mould; and this must render the surface of the cast less smooth.

When the two tripelas are thus separately powdered, the red kind must be mixed with so much water as will bring it to the consistence of paste, so that it may be moulded like a lump of dough between the fingers; this paste must be put into a small crucible of a flat shape, and about half an inch or a little more in depth, and of such a breadth at the surface as is a little more than that of the stone whose impression is to be taken. The crucible is to be nicely filled with this paste lightly pressed down into it, and the surface of the paste must be strewed over with the fine powder of the yellow tripela not wetted. When this is done, the stone, of which the impression is to be taken, must be laid upon the surface, and pressed evenly down into the paste with a finger and thumb, so as to make it give a strong and perfect impression; the tripela is then to be pressed nicely even to its sides with the fingers, or with an ivory knife. The stone must be thus left a few moments, for the humidity of the paste to moisten the dry powder of the yellow tripela which is strewed over it: then the stone is to be carefully raised by the point of a needle fixed in a handle of wood; and the crucible being then turned bottom upwards, it will fall out, and the impression will remain very beautifully on the tripoli.

If the sides of the cavity have been injured in the falling out of the stone, they may be repaired; and the crucible must then be set, for the paste to dry, in a place where it will not be incommoded by the dust.

The red tripoli being the more common and the cheaper kind, is here made to fill the crucible only to save the other, which alone is the substance fit for taking the impression. When the stone is taken out, it must be examined, to see whether any thing be lodged in any part of the engraving, because if there be any of the tripela left there, there will certainly be so much wanting in the impression. When the crucible and paste are dry, a piece of glass must be chosen of a proper colour, and cut to a size proper for the figure; this must be laid over the mould, but in such a manner that it does not touch the figures, otherwise it would spoil them. The crucible is then to be brought near the furnace by degrees, and gradually heated till it cannot be touched without burning the fingers; then it is to be placed on the furnace under a muffle, surrounded with charcoal. Several of these small crucibles may be placed under one muffle; and when they are properly disposed, the aperture of the muffle should have a large piece of burning charcoal put to it, and then the operator is to watch the process, and see when the glass begins to look bright; this is the signal of its being fit to receive the impression. The crucible is then to be taken out of the fire; and the hot glass must be pressed down upon the mould with an iron instrument to make it receive the regular impression: as soon as this is done, the crucible is to be set at the side of the furnace out of the way of the wind, that it may cool gradually without breaking. When it is cold, the glass is to be taken out, and its edges should be grated round with pincers, which will prevent its flying afterwards, which is an accident that sometimes happens when this caution has been omitted, especially when the glass is naturally tender. The different coloured glasses are of different degrees of hardness, according to their composition; but the hardest to melt are always the best for this purpose, and this is known by a few trials.

If it be desired to copy a stone in relief which is naturally in creux, or to take one in creux which is naturally in relief, there needs no more than to take an impression first in wax or sulphur, and to mould that upon the paste of tripela instead of the stone itself; then proceeding in the manner before directed, the process will have the desired success.

A more simple and easy method than the above, is by taking the casts in gypsum, or plaster of Paris as it is commonly called. For this purpose, the gypsum must be finely pulverized, and then mixed with clear water to the consistence of thick cream. This is poured upon the face of the gem or seal of which the impression is wanted, and which must be previously moistened with oil to facilitate the separation of the cast; and in order to confine the liquid plaster, it is only necessary to pin a slip of oiled paper round the sides of the seal by way of a cap or rim. When the plaster is dry, it is to be taken off, and set before the mouth of the furnace, in order to free it entirely from moisture; when it is fit to be used as a matrix in the same way as that formed with the tripoli earths. Only no crucible or other receptacle is at all necessary; the casts being formed like so many small cakes half an inch thick, and thus put into the furnace with bits of glass upon them. The glass, after coming to a proper heat, is pressed down upon the mould with an iron spatula to receive the desired impression, the pressure requisite being more or less according to the size of the stone. This method has been long practised very successfully, and with

Gem.

with no small emolument, by that ingenious seal engraver Mr Deuchar of Edinburgh. The only respect in which it is inferior to the other more operose and expensive methods, consists in the chance of air bubbles arising in pouring on the plaster; which chance, however, is less in proportion to the fineness of the gypsum employed. When air bubbles do occur, the casts may be laid aside, as it is so easy to replace them.

The application of pastes to multiply and preserve the impressions of camaieux and intaglios, is an object very interesting to artists and to antiquaries, as well as to men of learning and taste in the fine arts.

This art, though only lately restored in any degree of perfection, is of very considerable antiquity. The great prices which the ancients paid for the elegant gems engraved by the celebrated Greek artists, could not but early suggest to them the idea of multiplying their numbers, by taking off their impressions in wax, in sulphur, in plaster, or in clay; but more particularly in coloured glass, or that vitrified substance commonly called *paste*.

As the impressions on paste are durable, and imitate the colours and brilliancy of the original stones, they serve the same purposes as the gems themselves. This art was therefore practised not only by the Greeks, but by all the nations who cultivated Grecian taste.

Many of the finest gems of antiquity are now lost, and their impressions are to be found only on ancient pastes. Great therefore is the value of these pastes. Numerous collections of them have been formed by the curious. Instances of this are found in the Florentine Musæum, in Stosch's work on ancient gems with inscriptions, in Winkelmann's description of Stosch's cabinet, and in the noble collection of Mr Charles Townley in London.

The art of taking impressions of gems seems not to have been altogether lost even in the Gothic ages; for Heraclius, who probably lived in the ninth century, and wrote a book *De coloribus et artibus Romanorum*, teaches in very plain though not elegant terms how to make them. Indeed, some of the few persons who then possessed this art, taking advantage of the ignorance of the times, sold pastes for original gems. Thus the famous emerald of the abbey of Reichnaw near Constance, although a present made by Charlemagne, is now found to be a piece of glass. And thus the celebrated emerald vase in the cathedral of Genoa is likewise found to be a piece of paste (A). The Genoese got this vase at the taking of Cesarea in the year 1101 as an equivalent for a large sum of money; nor was any imposition then suspected, for in the year 1319 they pawned it for 1200 merks of gold.

But this ingenious art, revived indeed in Italy in the time of Laurence of Medici and Pope Leo X. was not cultivated in an extensive manner till the beginning of the present century, when M. Homberg restored it, as already mentioned. In this he is said to have been greatly assisted and encouraged by the then duke of Orleans regent of France, who used to amuse himself with that celebrated chemist in taking off impressions in paste from the king of France's, from his own, and other collections of gems.

According to the French Encyclopedists, M. Clachant the elder, an engraver of some note, who died at Paris in 1781, learned this art from his royal highness, to whose household his father or he seems to have belonged. Mademoiselle Feloix next cultivated this art, and it is believed still carries it on. She had been taught by her father, who in quality of garçon de chambre to the regent had often assisted in the laboratory of his master, where he acquired this knowledge. Her collection consists of 1800 articles.

Baron Stosch, a Prussian, who travelled over Europe in quest of original engraved stones and impressions of ancient gems for the elegant work which he published and Picart engraved (B), was well acquainted with this art. He had taught it to his servant Christian Dehn, who settled at Rome, where he made and sold his well known sulphur impressions and pastes. He had collected 2500 articles. Dolce has arranged them in a scientific order, and given a descriptive catalogue of them.

It was chiefly from Dehn's collection that the taste for sulphurs and pastes has become so universal. They are great objects of study, and often require much learning to explain them. They have unquestionably served to extend and improve the art of engraving on stones; and have been of infinite use to painters, to statuaries, and to other artists, as well as to men of classical learning and fine taste.

It is very difficult to take off impressions, and perfectly to imitate various-coloured cameos. It cannot be properly done in wax, sulphur, plaster, or glass of one colour only. The difficulties arising from their size and form, and from the various nature of the different sorts of glass which do not well unite into different strata, are very numerous: nor could the completest success in this chemical and mechanical branch of the art produce a tolerable cameo. Impressions or imitations, if unassisted by the tool of the engraver, do not succeed: because the undercutting and deep work of most of the originals require to be filled up with clay or wax, that the moulds may come off safe without injuring them. Hence the impressions from these moulds come off hard and destitute of delicacy, sharpness, and precision of outline, till the underworking of the moulder is cut away. But Mr Reiffenstein at Rome, by his genius, perseverance, and the assistance of able artists, has overcome these difficulties; and has had the satisfaction of succeeding, and producing variegated cameos which can hardly be distinguished from the originals.

Mr Lippart of Dresden, an ingenious glazier, and an enthusiast in the fine arts, practised this branch not unsuccessfully; but not finding sufficient encouragement for his pastes of coloured glass, or perhaps from local difficulties in making them well and cheap, he abandoned

(A) See M. de la Condamine's Diss. in Memoir. de l'Acad. Roy. de Paris, 1757.

(B) Gemmæ antiquæ coloratæ, sculptorum nominibus insignitæ, ære incisæ per Bernardum Picart. Amstelodam. 1724, folio.

doned this art. He substituted in its place impressions of fine white alabaster or selenite plaster. Such impressions, when carefully soaked in a solution of white Castile soap, then dried, and rubbed over with a soft brush, take a very agreeable polish. They show the work perhaps to better advantage than red or white sulphurs do; but they are not so durable, and are liable to be defaced by rubbing.

Of these impressions Mr Lippart published three different collections, each of them containing 1000 articles; and to the merit of having increased the number of Madamoiselle Feloix and Christiano Dehn's collections, which are all inserted in his, he added that of employing two learned Germans to arrange and describe them. The first thousand were arranged and described by the late Professor Christ at Leipsic, and the second and third thousand by Professor Heine at Goettingen. Nor did Mr Lippart stop here: but to make the study of antiquity more easy and acceptable to artists, he selected out of the whole collection of 3000, a smaller one of 2000 of the best and more instructive subjects, of which he himself drew up and published a description in German.

But of all the artists and ingenious men who have taken impressions of engraved gems in sulphur and in paste, no one seems to have carried that art to such perfection as Mr James Tassie, a native of Glasgow, who resided in London from the year 1766 till his death. His knowledge in various branches of the fine arts, particularly in that of drawing, naturally led him to it. The elegant portraits which he modelled in wax, and afterwards moulded and cast in paste, and which entirely resemble cameos, are well known to the public.

Mr Tassie, profiting of all the former publications of this sort, and by expence, industry, and access to many cabinets in England and other kingdoms to which former artists had not obtained admission, was enabled to increase his collection of impressions of ancient and modern gems to the number of above 15,000 articles. It is the greatest collection of this kind that ever existed; and serves for all the purposes of artists, antiquaries, scholars, men of taste, and even philosophers. The great demand for his pastes was perhaps owing in the beginning to the London jewellers, who introduced them into fashion by setting them in rings, seals, bracelets, necklaces, and other trinkets.

The reputation of this collection having reached the empress of Russia, she was pleased to order a complete set; which being accordingly executed in the best and most durable manner, were arranged in elegant cabinets, and are now placed in the noble apartments of her imperial majesty's superb palace at Czarsko Zelo.

Mr Tassie, in executing his commission, availed himself of all the advantages which the improved state of chemistry, the various ornamental arts, and the knowledge of the age, seemed to afford. The impressions were taken in a beautiful white enamel composition, which is not subject to shrink or form air bladders; which emits fire when struck with steel, and takes a fine polish; and which shows every stroke and touch of the artist in higher perfection than any other substance. When the colours, mixed colours, and nature of the respective originals, could be ascertained, they were imitated as completely as art can imitate them; insomuch that many of the paste intaglios and cameos in this collection are such faithful imitations, that artists themselves have owned they could hardly be distinguished from the originals. And when the colour and nature of the gems could not be authenticated, the pastes were executed in agreeable, and chiefly transparent, colours; constant attention being bestowed to preserve the outlines, extremities, attributes, and inscriptions.

It was the learned Mr Raspe (from whom this account (c) is taken) who arranged this great collection, and made out the descriptive catalogue. His arrangement is nearly the same with that of the late Abbé Winkelmann, in his decription of the gems which belonged to Baron Stosch. But as modern works were inserted in this collection, he found it necessary to make a few alterations, and added some divisions to those of M. Winkelmann, as will appear from the following conspectus, with which we shall conclude this detail.

I. Ancient Art and Engravings.
- Egyptian hieroglyphics, sacred animals, divinities, priests.
- Basilidian, Gnostic, and other talismans, &c.
- Oriental and barbarous ancient and modern engravings.
- Greek and Roman original copies, and imitations (the Etruscan are classed with the Greek works).
- A, Mythology or fabulous age. Gods, inferior divinities, religious ceremonies.
- B, Heroic age before the siege of Troy.
- C, Siege of Troy.
- D, Historic age. Of Carthage, Greece, Rome, subjects unknown.
- E, Fabulous animals and chimeras.
- F, Vases and urns.

II. Modern Art and Engravings.
- A, Religious subjects.
- B, Portraits of kings and sovereigns.
- C, Portraits of illustrious men in alphabetical order.
- D, Portraits unknown.
- E, Devices and emblems.
- F, Cyphers, arms, supporters, and medley of modern history.

GEMAPPE, a village of Austrian Hainault, three miles west-by-south of Mons, rendered memorable for a victory which the French under General Dumourier obtained over the Austrians, Nov. 5. 1792; in which the carnage on both sides was so dreadful, that three coal pits in the vicinity were filled up with the dead bodies of men and horses.

GEMARA, or GHEMARA, the second part of the TALMUD.

The

(c) Account of the present state and arrangement of Mr James Tassie's collection of pastes and impressions from ancient and modern gems, by R. C. Raspe, London, 1786, 8vo.

Gemara ‖ Geminiani.

The word גמרה *gemara*, is commonly supposed to denote a supplement; but in strictness it rather signifies complement, perfection: being formed of the Chaldee גמר, *gemar*, or *ghemer*, "to finish, perfect, or complete any thing."

The rabbins call the Pentateuch simply the *law*: the first part of the Talmud, which is only an explication of that law, or an application thereof to particular cases, with the decisions of the ancient rabbins thereon, they call the *Mischna*, i. e. "second law:" and the scond part, which is a more extensive and ample explication of the same law, and a collection of decisions of the rabbins posterior to the Mischna, they call *Gemara*, q. d. "perfection, completion, finishing;" because they esteem it the finishing of the law, or an explication beyond which there is nothing farther to be desired.

The Gemara is usually called simply *Talmud*, the common name of the whole work. In this sense we say, there are two Gemaras or Talmuds; that of Jerusalem and that of Babylon: though in strictness the Gemara is only an explication of the Mischna, given by the Jewish doctors in their schools: much as the commentaries of our school divines on St Thomas, or the master of the sentences, are an explication of the writings of those authors.

A commentary, Mons. Tillemont observes, was wrote on the Mischna, by one Johanan, whom the Jews place about the end of the second century; but Fa. Morin proves, from the work itself, wherein mention is made of the Turks, that it was not wrote till the time of Heraclius, or about the year 620; and this is what is called the *Gemara*, or *Talmud of Jerusalem*, which the Jews do not use or esteem much because of its obscurity.

They set a much greater value on the Gemara, or Talmud of Babylon, begun by one Asa; discontinued for 73 years, on occasion of the wars with the Saracens and Persians; and finished by one Josa, about the close of the seventh century. See TALMUD.

Though the name Talmud, in its latitude, includes both the Mischna and the two Gemaras, yet it is properly that of Asa and Josa alone which is meant under that name. This the Jews prize above all their other writings, and even set it on a level with Scripture itself: in effect, they conceive it as the word of God, derived by tradition from Moses, and preserved without interruption to their time. R. Jehuda, and afterwards R. Johanan, R. Asa, and R. Josa, fearing the traditions should be lost in the dispersion of the Jews, collected them into the Mischna and the Gemara. See CARAITES and RABBINISTS.

GEMINI, in *Astronomy*, the TWINS; a constellation or sign of the zodiac, the third in order, representing Castor and Pollux; and it is marked thus, ♊. The stars in the sign Gemini, in Ptolemy's catalogue, are 25; in Tycho's, 25; in Hevelius's, 38; in the Britannic catalogue, 85.

GEMINIANI, a celebrated musician and composer, was born at Lucca in the year 1680. He received his first instructions in music from Alessandro Scarlatti; and after that became a pupil of Carlo Ambrosio Lunati, surnamed *Il Gobbo*, a most celebrated performer on the violin; after which he became a disciple of Corelli, and under him finished his studies on that instrument. In the year 1714 he came to England; where in a short time he so recommended himself by his exquisite performance, that all who professed to love and understand music were captivated with hearing him.—Many of the nobility laid claim to the honour of being his patrons; but he seemed chiefly to attach himself to Baron Kilmansegge, chamberlain to King George I. as elector of Hanover, and a favourite of that prince. In 1716, he published and dedicated to his patron 12 sonatas *a violino violone e cembalo*: the first six with fugues, or double stops as they are vulgarly called; the last with airs of various measures, such as allemandes, courantes, and jiggs. This publication was so well relished by the baron, that he mentioned Geminiani to the king as an excellent performer; in consequence of which our musician had the honour to perform before his majesty, in concert with the celebrated Handel, who played on the harpsichord. But though Geminiani was exceedingly admired, yet he had not a talent at associating music with poetry, nor do we find that he ever became a public performer: he was therefore obliged to depend for his subsistence on the friendship of his patrons and the profits which accrued to him from teaching. He had also the misfortune to be an enthusiast in painting; and the versatility of his temper was such, that, in order to gratify this passion, he not only suspended his studies, and neglected to exercise his talents, but involved himself in debts. In 1727, he was offered the place of master and composer of the state music in Ireland; but this could not be conferred on a Catholic, and Geminiani refused to change his religion: upon which it was given to Matthew Dubourg, a young man who had been one of his pupils, and was a celebrated performer on the violin. Geminiani then set himself to compose parts to the *opera quinta* of Corelli; or, in other words, to make concertos of the first six of his solos. This work he completed, and, with the help of a subscription, at the head of which were the names of the royal family, published in 1726. In 1732, he published his *opera seconda*, which contains a celebrated minuet that goes by his name. He published many other pieces, the profits of which did not much mend his circumstances; but this perhaps was owing to his rambling disposition and enthusiastic fondness of painting. He was also an utter stranger to the business of an orchestra, and had no idea of the labour and pains necessary in the instruction of singers for the performance of music to which they were strangers. The consequence of this was, that a *concerto spirituale*, which he had advertised for his own benefit in 1748, failed in the performance. The audience, however, compassionated his distress, and sat very silent till the books were changed; when the performance was continued with compositions of the author's own, and which he executed in such a manner as was never forgotten. The profits arising from this performance enabled him to take a journey to Paris; where he staid long enough to get plates engraven for a score of solos, and the parts of two operas of concertos. About the year 1755 he returned to England, and advertised them for sale.—In 1761 Geminiani went over to Ireland; and was kindly entertained there by Mr Matthew Dubourg, who had been his pupil, and was then master of the king's band in Ireland. This person through the course

course of his life had ever been disposed to render him friendly offices; and it was but a short time after Geminiani's arrival at Dublin that he was called upon to do him the last. It appears that Geminiani had spent many years in compiling an elaborate treatise on music, which he intended for publication; but soon after his arrival at Dublin, by the treachery of a female servant, who, it was said, was recommended to him for no other end than that she might steal it, it was conveyed away, and could not be recovered. The greatness of this loss, and his inability to repair it, made a deep impression on his mind; and, as it is conjectured, hastened his end; at least he survived it but a short time, ending his days on the 17th of September 1762. The following list comprises the whole of his publications, except two or three articles of small account: Twelve solos for a violin, *opera prima;* six concertos in seven parts, *opera seconda;* six concertos in seven parts, *opera terza;* twelve solos for a violin, *opera quarta;* six solos for a violoncello, *opera quinta;* the same made into solos for a violin: six concertos from his *opera quarta;* six concertos in eight parts, *opera settima;* rules for playing in taste; a treatise on good taste; the art of playing the violin; 12 sonatas from his first solos, *opera undecima;* Ripieno parts to ditto; lessons for the harpsichord; *Guido Armonica;* supplement to ditto; the art of accompaniment, two books; his first two operas of concertos in score; and the Enchanted Forest.—Of his solos the *opera prima* is esteemed the best. Of his concertos some are excellent, others of them scarce pass the bounds of mediocrity. The sixth of the third opera not only surpasses all the rest, but, in the opinion of the best judges of harmony, is the finest instrumental composition extant.

GEMMA, or Bud, in *Botany:* a compendium or epitome of a plant, seated upon the stem and branches, and covered with scales, in order to defend the tender rudiments enclosed from cold and other external injuries, till, their parts being unfolded, they acquire strength, and render any further protection unnecessary.

Buds, together with bulbs, which are a species of buds generally seated upon or near the root, constitute that part of the herb called by Linnæus *hybernacula;* that is, the winter quarters of the future vegetable: a very proper appellation, as it is during that severe season that the tender rudiments are protected in the manner just mentioned.

Plants, considered in analogy to animals, may probably enough be reckoned both viviparous and oviparous. Seeds are the vegetable eggs; buds, living fetuses, or infant plants, which renew the species as certainly as the seeds.

Buds are placed at the extremity of the young shoots, and along the branches, being fixed by a short footstalk upon a kind of brackets, the remainder of the leaves, in the wings or angles of which the buds in question were formed the preceding year. They are sometimes placed single; sometimes two by two, and those either opposite or alternate; sometimes collected in greater numbers in whirls or rings.

With respect to their construction, buds are composed of several parts artificially arranged. Externally, we find a number of scales that are pretty hard, frequently armed with hairs, hollowed like a spoon, and placed over each other like tiles. These scales are fixed into the inner plates of the bark, of which they appear to be a prolongation. Their use is to defend the internal parts of the bud; which, being unfolded, will produce, some, flowers, leaves, and stipulæ; others, footstalks and scales. All these parts, while they remain in the bud, are tender, delicate, folded over each other, and covered with a thick clammy juice, which is sometimes resinous and odoriferous, as in the tacamahac tree. This juice serves not only to defend the more tender parts of the embryo plant from cold, the assaults of insects, and other external injuries; but likewise from excessive perspiration, which, in its young and infant state, would be very destructive. It is conspicuous in the buds of horse chesnut, poplar, and willow trees.

In general, we may distinguish three kinds of buds; that containing the flower, that containing the leaves, and that containing both flower and leaves.

The first, termed *gemma florifera*, and by the French *bouton à fleur* or *à fruit*, contains the rudiments of one or several flowers, folded over each other, and surrounded with scales. In several trees, this kind of bud is commonly found at the extremity of certain small branches, which are shorter, rougher, and less garnished with leaves, than the rest. The external scales of this species of bud are harder than the internal; both are furnished with hairs, and in general more swelled than those of the second sort. The bud containing the flower too is commonly thicker, shorter, almost square, less uniform, and less pointed; being generally terminated obtusely. It is called by Pliny *oculus gemmæ;* and is employed in that species of grafting called *inoculation*, or *budding*.

The second species of bud, viz. that containing the leaves, termed *gemma folifera*, and by the French *bouton à feuilles* or *à bois*, contains the rudiments of several leaves, which are variously folded over each other, and outwardly surrounded by scales, from which the small stipulæ that are seated on the foot of the young branches are chiefly produced. These buds are commonly more pointed than the former sort. In the hazel nut, however, they are perfectly round; and in horse chesnut, very thick.

The third sort of bud is smaller than either of the preceding; and produces both flowers and leaves, though not always in the same manner. Sometimes the flowers and leaves are unfolded at the same time. This mode of the flower and leaf bud is termed by Linnæus *gemma folifera et florifera*. Sometimes the leaves proceed or emerge out of this kind of bud upon a small branch, which afterwards produces flowers. This mode of the flower and leaf bud is termed by Linnæus *gemma folifera florifera*, and is the most common bud of any.

Such buds as produce branches adorned only with leaves, are called *barren;* such as contain both leaves and flowers, *fertile*. From the bulk of the bud we may often with ease foretel whether it contains leaves only, or leaves and flowers together, as in cherry and pear trees.

Neither the buds produced on or near the root, called by some authors *turiones*, nor those produced on the trunk, and from the angles or wings of the leaves, contain, in strict propriety, an entire delineation of the plant: since the roots are wanting; and in various buds, Gemma.

buds, as we have seen, shoots are contained with leaves only, and not with flowers: but as a branch may be considered as a part similar to the whole plant, and, if planted, would in process of revegetation exhibit or produce roots and flowers, we may in general allow, that the bud contains the whole plant, or the principles of the whole plant, which may be unfolded *ad libitum*; and thus resembles the seed, in containing a delineation of the future plant in embryo: for although the bud wants a radicle, or plumula, of which the seed is possessed, yet it would undoubtedly form one, if planted in the earth. But as the medullary part adhering to the bud is too tender, and by the abundance of juice flowing into it from the earth would be disposed to putrefaction, the buds are not planted in the soil, but generally inserted within the bark of another tree; yet placed so that the production of the marrow, or pith, adhering to them, may be inserted into the pith of the branch in which the fissure or cleft is made; by which means there is a large communication of juice. This propagation by gems or buds, called *inoculation*, is commonly practised with the first sort of buds above described.

From the obvious uses of the buds, we may collect the reason why the Supreme Author of nature has granted this sort of protection to most of the trees that are natives of cold climates: and, on the other hand, denied it to such as, enjoying a warm benign atmosphere, have not the tender parts of their embryo shoots exposed to injuries and depredations from the severities of the weather. Of this latter kind are the plants of the following list; some of them very large trees; others smaller woody vegetables, of the shrub and under-shrub kind: Citron, orange, lemon, cassava, mock orange, blad apple, shrubby swallow-wort, alaternus, shrubby geraniums, berry-bearing alder, Christ's thorn, Syrian mallow, boabab or Ethiopian sour gourd, justicia, mild sena, the acacias and sensitive plant, coral tree, stinking bean trefoil, medicago, oleander, viburnum, sumach, ivy, tamarisk, heath, Barbadoes cherry, lavatera, rue, shrubby nightshade, Guinea henweed, cypress, lignum vitæ, and savine, a species of juniper.

On annual plants, whose root as well as stalk perishes after a year, true buds are never produced; in their stead, however, are produced small branches, like a little feather, from the wings of the leaves, which wither without any farther expansion if the plants climb and have no lateral branches; but if, either by their own nature or from abundance of sap, the plants become branched, the ramuli just mentioned obtain an increase similar to that of the whole plant.

The same appearance obtains in the trees of warm countries, such as those enumerated in the above list, in which a plumula, or small feather, sends forth branches without a scaly covering; as, in such countries, this tender part requires no defence or protection from cold. A scaly covering then is peculiar to buds, as it protects the tender embryo enclosed from all external injuries. When we therefore speak of trees having buds that are naked or without scales, our meaning is the same as if we had said that they have no buds at all.

The buds that are to be unfolded the following year, break forth from the evolved buds of the present year, in such a manner as to put on the appearance of small eminences in the wings or angles of the leaves. These eminences or knots grow but little during the summer; as, in that season, the sap is expended on the increase of the parts of the plant: but in autumn, when the leaves begin to wither and fall off, the buds, placed on the wings, increase; and the embryo plant contained in the bud is so expanded, that the leaves and flowers, the parts to be evolved the following year, are distinctly visible. Thus in horse chesnut the leaves, and in cornel tree the flowers, are each to be observed in their respective buds.

As each bud contains the rudiments of a plant, and would, if separated from its parent vegetable, become every way similar to it; Linnæus, to show the wonderful fertility of nature, has made a calculation, by which it appears, that, in a trunk scarcely exceeding a span in breadth, 10,000 buds (that is, herbs) may be produced. What an infinite number, then, of plants might be raised from a very large tree!

Gemmatio.

GEMMATIO, from *gemma*, "a bud;" a term used by Linnæus, expressive of the form of the buds, their origin, and their contents. It includes both those properly called *buds*, and those which are seated at the roots, styled *bulbs*.

As to the origin of buds, they are formed either of the footstalks of the leaves, of stipulæ, or of scales of the bark. Their contents have been already discovered, in the preceding article, to be either flowers, leaves, or both.

GEMONIÆ SCALÆ, or *Gradus* GEMONII, among the Romans, was much the same as gallows or gibbet in England.—Some say they were thus denominated from the person who raised them; others, from the first criminals that suffered on them; and others, from the verb *gemo*, "I sigh or groan."

The *gradus gemonii*, according to Publius Victor or Sextus Rufus, was a place raised on several steps, from whence they precipitated their criminals; others represent it as a place whereon offenders were executed, and afterwards exposed to public view. The *gemoniæ scalæ* were in the tenth region of the city, near the temple of Juno. Camillus first appropriated the place to this use, in the year of Rome 358.

GENDARMES, or GENS D'ARMES, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour; (see *Scots* GENDARMES, *infra*.) These troops were commanded by captain lieutenants, the king and the princes of the blood being their captains; the king's troop, besides a captain-lieutenant, had two sublieutenants, three ensigns, and three guidons.

Grand GENDARMES, latterly were a troop composed of 250 gentlemen; the king himself was their captain, and one of the first peers their captain-lieutenant, who had under him two lieutenants, three ensigns, three guidons, and other officers.

Small GENDARMES, were the Scots gendarmes, the queen's, the dauphin's, the gendarmes of Anjou, Burgundy, the English and Flemish gendarmes, having each a captain lieutenant, sub-lieutenant, ensign, guidon, and quarter-master.

Scots GENDARMES, were originally instituted by Charles VII. of France, about the middle of the 15th century,

century, and formed a part of his guard; in which station also they acted under other princes. It was their prerogative to take precedence of all the companies of the gendarmerie of France; and, on particular occasions, they even preceded the two companies of the king's mousquetaires. The sons of the Scottish monarchs were the usual captains of this company; and, after Mary's accession to the throne, its command belonged to them as a right. It was thence that James VI. made a claim of it for his son Prince Henry. This honour, and its emoluments, were also enjoyed by Charles I. and the next in command to this prince was Louis Stuart duke of Lennox. George Gordon marquis of Huntly, succeeded the duke of Lennox in the year 1624, and took the title of captain or commander in chief when Charles I. mounted the English throne. It is not certain whether Charles II. was ever captain of this company; but it was conferred on his brother the duke of York, who was captain of the Scots gendarmes till the year 1667, when he resigned his commission into the hands of the French king. Since that time no native of Great Britain has enjoyed this command. See *Scots* GUARDS.

All the different gendarmeries are now abolished, in consequence of the reforming systems that have lately taken place in France.

GENDER, among grammarians, a division of nouns, or names, to distinguish the two sexes.

This was the original intention of gender: but afterwards other words, which had no proper relation either to one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor* in Latin is feminine, but *arbre* in French is masculine; and *dens* in Latin is masculine, but *dent* in French is feminine.

The oriental languages frequently neglect the use of genders, and the Persian language has none at all.

The Latins, Greeks, &c. generally content themselves to express the different genders by different terminations; as *bonus equus*, "a good horse;" *bona equa*, "a good mare," &c. But in English we frequently go further, and express the difference of sex by different words: as boar, sow; boy, girl; buck, doe; bull, cow; cock, hen; dog, bitch, &c.—We have only about 24 feminines, distinguished from the males, by the variation of the termination of the male into *ess;* of which number are abbot, abbess; count, countess; actor, actress; heir, heiress; prince, princess, &c. which is all that our language knows of any thing like genders.

The Greek and Latin, besides the masculine and feminine, have the neuter, common, and the doubtful gender; and likewise the epicene, or promiscuous, which under one single gender and termination includes both the kinds.

GENEALOGY, an enumeration of a series of ancestors; or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

The word is Greek, γενεαλογια; which is formed of γενος, "race or lineage," and λογος, "discourse."

In divers chapters and military orders, it is required, that the candidates produce their genealogy, to show that they are noble by so many descents.

GENEALOGICA ARBOR, or *Tree of Consanguinity*, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c. The genealogical degrees are usually represented in circles, ranged over, under, and aside each other. This the Greeks called *stemmata*, a word signifying crown, garland, or the like. See the articles CONSANGUINITY and DESCENT, and the plates there referred to.

GENEP, a strong town of Germany, in the circle of Westphalia, subject to the king of Prussia. E. Long. 4. 29. N. Lat. 51. 42.

GENERAL, an appellation given to whatever belongs to a whole genus.

GENERAL *Assembly*. See ASSEMBLY.

GENERAL *Charge*, in *Law*. See *CHARGE to enter Heir*.

GENERAL *Terms*, among logicians, those which are made the signs of general ideas. See LOGIC and METAPHYSICS.

GENERAL *Warrant*. See WARRANT.

GENERAL *of an Army*, in the art of WAR, he who commands in chief. See the article WAR, where his office and duties are particularly explained.

GENERAL *of the Artillery*. See ORDNANCE.

GENERAL *of Horse*, and GENERAL *of Foot*, are posts next under the general of the army, and these have upon all occasions an absolute authority over all the horse and foot in the army.

Adjutant GENERAL, one who attends the general, assists in council, and carries the general's orders to the army. He distributes the daily orders to the majors of brigade. He is likewise charged with the general detail of the duty of the army. The majors of brigade send every morning to the adjutant general an exact return, by battalion and company, of the men of his brigade. In a day of battle the adjutant general sees the infantry drawn up; after which, he places himself by the general, to receive any orders which may regard the corps of which he has the detail. In a siege, he orders the number of workmen demanded, and signs the warrant for their payment. He receives the guards of the trenches at their rendezvous, and examines their condition; he gives and signs all orders for parties. He has an orderly serjeant from each brigade of infantry in the line, to carry such orders as he may have occasion to send from the general.

Lieutenant GENERAL, is the next in command after the general; and provided he should die or be killed, the order is, that the oldest lieutenant general shall take the command. This office is the first military dignity after that of general. One part of their function is, to assist the general with their counsel: they ought therefore, if possible, to possess the same qualities with the general himself; and the more, as they often command armies in chief.

The number of lieutenant generals has been multiplied of late in Europe, in proportion as the armies have become numerous. They serve either in the field, or in sieges, according to the dates of their commissions. In battle, the oldest commands the right wing of the army, the second the left wing, the third the centre, the

General. the fourth the right wing of the second line, the fifth the left wing, the sixth the centre; and so on. In sieges, the lieutenant generals always command the right of the principal attack, and order what they judge proper for the advancement of the siege during the 24 hours they are in the trenches: except the attacks, which they are not to make without an order from the general in chief.

Lieutenant GENERAL *of the Ordnance*. See ORDNANCE.

Lieutenant GENERAL *of Artillery*, is, or ought to be, a very great mathematician, and an able engineer; to know all the powers of artillery; to understand the attack and defence of fortified places, in all its different branches; how to dispose of the artillery in the day of battle to the best advantage; to conduct its march and retreat; as also to be well acquainted with all the numerous apparatus belonging to the train, and to the laboratory, &c.

Major GENERAL, the next officer to the lieutenant general. His chief business is to receive orders from the general, or in his absence from the lieutenant general of the day; which he is to distribute to the brigade majors, with whom he is to regulate the guards, convoys, detachments, &c. On him rests the whole fatigue and detail of duty of the army roll. It is the major general of the day who is charged with the encampment of the army, who places himself at the head of it when they march, who marks out the ground of the camp to the quartermaster general, and who places the new guards for the safety of the camp.

The day the army is to march, he dictates to the field officers the order of the march, which he has received from the general, and on other days gives them the parole.

In a fixed camp he is charged with the foraging, with reconnoitring the ground for it, and posting the escorts, &c.

In sieges, if there are two separate attacks, the second belongs to him; but if there is but one, he takes, either from the right or left of the attack, that which the lieutenant general has not chosen.

When the army is under arms, he assists the lieutenant general, whose orders he executes.

If the army marches to an engagement, his post is at the head of the guards of the army, until they are near enough to the enemy to rejoin their different corps; after which he retires to his own proper post: for the major generals are disposed on the order of battle as the lieutenant generals are; to whom, however, they are subordinate, for the command of their divisions. The major-general has one aid-de-camp, paid for executing his orders.

GENERAL is also used for a particular march, or beat of drum; being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

GENERAL is likewise an appellation by which officers in law, in the revenues, &c. are distinguished; as *attorney general*, *solicitor general*, &c. *receiver general*, *comptroller general*, &c. See ATTORNEY, &c.

GENERAL is also used for the chief of an order of monks, or of all the houses and congregations established under the same rule. Thus we say, the general of the Franciscans, Cistertians, &c.

Generalissimo. GENERALISSIMO, called also *captain general*, and simply *general*, is an officer who commands all the military powers of a nation; who gives orders to all the other general officers; and receives no orders himself but from the king.

M. Balzac observes, that the cardinal de Richelieu first coined this word, of his own absolnte authority, upon his going to command the French army in Italy.

Generation. GENERATE, in *Music*, is used to signify the operation of that mechanical power in nature, which every sound has in producing one or more different sounds. Thus any given sonnd, however simple, produces along with itself, its octave, and two other sounds extremely sharp, viz. its twelfth above, that is to say, the octave of its fifth; and the other the seventeenth above, or, in other words, the double octave of its third major.

Whether we suppose this procreation of sounds to result from an aptitude in the texture and magnitude of certain particles in the air, for conveying to our ears vibrations that bear those proportions, one to another, as being determined at once by the partial and total oscillations of any musical string; or from whatever economy of nature we choose to trace it; the power of one sound thus to produce another, when in action, is said to *generate*. The same word is applied, by Signior Tartini and his followers, to any two sounds which, simultaneously heard, produce a third.

GENERATED, or GENITED, is used, by some mathematical writers, for whatever is produced, either in arithmetic, by the multiplication, division, or extraction of roots; or in geometry, by the invention of the contents, areas, and sides; or of extreme and mean proportionals, without arithmetical addition and subtraction.

GENERATING LINE, or FIGURE, in *Geometry*, is that which, by its motion of revolution, produces any other figure, plane or solid. See GENESIS.

GENERATION, in *Physiology*, the act of procreating and producing a being similar to the parent. See ANATOMY, N° 157.

GENERATION *of Fishes*. See COMPARATIVE *Anatomy*, N° 304, and ICHTHYOLOGY.

GENERATION *of Plants*. See BOTANY.

GENERATION *of Insects*. See COMPARATIVE *Anatomy*, p. 312, and ENTOMOLOGY, p. 234.

Parts of GENERATION. See ANATOMY, N° 157.

GENERATION, in *Mathematics*, is used for formation or production. Thus we meet with the generation of equations, curves, solids, &c.

GENERATION, in *Theology*. The Father is said by some divines to have produced his Word or Son from all eternity, by way of generation; on which occasion the word *generation* raises a peculiar idea: that procession, which is really effected in the way of understanding, is called *generation*, because, in virtue thereof, the Word becomes like to him from whom he takes this original; or, as St Paul expresses it, is the figure or image of his substance, i. e. of his being and nature. And hence it is, they say, that the second Person in the Trinity is called the Son.

GENERATION is also used, though somewhat improperly, for genealogy, or the series of children issued from the same stock. Thus the gospel of St Matthew commences with the book of the generation of Jesus Christ,

Christ, &c. The latter and more accurate translators, instead of *generation* use the word *genealogy*.

Generation is also used to signify a people, race, or nation, especially in the literal translations of the Scripture, where the word generally occurs wherever the Latin has *generatio*, and the Greek γενεσις. Thus, "A wicked and perverse generation seeketh a sign," &c. "One generation passes away, and another cometh," &c.

Generation is also used in the sense of an age, or the ordinary period of man's life. Thus we say, "to the third and fourth generation." In this sense historians usually reckon a generation the space of 33 years or thereabouts. See Age.

Herodotus makes three generations in a hundred years; which computation appears from the latter authors of political arithmetic to be pretty just.

GENERATOR, in *Music*, signifies the principal sound or sounds by which others are produced. Thus the lowest C for the treble of the harpsichord, besides its octave, will strike an attentive ear with its twelfth above, or G in alt, and with its seventeenth above, or E in alt. The C, therefore, is called their *generator*, the G and E its products or harmonics. But in the approximation of chords, for G, its octave below is substituted, which constitutes a fifth from the generator, or lowest C; and for E, is likewise substituted its fifteenth below, which, with the above-mentioned C, forms a third major. To the lowest notes, therefore, exchanged for those in alt by substitution, the denominations of products or harmonics are likewise given, whilst the C retains the name of their *generator*. But still according to the system of Tartini, two notes in concord, which when sounded produce a third, may be termed the *concurring generators* of that third. (See *Generation Harmonique, par M. Rameau;* see also that delineation of Tartini's system called The Power and Principles of Harmony.

GENERICAL name, in *Natural History*, the word used to signify all the species of natural bodies, which agree in certain essential and peculiar characters, and therefore all of the same family or kind; so that the word used as the generical name equally expresses every one of them, and some other words expressive of the peculiar qualities or figures of each are added, in order to denote them singly, and make up what is called the specific name. See Botany and *Natural History*.

GENESIS, the first book of the Old Testament, containing the history of the creation, and the lives of the first patriarchs.

The book of Genesis stands at the head of the Pentateuch. Its author is held to be Moses: it contains the relation of 2369 years, viz. from the beginning of the world to the death of Joseph. The Jews are forbidden to read the beginning of Genesis, and the beginning of Ezekiel, before 30 years of age.

The Hebrews call this book *Bereschith*, because it begins with that word, which in their language signifies *in principio*, or "in the beginning." The Greeks give it the name *Genesis*, Γενεσις, q. d. production, generation, because it begins with the history of the production or generation of all beings.

This book, besides the history of the creation, contains an account of the original innocence and fall of man; the propagation of mankind; the rise of religion; the general defection and corruption of the world; the deluge; the restoration of the world; the division and peopling of the earth; and the history of the first patriarchs to the death of Joseph. It was easy for Moses to be satisfied of the truth of what he delivers in this book, because it came down to him through a few hands; for from Adam to Noah there was one man, viz. Methuselah, who lived so long as to see them both: in like manner Shem conversed with Noah and Abraham; Isaac with Abraham and Joseph, from whom the records of this book might easily be conveyed to Moses by Amram, who was contemporary with Joseph.

Genesis, in *Geometry*, denotes the formation of a line, plane, or solid, by the motion or flux of a point, line, or surface. See Fluxions.

The genesis or formation, *e. gr.* of a globe or sphere, is conceived by supposing a semicircle to revolve upon a right line, drawn from one extreme thereof to the other, called its axis, or axis of circumvolution: the motion or revolution of that semicircle is the genesis of the sphere, &c.

In the genesis of figures, &c. the line or surface that moves is called the *describent;* and the line round which, or according to which, the revolution or motion is made, the *dirigent*.

GENET, Gennet, or *Jennet*, in the manege, denotes a small-sized well-proportioned Spanish horse.

To ride *à la genette*, is to ride after the Spanish fashion, so short, that the spurs bear upon the horse's flank.

GENETHLIA, in antiquity, a solemnity kept in memory of some person deceased.

GENETHLIACI, in *Astrology*, persons who erect horoscopes, or pretend to foretel what shall befal a man by means of the stars which presided at his nativity. The word is formed of the Greek γενεθλη, *origin, generation, nativity.*

The ancients called them *Chaldæi*, and by the general name *mathematici:* accordingly, the several civil and canon laws, which we find made against the mathematicians, only respect the *genethliaci* or astrologers.

They were expelled Rome by a formal decree of the senate; and yet found so much protection from the credulity of the people, that they remained therein unmolested. Hence an ancient author speaks of them as *hominum genus quod in civitate nostra semper et vetabitur et retinebetur.*

GENETTE, in *Zoology*. See Viverra, Mammalia *Index*.

GENEVA, a city of Switzerland, on the confines of France and Savoy, situated in 6° 9′ E. Long. and 46° 12′ 9″ N. Lat. It stands on the banks of the river Rhone, just at the place where the latter issues from the lake which takes its name from the city; and part of it is built on an island in the river. It is handsome, well fortified, and pretty large; the streets in general are clean and well paved, but the principal one is encumbered with a row of shops on each side between the carriage and foot-path. The latter is very wide, and protected from the weather by great wooden penthouses projecting from the roofs; which, though very convenient, give the street a dark and dull appearance. The houses are generally constructed of freestone, with basements of limestone; the gutters, spouts,

ridges,

Geneva. ridges, and outward ornaments, being made of tinned iron. Some of them have arched walks or piazzas in front. The place called *Treille* is very agreeable, being planted with linden trees, and commanding a fine prospect of the lake, with several ranges of rocks rising behind one another, some covered with vineyards and herbage, and others with snow, having openings between them. Immediately below Geneva the Rhone is joined by the Arve, a cold and muddy stream rising among the Alps, and deriving a considerable part of its waters from the Glaciers. The Rhone is quite clear and transparent, so that the muddy water of the Arve is distinguishable from it even after they have flowed for several miles together. There are four bridges over the Rhone before it joins the Arve; and from it the city is supplied with water by means of an hydraulic machine, which raises it 100 Paris feet above its level. The principal buildings are, 1. The maison de ville, or townhouse, a plain ancient edifice, with large rooms, in which the councils assemble, and public entertainments are held; and in one of them a weekly concert is held by subscription during the winter. The ascent to the upper story is not by steps but a paved acclivity: which, however, is so gentle, that horses and mules can go up to the top. 2. The church of St Peter's, formerly the cathedral, is an ancient Gothic building, with a modern portico of seven large Corinthian columns of red and white marble from Roche. The only thing remarkable in the inside is the tomb of Henry duke of Rohan. 3. The arsenal is in good order, and supplied with arms sufficient for 12,000 men. There are many ancient suits of armour; and the scaling ladders, lanthorns, hatchets, &c. used by the Savoyards in their treacherous attempt on the city in the year 1602, to be afterwards noticed, are here preserved. The magazines contain 110 cannon, besides mortars. 4. The hospital is a large handsome building, by which and other charities near 4000 poor people are maintained. 5. The fortifications on the side of Savoy are of the modern construction, but are commanded by some neighbouring grounds. On the side of France they are old fashioned, and at any rate are rather calculated to prevent a surprise than to sustain a regular siege. There are three gates, towards France, Savoy, and Switzerland; and the access to the lake is guarded by a double jetty and chain.

The territory belonging to this city contains about seven square leagues, and is divided into nine parishes; the town is by far the most populous in Switzerland, but less so than it was before the French revolution, the number of inhabitants being now about 22,800. It has a small district dependent on it, but this does not contain above 16,000. The adjacent country is extremely beautiful, and has many magnificent views arising from the different positions of the numerous hills and mountains with regard to the town and lake. The inhabitants were formerly distinguished into four classes, viz. citizens, burgesses, inhabitants, and natives; and since the revolution in 1782, a fifth class named *domicilius*, has been added, who annually receive permission from the magistrates to reside in the city. The citizens and burgesses alone, however, are admitted to a share in the government; those called *inhabitants* are strangers allowed to settle in the town with certain privileges; and the *natives* are the sons of those inhabitants, who possess additional advantages. The people are very active and industrious, carrying on an extensive commerce.

State of learning in Geneva. This city is remarkable for the number of learned men it has produced. The reformed doctrines of religion were very early received in it, being preached there in 1533 by William Farel and Peter Viret of Orbe, and afterwards finally established by the celebrated John Calvin. Of this reformer Voltaire observes, that he gave his name to the religious doctrines first broached by others, in the same manner that Americus Vesputius gave name to the continent of America, which had formerly been discovered by Columbus. It was by the assiduity of this celebrated reformer, and the influence that he acquired among the citizens, that a public academy was first established in the city, where he, Theodore Beza, and some of the more eminent first reformers, read lectures with uncommon success. The intolerant spirit of Calvin is well known; but little of it now appears in the government of Geneva: on the contrary, it is the most tolerating of all the estates in Switzerland, being the only one of them which permits the public exercise of the Lutheran religion. The advantages of the academy at Geneva are very conspicuous among the citizens at this day, even the lower class of them being exceedingly well informed; so that, according to Mr Coxe, there is not a city in Europe where learning is so generally diffused. "I received great satisfaction (says he) in conversing even with several tradesmen upon topics both of literature and politics; and was astonished to find in this class of men so uncommon a share of knowledge; but the wonder ceases when we are told that all of them were educated at the public academy." In this seminary the industry and emulation of the student are excited by the annual distribution of prizes to those who distinguish themselves in each class. The prizes consist of small medals, but are conferred with such solemnity as cannot fail to produce a striking effect on the minds of youth. There is also a public library to which the citizens have access, and which undoubtedly tends greatly to that universal diffusion of learning so remarkable among the inhabitants. It was founded by Bonnivard, remarkable for his sufferings in the cause of the liberties of his country. Having been a great antagonist of the dukes of Savoy, against whom he asserted the independence of Geneva, he had the misfortune at last to be taken prisoner, and was imprisoned for six years in a dungeon below the level of the lake, in the castle of Chillon, which stands on a rock in the lake, and is connected with the land by a drawbridge. In 1536 this castle was taken from Charles III. of Savoy by the canton of Berne, assisted by the Genevans, who furnished a frigate (their whole naval force) to besiege it by water. Bonnivard was now taken from his dungeon, where by constant walking backward and forward, his only amusement, he had worn a hollow in the floor which consisted of solid rock. Bonnivard considered the hardships he had endured as ties which endeared him to the city, and became a principal promoter of the reformation by the mild methods of persuasion and instruction. He closed his benefactions by the gift of his books and manuscripts, and bequeathing his fortune towards the establishment and support of the seminary. His works, which chiefly relate to the history

Geneva.

history of Geneva, are still preserved with great care and reverence. The library contains 25,000 volumes, with many curious manuscripts, of which an account has been published by the reverend M. Sennebier the librarian, who has likewise distinguished himself by several literary works. Messrs Bonnet, Saussure, Mallet, and De Luc, are the other most distingnished literary geniuses of which Geneva can boast. The last is particularly remarkable for the perfection to which he has brought the barometer, and which is now so great, that very little seems possible to be done by any body else. His cabinet merits the attention of naturalists, as containing many rare and curious specimens of fossils, which serve to illustrate the theory of the globe. It may be divided into three parts: 1. Such as enable the naturalist to compare the petrifactions of animals and vegetables with the same bodies which are still known to exist in our parts of the globe. 2. To compare these petrifactions of animals with the same bodies which are known to exist in different countries. 3. To consider the petrifactions of those bodies which are no longer known to exist. The second part comprehends the stones under three points of view: 1. Those of the primitive mountains, which contain no animal bodies; 2. Those of the secondary mountains, which contain only marine bodies; 3. Those which contain terrestrial bodies. The third part contains the lavas and other volcanic productions; which are distinguished into two classes: 1. Those which come from volcanoes now actually burning; 2. Those from extinguished volcanoes.

Account of De Luc's cabinet.

History and government of Geneva.

In the time of Charles the Great, the city and territory of Geneva made part of his empire; and, under his successors, it became subject to the German emperors. By reason of the imbecility of these princes, however, the bishops of Geneva acquired such authority over the inhabitants, that the emperor had no other means of counterbalancing it than by augmenting the privileges of the people. In these barbarous ages also the bishops and counts had constant disputes, of which the people took the advantage; and by siding sometimes with one, and sometimes with the other, they obtained an extension of their privileges from both. The house of Savoy at length purchased the territory, and succeeded the counts with additional power: against them therefore the bishops and people united in order to resist their encroachments; and, during this period, the government was strangely complicated, by reason of the various pretensions of the three parties. The counts of Savoy, however, had at last the address to dissolve the union between the bishops and citizens, by procuring the episcopal see for their brothers, and even their illegitimate children; by which means their power became gradually so extensive, that towards the commencement of the 16th century, Charles III. of Savoy (though the government was accounted entirely republican) obtained an almost absolute authority over the people, and exercised it in a most unjust and arbitrary manner. Thus violent commotions took place; and the citizens became divided into two parties, one of which, viz. the patriots, were styled *Eidgenossen* or *confederates;* the partisans of Savoy being disgraced by the appellation of *Mamelucs* or *slaves*. The true period of Genevan liberty may therefore be considered as commencing with the treaty concluded with Berne and Friburg in the year 1526; in consequence of which the duke was in a short time deprived of his authority, the bishop driven from the city, and the reformed religion and a republican form of government introduced. A long war commenced with Savoy on this account; but the Genevans proved an overmatch for their enemies by their own bravery and the assistance of the inhabitants of Berne. In 1584, the republic concluded a treaty with Zurich and Berne, by which it is allied to the Swiss cantons. The house of Savoy made their last attempt against Geneva in 1602, when the city was treacherously attacked in the night time during a profound peace. Two hundred soldiers had scaled the walls, and got into the town before the alarm was given; but they were repulsed by the desperate valour of a few citizens, who perished in the encounter. A petard had been fastened to one of the gates by the Savoyards; but the gunner was killed before it could be discharged. The war occasioned by this treachery was next year concluded by a solemn treaty, which has ever since been observed on both sides: though the independence of Geneva was not formally acknowledged by the king of Sardinia till the year 1754.

The restoration of tranquillity from without, in consequence of the above treaty, was however soon followed by the flames of internal discord, so common in popular governments; so that during the whole of the last century the history of Geneva affords little more than an account of the struggles betwixt the aristocratical and popular parties. About the beginning of the present century the power of the grand council was become almost absolute; but in order to restrain its authority, an edict was procured in 1707 by the popular party, enacting, that every five years a general council of the citizens and burghers should be summoned to deliberate upon the affairs of the republic. In consequence of this law a general assembly was convened in 1712; and the very first act of that assembly was to abolish the edict by which they had been convened. A proceeding so extraordinary can scarcely be accounted for on the principles of popular fickleness and inconstancy. Rousseau, in his Miscellaneous Works, ascribes it to the artifices of the magistrates, and the equivocal terms marked upon the billets then in use. For the question being put, "Whether the opinion of the councils for abolishing the periodical assemblies should pass into a law?" the words *approbation* or *rejection*, put upon the billets by which the votes were given, might be interpreted either way. Thus, if the billet was chosen on which the word *approbation* was written, the opinion of the councils which rejected the assemblies was approved; and by the word *rejection*, the periodical assembly was rejected of course. Hence several of the citizens complained that they had been deceived, and that they never meant to reject the general assembly, but only the opinion of the councils.

In consequence of the abolition of the general assemblies, the power of the aristocratical party was greatly augmented; till at length the inhabitants exerting themselves with uncommon spirit and perseverance, found means to limit the power of the magistrates, and enlarge their own rights. In 1776, as Mr Cox informs us, the government might be considered as a mean betwixt

Geneva.

4 Sketch of the government in 1776.

twixt that of the aristocratical and popular cantons of Switzerland. The members of the senate, or little council of 25, enjoyed in their corporate capacity several very considerable prerogatives. By them half the members of the great council were named; the principal magistrates were supplied from their own body; they convoked the great and general councils, deliberating previously upon every question which was to be brought before these councils. They were vested also with the chief executive power, the administration of finances, and had in a certain degree the jurisdiction in civil and criminal causes. Most of the smaller posts were likewise filled by them; and they enjoyed the sole privilege of conferring the burghership. These, and other prerogatives, however, were balanced by those of the great council and the privileges of the general council. The former had a right to choose the members of the senate from their own body; receiving appeals in all causes above a certain value, pardoning criminals, &c. besides which they had the important privilege of approving or rejecting whatever was proposed by the senate to be laid before the people.

The general council or assembly of the people is composed of the citizens and burghers of the town; their number in general amounting to 1500, though usually not more than 1200 were present; the remainder residing in foreign countries, or being otherwise absent. It meets twice a-year, chooses the principal magistrates, approves or rejects the laws and regulations proposed by the other councils, imposes taxes, contracts alliances, declares war or peace, and nominates half the members of the great council, &c. But the principal check to the power of the senate arose from the right of *re-election*, or the power of annually expelling four members from the senate at the nomination of the *syndics* or principal magistrates, and from the right of representation. The syndics are four in number, chosen annually from the senate by the general council; and three years elapse before the same members can be again appointed. In choosing these magistrates, the senate appointed from its own body eight candidates, from whom the four syndics were to be chosen by the general council. The latter, however, had it in their power to reject not only the first eight candidates, but also the whole body of senators in succession: in which case, four members of the senate retired into the great council: and their places were filled by an equal number from that council. With regard to the power of representation, every citizen or burgher has the privilege of applying to the senate in order to procure a new regulation in this respect, or of remonstrating against any act of the magistracy. To these remonstrances the magistrates were obliged to give an explicit answer; for if a satisfactory answer was not given to one, a second was immediately presented. The representation was made by a greater or smaller number of citizens according to the importance of the point in question.

5 Account of the revolution in 1782.

Since 1776, however, several changes have taken place. This right of *re-election*, which the aristocratical party were obliged to yield to the people in 1768, soon proved very disagreeable, being considered by the former as a kind of ostracism; for which reason they catched at every opportunity of procuring its abolition. They were now distinguished by the title of *negatives*, while the popular party had that of *representants*; and the point in dispute was the compilation of a new code of laws. This measure the negatives opposed, as supposing that it would tend to reduce their prerogatives; while, on the other hand, the representants used their utmost endeavours to promote it, in hopes of having their privileges augmented by this means. At last in the month of January 1777, the negatives were obliged to comply with the demands of their antagonists; and a committee for forming a new code of laws was appointed by the concurrence of the little, great, and general councils. The committee was to last for two years, and the code to be laid before the three councils for their joint approbation or rejection. A sketch of the first part of the code was presented to the little and great councils on the first of September 1779, that they might profit by their observations before it was presented to the general council. Great disputes arose; and at length it was carried by the negatives that the code should be rejected and the committee dissolved. The opposite party complained of this as unconstitutional, and violent disputes ensued; the issue of which was, that the great council offered to compile the code, and submit it to the decision of the public. This did not give satisfaction to the popular party, who considered it as insidious: the contentions revived with more fury than ever, until at length the negatives supposing, or pretending to suppose, that their country was in danger, applied to the guarantees, France, Zurich, and Berne, entreating them to protect the laws and constitution. This was productive of no good effect; so that the negatives found no other method of gaining their point than by sowing dissension among the different classes of inhabitants. The *natives* were discontented and jealous on acount of many exclusive privileges enjoyed by that class named *citizens*: they were besides exasperated against them for having, in 1770, banished eight of the principal natives, who pretended that the right of burghership belonged to the natives as well as to the citizens, and demanded that this right ought to be gratuitously conferred instead of being purchased. The negatives, in hopes of making such a considerable addition to their party, courted the natives by all the methods they could think of, promising by a public declaration that they were ready to confer upon them those privileges of trade and commerce which had hitherto been confined exclusively to the citizens. The designs of the negatives were likewise openly favoured by the court of France, and dispatches were even written to the French resident at Geneva to be communicated to the principal natives who sided with the aristocratic party. The attorney-general, conceiving this mode of interference to be highly unconstitutional, presented a spirited remonstrance; by which the French court were so much displeased, that they procured his deposition from his office; and thus their party was very considerably increased among the natives. The representants were by no means negligent in their endeavours to conciliate the favour of the same party, and even promised what they had hitherto opposed in the strongest manner, viz. to facilitate the acquisition of the burghership, and to bestow it as the recompense of industry and good behaviour. Thus two parties were formed among the natives themselves; and the dissensions becoming

Geneva.

coming every day worse and worse, a general insurrection took place on the 5th of February 1781. A dispute, accompanied with violent reproaches, having commenced betwixt two neighbouring and opposite parties of natives, a battle would have immediately taken place, had it not been for the interposition of the syndics on the one side, and the chiefs of the representants on the other. The tumult was beginning to subside, when a discharge of musquetry was heard from the arsenal. Some young men who sided with the negatives, having taken possession of the arsenal, had fired by mistake upon several natives of their own party, and had killed one and wounded another. This was considered by the representants as the signal for a general insurrection, on which they instantly took up arms and marched in three columns to the arsenal; but finding there only a few young men who had rashly fired without orders, they permitted the rest to retire without molestation. In the opinion of some people, however, this affair was preconcerted, and the representants are said to have been the first aggressors.

The representants having thus taken up arms, were in no haste to lay them down. They took possession of all the avenues to the city; and their committee being summoned next morning by the natives to fulfil their engagements with respect to the burghership, they held several meetings with the principal negatives on that subject, but without any success: for though the latter readily agreed to an augmentation of the commercial privileges of the natives, they absolutely refused to facilitate the acquisition of the burghership. The committee, however, embarrassed and alarmed at the number and threats of the natives, determined to abide by what they had promised; drew up an edict permitting the natives to carry on trade, and to hold the rank of officers in the military associations; and conferred the burghership on more than 100 persons taken from the natives and inhabitants, and even from the peasants of the territory. This was approved by the three councils; the negatives, dreading the power of their adversaries, who had made themselves masters of the city, not daring to make their appearance.

Thus the popular party imagined that they had got a complete victory; but they soon found themselves deceived. They were prevailed upon by the deputies from Zurich and Berne (who had been sent to conciliate the differences) to lay down their arms; and this was no sooner done, than the same deputies declared the edict in favour of the natives to be null and illegal. The senate declared themselves of the same opinion; and maintained, that the assent of the councils had been obtained only through fear of the representants who were under arms, and whom none at that time durst oppose. The representants, exasperated by this proceeding, presented another remonstrance on the 18th of March 1782, summoning the magistrates once more to confirm the edict; but a month afterwards received the laconic answer, that "government was neither willing nor able to confirm it." The natives, now finding themselves disappointed in their favourite object at the very time they had such strong hopes of obtaining it, behaved at first like frantic people; and these transports having subsided, an universal tumult took place. The most moderate of the popular party endeavoured in vain to allay their fury, by dispersing themselves in different quarters of the city; and the citizens, finding themselves at last obliged either to abandon the party of the natives or to join them openly, hastily adopted the latter measure; after which, as none could now oppose them, the officers of the representants took possession of the town, and quelled the insurrection. Various negotiations were carried on with the negatives in order to prevail upon them to ratify the edict, but without success: on which a few of the magistrates were confined by the popular party along with the principal negatives; and as they justly expected the interference of France on account of what they had done, they resolved to prolong the confinement of the prisoners, that they might answer the purpose of hostages for their own safety. In the mean time the body of citizens, deceived by the pretences of the popular party, acted as if their power was already established and permanent. In consequence of this, they deposed several members of the great and little councils, appointing in their room an equal number of persons who were favourable to the cause of the representants. The great council thus new modelled, executed the edict for conferring the burghership upon a number of the natives; and appointed a committee of safety, composed of eleven members, with very considerable authority. By this committee, the public tranquillity was re-established; after which, the fortifications were ordered to be repaired; and the people were buoyed up by the most dangerous notions of their own prowess, and a confidence that France either durst not attack them or did not incline to do so. In consequence of this fatal error, they refused every offer of reconciliation which was made them from the other party; until at last troops were dispatched against them by the king of Sardinia and the canton of Berne; and their respective generals, Messrs de la Marmora and Lentulus, were ordered to act in concert with the French commander, M. de Jaucourt, who had advanced to the frontiers with a considerable detachment. The Genevans, however, vainly puffed up by a confidence in their own abilities, continued to repair their fortifications with indefatigable labour; the peasants repaired from all quarters to the city, offering to mount guard and work at the fortifications without any pay; women of all ranks crowded to the walls as to a place of amusement, encouraging the men, and even assisting them in their labour. The besiegers, however, advanced in such force, that every person of discernment foresaw that all resistance would be vain. The French general Jaucourt, on the 29th of June 1782, despatched a message to the syndics; in which he insisted on the following humiliating conditions: 1. That no person should appear on the streets under pain of military punishment. 2. That a certain number of citizens, among whom were all the chiefs of the representants, should quit the place in 24 hours. 3. That all arms should be delivered to the three generals. 4. That the deposed magistrates should be instantly re-established: And, lastly, That an answer should be returned in two hours. By this message the people were thrown into the utmost despair; and all without exception resolved to perish rather than to accept of terms so very disgraceful. They instantly hurried to the ramparts with a view of putting their resolution in

Geneva. in force; but in the mean time the syndics found means to obtain from the generals a delay of 24 hours. During this interval, not only men of all ages prepared for the approaching danger, but even women and children tore the pavement from the streets, carrying the stones up to the tops of the houses, with a view of rolling them down upon the enomy in case they should force their way into the town. About 80 women and girls, dressed in uniforms, offered to form themselves into a company for the defence of their country. The committee of safety accepted their services, and placed them in a barrack secured from the cannon of the besiegers. The negatives were greatly alarmed at this appearance of desperate resistance; and some of the most moderate among them endeavoured, but without success, to effect a reconciliation. At the hour in which it was expected that the attack would begin, the ramparts were filled with defenders: and though the most zealous of the popular party had calculated only on 3000, upwards of 5000 appeared in the public cause. The French general, however, justly alarmed for the prisoners, who were now in imminent danger, again prolonged the period proposed for the capitulation. By these repeated delays the ardour of the defendants began to abate. The women first began to figure to themselves the horrors of a town taken by assault, and given up to an enraged and licentious soldiery; many timid persons found means not only to disguise their own fears, but to inspire others with them under the pretence of prudence and caution: at last the committee of safety themselves, who had so strenuously declared for hostilities, entirely changed their mind. Being well apprized, however, that it would be dangerous for them to propose surrendering in the present temper of the people, they assembled the citizens in their respective circles, representing, that if the city should be attacked in the night, it would be no longer possible to convene them: for which reason they recommended to them that each circle should nominate several deputies with full authority to decide in their stead; adding, that they ought rather to appoint those persons who from their age and respectable character were capable of assisting their country by their advice, while others were defending it by their valour. Thus a new council, composed of about 100 citizens, was formed; in which the chiefs, by various manœuvres, first intimidating, and then endeavouring to persuade the members of the necessity of surrendering, at last found means to take the thoughts of the people entirely off the defence of the city, and engage them in a scheme of general emigration. A declaration was drawn up to be delivered to the syndics with the keys of the city, the chiefs summoned the principal officers from their posts, ordered the cannon of several batteries to be rendered unfit for service, and at last took care of themselves by quitting the town. The people were in the utmost despair; and left the town in such multitudes, that when the Sardinians entered it in the morning, they found it almost deserted. This was followed by the restoration of the former magistrates, a complete subjection of the popular party, and the establishment of a military government.

6
New constitution established.

The changes which took place on this occasion were as follow: 1. An abolition of the right of re-election. 2. The abolition of that right by which the general council nominated half the vacancies in the great council. 3. The right of remonstrating was taken from the citizens at large, and vested in 36 adjuncts, who might be present in the great council the first Monday of every month. They enjoyed a right of representation, and in consequence of that had a deliberative voice; but on the whole were so insignificant, that they were nicknamed *Les Images*, or "The shadows." 4. The introduction of the grabeau, or annual confirmation of the members of the senate and of the great council, vested entirely in the latter. By this law part of the authority both of the senate and general council was transferred to the great council; and by subjecting the senate to this annual revision; its power was greatly lessened, and it was made in fact dependent upon the general councils. 5. The circles or clubs in which it was customary to convene the citizens, and all public assemblies whatever, were prohibited; and so rigorously was this carried into execution, that the society of arts was prohibited from meeting. 6. The militia were abolished; firing at marks, even with bows and arrows, was prohibited; and the town, instead of being guarded by the citizens, was now put under the care of 1000 foreign soldiers, whose colonel and major were both to be foreigners. These troops were to take an oath of fidelity to the republic, and of obedience to the great council and the committee of war: but were under the immediate command and inspection of the latter, and subject to the superior controul of the former. 7. No person was permitted to bear arms, whether citizen, native, or inhabitant. 8. Several taxes were imposed without the consent of the general council; but in time to come it was provided, that every change or augmentation of the revenue should be submitted to that body. 9. Several privileges with regard to trade and commerce, formerly possessed by the citizens alone, were now granted both to citizens and inhabitants.

It is not to be supposed that this revolution would be agreeable to people who had such a strong sense of liberty, and had been accustomed to put such a value upon it, as the Genevans. From what has been already related, it might seem reasonable to conclude, that an almost universal emigration would have taken place: but after their resentment had time to subside, most of those who fled at first, thought proper to return; and, in the opinion of Mr Coxe, not more than 600 finally left their country on account of the revolution in 1782. The emigrants principally settled at Brussels and Constance, where they introduced the arts of printing linens and watchmaking. Soon after the revolution, indeed, a memorial, signed by above 1000 persons of both sexes, all of them either possessed of some property or versed in trade or manufactures, was presented to the earl of Temple, then lord lieutenant of Ireland, expressing a desire to settle in that kingdom. The proposal met with general approbation; the Irish parliament voted 50,000l. towards defraying the expences of their journey, and affording them a proper settlement in the island. Lands were purchased for 8000l. in a convenient situation near Waterford; part of New Geneva was actually completed at the expence of 10,000l.; a charter was granted with very considerable privileges; the standard of gold was alter-

Geneva.

ed for the accommodation of the watch manufacturers; and the foundation of an academy laid upon an useful and liberal plan. Seven Genevans landed in Ireland in the month of July 1783: but when the nation had expended near 30,000l. on the scheme, it was suddenly abandoned. This seems principally to have been owing to the delays necessarily occasioned in the execution of such a complicated plan; and in some degree also by the high demands of the Genevan commissioners, who required many privileges inconsistent with the laws of Ireland. By these delays the Genevans, whose character seems not to be *perseverance*, were induced to abandon the scheme, and return to their former place of residence. Even the few who had already landed, though maintained at the public expence, were discontented at not finding the new town prepared for their reception; and as those among the proposed emigrants who possessed the greatest share of property had already withdrawn their names, the remainder did not choose to remain in a country where they had not capital sufficient to carry on any considerable trade or manufacture. A petition was then presented by the Genevan commissioners, requesting that 10,000l. of the 50,000l. voted might be appropriated to the forming a capital: but as this had been voted for other purposes, the petition was of course rejected; in consequence of which, the Genevans relinquished the settlement by an address, and soon after quitted the island.

New revolution in 17[illegible]

The people of Old Geneva, though returned to their former place of abode, were far from being inclined to submit to the yoke with patience. They were obliged to pay heavy taxes for maintaining a military force expressly calculated to keep themselves in subjection: and so intolerable did this appear, that in a few years every thing seemed ready for another revolution. The success of this seemed more probable than that of the former, as France was not now in a condition to interfere as formerly. The general ferment soon rose to such a height, that government was obliged to call in the aid of the military to quell a tumult which happened in the theatre. This produced only a temporary tranquillity; another tumult took place on the 26th of January 1789, on account of the publication of an edict raising the price of bread a farthing per pound. On this the people instantly rose, plundered the bakers shops: and next day a carriage loaded with bread and escorted by soldiers was plundered in its way to the distribution office. The soldiers fired on the populace, by which one man was killed and another wounded: but the tumult still increasing, the soldiers were driven away; and the body of the deceased was carried in a kind of procession before the town house, as a monument of the violence and oppression of the aristocratic party. The magistrates in the mean time spent their time in deliberation, instead of taking any effectual method of quelling the insurrection. The people made the best use of the time afforded them by this delay of the magistrates; they attacked and carried two of the gates, dangerously wounding the commanding officer as he attempted to allay the fury of both parties. At last the magistrates despatched against them a considerable body of troops, whom they thought the insurgents would not have the courage to resist; but in this they found themselves deceived. The people had formed a strong barricade, behind which they played off two fire pumps filled with boiling water and soap lyes against the extremities of two bridges which the military had to cross before they could attack them. The commanding officer was killed and several of his men wounded by the discharge of small arms from windows; and the pavement was carried up to the tops of houses in order to be thrown down upon the troops if they should force the barricades and penetrate into the streets. The tumult in the mean time continued to increase, and was in danger of becoming universal; when the magistrates, finding it would be impossible to quell the insurgents without a great effusion of blood, were reduced to the necessity of complying with their demands. One of the principal magistrates repaired in person to the quarter of St Gervais, proclaimed an edict for lowering the price of bread, granted a general amnesty, and released all the insurgents who had been taken into custody. Thus a momentary calm was produced; but the leaders of the insurrection, sensible that the magistrates were either unable or unwilling to employ a sufficient force against them, resolved to take advantage of the present opportunity to procure a new change of government. A new insurrection, therefore, took place on the 29th of the month, in which the soldiers were driven from their post, disarmed, and the gates seized by the people. The magistrates then, convinced that all opposition was fruitless, determined to comply with the demands of their antagonists in their full extent; and the aristocratical party suddenly changing their sentiments, renounced in a moment that system to which they had hitherto so obstinately adhered. On the application of the solicitor general, therefore, for the recovery of the ancient liberties of the people, the permission of bearing arms, re-establishment of the militia, and of their circles or political clubs, the removal of the garrison from the barracks, and the recal of the representants who were banished in 1782; these moderate demands were received with complacency, and even satisfaction. The preliminaries were settled without difficulty, and a new edict of pacification was published under the title of *Modifications à l'Edition de* 1782, and approved by the senate, great council, and general council. So great was the unanimity on this occasion, that the modifications were received by a majority of 1321 against 52. The pacification was instantly followed by marks of friendship betwixt the two parties which had never been experienced before; the sons of the principal negatives frequented the circles of the burghers; the magistrates obtained the confidence of the people; and no monument of the military force so odious to the people will be allowed to remain. "The barracks of the town-house (says Mr Coxe) are already evacuated, and will be converted into a public library; the new barracks, built at an enormous expence, and more calculated for the garrison of a powerful and despotic kingdom than for a small and free commonwealth, will be converted into a building for the university. The reformation of the studies, which have scarcely received any alteration since the time of Calvin, is now in agitation. In a word, all things seem at present to conspire for the general good; and it is to be hoped that both parties, shocked at the recollection of past troubles, will continue on as friendly terms

Geneva. terms as the jealous nature of a free constitution will admit."

Geneva, as well as the whole of Switzerland, fell a victim to French rapacity in 1802. The following observations, made by a traveller on the spot, afford us some information of the consequences of this event to Geneva, of its degraded state, and of the manners of the inhabitants.

"The population of Geneva is about 24,000: moreover it contains at present between 1200 and 1400 French troops: the parties intermix but little, and have had no disputes, although they certainly regard each other with an eye of jealousy. The Genevans do the French soldiers the justice to say, that they have demeaned themselves in a very becoming manner during their residence here: they acknowledge themselves to be a conquered people, and dare not open their mouths, except to an Englishman, against the treacherous invaders of their country, and destroyers of their liberties.

"You are too well versed in the history of this people to require being told, that, notwithstanding their present humiliated condition, Freedom is the goddess they worship; and that, had there been any possibility of securing her from violation, they would gladly have bled before her altars. However various has been their success, in the different revolutions which have agitated this secluded state, the Genevans have uniformly evinced a courage which awed their enemies, and a determined bravery in defence of their rights, which in shewing that they prized them highly, gave proof that they were worthy to enjoy them.

"The territory of Geneva is comprehended in the *Department du Leman*, which department contains about 16 square leagues of land: its population is estimated at 609,000 persons. It is divided into three cantons or hundreds, the largest of which has Geneva for its capital, and contains about 75,000 souls, of which 10,000 only are Genevans, 20,000 are French, and the remainder are Savoyards. The prefet, as in all the other departments, is appointed by the First Consul, *durante beneplacito*. The care of the high roads and public walks, public finances, executive justice, military affairs, and passports, are under his immediate direction. All military appointments are given to Frenchmen: one general commands the town, and another the country. At the first moment of the revolution all the old magistrates were displaced, and since that time the civil officers have been elected by the citizens at large, consequently some are Frenchmen, and some Genevans: the present mayor is one of the latter: he is a gentleman of great respectability, and is much esteemed by both parties. Whenever a new code of laws shall be established in France, its operations will be extended over the territory of Geneva; but at present the people here retain their old laws with some trifling alterations only, rather the form than the substance: thus, the guillotine is now substituted for the gallows, and the punishments in general, without varying the degree, are inflicted according to the French manner.

"In their treaty with France, the Genevans stipulated, that their hospital should not be obliged to receive French soldiers: this hospital was founded in the early part of the last century, by some of the richest citizens, and is so well supported by legacies, and by annual subscriptions, that the fund enables the directors to expend two thousand louis a year. In contempt of this treaty, Bonaparte has insisted on the admission of French soldiers, for whose accommodation, however, he promised to pay a certain sum *per diem*: in contempt of his promise, again, he has withheld the payment! An hospital, however, is now preparing at Carouge, a village in Savoy, between Geneva and Grange Colonge, for Frenchmen, to which, it is expected, the soldiers will be removed in May or June. Here is also a general hospital, once the nunnery of St Clair; it was founded, together with many other useful institutions, by that celebrated reformer, John Calvin, who fled from the persecution of Francis I. and found an asylum in Geneva. The revenue arising from the estates of this hospital has, till within these last few years, been commensurate with its expences: but, for some time back, it has been found necessary to collect almost an additional fourth, in order to supply its disbursements: twice in the year the treasurer goes round to every house, and solicits the charitable contribution of its inmates.

"Prior to the last revolution, I learn, that 600,000 French livres discharged all the public expences: with this very trifling sum were paid the salaries of the magistrates, of the master of the town, of the master of the country, the expences of the academy, of repairing the roads, of cleaning and lighting the town; in short, these 600,000 livres were sufficient to defray all the ordinary expences of the government. Since that too memorable event, the citizens of Geneva have been assessed to the amount of 1,500,000 livres, the salaries of the inferior magistrates are in arrears, the roads are not kept in good repair, the town is very dimly lighted, and the streets, a few of the principal ones excepted, are left with all their dirty honours thick upon them! The inhabitants go so far as to assert, that, in consequence of the neglect which the public drains have suffered, they have been affected with fevers and other illnesses to which they had hitherto been strangers.

"I understand, that the revenue of Geneva, since it has been annexed to the republic of France, arises chiefly from the following sources.—An excise duty is laid on all provisions (wheat excepted), on wine and merchandise of every description, which is brought into Geneva: the annual produce of this tax is about 120,000 French livres; a land tax; a tax on doors and windows; a tax on the sale of estates; a heavy tax on the collateral inheritance of an estate—where the inheritance is lineal and immediate, the tax is moderate. To these taxes or contributions, as they are called, must be added *la contribution mobilière*, which is a small tax on personal property, and produces annually about 75,000 livres. The collectors of these taxes are appointed by the First Consul, and are paid very highly for their trouble: the prefet, and all the principal public officers, are very regularly paid, but those in a subordinate situation seldom get above one-third of their stipends.

"Divorces seem to be obtained here with too much facility. But, in the first place, as to marriages, they must be celebrated, according to the French law, before the municipality, at the maison de ville. Marriage in France, you know, is merely a civil ceremony, the parties being obliged to swear before an appointed magistrate, that they are of age, and that they have consented

consented to become man and wife. The Genevans, however, do not consider this ceremony as sufficient: but, as our Gretna Green couples, on their return to Britain, think it necessary, after the fervour of passion is abated, and the mercury is fallen, in the animal thermometer, something lower than *blood heat*, to have the holy rites performed with the solemnity prescribed by law; so the Genevans, in addition to the civil ceremony prescribed by the laws of the republic of France, voluntarily conform to the religious ordinance of their own church. If a woman leaves her husband, and refuses to return to his habitation, after being summoned by him for that purpose, he can repudiate her for disobedience*." The inhabitants, though obliged to submit to superior force, were always averse to the French yoke; and when the French garrison capitulated to the Austrian general Bubna, in December 1813, the restoration of the republic was instantly decreed. On the 12th September 1814, Geneva was admitted a member of the Swiss confederation, and a new constitution was framed, in which it was declared, that "no patricians or privileged classes are acknowledged by the state, but that all the Genevese are equal before the law." Public affairs are managed by the great council of 250 members, and by the smaller council of 28, the latter being the executive. The territory of Geneva, which was originally very small, was augmented by late treaties, and now contains 120 square miles, and 25,000 inhabitants.

* ...nth. M. 1802.

Geneva *Lake*. This lake is in the shape of a crescent; along the concave side of which Mr Coxe travelled 54 miles. Switzerland forms the hollow, and Savoy the convex part; the greatest breadth being about 12 miles. The country on the side of Savoy is full of high and craggy mountains; but from Geneva to the environs of Lausanne it slopes to the margin of the lake, and is very rich and fertile. The banks rise considerably in the neighbourhood of Lausanne, and form a most beautiful terrace, with a rapid descent a few miles beyond the town. A plain begins in the neighbourhood of Vevay, which continues for a great way beyond the end of the lake, but contracting towards the water by the approach of the mountains. The lake itself appears at a distance of a beautiful blue colour, and the water is very clear and transparent. Near Geneva the coast of the lake abounds with pebbles; between that city and Lausanne it is sandy; from thence to Chilon it is bounded by hard calcareous rocks; and the extremity of the shores is a marsh formed by mud collected from the river Rhone. The greatest depth of this lake found by M. de Luc is 160 fathoms. Here the birds called *tippet grebes* make their appearance in December, and retire in February to other places where they breed. They make floating nests of reeds; but as the lake of Geneva affords none of these, they are obliged to migrate to other places where they grow. Their skins are much esteemed, and sell for 12s. or 14s. each. The lake of Geneva, like all others situated between mountains, is subject to sudden storms.

Geneva, or *Gin*, among distillers, an ordinary malt spirit, distilled a second time, with the addition of some juniper berries.

Originally, the berries were added to the malt in the grinding; so that the spirit thus obtained was flavoured with the berries from the first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which though it nearly resembles the flavour of juniper berries, has none of their valuable virtues.

GENEVIEVE, fathers or religious of; the name of a congregation of regular canons of the order of St Augustine, established in France.

The congregation of St Genevieve is a reform of the Augustine canons. It was begun by St Charles Faure, in the abbey of St Vincent de Senlis, of which he was a member, in the year 1618.

In the year 1634, the abbey was made elective; and a general chapter, composed of the superiors of 15 houses who had now received the reform, chose F. Faure coadjutor of the abbey of St Genevieve, and general of the whole congregation. Such were its beginnings.

It has since increased very much, and it now consists of above a hundred monasteries; in some whereof the religious are employed in the administration of the parishes and hospitals: and in others, in the celebration of divine service, and the instruction of ecclesiastics in seminaries for the purpose.

The congregation takes its name from the abbey of St Genevieve, which is the chief of the order, and whose abbot is the general thereof. The abbey itself took its name from St Genevieve, the patroness of the city of Paris, who died in the year 512. Five years after her death, Clovis erected the church of St Genevieve, under the name and invocation of St Peter, where her relicks are still, or were till lately preserved, her shrine visited, and her image carried with great processions and ceremonies upon extraordinary occasions, as when some great favour is to be entreated of heaven.

GENGIS KHAN, the renowned sovereign of the Moguls, a barbarous and bloody conqueror. See Jenghiz Khan, and (*History* of the) Moguls.

GENIAL, an epithet given by the Pagans to certain gods who were supposed to preside over generation.

The genial gods, says Festus, were earth, air, fire, and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the nnmber.

GENII, a sort of intermediate beings, by the Mahometans believed to exist, between men and angels. They are of a grosser fabric than the latter, but much more active and powerful than the former. Some of them are good, others bad, and they are capable of future salvation or damnation like men. The orientals pretend that these genii inhabited the world many thousand years before the creation of Adam, under the reigns of several princes, who all bore the common name of Solomon; that falling at length into an almost general corruption, Eblis was sent to drive them into a remote part of the earth, there to be confined; and that some of that generation still remaining were by Tahmurath, one of the ancient kings of Persia, forced to retreat into the famous mountain of *Kaf*; of whose successions and wars they have many fabulous and romantic stories. They also made several ranks and degrees among this kind of beings (if they are not rather

different

different species); some being absolutely called *Jin*; some *Peri*, or fairies: some *Div*, or giants; and others *Tacwins*, or fates.

GENIOGLOSSI, in *Anatomy*. See ANATOMY, *Table of the Muscles*.

GENIOHYOIDÆUS, in *Anatomy*. *Ibid*.

GENIOSTOMA, a genus of plants belonging to the pentandria class. See BOTANY *Index*.

GENIPPA, a genus of plants belonging to the pentandria class, and in the natural method ranking under the 30th order, *Contortæ*. See BOTANY *Index*.

GENISTA, BROOM, or DYERS WEED, a genus of plants belonging to the diadelphia class; and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY *Index*.

GENITAL, an appellation given to whatever belongs to the parts of generation. See ANATOMY, N° 107, 108.

GENITES, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

GENITIVE, in *Grammar*, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns called the *genitive case*; but in the vulgar tongues they make use of a sign to express the relation of this case. In English they prefix the particle *of*, in French *de* or *du*, &c. Though in strictness there are no cases in either of these languages; insomuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the Latin.

GENIUS, a good or evil spirit or dæmon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and to be his guard. See DÆMON.

Among the Romans, Festus observes, the name *genius* was given to the god who had the power of doing all things, *deum qui vim obtineret rerum omnium gerendarum*; which Vossius, *de Idol.* rather chooses to read *genendarum*, who has the power of producing all things; by reason Censorinus frequently uses *gerere* for *gignere*.

Accordingly St Augustin, *de Civitate Dei*, relates, from Varro, that the Genius was a god who had the power of generating all things; and presided over them when produced.

Festus adds, that Aufustius spake of the genius as the Son of God, and the Father of men, who gave them life; others, however, represented the genius as the peculiar or tutelary god of each place; and it is certain, the last is the most usual meaning of the word. The ancients had their *genii* of nations, of cities, of provinces, &c. Nothing is more common than the following inscription on medals, GENIUS POPULI ROM. "the genius of the Roman people;" or GENIO POP. ROM. "to the genius of the Roman people. In this sense *genius* and *lar* were the same thing; as, in effect, Censorinus and Apulius affirm they were. See LARES and PENATES.

The Platonists, and other eastern philosophers, supposed the *genii* to inhabit the vast region or extent of air between earth and heaven. They were a sort of intermediate powers, who did the office of mediators between gods and men. They were the interpreters and agents of the gods; communicated the wills of the deities to men; and the prayers and vows of men to the gods. As it was unbecoming the majesty of the gods to enter into such trifling concerns, this became the lot of the *genii*, whose nature was a mean between the two; who derived immortality from the one, and passions from the other; and who had a body framed of an aerial matter. Most of the philosophers, however, held, that the genii of particular men were born with them, and died; and Plutarch attributes the ceasing of oracles partly to the death of the genii.—See ORACLE.

The heathens, who considered the genii as the guardians of particular persons, believed that they rejoiced and were afflicted at all the good and ill fortune that befel their wards. They never, or very rarely, appeared to them; and then only in favour of some person of extraordinary virtue or dignity. They likewise held a great difference between the genii of different men; and that some were much more powerful than others: on which principle it was, that a wizzard in *Appian* bids Antony keep at a distance from Octavius, by reason Antony's genius was inferior to and stood in awe of that of Octavius. There were also evil genii, who took a pleasure in persecuting men, and bringing them evil tidings: such was that mentioned by Plutarch which appeared to Brutus the night before the battle of Philippi. These were also called *larvæ* and *lemures*. See LARVÆ and LEMURES.

GENIUS, in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which alone they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules; whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting.

A man born with a genius for commanding an army, and capable of becoming a great general by the help of experience, is one whose organical conformation is such, that his valour is no obstruction to his presence of mind, and his presence of mind makes no abatement of his valour. Such a disposition of mind cannot be acquired by art: it can be possessed only by a person who has brought it with him into the world. What has been said of these two arts may be equally applied to all other professions. The administration of great concerns, the art of putting people to those employments for which they are naturally formed, the study of physic, and even gaming itself, all require a genius. Nature has thought fit to make a distribution of her talents

Genius, Genoa. talents among men, in order to render them necessary to one another; the wants of men being the very first link of society: she has therefore pitched upon particular persons, to give them aptitude to perform rightly some things which she has rendered impossible to others; and the latter have a greater facility granted them for other things, which facility has been refused to the former. Nature indeed has made an unequal distribution of her blessings among her children; yet she has disinherited none; and a man divested of all kinds of abilities, is as great a phenomenon as an universal genius.

From the diversity of genius the difference of inclination arises in men, whom nature has had the precaution of leading to the employments for which she designs them, with more or less impetuosity in proportion to the greater or lesser number of obstacles they have to surmount in order to render themselves capable of answering this vocation. Thus the inclinations of men are so very different, because they follow the same mover, that is, the impulse of their genius. This, as with the painter, is what renders one poet pleasing, even when he trespasses against rules; while others are disagreeable, notwithstanding their strict regularity.

The genius of these arts, according to the abbé du Bos, consists in a happy arrangement of the organs of the brain; in a just conformation of each of these organs; as also in the quality of the blood, which disposes it to ferment, during exercise, so as to furnish plenty of spirits to the springs employed in the functions of the imagination. Here he imagines that the composer's blood is heated; for that painters and poets cannot invent in cool blood; nay, that it is evident they must be rapt into a kind of enthusiasm when they produce their ideas. Aristotle mentions a poet who never wrote so well as when his poetic fury hurried him into a kind of frenzy. The admirable pictures we have in Tasso of Armida and Clorinda were drawn at the expence of a disposition he had to real madness, into which he fell before he died. "Do you imagine, (says Cicero), that Pacuvius wrote in cold blood? No, it was impossible. He must have been inspired with a kind of fury, to be able to write such admirable verses."

GENOA, a city of Italy, and formerly capital of a republic of the same name, situated in E. Long. 8. 36. N. Lat. 44. 25.—By the Latin authors it is very frequently, though corruptly called *Janua*; and its present territories made part of the ancient Liguria. The era of its foundation is not known. In the time of the second Punic war it was a celebrated emporium; and having declared for the Romans, was plundered and burnt by Mago the Carthaginian. It was afterwards rebuilt by the Romans; and with the rest of Italy continued under their dominion till the decline of the western empire in 476. Soon after, it fell under the power of Theodoric the Ostrogoth; who having defeated the usurper Odoacer, became king of Italy. This happened in the year 498; and in a short time, the Goths being almost entirely subdued by Belisarius the emperor Justinian's general, Genoa was reannexed to the Roman empire. In 638, it was plundered and burnt by the Lombards, whose king Protharis erected it into a provincial dukedom.

Genoa. The Lombards continued masters of Genoa till the year 774, when they were conquered by Charles the Great, son to Pepin king of France. He reduced Liguria to the ancient bounds settled by Augustus, and erected it into a marquisate: appointing his relation *Audemarus* the first count or margrave. Genoa at this time being distinguished for its wealth and populousness, began to give its name to the whole coast; and continued under the dominion of these counts for about 100 years, till the race of the Pepins became entirely extinct in Italy, and the empire was transferred to the German princes.—In the year 935 or 936, while the Genoese forces were absent on some expedition, the Saracens surprised the city, which they plundered and burnt, putting to death a great number of the inhabitants, and carrying others into captivity. Having embarked their captives, together with an immense booty, they set sail for Africa; but the Genoese immediately returning, pursued the invaders; and having entirely defeated them, recovered all the captives and booty, and took a great many of the enemy's ships.

About the year 950, the Franks having lost all authority in Italy, the Genoese began to form themselves into a republic, and to be governed by their own magistrates, who were freely elected, and took the name of *Consuls*. In order to support their independence, they applied themselves with great assiduity to commerce and navigation; and being apprehensive that some of the German emperors, who frequently entered Italy as invaders, might renew their pretensions to their state, they consented to acknowledge Berengarius III. duke of Friuli, who had been elected emperor by a party of Italian nobles. Berengarius, who had much ado to maintain himself in his new dignity, endeavoured by his concessions to enlarge the number of his friends and adherents; and accordingly made no difficulty to confirm the new republic in all its rights and privileges. After this the Genoese began to extend their commerce from Spain to Syria, and from Egypt to Constantinople: their vessels, according to the custom of these times, being fitted for fighting as well as merchandise. Having thus acquired great reputation, they were invited in 1017, by the Pisans, who had likewise formed themselves into a republic, to join with them in an expedition against Sardinia, which had been conquered by the Moors. In this expedition they were successful; the island was reduced; but from this time an enmity commenced between the two republics, which did not end but with the ruin of the Pisans.

The first war with Pisa commenced about 30 years after the Sardinian expedition, and lasted 18 years; when the two contending parties having concluded a treaty of peace, jointly sent their forces against the Moors in Africa, of whom they are said to have killed 100,000. The Genoese were very active in the time of the crusades, and had a principal share in the taking of Jerusalem. They also waged considerable wars with the Moors in Spain, of whom they generally got the better. They also prevailed against the neighbouring states; and, in 1220, had enlarged their territories beyond the skirts of the Apennines, so that the rest of Italy looked upon them with a jealous eye; but in 1311 the factions which had for a long time reigned in the city, notwithstanding all its wealth and power, induced

Genoa. induced the inhabitants so submit themselves for 20 years to the dominion of Henry VII. emperor of Germany. That emperor, however, died in August 1312; and the vicar he had left soon after went to Pisa, upon which the dissensions in Genoa revived with greater fury than ever. In 1317, a quarrel happened between the families of Spinola and Doria; which came to such a height, that both parties fought in the streets for 24 days without intermission, raised battering engines against each other's houses, and filled the city with blood. At last the Spinolæ quitted the city, and retired to their territories in the Apennine mountains. The civil war continued till the year 1331; when, by the mediation of the king of Naples, it was concluded, that all exiles should return to the city; that the republic should be governed by the king's vicar; and all the offices of the state be equally divided between the Guelfs and the Gibellines, the two contending parties.

By this ruinous war, the coast of Genoa, formerly adorned with palaces and vineyards, was now reduced to the appearance of a barren waste. So great was the general desolation, that according to Petrarch, the spectators who sailed along were struck with astonishment and horror. Villani, a cotemporary author, relates, that it was supposed by the learned, that greater exploits had not been performed at the siege of Troy; and that the losses each party had sustained would have been sufficient to have purchased a kingdom, the Genoese republic being in his time the richest and most powerful state in Christendom. The annalist Stella informs us, that, before the war, the most extravagant profusion and luxury prevailed among the Genoese: but that, towards the end, many noble families were reduced to indigence and poverty; so that about 100 years after, it became fashionable for the nobles to live in a plain manner, without any show or magnificence.

In 1336, both parties, suspending their mutual animosities, sent two fleets of 20 galleys each into the German ocean, to the assistance of the king of France, who was engaged in a war with Edward III. king of England. This naval expedition proved the cause of a most remarkable revolution in the Genoese government. The sailors of the fleet, thinking themselves injured by their officers, whom they accused of defrauding them of their pay, proceeded to an open mutiny; and having expelled the admiral, and other commanders, seized the galleys. The king of France being chosen arbitrator, decided in favour of the officers, and imprisoned 16 of the chiefs of the mutineers. Upon this several of the sailors left the fleet, and returned to Genoa; where they went round the coasts, repeating their mutinous complaints, which were greatly hearkened to, upon a false report that the mutineers who had been imprisoned were broke upon the wheel. The factious spirit increased: and at last the Genoese insisted in a tumultuous manner for having an abbot of their own choosing, and 20 of the people with the consent of the captains of the republic assembled for that purpose. While the mob were impatiently expecting their decision, a mechanic, generally accounted a fool, mounted a wooden bench, and called out that one Simon Bucanigree should be chosen abbot. This being instantly echoed by the populace, he was first declared *abbot*, then *lord*, and at last *duke* of Genoa.

This new expedient did not at all answer the purpose. The dissensions continued as violent as ever, nothwithstanding the power of the new magistrates; and by these perpetual divisions the republic was at last so much weakened, that in 1390 the king of France was declared lord of Genoa. Under the French government, however, they soon became exceedingly impatient; and, in 1422, the duke of Milan obtained the sovereignty. With this situation they were equally displeased, and therefore revolted in 1436. Twenty-two years after, finding themselves pressed by a powerful fleet and army sent by Alphonso king of Naples, they again conferred the sovereignty of their state, upon the king of France. In 1460, they revolted from the French; and, four years after, put themselves again under the protection of the duke of Milan: from whom they revolted in 1478. He was again declared sovereign of the republic in 1488; and, 11 years after, the city and territories of Genoa were conquered by Louis XII. of France.

The almost unparalleled fickleness of the Genoese disposition was not to be corrected by this misfortune. They revolted in 1506; but next year were again subdued by Louis. Six years after, they again revolted: and in 1516, the city was taken and plundered by the Spaniards. In 1528, Andrew Doria, a Genoese admiral in the service of the French, undertook to rescue his country from the dominion of foreign princes, and restore it to its liberty. Knowing well the fickle disposition of his countrymen, he took all occasions of exciting discontents among them against the government. He persuaded them, that the French (who had again obtained the sovereignty) had left them only a shadow of liberty, while they pretended to protect them from their enemies. To the nobility he represented the disgrace of suffering the government to be vested in the hands of foreigners less worthy of authority than themselves. Thus he soon formed a strong faction, and formed his plan; for the execution of which he took the most proper time, namely, when almost three-fourths of the French garrison had been carried off by the plague. He advanced with 500 men; and his friends having opened the gates of the city to him, he seized the principal posts, and thus became master of it without drawing his sword. The garrison retired to the forts, where they soon after capitulated, and being driven out of the city, Doria re-established the ancient form of government. See Doria.

The republic hath since continued to preserve her liberty, though greatly fallen from her ancient splendour, and now become a very inconsiderable state. In 1684, the Genoese had the misfortune to fall under the resentment of Louis XIV. at which time the city was almost destroyed by a formidable bombardment. In the year 1688, it was bombarded by Admiral Byng, and forced to capitulate; but there were at that time no vews of making a permanent conquest of the city. In 1730, the island of Corsica revolted from the Genoese, and could never afterwards be reduced by them; for which reason it was sold to the French, who in the year 1770 totally reduced it.

The

Genoa. The Genoese territories extend along that part of the Mediterranean sea, commonly called the *Gulf of Genoa*, about 152 miles; but their breadth is very unequal, being from eight to about 20 miles. Where they are not bounded by the sea, the following states and countries, taking them from west to east, are their boundaries, viz. Piedmont, Montferrat, Milan, Placentia, Parma, the dukedom of Tuscany, and the republic of Lucca. This tract, though a great part of it is mountainous, and some of that barren enough, yet produces plenty of excellent fruit, good pasture, wood, garden stuff, and mulberry trees, with some wine and oil, but little corn. What they want of the last, they have either from Lombardy, Sicily, or Naples.

Genoa stands on the coast of the Mediterranean sea, at the bottom of a little gulf, partly on the flat, and partly on the declivity, of a pleasant hill; in consequence of which, it appears to great advantage from the sea. It is defended on the land side by a double wall, which in circumference is about ten Italian miles. Two of the streets consist entirely of a double straight row of magnificent palaces. The others, though clean and well paved, are crooked and narrow. The palaces of the nobility are almost all of marble, and many of them are painted on the outside. That there should be such a profusion of marble here, is not to be wondered at, as the neighbouring hills abound with it. The city contains a vast number of palaces, churches, and convents, and several hospitals. The palace where the doge resides, and where the great and little council, and the two colleges of the procuratori and governatori assemble, is a large stone building in the centre of the city. It contains some fine paintings in fresco; two statues of Andrew and John Doria in white marble; and an arsenal, in which are said to be arms for thirty-four thousand men, with a shield, containing one hundred and twenty pistol barrels, and thirty-three coats of mail, which, it is pretended, were worn by as many Genoese heroines in a croisade. Of the churches, the finest are those of the Annunciation, St Mary Carignan, St Dominic, and St Martha. In the cathedral is a dish made of a single emerald. All the inhabitants here, except the principal ladies, who are carried in chairs, walk on foot, on account of the narrowness or steepness of the streets. The fortifications of the city, towards the sea, are remarkably strong. There are two fine stone bridges over the rivers Bonzerva and Bisagno, the first whereof washes the west, and the other the east side of the city, within which there is also a surprising stone bridge joining two hills. The harbour, though large, is far from being safe; but no care or expence has been spared to render it as safe and commodious as possible. The wind to which it is most exposed, is that called *Labeccio*, or the south-west. The place where the republic's galleys lie, is called the Darsena, where are a great number of Turkish slaves. On a rock, on the west side of the harbour, is the fanal or lighthouse, a high tower on the top of which is a lanthorn, containing thirty-six lamps. The population of Genoa is estimated at 150,000, and the trade is chiefly in velvets, damasks, plush, and other silks, brocades, lace, gloves, sweetmeats, fruits, oil, Parmesan cheese, anchovies, and medicinal drugs from the Levant; but the badness of the harbour, and the high price of commodities, greatly checks the commerce. In 1751, Genoa was declared a free port for ten years, under certain restrictions: in that called *Porto Franco*, any merchant may have a warehouse, and import or export goods duty free; but such as are disposed of in the city, or on the continent, are taxed pretty high. The nobility are allowed to trade in the wholesale way; to carry on velvet, silk, and cloth manufactures; and to have shares in merchant ships: and some of them, as the Palavicini, are actually the greatest merchants in Genoa. Another very profitable article of trade carried on by them is banking, and dealing in bills of exchange. A new academy of painting, sculpture, civil and military architecture, was instituted here in 1751. One may walk the streets of Genoa in the night with the greatest safety, which is more than can be said of many cities in Italy. Excessive splendour and luxury are, in several respects, restrained by salutary laws. No beggars are permitted to ask alms in Genoa, and the inns are better than those at Turin. When a single person is buried, a kind of garland of all sorts of artificial flowers is placed on the coffin. The Genoese in general are esteemed crafty, industrious, and inured to hard labour above the other Italians.

Amidst the political convulsions which agitated Europe, in consequence of the unexampled French revolution, it was scarcely to be expected that Genoa would escape the shock. Accordingly in the year 1798, by the force and intrigues of the French republicans, its political constitution was totally subverted, and changed into what was afterwards denominated the *Ligurian Republic*, which was to be governed in a manner similar to that of their own, and the country also was divided into departments. As the preceding campaign had terminated in favour of the combined powers, and left them in the possession of every important place in Italy, this only excepted, the capture of it became an object of the utmost consequence to the contending parties. To regain it was the highest ambition of the house of Austria, while the retaining of it was matter of solicitude to the French republic. The reason is obvious. The conquest of it restored to the emperor of Germany the possession of all Italy, gave him the means of resuming his former positions in the Maritime Alps, and reinforcing his former position on the Rhine. To the French it was a place of the utmost consequence, because while they were enabled to retain it in their own hands, they could easily favour the operations of their army in Switzerland, or their entrance into Italy by the defiles of Piedmont.

As the allies were fully determined on its conquest for the reasons already assigned, as well as for others of an inferior nature and magnitude, it is but candid to admit that the general by whom it was defended had innumerable difficulties to struggle with, and obstacles to surmount. When Massena succeeded Championet, the army was reduced to the most melancholy situation. Confined during the winter season to the bleak summits of the Apennines, it was reduced in numbers more than one half, and a constant prey to famine and disease. To add to the difficulties which everywhere presented themselves to Massena, the higher classes of the Genoese looked upon the French only as the destroyers of their rank, commerce, and political importance; in consequence of which they secretly aided every measure by which they might be driven from the country. Instead of of 60,000 men which he was promised, Massena had no more than 20,000 after all his unwearied exertions, and with these he had to defend an extent of country from Mount Cenis to the frontiers of Tuscany. He wisely dismissed all the former generals, independent of their merit, because the soldiers associated with them the idea of former misery and disgrace. In addition to the superior strength of the Austrian army, Massena found a formidable insurrection raised against him in the eastern territory of the Genoese republic. The passage by sea was obstructed by the British fleet, and his expected succours from Marseilles only reached him in part. As he could not meet the army in the field by which he was blockaded, his only alternative was to remain in Genoa, every moment in dread of perishing by famine, if not speedily relieved. After enduring great hardships, humanity for the starving inhabitants induced him to surrender.

The victory of Marengo however restored it again to the French; and after being indulged with a nominal independence for some time, it was incorporated with France in 1805. When Bonaparte sustained his great reverses in 1814, Genoa surrendered to a British force, under a promise of independence, which promise was however broken, and the city with its territory was annexed to Sardinia. When the insurrection took place in this kingdom in March 1821, Genoa gladly seized the opportunity to throw off the foreign yoke. But the failure of the revolution in Piedmont led to the suppression of the independence of Genoa.

GENSING. See PANAX, BOTANY *Index*.

GENTIANA, GENTIAN, a genus of plants belonging to the pentandria class; and in the natural method ranking under the 20th order, *Rotaceæ*. See BOTANY *Index*.

GENTILE, in matters of religion, a Pagan, or worshipper of false gods.

The origin of this word is deduced from the Jews, who called all those who were not of their name גוים *gojim*, i. e. *gentes*, which in the Greek translations of the Old Testament is rendered τα εθνα; in which sense it frequently occurs in the New Testament; as in Matth. vi. 32. "All these things the nations or Gentiles seek." Whence the Latin church also used *gentes* in the same sense as our *Gentiles*, especially in the New Testament. But the word *gentes* soon got another signification, and no longer meant all such as were not Jews; but those only who were neither Jews nor Christians, but followed the superstitions of the Greeks and Romans, &c. In this sense it continued among the Christian writers, till their manner of speech, together with their religion, was publicly and by authority received in the empire; when *gentiles*, from *gentes*, came into use: and then both words had two significations, viz. in treatises or laws concerning religion, they signified Pagans, neither Jews nor Christians; and in civil affairs, they were used for all such as were not Romans.

GENTILE, in the Roman law and history, a name which sometimes expresses what the Romans otherwise called *barbarians*, whether they were allies of Rome or not: but this word was used in a more particular sense for all strangers and foreigners not subject to the Roman empire.

GENTILESCHI, HORATIO, an Italian painter, was born at Pisa in 1563. After having made himself famous at Florence, Rome, Genoa, and other parts of Italy, he removed to Savoy; from whence he went to France, and at last, upon the invitation of Charles I. came over to England. He was well received by that king, who appointed him lodgings in his court, together with a considerable salary; and employed him in his palace at Greenwich, and other public places. The most remarkable of his performances in England, were the ceilings of Greenwich, and York house. He did also a Madona, a Magdalen, and Lot with his two daughters, for King Charles; all which he performed admirably well. After the death of the king, when his collection was exposed to sale, nine pictures of Gentileschi were sold for 600l. and are now said to be the ornaments of the hall in Marlborough house. His most esteemed piece abroad was the portico of Cardinal Bentivoglio's palace at Rome. He made several attempts in face painting, but with little success; his talent lying altogether in histories, with figures as big as the life. He was much in favour with the duke of Buckingham, and many others of the nobility. After 12 years continuance in England, he died here at 84 years of age, and was buried in the queen's chapel at Somerset-house. His print is among the heads of Vandyke, he having been drawn by that great master. He left behind him a daughter, *Artemisia Gentileschi*, who was but little inferior to her father in history painting, and excelled him in portraits.

GENTILIS, ALBERICUS, professor of civil law at Oxford; an Italian by birth. He had quitted Italy with his father, on account of religion. He wrote several works; three books, in particular, *De jure belli*, which have not been unserviceable to Grotius. He died at London in 1608.

GENTILIS, *Scipio*, brother to the former, and as celebrated a civilian as he, forsook his native country that he might openly profess the Protestant religion. He was counsellor of the city of Nuremberg, and professor of law with uncommon reputation. He was a great humanist; and in his lectures, as well as books, mixed the flowers of polite learning with the thorns of the law. He died in 1616.

GENTLEMAN. Under this denomination are comprehended all above the rank of yeomen *, whereby noblemen are truly called *gentlemen*.

* See Commonalty.

A gentleman is usually defined to be one, who, without any title, bears a coat of arms, or whose ancestors have been freemen: and by the coat that a gentleman giveth, he is known to be, or not to be, descended from those of his name that lived many hundred years since.

The word is formed of the French *gentilhomme*; or rather of *gentil*, "fine, fashionable, or becoming;" and the Saxon *man*, q. d. *honestus*, or *honesto loco natus*.—The same signification has the Italian *gentilhuomo*, and the Spanish *hidalgo*, or *hijo dalgo*, that is, the son of somebody, or a person of note.—If we go farther back, we shall find *gentleman* originally derived from the Latin *gentilis homo*; which was used among the Romans for a race of noble persons of the same name, born of free or ingenuous parents, and whose ancestors had never been slaves or put to death by law. Thus Cicero in his *Topics*, "*Gentiles sunt, qui inter se eodem sunt nomine, ab ingenuis oriundi, quorum majorum nemo servitutem servivit, qui capite non sunt diminuti*," Gentleman, Gentoos. nuti," &c.—Some hold that it was formed from *gentile*, i. e. pagan; and that the ancient Franks, who conquered Gaul, which was then converted to Christianity, were called *gentiles* by the natives, as being yet heathens.—Others relate, that towards the declension of the Roman empire, as recorded by Ammianus Marcellinus, there were two companies of brave soldiers, the one called *gentiles*, and the other *scutarii*; and that it was hence we derive the names *gentleman* and *esquire*. See ESQUIRE.—This sentiment is confirmed by Pasquire, who supposes the appellation *gentiles* and *ecuyers* to have been transmitted to us from the Roman soldiery; it being to the *gentiles* and *scutarii*, who were the bravest of the soldiery, that the principal benefices and portions of land were assigned. See BENEFICE.—The Gauls observing, that during the empire of the Romans, the *scutarii* and *gentiles* had the best tenements or appointments of all the soldiers on the frontiers of the provinces, became insensibly accustomed to apply the same names, *gentilhommes* and *ecuyers*, to such as they found their kings gave the best provisions or appointments to.

GENTLEMAN *Usher of the Black Rod*. See ROD.

GENTLEMEN *of the Chapel*; officers whose duty and attendance is in the royal chapel, being in number 32. Twelve of them are priests; the other 20, commonly called *clerks of the chapel*, assist in the performance of divine service. One of the first 12 is chosen for confessor of the household; whose office is to read prayers every morning to the household servants, to visit the sick, examine and prepare communicants, and administer the sacrament. One of 20 clerks, well versed in music, is chosen first organist, who is master of the children, to instruct them in music, and whatever else is necessary for the service of the chapel; a second is likewise an organist; a third, a lutanist; and a fourth a violist. There are likewise three vergers, so called from the silver rods they carry in their hands; being a serjeant, a yeoman, and groom of the vestry; the first attends the dean and subdean, and finds surplices and other necessaries for the chapel; the second has the whole care of the chapel, keeps the pews, and seats of the nobility and gentry; the groom has his attendance within the chapel door, and looks after it.

GENTOOS, in modern history, according to the common acceptation of the term, denote the professors of the religion of the bramins or brachmans, who inhabit the country called *Hindostan*, in the East Indies, from the word *stan*, a "region," and *hind* or *hindoo*; which Ferishtah, as we learn from Colonel Dow's translation of his history, supposes to have been a son of Ham the son of Noah. It is observed, however, that Hindoo is not the name by which the inhabitants originally styled themselves; but according to the idiom of the *Shanscrit* which they use, *jumbodeep* from *jumboo*, a "jackall," an animal common in their country; and *deep*, a large portion of land surrounded by the sea; or *bhertekhunt*, from *khunt*, i. e. "a continent," and *bherrhut*, the name of one of the first Indian rajahs. It is also to be observed, that they have assumed the name of *Hindoos* only since the era of the Tartar government, to distinguish themselves from their conquerors the Mussulmans. The term *Gentoo* or *Gent*, in the Shanscrit dialect, denotes *animal* in general, and in its more confined sense *mankind*, and is never appropriated particularly to such as follow the doctrines of Brama. These are divided into four great tribes, each of which has its own separate appellation; but they have no common or collective term that comprehends the whole nation under the idea affixed by the Europeans to the word *Gentoo*. Mr Halhed, in the preface to his translation of the Code of Gentoo Laws, conjectures that the Portuguese, on their first arrival in India, hearing the word frequently in the mouths of the natives, as applied to mankind in general, might adopt it for the domestic appellation of the Indians themselves, or perhaps their bigotry might force from the word *Gentoo* a fanciful allusion to gentile or Pagan. The Hindoos, or Gentoos, vie with the Chinese as to the antiquity of their nation. They reckon the duration of the world by four jogues, or distinct ages; the first the Suttee jogue, or age of purity, which is said to have lasted about 3,200,000 years; during which the life of man was 100,000 years, and his stature 21 cubits: the second, the Tirtah jogue, or the age in which one-third of mankind were reprobate; which consisted of 2,400,000 years, when men lived to the age of 10,000 years: the third, the Dwaper jogue, in which half of the human race became depraved, which endured to 600,000 years, when men's lives were reduced to 1000 years: and fourthly, the Collee jogue, in which all mankind were corrupted, or rather diminished, which the word *collee* imports. This is the present era, which they suppose will subsist for 400,000 years, of which near 5000 are already past; and man's life in this period is limited to 100 years. It is supposed by many authors, that most of the Gentoo *shasters*, or scriptures, were composed about the beginning of the Collee jogue: but an objection occurs against this supposition, viz. that the shasters take no notice of the deluge; to which the bramins reply, that all their scriptures were written before the time of Noah, and the deluge never extended to Hindostan. Nevertheless, it appears from the shasters themselves, that they claim a much higher antiquity than this; instances of which are recited by Mr Halhed.

The doctrine of transmigration is one of the distinguishing tenets of the Gentoos. With regard to this subject, it is their opinion, according to Mr Holwell, that those souls which have attained to a certain degree of purity, either by the innocence of their manners or the severity of their mortifications, are removed to regions of happiness proportioned to their respective merits: but that those who cannot so far surmount the prevalence of bad example, and the powerful degeneracy of the times, as to deserve such a promotion, are condemned to undergo continual punishment in the animation of successive animal forms, until, at the stated period, another renovation of the four jogues shall commence, upon the dissolution of the present. They imagine six different spheres above this earth; the highest of which, called *suttee*, is the residence of Brama, and his particular favourites. This sphere is also the habitation of those men who never uttered a falsehood, and of those women who have voluntarily burned themselves with their husbands; the propriety of which practice is expressly enjoined in the code of the Gentoo laws. This code, printed by the East India Company in 1776, is a very curious collection of Hindoo

Gentoos, Genuflexion.

doo jurisprudence, which was selected by the most experienced pundits or lawyers from curious originals in the Shanscrit language, who were employed for this purpose from May 1773 to February 1775; afterwards translated into the Persian idiom, and then into the English language by Mr Halhed.

The several institutes contained in this collection are interwoven with the religion of the Gentoos, and revered as of the highest authority. The curious reader will discover an astonishing similarity between the institutes of this code and many of the ordinances of the Jewish law: between the character of the bramins or priests, and the Levites; and between the ceremony of the scape goat under the Mosaic dispensation, and a Gentoo ceremony called the *ashummed jug*, in which a horse answers the purpose of the goat. Many obsolete customs and usages alluded to in many parts of the Old Testament, may also receive illustrations from the institutes of this code. It appears from the code, that the bramins, who are the priests and legislators of the country, have resigned all the secular and executive power into the hands of another cast or tribe; and no bramin has been properly capable of the magistracy since the time of the suttee jogue. The only privilege of importance which they have appropriated to themselves, is an exemption from all capital punishment: they may be degraded, branded, imprisoned for life, or sent into perpetual exile; but it is everywhere expressly ordained, that a bramin shall not be put to death on any account whatsover.

We have already observed, that the Hindoos are divided into four great and original tribes, which according to the Gentoo theology proceeded from the four different members of Brama, the supposed immediate agent of the creation under the spirit of the Almighty. These tribes are the Bramins, which proceeded from his mouth, and whose office is to pray, read, and instruct; the Chehteree, which proceed from his arms, whose office is to draw the bow, to fight, and to govern; the Bice, proceeding from the belly or thighs, who are to provide the necessaries of life by agriculture and traffic; and the Soonder, from the feet, which are ordained to labour, serve, and travel.

Few Christians, says the translator of the Gentoo code, have expressed themselves with a more becoming reverence of the grand and impartial designs of Providence, in all his works, or with a more extensive charity towards all their fellow creatures of every profession, than the Gentoos. It is indeed an article of faith among the Bramins, that God's all merciful power would not have permitted such a number of different religions, if he had not found a pleasure in beholding their varieties.

GENUFLEXION, (of *genu*, "knee," and *flecto*, "I bend,") the act of bowing or bending the knee; or rather of kneeling down.

The Jesuit Rosweyd, in his Onomasticon, shows, that genufluxion, or kneeling, has been a very ancient custom in the church, and even under the Old Testament dispensation; and that this practice was observed throughout all the year, excepting on Sundays, and during the time from Easter to Whitsuntide, when kneeling was forbidden by the council of Nice.

Others have shown, that the custom of not kneeling on Sunday had obtained from the time of the apostles, as appears from St Irenæus, and Tertullian; and the Ethiopic church, scrupulously attached to the ancient ceremonies, still retain that of not kneeling at divine service. The Russians esteem it an indecent posture to worship God on the knees. Add, that the Jews usually prayed standing. Rosweyd gives the reasons of the prohibition of genuflexion on Sundays, &c. from St Basil, Anastasius, St Justin, &c.

Baronius is of opinion, that genuflexion was not established in the year of Christ 58, from that passage in Acts xx. 36. where St Paul is expressly mentioned to kneel down at prayer; but Saurin shows, that nothing can be thence concluded. The same author remarks, also, that the primitive Christians carried the practice of genuflexion so far, that some of them had worn cavities in the floor where they prayed: and St Jerome relates of St James, that he had contracted a hardness on his knees equal to that of camels.

GENUS, among metaphysicians and logicians, denotes a number of beings which agree in certain general properties common to them all: so that a genus is nothing else but an abstract idea, expressed by some general name or term. See LOGIC and METAPHYSICS.

GENUS, is also used for a character or manner applicable to every thing of a certain nature or condition: in which sense it serves to make capital divisions in divers sciences, as medicine, natural history, &c.

GENUS, in *Rhetoric*. Authors distinguish the art of rhetoric, as also orations or discourses produced thereby, into three genera or kinds, demonstrative, deliberative, and judiciary. To the demonstrative kind belong panegyrics, genethliacons, epithalamiums, funeral harangues, &c. To the deliberative belong persuasions, dissuasions, commendations, &c. To the judiciary kind belong defences and accusations.

GENUS, in *Medicine*. See MEDICINE, under the *Nosology*.

GENUS, in *Natural History*, a subdivision of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, which agree in certain common characters. See *NATURAL History*.

GENUS, in *Music*, by the ancients called *genus melodiæ*, is a certain manner of dividing and subdividing the principles of melody; that is, the consonant and dissonant intervals, into their concinuous parts.

The moderns considering the octave as the most perfect of intervals, and that whereon all the concords depend, in the present theory of music, the division of that interval is considered as containing the true division of the whole scale.

But the ancients went to work somewhat differently: the diatessaron, or fourth, was the least interval which they admitted as concord; and therefore they sought first how that might be most conveniently divided; from whence they constituted the diapente and diapason.

The diatessaron being thus, as it were, the root and foundation of the scale, what they called the *genera*, or kinds, arose from its various divisions; and hence they defined the *genus modulandi* to be the manner of dividing the tetrachord and disposing its four sounds as to succession.

The genera of music were three, the enharmonic, chromatic, and diatonic. The two first were variously subdivided;

subdivided; and even the last, though that is commonly reckoned to be without any species, yet different authors have proposed different divisions under that name, without giving any particular names to the species as was done to the other two.

For the characters, &c. of these several genera, see ENHARMONIC, CHROMATIC, and DIATONIC.

GEOCENTRIC, in *Astronomy*, is applied to a planet, or its orbit, to denote it concentric with the earth, or as having the earth for its centre, or the same centre with the earth.

GEOFFRÆA, a genus of plants belonging to the diadelphia class, and in the natural method ranking under the 32d order, *Papilionaceæ*. See BOTANY and MATERIA MEDICA *Index*.

GEOFFREY of MONMOUTH, bishop of St Asaph, called by our ancient biographers *Gallofridus Monumentensis*. Leland conjectures that he was educated in a Benedictine convent at Monmouth, where he was born; and that he became a monk of that order. Bale, and after him Pits, call him archdeacon of Monmouth; and it is generally asserted that he was made bishop of St Asaph in the year 1151 or 1152, in the reign of King Stephen. His history was probably finished after the year 1138. It contains a fabulous account of British kings, from the Trojan Brutus to the reign of Cadwallader in the year 690. But Geoffrey, whatever censure he may deserve for his credulity, was not the inventor of the stories he relates. It is a translation from a manuscript written in the British language, and brought to England from Armorica by his friend Gualter, archdeacon of Oxford. But the achievements of King Arthur, Merlin's prophecies, many speeches and letters, were chiefly his own addition. In excuse for this historian, Mr Wharton judiciously observes, that fabulous histories were then the fashion, and popular traditions a recommendation to his book.

Geoffroy.

GEOFFROY, STEPHEN-FRANCIS, a physician eminent for his chemical and botanical knowledge, was born at Paris in the year 1672, where his father kept an apothecary's shop, and had been several times in the magistracy. He received a liberal education; and, while prosecuting the study of medicine, he had conferences at his father's house with Cassini, du Verney, Homberg, and other men of distinguished eminence. At Montpellier he attended the lectures of the most able professors of physic, and afterwards visited the south of France, carefully viewing every object deserving of his attention. He accompanied count de Tallard to England in 1698, where he became acquainted with the chief men of science, and was made a member of the Royal Society. He next went into Holland, and in 1700 he attended the abbé de Louvois in a tour to Italy. He was, on his return, made bachelor of medicine in 1702, and, in two years after, he was created M. D. One of his theses was on the question, "*An hominis primordia vermis?*" which was translated into French for the sake of some ladies of exalted rank, by whom it was deemed interesting.

Geoffroy, Geographical.

Geoffroy did not hastily commence the practice of medicine, continuing the prosecution of his studies in retirement for some years. He never appeared anxious to push himself forward, although his knowledge made him be often consulted by several gentlemen of the faculty. He was so concerned for the recovery of his patients, that it gave him an air of melancholy, which at first alarmed them, till they became acquainted with the cause. He was, in 1709, made professor of physic by the king to the Royal College, vacant by the death of the celebrated Tournefort. He began with lectures on materia medica; and in 1712, M. Fagon resigned to him the chemical chair: on both which topics Geoffroy lectured with unwearied assiduity. He was twice chosen to the office of dean by the faculty of Paris, and he filled a place in the Royal Academy of Sciences, from the year 1699. His health at last yielded to his toils, and he died in January, 1731. He is known to the chemical world by his table of affinities, far superior to any which had appeared before his time. His greatest work was his History of the Materia Medica, which, in an unfinished state, was published after his death in the year 1741, in 3 vols. 8vo.

GEOGRAPHICAL MILE, the same with the sea mile; being one minute, or the 60th part of a degree of a great circle on the earth's surface.

GEOGRAPHY.

INTRODUCTION.

Definition.

GEOGRAPHY is that part of knowledge which describes the surface of the earth; its divisions, extent, and boundaries; the relative position of the several countries and places on the globe, and the manners, customs, and political relations of their inhabitants. The word is Greek, γεωγραφια from γῆ or γεα, *terra*, "the earth," and γραφω, *scribo*, "I write." As every thing that immediately contributes to the ascertaining of the situation and limits of countries and places on the surface of the earth, is within the province of geography, this science includes the description and use of globes, maps, and charts, with the methods of constructing them.

2 Division of geography.

This science has been divided into GEOGRAPHY properly so called, or a description of the *lands* of the globe, and HYDROGRAPHY, or a description of the waters; but this division is of little consequence, and is now seldom employed. Geography has also been divided into *general* and *particular*, terms which are variously understood by different writers on the subject. By Varenius, one of the oldest and best modern writers on general geography, general or universal geography is used to denote that part of the subject which considers the earth in general, and explains its affections as a terrestrial globe, without attending to its arbitrary division into different regions; and by particular or special geography, this writer understands the description of the particular regions of the earth: and he divides this latter into two parts; *chorography*, describing some considerable

Introduction.

siderable parts of the earth, as of the quarters, and *topography*, describing a particular province or district.

Geography may be conveniently divided into *descriptive* geography, or that part of the science which describes the form, limits, extent, and variety of surface of different countries, with the manners and customs of their inhabitants; and *physical* geography, or that part which teaches how to determine the situations of different places in the globe, and to lay down and delineate their positions for the information of others. Descriptive geography is the more popular and entertaining part of the subject. It is usually divided into ancient or classical geography, geography of the middle ages, and modern geography. The first branch of the subject considers the state of the earth so far as it was known or discovered at different periods, previous to the sixth century of the Christian era. The geography of the middle ages extends from the sixth to the fifteenth century, and modern geography from the fifteenth century to the present time. One of the most useful subdivisions of descriptive geography is that employed by Mr Pinkerton, who considers the geography of the several countries which he describes under four different heads. 1. *Historical* or *progressive geography;* in which he treats of the names, extent, original population, progressive geographical improvements, historical epochs and antiquities of the countries. 2. *Political geography;* under which he describes the religion and ecclesiastic institutions, government, laws, population, colonies, military force, revenue, and political relations. 3. *Civil geography*, comprehendig manners and customs, language, literature, and the arts, education, cities and towns, principal edifices, roads, manufactures and commerce. And, 4. *Natural geography*, comprehending an account of the climate and seasons, face of the country, its soil, and state of agriculture, its rivers, lakes, mountains, and forests, and an enumeration of the natural productions and natural curiosities, which are usually found within each district *. Descriptive geography is sometimes styled *political* geography, while physical or general geography is called *natural* geography.

* Vid. *Pinkerton's Geography*, vol. i. p. 3.

Among the other departments of this study we may mention sacred geography, or that which illustrates the sacred writings; and ecclesiastic geography, which describes the division of a country according to its church government, as into archbishoprics, bishoprics, &c.

Many writers of treatises or systems of geography give a detailed account of the historical events and commercial concerns of the several countries which they decribe; but we consider this as unnecessary in a pure geographical work, as these departments belong rather to HISTORY and *POLITICAL Economy*.

Some systematic writers on geography considering the term in a very comprehensive view, as including a description of the internal structure of the earth, as well as of its surface, have thought it necessary to enter into discussions respecting the original formation of the earth, and the minerals of which it is composed. How far they are right in this we shall not pretend to determine. In this work, these subjects will be treated of under the articles GEOLOGY and MINERALOGY.

Another subject relative to the affections of the earth, respects the physical and chemical changes that take place in its atmosphere. These properly belong to the science of METEOROLOGY, and will be found under that article.

3 Object of this treatise.

We propose in this article to offer only an introductory outline of descriptive geography, as the several quarters of the globe, and their subdivisions into empires, kingdoms, and states, are described as particularly as is compatible with the limits of this work, under the several articles to which they belong in the general alphabet.

Our attention will be chiefly directed to physical geography, especially that part of it which describes the construction and use of globes, maps, and charts.

4 Of physical geography.

Physical geography is properly a branch of mixed mathematics, and its principles depend on geometry, and its kindred sciences, trigonometry and perspective. It is intimately connected with astronomy; and as these two sciences mutually illustrate each other, they are commonly taught at the same time. The physical changes that take place on the earth, as far as it is considered in its general character of an individual of the solar system, have been already explained under ASTRONOMY; and we shall have little here to add respecting them, except as they are modified by the situation of the observer on different parts of the earth's surface.

The principles and practice of physical geography, though strictly dependent on pure mathematics, may be, for the most part, explained in a popular way, so as to be understood by the generality of readers. This popular view of the subject we shall attempt in the present article, throwing every thing that is purely mathematical into the form of notes. It must be evident, however, that a reader who is conversant with mathematics will study physical geography to more advantage; and for this purpose, it will be sufficient to possess a moderate acquaintance with arithmetic, the elements of geometry, plane trigonometry, spherics, and perspective.

5 Importance of geography.

It is scarcely necessary to enlarge on the importance or utility of geography. It is one of those sciences, the knowledge of which is almost constantly required. Without an acquaintance with the geography of the countries that are the scenes of the actions which he relates, the historian must either be extremely concise, or his narration must be obscure and unintelligible. Geography affords the best illustration of history, and is equally necessary to the historian and his reader. To the traveller, under which denomination we may class the soldier, the sailor, the merchant, as well as those who travel for pleasure or curiosity, a previous knowledge of the countries, through which he is to pass, is always useful, and often indispensable. To the politician a comprehensive knowledge of geography is of the highest importance. If he is ignorant of the extent, form, boundaries, appearances, climates, &c. of the country with which he is at war, he will plan his hostile expeditions without effect, and will send his invading armies only to perish among the defiles of the enemy, or to meet a more inglorious and deplorable fate from the diseases of the climate.

Even, if we consider geography as a study of mere amusement and curiosity, it forms one of the most rational and interesting studies in which we can engage. Nothing can be more gratifying to the observer of mankind than to survey the manners and customs of various

History.

rious nations, and to compare the relative state of civilization and improvement in countries widely remote from each other. The student of geography can sit in his closet, and accompany the adventurous traveller in his toilsome journey, through

——————" antres vast, and deserts wild,
Rough quarries, rocks, and hills, whose heads touch heav'n!"

trace his progress over the boundless ocean, and draw from his narration a delightful fund of instruction and amusement, free (except in imagination) from those perils and hardships, which the writer had undergone.

At the end of this article, we shall offer a few remarks on the best method of teaching and learning geography. We must now take a brief view of the origin and progress of the science.

PART I. HISTORY AND PRESENT STATE OF GEOGRAPHY.

6
History of Geography.

AN historical account of geography would be extremely interesting, as it would include, not only the progressive improvements of the science, considered as a branch of mixed mathematics, but an account of the successive discoveries of different parts of the earth that have been made by the more civilized communities. Such an account in detail, however, cannot be expected here; and we shall confine ourselves principally to a cursory view of the geographical discoveries of ancient and modern nations, reserving the progressive improvements of physical geography for those parts of the article to which they properly belong; as they would neither be so interesting nor so intelligible to a general reader, before he has been made acquainted with the principles of the science.

7
Origin.

As soon as mankind had formed themselves into societies, and begun to establish connexions with their neighbours, they would find it necessary to inform themselves of the position of the countries which bordered on their own; and very soon their curiosity would lead them to desire to form an acquaintance with the extent of the country in which they lived, and with many particulars respecting those which were remote from them. Thus, we see that scarcely had the sciences arisen among the Greeks, before their philosophers began to occupy themselves in geographical pursuits. We are told that Anaximander exhibited to his countrymen a plan of Greece and the neighbouring countries, and in this he was imitated by his countryman Hecatcus of Miletus. Of the nature of these ancient plans or maps, and their progressive improvements, we shall speak more at large hereafter.

Discoveries of the Phœnicians.

Commerce, and the taste for adventures, which usually accompanies it, were doubtless among the first causes of geographical researches; but the Phœnicians are the earliest commercial people of whose discoveries we have any correct accounts. This people seem first to have investigated the coasts on the Mediterranean; and their navigators, extending their voyages beyond this sea, through the narrow channel which is now called the Straits of Gibraltar, entered the Atlantic ocean, and planted colonies in Iberia, a part of Spain, in the country of Tharshish, which is probably the modern Andalusia, and upon the western shores of Africa.

The learned Bochart, led by the analogy between the Phœnician tongue, and the oriental languages, has followed the tracks of the Phœnicians, both along the shores of the Mediterranean, and those of the Atlantic. These analogies are not always sure guides; but we can scarcely doubt that the city of Cadiz was a Phœnician colony, and it is not likely that this was the only one formed by that enterprising people.

9
Situation of Ophir.

In the time of Solomon, Phœnician ships, employed by him, set sail from a port in the Red sea, called Azion-Gaber, and passing from that sea through the straits of Babelmandel, carried on their commerce in the Indian ocean. The country of Ophir, to which they sailed, must have been at a considerable distance from the Red sea, as we are told that a voyage thither required three years. "The king (says the author of the first book of Kings) had a navy of Tharshish, with the navy of Hiram. Once in three years came the navy of Tharshish, bringing gold and silver, ivory, and apes and peacocks." Some have placed Ophir upon the coast of Africa, where the modern Sofala is situated: Others suppose it was a port in the island of Ceylon, or in the island of Sumatra, in which latter island there is still a place called Ophir. The gold dust and ivory brought from thence, seem to shew that it was an African port. (See OPHIR). M. Montucla supposes that the Phœnicians must even at this period have sailed round the continent of Africa, and that Ophir was some place on the Gold Coast (A).

Montucla Hist. de Mathem. p. 590.

10
Carthaginians.

The Carthaginians, a Phœnician colony, imitated their predecessors. We know that they sailed into the Atlantic ocean, as far as the coast of Cornwall in England, whence they procured large quantities of tin. The same people made several attempts towards a complete survey of the western coast of Africa. Of these we have an account only of one expedition, that of Hanno, of which we have already given an account under the article AFRICA.

The Carthaginian navigators, if we may believe the recital of Diodorus Siculus, (lib. xv.) discovered a country situated in the Atlantic ocean, which furnished all the necessaries and conveniences of life. Some pretend that this country was America, but it is much more probable that it was some one of the Cape de Verd islands.

(A) The most celebrated writers who have supported the opinion, that Ophir was a port in Africa, are Montesquieu, Bruce, and d'Anville. Dr Prideaux and M. Gosselin again contend, that Ophir was a port in Arabia Felix, and the same with *Sabéa* or Sheba; and their opinions have lately been ably supported by Dr Vincent. See *Vincent's Periplus of the Erythrean Sea*, Part II.

History.

islands. The Carthaginian senate, fearful that the relation of the sailors who had discovered such a country, might be the means of producing frequent emigrations, are said to have used every endeavour to stifle the memory of this expedition.

11 Circumnavigation of Africa.

History speaks of several voyages undertaken by order of the kings of Egypt and of Persia, for the purpose of ascertaining the extent of Africa; and Herodotus relates that Pharaoh Necho, king of Egypt, employed some Phœnician navigators to sail along the coast of Africa, for the purpose of taking a more exact survey of it. See AFRICA.

M. Gosselin, who has considered the geography of the ancients in a very learned dissertation, maintains, that the different passages of ancient writers, who have always declared that the Phœnicians and the Greeks circumnavigated Africa, are not sufficient to prove the certainty of such a voyage. The passage in Herodotus has been discussed by him at considerable length, and he seems to have proved his relation to be nothing more than a romance, founded on the historical knowledge of the Egyptians. M. Gosselin, however, admits, that many ancient voyages took place from those countries in which geography had arrived at some perfection; and there are numerous arguments, proving that all the shores of the old continent had been sailed round. See *Bailly's History of Astronomy*, p. 307. edit. 1755.

12 Voyage of Sataspes.

Xerxes king of Persia, according to Herodotus, gave a similar commission about the year before Christ 480, to one of his satraps named Sataspes, who had been condemned to die. Sataspes entered the Atlantic ocean through the straits of Gibraltar, and bending his course towards the south, he coasted the continent of Africa, till he doubled a cape which was called Syloco, and which Riccioli considers as the same with the Cape of Good Hope. He is said to have continued his course to the south for some time, and then to have returned home, assigning as a reason for not proceeding farther, that he had encountered a sea so full of herbage, that his passage had been completely obstructed. This reason appeared so ridiculous to Xerxes, that he ordered Sataspes to be crucified; but in this sentence he appears to have been rather too precipitate, as it is certain that in some latitudes there grows such a quantity of sea weed, that a vessel can scarcely make way through it; as in that part of the sea which lies between the Cape de Verd islands, the Canaries, and the coast of Africa, and is called by the Portuguese the sea of Saragossa. This shews that the relation of Sataspes may have been correct, as he might think it dangerous to attempt proceeding where he found himself so much entangled.

13 Expedition of Scylax.

Herodotus has commemorated another marine expedition, undertaken by Scylax, by order of Darius the son of Hystaspes, and which probably took place about the year 422 B. C. Scylax embarked upon the river Indus, the course of which he followed to its mouth, from whence he sailed in the course of 30 months, either into the Arabian gulf, or the Red sea. This Scylax must not be confounded with a navigator of the same name, who, at a later period, made a voyage of investigation round the Red sea.

14 Geography improved by Alexander.

The conquests of Alexander the Great, if they added little to the happiness of mankind, had at least the advantage of throwing considerable light on the state of geography at that time, as they afforded to the Greeks a more perfect knowledge of the river Indus, and of many parts of that vast country which derives its name from that river. Alexander does not seem to have penetrated to the Ganges, though his expedition led the way to the knowledge of that river; for soon after he went as far as Palibothra, a town situated on the river Indus, at its confluence with another river coming from the west. The followers of Alexander went down the Indus, as far as its opening into the Indian ocean, where they witnessed for the first time the phenomenon of the flux and reflux of the sea,—a phenomenon which excited in them great astonishment and terror. It was after this that Alexander detached, about the year 327 before Christ, two of his captains, Nearchus and Onesicritus, to investigate the coast of the Indian sea. Nearchus was ordered to return by the Red sea, and this he effected. Some fragments of his voyage have come down to us, and upon these has been formed an excellent work by Dr Vincent, entitled the "Periplus of the Erythrean Sea." This learned and valuable work is just completed by the publication of the Second Part, and affords much additional illustration of the geographical information and commercial enterprises of the ancients.

Onesicritus sailed to the east, and if we may believe the account that is left of his voyage, he gave us the first exact information respecting the island of Ceylon. The measure given by Onesicritus, of the extent of the island which he investigated, viz. 7000 stadia, does not correspond to Ceylon, whether we consider the length or circumference of the island, (see CEYLON); and if we take it as the measure of the length, it more nearly corresponds to that of Sumatra. The relations of Nearchus and Onesicritus were extant in the time of Strabo, by whom the latter is said to exceed, in point of exaggeration, all the other historians of Alexander's expedition. At the same time, it must be acknowledged that there are many things related by Onesicritus, as quoted by Strabo, which sufficiently agree with what we know of India, and the productions of that country: for he speaks of the sugar cane, the cotton plant, the bamboo, &c.

15 By Ptolemy Philadelphus.

The kings of Egypt who succeeded Alexander, took considerable interest in the progress of geography. The second of these kings, Ptolemy Philadelphus, about the year 280 before Christ, sent into India two ambassadors, Megasthenes and Daimachus, accompanied by the mathematician Dionysius. Megasthenes was sent to the king of Palibothra on the banks of the Ganges, and Daimachus to another Indian potentate. No account remains of the proceedings of Dionysius and Daimachus, but Megasthenes left an account of his journey, which is frequently quoted by Strabo, by whom it is considered as a mixture of real adventures and improbable exaggerations. These quotations of Strabo are certainly all that remain of the relation of Megasthenes; for the work published under the name of Megasthenes is a literary imposture, similar to the works of Berosus, Manetho, and Ctesius.

16

In the reign of Ptolemy Lathyrus, about 115 years before Christ, other expeditions were undertaken, for the purpose of sailing round the continent of Africa.

Eudoxus and Cysicus having incurred the displeasure of Ptolemy, were sent on this voyage of discovery. They

History.

They passed through the straits of Gibraltar, and circumnavigating Africa, returned by the Red sea. Lastly, in the reign of Ptolemy, surnamed Alexander, about 90 years before Christ, Agatarchides, who had been the king's governor, was sent to take a complete survey of the Red sea, and wrote an account of his voyage, of which, however, there remain only a few extracts that are preserved by Photius, in his Bibliotheca, a work of the ninth century.

17 Voyage of Pythias.

The extension of commerce seems always to have been one of the principal objects of these voyages of discovery. It is not surprising, therefore, that the inhabitants of Marseilles, which was early celebrated as a commercial city, appear among the ancient navigators who laboured to extend geographical knowledge. Two voyagers, Pythias and Euthymenes, undertook an expedition about 320 years before the Christian æra. Euthymenes entered the Atlantic through the straits of Gibraltar, and turned towards the south, for the purpose of taking a survey of the coast of Africa. This is all that we know of his route; but Pythias steered northward, and after reconnoitring the coasts of Spain and Gaul, sailed round the island of Albion, and stretching still farther to the north, discovered an island which is believed to be the modern Iceland, or the Thule of the ancients, *terrarum ultima Thule*. Perhaps, however, this was only one of the Ferro islands. Strabo, who appears to have been prejudiced against Pythias, treats his relation as fabulous, founding his opinion principally on the number of incredible circumstances that occur in his narration. Taking these circumstances, however, not according to their literal meaning, but in a figurative sense, they represent pretty well the state of the sea and sky in these countries which are so little favoured by nature. Pythias certainly seems to have been one of the first Greek navigators who entered the Baltic.

18 Ancient geographers.

We have thus traced the progress of geographical discoveries to very nearly the period which we assigned as the limit of ancient geography; and shall now notice very briefly some of the principal scientific geographers of antiquity, whose names or writings have descended to posterity, and shall afterwards give a summary sketch of the knowledge which the ancients seem to have possessed of the habitable globe.

As geography is a branch of knowledge intimately connected with geometry and astronomy, it became an object of consideration with many of the ancient geometers and astronomers. We have already mentioned the names of Anaximander of Miletus, and his countryman Hecateus. Strabo also notices Democritus, Eudoxus of Cnidos, and Parmenides, to the last of whom he attributes the division of the earth into zones. These were followed by Eratosthenes, who lived about 240 years before the Christian æra, and Hipparchus, who flourished about 80 years afterwards; Polybius, Geminus, and Possidonius. Eratosthenes wrote three books on geography, of which Strabo criticises some passages, though he frequently defends him against Hipparchus, who often affects an opposite opinion. Polybius wrote on geography as well as history, and, as well as Geminus and Possidonius, is frequently quoted by Strabo. Polybius and Geminus argue with considerable acuteness for the possibility of the torrid zone being inhabited, a circumstance which was generally disbelieved by the ancients; and they even adduce arguments which are very plausible, to prove that the climate of the countries under the equator is more temperate than that of those which are situated near the tropics.

We must not here omit a geographer and mathematician who lived about the time of Alexander the Great. This was Dicearchus of Messina, the disciple of Theophrastus, who wrote a description of Greece in iambic verses, of which some fragments yet remain. What renders this work most remarkable is, that it contains the height of several mountains measured geometrically by Dicearchus. Thus, for instance, the height of Mount Cylene is stated at 15 stadia, and that of Satabyce at about 14. Taking the stadium at $94\frac{1}{2}$ toises, we have for the latter of these heights, at most 1400 toises, whereas many of the ancients assigned 300, 400, or even 500 stadia, as the height of some of their mountains.

With Dicearchus we may mention another geometer noticed by Plutarch in his life of Paulus Emilius; viz. Xenagoras, a disciple of Aristotle, who also employed himself in measuring mountains, and has assigned only 15 stadia, which is equal to about 1417 toises, as the height of Mount Olympus. In some of the later periods previous to the Christian æra, we find the names of several geographers, as Artemidorus of Ephesus, who wrote a geographical work in eleven books, of which nothing remains; Scymnus of Chio, author of a description of the earth in iambic verses, which remains in a very mutilated state; Isidorus of Charax, who left a description of the Parthian empire, and Scylax of Caryades, author of a voyage round the Mediterranean sea, which is still extant.

The works of all these geographers, however, are trifling when compared with the geography of Strabo, a work in 16 books, which has come down to us entire. This is one of the most valuable works of antiquity, both from the spirit of discussion which runs through it, and the number of curious observations which the author has collected of different geographers and navigators who preceded him; and of whose works nothing remains except these extracts. Strabo lived in the reigns of Augustus and Tiberius, and was nearly cotemporary with Pomponius Mela. This latter geographer wrote a work *de situ orbis*, which is little more than a bare summary, though it is valuable, as it gives us a sketch of what was known in his time respecting the state of the habitable globe. Pomponius Mela was followed by Julius Solenus, who has also treated of geography in his Polyhistor, a compilation which is sufficiently valuable from the number of curious observations which are there collected. 19 Strabo. 20 Pomponius Mela.

Of all the ancient geographers, posterity is most indebted to Ptolemy, who produced a work much more scientific than had ever before been written on this science; a geography in eight books, which must ever be considered as one of the principal monuments of the labours of its author. In this work there appear, for the first time, an application of geometrical principles to the construction of maps; the different projections of the sphere, and a distribution of the several places on the earth, according to their latitudes and longitudes. This work must have been the result of a great many relations both historical and geographical, that had been collected by Ptolemy. It has passed through numerous editions. 21 Ptolemy.

History.

22 Dionysius the Periegetic.

Some time after Ptolemy, lived Dionysius the African, commonly called the *Periegetic*, from the title of a work that he composed in verse, containing a description of the world, which may be considered as one of the most correct systems of ancient geography, and was by Pliny proposed to himself as a pattern. This work was afterwards translated into Latin verses by Priscian, and by Avienus, the latter of whom also wrote a description of the maritime coasts in iambic verses, of which there remain about 700. Among the latest geographers of this period are reckoned Marcianus and Agathemares, of whom little is known, except that the latter was author of two books on geography.

23 Hudson's collection.

The scattered works of most of these authors being difficult to procure, were collected by Hudson into one work, and published by him in four volumes octavo, in the years 1698, 1702, and 1712, under the title of *Geographiæ veteris scriptores Greciæ minores*, together with a Latin translation, and notes and dissertations on each by Dodwell. In this work we find the remains of Hanno, Scylax, Nearchus, Agatarchides, Arrian, Marcianus, Dicearchus, Isidore of Charax, Scymnus, Agathemares, Dionysius the Periegetic, Artemidorus, Dionysius of Bisance, Avienus, Priscian, and some fragments of Strabo, of Plutarch, of Ptolemy, of Albulfeda, and of Ulug Beg. This is a most valuable collection, and as it had become extremely scarce, was a few years ago reprinted at Leipsic.

24

The above is a hasty sketch of the names and characters of most of the geographical writers within the period which we have assigned to the ancient history of the science. We shall have occasion to make some further observations on the more eminent of these geographers in a future part of this article.

25 Geographical knowledge of the ancients.

With respect to the knowledge of the globe that was possessed by the ancients, there have been various opinions; some have considered them as very extensively acquainted with almost every part of it, not excepting some portion of America; while others have confined their geographical knowledge within very narrow limits. The following observations are chiefly drawn from M. Montucla, an eminent judge in every thing that relates to the history of the mathematical sciences.

26 Europe.

As to the knowledge which the ancients possessed of the habitable globe, it is certain that they were well acquainted with Europe, or at least all that part of it which had been made subject to the Roman empire, as far as the banks of the Rhine and the Danube. They were tolerably well acquainted with Germany and Sarmatia. They had some knowledge of the Baltic sea, as a fleet had been sent by Augustus, which sailed as far as the peninsula then called the Cimbrian Chersonesus, the modern Jutland. The Baltic was at that time celebrated for the production of ambergrise. They had acquired a knowledge of the island of Britain, from the expeditions of Julius Cæsar and Claudius; but the northern parts of this island, and the whole of Ireland, were to them nations of rude, uncivilized savages. The boundary of their knowledge of Europe to the north, was the Thule of Pythias, or Iceland; at least if it is certain, as is the general opinion, that this island is the *ultima Thule*.

27 Asia.

With respect to Asia, they seem to have surveyed the country as far towards the east as the river Ganges; and the immense extent of country comprehended between the Indus and the Ganges, was called by them *India on this side the Ganges*. Further on towards the north of China, in the neighbourhood of the mountains where these rivers derive their source, they placed several nations of people, of whom they related the most ridiculous fables. Beyond these, still more towards the east, they placed the Seres, and upon the coast of the gulf, which is now the bay of Cochin China, called by Ptolemy the Great Bay, were situated the Sinæ, so called by Ptolemy, though they are not mentioned by Strabo, Pomponius Mela, or Solinus. The Seres were probably the inhabitants of the northern parts of China, and the Sinæ, those of the southern parts of China, who very early occupied Cochin China, Tonquin, &c. countries which in the sequel they have entirely subjugated. They maintained a commerce by land with the Seres, and their route is pointed out in one of Ptolemy's maps. Beyond the Seres, according to Strabo and Pomponius Mela, lay between the Oriental sea, though Ptolemy, for want of certain intelligence respecting that part of Asia, considers the point as undecided, and places there several unknown countries. The ancients carried this extremity of Asia much farther to the east than it is found to extend by modern geographers; for, according to them, the Seres and the Sinæ were situated about the longitude of 180°, while the meridian of Pekin, or about the middle of the Chinese empire, reaches no farther than to 134°, reckoning the longitude from the most distant of the Canary islands, as was done by Ptolemy. To the north of the Indus the ancient geographers placed the Scythians, and Hyperboreans (the Tartars and Samoiedes of more modern date) and some other nations to an indefinite extent, who were supposed to form on that side an insurmountable barrier, having behind them an ocean of ice, which was believed to communicate with the Caspian sea, though this was at least at the distance of 450 leagues.

The boundary of Asia, assigned by the ancients to the south, was the Indian ocean, and they were acquainted with its communication with the Red sea, by means of a strait, the figure of which is very ill expressed in their maps. This is also the case with the Persian gulf, with which they were acquainted, but which in the ancient maps has nearly the form of a rhombus, one side of which, towards the mouths of the Indus, was pretty well known to them, but the side next the mouths of the Ganges is very inaccurately delineated, being continued nearly in a straight line. It is even probable that the island which Ptolemy calls Taprobana, was only the peninsula of India very much disfigured in the delineation.

28 Situation of the Taprobana.

The situation of this island of Taprobana, so celebrated among the ancients, is a problem in geography that is yet unsolved. It is commonly supposed to be the modern island of Ceylon; but the dimensions of it as laid down by ancient geographers, render this supposition doubtful, and there are some who rather believe it to be the modern Sumatra. The ancients had also some obscure knowledge of the peninsula of Malacca, which they called the *Golden Chersonesus*; and they seem to have examined the gulf formed by that land, which is now the gulf of Cochin China, or commonly called the *gulf of Tonkin*. It is somewhat extraordinary that they do not seem to have been acquainted

History.

quainted with Java, Borneo, and that numerous group of islands which form, in that quarter, the greatest Archipelago in world. It is equally singular that the Maldives had escaped the observation of these navigators. This seems to prove that they never ventured out into the open sea, but kept close along the shore. Ptolemy indeed says, that his island of Taprobana was surrounded with many hundreds of smaller islands, to some of which he gives names; but all this is involved in impenetrable obscurity.

29 Africa.

Of Africa, the ancients knew only those parts which lay along the coast, and to a very small distance inland, if we except Egypt, with which they were well acquainted, at least as far as the cataracts of the Nile, and a little beyond them, as far as the island of Meroë, towards the 20th degree of north latitude. Their knowledge of the coasts of Africa on the side of the Red sea, extended no farther than the shores of that sea, except that part which was dependent on Egypt; the interior of the country being inhabited by ferocious and untractable people. They were still less acquainted with the countries which lay beyond the strait, and Ptolemy appears to have given no credit to the navigators who were said to have sailed round that part of the world, for he has left the continent of Africa imperfect towards the south. Strabo and Pomponius Mela were, however, decidedly of opinion that Africa was a peninsula, and that it was joined to the rest of the continent only by that narrow neck of land which is now called the isthmus of Suez. The ancients seem to have had no knowledge of that large and beautiful island of Madagascar, unless we suppose that Ptolemy had some imperfect acquaintance with it, under the name of the island *Menuthius*. The coast of Africa upon the Mediterranean sea, was once covered with towns, dependent on the Roman empire, flourishing and polished, while it presents at present nothing but a nest of pirates, whom the jealousy of the great commercial nations supports, to the disgrace and prejudice of civilized states. Proceeding from the straits of Gadez or Gibraltar, they had become acquainted with the coast as far as a cape which they called *Hesperion-Keras*, probably the modern Cape de Verd, or the cape that lies a little to the west of it, though in the maps of Ptolemy it is thrown a little back inland. The Fortunate islands, or the Hesperides, at present the Canaries, better known by fame than in reality, seem to have been the boundaries of ancient geography to the west, as the Seres and Sinæ were to the east. It appears, however, that the Cape de Verd islands were not entirely unknown to the ancients, and they are probably the same with what were then called the Gorgades or Gorgones, which were supposed to be two days sail to the west of Hesperion-Keras.

"There is little doubt (says Mr Patteson) concerning the names by which most of the principal countries of Europe were known to the ancients; nor is there any difficulty in disposing the chief nations, which ancient writers have enumerated in the south-west part of Asia or on the African coast of the Mediterranean; but with the north and north-east parts of Europe, about two-thirds of Asia towards the same quarters, and nearly the same proportion of Africa towards the south, they appear to have been wholly unacquainted. Of America they did not even suspect the existence; and if it ever happened, as some writers have imagined, that Phœnician merchants ships were driven by storms across the Atlantic to the American shores, it does not appear that any of them returned from thence to report the discovery.

"The names of provinces, subdivisions, and petty tribes, mentioned by ancient authors, in those countries which were the chief scenes of Roman, Grecian, or Israelitish transactions, are almost as numerous as in a modern map of the same countries; and the situations of many of them can be very nearly assigned: but the limits of each, or indeed of the states or nations to which they belonged, can, in very few instances, be precisely fixed. Thus the southern boundaries of the Sarmatæ in Europe, cannot be ascertained within a degree at the nearest; and in France, neither the limits of the people called the Belgæ, Celtæ, and Aquitani; nor those of the Roman divisions, viz. Belgica, Lugdunensis, Aquitania, Narbonensis, and the Province, can be laid down, in many places, but by a hardy conjecture. The same observation may be justly applied to the Tarraconensis, Lusitania, and Betica of Spain; to the Cauci, Catti, Suevi, &c. of Germany; and, above all, to the Britannia prima et secunda, and other divisions of the Roman government in Britain: of which not only the limits, but the situations are still in dispute*."

* Patteson's Atlas, Part I. page 27.

31 Geography of the middle ages.

During the middle ages geography, as well as most other arts and sciences, seems rather to have gone backwards than advanced. The weakness of the Roman emperors, the relaxation of military discipline, the boundless passion for luxury and pleasure, and the continual incursions of the barbarous nations, while they contributed to hasten the fall of the western empire, also accelerated the ruin of the arts. It seems as if these destructive hordes of barbarians, the Goths, the Huns, and the Vandals, had enveloped the whole world in one profound and universal ignorance. This darkness, which overspread the whole of Europe, did not permit geography to make any advances for a very considerable time. There were indeed some navigators who investigated countries that were still little known, but they were so ignorant, that they afford us very little new light. There was one named Cosmas, who made a voyage to India, which procured him the name of Indo-Pleustes, and who gave an account of his voyage under the title of *Sacred Geography*. This man was so egregiously ignorant, as to believe that he had discovered that the earth was a plane, and that the diversity of the seasons, and the inequality of the days and nights, were owing to a very high mountain situated to the north, behind which the sun set to a greater or less depth.

32 Discoveries of the Arabians.

The voyages of the Arabians to the East Indies (see the history of COMMERCE), contributed to throw farther light on that extensive part of the globe. Conquerors of the countries on the Red sea, and enthusiastic propagators of their religion, they carried their arms as far as the extremity of India. We see them in the 9th century extending to China; and Renaudot has published two of their narrations, in which we can trace, with tolerable accuracy, the places visited by their authors. The island of Serendib, so celebrated in their tales, is certainly the modern Ceylon; for *dib* or *dit*, in the Malay language, signifies *island*, so that Serendib, signifies the island of Seren or Selan. Farther, these

relations

History.

relations do not give us as favourable an idea of the Chinese as we derive from their own history; on the contrary, if we may believe these Arabian travellers, this people were, even at that time, in a state not very civilized.

33 Modern discoveries.

We are now arrived at the modern period of our history, during which the most important discoveries have been made, and our knowledge of the habitable globe more than doubled. The discoveries and improvements during this period are so numerous, that it will be impossible to give here any thing more than a chronological view of the most remarkable, referring for a detailed account of them to the geographical and historical articles in this work.

The taste for voyages of discovery began in Europe soon after the revival of literature in the 15th century, just before the commencement of which, namely, in the reign of Henry III. king of Spain, about the year 1395, the Canary islands were more fully surveyed than at any former period.

1415. Prince Henry III. son of John king of Portugal, sailed round the coast of Africa.

1417. The Canary islands were subdued by Bethancourt, nephew of the admiral of France.

1420. The island of Madeira was examined by John Gonsalvo and Tristan Vaz, two Portuguese.

1446. Cape de Verd was discovered by Dennis Fernandez.

1487. The Cape of Good Hope was discovered by Barthelemi Diaz. The discovery of this cape led the way to that of the new world. This great event, which gave a new flight to the genius of mankind, is one of the most important in the history of geography. A particular account of this discovery will be found under the article AMERICA. The following are the dates of the principal geographical discoveries which have taken place between that of Columbus, and the voyages of our celebrated navigator Cook.

1496. Florida, by Sebastian Gabot, an Englishman.
1498. The Indies, by Vasco di Gama.
1499. The river of Amazons, by Yanez Pinçon.
1500. Brazil, by Alvarez Cabral, a Portuguese.
1504. Newfoundland, by some Normans.
1518. Mexico, by Ferdinand Cortes.
1519. The straits of Magellan, South sea, and Philippine islands, by Ferdinand Magellan.
1525. Canada, by Jean Verrazan, a Florentine, sent by Francis I. of France.—Peru, by F. Pizarro of Spain.
1527. New Guinea, by Alvaro de Salvedra.
1534. Chili, by Diego Almagro.
1535. California, by Ferdinand Cortes.
1567. The islands of Solomon, by Alvaro de Mendoza.
1618. New Holland, by Zechaen.
1642. Van Diemen's land, by Abel Jansen Tasman.
1643. Brower's land.
1654. New Zealand.
1678. Louisiana, by Robert Cavelier de Lasalle, governor of Frontiniac.
1700. New Britain, by Dampier, an Englishman.
1739. Cape Circumcision, contested between the French and English. Said by Montucla to be discovered by two French vessels.
1767. The island of Taiti, by Wallis, an Englishman.
1778. The Sandwich islands, by Cook.

34 Number of voyages round the world.

Within this period there are reckoned 25 voyages round the world, viz. those of Magellan, Drake, Cavendish, Noort, Spilburg, Lemaire, L'Hermite, Clepington, Carreri, Shelvack, Dampier, Cowley, Woodes Rogers, Le Gentil, Anson, Wallis, Roggewein, Bougainville, Sarville, Dixon, three voyages of Cook, La Peyrouse, Marchand, Vancouver, and Pages.

35

Within these few years, very considerable light has been thrown on the state of our geographical knowledge, by several valuable voyages and travels that have lately appeared. The discoveries that have been successively made in the great South sea, and in other parts of the world, especially the extensive island of New Holland, are now so fully established, as to add considerably to the certainty of our geographical knowledge; and the voyages of Cook, La Peyrouse, and Vancouver, have afforded us more exact surveys of the coasts of these countries, than we could, some years ago, have dared to hope for. The accounts of the late embassies to China, Tibet and Ava, afford many authentic materials for a modern system of geography, the place of which must have been supplied by more remote and doubtful information. From the latter of these accounts we are become familiarly acquainted with an empire (that of the Birmans), which a short time ago was scarcely known (see ASIA, 81—152). Our knowledge of Hindostan and the neighbouring countries has been greatly extended by the researches of the Asiatic Society, and some other late works; while our acquaintance with the interior of Africa has been rendered less imperfect by the exertions of the African Society, and by the travels of Park, Brown, and Barrow; and the northern boundaries of America, even as far as the sea which appears to surround the northern extremity of that vast continent, have been more fully disclosed by the journeys of Hearne and Mackenzie.

The late voyage of Turnbull, however insignificant it may be in other respects, has at least the merit of enlarging our knowledge of the manners and political transactions of the South sea islanders, and of introducing to our acquaintance, in the person of Tamahama, the chief of Owhyhee, a sovereign, who, in ambition and desire of improvement, bids fair to vie with Peter the Great, and to transform a nation of savages, to a civilized people.

36 Present defects of geography.

With all the advantages which geography has lately received, the science is still far from being perfect; and the exclamation which D'Anville is said to have made in his old age, "Ah! mes amis, il y a bien d'erreurs dans la geographie"—*Ah! my friends, there are a great many errors in geography*, may still be applied with considerable justice. Many points in the science have been but very lately ascertained. Thus, the extent of the Mediterranean sea was almost unknown at the beginning of the 17th century, although it is now almost as exactly ascertained as that of any country in Europe. In a book published by Gemma Frisius, *de orbis divisione*, in 1530, we find the difference of longitude between Cairo in Egypt and Toledo in Spain stated at 53° instead of 35°, and other measures of extent are proportionally erroneous. Not many years ago there was an uncertainty with respect to the extremity of the Black sea and the Caspian, to the amount of 3° or 4°; and

and so lately as the year 1769, the longitude of Gibraltar and of Cadiz was not known within half a degree.

Many parts of the geography of Europe are still very defective; Spain and Portugal have been but imperfectly explored, and European Turkey is still less known. It may appear extraordinary that we have yet no correct chart of the British channel, though we are assured by Major Rennel that this is the case; and it has been proved by the trigonometrical surveys of Britain that have yet been published, that there are many gross errors in our best county maps. We have had occasion to remark that geography has sometimes been retrogressive, and there cannot be a greater proof of the truth of the observation, than that in a map of the Shetland islands, published not long ago, by Preston, they are represented as too large by one third, both in length and breadth, and their relative positions are very inaccurate, though in the maps of the same islands published before the year 1750, they are laid down with much greater accuracy, as appears from surveys made by order of the late king of France, and from the maps published by Captain Donelly, and at Copenhagen, in the year 1787.

In Asia we are imperfectly acquainted with Thibet, and some other central regions; and even Persia, Arabia, and Asiatic Turkey, are but little known. Of Australasia, or New Holland, and New Guinea, almost nothing is known except the coasts, and a great part of them towards the south has been but imperfectly explored. Of Polynesia, or the numerous islands in the South Pacific ocean, we are also very ignorant; and in the Pacific ocean, particularly towards the south pole, many discoveries probably remain to be made.

Our ignorance of the central parts of Africa is notorious, and the improvement of our geographical knowledge in that quarter has, for some years, been a favourite object. It may admit of doubt, however, whether this object will be speedily attained, as the obstacles to investigation in those inhospitable tracts, seem nearly insurmountable by human prudence and courage. Even the shores of Africa have not been completely surveyed, especially those towards the south and east.

America has of late been much more fully explored than at any former period: but still the western parts of North America, and the central and southern regions of South America are very little known; and the Spanish settlements towards the north are scarcely known, except to their own inhabitants.

The science of geography will probably be never perfectly understood, as, beside the numerous obstacles which oppose the progress of the traveller, it is scarcely possible that exact trigonometrical surveys of every place and country, the only certain method of ascertaining their exact situations and relative positions, can be made.

37 Political geography must ever remain the most uncertain part of the science. New changes are perpetually taking place in the relations of neighbouring states, according as ambition, tyranny, or commercial convenience dictates. Territory is transferred, by cession or by conquest, from one nation to another. Whoever will compare the relations of the European states, as they appear in the present maps, and in those published half a century ago, will scarcely recognise the countries to be the same. The great divisions indeed remain as before, but the boundaries of most of them are entirely changed. A number of independent states, and in one instance, a large kingdom, have been swallowed up by the unjustifiable ambition of their more powerful neighbours, and their names may be blotted from the map of Europe. The republics of Holland, of Switzerland, of Venice, are no more: the kingdoms of Poland and Sardinia have ceased to exist; the successor of St Peter, who once gave laws to princes, and governed Europe with unbounded sway, is now a wretched exile, and his dominions are doomed to increase the already overgrown power of despotic upstarts. Whether the present generation of emperors and kings, erected by the mighty Napoleon, will remain as long as did the states on whose ruins they have been raised, or are rather ephemeral productions, doomed to perish at the setting of that sun which now gives them life and vigour, is a question which future experience alone can determine.

The limits prescribed to this article do not permit us to enter on a critical examination, or even a characteristic sketch of the geographical works that have appeared in the modern period of the history of the science; and a bare enumeration of names would be equally tiresome and uninteresting. Some of the best modern works will be mentioned in the sequel; at present we shall conclude this Part in the words of an able judge of the present state of the science.

"The Spaniards and Italians (says Mr Pinkerton) have been dormant in this science; the French works of La Croix and others are too brief; while the German compilations of Busching, Fabri, Ebeling, &c. are of a most tremendous prolixity, arranged in the most tasteless manner, and exceeding in dry names, and trifling details, even the minuteness of our gazetteers. A description of Europe in 14 quarto volumes, may well be contrasted with Strabo's description of the world in one volume: and geography seems to be that branch of science, in which the ancients have established a more classical reputation than the moderns. Every great literary monument may be said to be erected by compilation, from the time of Herodotus to that of Gibbon, and from the age of Homer to that of Shakespeare; but in the use of the materials there is a wide difference between Strabo, Arrian, Ptolemy, Pausanias, Mela, Pliny, and other celebrated ancient names, and modern general geographers; all of whom, except d'Anville, seem under-graduates in literature, without the distinguished talents or reputation, which have accompanied almost every other literary exertion. Yet it may safely be affirmed, that a production of real value in universal geography requires a wider extent of various knowledge than any other literary department, as embracing topics of the most multifarious description. There is, however, one name, that of d'Anville, peculiarly and justly eminent in this science; but his reputation is chiefly derived from his maps, and from his illustrations of various parts of ancient geography. In special departments Gosselin, and other foreigners, have also been recently distinguished; nor is it necessary to remind the reader of the great merit of Rennel and Vincent in our own country *."

* *Pinkerton's Geography*, p. 3.

PART

Principles and Practice.

PART II. PRINCIPLES AND PRACTICE OF GEOGRAPHY.

38

CHAP. I. *Of the Surface and General Divisions of the Earth.*

IT has been supposed, by the less enlightened part of mankind in all ages, that the surface of the earth is nearly a plane, bounded on all sides by the sky. It was shewn, however, in the article ASTRONOMY, (N° 269—272.) that the earth is of a spherical figure, and an account was there given of the manner in which the true form of it was determined. Independently of the considerations there detailed, the spherical figure of the earth may be inferred, in a popular view, from the following facts.

39 Proofs of the spherical form of the earth.

1. When we stand on the sea-shore while the sea is perfectly calm, we easily perceive that the surface of the water is not quite plain, but convex or rounded; and if we are on one side of a broad river or arm of the sea, as the frith of Forth, and, with our eyes near the water, look towards the opposite coast, we shall plainly see the water elevated between our eyes and the opposite shore, so as to prevent our seeing the land near the edge of the water.

2. When we observe a ship leaving the shore, and going out to sea, we first lose sight of the *hull*, then of the sails and lower rigging, and lastly of the upper part of the masts. Again, when a ship is approaching the shore, the first part of her that is seen from the land is the topmast, then the sails and rigging appear, and lastly the hull comes gradually into view. These appearances can arise only from the ship's sailing on a convex surface; as, if the surface of the sea was plain, a ship on its first appearance would be visible, though very small, in all its parts at the same time, or rather the hull would first appear, as being most distinguishable; and, in going out of sight, it would in the same manner disappear at once, or the hull would be the last part of which we should lose sight.

3. Many navigators sent on voyages of discovery, have, by keeping the same course, at length arrived at the port from which they set out, having literally sailed round the globe. This could not happen if the sea were a plain.

4. When we travel to a considerable distance, in a direction due north or due south, a number of new stars successively appear in the heavens, in the quarter to which we are travelling; while many of those in the opposite quarter gradually and successively disappear, and are seen no more till we return in a contrary direction.

5. In an eclipse of the moon, which has been shown (ASTRONOMY, N° 199.) to be owing to the obscuration of the moon's surface by the shadow of the earth, the boundary of the obscured part of the moon is always circular. Now, it is evident that no body, which is not spherical, can, in all situations, cast a circular shadow.

40 Magnitude of the earth.

The diameter of the earth is generally computed at 7958 miles, though Mr Vince makes it 7930, nearer the medium derived from a comparison of the polar with the equatorial axis. Taking this last, therefore, as the mean diameter, the circumference will be =24,912 miles, and consequently the extent of the superfices will be = 197,552,160 miles, of which it is computed that at least two-thirds are covered with water.

In the above computation no account is taken of the mountains and other eminences on the surface of the globe; for, although these are of considerable consequence in a geographical point of view, as they constitute the most natural and remarkable boundaries of countries, and by their influence on the soil and climate of the different regions, contribute in a great degree to form those shades of distinction which diversify the inhabitants of the several quarters of the earth, they are, however, too trifling when compared with the diameter of so great a body, to make any sensible error in the calculation.

4[illegible] Divisions of the earth.

The surface of the earth is exceedingly diversified, almost everywhere rising into hills and mountains, or sinking into valleys; and plains of any great extent are extremely rare. Among the most extensive plains, are the sandy deserts of Arabia and Africa, the internal part of European Russia, and a tract of considerable extent in the late kingdom of Poland, now called Prussian Poland. But the most remarkable extent of level ground, is the vast platform of Tibet in Asia, which forms an immense table, supported by mountains running in every direction, and is the most elevated tract of level country on the globe. The chief elevations or mountains that occur, with their elevation, &c. will be mentioned under GEOLOGY. The greatest concavities of the globe are those which are occupied by the waters of the sea, and of these by far the largest forms the bed of the Pacific ocean, which stretching from the eastern shores of New Holland to the western coast of America, covers nearly half the globe. The concavity next in size and importance, is that which forms the bed of the Atlantic ocean, extending between the new and the old worlds; and a third concavity is filled by the Indian ocean. Smaller collections of water, though still large enough to receive the name of oceans, fill up the remaining concavities, and take the names of Arctic and Antarctic oceans. 4[illegible] Oceans.

4[illegible] Seas. Pl. CCX[illegible]

Smaller collections of water that communicate freely with the oceans, are called *seas*, (vid. A; fig. 1.), and of these the principal are the Mediterranean, the Baltic the Black sea, and the White sea. These seas sometimes take their names from the country near which they flow; as the Irish sea and the German ocean. Some large bodies of water which appear to have no immediate connexion with the great body of waters, being everywhere surrounded by land, are yet called *seas;* as the Caspian sea.

Bays or gulfs.

A part of the sea running up within the land, so as to form a hollow, if it be large, is called a *bay* or *gulf;* as the bay of Biscay, gulf of Mexico: if small, a *creek*, *road*, or *haven*.

Straits.

When two large bodies of water communicate by a narrow pass between two adjacent lands, this pass is called

Principles and Practice.

called a *strait*, or *straits* (C, fig. 1.) as the straits of Gibraltar, the straits of Dover, of Babelmandel, &c. The water usually flows through a strait with considerable force and velocity, forming what is called a current, and frequently this current always flows in the same direction. Thus, in the straits of Gibraltar there is a constant current from the Atlantic into the Mediterranean, though the surface of the latter never seems to be elevated beyond its usual level. There is always a current round Cape Finisterre and Cape Ortegal, setting into the bay of Biscay, and it has been discovered by Major Rennel, that this current is continued in a direction N. W. by W. from the coast of France to the westward of Ireland and the Scilly islands. Hence he draws this useful practical instruction for navigators who are entering the English channel from the Atlantic, viz. that they should keep no higher latitude than 48° 45′, lest they should be carried by the current upon the rocks of Scilly. For want of this necessary precaution, it is said that many ships have been lost on these rocks.

Lakes. A body of fresh water, entirely surrounded by land, is called a *lake*, *loch*, or *lough* (as D, fig. 1.), with the exception of the sea above mentioned; as the lake of Geneva, Lake Ontario, Lake Champlain, Loch Lomond &c.

This term, or its synonimes, loch or lough, is sometimes applied to what is properly a gulf or inlet of the sea, as Loch Fyne in Scotland, and Lough Swilly in Ireland.

Rivers. A considerable stream of water rising inland, and running towards the sea, is called a *river*; a smaller stream of the same kind is called a *rivulet* or *brook*. Vid. E, fig. 1.

Continents. The great extent of land which forms the rest of the globe, is divided into innumerable bodies, some of which are very large, but the majority extremely small. There are three very extensive tracts of country, which may all be denominated continents, though only two of them have hitherto been distinguished by that appellation. The most considerable of these continents is what has been called *the old world*, comprising Europe, Asia, and Africa. The second comprehends North and South America, or what has been denominated *the new world*, and is little inferior in extent to the former. The third great division forms the country called New Holland.

Islands. A body of land entirely surrounded by water is called an *island*, (vid. *a*, fig. 1.) as Britain, Ireland, Jamaica, Madagascar, &c. According to the strict meaning of this definition, the large divisions just mentioned are islands; for it is almost certainly ascertained, that the continent of North America is everywhere bounded by the sea, and it has long ceased to be doubtful that New Holland is in the same circumstances, and it is generally called the largest island in the world. But perhaps it would be better to confine the term to those numberless smaller islands that appear above the surface of the waters. When a number of smaller islands are situated near each other, the whole assemblage is commonly called a group of islands, as *b*, *b*. The large assemblages of islands that have been discovered in the South Pacific ocean, have lately been comprehended under the name of Polynesia, constituting a sixth division of the whole earth; the other five being Europe, Asia, Africa, America, and the islands of New Holland and New Guinea, under the name of Australasia.

A body of land that is almost entirely surrounded by water is called a *peninsula*, as *c*, fig. 1.; as the peninsula of Malacca, the Morea, or Grecian Peloponnesus, &c. Indeed the continent of Africa may be considered as a vast peninsula, being united to Asia only by the small isthmus of Suez. 51 Peninsula.

The narrow neck of land which joins a peninsula to the main land, or which connects two tracts of country together, is called an *isthmus*, as *d*. The most remarkable isthmuses are the isthmus of Darien, connecting the continents of North and South America, and the isthmus of Suez, joining Africa to Asia. 52 Isthmus.

A narrow tract of land stretching far out into the sea, being united to the main land by an isthmus, is called a *promontory*, and its extremity next the sea, is called a *cape*, as *e f*, fig. 1. The most remarkable capes are the Cape of Good Hope, at the southern extremity of Africa; Cape Horn at the southern extremity of South America; the North Cape at the northern extremity of Europe; and Cape Talmara, at the northern extremity of Asia. 53 Promontory and Cape.

It may assist the memory of the young geographer, to compare together the above divisions of land and water. We may remark that the large bodies of land, called continents, correspond to the extensive tracts of water called oceans; that islands are analogous to lakes; peninsulas to seas or gulfs; isthmuses to straits; promontories to creeks, &c.

The inhabited parts of the earth are calculated to occupy a space of 38,990,569 square miles, of which the four quarters into which the globe is usually divided are supposed to have the following proportions:—

Europe,	4,456,065
Asia,	10,768,823
Africa,	9,654,807
America,	14,110,874

The whole population of the earth has been computed at 700,500,000 souls; and of these

Asia is supposed to contain	500,000,000
Europe,	150,000,000
Africa,	30,000,000
America,	20,000,000
and Australasia and Polynesia, &c.	500,000

Hence the proportional number of inhabitants to every square mile in each quarter is as follows:—

In Asia	46
Europe	34
Africa	3
America	3 to every two square miles.

Chap. II. *Of the Construction and Use of the Globes.*

Sect. I. *Description and Use of the Terrestrial Globes.*

For the purpose of representing more accurately the globe which we inhabit, geographers have long had recourse to spherical balls, on the face of which are drawn the various divisions of the earth, and which are fitted up with such an apparatus, as enables us to illustrate and explain the phenomena produced by the motions 54 Nature of the globes.

Principles and Practice.

tions of the earth, and the different situations of its various inhabitants. The ball thus prepared, is called an *artificial globe*, and what we have described is properly the *terrestrial globe*, so called to distinguish it from another of a similar form, and furnished in a similar manner, but the surface of which represents the various assemblages of stars or constellations that appear in the heavens, and therefore this is called the *celestial globe*.

55 Circles on the globes.

In order to ascertain the relative positions of places and countries on the earth, certain circles are supposed to be drawn on its surface, analogous to those which were mentioned in ASTRONOMY, as supposed to be drawn in the heavens. As these circles are really represented on the artificial globes, it will be proper here to consider a little more particularly their nature and uses.

56 Axis and poles.

As the earth turns about on an imaginary axis, once in 24 hours, the artificial globe is furnished with a real axis, formed by a wire passing through the centre, and on which the globe revolves. The two extremities of this axis are its poles, the one being called the *north*, and the other the *south pole*.

57 Equator or equinoctial.

A great circle drawn on the globe, at an equal distance from both poles, is the equator or equinoctial line, and represents on the globe a similar circle, supposed to be drawn round the earth, and distinguished by the same name. By sailors this is commonly called the *line*, and when they pass over that part of the water, where it is imagined to be drawn, they often make use of various superstitious ceremonies. The two parts of the globe into which it is divided by the equator, are called the *northern and southern hemispheres*.

The equinoctial line on the earth passes through the middle of Africa, in the almost unknown territories of Macoco, and Monemugi, traverses the Indian ocean, passes through the islands of Sumatra and Borneo, and the immense expanse of the Pacific ocean; then extends over the province of Quito in South America, to the mouth of the river Amazons.

As every circle is supposed to be divided into 360°, so the equator is thus divided on the artificial globe.

58 Meridians.

Through every 15° of the equator there is drawn on the globe a great circle passing through the poles. These circles are called *meridians*, because when the sun in his apparent course from east to west reaches the corresponding circle in the heavens, it is noon on that part of the earth over which the meridian is supposed to pass. Properly speaking, every place on the earth has its own meridian, though to prevent confusion, these circles are drawn on the artificial globe, only through every 15° of the equator. To supply the place of the other meridians, the globe is hung in a strong brazen circle, which is called the *brazen meridian*, or sometimes only the *meridian*. The brazen meridian, like the equator, is divided into 360°, but these are marked by nineties on each quadrant, being on one half of the meridian numbered from the equator to the poles, and on the other half from the poles to the equator. On the opposite side of the brazen meridian there are two concentric spaces, which are divided into degrees corresponding to the months and days of each month, the degrees being marked on concentric spaces from the north pole to about 23½° both ways. The use of these divisions will appear hereafter (B).

Brazen meridian.

Through every tenth degree of the meridians, there are drawn on the globe circles parallel to the equator, which, for a reason that will appear presently, are called *parallels of latitude*.

Parallels of latitude.

Before we proceed in describing the other circles, &c. of the artificial globe, we shall here make a few remarks on the uses of the equator, the meridians and parallels (C).

Of latitude and longitude.

The equator serves to measure the distance of one place from another, either to the eastward or westward, and this distance is called the *longitude* of the place. The meridians serve in like manner to measure the distance of one place from another in a direct line north or south of the equator, and the distance of the place thus measured is called its *latitude*.

The longitude and latitude of places may be illustrated in the following manner. Let PEP′Q (fig. 3.) represent the earth or the globe, (supposed to be transverse) whose axis is PCP′, the north pole being P, and the south pole P′; and let EAQR represent a circle passing through the centre C, in a direction perpendicular to the axis PP′. This circle corresponds to the equator, and it divides the earth of the globe into two hemispheres, EPQ being the northern, and EP′Q the southern hemisphere. Let G, I, K, represent the situations of three places on the surface of the globe, through which let the great circles PKP′, PIP′, and PGP′, be drawn, intersecting the equator EQ, in *n*, *m*, *a*, respectively. The circles are the meridians of the places K, I, G. As every circle is supposed to be divided into 360°, there must be 90° from each pole to the equator. Hence the latitude of the place K is measured by the degrees of the arc intercepted between K and *n*, and the latitudes of G and I are measured by the degrees of the arcs intercepted between G and *a*, and I and *m* respectively. These latitudes will be called north

(B) The meridians are properly only semicircles, reaching from pole to pole, and of these there are twenty-four.

(C) In Geography, as in other sciences, there are two methods of conveying instruction. One is, to lay down the principles of the science first, and afterwards apply these to the practice of it; the other method is, to combine the principles and practice in one view. The former is usually considered as the more scientific, but we are inclined to think that the latter is often to be preferred, as being less dry and tedious, especially to a general reader. We have here, therefore, chosen to explain the nature of latitude and longitude, and the problems respecting them, before completing the description of the globe. We shall proceed in the same manner, uniting, as far as possible, the principles and practice in one view. Making, therefore, the terrestrial globe our text book, we shall thence explain the principles of geography, rather than detail these in a separate section, and afterwards illustrate them by the globe.

Principles and Practice.

north latitudes, because the places lie in the northern hemisphere. Let there be two other places, WV, in the southern hemisphere; the latitude of W will be measured by the degrees of the arc intercepted between W and *a*; and the latitude of V by the arc intercepted between V and *m*; and these will be called south latitudes. Further, let the circle *c*, *e*, *d*, *v*, G, be drawn parallel to the equator; this circle is called a parallel of latitude, and as it does not pass through the centre, it is evidently less than the equator, or it is a small circle. Now, all the arcs, such as R, *e*, *a*, G, &c. intercepted between the parallel and the equator, must be equal, since the circle is parallel to the equator; and hence every point in this parallel, or every place on the earth through which it is supposed to pass, has the same latitude.

Latitnde is the same all over the earth, being constantly measured from the equator to the poles.

The longitude of a place is measured by the degrees of an arc of the equator, intercepted between some particular meridian, and the meridian passing through the place. Thus, suppose G to represent the particular meridian, and *m* to represent the place whose longitude is required; the longitude of *m* is measured by the arc *m a* of the equator, intercepted between *a*, the point where the meridian of G meets the equator, and *m* the point of the equator where it is cut by the meridian of the place *m*. The particular meridian from which we begin to reckon the degrees of longitude is called the *prime* or *first meridian*, and it is different in different countries.

The method of estimating the distances of places by longitudes and latitudes, is of considerable antiquity, and was employed by Eratosthenes, who first introduced a regular parallel of latitude, which began at the straits of Gibraltar, passed eastwards through the island of Rhodes to the mountains of India; all the intermediate places through which it passed being carefully noted. Soon after drawing this parallel through Rhodes, which was long considered with a degree of preference, Eratosthenes undertook to trace a meridian, passing through Rhodes and Alexandria, as far as Syene and Meroë. Pythias of Marseilles, according to Strabo, considering the island of Thule as the most western point of the then known world, began to count the longitnde from thence, while Marianus of Tyre placed their first meridian at the Fortunate islands, or the Canaries; but they did not determine which was the westermost of these islands, and consequently which ought to serve as a first meridian. Among the Arabians, Alfragan, Albategnus, Nassir Eddin, and Ulug Beg, also reckoned from the Fortunate islands; but Abulfeda began to reckon his longitude from a meridian 10° to the eastward of that of Ptolemy, probably because it passed through the western extremity of Africa, where, according to him, were situated the pillars of Hercules; or because it passed through Cadiz, which was at that time rendered famous by the conquests of the Moors in Spain.

When the Azores were discovered by the Portuguese in 1448, some geographers made use of the island of Tercera as the first meridian. Other geographers, at Bleau, father and son, placed the first meridian at the Peak of Teneriffe, a mountain so far elevated above the sea, that it may be easily known by navigators; while others have made the island of St Philip, one of the Cape de Verds, the first meridian, because they conceived this to be the place where the magnetic needle had no variation. For a long time it was customary to reckon the longitude in most countries from the isle of Ferro, one of the Canary isles; but it is now customary for each nation to reckon the longitude, either from the metropolis of the country, or from the national observatory situated near it. Thus in France, Paris is the first meridian, and in Great Britain, the Royal Observatory of Greenwich. As in several good maps, the isle of Ferro is still used as a first meridian, it may be proper to remark, that the observatory at Greenwich lies 17° 45′ to the east of Ferro. Hence it is very easy to reduce the longitude of Ferro to that of Greenwich; for if the longitude required be east, we have only to subtract 17° 45′ from the longitude of Ferro, and the remainder is the longitude east from London; on the other hand, if the place be west from Ferro, we obtain the longitude west from London by adding to that of Ferro 17° 45′. If the place lies between Ferro and London, its longitude from London will be obtained by subtracting its longitude east from Ferro from 17° 45′. It is evident that by the reverse of this method, we may reduce the longitude from London to that of Ferro.

62 Method of reducing longitudes to the same meridian.

In the diagram referred to above, if G represent the observatory of Greenwich, *a* will be the point from which we begin to reckon the degrees of longitnde, and all places situated to the east of *a*, snch as R, *m*, will have east longitude, while those situated to the west, as *n*, will have west longitude. In reckoning the longitude, we sometimes number the degrees only as far as 180°, but at other times they are numbered all round the equator from the point *a*; for instance 180°, till we come to *a* again; hence reckoning in the direction *a*, R, *m*, we should say that every place was in so many degrees east longitnde, while if we reckon in the direction *n*, E, we should say that all the places had so many degrees west longitude all round the equator. To accommodate the globes to both these modes of reckoning the longitude, the equator is usually divided both ways, in a continued series from 0 at the first meridian to 360°.

It is evident, that as the parallels of latitude become smaller as they approach the poles, the arcs of these parallels intercepted between the same two meridians will be also smaller as we proceed from the equator to the poles, though in fact they consist of the same absolute number of degrees. Hence it will be easy to see that a degree of longitude must be smaller towards the poles than at the equator, and must become gradually smaller and smaller till we arrive at the poles, where it will be equal to nothing. Thus the arc G *v*. contains the same number of degrees as the arc *a*, *m*, though the former arc is much smaller than the latter. As a degree of longitude is therefore different at every degree of latitude, it becomes necessary to ascertain the relative proportion between the two; and for this purpose the following table has been constructed, which shews the absolute measure of a degree of longitude in geographical miles and parts of a mile for every degree of latitude, taking the degree of longitude at the equator, equal to 60 geographical miles.

Table

TABLE I. *Shewing the length of a degree of longitude for every degree of latitude, in geographical miles.*

Lat.	Geo.miles	Lat.	Geo.miles.	Lat.	Geo.miles	Lat.	Geo.miles	Lat.	Geo.miles.	Lat.	Geo.miles.

63 Method of reducing degrees to miles, and v. v.

Hence it appears that the degrees of latitude are all equal, and that a degree of longitude at the equator is equal to a degree of latitude, as each is $\frac{1}{360}$th of a great circle. In the second of the above tables, a degree of longitude at the equator is estimated at 69.2 English miles, or about $69\frac{1}{4}$. The length of a degree in miles is usually estimated at $69\frac{1}{2}$, but this is too much. Hence, to reduce degrees of latitude, and those of longitude near the equator, to English miles, it is necessary to multiply them by 69.2, or, if great accuracy is not required, by 70.

64 Problems on latitude and longitude.

PROBLEM I. *To find the latitude and longitude of a given place.*

Bring the place below the graduated edge of the *brazen meridian*, and the degree of the meridian that lies immediately over the place is its *latitude*. Observe where the meridian cuts the equator, and that degree will be the *longitude* of the place.

Example. To find the latitude and longitude of Edinburgh.—Bringing Edinburgh below the meridian, we find over it nearly the 56th degree of north latitude ($55^{\circ}\ 58'$), and the point where the meridian cuts the equator is nearly $3\frac{1}{4}$ ($3^{\circ}\ 12'$ W. Long.) degrees west from London.

N. B. The longitude and latitude of places cannot be ascertained exactly by the globes, as these are not calculated to show the fractional parts of a degree; but they may be found with sufficient correctness for ordinary purposes.

COROLLARY I. The difference of latitude and longitude

Principles and Practice.

gitude between two places is found by subtracting the less from the greater, if they lie the same way, i. e. north or south, east or west; or by adding the two together, if they lie in a different direction.

COR. 2. Those places that have the same latitude with any given place are found, by bringing the given place to the meridian, and observing what places pass under the same degree, while the globe is turned round.

COR. 3. Those places which have the same longitude with a given place, are found by bringing the place to the meridian, and observing what other places lie under the graduated edge, while the globe is at rest.

PROBLEM II. *The latitude and longitude of a place being given, to find the place itself on the globe.*

Turn the globe till the given longitude comes under the brazen meridian; then mark the given latitude on the meridian, and immediately below it is the place required.

Example. What place is situated in 48° 23′ N. Lat. and 4° 29′ E. Long. from Greenwich? *Ans.* Brest in France.

Computation of longitude in time.

As the sun, in his apparent motion round the earth, measures a great circle in about 24 hours, or in one hour passes over $\frac{1}{24}$th of such circle, or 15°; it is evident that all places which lie 15° west of any meridian, must have noon or any other time of the day, an hour *later* than those situated under that meridian; and that all places which lie 15° *east* of any meridian, must have the same times of the day an hour *sooner*. Hence, because the meridians drawn on the globe make a difference of an hour each in the time of places, they are sometimes called hour-circles; and the longitude of places is sometimes reckoned in *time* as well as in *degrees*.

Degrees of longitude are reduced to hours and minutes, and *v. v.* by allowing an hour for every 15°, and four minutes for every degree.

Horary circles.

Though the meridians on the globe are sometimes called *horary circles*, this name is generally confined to a small brass circle, which is adapted to one or each pole, and graduated into twice twelve hours; so that an index fixed to the axis, or the meridian, points out the several hours of day and night as the globe revolves.

In globes of the old construction the hour circles are fixed on the outside of the meridian, but this prevents the meridian from being moved quite round, which is required in some problems.

Mr Joseph Harris, formerly assay-master of the mint, contrived an ingenious method of remedying this inconvenience. He placed two horary circles between the meridian and the globe, one at each pole, and they were fixed tightly between two brass rollers, placed about the axis, so that when the globe was turned, they were carried round with it, while the edge of the brazen meridian served as an index to cut the horary divisions. A globe, thus furnished, serves universally and readily for performing problems in both northern and southern latitudes; and also in places near the equator; whereas, in globes of the old construction, the axis and horary circle prevent the brazen meridian from being moved quite round in the horizon.

The construction of the hour circles was rendered somewhat more simple by Mr G. Wright of London. In his globes, there are engraved two hour circles, one at each pole, on the map of the globe, each circle being divided into a double set of 12 hours, as in the usual hour circles; but here the hours are numbered both to the right and left. (See fig. 4.). The hour hand, or index, is placed below the brazen meridian, in such a way that it may be moved at pleasure to any required part of the circle, and remain there sufficiently steady during the revolution of the globe on its axis, being entirely independent of the pole. In this manner the motion of the globe round its axis, carrying the hour circle, the time is pointed out by the stationary index.

In the globes constructed by the late Mr George Adams, the equator is made to answer the purpose of an hour circle, by means of a semicircular wire placed in its plane, (see Q F, fig. 5.) and carrying two indices F, one on the eastern, the other on the western, side of the brazen meridian. The method of using these indices will be shewn presently. In these globes the equator is also marked with twice 12 hours, which increase from east to west, the hours to the west of the first 12 being afternoon hours.

67
Problems relating to time.

PROBLEM III. *The hour at any place being given, to find what hour it is at any other place.*

a, By the ordinary globes.

Bring the place at which the hour is given to the meridian, and set the index of the hour circle to the given hour. Then turn the globe till the other place comes under the meridian, and the index will now point to the hour required.

N. B. Where there is no index, the edge of the meridian will in both cases point out the hour.

b, By Adams's globes.

The steps are here the reverse of the former. Bring the place at which the time is required to the brazen meridian, and set the index to the given hour. Then turn the globe till the other place comes below the meridian, and the index will shew the time required.

N. B. In the ordinary globes, where the hour circle is usually marked with two sets of figures, it is proper, in performing this problem, to make use of that set which increases towards the right hand, observing that whichever XII. is fixed on for noon, the hours to the right or *east* of this are hours P. M. and those to the left or *west* are hours A. M. On Adams's globes the contrary of this takes place, from the hours being marked on the equator. They increase from east to west, and, of course, those to the east of XII. are morning hours, and those to the west of it afternoon hours.

Example 1. When it is noon at London, what hour is it in the Society isles? *Ans.* Two A. M.

Ex. 2. When it is 3 P. M. at Edinburgh, what hour is it at Delhi in Hindoostan? *Ans.* Thirty minutes past eight P. M.

Problem IV. *Having the hour at any place given, to find all those places where it is noon.*

a, By the ordinary globes.

Bring the given place to the meridian, and set the index to the given hour. Then turn the globe till the index point to 12 at noon, and the places then under the meridian are those required.

b, By Adams's globes.

Bring the given place to the meridian, and set the index to 12 at noon. Then turn the globe till the index shall point to the given hour; and all the places then under the meridian have noon at that time.

Ex. 1. It is now 30 min. past 10 A. M. at Edinburgh; In what places is it noon? *Ans.* Near Stockholm; at Dantzic, Breslaw, Presburg, Vienna, Posega, Ragusa, Tarento, and the Cape of Good Hope.

Ex. It is now midnight at London; Where is it noon? *Ans.* In the north-east parts of Asia, in the middle of Fox isles; at the Friendly isles (nearly), and at the east cape of New Zealand.

From the different situation of places with respect to latitude and longitude, the inhabitants of these places received from the ancients denominations that are still retained.

68 Antœci. Thus, those places which have the same longitude, or are situated under the same meridian, but are in opposite latitudes, the one lying as many degrees to the north of the equator as the other lies to the south of it, are said to be ANTOECI to each other. From this definition it is evident, that those places situated under the equator have no *antœci.*

The appearances arising from the changes of the heavenly bodies are different in the opposite places. Thus, 1. The days of the one are equal to the nights of the other, and *vice versa;* but they have noon, midnight, and all the other hours at the same time. 2. They have contrary seasons at the same time: when it is summer at one place it is winter at the other, and so of spring and autumn. 3. The stars that never set at one place, never rise at the other, and *vice versa.*

69 Periœci. Again, those places that have the same latitude, or are under the same parallel, but are in opposite longitudes, i. e. lie under opposite arcs of the same meridional circle, or 180° from each other, are said to be PERIOECI to each other. Those places which may be situated at the poles, have evidently no *periœci.*

The celestial appearances to the periœci are as follow. 1. The length of the day or night is the same to both places; but the hours, though distinguished by the same numbers, are contrary; noon at the one being midnight at the other; and any hour in the forenoon at the one being the same of the afternoon to the other. 2. Both places have the same seasons of the year at the same time. 3. The same stars that never rise or set to one place, also never rise or set to the other. 4. The heavenly bodies rise in the same point of the horizon at both places, and continue for the same interval above or below it.

70 Antipodes. Lastly, Those places which are situated directly opposite to each other, by a distance equal to the diameter of the earth, are said to be ANTIPODES to each other. If we conceive a line through the centre of the earth, and terminated in two points of its surface, these extreme points are antipodes to each other. Thus, the city of Lima in Peru is nearly the antipodes to Siam in the East Indies; and Pekin in China has for its antipodes Buenos Ayres in South America. These places are always in opposite longitudes, and (except under the equator) in opposite latitudes.

The celestial appearances to the antipodes are these. 1. The hours are contrary, as to the periœci. 2. The days of the one are of the same length with the nights of the other; hence the longest day to one is the shortest to the other, and *vice versa.* 3. They have contrary seasons at the same time. 4. Those stars which, at one place are always above the horizon, are, to the other, always below it. 5. When the heavenly bodies are rising at one place, they are setting at its *antipodes*, and *vice versa.* For various opinions respecting the antipodes, see the article ANTIPODES.

The antipodes of any places are the periœci to the antœci of that place; and the antœci to their periœci. This will account for the method presently described of finding the antipodes on the globe.

Problem V. *To find the* antœci *to any given place.* 71 Problem.

Bring the given place to the meridian, and thus ascertain its latitude. Then count from the equator towards the opposite pole as many degrees as are equal to the latitude of the place; and the point where this reckoning ends is the place required.

Ex. 1. Where are the *antœci* to the Cape of Good Hope? *Ans.* At Malta nearly.

Ex. 2. What people are the *antœci* to the inhabitants of Quebec in North America? *Ans.* The inhabitants of Patagonia in South America.

Problem VI. *To find the* periœci *of any given place.*

Bring the given place to the brazen meridian, and set the horary index to the upper XII. Then turn the globe till the index point to the lower XII. The place which is then below the meridian in the same latitude with that of the given place, is the situation required.

Ex. 1. Where are situated the *periœci* of Newcastle upon Tyne? *Ans.* In the Aleouski or Fox islands.

Ex. 2. Required the periœci to California in North America. *Ans.* Near the mouth of the river Indus.

Problem VII. *To find the* antipodes *to any given place.*

Find the *antœci* of the given place (by Problem V.) and then find the *periœci* of the latter (by Problem VI.). This last is the place required.

Ex. 1. It is required to find the antipodes of London. *Ans.* The latitude of London is 51° 31′ N. the antœci to this, or 51° 31′ S. on the prime meridian, is in the south Atlantic ocean; the periœci to this is in 180° W. Long. and 51° 31′ S. Lat. a little to the south of the islands of New Zealand. The inhabitants of the southern island of New Zealand are therefore the nearest antipodes to London.

Several other circles besides those which we have mentioned are described on the artificial globe, and are supposed to be drawn on the earth. These we shall now proceed to describe, and explain their geographical uses.

The

The Ecliptic. The *Ecliptic* (ASTRONOMY, N° 43.) is a great circle drawn on the globe, crossing the equator obliquely in two points, called the equinoctial points. (ASTRONOMY, N° 44.). This circle extends on each side of the equator to the latitude of 23° 28′, and is divided into 12 great parts corresponding to the 12 signs of the zodiac (see ASTRONOMY, N° 52.), and marked with their characters, and each sign is subdivided into 30 degrees. The ecliptic has also its poles, which are two points that are distant 90° every way from the circle on each side. As the ecliptic declines from the equator 23° 28′, its poles are consequently distant from those of the equator, or of the globe, by the same measure. This circle properly belongs to the celestial globe, but as it is extremely useful in performing many geographical problems, it is always drawn on both globes, and requires to be noticed here, since it determines the position of several of the circles which we are about to mention.

Tropics. Through those two points of the ecliptic, where it is at the greatest distance from the equator, there are drawn on the globes two circles parallel to the equator, called *tropics.* That in the northern hemisphere is called the *Tropic of Cancer*, as it passes through the sign Cancer; and, for a similar reason, that which is in the southern hemisphere is called the *Tropic of Capricorn.* The two points through which they are drawn are called *solstitial points.* The imaginary line which corresponds to the tropic of Cancer on the earth passes from near Mount Atlas on the western coast of Africa, past Syene in Ethiopia: thence, over the Red sea, it passes to Mount Sinai, by Mecca the city of Mahomet, across Arabia Felix to the extremity of Persia, the East Indies, China, over the Pacific ocean to Mexico, and the island of Cuba. The tropic of Capricorn takes a much less interesting course, passing through the country of the Hottentots, across Brazil, to Paraguay and Peru.

Polar circles. If the poles of the ecliptic be supposed to revolve about the poles of the earth, they will describe two circles parallel to the equator, and 23° 28′ distant from it. Two such circles are drawn on the globes, and are called *Polar Circles*, that in the north being called the *Arctic Polar Circle*, or merely the *Arctic Circle*, while that in the south is called the *Antarctic Polar Circle*, or *Antarctic Circle.*

Both the tropics and the polar circles are marked on the globes by dotted lines, to distinguish them from the other parallels.

75 Colures. The meridional circles that pass through the equinoctial and solstitial points are called *Colures;* the former being called the *Equinoctial* and the latter the *Solstitial Colure.*

For an account of the variety of day and night in different parts of the globe, see ASTRONOMY, Part II. ch. i. sect. 2.

76 Zones. By means of the tropics and polar circles, the earth is supposed to be divided into five spaces, to which the ancients gave the name of *Zones*, or *Belts.* Thus the space included between the two tropics was called the *Torrid Zone*, because it was supposed to be so much heated or *roasted* by the vertical sun, which there prevails, as to be uninhabitable. The ancient terms are still occasionally used, but the countries between the tropics are now more commonly called the *Intratropical Regions.* The two spaces included between each tropic and its corresponding polar circle were called *Temperate Zones*, and were distinguished according to their position into *Northern* and *Southern Temperate Zones.* Lastly, The spaces between the polar circles and the poles were called the northern and southern *Frigid Zones*, and were supposed uninhabitable from excessive cold. These last are usually denominated the *Polar Regions.*

The countries lying between the tropics are the greater part of Africa, the southern parts of Arabia, the eastern and western peninsulas of India; all those clusters of islands lying between the southern continent of Asia and New Holland, called the Sunda, Molucca, Philippine, Pelew, Ladrone, and Carolina islands; the northern half of New Holland, New Guinea, New Britain; most of the groups of islands in the Pacific ocean, as the New Hebrides, New Caledonia, the Friendly and Society isles, the Sandwich and Navigators isles; the West India islands; the greater part of South America; the Cape de Verd islands, and those of St Helena, Ascension, St Matthew, and St Thomas. See the map of the world in Plate CCXXXVI. or the plain chart in Plate CCXXXVII. 77 Countries between the tropics.

All places situated between the tropics have the sun vertical twice in the year, at noon; but the time of the year when this happens is different in the different latitudes; at the equator, the sun is vertical when he is in the equinoctial points, or when he has no declination. The inhabitants of the other *intratropical regions* have the sun vertical when his declination is equal to their latitude, and on the same side of the equator. Thus, the inhabitants of New Caledonia, about 20° S. Lat. have the sun vertical when his declination is 20° S. To illustrate this, it will be sufficient to observe that, as the ecliptic is that circle in the heavens in which the sun is supposed to move, the sun's rays are perpendicular successively to every point of the earth which lies below that point of the ecliptic in which the sun happens to be, and he will therefore be vertical to all the places through which the ecliptic (continued to the earth) passes successively.

The inhabitants of the torrid zone have their shadows at noon day sometimes to the south, i. e. when the sun's declination is north, and sometimes to the north, i. e. when the sun's declination is south. They were therefore called by the ancients *Amphiscii*, from αμφι, *about*, and σκια, *shadow.* See AMPHISCII and ASCII. 78 Amphiscii.

In the north temperate zone are situated the whole of Europe except Lapland; Barbary, and part of Egypt, in Africa; nearly the whole continent of Asia; a great part of North America; the Azores, and the Canary and Madeira islands. 79 Countries in the temperate zone.

In the south temperate zone lie the southern part of Africa, the southern half of New Holland, New Zealand, and the southern part of South America.

In the temperate zones the sun is never vertical, and the length of the days and nights differs much more than in the torrid zone.

The inhabitants of these regions have their shadows at noon always in the same direction; those in the north temperate zone having them directed to the north, 80 Heteroscii.

north, and those in the southern zone, towards the south. They were hence called by the ancients *Heteroscii*. See HETEROSCII.

81
Countries in the frigid zones.

The countries that are situated in the northern frigid zone, are Lapland, Spitzbergen, Nova Zembla, the northern parts of Asia and America, and part of Greenland.

No land has yet been discovered within the south polar circle, though it was long supposed that a large continent was situated there, which was called *Terra Australis Incognita*. Our celebrated navigator Cook made many attempts to penetrate the icy fields which abound in these seas, in search of this imaginary continent, but without success, he having penetrated no farther than 72°. See COOK's *Discoveries*, N° 49. and 71.

Within the polar circles the sun does not always rise or set every 24 hours as in the other zones; but for a certain number of days in summer he never sets, and for a certain number of days in winter he never rises; the number of days during which the sun is present or absent increasing from the polar circles to the poles, so that at the poles he never sets for six months, nor rises during a like period.

82
Periscii.

When the sun continues above the horizon more than 24 hours, the inhabitants of the polar regions have their shadows cast all around them; and hence they have been called *Periscii*. See PERISCII.

83
Climates.

The ancients did not employ regular parallels of latitude, but they divided the spaces between the equator and the poles into small zones corresponding to the length of the longest day in each division. To these subdivisions they gave the name of climates, the situation and extent of which they determined in the following manner. As the day at the equator is exactly 12 hours throughout the year, but the longest day increases as we approach the poles, the ancients made the first climate to end at that latitude where the longest day was $12\frac{1}{2}$ hours, which by observation they found to be in the latitude of 8° 25′. The second climate extended to latitude 16° 25′, where the longest day is 13 hours, and thus a new climate extended, so as to divide the whole tract between the equator and the poles into 24 climates, in each of which the longest day was longer by half an hour than in that nearer the equator. The space between the polar circles and the poles they divided into six climates, in each of which the length of the longest day increased by a month, till at the poles it was six months long. Hence, the 24 climates between the equator and the polar circles are called *Hour Climates*; and the six between the polar circles and the poles are called *Month Climates*. For further particulars respecting this ancient division of the globe, and a table of the climates by Ricciolus, see CLIMATE. As the table given under that article is calculated only for the middle of each climate, and neither mentions the breadth of each, nor is extended to all the climates, we shall here subjoin one in which are given the latitude at which each climate terminates, its breadth in degrees, and the length of the longest day at the parallel terminating each.

Table of climates.

HOUR CLIMATES.

Climates.	Latitude.		Breadth		Longest Days	
I	8°	25′	8°	25′	12^h	30^m
II	16	25	8		13	
III	23	50	7	25	13	30
IV	30	25	6	30	14

VI	90		5	55	6

Places in the northern climates.

As the division of the globe into climates, though now almost disused, is of service in shewing the length of the longest day in different countries, we shall here enumerate the principal places in each northern climate, these being best known and most interesting.

I. The Gold and Silver Coasts in Africa; Malacca in the East Indies; and Cayenne and Surinam in South America.

II. Abyssinia in Africa; Siam, Madras, and Pondicherry, in the East Indies; the isthmus of Darien; Tobago, the Grenades, St Vincent, and Barbadoes, in the West Indies.

III. Mecca in Arabia; Bombay, part of Bengal, in the East Indies; Canton in China; Mexico and the bay of Campeachy, in North America; and Jamaica, Hispaniola, St Christopher's, Antigua, Martinique, and Guadaloupe, in the West Indies.

IV.

IV. Egypt and the Canaries in Africa; Delhi, the capital of the Mogul empire, in Asia; most of the gulf of Mexico, and East Florida, in North America; and the Havannah in the West Indies.

V. Gibraltar; part of the Mediterranean sea; the Barbary coast in Africa; Jerusalem, Ispahan, capital of Persia, and Nankin, in China, in Asia; and California, New Mexico, West Florida, Georgia, and the Carolinas in North America.

VI. In Europe, Lisbon, Madrid, the islands of Minorca and Sardinia, and part of Greece or the Morea; in Asia, Asia Minor, part of the Caspian sea, Samarcand, Pekin, Corea, and Japan; and in North America, Maryland, Philadelphia, and Williamsburgh in Virginia.

VII. In Europe, the northern provinces of Spain, the southern provinces of France, Turin, Genoa, Rome, and Constantinople; in Asia, the rest of the Caspian, and part of Tartary; and in North America, Boston and New York.

VIII. Paris and Vienna, in Europe; and New Scotland, Newfoundland, and Canada, in North America.

IX. London, Flanders, Prague, Dresden, Cracow, in Europe; the southern provinces of Russia, and the middle of Tartary in Asia; and the northern part of Newfoundland, in America.

X. Dublin, York, Holland, Hanover, Warsaw; the west of Tartary, Labrador, and New South Wales, in North America.

XI. Newcastle, Edinburgh, Copenhagen, and Moscow.

XII. Southern part of Sweden; and Tobolsk in Siberia.

XIII. Stockholm; and the Orkney isles.

XIV. Bergen in Norway, and St Petersburgh.

XV. Hudson's Straits in North America.

XVI. Most of Siberia; and the southern parts of Greenland.

XVII. Drontheim in Norway.

XVIII. Part of Finland in the Russian empire.

XIX. Archangel on the White sea.

XX. Iceland.

XXI. Northern parts of Russia in Europe, and Siberia in Asia.

XXII. New North Wales, in North America.

XXIII. Davis's Straits, in North America.

XXIV. Samoieda in Asia.

XXV. Northern parts of Lapland.

XXVI. West Greenland.

XXVII. Southern part of Nova Zembla.

XXVIII. Northern part of Nova Zembla.

XXIX. Spitzbergen.

XXX. Unknown.

The only parts of the terrestrial globe that we have yet to describe and illustrate are the *Quadrant of Altitude*, and the *Wooden Horizon*; and these it is necessary to explain, before we proceed to consider the remaining problems performed with this globe.

86 Quadrant of altitude.

The *Quadrant of Altitude* is a thin flexible slip of brass, graduated into 90°, and made to fix on any part of the brazen meridian by means of a nut and screw. Round this nut it moves on a pivot, and by its flexibility may be applied close to the surface of the globe. The quadrant of altitude is used to measure the distances of places from each other on the terrestrial globe, and to ascertain the altitudes of the sun, stars, &c. on the celestial globe.

To measure the distance between two places on the globe, nothing more is required than to stretch the graduated edge of the quadrant between them, and mark the number of degrees intercepted. These reduced to geographical, or to English miles (by N° 63.) give the absolute distance between the places. It is most convenient to bring one of the places to the zenith, which may be done by rectifying the globe for the latitude of that place as immediately to be explained, and then to stretch the quadrant to the other place, the distance marked, subtracted from 90°, gives the true distance in degrees. If the distance required be greater than 90°, it is proper to rectify the globe for the *antipodes* of the given places, and add the distance observed to 90°: the sum is the distance required.

It has been very generally stated that the bearing of one of the places from the other may be found by observing, on the wooden horizon, in what point of the compass the quadrant of altitude, thus fixed in the zenith, cuts the horizon. This is considered by Mr Pattcson as a mistake: "For (says he) supposing one of the places to lie due east of the other, they are in the same parallel of latitude, and consequently it is impossible that the prime vertical of either of them (that is, a circle cutting the east and wests points of the horizon), should pass through the other, unless they both lay under the equator. A line shewing the bearings of places is called a rhumb line. The lines of north and south on the globe, being meridians, and those of east and west being parallels of latitude, are consequently circles; but all the remaining rhumbs are a kind of spiral lines."

87 Wooden horizon.

The globes are supported by a wooden frame ending above in a broad flat margin, on which is pasted a paper marked with several graduated circles. This broad margin is called the wooden horizon, and represents the rational horizon of the earth, or the limit between the visible and the invisible hemispheres. On the paper with which the wooden horizon is covered, are drawn four concentric circles. The innermost of these is divided into 360 degrees, divided into four quadrants. The second circle is marked with the points of the compass, i. e. the four cardinal points, east, west, north, and south (D), each being subdivided into eight parts or rhumbs, (see COMPASS). The circle next to that just mentioned contains the twelve signs of the zodiac, distinguished by their proper names and characters; and

(D) The cardinal points of the compass are thus determined. The two points in which the meridian of any place when produced so as to pass through the nearest pole, cuts the horizon, (using this in an astronomical sense, see ASTRONOMY,) are the north and south points; the former being that point where the meridian first cuts the horizon in the *northern* hemisphere, and the south, that where it first meets the horizon in the southern hemisphere. Again, the two points where a great circle, passing through the zenith at right angles with the meridian, (and called

Principles and Practice.

and each sign is divided into 30 degrees. The last circle shews the months and days corresponding to each sign.

This wooden ring can represent the rational horizon of any place marked on the terrestrial globe only, when that place is situated in the zenith; and the method of bringing the place into this situation is called *rectifying the globe.*

88 To rectify the globe.

PROBLEM VIII. *To rectify the globe according to the latitude of any place.*

Find the latitude of the place, (by Problem I.) and see whether it be north or south. Then elevate the pole of the globe which is in the same hemisphere with the latitude, as far above the wooden horizon as is equal to the latitude; bring the given place to the brazen meridian, and it will be in the zenith.

Example. To rectify the globe for the latitude of Edinburgh. The latitude of Edinburgh is 55° 58′ N. therefore raise the *north* pole 55° 58′ above the horizon, and bring Edinburgh below the brass meridian.

It is for the purpose of more easily rectifying the globe, that one half of the brazen meridian is graduated from the poles to the equator; as, where this is not done, it is necessary to take the complement of the latitude, or the difference between it and 90°, which in some cases requires a calculation.

The place being brought below the meridian, when the pole is elevated to the proper degree, it is evidently in the zenith, or 90° distant every way from the horizon. Thus, in the above example, if we count the degrees from that part of the meridian below which Edinburgh is situated, we shall find that they amount to 90° each way; for counting from Edinburgh along the meridian to the north pole, we have 34° 2′; which added to 55° 58′, the elevation of the poles, gives 90° on that side. Again, counting from the same point of the meridian towards the southern part of the horizon, we have 55° 58′, as far as the equator, and 34° 2′ from thence to the horizon, making, as before, 90°, and as the graduated edge of the meridian is 90° both from the eastern and western side of the horizon, Edinburgh, in this situation of the globe, is in the zenith.

89 Oblique sphere.

When either of the poles of the globe is thus elevated above the horizon, so as not to be in the zenith, the globe is said to be in the position of an *oblique sphere*, in which the equator and all its parallels are unequally divided by the horizon. This is the most common situation of the earth, or it is the situation which it has with respect to all its inhabitants, except those at the equator and the poles. To the inhabitants of an oblique sphere the pole of their hemisphere is elevated above the horizon as many degrees as are equal to their latitude, and the opposite pole is depressed as much below the horizon, so that the stars only at the former are seen; the sun and all the heavenly bodies rise and set obliquely, the seasons are variable, and the days and nights unequal. This position of the sphere is represented at fig. 6. where the equator EQ, and the parallels cut the horizon HO obliquely, and the axis PS is inclined to it. Hence this position is called *oblique.*

90 Right sphere.

If the globe is placed in such a position that any point of the equator is in the zenith, it is said to be in the position of a *right* or *direct sphere*, because the equator and its parallels are vertical, or over the horizon at right angles. This position is seen at fig. 7. where the axis PS is in the plane of the horizon, and the equator EQ is in a plane perpendicular to it. The inhabitants of such a sphere, which are the inhabitants of the earth below the line, have no elevation of the poles, and consequently no latitude: they can see the stars at both poles, all the stars rise, culminate, and set to them; and the sun always moves in a curve at right angles to their horizon, and is an equal number of hours above and below it, making the days and nights always equal.

91 Parallel sphere.

If the globe be so placed that one of the poles is in the zenith, and consequently the other in the nadir, it is in the position of a *parallel sphere;* so called because the equator EQ (fig. 8.) coincides with the horizon, and the parallels are of course parallel to it; while all the meridians cut the horizon at right angles. The inhabitants of a sphere, in this position, have the greatest possible latitude; the stars, which are situated in the hemisphere to which the inhabitants belong, never set, but describe circles all around; while those of the contrary hemisphere never rise: the sun is above the horizon for six months, during which it is day, and is below the horizon for an equal interval, when it is night.

The wooden horizon is a necessary part of the apparatus of both globes; but it has been shewn, that in the terrestrial globe, it can represent the rational horizon of a place, only when the globe is rectified for the latitude of that place. In the celestial globe, it represents the rational horizon in all positions.

In Adams's globes there is a thin brass semicircle NHS (fig. 5.) that is moveable about the poles, and has a small thin circle N sliding on it. This semicircle is graduated into two quadrants, the degrees of which are marked both ways from the equator to the poles in the terrestrial globe: this semicircle represents a moveable meridian; and the small sliding circle, which is marked with a few of the points of the compass, is called a *visible horizon*, the use of which will appear presently.

Before we proceed to the remaining problems on the terrestrial globe, it will be proper to take notice of some geographical principles that are connected with the horizon.

It is evident, that the extent of the sensible horizon of an observer depends on the height of his eye above the level surface of the earth. An eye placed on the surface of the earth sees scarcely any thing around it; but if it is elevated above that surface, it sees farther in proportion to its elevation, provided always that its view is not obstructed by intervening objects. Thus, in an extensive plain, the eye can see farther, if elevated to

called the *prime vertical*) cuts the horizon, are the east and west points; the former being on the *left* hand of a person facing the sun at noonday, while the latter is on his *right* hand.

Principles and Practice.

to a proper height, than it can from the same height in a town or among hills; and, at sea, where the surface is perfectly equal, the view is in proportion to the height of the eye. It becomes an interesting problem to ascertain the extent of the visible horizon, or the distance to which a person can see at any given height of the eye; as, when this is known, we can calculate pretty accurately the distance of an object seen from such a height, as land seen from the topmast of a ship at sea.

For solving this problem, it must be remarked, that the distance of an observer from the boundary of the horizon, or from a distant object, is different when measured along the surface of the earth, and when measured in a direct line. To illustrate this, let HDN (fig. 9.) represent a section of the earth, of which C is the centre, and let D be the situation of an observer, whose eye is elevated to B. The lines BA, BE, tangents to the curve at H and E, represent the limit of the visible horizon, or the radii of the circle circumscribing vision. If the eye were elevated still higher, as to G, it is evident, that the extent of the visible horizon will be increased, being now represented by the tangent GF. The length of the tangent BA, or GF, is easily found by plane trigonometry (E).

93 Horizon of the sea.

It was remarked above, that the visible horizon is most distinct at sea, from the absence of those objects which obstruct vision on land. Hence the sensible horizon is sometimes called the horizon of the sea, and this may be observed by looking through the sights of a quadrant at the most distant part of the sea. In making this observation, the visual rays BA, or GF, by reason of the spherical surface of the sea, always extend a little below the true sensible horizon SS, and consequently below the rational horizon HN, which is parallel to it. Hence the quadrant shews the depression of the horizon of the sea lower than it really is; and it is obvious from the figure, that the higher the eye is situated, the greater must be this depression. Thus, the depression, when the eye is at G, marked by GF, is evidently much greater than that marked by BE, when the eye is at B. The depression of the horizon of the sea is not always the same, though there be no variation in the height of the eye; but the difference in this case is very small, amounting only to a few seconds, and is owing to a difference of the degree of refraction in the atmosphere. Were there no refraction, the visual ray would be BE (when the eye is at B), and E would be the most distant point; but, by reason of the refraction, a point on the surface of the earth beyond E, as F, may be seen by an eye situated no higher than B; and if the refraction were still greater, a still more distant point might be observed.

94 Difference between the apparent and true level.

It will be necessary here to anticipate a few remarks respecting the difference between the apparent and true levels; a subject that will be more fully discussed under LEVELLING. Two or more places are on a true level, when they are equally distant from the centre of the earth, and one place is higher than another, or above the true level, when it is farther from the centre of the earth. A line that is equally distant in all its points from the centre, is called the line of true level, and it is evident that this line must be curved: and either make part of the earth's surface, or be concentrical with it. Thus the line DAO, which has all its points, D, A, O, equally distant from the centre C, is the line of true level. But the line of sight DMP, as given by the operation of a level, is a straight line, which is a tangent to the earth's surface at D, always rising higher above the true line of level, according as it extends to a greater distance. This straight line is called the line of apparent level. Thus MA is the height of the apparent level above the true at the distance DA, and OP is the excess of the apparent above the true level, at the distance DO.

The following table was constructed by Cassini, for the purpose of shewing the excess of the apparent above the true level at various distances from the point of observation. It consists of three columns, in the first of which the distance of the observed object from the place of observation is given, from one second to 60 minutes, or a degree. In the second is given the length of the arc measured on a great circle of the earth, that corresponds to the observed distance, in feet and inches; and in the third is given the height of the apparent above the true level in feet and inches, corresponding to each observed and real distance of the object.

(E) In the right-angled triangle ACB (fig. 9.), the length of CB is given, supposing the height of the eye BD to be 6 feet; for adding 6 feet to 19,943,400 feet, the length of the semidiameter of the earth, we have 19,943,406 feet for the length of BC. Then, making the hypothenuse CB radius, we shall have, As radius to the sine of the angle BCA, so is CB to BA; and this will be nearly the same as the arc DA. Again, without finding the quantity of the angle at C, BA may be found, by considering that BA^2 is equal to the difference of the squares of CB and CA, i. e. $BA^2=CB^2-CA^2=(CB+CA)\times(CB-CA)=\overline{CB+CA}$ into BD; and hence $BA=\sqrt{(CB+CA)\times BD}$.

To illustrate the last in numbers, we have CB=19,943,406 feet, and CA=19,943,400 feet. Then, to find BA, we have $\overline{19,943,406+19,943,400}$ (=39,886,806) × 19,943,406—19,943,400 (=6) = 239,320,836; whence $BA=\sqrt{239,320,836}=15470$ feet nearly, or about three miles.

The distance, to which a person can see, is found to vary as the square root of the altitude of the eye. To find a general expression for this quantity,

let a be the altitude of the eye in feet,
d the distance at that altitude in miles;

then we have $\sqrt{6}:\sqrt{a}=3:d=\frac{3}{\sqrt{6}}\times\sqrt{a}=1.2247\times\sqrt{a}$. Hence, we deduce this general rule: *Multiply the square root of the height of the eye in feet by 1.2247, and the product will be the distance to which we can see from*

from that height in miles. Example. Let the height of the eye be 49 feet. Multiply the square root of 49 or 7, by 1.2247, and we have 8.5729 or about $8\frac{1}{2}$ miles for the distance to which the eye can see at the height of 49 feet.

From

Principles and Practice.

The above table will answer several useful purposes. In the first place, the height of the apparent level above the true may be found by it at any distance, from one second to one degree, or $69\frac{2}{10}$ miles. Thus, at the distance of 30′=about 35 miles, we have 182820 feet for the length of the arch of a great circle on the earth, and corresponding to this we have 797 feet 8 inches 484 parts for the excess of the apparent level above the true. 2. The extent of the visible horizon corresponding to any height of the eye, may be found from the table by observation. The semidiameter of the horizon does not sensibly differ from an arc of a great circle on the earth, containing as many minutes and seconds as are equal to the angle of depression observed, and the number of feet contained in such an arc may be found in the table. Thus, if the depression, as observed by observation, be 40″, its semidiameter is also about 40″, and the length of the arc corresponding to it is 243,760 feet.

The following table, also taken from Cassini, shews the different depressions of the horizon of the sea at different heights of the eye, both by observation and calculation; with the difference betwixt the two occasioned by refraction.

The height of the eye above the surface of the sea.		*The depression of the horizon of the sea.*		
Feet.	Inches.	′	″	
1157	6,9	32	30	by observation
		36	18	by calculation
Difference by refraction		3	48	
775	2,3	27	0	by observation
		29	36	by calculation
Difference by refraction		2	36	
571	11,0	24	0	by observation
		25	25	by calculation
Difference by refraction		1	25	
387	3,4	19	45	by observation
		20	54	by calculation
Difference by refraction		1	9	
288	4,3	15	0	by observation
		17	1	by calculation
Difference by refraction		2	1	

The height of the eye above the surface of the sea.		*The depression of the horizon of the sea.*		
Feet.	Inches.	′	″	
187	0,9	13	0	by observation
		14	41	by calculation
Difference by refraction		1	41	
9	7,3	3	20	by observation
		3	18	by calculation
Difference by refraction		0	2	

In the above table, the depression, as estimated by calculation, is greater than that by observation in every case except the last, in which the latter is greater by two seconds than the former; but this difference was too small to be discovered by the instrument that Cassini employed.

Refraction lessens the angle of depression, by raising the objects observed; but as this refraction is itself variable, the depression and extent of the horizon also vary. We are informed by Cassini, that even in the finest weather he observed the refraction to differ at the same hour of different days, and at different hours of the same day. The truth of this observation may be easily ascertained by looking through a telescope furnished with cross hairs, and fixed in such a position that some highly elevated object, as the weathercock of a steeple, may be seen through it; for, on observing the weathercock at different times of the day, it will be seen sometimes on the centre of the object-glass; sometimes above, and sometimes below it. A similar experiment may also be made with plane sights fixed on a cross-staff. It has long been observed, that the top of a distant hill may sometimes, when the refraction is very great, be distinctly seen from a situation from which, at other times, when the refraction is much less, it is not discernible, even though the sky be very clear.

Many of the following problems may seem to belong to the celestial rather than the terrestrial globe; but as they may be solved equally well by means of both, and as persons not uncommonly possess a terrestrial globe without its usual companion, we shall throw as many problems as possible under this head.

PROBLEM IX. *To find the sun's place in the ecliptic for any given time.* 95 Problems respecting the sun.

Find the day of the month in the calendar on the wooden horizon; and opposite to it, in the adjoining circle, will be found the sign and degree in which the sun

From the above, it is easy to deduce the method of computing the distance of any object seen in the horizon from a certain height. Thus, suppose a man at the mast-head, 130 feet above the water, sees land or a ship just coming in sight. We know, that, at this height, an eye can see 14 miles, consequently the object seen will be about 14 miles or about five leagues distant. If the object is within the horizon, or nearer the place of observation, its distance may be calculated pretty exactly, by descending from the mast-head till the object just comes to the horizon; measuring the height at which this takes place, and thence computing the distance.

sun is on the given day. Then look for the same sign and degree in the circle of the ecliptic drawn on the globe, and that is the sun's place at noon for the given time.

Ex. 1. What is the sun's place on the 4th of June? *Ans.* In 13° 57′ of the sign Gemini.

Ex. 2. Required the sun's place for the first day of every calendar month?

For January	♑	11°	23′	July	♋	9°	42′
February	♒	12	35	August	♌	9	18
March	♓	11	9	September	♍	9	9
April	♈	11	56	October	♎	8	27
May	♉	11	14	November	♏	9	16
June	♊	11	3	December	♐	9	33

PROBLEM X. *To find the sun's declination for any given time.*

Find the sun's place for the given day by Prob. X. and bring it to the brazen meridian. The degree marked on the meridian immediately over the place is the declination required.

Ex. Required the sun's declination for 18th March? The sun's place for the given day is 20° 7′ of ♓, and this being brought to the meridian, will be immediately below 3° 54′ S. which is therefore the declination required.

From the above example, it is evident that the method of finding the declination of the sun corresponds to that of finding the latitude of a place on the globe, given in Problem I. the sun's declination being measured in the same way by an arc of the meridian interposed between the equator and the sun's place in the ecliptic (F).

PROBLEM XI. *To rectify the globe for the sun's place and the day of the month.*

Find the sun's declination for the given day, by Problem XI.; then elevate the pole that is in the same hemisphere with the degree of declination, as many degrees as are equal to the declination.

Ex. Rectify the globe for the sun's place on the 6th October? *Ans.* The sun's declination on that day is 5° S. therefore the south pole must be elevated 5° above the horizon.

Rectifying the globe for the sun's declination corresponds to the rectifying of it for the latitude of a given place. See N° 88.

PROBLEM XII. *To find the time of the sun's rising and setting at a given place, for any given day.*

Rectify the globe for the declination on the given day, and bring the given place to the meridian, and set the index of the hour circle at XII. Turn the globe, till the given place come to the eastern edge of the horizon, and the time of sunrise will be shewn by the position of the index. Then turn the globe till the given place come to the western part of the horizon, and the position of the index will point out the time of sunset.

To perform the same problem by Adams's globes. Rectify the globe for the declination, bring the given place to the meridian, and set the horary index at 12 as before; then turn the globe towards the west, till the given place reach the western edge of the horizon, and the index will point to the time of sunrise. The time of sunset will be known, in like manner, by bringing the place to the eastern side of the horizon.

If the hour circle in the ordinary globes has a double row of figures, the sun's rising and setting may be found at the same time; for if the place be brought to the eastern part of the horizon, the time of sunrise will be shewn by the index, in that circle where the hours increase towards the east; and the time cut by the index in the circle where the hours increase towards the west, will shew the time of sunset.

Ex. 1. Required the time of the sun's rising and setting at London, on the 29th August? *Ans.* The sun rises at nine minutes after five, and sets nine minutes before seven.

Ex. 2. Required the time of sunrise and sunset at Edinburgh on the 1st of June? *Ans.* For sunrise, 27 minutes after three; for sunset, 33 minutes after eight.

COROLLARY. From this problem we may easily find the length of the day and night for any given time; for, having found by the globe the time of sunrise and sunset, the double of the latter is the length of the day, and the double of the former the length of the night.

PROBLEM XIII. *To find the sun's meridian altitude on any given day, at a given place.*

Rectify the globe for the latitude of the given place, by Problem VIII.; find the sun's place on the given day by Problem IX. and bring it to the brazen meridian. Then fix the quadrant of altitude in the zenith, or over the given place, and bring it over the sun's place; and the degree of the quadrant lying over the sun's place will shew the meridian altitude.

If the globe has no quadrant of altitude, the sun's meridian altitude may be found by counting the number of degrees on the meridian, between the horizon and the sun's place.

Ex. Required the sun's meridian altitude at Edinburgh on the 21st of June? *Ans.* 57° 30′, or the greatest possible, this being the summer solstice.

COROLLARY. It may be known whether the sun's meridian altitude be north or south, by the following observations. When the sun's declination and the latitude of the place are of different names, i. e. the one north and the other south, the meridian altitude is of the same name with the declination. If the declination and latitude be both north or both south, the altitude is of the same name with the declination, if the latter be the greater; but, otherwise, the altitude is of an opposite name.

PROBLEM XIV. *Having the latitude of the place and the day of the month given, to find the sun's altitude for any given hour.*

Rectify the globe for the latitude; find the sun's place, and bring it to the meridian, and set the horary index

(F) For a table of the sun's declination corresponding to his true place, see Vol. III. p. 170.

index to noon; turn the globe till the index point to the given hour, then fix the quadrant of altitude in the zenith, and bring its graduated edge over the sun's place, and the degree cut by the sun's place will be the altitude required.

Ex. What will be the sun's altitude at 10 o'clock A. M. on the 30th of November at Edinburgh? *Ans.* 8° 50′.

PROBLEM XV. *Having the sun's meridian altitude given at any place, to find the latitude of the place.*

Bring the sun's place for the given day to the meridian, and move the globe in the horizon till the distance between the sun's place and the northern or southern edge of the horizon, (according as the case may require), be equal to the given altitude. The degree of elevation of the pole will shew the latitude required.

Ex. The sun's meridian altitude observed at a certain place on 5th August is 74° 24′ N. What is the latitude of the place? *Ans.* 1° 36′ N.

PROBLEM XVI. *The latitude of the place and the day of the month being given, to find when the sun is due east or due west.*

Rectify the globe for the latitude of the place, bring the sun's place to the meridian, and set the index to XII. Fix the quadrant of altitude in the zenith, and if the sun's declination be of the same name with the latitude, bring the graduated edge of the quadrant to the eastern side of the horizon; but if the declination is of a different name from the latitude, bring the quadrant to the western part of the horizon. Turn the globe till the sun's place in the ecliptic come below the edge of the quadrant, and the index will point to the hour when the sun is due east. Subtract this from XII. and the remainder shews the time when the sun is due west.

Ex. At what hours is the sun due east and west at the summer and winter solstice at Greenwich? *Ans.* At the summer solstice he is due east at 20 minutes past seven, and due west at 20 minutes before five. At the winter solstice he is due east at 20 minutes before five, and due west at 20 minutes past seven.

COROLLARY. When the declination and latitude are of the same name, the sun is due east after rising; but when the declination and latitude are of different names, he is due east before rising. As it is not convenient to observe on the globe when the sun is due east before rising, or while he is under the horizon, it is better to bring the opposite point of the ecliptic due west, and then the index shews the time when he is due east.

PROBLEM XVII. *Having a place in the torrid zone given, to find on what two days of the year the sun is vertical at that place.*

Find the latitude of the given place, and keeping that in view, turn the globe round, noting the two points at the ecliptic that pass below the degree of latitude. Find in the calendar circle of the horizon the days corresponding to those points of the ecliptic; and these are the days on which the sun is vertical at the given place.

Ex. 1. On what days is the sun vertical at St Helena, in latitude 15° 55′ S.? *Ans.* On the 6th February and 6th November.

Ex. 2. Required the days on which the sun is vertical at Tobago, in latitude 11° 29′ N.? *Ans.* On April 19. and August 23.

PROBLEM XVIII. *To find those places in the torrid zone where the sun is vertical on a given day.*

Find the sun's place for the given day, and bring it to the brazen meridian; then turn the globe, and note all the places which pass under that point of the meridian: these will be the places to which the sun is vertical on the given day.

Ex. 1. In what places is the sun vertical at the summer solstice? *Ans.* At Canton in China, at Calcutta in Bengal, at Mecca in Arabia, and at the Havannah.

Ex. 2. To what places is the sun vertical on the 16th of May and 29th of July? *Ans.* At Bombay, Pegu, in the northern part of Manilla, in the middle of the Ladrone islands, at Owhyhee, Mexico, in Hispaniola, and at Tombuctoo in the central parts of Africa.

PROBLEM XIX. *Having the day and hour at any given place, to find where the sun is then vertical.*

Find the sun's declination by Problem XI. and the places where it is noon at the given time, by Problem III.; then any of those places where it is noon, whose latitude is the same as the sun's declination, will have the sun vertical at the given time.

Ex. On the 1st of August at Edinburgh, it being 35 minutes past four, P. M. it is required to find where the sun is vertical? *Ans.* The sun's declination on that day is 18° 14′ N. and the place where it is noon at the given time, that lies nearest in latitude to the declination, is Kingston in Jamaica: this, therefore, is the place required.

PROBLEM XX. *A place in the northern frigid zone being given, to find when the sun begins to appear above the horizon, and when to disappear; as also the length of the longest day and night.*

Rectify the globe for the latitude, and bring the *ascending* signs of the zodiac (see ASTRONOMY, N° 52.) to the southern part of the horizon; observe what degree of the ecliptic is intersected by that point of the horizon, and in the calendar circle find the day of the month answering to that degree. That will shew the time of the sun's first appearance above the horizon at the given place, and this is the end of the longest night in that latitude. Then bring the *descending* signs to the same part of the horizon, and observe the day which answers to the degree of the ecliptic intersected; this will shew the time of the sun's disappearance, or the beginning of the longest night. Now bring the ascending signs to the northern part of the horizon, and observe the degree of the ecliptic, and the corresponding day as before, which will give the time when the sun begins to shine continually, or the beginning of the longest day. Again, bring the descending signs to the same point, and thus will be given the time when the sun ceases to shine continually, or the end of the longest day.

Ex. At what time does the sun begin to appear above

above the horizon at North Cape in Lapland, the latitude of which is 72° N.? When does he disappear, and how long is he entirely absent during the longest night? *Ans.* He begins to appear on the 26th of January, and entirely disappears on the 16th of November; he is therefore absent for 71 days.

Cor. From the sun's first appearance at the end of the longest night to the beginning of the longest day, and from the end of the longest day to the sun's total disappearance at the beginning of the longest night, he rises and sets every day.

Problem XXI. *To find in what part of the northern frigid zone the sun begins to shine continually on a given day.*

Find the sun's declination for the given day, and subtract this from 90°, the remainder will shew the latitude required.

Note.—The given day must be between the 21st of March and the 21st of June, as at no other time does the sun begin to shine continually in the northern frigid zone.

Ex. Required the latitude in which the sun begins to shine without setting on the 1st of June? *Ans.* The sun's declination for that day is 22° N. and this subtracted from 90° leaves 68° N. the latitude required.

96 Problems respecting the climates.

Problem XXII. *The length of the longest day in any place being given, to find the latitude of that place.*

Bring the 1st degree of Cancer to the meridian, and set the horary index at noon. Then turn the globe towards the west, till the index point to the hour of sunset, or half of the length of the given day; raise or depress the pole, till the sun's place in the ecliptic is exactly in the western edge of the horizon. The elevation thus obtained will be equal to the required latitude.

In Adams's globes, after bringing the first degree of Cancer to the meridian, and setting the index to noon, the globe must be turned towards the west, till the index shew the time of sunset, and the sun's place must be brought to the eastern side of the horizon.

Ex. In what latitude is the longest day 18 hours long? *Ans.* In latitude 58° 30′ N.

By this problem the limits of the hour climates may be pretty nearly ascertained.

Problem XXIII. *To find the latitudes of those places in the frigid zone where the sun is continually above the horizon for a given number of days.*

Count from the first degree of Cancer towards the nearest equinoctial point, as many degrees as is equal to half the given number of days; bring the point thus obtained below the meridian, and note the degree of the meridian which it intersects. This subtracted from 90° will leave a remainder that is nearly equal to the latitude of the place.

Ex. In what latitude does the sun never set during 76 days? *Ans.* In latitude 71° 30′, or very near the southern part of Nova Zembla.

Note.—This problem cannot be performed accurately by the globe; for as the sun requires 365 days six hours to move through the whole 360° of the ecliptic, he does not advance quite a degree in 24 hours.

By this problem the limits of the month climates may be pretty nearly ascertained.

Problem XXIV. *The hour and day being given at any place, to find in what places the sun is rising, and in what he is setting; where it is noon, and where midnight.*

Find by Problem XIX. the place to which the sun is vertical at the given time; rectify the globe for the latitude of that place, and bring the place below the meridian. In this position of the globe all those places that lie within the western edge of the horizon will have the sun rising, and all those which are in the eastern edge of the horizon will have it setting. Again, to those places which lie under the upper semicircle of the brazen meridian, it will be noon; and to those which lie below the lower semicircle, it will be midnight.

Ex. Suppose it be four o'clock P. M. on the 4th of June at London; where is the sun at that time rising, and where is he setting; to what places is it noon, and to what midnight? *Ans.* The north-eastern part of Siberia, Kamtschatka, the most western of the Sandwich isles, and the most eastern of the Society isles, are within the western edge of the horizon, and consequently to these the sun is rising. At Tobolsk, in the Caspian sea, in the desert of Arabia, in the middle of the Red sea, in Abyssinia, in the central parts of Africa, and in the country of the Hottentots, the sun will be setting, as these places lie within the eastern edge of the horizon. New Britain, the islands of Martinique and Trinidad, and the middle part of South America, which lie below the upper semicircle of the meridian, have noon; and Chinese Tartary, the eastern part of China, the Philippine isles, and the western part of New Holland, which are situated below the under edge of the semicircle, have midnight.

As the remaining problems on the terrestrial globe chiefly respect the continuance of twilight, it is proper, before we proceed, to make a few remarks on this subject. For the explanation of the term, see Crepusculum and Twilight.

The *Crepusculum*, or *Twilight*, it is supposed, usually begins and ends when the sun is about 18° below the horizon; for then the stars of the 6th magnitude disappear in the morning, and appear in the evening. It is of longer duration in the solstices than in the equinoxes, and longer in an oblique sphere than in a right one; because in those cases the sun, by the obliquity of his path, is longer in ascending through 18° of latitude.

Twilight is occasioned by the sun's rays refracted in our atmosphere, and reflected from the particles of it to the eye. For let A (fig. 10.) be the place of an observer on the earth ADL, AB the sensible horizon, meeting in B the circle CBM bounding that part of the atmosphere which is capable of refracting and reflecting light to the eye. It is plain that when the sun is under the horizon, no direct rays can come to the eye at A: but the sun being in the refracted line CG, the particle C will be illuminated by the direct rays of the sun; and that particle may reflect those rays to A, where they enter the eye of the spectator. And thus the sun's light illuminating an innumerable multitude of particles, may be all reflected to the spectator at A.

Principles and Practice.

A. From B draw BD touching the circle ADL in D, and let the sun be at S in the line AD; then the ray SB will be reflected into the situation BA, and will enter the eye, because from a principle in optics the angle of incidence DRC is equal to the angle of reflection ABE. See OPTICS. This ray SB, or BA, will therefore be the first that reaches the eye at dawn in the morning, and the last that falls on the eye at night, when twilight ceases, because as the sun gets lower down, the particles of the air at B will no longer be illuminated.

The depth of the sun below the horizon at the beginning of the morning or end of the evening twilight, is determined by observing the moment when the air first begins to shine in the morning, or ceases to shine in the evening; then finding the sun's place for that time, and hence the time till his rising in the horizon, or after his disappearance below. This depth of the sun below the horizon has been variously stated by different astronomers, but it is now generally estimated at 18°. Accordingly in Mr Adams's globes there is a circular wire fixed 18° below the horizon, to represent the limits of the crepusculum (see PWY, fig. 5.).

As the cause of twilight is not constant, its limits must continually vary; for if the exhalations in the atmosphere be more copious or more extensive than usual, the morning twilight will begin sooner, and that of the evening last longer than ordinary; as the more copious the exhalations, the more rays will be reflected from them, and consequently the more they will shine, and again, the higher they are, the sooner they will be illuminated by the sun. From this circumstance the evening twilight is commonly longer than the morning, at the same time, and in the same place. The refraction is also greater according as the air is more dense, and not only is the brightness of the atmosphere variable, but the same takes place in its height above the earth; therefore, the twilight is longest in hot weather, and in hot countries, all other things being equal. The chief differences, however, arise from the different situations of places on the earth, or from the difference of the sun's place in the heavens. Thus, the twilight is longest when the earth is in the position of a parallel sphere, and shortest in that of a right sphere (see N° 90.): and in an oblique sphere, the twilight continues longer at any place, in proportion as that place is nearer to either of the poles; a circumstance which affords considerable relief to the inhabitants of the northern countries in their long winter nights. Twilight continues longest in all places of north latitude, when the sun is in the tropic of Cancer, and to those in south latitude when he is in the tropic of Capricorn. The time of the shortest twilight also varies in different latitudes; thus, in England, the shortest twilight is about the beginning of October and of March, when the sun is in ♎ and ♓; hence, when the difference between the sun's declination and the depth of the equator is less than 18°, so that the sun does not descend more than 18° below the horizon, the twilight will continue through the whole night, as happens in Britain from the 22d of May to the 22d of July.

In the latitude of 49° N. twilight continues for the whole night, only on the 21st of June, or the time of the summer solstice: but at all places further to the north it continues for a certain number of days before and after the summer solstice.

Near the north pole there is continual twilight from the 22d of September, the time of the sun's permanent absence, to the 12th of November. It then ceases till about the 30th of January, when it again appears, and continues till the 21st of March, the time of the sun's permanent appearance. Hence the inhabitants of those places nearest the pole, though they never see the sun for nearly six months, have, however, the benefit of twilight for above the half of that time, and are entirely excluded from the sun's light little more than 12 weeks, during six of which the moon is constantly above the horizon.

98 Uses of twilight.

Were it not for the gradual change from light to darkness, and *vice versa*, which is the consequence of twilight, much inconvenience would arise. A sudden change from the darkness of midnight to the full splendour of the sun, and the reverse, would injure the sight, and would, in many cases, be productive of much danger to travellers, who would be overtaken by utter darkness before they had time to prepare for its approach.

99 Problems respecting twilight.

PROBLEM XXV. *To find where it is twilight at any given time.*

Find where the sun is vertical at the given time, and rectify the globe for the latitude of that place. Observe what places are within the limits of twilight, or not quite 18° below the horizon. To those which are situated within the western zone, between the horizon and the parallel of 18°, it will be twilight in the morning; and those which are in the eastern zone will have it twilight in the evening.

This problem may be more conveniently performed by rectifying the globe for the antipodes of the place which has the sun then vertical, and observing what places are situated in the zone formed above the horizon, between it and a parallel circle of 18°.

Ex. It is required to find where it is twilight on the 4th of June, when it is three o'clock P.M. at London. *Ans.* Kamtschatka, the Sandwich isles, and the Marquesas, have twilight in the morning; and the inhabitants of Madagascar, of Tibet, and the eastern part of Persia, have twilight in the evening.

PROBLEM XXVI. *To find the duration of twilight at a given place on any given day.*

Rectify the globe for the latitude of the place; find the sun's place for the given day by Problem X. and bring it below the meridian, and set the horary index to XII. Turn the globe till the sun's place be just within the circle that marks the limits of twilight, and the index will shew the beginning of twilight. Subtract the time of the beginning of twilight from the time of sunrising at the given place (found by Problem XII.) and the remainder will shew the duration of twilight at the given place.

Note.—The above rule will answer both for the ordinary globes, and for those of Adams, except that in the latter the sun's place must be brought below the western part of the horizon. A more convenient way in both globes will be, to bring that point of the ecliptic which is opposite to the sun's place, 18° above the

Principles and Practice.

the western horizon, and the index will then shew the beginning of twilight.

Ex. How long will twilight continue at London on the following days: March 2d; September 25th; and December 26th? *Ans.* On the 2d of March it will continue one hour and fifty minutes; on the 25th of September two hours; and on the 26th of December, two hours ten minutes (G).

100 Cause of day and night.

PROBLEM XXVII. *To shew the cause of day and night by the globe.*

It will have appeared, from the consideration of the cause of day and night given under the article ASTRONOMY, that only that half of the earth which is opposite to the sun, is illuminated by his rays, while that which is turned from him is involved in darkness. As the earth revolves on its axis from west to east, in the space of 24 hours, every place on the earth in the course of that time alternately enjoys the light of the sun, and is deprived of it.

To illustrate this by the globe, rectify the globe for the sun's declination, so as to place the sun in the zenith, and the horizon will represent the boundary between light and darkness; that hemisphere which is above the horizon being illuminated by the sun's rays, and that which is below the horizon being deprived of light. If now a patch is put on the globe, so as to represent any place, and if the globe be made to revolve from west to east; when the place is brought to the western edge of the horizon, the sun will appear to the inhabitants of that place to be rising in the east, though, in fact, the appearance arises from the place itself coming beyond the limit of darkness. As the globe continues to turn, the place rises towards the meridian, and this produces the appearance as if the sun were advancing towards the meridian in a contrary direction. When the place comes below the meridian, it is noon to that place, and the sun appears to have attained its greatest height.

As the place proceeds towards the east, it gradually recedes from the meridian, and the sun appears descending in the west. When it reaches the eastern edge of the horizon, and is proceeding below the boundary of light aud darkness, the sun appears to be setting; and during the whole time that the place is moving below the horizon, the sun will not appear till the place once more rises in the west.

101 Problem on lunar eclipses.

PROBLEM XXVIII. *To find at what places an eclipse of the moon is visible at any given time.*

Find the place to which the sun is vertical at the given time, and rectify the globe for the latitude of that place. As the moon is opposite to the sun, which illuminates the superior hemisphere of the globe, the eclipse of the moon will be visible to all the places that lie below the horizon.

As the places below the horizon are not easily examined, this problem may be more conveniently performed by rectifying the globe for the antipodes of the place to which the sun is vertical at the given time, rather than for the place itself; as in this latter position of the globe the moon being in opposition to the sun, will be vertical to the place below the zenith, and its eclipse will be visible at all the places now above the horizon.

Ex. 1. On the 4th of January 1806, at 55 minutes past 11 P. M. reckoning the time at Greenwich, there was an eclipse of the moon. It is required to find those places to which the eclipse was visible? *Ans.* Through the greatest part of Africa, in some part of Europe, in Asiat South America, and a great part of North America.

Ex. 2. On the 10th of May 1808, when it is eight o'clock A. M. at Greenwich, the moon will be totally eclipsed. In what places will the eclipse be visible? *Ans.* In most parts of America; in the islands of the Pacific ocean, and on the eastern coast of New Holland.

SECT. II. *Of the Use of the Celestial Globe.*

1 Celestial globe.

The celestial globe, with respect to the circles that are described on it, and the apparatus with which it is furnished, scarcely differs from the terrestrial globe, which has been so fully described in the preceding section. The surface of the celestial globe is made to represent all the stars that are commonly visible to the naked eye, arranged under their constellations, and bounded by the figures which have been given to these constellations by the early astronomers. (See fig. 5.). In Adams's celestial globe the moveable semicircle (N° 91.) turning round the poles represents a circle of declination, and the small circle on it, an artificial sun or planet.

Both the globes are often furnished with a mariner's compass, which is usually placed in the lower part of the frame.

It must here be remarked, that the representation of the heavens on the celestial globe, though probably much more accurate than that of the earth on the terrestrial, is not so natural as the latter; for, in viewing the stars on the external surface of a globe, the spectator sees them in an opposite position to that in which he observes them in the heavens, so that to form a just conception of their exact situation, he must suppose his eye to be seated in the centre of the globe. Hence, if a large hollow hemisphere were made of glass, and if the stars in the corresponding hemisphere of the firmament were painted in transparent colours on its surface; an eye situated in the centre of such a hemisphere

(G) If we have the latitude of a place, and the sun's declination given, we may find the beginning of the morning and the end of the evening twilight by calculation. Thus, in the oblique-angled spherical triangle ZPN (fig. 11.) we have given ZP the co-latitude; PN the co-declination, and ZN$=108°$ being the sum of $90°$ the quadrant, and $18°$ the depression at the extremity of twilight. Then by spherical trigonometry we may calculate the triangle ZPN, the hour angle from noon, and this reduced to time, at the rate of $15°$ per hour, gives the time from noon to the beginning or end of twilight. For the mode of calculation, see SPHERICS.

sphere would see the stars exactly as they appear in the heavens.

The great use of the celestial globe is to perform a variety of problems with respect to the stars, and the motions of the heavenly bodies through the space which they occupy.

PROBLEM I. *To place the celestial globe in such a situation as that it shall exhibit an accurate representation of the face of the heavens at any given place, and at any given time.*

Rectify the globe for the latitude of the place, as in Problem VII. of the terrestrial globe, or by setting the pole of the celestial globe pointing to the pole of the earth, by means of the compass that is usually annexed to the globes; find the sun's place in the ecliptic; bring this to the meridian, and set the horary index at noon. Again, make the globe turn on its axis till the index point to the given time, and in this position the globe will exactly represent the face of the heavens, corresponding to the given time and place; every constellation and star in the heavens answering in position to those on the globe. Hence, by examining the globe, it will immediately be seen what stars are above or below the horizon, which are on the eastern and western parts of the heavens, which have just risen above the horizon, and which are about to sink below it.

As this problem will be found extremely useful to the student of astronomy, we shall here quote the example given in illustration of it by Messrs Bruce of Newcastle.

"Required the situation of the stars for the latitude of Newcastle, on October 6th, at eight o'clock in the evening?

"In our present survey of the heavens, we shall commence at the north point of the horizon, and proceed round eastward; noticing the different constellations, and the relative situation of the principal stars in these constellations.

"The first star which strikes the eye of the observer, in the north-east part of the heavens, is Capella, in the constellation Auriga, or the Waggoner: It is of the first magnitude, of the altitude of 23°, or nearly the fourth part of the distance from the horizon to the zenith. There are two stars of the second magnitude, which form with Capella a triangle:—The star which forms the short side of the triangle is in the right shoulder of Auriga, and is marked β; it lies at the distance of about 8° from Capella, further to the north; its altitude is 18°:—The star forming the longer side of the triangle is in the Bull's northern horn; its distance from Capella is more than 26°; its altitude not more than 5°, and azimuth N. E. There are three stars of the fourth magnitude, a little to the south of Capella, that bear the name of the *Kids*.

"If a line be drawn through the two stars that form the upper side of the triangle, and continued to the horizon, it will point out Castor, α, in Gemini just rising, azimuth E. N. E: it is between the first and second magnitude. The other stars in this constellation have not yet risen.

"A line drawn between Castor and Capella, and continued higher in the heavens, will point out Perseus, in which there are three stars, one of the second magnitude, α, named *Algenib*, and two of the third magnitude, one on each side of Algenib, at the distance of about 5°: they form a line a little curved on the side next Auriga. The altitude of Algenib is 37°; azimuth N. E. by E.

"A little to the south of Perseus is the Head of Medusa, which Persens is holding in his hand. Besides two or three small stars it contains one of the second, and one of the third magnitude. The name of the brightest is *Algol;* altitude 33°, azimuth E. N. E. Algol is only 10° distant from Algenib.

"Directly below the Head of Medusa, about 14° above the horizon, are the Pleiades or seven stars: They are seated in the shoulder of Taurus, and are so easily known, that no description is necessary. Aldebaran, a star of the first magnitude, which forms the eye of Taurus, is just rising; azimuth E. N. E. A vertical circle drawn through Algol will point to it. There are two stars of the third magnitude, and several smaller very near Aldebaran, which form with it a triangle. The whole cluster is called the *Hyades*.

"A line drawn from Aldebaran through Algol, and continued to the zenith, will direct to Cassiopeia. This contains five stars of the third magnitude, besides several of the fourth: it is in form something like the letter Y, or, as some think, an inverted chair. It is situated above Persens, within 30° of the zenith. The altitude of the brightest star, α, called *Schedar*, is 60°; azimuth, E. N. E,

"Below Cassiopeia and west of Perseus is Andromeda, which contains three stars of the second magnitude. A line from Algenib, parallel to the horizon towards the south, will pass very near these three stars; and, as they are all of the same magnitude, and placed nearly at the same distance of 15° from each other, they may easily be known. The name of the star nearest Perseus, and which is in the foot of Andromeda, marked γ, is Almaak: its altitude is 49°; azimuth E. N. E. The name of β, in the girdle, is Mirach: its altitude 44°; azimuth E. The altitude of α, in the head of Andromeda, is 46°; azimuth E. S. E.

"About 18° below Mirach are two stars in Aries, not more than 5° distant from each other, forming with Mirach an isosceles triangle: the most eastern star, α, is of the second magnitude; the other, β, of the third, attended by a smaller star, marked γ, of the fourth magnitude. A line drawn from Mirach, perpendicular to the horizon, will pass between the two, and besides, will point to a star of the second magnitude, directly E. not above 3° from the horizon.

"This star is the first of Cetus, maked α, and is of the second magnitude: it is named *Menkar*. A line drawn from Capella through the Pleiades will also point to it. Cetus is a large constellation, and contains eight stars of the third magnitude; they all lie to the west of Menkar; β, a star in the tail, is more than 40° distant from it. The azimuth of β is S. E. by E; altitude nearly the same as Menkar.

"The constellation Pisces is situated next to Aries; it contains one star of the third magnitude, marked α: its altitude is 10°, azimuth E. by S. It is distant from Menkar 15°. A line drawn from Almaak, through α in Aries, will point to it.

"If we return again to α in the head of Andromeda, we shall find three other stars nearer the meridian, which, with

Principles and Practice.

with it, form a square. These stars are in Pegasus, and are placed at the distance of 15° from each other; they are all of the second magnitude. The two stars forming the western side of the square are called—the upper one Scheat, which is marked β, and which is in the thigh of Pesagus; the under one Markab, which is marked α, and which is in the wing; the lowest star in the eastern side of the square is in the tip of the wing, and is marked γ. The altitude of Scheat is 55°; azimuth S. E. ½ E. Altitude of Markab, 43°; azimuth S. E. by S. ½ E.

"A line drawn through γ and β (the diagonal in the square of Pegasus) and continued to the meridian, will point out Cygnus, a remarkable constellation in the form of a large cross, in which there is a star of the second magnitude, named *Deneb* or *Arided;* it is marked α, and is almost directly upon the meridian at the altitude of 80°. Cygnus contains six stars of the third magnitude. The constellation Cepheus, which contains no remarkable stars, is situated between Cygnus and the north pole.

"Below Pegasus, and nearer the meridian, is Aquarius, containing four stars of the third magnitude. A line drawn from α in Andromeda, through Markab, will point to α in Aquarius. Its altitude is 32°; azimuth S. S. E.

"A bright star of the first magnitude named *Fomelhaut*, in Pisces Australis, is then upon the horizon; azimuth S. S. E.

"Delphinus is a small constellation, situated about 30° below Cygnus upon the meridian; it contains five stars of the third magnitude, four of them being placed close together, and forming the figure of a rhombus or lozenge. A line drawn through the two under stars of the square will point to it. Its altitude is about 50°.

"A little to the west of Delphinus, but not quite so high, is Aquila, containing one very bright star of the first magnitude, named *Atair:* It may very easily be known from having a star on each side of it of the third magnitude, forming a straight line. The length of the line is only about 5°; altitude of Atair 40°; azimuth S. S. W.

"Considerably above Atair, and a little to the W. of Cygnus, is Lyra, containing a star of the first magnitude, one of the most brilliant in the firmament. It is called Lyra or Vega, and is 35° to the N. W. of Atair; altitude 60°; azimuth W. S. W. Lyra, Atair, and Arided, form a large triangle.

"We come now to notice three constellations, which occupy a large space in the western side of the heavens: these are Hercules immediately below Lyra; Serpentarius between Hercules and the horizon, extending a little more towards the south; and Boötes, reaching from the horizon W. N. W. to the altitude of 45°.

"Hercules contains eight stars of the third magnitude; the star in the head, α, named Ras Algethi, is within 5° of α in the head of Serpentarius. This last is a star of the second magnitude, and is named Ras Alhague: its altitude is 30°; azimuth, S. W. by W. ½ W. A line drawn from Lyra, perpendicular to the horizon, will pass between these two stars. The other stars in Hercules extend towards the zenith, and those in Serpentarius towards the horizon.

"The constellation Boötes may easily be known from the brilliancy of Arcturus, a star of the first magnitude, and supposed to be the nearest to our system of any in the northern hemisphere: it is within 10° of the horizon; azimuth W. N. W. Boötes also contains seven stars of the third magnitude, mostly situated higher in the heavens than Arcturus. The star immediately above Arcturus is called Mezen Mirach, and is marked ε. The star in the left shoulder, δ, named Seginus, forms with Mirach and Arcturns a straight line.

"Between Serpentarius and Boötes is *Serpens*, containing one star of the second magnitude, and eight of the third: α in *Serpens* is nearly at the same distance from the horizon, as Arcturus; azimuth W.

"Above Serpens, and a little to the east of Boötes, is the Northern Crown, containing one star of the second magnitude, named Gemma, and several of the third, which have the appearance of a semicircle. A line drawn from Lyra to Arcturus will pass through this constellation.

"We come now to Ursa Major, a constellation containing one star of the first, three of the second, and seven of the third magnitude. It may easily be distinguished by those seven stars, which, from their resemblance to a waggon, are called Charles's Wain. The four stars in the form of a long square, are the four wheels of the waggon; the three stars in the tail of the Bear, are the three horses, which appear fixed to one of the wheels. The two hind wheels, α named Dubhe, and β, are called the pointers, from their always pointing nearly to the north pole. Hence the pole star may be known. The altitude of Dubhe is 30°; azimuth N. by W. ½ W. The distance between the two pointers is 5°; the distance between the pole star and Dubhe, the upper pointer, is 30°.

"Ursa Minor, besides the pole star of the second magnitude, situated in the tail, contains three of the third, and three of the fourth magnitude. These form some resemblance to the figure of Charles's Wain inverted, and may easily be traced.

"Draco, containing four stars of the second and seven of the third magnitude, spreads itself in the heavens near Ursa Minor: the four stars in the head are in the form of a rhombus or lozenge: the tail is between the pole star and Charles's Wain.

"Besides these constellations, there are a number of others, which, as they contain no remarkable stars, we have not described; an enumeration of these will suffice. The Lynx, between Ursa Major and Auriga; Camelopardalus, between Ursa Major and Cassiopeia; Musca, and the Greater and Less Triangles between Aries and Perseus, Aculeus, close to the head of Pegasus; Sagittarius setting in the south-west; Antinous and Sobieski's Shield below Aquila; the Fox and Goose between Aquila and Cygnus; the Greyhounds and Berenice's Hair between Boötes and Ursa Major, and Leo Minor below Ursa Major *."

The astronomical terms that we must here employ in describing the method of performing the problems on the celestial globe, will be found explained in the article ASTRONOMY, or under their proper heads in the general alphabet of this work. See ASCENSION, AZIMUTH, DECLINATION, &c.

PROBLEM

Problems respecting the stars.

PROBLEM II. *To find the right ascension and declination of any given star.*

Bring the given star below the brazen meridian, and mark the degree of the meridian under which it lies. That degree shews the declination of the star, and the degree of the equator cut by the meridian gives the star's right ascension.

The right ascension of a star may also be found by placing the globe in the position of a right sphere, and then bringing the star to the eastern part of the horizon; for that point of the equator which comes to the horizon at the same time with the star, marks its right ascension. See ASTRONOMY, N° 249, 250.

Ex. 1. What is the right ascension and declination of the star Sirius? *Ans.* Its right ascension is 99°, and its declination 16° 27′ S.

Ex. 2. Required the right ascension and declination of Aldebaran, or the star in the Bull's Eye marked α? *Ans.* Its right ascension is 66°, and its declination 16° 5′ N.

PROBLEM III. *Having the right ascension and declination of a star given, to find the star on the globe.*

Bring the degree of the equator which marks the right ascension below the brazen meridian, and counting along the meridian towards the north or south, as far as the degree of declination, the required star will be there found.

Ex. 1. The right ascension of a certain star is 162° 15′, and its declination is 57° 27′ N.; What is the name of the star? *Ans.* The lower pointer of Ursa Major, marked β.

Ex. 2. The right ascension of Arcturus is 211° 30′, and its declination is 20° 13′ N.: it is required to find it on the globe.

This problem is extremely useful in discovering the names and relative situations of the different stars.

PROBLEM IV. *To find the latitude and longitude of a given star.*

Bring the solstitial colure (see N° 75.) below the brazen meridian, and there fix the quadrant of altitude over the pole of the ecliptic which is in the same hemisphere with the given star. Then, keeping the globe steady, bring the graduated edge of the quadrant over the given star, and the degree of the quadrant cut by the star, counted from the ecliptic, marks its latitude, and the degree of the ecliptic that is cut by the quadrant is the longitude of the given star (H). See ASTRONOMY, N° 252, 253.

Ex. 1. What is the latitude and longitude of Arcturus? *Ans.* Lat. 31° N. Long. Libra 20°.

Ex. 2. What is the latitude and longitude of Capella? *Ans.* Lat. 23° N. Long. Gemini 18° 30′.

PROBLEM V. *Having the day of the month given, to find at what hour any star comes below the meridian.*

Find the sun's place, and bring it to the meridian, and set the horary index to XII.; turn the globe till the given star come below the meridian, and the index will point out the hour.

To know whether the hour is in the forenoon or afternoon, it is necessary to observe, that if the star be to the east of the sun, it will reach the meridian later than the sun, but if it be to the west of that luminary, it will come to the meridian sooner: hence, in the former case, the hour will be P. M. and in the latter A. M.

Ex. 1. At what hour does Sirius come to the meridian on the 9th of February? *Ans.* At 7 minutes past 9 P. M.

Ex. 2. Required the hour when Castor passes the meridian on the same day. *Ans.* At 52 minutes past 9 P. M.

PROBLEM VI. *Having any star given, and a given hour, to find on what day the star will come to the meridian at a given hour.*

Bring the given star below the meridian, and set the horary index to the given hour. Make the globe revolve till the index come to twelve at noon; and the day of the month which corresponds to the degree of the ecliptic then below the meridian, found in the calendar circle of the wooden horizon, will be the day required.

Ex. 1. On what day does Algenib, the first star of Perseus, come to the meridian at midnight? *Ans.* On the 13th of November.

Ex. 2. On what day does Arcturus come to the meridian at 9 o'clock P. M. *Ans.* On the 10th of June.

PROBLEM VII. *Having the latitude, the day of the month, and the hour of the night given, to find the altitude and azimuth of any given star.*

Rectify the globe for the given latitude; bring the sun's place below the meridian, and set the horary index at XII. then turn the globe till the index point at the given hour. Fix the quadrant of altitude at 90° from the horizon, that is, in the zenith, and bring its graduated edge over the place of the star: the degree of the quadrant intercepted between the horizon and the star is the altitude required; and the distance between the foot of the quadrant and the nearest part of the horizon, will be the azimuth.

It is evident that this problem on the celestial globe is exactly similar to Problem XIII. on the terrestrial globe, for finding the altitude of the sun.

Ex. 1. What will be the altitude and azimuth of Cor Hydræ on the 21st of December at London, at 4 o'clock A. M.? *Ans.* The altitude 30°, the azimuth S. 14° W.

Ex. 2. Suppose an observer at the Cape of Good Hope, on the 21st of June at midnight; required the altitude and azimuth of Arcturus to him? *Ans.* Altitude 12°, azimuth N. 55° W.

PROBLEM VIII. *Having given the azimuth of any given star, and the day of the month in a given latitude; to find the hour of the night, and altitude of the star.*

Rectify the globe as in the last problem; fix the quadrant of altitude in the zenith, and bring it to the given azimuth. Turn the globe till the star comes below

(H) It must be remembered that the longitude of the heavenly bodies is not estimated in degrees and minutes like their right ascension, but in signs, degrees, and minutes, as the sun's place is reckoned.

Principles and Practice.

low the graduated edge of the quadrant, when the horary index will point out the hour, and the altitude of the star will be seen by the quadrant.

Ex. Suppose the azimuth of Dubhe to be N. 23° W. at London on the first of September; it is required to find the altitude of the star, and the hour of the night? *Ans.* The altitude of Dubhe at that time is 31°, and the hour is 9 o'clock P. M.

PROBLEM IX. *The latitude of the place, the altitude of a star, and the day of the month, being given; to find the azimuth and the hour of the night.*

Rectify the globe as before, and having fixed the quadrant of altitude in the zenith, turn the globe and quadrant of altitude till the latter comes over the star at the given degree of altitude. In this position the index will shew the time of night, and the position of the quadrant at the horizon will shew the azimuth of the star.

In the same way the hour of the night and the azimuth of the sun may be found, by fixing a patch on the globe in the sun's place, and bringing it to the quadrant as directed for the star.

As the sun and stars have the same altitude twice in the day, it is proper to know whether they are to be east or west of the meridian; or whether the hour required be in the evening or the morning.

Ex. At Edinburgh, on the 25th of December, in the forenoon, when the sun's altitude is 7° 20′, required the hour and the sun's azimuth? *Ans.* It is 10 o'clock A. M. and the sun's azimuth is S. 27° 30′ E.

PROBLEM X. *Having the azimuth of the sun or a star, the latitude of the place, and the hour of the day given; to find the altitude and day of the month.*

Rectify the globe for the latitude of the place, fix the quadrant in the zenith, and bring its edge under the given azimuth. Bring the sun's place or the star to the edge of the quadrant, and set the index at the given hour. The degree marked in the quadrant will shew the altitude; and if the globe be turned till the index points to twelve at noon, the day of the month, answering to that degree of the ecliptic which is intersected by the brazen meridian, is the day required.

Ex. The azimuth of the star α in the Northern Crown was observed at London at 9 o'clock P. M. to be S. 89° W.; required the altitude and day of the month? *Ans.* Altitude 30°; day of the month 1st of September.

PROBLEM XI. *Having observed two stars to have the same azimuth; to find the hour of the night.*

Rectify the globe as before; turn the globe and move the quadrant till the edge of the latter comes over both stars, and the horary index in this position of the globe will give the hour required.

The following is a simple and easy method of finding when two stars have the same azimuth. Hold a small line with a plummet at its lower extremity between the eye and the two stars, and if both stars fall within the line, they have the same azimuth. The same may be done by observing when any two stars pass behind the perpendicular edge of a wall at the same time.

Ex. Vega and Atair were observed to have the same azimuth at London on the 11th of May; required the hour of the night? *Ans.* 15 minutes past 2 A. M.

This problem may be applied to the regulating of clocks and watches, by reducing apparent to real time, as explained under ASTRONOMY.

PROBLEM XII. *To find the rising, setting, and culminating of any star or planet, its continuance above the horizon, its oblique ascension and descension, and its eastern and western amplitude; the place and day being given.*

Rectify the globe as in the foregoing problems; bring the given star or the given planet (finding its place in an ephemeris for the given day, and marking it by a patch on the globe) to the eastern part of the horizon, and the index of the hour circle will point out the time of rising: the degree of the equator that comes to the horizon with the given star or planet, marks its oblique ascension, and the eastern amplitude is shewn by the distance of the star or planet from the eastern part of the horizon.

Bring the star or planet to the meridian, and the index will point to the time of its culminating.

Move the globe till the star or planet come to the western part of the horizon, and the time of its setting, its oblique descension, and its western amplitude, may be found in the same manner as directed above; for its rising, oblique ascension, and eastern amplitude, the number of hours passed over by the index, while the star or planet is moving from east to west, will shew the time of its continuance above the horizon.

Ex. 1. Required the above circumstances with respect to Sirius on the 14th of March at London. *Ans.* It rises at 24 minutes past two P. M.; comes to the meridian, or culminates, at 57 minutes past six P. M.; and sets at half-past eleven P. M. Hence it remains above the horizon nine hours and six minutes. Its oblique ascension is 120° 47′, its oblique descension 77° 17′, and its amplitude 27° S.

Ex. 2. It is required to find the situation of the several planets on the 19th of January 1806. *Ans.* Mercury is about 22° to the west of the sun, and rises south-east by east, at 20 minutes before seven A. M. Venus is an evening star, and sets about half past eight. Mars is a very little to the east of the sun, and rises and sets so near the same time with the sun, that he cannot be seen. Jupiter is a morning star, and rises about six o'clock. Saturn is a little to the east of the star Spica Virginis, and rises about half an hour after midnight. Herschel is very near Saturn, and rises about the same time.

PROBLEM XIII. *To find those stars which never rise, and those which never set, in a given latitude.*

Rectify the globe for the latitude of the place; then, holding a black lead pencil so as to touch the surface of the globe at the northern point of the horizon, turn the globe, so that the pencil may describe a circle: all the stars which are between this circle and the elevated pole, never set. Again, holding the pencil at the southern point of the horizon, turn the globe so as to describe another circle there, and all the stars that are between that circle and the pole, below the horizon, never rise.

If the place is in southern latitude, the stars that never set are found by describing a circle at the southern point

point of the horizon, and those that never rise by a similar circle at the northern point (1).

Throughout almost the whole year, the moon rises later every successive day, by above three quarters of an hour; but at a considerable distance from the equator, as in the latitude of Britain, France, and some other countries, a remarkable anomaly takes place in the moon's motion about the time of harvest. At this season, when the moon is about full, she rises for several nights successively at about 17 minutes later only than on the preceding day. This is attended with considerable advantage, for as the moon rises before twilight is well ended, the light is as it were prolonged, and thus an opportunity given to the industrious farmer to continue longer in the field, for the purpose of gathering in the fruits of the earth. From the advantage derived from the full moon at the season of harvest, it has been called the *harvest moon*. The following problem has been contrived for the purpose of illustrating the phenomenon by means of the globe.

Problem XIV.

Rectify the globe for any considerable northern latitude, suppose that of London. As the angle which the moon's orbit makes with the ecliptic is but small, we may suppose, without any considerable error, her orbit to be represented by the ecliptic. In September the sun is in the beginning of ♎, so that the moon, when full, being in opposition to the sun, must be in or near the beginning of ♈. Put a patch, therefore, in the globe at the first point of ♈ in the ecliptic; and as the moon's mean motion is about 13° in a day, put another patch on the ecliptic 13° beyond the former, and it will point out the moon's place the night after it is full. A third and fourth patch, put at the distance of 13° further on, will shew the moon's place on the second and third nights after full, &c. Now, bring the first patch to the horizon, and observe the hour pointed out by the index; turn the globe till the second patch comes to the horizon, and it will appear by the index that there are only 17 minutes between the time of the first patch rising, and that of the second. This small difference in the motion of the moon evidently arises from the small angle which her orbit makes with the horizon. The remaining patches will come to the horizon with a little greater difference of time, and this difference will gradually increase as the moon advances in the ecliptic; but for the first week after the full moon at harvest the difference will not be more than two hours. If patches be continued on to the first point in ♎, it will be found that the time of their 'rising,' or coming to the horizon, will increase considerably till the last will be above 1¼ hour later in coming to the horizon, because that point of the ecliptic makes the greatest angle with the horizon.

The point of the eliptic, which makes the least angle with the horizon at rising, makes the greatest angle at setting; and, consequently, when the difference is least at the time of rising, it is greatest at the time of setting.

Principles and Practice.

104 Equation of time illustrated.

Problem XV. *To explain the equation of time by the globe.*

The difference between apparent time and mean or equal time, has been explained in Astronomy, from N° 50 to 60; and the method of computing the equation of time is also there described.

To explain the equation of time on the globe, make, with a black lead pencil, marks all round the equator and ecliptic, beginning with ♈, at equal distances from each other, suppose about 15°. Then, on turning the globe, it will be seen that all the marks on the first quadrant of the ecliptic, reckoning from ♈ to ♋, come to the brazen meridian sooner than the corresponding marks on the first quadrant of the equator. Now, as the former marks represent time as measured by the sun, or a dial, and the latter represent it as measured by an accurate clock, it will be evident, that through the first quarter the dial is faster than the clock.

Still turning the globe, it will be seen that the marks on the second quarter of the ecliptic, reckoning from ♋ to ♎, come to the meridian later than the corresponding marks of the equator; consequently in this quarter the sun or the dial is slower than the clock. By moving the globe round, and marking the approach of the dots in the third quadrant, it will be seen that, as in the first, the dial now precedes the clock, and in the fourth quadrant, that it is behind it, according to the explanation given in Astronomy.

Sect. III. *Of the Constructiou of Globes.*

105 General construction of globes.

The construction of globes is of considerable importance; as, in performing the problems in which they are employed, very much depends on the accuracy with which they have been constructed. We shall here, therefore, describe pretty minutely the methods in which the artists of Britain and France make their globes.

There are certain general circumstances which are attended to in the construction of every globe.

There is first provided a wooden axis, somewhat less than the intended diameter of the globe, and to the extremities of this axis, which is the basis of the whole succeeding structure, there are fixed two metallic wires, to serve as poles. Now, two hemispherical caps formed on a wooden mould or clock, are applied in the axis. These caps are composed of pasteboard, or folds of paper laid one over another on the mould, till they are of the thickness of a crown piece; and after the whole has stood to dry, and has become a solid body, an incision is made with a sharp knife along the middle, and the two caps are thus slipped off the mould. These caps are now to be applied on the poles of the axis, as they were before on those of the mould; and to fix them

(1) This problem may be performed without the globe, by the following method. Find the latitude of the place in a table, and subtract it from 90°; the remainder will be the complement of the latitude. Then, if the declination of the given star be of the same name with the co-latitude, and exceed it in quantity, it will never set. If it be of a contrary name, and exceed it, it will never rise.

Principles and Practice.

them firmly on the axis, the two edges are sewed together with packthread.

When the rudiments of the globe are thus laid, the artist proceeds to strengthen the work, and make the surface smooth and equal. For this purpose, the two poles are fixed in a metallic semicircle, of the proposed size; and a composition made of whitening, mixed with water and glue, heated, melted, and incorporated together, is daubed all over the paper surface. While the plaster is applied, the globe is turned round in the semicircle, the edge of which pares away all the matter that is superfluous and exceeds the proper dimensions, and spreads the rest over those parts that require it. After this operation the ball stands to dry, and when it is thoroughly dried, it is again put in the semicircle, and fresh plaster applied to it; and thus they continue to apply composition and dry the ball alternately, till the surface accurately touches the semicircle in every point, when it becomes perfectly firm, smooth, and equal.

When the ball of the globe is thus finished, the map, containing a delineation of the surface of the earth, is to be pasted on the globe. For this purpose, the map is engraved in several gores or gussets, so that when these are accurately joined together on the spherical surface, they may cover every part of the ball, without overlapping each other. The greatest nicety is required in forming these engraved gussets, as well in the accuracy of the engraving, as in the choice and shape of the paper employed. The method of describing the gores or gussets, usually employed by the British artists, is as follows.

1. From the given diameter of the globe there is found a right line AB (fig. 12.), equal to the circumference of a great circle corresponding to that diameter; and this line is divided into 12 equal parts.

2. Through the several points of division, 1, 2, 3, 4, &c. with a distance equal to ten of the divisions, arches are described crossing each other as in D and E; and these figures are pasted on the globe, so as when joined together to cover its whole surface.

3. Each part of the line AB is divided into 30 equal parts, so that the whole line, which may represent the equator, is divided into 360°.

4. From the points D and E, which represent the poles, with a distance $=23\frac{1}{2}°$, there are described arches *a b*, *a b*, (fig. 13.) which form twelfth parts of the polar circles.

5. In a similar manner about the same poles D and E, with a distance $=66\frac{1}{2}°$, reckoned from the equator, there are described other arches, *c d*, *c d*, which are the twelfth parts of the tropics.

6. In forming the celestial globe, through the point of the equator marked *e* (fig. 13.) representing the right ascension of a given star, and through the two poles D and E, there is drawn an arch of a circle; and if the complement of the declination from the pole D be taken in the compasses, and an arch be described, intersecting the former in the point *i*, this point *i* will be the place of the given star.

7. In this way all the stars of each constellation are laid down, and the circumscribing outline of the constellation is drawn as figured in the tables of Bayer, Flamstead, &c.

8. In the same manner are determined the declinations and right ascensions of every degree of the ecliptic, *d g*.

The above is the method described by Mr Chambers, of laying down or delineating the gores of a celestial globe. Those of the terrestrial globe are delineated in much the same manner, only that every place is laid down on the gores, according to its longitude and latitude, determined by the intersection of circles; and then the outline of the coasts, boundaries of countries, &c. are added, like the figures of the constellations above mentioned.

9. When the surface of the globe has been thus projected on a plane, the gussets are to be engraved on copper, to save the trouble of making a new projection for every globe.

10. In the mean time, a ball of paper, plaster, or the like, of the intended diameter of the globe, is prepared in the manner above described, and by means of a semicircle and style, great circles are drawn on its surface, so as to divide it into a number of equal parts, corresponding to the number of gussets; and subdividing each of these according to the other lines and divisions of the globe. When the ball is thus prepared, the gussets are to be accurately cut from the printed engraving, and pasted on the ball.

When the papers have been thus pasted on, and suffered to dry, nothing remains but to colour and illuminate the globe, and to cover it with a thin layer of the finest varnish, that it may the better resist dust and moisture. The ball of the globe is now finished, and is to be hung in a strong brazen meridian furnished with hour circles and a quadrant of altitude, and fitted into a strong wooden horizon.

The method employed by the French artists in projecting the gussets of globes, is thus described by M. La Lande.

"To form celestial and terrestrial globes, it is necessary to engrave gores, which are a sort of projection or developement of the globe. The length PC (fig. 14.) of the axis of the curve, is equal to a fourth part of the circumference of the intended globe; the intervals of the parallels on the axis PC are all equal; the radii of the circles K D I, which represent the parallels, are equal to the co-tangents of the latitude, and the arches of each, such as KI, are nearly equal to the number of degrees that correspond to the breadth of the gore (usually 30°), multiplied by the sine of the latitude; thus, there will be found no difficulty in tracing them; but the principal difficulty proceeds from the change which those parts of the gores undergo, when they are glued upon the globe; as, in order to adjust them to the space which they ought to occupy, it is necessary to make the paper less on the sides than in the middle, because the sides are too long.

"The method employed by artists for engraving these gores, is thus described by Bion (*Usages des Globes*, tom. iii.), and by Robert de Vaugondy in the seventh volume of the Encyclopedié, and this method is sufficient for practical purposes.

"Draw on the paper a line AC, equal to the chord of 15°, to make the half breadth of the gore; and a perpendicular PC, equal to three times the chord of 30°, to make the half length: for these papers, the dimensions of which will be equal to the chords, become equal to the arcs themselves when they are pasted on the globe. Divide the height CP into nine parts, if the parallels are to be drawn in every 10°; divide also the quadrant BE into nine equal parts; through each division

Principles and Practice.

vision point of the quadrant, as G, and through the corresponding point D of the right line CP, draw the perpendiculars HGF and DF, the meeting of which in F gives one of the points of the curve BFP, which will terminate the circumference of the gore. When a sufficient number of points are thus found, trace the outline PIB with a curved rule. By this construction are given the gore breadths, which are on the globe, in the ratio of the cosines of the latitudes, supposing those breadths taken perpendicular to CD, which is not very exact; but it is impossible to prescribe a rigid operation sufficient to make a plane which shall cover a curved surface, and that on a right line AB shall make lines PA, PC, PD, equal to each other, as they ought to be on the globe. To describe the circle KDI, which is at the distance of 30° from the equator, there must be taken above O, a point that shall be distant from D the value of the tangent of 60°, which may be taken either from tables, or may be measured on a circle equal to the circumference of the globe that is to be drawn; this point will serve as a centre for the parallel DI, which ought to pass through the point D; for it is supposed equal to that of a cone circumscribing the globe, and which would touch it at the point D.

"The meridians are traced to every 10°, by dividing each parallel, as KI, into three equal parts at the points L and M, and drawing from the pole P, through all these points of division, curves which represent the intermediate meridians lying between PA and PB, such as BR and ST (fig. 15.).

"The ecliptic AQ (fig. 15.) is traced by means of the known declination, from different points of the equator, as found in the tables; for 10° it is equal to 3° 58′; for 20°=7° 50′=BQ 20; for 30°=11° 29′, &c."

In general, it is observed that the paper on which maps are printed, such as that called in France *colombier*, contracts itself $\frac{1}{72}$, or a line in six inches, upon an average, when it is dried after printing; hence it is necessary to prevent this inconvenience in engraving the gores: if, however, notwithstanding this, the gores are still found too short, it must be remedied by taking from the surface of the ball a little of the white with which it is covered; thus making the dimensions of the ball correspond to those of the gores as they are printed. But, what is singular, in drawing the gore, moistened with the paste to apply it on the globe, the axis GH lengthens, and the side AN shortens in such a manner that neither the length of the side ACK, nor that of the axis GEH of the gore are exactly equal to the quarter of the circumference of the quarter of the globe, when compared to the figure on the copper, or to the numbers shewn on the side of fig. 15.

"Mr Bonne having made several experiments on the dimensions which the gores take after being covered with paste in order to apply them to the globe, especially of the paper called *jesus*, which had been employed in covering globes of a foot in diameter; found that it was necessary to give to the gore engraved on copper the dimensions laid down in fig. 15. Supposing that the radius of the globe contains 720 parts, the half of the breadth of the gore AG=188.5; the distance AC for the parallel of 10° taken on the straight line LM is =128.1, the small deviation from the parallel of 10° in the middle of the gore ED is 4, the line ABN is a straight line, the radius of the parallel of 10° or of the circle CET, is 4083, &c. The small circular cap which is placed under H, has its radius 253, instead of 247, which it would have if the sine of 20° had been the radius of it *."

* *La Lande Astronomie*, tom. iii. p. 616. 3d ed.

Globes are made of various sizes, from a diameter of three inches, to that of as many feet; but their most usual diameter is that of 18 inches, which are sufficiently large for most of the purposes for which globes are employed. Some large globes were made about 100 years ago, in France, by P. Coronelli, a Franciscan monk, which were in considerable reputation. They were engraved, and the plates are still to be seen at Paris, at the house of M. Desnos, in the Rue St Jacques. There are some large globes at Cambridge, which were drawn by the hand; but the largest globes of which we have any account, are those which were made for the late unfortunate Louis XVI. and were kept in the palace of Marly. They were 12 feet in diameter, and we believe, are still existing at Paris, where they occupy four entire rooms, each of them being partly in an upper room, and partly in that below it, the floor of the upper room forming the horizon.

The account which we have given of the method of constructing globes, will be useful to those who purchase these instruments; but to assist them still further, we shall subjoin the following practical rules for the choice of globes.

107 Rules for choosing globes.

1. The papers should be well and neatly pasted on the globes, which may be known by the lines and circles meeting exactly, and continuing all the way even and whole; the circles not breaking into several arches, nor the papers either coming short, or lapping over one another.

2. The colours should be transparent, and not laid too thick upon the globe, to hide the names of the places.

3. The globe should hang evenly between the brazen meridian and the wooden horizon, not inclining either to the one side or the other.

4. The globe should move as close to the horizon and the meridian as it conveniently may, otherwise there will be too much trouble to find against what part of the globe any degree of the meridian or horizon is.

5. The equinoctial line should be even with the horizon all round, when the north or south pole is elevated 90° above the horizon.

6. The equinoctial line should cut the horizon in the east and west points, in all the elevations of the pole from 0 to 90°.

7. The degree of the brazen meridian marked 0, should be exactly over the equinoctial line of the globe.

8. Exactly half of the brazen meridian should be above the horizon, which may be known by bringing any of the decimal divisions on the meridian to the north point of the horizon, and finding their complement to 90° on the south point.

9. When the quadrant of altitude is placed as far from the equator, or the brazen meridian, as the pole is elevated above the horizon, the beginning of the degrees of the quadrant should reach just to the plane surface of the horizon.

10. When the index of the hour circle passes from one

Principles and Practice.

one hour to another, 15 degrees of the equator must pass under the graduated edge of the brazen meridian.

11. The wooden horizon should be made substantial and strong; it being generally observed, that, in most globes, the horizon is the first part that fails, on account of its having been made too slight.

108 In using a globe, the eastern side of the horizon should be kept towards the observer, (unless in particular problems which require a different position); and that side may be known by the word *east* on the horizon. In this position the observer will have the graduated side of the meridian towards him, and the quadrant of altitude directly before him; and the globe will be exactly divided into two equal parts by the graduated side of the meridian.

In performing some problems, it will be necessary to turn about the whole globe and horizon, in order to look at the west side; but this turning will be apt to disturb the ball, so as to shift away that degree of the globe which was before set to the horizon or meridian. This inconvenience may be avoided by thrusting the feather end of a quill between the ball of the globe and the brazen meridian, and thus, without injuring the surface of the globe, it will be kept from turning in the meridian, while the whole is moved round, so as to examine the western side.

We have already mentioned some improvements which have been made on the globes, for the purpose of remedying the defect in the old construction, of placing the hour circles on the outside of the brazen meridian. Some other improvements and modifications have been contrived by various artists; but of these we shall only mention those of Mr Senex, Mr B. Martin, Mr Smeaton, and Mr Adams.

109 Mr Senex's improvement in the globes.

Mr John Senex, F. R. S. invented a contrivance for remedying these defects, by fixing the poles of the diurnal motion to two shoulders or arms of brass, at the distance of $23\frac{1}{2}^{o}$ from the poles of the ecliptic. These shoulders are strongly fastened at the other end to an iron axis, which passes through the poles of the ecliptic, and is made to move round with a very stiff motion; so that when it is adjusted to any point of the ecliptic which the equator is made to intersect, the diurnal motion of the globe on its axis will not disturb it. When it is to be adjusted for any particular time, either past or future, one of the brazen shoulders is brought under the meridian, and held fast to it with one hand, while the globe is turned about with the other; so that the point of the ecliptic which the equator is to intersect may pass under the o degree of the brazen meridian; then holding a pencil to that point, and turning the globe about, it will describe the equator according to its position at the time required; and transferring the pencil to $23\frac{1}{2}$ and $66\frac{1}{2}$ degrees on the brazen meridian, the tropics and polar circles will be so described for the same time. By this contrivance, the celestial globe may be so adjusted, as to exhibit not only the rising and setting of the stars in all ages and in all latitudes, but likewise the other phenomena that depend upon the motion of the diurnal round the annual axis. Senex's celestial globes, especially the two greatest, of 27 and 28 inches in diameter, have been constructed upon this principle; so that by means of a nut and screw, the pole of the equator is made to revolve about the pole of the ecliptic.

To represent the above appearances in the most natural and easy manner, Mr B. Martin applied to the contrivance of Mr Senex a moveable equinoctial and solstitial colure, a moveable equinoctial circle, and a moveable ecliptic; all so connected together as to represent those imaginary circles in the heavens for any age of the world.

Improvements by Mr Smeaton.

In order to the performance of the problems which relate to the altitudes and azimuths of celestial objects, Mr Smeaton, F. R. S. has made some improvements applicable to the celestial globe; and to give some idea of the construction, they may be described as follows: Instead of a thin flexible slip of brass, which generally accompanies the quadrant of altitude, Mr Smeaton substitutes an arch or a circle of the same radius, breadth, and substance, as the brass meridian, divided into degrees, &c. similar to the divisions of that circle, and which, on account of its strength, is not liable to be bent out of the plane of a vertical circle, as is usual with the common quadrant put to globes. That end of this circular arch at which the division begins, rests on the horizon, being filed off square to fit and rest steadily on it throughout its whole breadth; and the upper end of the arch is firmly attached, by means of an arm, to a vertical socket, in such a manner that when the lower end of the arch rests on the horizon, the lower end of this socket shall rest on the upper end of the brass meridian, directly over the zenith of the globe. This socket is fitted to and ground with a steel spindle of the length, so that it will turn freely on it without shaking; and the steel spindle has an apparatus attached to its lower end, by which it can be fastened in a vertical position to the brass meridian, with its centre directly over the zenith point of the globe. The spindle being fixed firmly in this position, and the socket which is attached to the circular arch put on it, and so adjusted that the lower end of the arch just rests on and fits close to the horizon; it is evident that the altitude of any object above the horizon will be shewn by the degree which it intersects on this arch, and its azimuth by that end of the arch which rests on the horizon.

Besides this improvement, Mr Smeaton proposes that, instead of fixing the hour index, as is usually done, on one end of the axis, it be placed in such a manner that its upper surface may move in the plane of the hour circle rather than above it. To effect this, he directs the extremity of the index to be filed off so as to form a circular arc, of the same radius with the inner edge of the hour circle, to which it is made to fit exactly, and a fine line is drawn in the middle of its upper surface, to point out the hour, instead of the tapering point usually employed. By this contrivance, if the hour circle be made four inches in diameter, the time may be shewn to half a minute. For a more particular account of Mr Smeaton's improvements, we refer the reader to the 79th volume of the Philosophical Transactions.

Another improvement of the celestial globe, by which it is better adapted to astronomical purposes, is described in the article ASTRONOMY, Vol. III. p. 178.

Besides the modifications in the construction of globes, introduced by Mr Adams, and which have been already

Principles and Practice.

ready described, there are some others which we must briefly mention, respecting principally the placing the globe in an inclined position, and fitting it with a moveable or floating meridian and horizon.

The globes constructed after this manner do not hang in a frame like the ordinary globes, but are fixed on a pedestal, and supported by an axis which is inclined $66\frac{1}{2}°$ to the ecliptic, and is of course always parallel to the axis of the earth, supposing the orbit of this planet to be parallel to the ecliptic. On the pedestal below the globe is a graduated circle, marked with the signs and degrees of the ecliptic; and adjoining to this is a circle of months and days, answering to every degree of the ecliptic; and within this is a third circle shewing the sun's declination for every day of the month. There is a moveable arm on the pedestal, which being set to the day of the month, immediately points out the sun's place and declination.

Round the globe there is a circle representing the horizon of any place, and at right angles to this is fixed a semicircle, serving for a general meridian. The middle point of this semicircle serves to represent the situation of any inhabitant on the earth; for this purpose there is fixed a steel pin over the middle point of this semicircle.

Mr Adams alleges that only one supposition is necessary for performing every problem with this globe, namely, that a spherical luminous body will enlighten one half of a spherical opaque body, and consequently that a circle at right angles with the central solar ray, and dividing the globe in half, will be a terminator shewing the boundary of light and darkness for any given day. For this purpose, at the end of the moveable arm, opposite to the sun, there is a pillar, from the top of which projects a piece carrying a circle that surrounds the globe, dividing it into equal portions, and separating the illuminated from the dark parts; and 18° behind this there is another circle parallel to it, representing the limit of twilight.

There are two plates below the globe, which are turned by the diurnal revolution of the globe, each of them being divided into twice 12 hours, and on the outside being marked with the degrees of longitude corresponding to every hour; so that these circles give at sight the hour of the day at any two places on the globe, and the corresponding difference of longitude.

The celestial globe is mounted in a similar manner, except that it is fixed on the axis, and the ecliptic exactly coincides with the sun's apparent path from the earth *.

* Adams Lectures, vol. iv. p. 199.

Sect. IV. *Of the Armillary Sphere.*

112 Armillary Sphere.

If a machine be constructed that is composed only of the circles of the sphere, and made so as to revolve like a globe, a great many of the most useful problems relating to the heavenly bodies may be solved by it. An instrument of this kind is called an *armillary sphere*, and of these there are various forms. One of the most convenient is that contrived by the late Mr James Ferguson, and is thus described in his Lectures. It is represented at fig. 16.

The exterior parts of this machine are a compages of brass rings, which represent the principal circles of the heaven, viz. 1. The equinoctial AA, which is divided into 360 degrees, (beginning at its intersection with the ecliptic in Aries) for shewing the sun's right ascension in degrees; and also into 24 hours, for shewing his right ascension in time. 2. The ecliptic BB, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year, in such a manner, that the degrees or points of the ecliptic in which the sun is on any given day, stands over that day in the circle of months. 3. The tropic of *Cancer*, CC, touching the ecliptic at the beginning of Cancer in *e*; and the tropic of *Capricorn* DD, touching the ecliptic at the beginning of Capricorn in *f*; each $23\frac{1}{2}$ degrees from the equinoctial circle. 4. The Arctic circle E, and the Antarctic circle F, each $23\frac{1}{2}$ degrees from its respective pole at N and S. 5. The equinoctial colure GG, passing through the south and north poles of the heaven at N and S, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial colure HH, passing through the poles of the heaven, and through the solstitial points Cancer and Capricorn, in the ecliptic. Each quarter of the former of these colures is divided into 90 degrees, from the equinoctial to the poles of the world, for shewing the declination of the sun, moon, and stars; and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for shewing the latitude of the stars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a small sun Y, which is carried round the ecliptic BB, by turning the nut: and in the south pole of the ecliptic is a pin at *d*, on which is another quadrantal wire, with a small moon Z upon it, which may be moved round by hand; but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of $5\frac{1}{3}$ degrees, in two opposite points called the moon's nodes; and also for shifting these points backward in the ecliptic, as the moon's nodes shift in the heaven.

Within these circular rings is a small terrestrial globe I, fixed on the axis KK, which extends from the north and south poles of the globe at *n* and *s*, to those of the celestial sphere at N and S. On this axis is fixed the flat celestial meridian LL, which may be set directly over the meridian of any place on the globe, and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of a common globe, and its use is much the same. To this globe is fitted the moveable horizon MM, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at opposite points of its equator, which is a moveable brass ring let into the globe in a groove all around its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian LL. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass, for shewing the amplitude of the sun and moon, both in degrees and points. The celestial meridian LL, passes through two notches in the north and south points of the horizon, as in a common globe; but here, if the globe be turned round, the horizon and the meridian turn with it. At the south pole of

Principles and Practice.

of the sphere is a circle of 24 hours, fixed to the rings, and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal N, and may be elevated or depressed upon the joint O, to any number of degrees from 0 to 90, by means of the arc P, which is fixed into the strong brass arm Q, and slides in the upright piece R, in which is a screw at *r*, to fix it at any proper elevation.

In the box T are two wheels and two pinions, whose axes come out at V and U; either of which may be turned by the small winch W. When the winch is put upon the axis V, and turned backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun Y, and moon Z, round the same way, causing them to rise above and set below the horizon. But when the winch is put upon the axis U, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by south, to east; and bring the same points of the horizon to the sun and moon, to which these bodies come when the earth kept at rest, and they were carried round it; shewing that they rise and set in the same points of the horizon, and at the same times in the hour circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour index goes round its hour circle; but if the sphere be turned, the hour circle goes round below the index.

And so, by this construction, the machine is equally fitted to shew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw *r* in the upright stem R, and taking hold of the arm Q, move it up or down until the given degree of latitude for any place be at the side of the stem R; and then the axis of the sphere will be properly elevated, so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass; this done, count the latitude from the north pole upon the celestial meridian LL, down towards the north notch of the horizon, and set the horizon to that latitude; then turn the nut *b* until the sun Y comes to the given day of the year in the ecliptic, and the sun will be at its proper place for that day; find the place of the moon's ascending node, and also the place of the moon, by an Ephemeris, and set them right accordingly; lastly, turn the winch W, until either the sun comes to the meridian LL, or until the meridian comes to the sun (according as you want the sphere or the earth to move), and set the hour index to the XII. marked noon, and the whole machine will be rectified. Then turn the winch, and observe when the sun or moon rise and set in the horizon, and the hour index will shew the times thereof for the given day.

Those who have made themselves acquainted with the use of the globes, as described in the first and second sections of this chapter, will be at no loss to perform many problems respecting the motions of the heavenly bodies by means of this sphere.

113
Dr Long's sphere.

Dr Long, some years ago, constructed an armillary sphere of glass, in Pembroke hall at Cambridge. It was 18 feet in diameter, and could contain below it more than 30 persons, sitting in such a manner within the sphere, as to view from its centre the representation of the heavens drawn in its concavity. The lower part of the sphere, or that part which is not visible in the latitude of Britain, is wanting; and the whole apparatus is so contrived, that it may be turned round with as little exertion as is requisite to wind up a common jack. Dr Long has given a description of this sphere, accompanied with a figure, in his Astronomy.

The invention of the armillary sphere is thought by La Lande to be as ancient as that of astronomy itself. It has been attributed to Atlas, to Hercules, to Anaximander, and Musæus; while others have supposed that it originated in Egypt. The sphere of Archimedes, which became so celebrated, appears to have been something like that of Dr Long, as it was certainly composed of a globe of glass, which, besides containing the circles of the sphere, served as a planetarium, and represented the motions of the planets. Claudian has celebrated it in some beautiful lines. See Archimedes.

A combination of the armillary sphere with a planetarium was constructed by the late Mr George Adams, and is figured in Plate XIII. fig. 1. of his Astronomical and Geographical Essays.

Chap. III. *Of the Construction and Use of Maps and Charts.*

Sect. I. *Description of Maps and Charts.*

114
Distinction of maps and charts.

It has been seen, that the surface of the earth may be delineated, in the most accurate manner, on the surface of a globe or sphere. This mode of delineation, however, can be employed only for the purpose of representing the general form and relative proportions of countries on a very confined scale; and is, besides, from its bulk and figure, not well suited to many of the purposes of the geographer. To obviate these inconveniences, recourse has been had to maps and charts, or delineations of the earth's surface on a plane; where the form and boundaries of the several countries, and the objects most remarkable in each, whether by sea or land, are represented according to the rules of perspective, so as to preserve the remembrance that they are parts of a spherical surface. In this way, the several countries or districts of the earth may be represented on a larger scale, and delineations of this kind admit of more easy reference.

115
Description of a map.

In maps, the circles of the sphere, and the boundaries of the countries within them, are drawn as they would appear to an eye situated in some point of the sphere, or at a considerable distance above it. In maps of any considerable extent of country, the meridians and parallels of latitude are circular lines, but, if the map represents only a small district, as a province or county, those circles become so large, that they may, without any considerable error, be represented by straight lines. In charts, which are also called *hydrographical maps*, as they are representations rather of the water than land, the meridians and parallels are usually represented by straight lines, crossing each other at right angles, as in the smaller maps; and, in particular parts, there are drawn lines diverging from several points, in the direction of the points of the compass, in order to mark the

the bearings of particular places. In maps, the inland face of the country is chiefly regarded in the delineation; but in charts, which are designed for the purposes of navigation, the internal face of the land is left nearly blank, and only the sea coast, with the principal objects on it, such as churches, light-houses, beacons, &c. are accurately delineated; while particular care is taken to mark the rocks, shoals, and quicksands in the sea, that may endanger the safety of vessels; the depths or soundings of the principal bays and harbours, and the direction of the winds, where these are stationary or peculiarly prevalent. Another distinction of maps and charts is, that in the former, the sea-coast is shaded on the side next the land, while, in the latter, it is shaded towards the sea.

In maps the upper side represents the north, the lower side the south; that on the right hand the east, and that on the left hand the west. All the margins of the map are graduated; the upper and lower showing the degrees of longitude, and the right and left margins the degrees of latitude. (See fig. 1. to which the reader must refer in going over the following description). If the map is on a small scale, only every ten degrees of longitude or latitude are marked on the margin; but, if the map is drawn on a large scale, every degree is numbered, and sometimes every half degree is marked with the number 30 in smaller figures. The space included between every two degrees in small maps, or between every two degrees in those on a larger scale, is usually divided into ten spaces, which are alternately left blank, and marked with parallel lines, to denote the subdivisions of single degrees or minutes. Through every ten degrees of latitude a line is drawn, representing a parallel of latitude; and through every ten degrees of longitude, or at smaller intervals in each, where the size of the map will admit of it, there are drawn lines representing meridians. In some maps these lines are continued from side to side, or from top to bottom, across both sea and land; but in other maps, they are sometimes only drawn across the sea. The first meridian, however, and the principal circles of the sphere, as the equator, tropics, &c. should always be drawn directly across the map. In most maps, it is marked on the margins whether the longitude is east or west, and the latitude north or south; but, if this is not marked, it may easily be known, by observing towards what part of the map the degrees increase. If the degrees of latitude increase from the lower to the upper part of the map, the country delineated lies in north latitude; but if they increase from above downwards, it lies in south latitude. Again, if the degrees of longitude increase towards the right, the countries are in east longitude; but if towards the left, they are in west longitude.

The principal objects that diversify the face of the country delineated in the map, such as rivers, mountains, forests, lakes, roads, cities, towns, forts, &c. are marked in such a manner as that they may be most easily distinguished. A river is denoted by a black crooked line, drawn very fine towards the source or head of the river, and gradually becoming broader as it approaches towards the mouth; and the lesser rivers or rivulets, which unite their waters with those of their principal stream, are denoted by similar lines appearing to branch off from the first.

Mountains are represented by the figures of little hills; and if these figures are placed in a row, they denote a ridge of mountains running across the land. If a mountain is a volcano, it is denoted in the map by the appearance of smoke issuing from its summit. Woods or forests are represented by a number of little trees or shrubs, placed in a group. Lakes are denoted by a circumscribed spot shaded with dark lines, and bogs or fens by a more regular spot of the same kind, more lightly shaded, or, where the map is coloured, painted of a light green. Roads are represented in a map by two straight lines drawn parallel to each other, for the principal roads, or by a single straight line for the lesser or cross roads. Cities are denoted by a large house, or the figure of a church with the steeple in the middle; and if the city is the metropolis of the country, this is denoted by a white circular space in the middle of the house or church. Small towns are usually represented by circles; and where a small church with the steeple at one end occurs, it denotes a parish. Where the map is on a large scale, or represents only a small district, the towns are denoted by a group of small houses, or more commonly by a number of small shaded spots on each side of the road. A fort, castle, or fortified town, is denoted by a semicircular space surrounded by an angular edge representing bastions. The shoals upon the coast are represented by small dots; the depth of water in bays and harbours by figures, denoting the number of fathoms, among which is sometimes drawn the figure of an anchor, to shew that in that place there is good anchorage for ships.

The boundaries or limits that divide countries from each other are distinguished in maps by dotted lines drawn round each country or district, in such a direction as to shew its proper form. Where the map is coloured, the countries or districts are distingnished from each other by the side of the boundary next each being shaded by a different colour from that of the adjoining. Thus, in a map of Europe the boundary of France may be shaded green, that of Spain red, that of Italy yellow, that of Germany blue, &c. In one corner of the map there is usually drawn a scale divided into a number of equal parts, by which the number of miles or leagues, from one part of the map to another may be measured. Sometimes the parts into which the scale is divided are used to denote geographical miles, of 60 to a degree; but more commonly they correspond to the miles in use in the country where the map is made, as in Britain, to British statute miles of $69\frac{1}{4}$ to a degree.

To mark more distinctly the bearings of different parts of the map, there is usually added in some blank space a circle with four radii, marking the four cardinal points of the compass; the north point being distinguished by the figure of a *fleur de lis*, and the east point by a cross.

Till of late, the only distinction between the land and water in maps and charts, was afforded by the shading of the sea-coasts, as mentioned above. In this way, however, the eye cannot easily and expeditiously distinguish the form and extent of the land; and, where the shading is carried much beyond the boundary of the coast, as is often done, especially in engraving small islands, the land is made to appear much larger than it really is.

The ingenious Mr Wilson Lowry having lately contrived an instrument for engraving parallel straight lines, in a much more clear and commodious way than

Principles and Practice.

than could be done by the common graver, it occurred to Mr Pinkerton, while preparing his Modern Geography, that this invention might be applied with advantage to the improvement of maps. A set of maps was accordingly engraved by Mr Lowry for Pinkerton's Geography, in which the water was marked by dark parallel lines to discriminate it from the land. These lines are drawn horizontally; and Mr Pinkerton proposed that, in engraving charts, the land should be marked with similar lines drawn in a perpendicular direction, while the water should be left blank. This improvement has since been adopted by other constructors of maps and charts, and bids fair to be generally used. The effect is pleasing; and the progress of instruction will be greatly facilitated by the new method, as the extent and bearings of the several countries are seen, as it were, with a glance of the eye. In many of these maps which we have seen, however, the lines are drawn too strongly, which renders the sea so dark, that the names of islands and places on the sea coast can with difficulty be perused. As the line of coast in these maps is strongly marked, the parallel lines denoting the sea should be engraved in a light and soft style; and in this way Mr Lowry's first specimens are executed.

Sect. II. *Of the Construction of Maps and Charts.*

116 Construction of maps.

The construction of maps consists in making a projection of the surface of the globe on the plane of some one of its circles, supposing the eye to be placed in some particular point. The describing of these projections depends on the principles of perspective, and the projection of the sphere. The general principles will be explained under those articles, but the particular mode of drawing maps properly forms a part of the present treatise.

The methods of constructing maps vary according to the size or scale of the map, and to the projection employed in constructing it.

117 Orthographic projections.

There are three projections employed in constructing maps, the *orthographic*, the *stereographic*, and the *globular*. In the orthographic projection the eye is supposed to view the part of the globe to be projected, from an infinite distance. In this projection the parts about the middle of the map are very well represented, but those towards the margin are too much contracted.

118 Stereographic projections.

In the stereographic projection, the eye is supposed to be situated in the surface of the globe to be represented, and looking towards the opposite surface. This is the method usually employed in constructing most maps, especially maps of the world, or planispheres.

In constructing a map of the world, as well as most partial maps, the part of the sphere to be represented is supposed to be in the position of a right sphere (see N° 90.). In this mode of projection, the hemisphere to be represented is supposed to be delineated on the plane of that meridian by which it is bounded, in the same manner as its concave surface, conceiving the sphere to be transparent, would appear to an eye placed in the opposite hemisphere, where the equator crosses a meridian; that is 90° distant from that which forms the plane of the projection. In a delineation of this kind, the meridians and parallels of latitude are represented by arches of circles, except the equator and the central meridian, which are straight lines; and each parallel or meridian forms an arc of a greater circle, in proportion as it approaches nearer to the centre of the map.

By either of these projections only half the globe can be represented in one projection; but in the map of the world, the two hemispheres are usually drawn on the plane of the same circle, adjacent to each other. By Mercator's projection, usually employed for charts, and to be described presently, the whole globe may be represented in one projection, but much distorted.

If the projection of a map of the world be formed on the plane of a meridian, the two projections will represent the eastern and western hemispheres of the globe.

When the projection is made on the plane of the equator, in the situation of a parallel sphere, the projections represent the northern and southern hemispheres, which appear as their concave surface would be seen by an eye placed at the opposite pole. In this way the meridians become straight lines diverging from the same centre, and the parallels are circles having the same common centre.

The following is the method of constructing a map of the world, on the plane of a meridian, according to the globular projection. (See fig. 17.).

11[9] Globular projection of a map of the world.

About the centre C, with any radius as CB, describe a circle, representing the meridian that is to form the plane of the hemisphere. Draw the diameters NS, and AB, crossing each other at right angles, and the former of these will be the central meridian, and the latter the equator. Divide each semidiameter into nine equal parts, and divide each quadrant of the circle also into nine equal parts, each of which will be equal to 11°. If the scale of the map be sufficiently large, each of these may again be divided into ten equal parts or degrees. The next object is to describe the meridians passing through every 10° of the equator. Suppose we are to draw the meridian of 80° west of Greenwich. We have here three points given, the two poles and the point 80° on the equator, and it is easy to describe a circle that shall pass through these three points. This arch will be the meridian. The method of drawing a circle through any three points is, in this case as follows: About the centre S, with the radius SC, describe a circular arch, as XX; and about the centre N, with the same radius, describe the arch ZZ; then about the centre 80° with the same distance, describe arches 1, 1, 2, 2, crossing the former, and draw lines from 2 to 1 on each side of AB, crossing each other, and AB produced, in D. D is the centre of the circular arc, representing the meridian of 80° west from Greenwich; and with the same radius the meridian of 130° west longitude may be drawn. All the other meridians are to be drawn in a similar manner by describing a circular arch through three points N, S, and the required degree. (See Geometry).

For describing the parallels, suppose that of 60° N. Lat.; about the centre O, with any radius, describe the circle FGH, and about the points 60°, 60°, in the primitive circle, with the same distance, describe the arcs *cc*, *dd*, cutting the circle FGH: through the points of intersection draw straight lines, and the point where these lines meet in NS produced, as in I, is the centre of the arch that will represent the parallel of 60°. The other parallels are drawn in a similar manner, observing that the first circle, such as FGH, must have for its centre that point in the central meridian through which the parallel is to be drawn. Fig. 18. represents this projection

projection with all the meridians and parallels completed.

If the map is very large, and the paper on which it is to be drawn does not admit of so many circles, the centres of the meridians and parallels are more easily found in the following manner. Having divided the semi-diameters and quadrants, each into 9 equal parts, find, from a scale of equal parts, the length of the half chord of each arc, and the versed sine of half the same arc; then add together the square of the half chord, and the square of the versed sine, and divide the sum by the versed sine; the quotient is equal to the diameter, and $\frac{1}{2}$ of this to the radius of the circle required. In this manner the radii of all the meridians and parallels may be found.

As, in drawing maps on a large scale, compasses of an ordinary size will not answer for describing the circular arcs, it is convenient to have some other mechanical contrivance for this purpose; and it is found that a thin flexible ruler of tough wood, called a *bow*, may be so bended as to form a curve, very nearly circular, that will pass through the three points that are to determine the meridian or parallel. In this way the circles on maps on a large scale are usually drawn by engravers and students of geography, and where the circle is of very large radius, the method is sufficiently accurate; but it ought by no means to be employed where compasses of a proper size can be procured, or conveniently used.

The following is the method given by Dr Hutton, for describing a globular projection of the earth on the plane of the equator. For the north or south hemispheres draw AQBE, for the equinoctial (fig. 19.), dividing it into the four quadrants EA, AQ, QB, and BE; and each quadrant into 9 equal parts, representing each 10° of longitude; and then from the points of division, draw lines to the centre C, for the circles of longitude. Divide any circle of longitude, as the first meridian EC, into 9 equal parts, and through these points describe circles from the centre C, for the parallels of latitude, numbering them as in the figure. In this method equal spaces on the earth are represented by equal spaces on the map, as nearly as any projection will bear; for a spherical surface can in no way be represented exactly upon a plane. Then the several countries of the world, seas, islands, sea-coasts, towns, &c. are to be entered in the map, according to their latitudes and longitudes.

To draw a Map of any particular Country.

124 Construction of particular maps.

There are three methods of doing this.

1st, For this purpose its extent must be known as to latitude and longitude; as suppose Spain, lying between the north latitudes 36° and 44°, and extending from 10° to 23° of longitude, so that its extent from north to south is 8°, and from east to west 13°.

Draw the line AB for a meridian passing through the middle of the country (fig. 20.), on which set off 8° from B to A, taken from any convenient scale; A being the north and B the south point. Through A and B draw the perpendiculars CD, EF, for the extreme parallels of latitude. Divide AB into eight parts, or degrees, through which draw the other parallels of latitude parallel to the former.

For the meridians, divide any degree in AB into 60 equal parts, or geographical miles. Then, because the length in each parallel decreases towards the pole, from the table shewing this decrease given in p. 514. take the number of miles answering to the latitude of B, which is $48\frac{1}{2}$ nearly, and set it from B, seven times to E, and six times to F; so is FF divided into degrees. Again, from the same table take the number of miles of a degree in the latitude A, viz. $43\frac{1}{6}$ nearly; which set off from A, seven times to C, and six times to D. Then from the points of division in the line CD, to the corresponding points in the line EF, draw so many right lines for the meridians. Number the degrees of latitude up both sides of the map, and the degrees of longitude on the top and bottom. Also in some vacant place make a scale of miles, or of degrees, if the map represent a large part of the earth; to serve for finding the distances of places upon the map.

Then make the proper divisions and subdivisions of the country; and having the latitudes and longitudes of the principal places, it will be easy to set them down in the map; for any town, &c. must be placed where the circles of its latitude and longitude intersect. For instance, Gibraltar, whose latitude is 36° 11′, and longitude 12° 27′, will be at G; and Madrid, whose latitude is 40° 10′, and longitude 14° 44′, will be at M. In the same manner the mouth of a river may be set down; but to describe the whole course of the river, the latitude and longitude of every turning, and of the towns and bridges by which it passes, must also be marked down. The same is necessary for woods, forests, mountains, lakes, castles, &c. The boundaries are described by setting down the remarkable places on the sea coast, and drawing a continued line through them all. This method is very proper for small countries.

2d *Method.* Maps of particular places are but portions of the globe, and may therefore be drawn in the same manner as the whole globe, either by the orthographic or stereographic projection of the sphere. But in partial maps a more easy method is as follows. Having drawn the meridian AB in the last figure, and divided it into equal parts as before, draw lines through all the points of division; put them together to AB, to represent the parallels of latitude. Then to divide these, set off the degrees in each parallel; diminish after the manner directed for the two extreme parallels CD and EF, and through all the corresponding points draw the meridians, which will be curved lines; these were right lines in the last method, because only the extreme parallels were divided according to the table. This method is proper for a large tract, as Europe, &c. in which case the parallels and meridians need be drawn only through every 5° or 10°. This method is much used in drawing maps, as all the parts are nearly of their due magnitude, except being a little distorted towards the outside, from the oblique intersection of the meridians and parallels.

3d *Method.* Draw PB of a convenient length, for a meridian; divide it into nine equal parts, and through the points of division, describe as many circles for the parallels of latitude, from the centre P, which represents the pole. Suppose AB (fig. 21.) the height of the map; then CD will be the parallel passing through the greatest latitude, and EF will represent the equator. Divide the equator EF into 9 equal parts of the same size as those in AB, both ways beginning AB; divide

Principles and Practice.

divide also all the parallels into the same number of equal parts, but lesser, in proportion to the numbers for the several latitudes, as directed in the last method for the rectilineal parallels. Then through all the corresponding divisions draw curved lines which will represent the meridians, the extreme meridians being EC and FD. Lastly, number the degrees of latitude and longitude, and place a scale of equal parts, either in miles or degrees, for measuring distances.

When the place of which a map is to be made is but small, as when a county is to be delineated, the meridians will be so nearly parallel to one another, and the whole will differ so little from a plane, that the map may be laid down in a much more easy manner than what is given above. It will be here sufficient to measure the distances of places in miles, and note them down in a plane rectangular manner. The method of delineating such partial maps is the province of the surveyor. See SURVEYING.

121 Mercator's projection.

Mercator's projection is chiefly confined to charts for the purposes of navigation. In this projection the meridians, parallels, and rhumbs, are all straight lines; but instead of the degrees of longitude being everywhere equal to those of latitude, as is the case in plain charts, the degrees of latitude are increased as we approach towards either pole, being made to those of longitude in the proportion of radius to the sine of the distance from the pole, or cosine of the latitude, or, what is the same thing, in the ratio of the secant of the latitude to radius. Hence all the parallel circles are represented by equal and parallel straight lines, and all the meridians are parallel lines also; but these increase indefinitely towards the poles.

From this proportional increase of the degrees of the meridian, it is evident that the length of an arc of the meridian beginning at the equator is proportional to the sum of all the secants of the latitude; or that the increased meridian bears the same proportion to its true arc as the sum of all the secants of the latitude to as many times the radius. The increased meridian is also analogous to a scale of the logarithmic tangents, though this is not at first very evident. It is not certain by whom this analogy was first discovered, but the discovery appears to have been made by accident. It was first published and introduced into the practice of navigation by Mr Henry Bond, by whom this property is mentioned in an edition of Norwood's Epitome of Navigation, printed about 1645. This analogy, though it had been found true by actual measurement, was not accurately demonstrated. Nicholas Mercator offered to disclose, for a sum of money, a method which he had discovered for demonstrating it; but this was not accepted, and the demonstration was, we believe, never disclosed. See *Nicholas* MERCATOR. About two years after, however, the demonstration was again discovered, and published by James Gregory.

The meridian line in Mercator's scale is a scale of logarithmic tangents of the half colatitudes. The differences of longitude on any rhumb, are the logarithms of the same tangents, but of a different species; those species being to each other as the tangents of the angles made with the meridian. Hence any scale of logarithmic tangents is a table of the differences of longitude, to several latitudes, upon some one determinate rhumb; and therefore as the tangent of the angle of such a rhumb is to the tangent of any other rhumb, so is the difference of the logarithms of any two tangents, to the difference of longitude on the proposed rhumb, intercepted between the two latitudes, of whose half complements the logarithmic tangents were taken.

It was the great study of our predecessors to contrive such a chart in plano, with straight lines, on which all or any parts of the world might be truly set down, according to their longitudes and latitudes, bearings, and distances. A method for this purpose was hinted at by Ptolemy, near 2000 years since, and a general map, in such an idea, was made by Mercator: but the principles were not demonstrated, and a ready way shown of describing the chart, till Wright explained how to enlarge the meridian line by the continual addition of secants, so that all degrees of longitude might be proportional to those of latitude, as on the globe; which renders this chart, in several respects, far more convenient for the navigator's use, than the globe itself, and which will truly shew the course and distance from place to place, in all cases of sailing.

For further particulars respecting the construction, and for the use of charts, see NAVIGATION.

In choosing maps, it is proper to examine particularly whether the curved lines of those that ought to have the meridians and parallels arches of circles be truly circular. If the map is composed of more than one sheet, the sheets should be so joined together as that the corresponding meridional lines and parallels be each in one continued line. The colours in painted maps, as was observed with respect to globes, should be fine and transparent, and not laid on too thickly.

Maps folded for the pocket answer very well for travelling, in so far as they point out the relative situation of places; but owing to the intervals at which the parts are pasted on the canvas, the distances between places cannot be ascertained with any degree of accuracy.

SECT. III. *Of the use of Maps.*

Maps are of great utility in the study of geography and history; and if they are accurately drawn, many of the problems that are usually performed on the globes, may be solved mechanically by means of maps.

In consulting a map, it is not sufficient to find out in it the name of the place of which you desire to know the situation, although this is frequently all at which the consulter of a map aims: it is, besides, proper for the student to inform himself respecting the relative position of the place, with regard to its vicinity to other places; its bearings and distance from the principal places in the same or neighbouring districts; whether it is near the sea-shore, and is near a convenient harbour; whether it be seated on some principal river, and on what side of the river; whether it is in the neighbourhood of a considerable canal; whether it be near a lake, mountain, forest, &c. and many other little particulars that will readily suggest themselves to an attentive reader.

The problems that are usually performed by means of maps, are the following.

PROBLEM I. *To find the latitude and longitude of any given place.*

1[illegible] Use of Maps.

In maps on a large scale, or where the meridians and parallels of latitude are straight lines, the latitude of the place

place may be easily found by stretching a thread over the place, so that it may cross the same degree of latitude on each side of the map; and the degree crossed will be the latitude required. Or, with a pair of compasses measure the shortest distance of the place from the nearest parallel, and apply this distance to either side of the map, so as to keep one point of the compasses on the same parallel; then the other point will shew the degree of latitude as measured on the graduated margin, counting from the parallel north or south, according as the place is in north or south latitude.

The longitude of the place may be found in a similar manner, by stretching the thread over the place, or laying a ruler across it, so as to cut the same degree of longitude on the top and bottom of the map, and that is the degree required.

The above methods answer very well in plain charts or in maps of counties; but when the meridians and parallels are curved lines, we must find how often the distance of the place, measured by the compasses from the nearest parallel, will reach the next parallel in a straight direction, and from thence the latitude may be found with sufficient exactness. Thus, suppose we are required to find the latitude of Berlin, the capital of Prussia. The nearest parallel is that of 50° north latitude; the distance of Berlin from this parallel will reach the parallel of 60° in four times, measuring on the map of Europe. The fourth part of ten, or two and a half, added to 50, gives the latitude required, or $52\frac{1}{2}$.

To find the longitude on such maps, measure how often the distance of the place from the nearest meridian will reach the next meridian. Thus, in the same instance, the distance of Berlin from the meridian of 10, which is the nearest towards the east, taken three times, will extend a little beyond the meridian of 20. Add to 10 the third part of this distance, which is about three and a half, and we have 13° 30′ for the longitude of Berlin east from London.

Problem II. *The latitude and longitude of a place being given; to find the place on the map.*

Where the meridians and parallels are straight lines, this is done by stretching one thread from the given latitude on one side of the map to the same latitude on the other side; while another thread is stretched between the corresponding degrees of longitude. The intersecting point of the two threads shews the place required. Thus, suppose we are required to find the place whose latitude is 34° 29′ S. and longitude 18° 23′ E. Stretching one thread between the given latitudes, and another between the given longitudes, we shall find that they cross over the Cape of Good Hope, which is therefore the place required.

When the meridians and parallels are curved lines, the most accurate way will be to describe a circle of latitude through the given degree of latitude on each side, and a circle of longitude through the corresponding degrees of longitude, and the intersection of these circles will shew the place. An easier method will be, knowing between what two parallels of latitude and longitude the place lies, and consequently by what four lines it is bounded, to find the place by trial, by considering the proportional distance of it from each line.

Problem III. *The latitude of a place being given; to find all those places on the same map that have the same latitude.*

If a parallel of latitude happen to be drawn on the map through the given place, this problem is easily solved, by tracing along the parallel, and seeing what other places it passes through. If a parallel is not drawn through the given place, take with a pair of compasses the distance of the place from the nearest parallel; then keeping one foot on the parallel, and the other in such a position as to describe a line parallel to the parallel of latitude, move the compasses, and all the places over which the point that is not on the parallel passes, have the same latitude with the given place.

This method will not succeed in maps on which a large tract of country is delineated on a small scale.

Problem IV. *Given the longitude of a place; to find on the map all those places that have the same longitude.*

Find the longitude of the given place, and if a meridian passes through it, observe all the places that lie under this meridian; or, if a meridian does not pass through the place, find by the compasses, as in the last problem, those places that are situated at the same parallel distance with the given place from the nearest meridian. These places have nearly the same longitude with the given place.

Problem V. *To find the antœci of a given place.*

Find the latitude and longitude of the place by Problem I. and find another place of the same longitude, whose latitude is equal to that of the former, but in a contrary direction. The inhabitants of this latter place are the antœci to the latter.

Ex. Suppose a ship to be in the Indian ocean, in lat. 13° S. and long. 80° E. it is required to find the antœci to her present situation? *Ans.* The place which has nearly the same longitude, and an equal latitude in a contrary direction, viz. 13° N. is Madras.

Problem VI. *To find the periœci of a given place.*

Find the longitude of the given place, and subtract it from 180°: the remainder will be the longitude in an opposite direction of the periœci. Then find a place having an equal longitude with this last, and having the same latitude with that of the given place: this latter is the situation required.

Ex. It is required to find the periœci to the inhabitants of the gulf of Siam. *Ans.* The longitude of Siam is 100° 50′ E. which, subtracted from 180°, leaves 79° 10′ W. Now, the place that has this longitude, and the same latitude with Siam, viz. about 14° N. is the isthmus of Darien.

Problem VII. *To find the antipodes of a given place.*

This problem is solved on maps in the same manner as on the globe.

Problem VIII. *Having the hour at any place given; to find what hour it is in any part of the world.*

Find the difference of longitude between the two places, and reduce this to its equal value in time, by

Principles and Practice.

N° 65. Add this value to the given hour, if the place where the time is required be to the eastward of the given place, and the sum is the time required. If the place at which the time is required lie to the westward of the given place, subtract the difference of longitude in time from the given hour, and the difference is the time sought.

Note.—If, after adding, the sum is found greater than 12, 12 must be cancelled, and the hours must be changed from A. M. to P. M. and *vice versa;* and if, on subtracting, the difference in time between the two places happens to be greater than the given hour, 12 must be added to the given hour, and the hours changed as before mentioned.

Ex. Suppose it to be at present 9 A. M. at Lisbon, what time of the day is it at Pekin in China? *Ans.* The difference of longitude between Pekin and Lisbon is 125° 33′, which reduced to time gives 8 hours 22 minutes; and since Pekin lies to the east of Lisbon, this must be added to 9, the given hour, giving a sum of 17 hours, 22 minutes; but as this is greater than 12, we must take 12 away, and the difference, 5 hours 22 minutes, changed from morning to afternoon hours, is the time required. It is therefore 22 minutes past five P. M. at Pekin.

PROBLEM IX. *To find those places in the torrid zone to which the sun is vertical on any given day.*

Find in an ephemeris, or nautical almanack, the sun's declination for the given day; then observe, in the map of the world, all those places which lie under that parallel of latitude, which is the same with the declination, and these will be the places required.

Ex. It is required to find at what places the sun will be vertical on the 20th of March and 23d of September? *Ans.* The sun's declination on the 20th of March, is 19′ S. and on the 23d of September 6′ N. Now the principal places that lie near the parallel of 19′ S. and 6′ N. are the island of St Thomas, the middle part of the islands of Sumatra and Borneo; the Gallipagos isles, and Quito in South America.

123 Analemma for solving geographical problems.

The Analemma, or Orthographic Projection delineated in Plate CCXXXV. will solve many of the most curious problems, and with the assistance of maps will be almost equivalent to a terrestrial globe. The parallel lines drawn on this figure represent the degrees of the sun's declination from the equator, whether north or south, amounting to $23\frac{1}{2}$ nearly. On these lines are marked the months and days which correspond to such and such declinations. The size of the figure does not admit of having every day of the year inserted; but by making allowance for the intermediate days, in proportion to the rest, the declination may be guessed at with tolerable exactness. The elliptical lines are designed to shew the hour of sunrising or sunsetting before or after six o'clock. As 60 minutes make an hour of time, a fourth part of the space between each of the hour-lines will represent 15 minutes; which the eye can readily guess at, and which is as great exactness as can be expected from any mechanical invention, or as is necessary to answer any common purpose. The circles drawn round the centre at the distance of $11\frac{1}{4}$ each, shew the point of the compass on which the sun rises and sets, and on what point the twilight begins and ends.

In order to make use of this analemma, it is only necessary to consider, that, when the latitude of the place and the sun's declination are both north or both south, the sun rises before six o'clock, between the east and the elevated pole; that is, towards the north, if the latitude and declination are north; or towards the south, if the latitude and declination are south. Let us now suppose it is required to find the time of the sun's rising and setting, the length of the days and nights, the time when the twilight begins and ends, and what point of the horizon the sun rises and sets on, for the Lizard point in England, Frankfort in Germany, or Abbeville in France, on the 30th of April. The latitude of these places by the maps will be found nearly 50° N. Place the moveable index so that its point may touch 50° on the quadrant of north latitude in the figure; then observe where its edge cuts the parallel line on which April 30th is written. From this reckon the hour-lines towards the centre, and you will find that the parallel line is cut by the index nearly at the distance of one hour and 15 minutes. So the sun rises at one hour 15 minutes before six, or 45 minutes after four in the morning, and sets 15 minutes after seven in the evening. The length of the day is 14 hours 30 minutes. Observe how far the intersection of the edge of the index with the parallel of April 30th is distant from any of the concentric circles, which you will find to be a little beyond that marked two points of the compass, and this shews that on the 30th of April the sun rises two points and somewhat more from the east towards the north, or a little to the northward of east-north-east, and sets a little to the northward of west-north-west. To find the beginning and ending of the twilight, take from the graduated arch of the circle $17\frac{1}{2}$ degrees with a pair of compasses; move one foot of the compasses extended to this distance along the parallel of April 30th, till the other just touches the edge of the index, which must still point at 50. The place where the other foot rests on the parallel of April 30th, then denotes the number of hours before six at which the twilight begins. This is somewhat more than three hours and a half, which shews that the twilight then begins soon after two in the morning, and likewise that it begins to appear near five points from the east towards the north. The uses of this analemma may be varied in a great number of ways; but the example just now given will be sufficient for the ingenious reader.

SECT. IV. *Of the Origin and Progress of Maps.*

1 Origin of maps.

The first map of which we have any certain record, is that of Anaximander, about 560 years before the Christian era. This is mentioned by Strabo, book i. and is supposed to be that referred to by Hipparchus, under the name of the ancient map.

It has been alleged, that Sesostris, king of Egypt, on his return from his boasted expedition, after having traversed great part of the earth, recorded his march in maps, of which he gave copies, not only to the Egyptians, but to the Scythians, to the great admiration of both people. This is the relation of Eustathius; but M. Montucla considers it as a very improbable story, and thinks that the invention of maps cannot be dated prior to Anaximander *. Some have supposed that the Jews laid down the holy land in a map, when they distributed

Principles and Practice.

tributed the different portions to the nine tribes at Shiloh; a supposition which is derived from Joshua's account, that they were sent to walk through the land, and that they described it in seven parts in a book. Josephus also relates, that when Joshua sent people from the different tribes to measure the land of promise, he sent with them men well skilled in geometry. All this, however, is no proof that these persons drew a sketch of the country, according to our idea of a map; but probably only wrote down, for the satisfaction of their employers, the extent, boundaries, and general characteristics of the divisions of the land.

Herodotus has given a minute description of a map constructed by Aristagoras, tyrant of Miletus, an abridgement of which will serve to give some notion of the maps of those times. It was drawn upon brass or copper, and seems to have been merely an itinerary containing the route through the countries which were to be traversed in a march which Aristagoras proposed to Cleomenes, king of Sparta, for the purpose of attacking the king of Persia at Susa, that he might thus assist in restoring the Ionians to their liberty. The rivers Halis, Euphrates, and Tigris, which, according to Herodotus, must have been crossed in that expedition, were laid down in this map; and it contained one straight line, called the royal road or high way, which comprehended all the stations or places of encampment, from Sardis, the beginning of the route, to Susa, a distance of 13,500 stadia, or 1687½ Roman miles of 5000 feet each. The number of encampments in this whole route was 111.

Ptolemy of Alexandria, the celebrated geographer mentioned in N° 21. constructed maps to illustrate his description of places, and these are the first that have regular meridians and parallels, the better to define and determine the situation of places. Ptolemy acknowledges that his maps, with the addition of some improvements of his own, the principal of which was certainly the introduction of meridians and parallels, were copied from previous maps made by Marianus Tyrius, &c. They are, however, often very inaccurate.

According to Atheneus, a work which seems to have contained maps, was written by Baeton, under the title of Alexander's march; and a work on the same subject is mentioned as the production of Amynthus. We are informed by Pliny, that this Baeton was one of the surveyors of Alexander's marches; and he quotes the exact number of miles of these marches, according to Baeton's mensuration, and confirms their authenticity by the letters of Alexander. Pliny also remarks, that a copy of this conqueror's surveys was given by Zenobius, his treasurer, to the geographer Patrocles, who was admiral of the fleets of Seleucus and Antiochus.

Peutingerian table.

Among the most celebrated of the ancient maps, are the Peutingerian tables, so called, because published by Peutinger of Augsburg. These tables contain an itinerary of the whole Roman empire; all places except seas, wood, and deserts, being laid down according to their measured distances, though without any mention of latitude, longitude, or bearing. A particular description of this monument of antiquity is given in the 18th volume of the History of the Academy of Inscriptions, and in the History of the Academy of Sciences for 1761, from which M. Montucla has dawn up the following acconnt. The map of Peutinger, as it is in the original in the imperial library, is exactly one French foot in height, and 20 feet eight inches in length, according to measures taken by Buache, from a copy of the splended edition given by Scheele in 1753. It comprehends the whole extent of the Roman empire, from Constantinople to the ocean, and from the shores of Africa to the northern parts of Gaul; but the table which it affords of this vast extent of country is by no means calculated to give us an idea of its figure, since the 35° of longitude which it comprehends, occupy 20 feet 8 inches, while the 13° of latitude are comprised within the space of one foot; thus the countries represented are so disfigured, that the Mediterranean appears only like a broad river, and all the countries are so distorted, towards the north and south, that they cannot be recognised.

Most of those who have seen this ancient map, have considered it as the rude and bungling work of a man little conversant with geography, and still less so with mathematics; but Edmund Brutz considers the distortion of this map as similar to what we see in some pieces of perspective, and that it ought to be examined from some certain near point in order to perceive the objects in their natural proportion.

Buache supposed long ago, that this map was constructed with more scientific skill than it appears to be at the first glance; and that the apparent irregularities which we observe in it, might have been introduced designedly, for the purpose of deriving greater advantages as to what was intended for the principal object. In fact, as the Roman routes extended almost entirely from east to west, they paid more attention to the measures in this direction than those between north and south; and the map in this way might have had the greater convenience of being more easily rolled up, and consequently more portable.

Thus far Buache hazarded no more than conjecture; but a labour undertaken by him with a very different view, led him to the true design of the map of Peutinger. He had been tracing a scale of climates, and of the length of the days and nights, for the purpose of attaching it to small maps of the different countries of Europe. As the space occupied by the scale was pretty much extended in height, but had very little breadth, he formed the idea of drawing a kind of map upon two scales, one pretty much extended for the latitude, and the other very much contracted for the longitudes, preserving the hollows of the coasts and boundaries of each state. As this disposition of his map strangely disfigured the countries which it was intended to represent, he was led to imagine that this map might be the reverse of that of Peutinger. This was sufficient to engage him to construct another map upon the same principle; but in which the scale of longitudes was much greater than that of the latitudes. He then saw that he had been right in his supposition, and that the map which he had last constructed had a considerable resemblance to that of Peutinger. This latter is in fact only a plain chart, constructed upon two scales, of which that of the longitudes is very great, and that of the latitudes much smaller.

One difficulty alone arose. By supposing that he observed in this map a custom at present established among geographers, of representing the meridians by lines drawn perpendicular to the base of the chart, and the parallels

Principles and Practice.

parallels to the equator by straight lines drawn parallel to this same base, Buache found a considerable error. The bottom of the gulf of Venice and Rome did not then appear, as they ought to do, under the same meridian. He soon, however, saw the solution of this difficulty. The method of drawing the meridians parallel to the sides of the chart, is a matter of pure agreement, and had probably not been observed in the map of which we are speaking. The ancient Roman geographers having considered that Italy was naturally divided by the Appenines, according to its length, into two parts that were nearly equal, had therefore delineated the length of Italy from Trent to the end of the peninsula, parallel to the lower margin of the map, and had afterwards arranged the other parts which the map was to contain, conformably to this disposition; and as the length of Italy is not in a direction parallel to the equator, it would happen necessarily that the meridians and parallels, if they had been drawn on this map, would have been parallel neither to the sides nor to the lower margins of the map, and that the vertical line passing through Rome must intersect the gulf of Venice at about the middle: but this line is not a meridian.

Thus, this map is not so rude a work as has been imagined, but has been entirely constructed according to rule; and it even appears that the author had employed pretty good materials in its compilation, as the positions are laid down in a manner that differs little from modern observation *.

* *M. Montucla*, tom. iv. p. 599.

From the time of Ptolemy till about the 14th century, no new maps were published; and the first maps of any esteem among the moderns were constructed by Mercator, to whom we are indebted for the projection according to which marine charts are constructed. Mercator was followed by Ortelius, who undertook to construct a new set of maps with the modern divisions of countries and names of places, for want of which the maps of Ptolemy were become almost useless. After Mercator and Ortelius, many others published maps, which were chiefly copied from those above mentioned, till about the middle of the 17th century, when Blaeu published his large atlas, or *Cosmographie blaviane*, in which is a pretty accurate description of the earth, the sea, and the heavens, comprised in 12 folio volumes. About the same time an atlas in two folio volumes was published in France by M. Sanson, the maps of which are in general very correct, containing many improvements of the travellers of those times. The maps of Blaeu and Sanson were copied with little variation both in England, France, and Holland, till from later observations De Lisle, Robert, Wall, &c. published still more accurate and copious sets of maps.

The works of recent travellers and navigators have considerably improved the construction and accuracy of our maps and charts; but there is still much to be done, especially with respect to trigonometrical surveys, before any high degree of correctness can be acquired. Among the latest maps and charts, those constructed by Mr Arrowsmith are in the greatest estimation.

126
Catalogue of the best maps.

As a collection of good and accurate maps is of the greatest importance in the study of geography and history, we shall here subjoin a list of some of the best modern maps that have been published.

Those maps which may be collected for the purpose of forming an atlas, have been arranged under three heads, according to their size, or the extent of their scale. 1st, Those which consist of more than six sheets, such as De Bouge's map of Europe in 50 half sheets, and Cassini's map of France in 183 sheets. 2dly, Those from six to four sheets, to which class belong several maps of kingdoms. And, 3dly, Those from one sheet to four, which is the smallest size that can answer the purpose of an atlas. We shall briefly notice the best maps of each size.

Planispheres, or *Maps of the World*.—We know of no very large map of the world that can at present be confidentially relied on: the best is that of Mr Arrowsmith in four sheets; and Faden has published very good maps in one sheet.

Maps of Europe.—1st Size. That of De Bouge, published at Vienna, or that by Sortzmann in 16 sheets, which is the better of the two. 2d Size. Arrowsmith's in four sheets. 3d Size. That by Faden in one sheet.

Maps of England.—I. The trigonometrical surveys of the counties, published by Lindley and Gardner, and by Faden. II. Cary's atlas of the counties, and his England and Wales in 81 sheets. III. Faden's map in one sheet.

Maps of Wales.—I. That of Evans in nine sheets. III. The maps in Pennant's Tours, and Evans's Cambrian Itinerary.

Maps of Scotland.—I. The surveys of the several counties. II. Ainslie's nine sheet map. III. An excellent map by General Roy, and Ainslie's reduced map, in one sheet.

Maps of Ireland.—I. Survey of counties. III. A valuable map by Dr Beaufort, in two sheets, or Faden's in one sheet.

Maps of France.—I. Cassini's mentioned above, and the *atlas nationale*, in 85 sheets. III. Faden's one sheet map, and a map, in departments, by Bellycime, in four sheets.

Maps of the Netherlands.—I. Ferran's map in 25 sheets. II. *Atlas de Department Belgique*. III. Ferrari's map reduced by Faden.

Maps of Holland.—II. Kep's maps of the United Provinces. III. Faden's map of the Seven United Provinces in one sheet.

Maps of Germany.—II. Chauchard's map of Germany. III. A map of the Austrian dominions, in one sheet, by Baron Lichtenstern.

Maps of Prussia.—I. Sortzmann's atlas in 21 sheets. III. Sortzmann's reduced, in one sheet.

Maps of Spain.—Lopez's atlas, not, however, very accurate. II. A map of Spain in nine sheets by Montelle and Chanlaire. III. Faden's map in one sheet.

Maps of Portugal.—II. Geoffry's improved by Rainsford, in six sheets. III. De la Rochette's chorographical map in one sheep, published by Faden.

Maps of Italy.—I. The maps of the several states. III. D'Anville's map of Italy improved by De la Rochette, in four sheets, published by Faden.

Maps of Turkey in Europe.—III. Arrowsmith's map of Turkey in two sheets. De la Rochette's map of Greece in one sheet.

Maps of Switzerland.—I. Weiss's atlas, published at Strasburg in 1800. III. Weiss's reduced map in one sheet.

Maps of Denmark.—I. Maps of the provinces, under the direction of Bygge. III. Faden's maps of Denmark, Sweden, and Norway, in one sheet.

Maps

Maps of Sweden.—I. Atlas of the Swedish provinces, by Baron Hermelin. III. De la Rochette's, by Faden, in one sheet.

Maps of Asia.—The best general map of Asia is that by Arrowsmith in four sheets, published in 1801; and D'Anville's, in six sheets, may still be consulted with advantage.

There are few good maps of the individual countries; but the following are esteemed among the best.

Of China.—D'Anville's atlas, and a map by Arrowsmith.

Of Tartary.—A map by Witsen, in six sheets, and one by De Witt in one sheet.

Of Japan.—Robert's map in one sheet.

Of the Birman Empire.—The maps published in Mr Symes's embassy.

Of Hindostan.—Rennell's map in four sheets. His atlas of Bengal, and his map of the southern provinces.

Of Persia.—La Rochette published a beautiful map to illustrate the expedition of Alexander the Great; and a good modern map has been published by Mr M'Donald Kinneir.

Of Arabia there are some good partial maps in Niebuhr's journey.

Of the Asiatic Islands there is an excellent chart by Arrowsmith, in four sheets.

Of Australasia, or *New Holland*, the best drawing is contained in Arrowsmith's chart of the Pacific ocean.

Maps of Africa.—The best general map of Africa is still that of D'Anville, though some little additions may be made to it, derived from the journeys of Park and Brown. Major Rennell's partial maps may be consulted with advantage.

Of Abyssinia there is a good map in Bruce's travels.

Of Egypt, the best maps are that of the Delta by Niebuhr, and that of Lower Egypt by la Rochette.

Of the Mahometan States, the best maps are those by Shaw, and a chart of the Mediterranean in four sheets, by Faden.

Of the Cape of Good Hope, the best is Barrow's survey.

Maps of America.—There is no modern general map of America that can be relied on. The best is that of D'Anville, in five sheets, published in 1746 and 1748.

Mr Arrowsmith has published an excellent map of North America, on a very large scale, but has omitted the Spanish dominions.

Of the United States, the best map is Arrowsmith's in four sheets, published in 1802; and a good map, including the recent states, was published by Mr Mellish in 1816.

Of the British Possessions in America, besides Arrowsmith's map above mentioned, there is a good map of Upper Canada by Smith, in one sheet.

Of the West India Islands, the best map is that of Jefferys in 16 sheets, from which a smaller one in one sheet has been reduced.

Of South America, the best map is that published by Faden in 1799, in six sheets, from an engraving done at Madrid some years before.

APPENDIX.

27 Observation on the study of geography.

BEFORE we conclude this article, we must make a few observations on the method to be followed for acquiring or imparting geographical knowledge.

As some knowledge of geography, as well as of chronology, is absolutely necessary, before history can be properly understood, the rudiments of these sciences should be learned, as soon as the capacity of the pupil will allow. It happens fortunately, that some of the most useful parts of geography, those which consider the relative situations, extent and boundaries of countries, with the manners and customs of their inhabitants, are highly interesting; and provided that a knowledge of them be conveyed to a child in a pleasing manner, they are well fitted to interest his curiosity, and awaken his attention. The more scientific parts of geography, and a detailed account of the minute circumstances respecting each country, though extremely useful, and indeed necessary to the more advanced student, may be withheld for a little without any great loss, till his age and judgment permit him to see their utility and application.

In teaching geography to very young children, their chief attention should be directed to those circumstances which are most interesting; and even with this limited view much may be learned at a very early period. For this purpose the dissected maps that are usually sold at toy shops, may be employed with considerable advantage; but it is to be regretted, that the maps used in preparing these are seldom taken from the most correct copies. Those works also which, under the disguise of fictitious voyages and travels, are intended to convey a geographical knowledge of various countries, afford a very pleasing and profitable method of instruction. A late work of this kind, by M. Jaufret, entitled *the Travels of Rolando*, may be advantageously put into the hands of young people; and, as they are farther advanced, the travels of Anacharsis the younger by the abbé Barthelemi will give them considerable information respecting the manners, customs, and historical events of ancient Greece.

When the young student is sufficiently advanced to prosecute the study of geography on a more extensive and scientific plan, it would be desirable that he should begin by reading some elementary treatise on astronomy, such as that of Mr Bonnycastle, or the *Spectacle de la Nature*; or, if he has acquired a proper degree of mathematical knowledge, he may read Laplace's *Systeme du Monde*, the astronomical part of *Robison's Mechanical Philosophy*, or the astronomical article in this dictionary.

It may happen, that, from a defect of early education, or want of time, a preliminary course of astronomy cannot be commanded. Still, however, considerable progress may be made in geography, by the mechanical means of maps and globes. The student should, therefore, provide himself with a pair of the best globes, chosen according to the directions laid down in N° 107; and with a few good maps of those countries which are most interesting, particularly maps of Europe, Asia, Africa, and North and South America, the British islands, France, Germany, Italy, Russia, and Denmark, which may be collected from the list given at N° 126.

Being provided with these materials, the student should first read over Chap. I. of Part II. of this treatise, or a similar part of some elementary work in geography. On the elementary principles of geography we would recommend the general principles prefixed to Mr Patteson's general and classical Atlas; and for teaching the use of the globes, Bruce's Introduction to Geography and Astronomy. For a complete account of modern geography we cannot refer to a better work than that of Mr Pinkerton; and for a combined account of ancient and modern geography, the pupil may have recourse to a work on that subject by Dr Adam of Edinburgh.

After reading over the preliminary part above mentioned, the pupil may go through the second Chapter of Part II. solving all the problems as he goes along on the terrestrial globe; and thus he may proceed progressively through the whole article, leaving that part of Part I. which treats of the history of geography for the last object of his enquiry.

In studying the particular circumstances of each country, the pupil should always have the map of the country before him; and, as he goes along, should trace there the situation of each particular place; of the principal mountains, lakes, the sources and directions of the rivers, the form and bounding of the shores, &c. In his progressive view of particular geography, it will be proper for the pupil to begin with the country in which he resides; and, after having made himself master of that, to proceed successively to those which border on it, or whose connection with it is the most interesting.

Thus an inhabitant of these islands, after having taken a view of EUROPE in general, should make himself acquainted with BRITAIN and IRELAND (by perusing the articles ENGLAND, SCOTLAND, and IRELAND in this Dictionary or in other works); whence he may proceed to FRANCE and its dependencies in the NETHERLANDS, SWITZERLAND, ITALY; thence to GERMANY and the AUSTRIAN territories, PRUSSIA, SWEDEN, DENMARK, and RUSSIA; whence he may return to the south of Europe to SPAIN, PORTUGAL, and TURKEY, &c. After Europe, the United States of AMERICA will probably be found the most interesting; the pupil may therefore study the geography of NORTH AMERICA before that of ASIA. From ASIA he may proceed to AUSTRALASIA and POLYNESIA; thence to AFRICA, and so conclude with SOUTH AMERICA. Nothing will contribute more to the advancement of geographical studies than the construction of maps. If the pupil has time therefore he should early be instructed in this part of the subject by at first drawing a map of the world according to the directions laid down in N° 118. then one of Europe, and so of other quarters and countries. In constructing this map, it will be proper first to lay down those places which are near the coast, in order to form the outline of the maritime part of the country, and only the most remarkable places inland, especially those which are situated in the course of the principal rivers. In every map the most prominent features of the country, as the mountains, lakes, rivers, and principal cities and towns, should first be attended to, and from these the pupil may be introduced to the other places in the order of their magnitude or importance.

The most agreeable and interesting method of studying particular geography, after having become acquainted with the elementary principles of the science, would be to peruse the best books of voyages and travels; for from those, where the traveller can be depended upon, the most correct systems of geography are compiled. Many of these, however, are too prolix and particular to be put into the hands of most young people, and a judicious abridgement of the best of them will answer every purpose; and perhaps Dr Mavor's collection may be recommended, as the best of the kind in the English language. For those whose time and convenience will admit of their reading the best writers of voyages and travels, there is no want of such works; and Mr Pinkerton has given at the end of his excellent work, a list of the best in most languages. We shall here only notice a few of the best and latest.

Pennant's Tours in Britain.

INDEX.

Problems

GEOLOGY.

INTRODUCTION.

Introduction.

1 Definition and object of geology.

THAT part of natural history which treats of the internal structure of the earth, as far as we have been able to penetrate below its surface; of the arrangement of the materials of which it is composed, and of the changes which have taken place in these, is called GEOLOGY, from γη, the *earth*, and λόγος, *a discourse*. This science has been called by Werner, GEOGNOSY, and is by him defined to be *that part of mineralogy which considering minerals as a part of our globe, treats chiefly of their bearings and positions with respect to each other* (A). Till of late this department of literature was called physical geography, but at present the terms GEOLOGY and GEOGNOSY are generally adopted; of these we have preferred the former, as being equally expressive and more familiar; under this head we propose to include every thing that is usually comprehended under what have been called *theories of the earth*.

GEOLOGY differs from COSMOGONY as a *part* from the

(A) Werner has probably made this trifling change from a desire of novelty; and some of his admiring pupils have attempted to display in very pompous but puerile terms, that it is of great value and importance.

Introduction.

the whole; the object of the latter is to give an account of the creation of the *universe*, while the former confines itself to the consideration of the planet which we inhabit.

Geology is intimately connected with mineralogy, and may indeed be said to depend on this as its very foundation. Werner, as we have seen, considers *Geognosy* as a part of *Mineralogy;* but we are disposed to concur with Mr Kirwan, who, speaking of mineralogy with respect to its relation to geology, calls it "the alphabet of the huge and mysterious volume of inanimate nature."

Definition.

Geology may be divided into descriptive and speculative; the former giving a general account of the materials of which the globe is composed, and of their arrangement; while the latter is strictly confined to what may be called a theory of the earth, or an attempt to explain the manner in which the structure and arrangement have been brought about, and the changes that have taken place in the disposition of the component parts of the earth.

Importance of the science

The science of geology is of considerable importance in many points of view.

to the naturalist;

1. The student of natural history cannot but derive a great fund of profit and advantage from a science, which makes him acquainted with so large a department of nature. Mineral bodies, whether we consider them as individuals of nature, or as collected into those masses which form the strata of the earth, and the mountains that rise above its surface, are peculiarly interesting to the naturalist, as well from the variety of form and beauty of appearance which some of them present, as the useful purposes to which many of them are applied. The other kingdoms of nature delight us with the display of order and design exhibited in their organization, or interest us from the intimate connexion which subsists between many of them and ourselves. These are objects of the *beautiful;* while the stupendous mountain, the awful volcano, the towering cliff, the gloomy mine, and the majestic cavern, are objects of the *grand* and the *sublime.*

to the miner

2. To the miner, and all those who are employed in searching the bowels of the earth for the treasures which they contain, geology, as well as mineralogy, forms an essential qualification. Experience has shewn that certain minerals and metals are found more frequently attached to some of the stony materials of the earth than to others, and that a few of them are only found in particular strata. Examples of this kind will be given presently. We have also learned that the arrangement of the materials in the earth is so far regular and uniform, that when we know the particular materials near which certain metals and minerals are commonly found, and the usual disposition in these places; and when we find in another situation the same materials disposed in a similar manner, we are pretty certain that the metal or mineral of which we are in search is not far distant. We are therefore encouraged to prosecute the search with every probability of success. Those who undertake to direct an investigation of this kind, or to carry on the operations requisite for the obtaining what is sought, would do well to inform themselves beforehand of such facts as are well established respecting the distribution of the materials of the earth, and the substances usually found connected with them. For want of this necessary information, we often see projectors impose on the credulity, and impoverish the finances, of gentlemen of landed property, who are led to suppose that they possess on some part of their estate a rich vein of metal, seam of coal, &c. the working of which will considerably improve their income.

6 to the landed proprietor;

3. The failure of undertakings of this kind, partly from the villany of the projector, and partly from the ignorance of his employer, shews the advantages that gentlemen of landed estates would derive from the study of geology. An acquaintance with this science would guard them against the artifices of designing men, and prevent them from embarking in uncertain and expensive projects, the issue of which is too often ruin and disappointment.

7 and to the Christian.

4. But the study of geology boasts a still higher advantage. Nothing has more contributed to demonstrate the truth of the divine writings, and to clear up many doubtful passages in them, than the discoveries that have lately been made in the structure and formation of the earth. The original state of the globe is so intimately connected with that which it at present exhibits, that we cannot properly understand the latter without referring to the former; and recent experience has shewn that the obscurity in which the philosophical knowledge of this subject was involved, has been highly favourable to those systems of atheism and infidelity which prevailed in the last age. Much of this obscurity is now removed; and the investigations of Whitehurst, Werner, Kirwan, Howard, and some other geologists, by proving that the supposition of a deluge is the only hypothesis on which we can account for the present state of our globe, have contributed as much to the advancement of true religion as of philosophical knowledge.

"So numerous indeed, and so luminous, have been the more modern geological researches, and so obviously connected with the object we have now in view, that since the obscuration or obliteration of the primitive traditions, strange as it may appear, no period has occurred so favourable to the illustration of the original state of the globe as the present, though so far removed from it. At no period has its surface been traversed in so many different directions, or its shape and extent under its different modifications of earth and water been so nearly ascertained, and the relative density of the whole so accurately determined, its solid constituent parts so exactly distinguished, their mutual relation, both as to position and composition, so clearly traced or pursued to such considerable depths, as within these last thirty years. Neither have the testimonies that relate to it been ever so critically examined and carefully weighed, nor consequently so well understood, as within the latter half of the 18th century †."

† *Kirwan's Geol. Essays.*

8 Difficulties attending the study not insurmountable.

Geological researches seem at first view to be attended with almost insurmountable difficulty. It is evident that the part of the earth which it is in our power to examine, is infinitely small when compared to that which is entirely beyond our reach: and even much of the elevated parts, that appear above the surface, would seem to be so completely cut off from us by inaccessible precipices, and the ice and snow with which the summits

Introduction. mits of some of them are perpetually covered, that our knowledge of their structure and compositions must for ever remain imperfect. Much of these difficulties, however, is rather apparent than real. It is true that our researches can extend but a very little way below the surface; but so far as our experience has yet taught us, any farther investigation would be rather a matter of curiosity than utility. Those metals and minerals which prove of most service to mankind, are found at no very great depth in the earth, and some of them almost on its surface; and when we have penetrated beyond these, the materials discovered are of a nature so uniform, and of a texture so firm and hard, that it is possible they may extend even to the centre. Again, the investigations of Saussure, De Luc, Dolomieu, and Humboldt, have proved that the most dangerous precipices, and the highest summits of those immense mountainous chains which traverse the earth in so many directions, oppose but feeble barriers to persevering industry and philosophic ardour.

The diversity which occurs in the structure and local arrangement of subterraneous substances, seems to throw another difficulty in the way of the geologist; but the farther his researches are extended, the more will this apparent diversity be diminished. The practical skill which some miners possess in many parts of the world, proves that the mazes of this labyrinth are not without a clue; and we may safely conclude, that when our knowledge of the structure of the earth, and the disposition of its materials, shall be still farther extended, the greater part of the obscurities under which the subject is now veiled, will be entirely removed. Multiplied observations of later years have enabled us to form certain general conclusions, and lay down certain general laws, which must materially assist future observers.

9 Principal improvers of geology. In the modern improvements of geology the Germans led the way, and Lehmann may be considered as the father of the science. Eminently skilled in general physics, practical mining, mineralogy, and chemistry, and fully acquainted with the circumstances attending the relative situation of most mineral bodies in very extensive tracts of different countries which he examined, he was enabled to deduce, from a long series of observations, some general conclusions, which have, with some exceptions, been since verified in every part of the world.

Lehmann was followed in his own country by Ferber, Gmelin, Born, and Werner; in Sweden by Bergman, Cronstedt, and Tilas; in Italy by Arduini; in Switzerland, by Saussure and De Luc; in Russia, by Pallas; in France, by Delametherie, Saint Fond, Dolomieu, and Lavoisier; and in Britain, by Hutton and Kirwan, names which must ever be held in the highest estimation by the cultivators of this part of natural history.

10 Method of studying geology. Before entering on the study of geology, it is necessary to acquire a competent knowledge of chemistry, and a pretty extensive acquaintance with mineralogy, as these sciences form an essential introduction to the more general researches respecting the structure of the earth. The former supplies the means of ascertaining the nature of the substances met with; and the latter must be well understood, before we can arrange these substances under their proper heads, and before we can comprehend the terms employed by geological writers.

The study of this science, like that of some other parts of natural history, particularly botany, can be prosecuted with but little advantage in the closet. The student must examine the declivities of hills, the beds of rivers, the interior of caverns and of mines, the recesses of the ravine, and the utmost summits of the mountain, before he can obtain that degree of knowledge which is necessary to constitute a skilful and philosophic geologist. While making these personal observations, he should study the works of the best writers, and compare the facts related and described by them, with those which he himself has observed. The writings on this subject may be divided into two principal classes, one comprehending these works which contain a systematic account of the whole, or some part of the subject; such as Bergman's Physical Geography, the Geological Essays of Kirwan, the *Theorie de la Terre* of Delametherie, the writings of Werner, &c.: and the second comprising those works which treat of the geology of particular countries in the familiar style of travels; as Born's Travels in Hungary, Ferber's Travels through Italy, Saussure's *Voyage dans les Alpes*, Pallas's Travels, Jar's *Voyages Metallurgiques*, Saint Fond's Travels in England and Scotland, &c. After having acquired a knowledge of the principles and general facts of the science from the former, the student will, by means of the latter, increase his knowledge in the most familiar and agreeable way.

11 Arrangement. In the sketch of geology which we are to give in the following article, we shall consider the subject under four general heads, which will be the subject of as many chapters.

In the first chapter we shall describe the arrangement and distribution of the materials of which the earth is composed. Here, after giving some general notion of that arrangement, we shall consider each of the principal materials under a separate section, in which we shall first lay down those general marks by which each is distinguished, describe its general arrangement, and mention the places, especially in Britain, where the substance is found in greatest abundance, and those metallic or mineral bodies which are commonly found in connection with it.

After having briefly considered each substance, we shall, in the second chapter, bring the more general distribution of them under one view, still directing our attention to the arrangement of these materials in the British islands.

In the third chapter we shall give a brief outline of the most remarkable theories that have been framed in modern times, to account for the distribution of mineral bodies, and the manner in which we find them now arranged. In this chapter we shall dwell more particularly on the two rival theories which at present divide the geological world, and shall enumerate some of the objections which have been made to each.

In the fourth chapter we shall give some account of the derangement of the substances that compose our globe, so far as it has originated from known causes; and this will lead us to the consideration of EARTHQUAKES and VOLCANOES.

CHAP.

rangement, &c. of the Materials of the Earth.

CHAP. I. *Of the Arrangement and Distribution of the Materials of which the Earth is Composed.*

2 General distribution of the materials of the earth. THE materials of which the general mass of the earth is composed, are variously distributed in different parts. In some places they form irregular masses or blocks, either buried below the surface, or elevated to a greater or less height above it. In most places, however, the materials are arranged in a more regular manner; those of the same kind being collected into extensive masses, lying in layers or strata, above or below a similar mass of another kind, or these alternate with each other to a considerable depth. These strata are sometimes found arranged in a direction parallel to the horizon; at others they are vertical, or perpendicular to the horizon, appearing as if the horizontal strata had been lifted up, and laid upon their edges. More commonly the strata are arranged in a direction inclining to the horizon, when they are said *to dip*.

3 Stratification. The uppermost stratum is in most places covered to a certain depth with mould that has evidently been formed from the decomposition of organized substances. In many parts of the earth this mould extends to a very considerable depth, and constitutes the soil; in other places it is barely sufficient to form a coating to the strata, and in others it is entirely wanting.

4 Horizontal and vertical strata. A good instance of horizontal strata occurs about two miles to the east of Ballcycastle in the north of Ireland, of which we shall speak more particularly by and by. One of the most curious examples of vertical strata in Britain is found in the small island of Caldey, on the coast of Pembrokeshire, where the strata of which the whole island is composed are placed in such a manner, that their edges are all exposed to view, and they may be successively examined from the one end of the island to the other. It is seldom that an opportunity offers of examining the arrangement of strata so easily as is afforded in this small island. In most cases it is necessary to penetrate to great depths before we can acquire an imperfect knowledge of the stratification of the earth; and in no instance have we yet proceeded a mile below the surface. In Caldey island, however, the strata may be examined to the extent of more than a mile, beginning at what may be supposed the uppermost stratum, which is not more than a foot thick, to that which may be called the lowest, at the opposite end of the island, being a mass of red stone of more than a mile in depth.

Derangement of the strata. Sometimes the strata are continued in a regular arrangement, preserving the same inclination to a very considerable extent; but more commonly they appear in some parts separated, as if they had been broken asunder. These separations are usually in a perpendicular direction, and the cavities are found filled with various heterogeneous matters. Sometimes these are chiefly composed of fragments of the adjacent strata, but for the most part they consist of mineral or metallic substances of a different nature.

When these fissures are filled up with broken fragments or rubble, as it is called, it very commonly happens that they become the beds of brooks or rivers. Thus the river Derwent runs for a considerable extent in Derbyshire over a fissure of this kind. When the fissure is filled up with a solid stony matter, this forms what in Scotland is called a *dyke*. If a mass of mineral or metallic matters fill the fissure, or be insinuated between the strata, it forms what is called a vein, and these veins sometimes branch between the strata in various directions.

When a fracture has taken place in the stratified mass, one part of the mass sometimes preserves the same position as it had before, or still forms a continued line with the other parts of the mass, or is parallel to it; but more frequently one part is thrown out of its original position, and becomes more inclined to the horizon than before. Sometimes one side of the mass is more depressed than the other, as is commonly seen in many of the strata in Derbyshire; at others the two parts of the mass are so disturbed as to incline towards each other, as if they had been broken upwards. When the edges of the strata on each side of the fissure are thus divided and disarranged, they are said by the miners *to trap*.

The chasms thus formed are sometimes of considerable width. Some are found in Cornwall nearly 20 feet across, and almost full of metallic and other mineral substances. It not unfrequently happens, that these fissures are empty, containing nothing but water in the bottom. A celebrated chasm of this kind is shewn at the Peak in Derbyshire; and if a stone be thrown in, it is heard to strike from side to side for a considerable time, till at length it seems lost in subterraneous water.

If the country in which the strata lie runs in a waving direction of hill and dale, the strata usually preserve the same waving direction, keeping pretty nearly parallel to each other. A curious example of this kind has been described by Gerhard, as occurring in the district of Mansfield in Germany. See fig. 1. In those places where some remarkable dislocation of the strata has not taken place, their distribution is in general extremely regular, certain materials lying above or below certain others in an uniform manner. The observations of later geologists have discovered pretty nearly the arrangement that takes place in most countries; and we shall presently give some examples of the stratification of several parts of Europe. Before we attempt this, however, we must mention some circumstances in which the materials composing the strata differ from each other. Plate CCXXXVIII. 16 Strata in general regular.

17 Division of the materials. The general observation of all modern geologists proves, that all these materials may be distributed under two general classes; one consisting of those substances which are found more or less connected with the remains of organized bodies, as the bones, teeth, and shells of animals, the trunks of trees, and other parts of vegetable bodies; and the other comprehending those in the substance of which these organic remains are never found. As it is now generally believed that the latter of these are of a formation prior to the former, we shall here adopt the general division of them into primary and secondary. We might go still farther in this division, by arranging them under more heads; one, for example, containing those in which organic remains are sparingly found, and others containing those substances which are found only in particular places; but as the first of these involves in it a particular theory which we shall notice fully hereafter, and the others allude to facts which will be mentioned when treating of the separate materials, we shall not here extend our division

Arrangement, &c. of the Materials of the Earth

division beyond the distribution of the materials into primary and secondary.

In the following short detail, many terms will occur which can be understood only by the mineralogist. They will be fully explained under the article MINERALOGY. The names which we shall give to the substances described will be such as have been most generally adopted in this country; but to prevent ambiguity, we shall, where it seems to be necessary, add the synonymous names that occur in the best geological writings.

A. Primitive Compounds.

SECT. I. *Of Granite.*

18 Granite described.

THE name *granite* has long been applied to all stones which are composed of an aggregate of quartz, feldspar, and mica, distributed in such a manner as that each of them appear in a separate state; but as this definition has been considered as too loose, and comprehending too many varieties, the name is at present restricted to that kind of granitic stone in which the quartz, feldspar, and mica, are found in grains or crystals. Of the three substances, the feldspar is generally the most abundant, and the mica the least so.

Granite is found in the lowest and the highest situations of the earth that have yet been examined. It forms the basis of all the other strata: and though these are sometimes found below it, this situation seems to have been the consequence of some accident, by which the inferior substances were thrown below the granite. Many mountains seem almost entirely composed of granite, as Gefrorn one of the Rhætian Alps; and there is a high hill of white granite about six miles to the west of Strontian in Scotland. Sometimes large masses of granite are found in a detached situation at some distance from the mountains to which they appear to belong; and these masses seem in some instances to have been broken off, and rolled down the mountain, and in others to have been carried away by irresistible torrents, or dislodged by earthquakes. On the summits of the mountains near Port Sonnachin in Scotland, are found large quantities of detached pieces of granite, some of them of amazing size *.

* *Mawe's Derbyshire*, p. 132.

19 Its different states.

Granite is most commonly found in vast blocks, separated from each other by rifts or chasms, irregularly disposed. This is the case in most mountains, especially in those which have high, pointed spires. The structure of those blocks is pretty uniform, there occurring seldom more than two varieties, one called porphyritic granite, in which the basis is of a fine grain, containing large crystals of feldspar. Of this variety many instances occur in the north of Scotland, and near Carlsbad in Bohemia. The other principal variety is that in which the granite is found in distinct globular concretions, composed of concentric lamellæ. This variety was observed by Mr Jameson, on the road between Dresden and Bautzen; and Mr Barrow, in his description of the Cape of Good Hope, mentions several globular concretions of immense size. The isle of Arran in Scotland also affords instances of the same variety. It is also found in Corsica, and is often called Corsica granite.

20 Stratified.

It has been doubted by some geologists, whether the true granite is ever found stratified; but numerous instances of its stratification have been lately adduced, that leave no room to doubt that this is sometimes the case. Pallas takes notice of some stratified granite on the banks of the river Berda, where what he considered as perfect primitive granite, compactly crystallized, is disposed in layers of various degrees of thickness, some not exceeding one-eighth of an inch, and bounded both above and below by blocks of solid granite †. Again, on the banks of the Gromoklea, he observed similar layers of granite running in a direction from north to south, each bed being from one span to three feet six inches in breadth, and consisting of the most perfect primitive granite, which he considers as a continuation of that mineral tract which produces the cataracts of the Dnieper ‡. Mr Playfair mentions an example of stratified granite which he saw in Chorley forest in Leicestershire, where real granite is disposed in beds on the eastern border of the forest, especially near Mount Sorrel. Another instance of real granite disposed in regular beds, is also mentioned by Mr Playfair as occurring near the village of Priestlaw in Berwickshire||. Mr Jameson observed the Riesengebirge, which separates Silesia from Bohemia, to be for 150 miles composed of granite disposed in horizontal strata, and he observed a similar stratification in Saxony and Lusatia §.

† *Pallas Trav.* i. p. 5..

‡ *Ibid.* ii. p.

|| *Playfair's Illustrations*, 328.

§ *Nic. Jour.* vol. ..

Granite constitutes the base of most of the British mountains, but is more commonly met with in the north and western parts of the island. There is a considerable mass of granite which runs longitudinally through Cornwall, from Dartmore to the Land's End *. Considerable masses are found in Scotland, but their extent has not been accurately ascertained. According to Mr Playfair, there is no mass of any magnitude in the southern parts, except that of Galloway, which occurs in two pretty large insulated tracts. Mr Playfair thinks that Dr Hutton greatly underrated the quantity of granite in Scotland, which, especially in the north, he considers as extending over a large district. If we suppose a line to be drawn from a few miles south of Aberdeen, to a few miles south of Fort William, it will, according to Mr Playfair, mark out the central chain of the Grampians, along which line there are many granite mountains, and large tracts in which granite is the prevailing rock †.

* *Playfair*, 310.

† *Illustrations*, 346.

It is remarkable that in the mountainous regions of Peru, especially in the environs of the volcanoes, no granite is found, except in very low situations, at the bottoms of valleys ‡.

‡ *Ann. ... Mus.* tom. 399.

Decay of granite.

Several varieties of granite are subject to decay, from the decomposition of the feldspar which they contain. This circumstance will probably explain a curious fact. It is found that the granite existing in the interior of mountains is much softer than that near the surface, probably from the decay of the feldspar in the latter, while it remains in its original state in the former (B).

Granite

(B) The decomposition of granite appears to go through several stages, from the solid rock to the loose sand. These

[Arr]ange-[men]t, &c. [of th]e Ma-[ter]ials of [the] Earth. Granite is by no means abundant in metallic and the richer mineral substances; it, however, contains a considerable variety, some of which have as yet been found in no other substance, especially molybdena. Iron ores are very commonly found in granite, especially the

23 [Met]als [foun]d in [gra]nite. compact brown iron stone. It seems to be owing to the presence of iron that granite assumes that fine reddish colour with which we sometimes see it tinged. One of the most remarkable instances of this kind is afforded by the rocks to the south-east of the valley of Chamouni, at the foot of the Alps. These rocks, from their red appearance, are called *Les Aiguilles Rouges*, or the red needles. These rocks were mentioned by Saussure, but he had not ascertained their composition. This has since been done by M. Berger, who found them to be composed of granite, with a considerable quantity of oxide of iron *. Bismuth, cobalt, blende, galena (an ore of lead), and several ores of copper, are also sometimes met with; but the metal most frequently found in granite is tin, especially in the great mining field in Cornwall.

* *[J]our. de [Ph]ys. tom.* p. 277.

Sect. II. *Gneiss.*

24 [Gne]iss de[scri]bed. Gneiss, by some writers called *kneiss*, is not unfrequently confounded with granite, from which it differs rather in the arrangement than in the nature of its component parts. These in gneiss are arranged in a schistose or slaty form, whereas in granite, they are in distinct grains or crystals, the layers being generally in the direction of the mica. It sometimes is intimately incorporated with masses of granite, but, in most instances, it reposes on the granite, being generally the second layer. In descending into the valley of Chamouni, Saussure observed a fine bed of true granite incorporated with a rock of gneiss, which was arranged in very fine leaves †. Sometimes the gneiss lies entirely below the granite; but this is uncommon. More generally there is found a vertical mass of granite, with strata of gneiss on each side of it. Very frequently granite and gneiss alternate with each other.

† *[Vo]yage [des] Alpes,* [..]6.

25 [Whe]re [foun]d. Sometimes whole mountains are composed of gneiss. Thus Ben Lomond scarcely contains any other substance, and the Schaw, which is the most northern point of the northernmost of the Shetland islands, is entirely gneiss. Mountains of this kind are, in general, neither so high nor so steep as those of granite, though Mount Rosa in Italy, and a few others, must be excepted. The summits of these mountains are also generally more rounded than those of granite mountains. The bases of all the Shetland islands seem chiefly composed of gneiss, and the middle part of the Pyrenees is almost wholly formed of this and granite.

It is curious that where gneiss is contiguous to granite, its quartz and feldspar are more apparent, and the mica less so; while, where it is more distant from granite, the contrary happens ‡. Arrangement, &c. of the Materials of the Earth.

Several metallic ores are found in gneiss, particularly those of iron, as the magnetic iron stone, and martial pyrites; lead ores, tin ores, blende, cobalt, copper, and arsenical pyrites, and not unfrequently silver ores. 26 Metals found in gneiss.

‡ *Kirwan's Essays,* p. 175.

Sect. III. *Micaceous Schistus.*

This is otherwise called *schistose mica*, and *mica slate*. It is also composed of the same materials with granite and gneiss, except that it contains little or no feldspar; the quartz and mica being arranged in layers as in gneiss. 27 Micaceous schistus.

This substance also is very abundant in most rocks and mountains. It generally composes the third layer or stratum, being immediately above or without the gneiss. It not uncommonly appears to be the only substance composing the hill or mountain, from the gneiss and granite being probably so completely covered as to be out of sight.

Micaceous schistus composes the rocks that are found immediately to the north of Dunkeld in Scotland, and it is here penetrated in every direction by veins of quartz. The southern shores of Loch Tay, the mountains of Glen Lochy, the vale of Tumel between Loch Tumel and Loch Rannoch, contain much of the same substance; and the lower part of Glen Tilt is chiefly composed of it. In the western Highlands towards Ben Lomond, micaceous schistus also abounds, and some of it is found in the north of Argyleshire. The Shetland islands are mostly composed of micaceous schistus, in thick layers above the gneiss, with a few masses of granite interspersed. 28 Where found.

It not unfrequently happens that a bed of micaceous schistus is intersected by veins of granite. Mr Jameson observed an example of this in Glen Drummond in Badenoch, of which he has given a plate. The veins are very large, and run across the strata of schistus in a direction nearly parallel to each other *.

* *Min. of the Isles,* vol. ii. p. 173.

The metallic ores found in micaceous schistus, are chiefly those of iron, copper, tin, lead, cobalt, and antimony. 29 Metals in it.

Sect. IV. *Quartz.*

Quartz is not unfrequently found distinct from feldspar and mica, and sometimes whole mountains are found composed of it. In particular, the mountain of Kultuc, at the south-east end of the lake of Baikal, among the Altaischan mountains, which is 4800 feet long, 350 high, and above 4000 broad, consists entirely of milk-white quartz; and the mountain of Flinzberg 30 Quartz.

These are thus marked by Mr Jameson. In its beginning disintegration it splits into masses, having a greater or less tendency to the quadrangular form; but these masses have still a degree of connexion amongst themselves, as is the case upon the mountain top. The next step is the enlargement of the fissures, by which the masses are loosened from their connexion, and tumble down from their elevated situations, upon the summits of the neighbouring mountains, or are hurried with impetuous velocity down the mountain side, covering the bottom of the glens with their stupendous ruins. Lastly, These detached masses, by the action of the weather, are completely disintegrated, forming a loose sand, which is left upon the tops or sides of the mountains, or is carried in great quantities to the sea shore by the torrents. *Jameson's Mineralogy of the Scottish Isles,* vol. i. p. 82.

Arrangement, &c. of the Materials of the Earth.

berg in Lusace, is almost wholly composed of it. There is also an extensive ridge of quartz, some miles long, in Bavaria, and Monnet mentions a rock of it 60 feet high. Mountains of it are also found in Thuringia, Silesia, and Saxony. It sometimes forms layers between gneiss and micaceous schistus. A considerable body of granular quartz is found lying under micaceous schistus in the island of Islay, see fig. 4. *b*. It is often found forming spires on the tops of mountains, and appearing like snow.

Quartz is found in several parts of Britain; but there is very little of it in the southern part of the island. Williams found it very common in the Highlands of Scotland, where he has seen it regularly stratified, with other regular strata immediately above and below it; and sometimes composing high mountains entirely of its own strata. These strata are sometimes moderately solid; but often are naturally broken into small irregular masses, with sharp angles, and of a uniformly fine granulated texture, resembling the finest loaf sugar.

There are large and high mountains of this stone in the shires of Ross and Inverness; and in a clear day these appear at a distance as white as snow, being quite bare of vegetation, except a little dry heath around the base of the hill *.

* *Williams' Mineral Kingdom*, vol. ii. p. 52.

The mountain of Swetlaia Gera, one of the Uralian chain, consists of round grains of quartz, white and transparent, and of the size of a pea, united without any cement.

31 No metals in quartz.

No metals are found in quartz, though it sometimes contains petroleum.

Sect. V. *Argillaceous Schistus.*

32 Argillaceous schistus described.

This stone, which is otherwise called *clay slate*, is the *thonchieffer* of Werner, and the *argillite* of Kirwan. It is of the same nature with gneiss and micaceous schistus; but in this the stratification is still more complete, and all traces of crystallized granite entirely disappear. Doubts have arisen whether this stone is primitive; but these are now cleared up, as it is frequently found alternating with gneiss and micaceous schistus, especially in Saxony, and with other primitive strata. It sometimes happens, too, that both gneiss and granite rest upon it.

There are two varieties of this stone, one hard, and the other soft; but the hard often graduates into the softer.

33 Where found.

Sometimes this stone is found forming whole mountains; but more commonly it enters into them only partially. In some, however, there are entire strata of it, as at Zillerthal, in the Tyrol. The famous mountains of Potosi consist entirely of argillaceous schistus, and Saussure found it on the summit of Mont Blanc.

In Britain it is not very common; but is sometimes found on the higher parts of mountains. Thus it forms the summit of Skiddaw in Cumberland.

34 Metals found in

Argillaceous schistus, especially the softer variety, is remarkably rich in metals. We have said that it forms the greater part of Potosi, one of the richest silver mines. The ores of copper and lead, sulphur, pyrites, blende, and calamine, are also found in it. The great body of copper ore in the Parys mountain in Anglesea, is found below this substance. It also sometimes contains antimonial and mercurial ores.

Sect. VI. *Jasper.*

35 Jasper described.

It was supposed, by the earlier mineralogists of the last century, that jasper was only pure quartz, so much penetrated by a colouring metallic oxide as entirely to deprive it of its transparency; but Saussure and Dolomieu, with their usual accuracy, discovered that it consists of flint, and not of pure quartz, having in combination a quantity of argillaceous matter, more or less mixed with oxide of iron.

Primitive jasper is always opaque. It is commonly found imbedded in other stony matters. In colour it varies from red to green, and frequently consists of alternate stripes of red and green, sometimes perfectly distinct, at others running together. There is a beautiful variety figured by Patrin, in which a dark-red ground is crossed in every direction with curved white lines, leaving here and there circular spaces of red surrounded with white, forming eyes.

36 Where found.

Striped jasper is sometimes so abundant, as to be the chief material of some mountains, in which it is mixed with broken fragments of granite and other primary compounds (c). Mountains of red and green jasper also occur. Generally, however, it appears in strata, interposed between layers of micaceous schistus, or alternating, and sometimes mixed with compact red iron stone. It is found in the south of France, reposing on granite; and in the Altaischan mountains, it sometimes lies below argillaceous schistus, but has there never been found in contact with granite. A coarse kind of jasper is sometimes found in the hills near Edinburgh; and some fine specimens are met with in the northern mountains.

Sect. VII. *Hornstone.*

37 Hornstone described.

This stone is considered by Mr Kirwan as the same with *petrosilex*, but Patrin and some others distinguish them.

(c) There is often found interspersed between the strata of rocks, or sometimes above the upper stratum, a bed of fragments that have been broken off from the principal strata. When these fragments chiefly consist of limestone and calcareous compounds, whether they be of an angular form, or consist of rounded pebbles, they are generally called by the name of *breccia*; but when the fragments are of a siliceous or quartzy nature, especially if they are agglutinated together, so as to form a solid mass, they have usually been called *pudding stone*. From the uncertain manner in which these terms were employed, much confusion arose, till Romé de l'Isle, and other later naturalists, have given the name of breccia to every stony mass that is composed of angular fragments, of whatever nature they be; and they call by the name of puddingstone every agglutinated mass that is composed of round pebbles, whether they be calcareous, quartzose, or of any other nature. These compounds will be spoken of presently in a separate section.

them. According to Patrin, hornstone is a compound primitive rock, composed of the same elements with granite, in which schorl is very abundant, communicating to the stone a dull gray, or sometimes blackish, colour, and containing a pretty large quantity of the argillaceous matter of mica. Petrosilex, according to him, is purer than hornstone, and commonly of a grayish or greenish colour, semitransparent, and very hard, so as to give fire with steel. They are often found united, and sometimes form entire mountains, containing fragments of feldspar interspersed. They are commonly found in large thick masses or blocks, though they are sometimes stratified like the schistose stones. Dolomieu is mistaken, when he asserts that petrosilex is only found in primitive mountains, is it will appear hereafter, that it is sometimes a secondary compound. At Tuhumas, in the isle of Rona, Mr Jameson found a mass of rock chiefly composed of hornstone and quartz, from 12 to 15 feet wide, and of considerable length, lying between two beds of gneiss.

SECT. VIII. *Pitchstone.*

THE Germans have given the name of *pitchstone*, or *pechstein*, to a stony matter, which is found in large masses of an irregular form, and of different colours, as yellow, brown, red, green, &c. having sometimes the appearance of rosin, and sometimes that of an enamel, or of glass imperfectly transparent. It is never crystallized.

It is found, either in large masses, or in veins. At Misnia, it is found forming entire mountains; and in other countries there are mountains containing strata of pitchstone, sometimes alternating with granite, at others with porphyry. Mr Jameson describes a large vein of it of a green colour, several feet wide, traversing a mass of red argillaceons sandstone, at Tormore in the isle of Arran. This vein is extremely curious, and contains stratulæ of different substances deposited in the same fissure *. Another curious vein of pitchstone is described by him as traversing a basaltic rock, together with a vein of hornstone, in the island of Eigg†. Mr Jameson considers this as the first example of pitchstone traversing basalt, discovered in Europe, though similar appearances have been found on the top of the peak of Teneriffe.

Pitchstone is only considered as a primitive rock, when it is nearly allied to porphyry.

SECT. IX. *Hornblende, and Hornblende Slate.*

HORNBLENDE is sometimes found existing separately from the compounds in which it usually occurs, as is the case in Siberia, where there are mountains of black hornblende. It is often found mixed with quartz, mica, feldspar, or schorl, of a greenish or black colour. More commonly, however, it occurs in immense strata, sometimes in layers of gneiss, argillaceous schistus, or primitive limestone. A stratum of it above primitive limestone has been found at Miltiz. It is sometimes seen below granite, or granite is even found imbedded in it. A rock of hornblende, reposing on granite, has been seen by Mr Jameson in the isle of Arran; and on the side of Loch Fine he found it alternating with strata of micaceous schistus ‡.

The principal metallic substances found in hornblende slate, are native sulphuret of iron and copper ore. Arrangement, &c. of the Materials of the Earth.

SECT. X. *Serpentine.*

SERPENTINE is a stone of a similar nature with respect to its ingredients with those we have been describing. It takes its name from its appearance, being generally of a greenish ground, marked with white, yellow, brown, or reddish spots, so as to bear some resemblance to the skin of a snake. Its green colour is owing to a quantity of slightly oxidated iron which it contains. It is usually opaque; but sometimes parts of it are semitransparent, and though not very hard, is capable of receiving a good polish.

41 Metals found in it.
42 Serpentine described.

Serpentine is by no means uncommon, and is often found in layers alternating with primitive limestone, or below gneiss. The hill of Zobtenbeg in Lower Silesia, consists almost entirely of serpentine, disposed in nearly vertical strata, with a little hornblende interspersed. Whole mountains of green serpentine are also found in Siberia, and near Genoa, where it is called *gabbro* or *pulverezza*. It is also found near the White sea, and the mountain of Regelberg in Germany is chiefly composed of it. Rocks of it are found near the Lizard Point, on the coast of Cornwall; and hills of it occur in some of the Shetland islands. 43 Where found.

Metals are seldom found in serpentine, except a magnetic ore of iron, which not unfrequently forms a part of the serpentine rocks, imparting to them its magnetic power. Veins of copper sometimes traverse it.

SECT. XI. *Porphyry.*

PORPHYRY generally consists of the same materials as granite, but in different proportions, and having altogether a different appearance; for instead of being crystallized as in granite, we find in the true porphyries an uniform compact mass, in which are disseminated small crystals of feldspar, and sometimes of schorl. There are, however, many varieties forming shades between granite and true porphyry, several of which are described by mineralogists. 44 Porphyry described.

Porphyry is very abundant in many situations, forming a considerable part of hills, and even mountains. It sometimes alternates with gneiss, and has been found below it. Gneiss has also been found in the midst of porphyry. It sometimes occurs in the midst of micaceous schistus, and sometimes forms an external covering to other primitive strata. Whole mountains of porphyry, arranged in immense strata, sometimes repose on a base of granite or gneiss. This stone is found in the greatest abundance in several places between the tropics, especially in South America, where it is sometimes met with at immense heights*. 45 Where found.

Porphyry is very common in most parts of Scotland, and, in particular, forms a considerable stratum at the top of the Calton hill at Edinburgh, being in some places 12 or 15 yards thick, covering a bed of breccia.

Porphyry is found in considerable quantity between Newcastle and Wooler, and blocks of it of considerable size may be every where seen scattered about in the fields. The feldspar of these porphyries being less durable than the rest of the stone, is partly destroyed in some

* Ann. de Mus. Nat. vol. iii. p. 400.

Arrangement, &c. of the Materials of the Earth.

some blocks, and appears corroded in others; from which circumstance the porphyries are so porous, as to appear as if they had been burnt. Porphyries of a similar appearance are found in the mountain of Esterele in Provence, on the road from Frejus to Antibes *.

There is a variety of porphyry mentioned by Charpentier, a great part of whose composition is indurated clay, and nodules of clay of different colours are found in its substance. Specimens of a similar nature occur in the western islands of Scotland. There is also a species of porphyry nearly allied to hornstone.

* *Saint-fond's Travels*, vol. I. p. 164.

46 Metals found in it.

The two varieties last mentioned are rich in metallic ores; in the former there being formed ores of silver, copper, iron, lead, and antimony; and, in the latter, sparry iron ore, native sulphuret of iron, galena, black blende, and ores of bismuth.

47 Schistose porphyry.

A stone of a porphyritic nature is described by Werner under the name of *schistose porphyry*, and is considered by Kirwan as the same with the horn slate of Charpentier. It is found among the primitive rocks of Altai, and on the borders of the lake of Baikal, in which latter place it is mixed with granite and hornblende. It is also found in Siberia, and in Bohemia. Saussure found it near Psaffensprung, intercepted between strata of gneiss.

48 Puddingstone and breccia.

Sect. XII. *Puddingstone and Breccia.*

49 Examples of breccia.

The distinction between these two stony matters was mentioned in note C: they are both sufficiently common, consisting of different materials. The breccia usually lies in bodies, almost at the top of the other primitive strata, with some of which it sometimes alternates. Stratified breccias, consisting of fragments of flints and jasper, cemented by hardened clay, are frequently found in Siberia, and sometimes alternate strata of breccia, porphyry, jasper, and other primary compounds, compose a considerable part of mountains. Some mountains in the north of Scotland contain masses of breccia, composed of fragments of red granite, micaceous schistus, and quartz, in a base of sandstone. Mount Scuraben contains strata of this kind, surmounted by a rock of white quartz. Similar appearances take place at Cromarty, at Murray frith, and two or three miles to the south of Aberdeen; but in many of these instances the breccia must be considered as secondary. Much of the northern coast of Scotland abounds with breccia.

50 Of puddingstone.

Puddingstone is also extremely common. A mountain of it is found in Siberia, near the rivulet of Tulat, being composed of fragments of jasper, chalcedony, aigue marine, and cornelian, cemented by a quartzose matter. Immense heaps, and even a mountain of puddingstone, are found at Meisenheim, in the Palatinate. Puddingstone is found in considerable abundance in passing from Loch Ness to Oban, in Scotland, and between Inverness and Dunolla. Large detached rocks of puddingstone were seen by Pallas in the village of Temirdski, in the Crimea. Some of these masses are seven or eight fathoms long, lying one above another †.

† *Pallas's Trav. in Crimea*, vol. ii. p. 197.

Sect. XIII. *Syenite.*

51 Syenite.

This name has been introduced by Werner, to denote a primary rock, essentially composed of grains of feldspar and hornblende, intimately blended together, in which the hornblende is generally most predominant. He first called it *greenstone*, but afterwards gave it the name of *syenite*, as he supposed it similar to a stone described by Pliny, as found at Syene in Upper Egypt, where it was dug in great quantities, and from thence carried to Rome, for the purpose of building public edifices.

Syenite sometimes contains a few grains of quartz and mica; but these seem to be accidental, and are always in very small quantity. This stone is not commonly stratified.

Syenite usually overlays most of the other primary rocks, and has often a bed of breccia interposed between it and the inferior strata. It is very commonly found reposing on porphyry.

Where found.

It is found in Saxony, in the environs of Dresden; at Meissen in Thuringia; in Hungary, and in general in almost all primitive chains of mountains, especially in the Alps. It is doubtless the same which Saussure found in the summit of Mont Blanc, and which he calls *granitelle*.

Metals in it.

Metallic veins are not unfrequently found in syenite. At Scharffenberg, veins of silver and lead are found in it; and it is said, that the veins of strontian in Argyleshire run in a similar rock.

Sect. XIV. *Primitive or Granular Limestone.*

Primitive limestone.

It was long doubted whether limestone was ever to be found unmixed with organic remains, or primitive; but the observations of late mineralogists and geologists have fully proved, that primitive limestone exists in considerable quantity. This stone is of granular structure, and of a whitish gray colour, though frequently of a dark iron gray, or reddish brown. It is sometimes scaly or lamellar; at others nearly compact, and is now and then found to have a splintery fracture. It is generally unmixed with other primary compounds; but sometimes particles of mica, quartz, hornblende, &c. occur in it.

Where found.

This stone is always found alternating with the primary strata, especially with gneiss, micaceous, and argillaceous schistus. It sometimes forms whole mountains, as in Stiria, Carinthia, and Carniola, in Switzerland and in the Pyrenees, being often found seven or eight thousand feet high. Three mountains in Switzerland, all exceeding 10,000 feet in height, are chiefly composed of it. In these situations it commonly forms immense blocks, without any regular dip or direction; but it is sometimes stratified, as at Altenberg near the lake of Neuenberg. It is sometimes interposed between syenite and hornblende slate. One of the most singular mountains of granular limestone is that of Filabres in Spain, consisting of a block of white marble three miles in circumference, and 2000 feet high, without any mixture of other earths or stones, and with scarcely any fissure.

A considerable part of Mont Perdu in the Pyrenees is composed of alternate vertical bands of granite, porphyry, limestone, hornblende, and petrosilex.

Granular limestone is found in various parts of Britain, especially in the north of Scotland. One of the most remarkable examples of it occurs in the island of Islay;

Islay; the central part of which is formed of a compact bed of it of considerable extent. See fig. 4. *d*. It also occurs in some other of the Western isles.

Primitive limestone often contains veins of metallic ore, especially those of galena, magnetic iron ore, blende, and pyrites.

Metals in it.

Sect. XV. *Primitive Trap.*

Primitive trap described.

Trap is a name that was long ago given by the Swedish mineralogists, to distinguish certain stones that are of a compact texture, and a dark colour, composing part of several mountains. The word originally signifies a staircase, and was given to mountains containing this stone, because their strata retire one behind the other like the steps of a staircase. But as many rocks of a very different kind, both in their nature and formation, have received the common name of *trap*, considerable confusion arose among mineralogists, with respect to what particular stones should receive this appellation. Most of the French mineralogists, as Saussure, Dolomieu, and Saintfond, make trap to signify a primitive rock, but they do not always mean the same rock. Other mineralogists, especially the Germans, understand by the name of trap, certain secondary rocks, and especially what are commonly called *basalts*.

Werner comprehends under the name of trap, several series of rocks, which are principally characterized by their containing hornblende, which is found almost pure in those which he considers as the most ancient, or what generally lie the lowest; and it degenerates gradually in the succeeding strata into a kind of blackish, ferruginous, hardened clay. He distinguishes three series or formations of traps; primitive traps, transition or intermediate traps, and stratiform or floetz traps. We shall here consider the first of these.

Primitive trap is almost wholly composed of hornblende, though it is sometimes mixed with feldspar, or more rarely with mica and some other substances. Under this general description Werner comprehends four stony substances; hornblende and hornblende slate, which we have already noticed in Section IX. primitive greenstone, and schistose greenstone.

Primitive greenstone is a mixture of hornblende and feldspar; under this there are several varieties, according as its texture is more or less granular, or compact. 1. Common greenstone, in which the hornblende and feldspar are intimately blended, is granular, and bears considerable resemblance to syenite, in which the hornblende is predominant. 2. A second variety has smaller grains, in which are imbedded crystals of feldspar, being of a structure between the granular and porphyritic. 3. A third variety has the grains of hornblende and feldspar extremely small, so as to be scarcely distinguishable. This stone loses its granular appearance, and becomes entirely porphyritic. 4. Lastly, when the mass becomes quite homogeneous, and of a complete green colour, it forms what was once called *green porphyry*, and constitutes the fourth variety †.

† Brochant, Mineral. tom. ii. p. 582.

Schistose greenstone is composed of compact feldspar, hornblende, and a little mica, of which the hornblende and feldspar are nearly in equal quantity, and it now and then contains a little quartz. Its structure is schistose.

We have been thus particular in describing what Werner understands by primitive trap, as whatever may be thought of his theoretical opinions, his talent for mineralogical distinctions and characters cannot be called in question.

Arrangement, &c. of the Materials of the Earth.

Mr Kirwan has given a long section on the distinguishing characters of trap, and its relation to basalt, &c. in his Geological Essays. He thinks that there might be formed a natural series of stones of a trap nature, taking in not only the composition, but also the texture, grain, and specific gravity, as something of this kind has been conceived and done by Werner.

58 Where found.

Primitive trap is often found in vast strata in the midst of gneiss, and veins of it running through gneiss, have been found in Knobsdorf in Silesia, and in Bohemia. It is also sometimes found in granite, and it is found passing through granite and micaceous schistus in the Western isles of Scotland. Saintfond found it alternating with granite, near St Malo; and Charpentier, with gneiss. It sometimes forms entire mountains, as in the territory of Deux Ponts; and in Norway it is found reposing on granite. It sometimes alternates with argillaceous schistus, as at Leidenburgh.

59 Metals found in it.

Primitive trap frequently contains metals, especially the ores of iron and copper.

Sect. XVI. *Topaz Rock.*

60 Topaz rock.

This stone is composed of quartz, schorl, topaz, and lithomarga, (a kind of hardened clay) the three former substances constituting small layers or plates alternating with each other. It sometimes contains cavities or geods, lined on the inside with crystals of quartz and topazes. The texture of this stone is between the schistose and the granular; that is, it is composed of plates or laminæ; but these laminæ are of a granular structure.

Topaz rock is very rare. It forms part of a mountain near Averbach, in the metallic mountains of Saxony; but no metallic matter has hitherto been discovered in it.

Sect. XVII. *Siliceous Schistus.*

61 Siliceous schistus described.

Siliceous schistus, or flinty slate, is the kieselschiefer of Werner; but there seems some dispute between his disciples, whether it be a primitive or a secondary rock; on which account we have placed it last in the former series. Brochant does the same; but Mr Jameson, in his sketch of the Wernerian geognosy, places it among the transition formations, or those which immediately succeed the primitive. It is thus described by Mr Jameson. Its colour is bluish gray; it is internally dull; its fracture in the great is imperfectly slaty; in the small, large splintery, passing into flat conchoidal; its fragments are indeterminately angular, and pretty sharp edged; it is strongly translucent on the edges; it is hard and brittle, difficultly frangible, and not particularly heavy *.

* *Jameson's Min. of Dumfries*, p. 48.

62 Where found.

An entire mountain formed of this stone is found in Lusatia, in which there are no petrifactions. It is also found in the Alps, interposed between gneiss and hornstone. Schlendgenberg, a mountain in Saxony, is for the most part composed of it, mixed with hornblende and feldspar. Kirwan considers it as the same substance

Arrangement, &c. of the Materials of the Earth.

stance which Saussure calls *palaiopetre*, which is commonly considered as petrosilex.

Flinty slate is described by Mr Jameson as among the mineral substances found in Dumfrieshire. He particularly notices an immense rocky mass of it at the entrance of the valley at Leadhills, by which the metallic veins are completely interrupted *.

No metals have been fonnd in it.

* *Mineralogy of Dumfries*, p. 64.

B. Secondary Compounds.

63 Secondary compounds.

THE substances which we are now to notice are distinguished from those which we have been describing, in containing more or less the remains of organized beings. As the inferior strata of these secondary compounds usually contain fewer organic remains than those above them, they are sometimes subdivided into two orders, one of which is considered to be intermediate between the primary and secondary strata. This is Werner's classification, of which we shall give an account in the next chapter.

SECT. XVIII. *Secondary Limestone.*

64 Secondary limestone described.

UNDER this title we shall comprehend what Werner calls transition limestone, floetz limestone, and limestone. Secondary limestone is a calcareous mass, sometimes granular, and sometimes compact, the former approaching to primitive limestone. Its fracture is scaly, and it is sometimes semitransparent. In colour it is very various, sometimes red, or rather blackish, with white veins, consisting of calcareous spar. It is often of a grayish cast. It sometimes forms vast blocks, without any appearance of stratification ; at other times it is evidently stratified. It abounds with remains of marine animals, and often contains nodules of agate, and other similar stones.

A variety of calcareous stone is described by mineralogists under the name of swinestone. It is either compact, slaty, or porous, and is said in general to contain no petrifactions, though some found in the mountain of Kinneculla contains many. It is considered by Kirwan as primeval limestone, impregnated with petroleum.

Limestone is sometimes found in oviform balls, commonly containing a grain of sand in them.

There is a variety of limestone that is very porons, and abounds in remains of vegetable matter, as impressions of leaves, &c.

65 Where found.

Secondary limestone is very abundant in most parts of the world, forming a considerable part of many mountains, and being often the principal stratum to a considerable depth below the surface. The mountain Iberg, in the Hartz, is composed of vast masses of it, irregularly rifted ; and mountains of a similar kind are found in Siberia and in the Vivarais. In some of those mountains vast caverns have been formed. Secondary limestone mountains always repose on some primitive stone ; thus, in Siberia their base consists of granite, porphyry or hornblende ; in Saxony, of granite, or granular limestone, and sometimes of argillaceous schistus ; in Switzerland, these mountains repose on argillaceous schistus or gneiss, or sometimes on calcareous puddingstone. In the Crimea, there is an immense extent of secondary limestone, between Roslof and Perekop, which is minutely described by Pallas. Great part of the summit of Mont Perdu, the highest of the Pyrenees, is composed of secondary limestone, arranged in nearly vertical strata, and so full of the remains of marine animals as in some places to appear as if composed of nothing else. Here it seems to repose on granular limestone.

The base of Mount Ingleborough in Yorkshire, which is near 30 miles in circuit, consists entirely of limestone, containing vast quantities of sea shells. This stone also forms the principal inferior strata through the greater part of Derbyshire, being arranged in beds of various degrees of thickness, from a few inches to about 200 fathoms in some places, not having been perforated; and abounding with shells, and other marine remains.

It is found in many quarries in Scotland distinctly stratified. Mr Jameson notices quarries of limestone at Closeburn, and Barjarg, and at Kellhead in Dumfriesshire.

66 Metals found in it.

Secondary limestone often contains metallic veins, especially in Derbyshire, where it abounds with galena, blende, sulphur pyrites, and copper pyrites. Sulphur is also sometimes found in it. Kirwan remarks, that in the rest of Europe limestone is seldom metalliferous.

67 Alabaster.

The stone commonly called *alabaster*, employed in making statues and ornaments, is properly a carbonated lime, nearly allied to marble ; though it is usually supposed to be a variety of gypsum or plaster stone. There is a gypseous alabaster that will be noticed presently.

Calcareous alabaster is not often white (though *as white as alabaster* is a common proverb), but generally tinctured with iron of a yellow, brown, or reddish cast. It is semipellucid, and usually so soft as to be scratched by the nail.

It is commonly found in blocks, in marble quarries, as in the island of Paros, and in several parts of Italy, particularly in the territory of Volterra in Tuscany, in Malta, &c. A variety is found in the form of stalactites of a conical or cylindrical form.

SECT. XIX. *Gray Wacke.*

68 Gray wacke described.

GRAY wacke is a stone composed of fragments of quartz and argillaceous schistus, cemented by an argillaceous matter similar to the schistus, varying in size, from that of a hen's egg, till they are so minute as to be no longer visible. It sometimes contains a matter similar to siliceons schistus.

There is a variety of this stone, called by Werner gray wacke slate, which is a simple slaty stone, which bears a considerable resemblance to argillaceous schistus. From this, however, it is to be distinguished, according to Mr Jameson, by the following characters.

" It has seldom a greenish or light yellowish gray colour, as is the case with primitive slate, but is usually ash and smoke gray. It does not shew the silvery continuous lustre of primitive clay slate, but is rather glimmering, which originates from intermixed scales of mica. Quartz scarcely occurs in it in layers, but usually traverses it in the form of veins. Further we do not find crystals of feldspar, schorl, talc, chlorite slate, or magnetic iron stone are to be observed in it. It contains petrifactions, particularly those varieties that border on gray wacke. It alternates with gray wacke *."

These stones are distinctly stratified, but the direction

* *Mineralogy of Dumf*...

of their strata is not parallel to that of the other rocks on which they lie. They are very commonly found covering limestone, especially at the foot of mountains.

Gray wacke is found in Erzgebirge, at Braunsdorf, Riesberg, and Averbach, in Voegtland, in Transylvania, on the banks of the Rhine, in Lahnthal, and some other places in Germany. It is also found in Britain; and Mr Jameson notices it among the minerals of Dumfries-shire, where the gray wacke slate is found near Moffat, in the vicinity of Langholm, in the higher parts of the valley of Esk, and behind Burnswark. The strata found in these places yield a very good slate, nearly free from mechanical mixture, and well adapted to the roofing of houses.

This species of stone is rich in metals; the greater part of the veins of lead and silver in the Hartz, especially those of Clausthal and Zellerfeld, are in gray wacke. In Transylvania, in Vorespath, it contains even rich mines of gold. The gray wacke strata on the banks of the Rhine are also traversed by some metallic veins, but those of Saxony contain nothing but blind coal.

Sect. XX. *Secondary Trap.*

Several varieties of trap occur among the secondary strata, and must be here enumerated. They all consist principally of greenstone, or that mixture of hornblende and feldspar, which constitutes the primitive traps, noticed in Section XV. but in the traps we are now to mention, the mixture is much more intimate, the grains considerably finer, and the mass appears homogeneous. We shall here notice only three principal varieties; the amygdaloid or toadstone, the globular trap, and the greenstone, called by the Wernerians transition greenstone.

1. The amygdaloid, called in Derbyshire toadstone, and sometimes *cat dirt*, appears to consist of hornblende slate in a state of decomposition, and appears very similar to a kind of wacke, of a very fine grain. It is of a blackish colour, and very hard, and often contains a number of bladder holes, which are sometimes entirely empty, at others are partially or wholly filled with spar.

It runs in immense solid beds, without any appearance of stratification or fissure, of unequal thickness, having been seen from 6 feet to 600 thick. It commonly alternates with the strata of secondary limestone, as in Derbyshire, and sometimes seems to penetrate the inferior stratum of limestone to a very considerable depth. It contains no metallic veins, and it is said entirely to intercept those which it passes in the limestone strata. Saintfond affirms that lead ore is sometimes found in cat dirt; but he seems to have been deceived by the vagueness of the term, as the miners of Derbyshire give the same name to a greenish variety of limestone, which is sometimes traversed by veins of lead ore.

2. Globular trap. This is a schistose greenstone, partially decomposed, and also resembles a fine-grained wacke; but it appears in the form of large balls, composed of concentric layers, with a hard nucleus. It is found at Altenzulze in Voegtland, and some other places. It sometimes contains veins of copper and iron.

3. Greenstone. This is almost entirely composed of feldspar, usually of a pale flesh-red colour, having sometimes imbedded in it grains of grayish quartz, scales of iron, blackish mica, and crystals of pale flesh-coloured feldspar. This rock may be confounded with porphyry, or with feldspar; but is generally considered as different from both. Mr Jameson found it in beds from three to twelve feet thick on the upper side of the Susanna vein in the valley of Leadhills, and in the mountain between Wamphray and Eskdalemuir.

Sect. XXI. *Sandstone, or Grit.*

These terms, like many others which we meet with in mineralogy, are very vague and indefinite, and are used to denote three or four kinds of stone; a calcareous, an argillaceous, and a siliceous sandstone. We shall here consider only two of them, the argillaceous and the siliceous. 75 Sandstone.

1. Argillaceous sandstone. This is the *sandstein* of Werner, and the argillaceous grit of the ordinary miners. It is composed of grains of quartz, and sometimes of siliceous schistus; more rarely of feldspar. These grains are of various sizes, and are cemented in an argillaceous matter, commonly containing iron: whence this stone is sometimes called *ferruginous* sandstone. From the coarseness or fineness of the grains, it receives the names of coarse and fine standstone. There is a very coarse kind found in Derbyshire; containing a considerable quantity of quartz pebbles. 76 Argillaceous sandstone.

This species of sandstone is found in immense beds, sometimes above 100 yards thick.

It is very distinctly stratified, and is commonly divided by fissures, into the shape of parallelopipeds. It sometimes alternates with layers of compact limestone, and often lies above a stone which we are immediately to mention, *shale* or *shiver*.

Sandstone is sometimes formed into globular concretions, composed of concentric lamellæ.

Sandstone is one of the most abundant products of nature, occurring in almost every country. In Britain it forms the uppermost stratum in many parts of Derbyshire; and in the isle of Arran there is an immense separate mass of it, forming what is called *the cock* †. In the same island it is found in Glenranza, reposing on secondary limestone. 77 Where found.

The globular concretions of sandstone are uncommon. Mr Jameson observed them in the isle of Skye, near the harbour of Portree ‡; and Reuss observed the same in Bohemia §.

This species of sandstone usually contains many petrifactions, but is generally not very abundant in metals; it however sometimes contains veins of cobalt.

2. Siliceous sandstone. This is a stone of a similar nature with the last, except that the cementing mass is also of a siliceous nature. It is found in the ports of Domica and Campara, in the isle of Arbe, and on the coast of Dalmatia, where it contains petrifactions. The hill of Platinburg consists of sandstone, with a chalcedony cement. Some fine specimens of siliceous sandstone are found in Salisbury Crags at Edinburgh, containing shells which have assumed the nature of chalcedony. It does not appear to contain metals. 78 Siliceous sandstone.

† Jameson's *Min. of the Isles*, vol. i. p. 76.

‡ *Mineral. of the Isles*, vol. ii. p. 87.

§ *Mineral. Geograph. von Bohmen*, vol. ii. s. 46.

Sect. XXII. *Gypsum, or Plasterstone.*

This is native sulphate of lime, and it appears in several forms. Six varieties are usually enumerated; common 79 Gypsum.

Arrangement, &c. of the Materials of the Earth.

mon gypsum, lenticular gypsum, crystallized gypsum, fibrous gypsum, stalactitic gypsum, and gypseous alabaster.

80 Common. 1. *Common gypsum* is a compact, granulated stone, commonly of a grayish colour, and mixed with impurities, containing a considerable quantity of carbonate of lime. Its texture is seldom laminated, but it appears like coarse loaf sugar. This kind is very abundant, many hills being entirely formed of it. Of these the most remarkable are the plasterhills in the neighbourhood of Paris, those in the canton of Bern in Switzerland, and others among the Alps. Hills of gypsum occur also in Spain and Poland; near the White sea; in Asia, where they are mostly in horizontal strata; in the north Archipelago, between Asia and America. Saussure found a mountain in Switzerland composed of gypsum, sand, and clay *. This kind sometimes contains petrifactions, and often abounds with the impressions of animal and vegetable matters; some very curious examples of which will be mentioned in a future section. It contains few metals, although copper is sometimes found in it, as are rock-salt and sulphur.

* *Voyage aux Alpes*, tom. ii. p. 528.

81 Lenticular. 2. *Lenticular gypsum* is a curious variety, which seems peculiar to Montmartre near Paris. In one of the banks in this mountain, specimens of it are found containing little lenticular bodies, distinct and disseminated through the stony matter, so as to form a great part of its mass. A specimen of this kind is figured by Patrin, in his natural history of minerals.

82 Crystallized. 3. The *crystallized gypsum* is also found chiefly in the environs of Paris, in crystals that are decaedral, or sometimes like a rhomboidal octaedron, with the pyramids truncated near the base.

83 Fibrous. 4. *Fibrous gypsum*, composed of short brittle threads disposed in bundles, is found in Derbyshire, and near Riom in Auvergne. A very beautiful variety, of a silky feel, and reticulated texture, is described by Patrin, as found in Poland, in the salt mines of Wielitska; in Russia, near the junction of the river Oka with the Wolga; in Spain; and in China,

A variety of gypsum with the appearance of vegetation is found in caverns near the baths at Matlock in Derbyshire. A beautiful specimen of it is figured by Patrin *.

* *Hist. Nat. de Miner.* tom. iii. p. 218.

84 Stalactitic. 5. Gypsum is sometimes found hanging from the sides and roof of caverns in the form of stalactites, a transverse section of which shews their internal structure to be radiated. This variety is commonly called *schlot* *.

† *Patrin ut supra*. p. 222.

85 Gypseous alabaster. 6. *Gypseous alabaster* is very similar to true alabaster, except that it does not, like that, effervesce with acids, and is in general not so strong. It is found in great abundance in Derbyshire in large masses, filling up cavities in argillaceous grit. It never forms a stratum, but is generally attended with gravel, red clay, and shells. Mr Mawe represents the lower portions as being very strong and compact, so as to form columns and pilasters ‡. This kind is also found in Franche Comté, and on the Marne about six leagues from Paris, at Lagny.

‡ *Mineral. of Derbysh.* p. 84.

Though from the ordinary form or situation of gypsum, and the organic remains so commonly found in it, there can be no doubt of its being in most cases a secondary rock; yet from its having been found mixed with mica in St Gothard, it is enumerated by some among the primary compounds.

Sect. XXIII. *Fluor Spar.*

86 Fluor spar described. This beautiful substance, which is native *fluat of lime*, is found either in large unformed masses or blocks, or crystallized in cubes or octaedrons. It is of different colours: but the most prevailing varieties are that in parallel zones or bands of green, blue, yellow, and white: and that in which a white ground is veined with a reddish brown. Some specimens are so shaded as to represent a geographical map; but these are very rare. It is so soft as to be easily turned in a lathe into those vases and other ornaments which are so commonly seen on chimneypieces.

87 Where found. Fluor spar is found in several countries of Europe, but especially in France and Britain. According to Patrin, there are mines of it in the primitive mountains of Gyromagny, in the Vosges, in the neighbourhood of Langeac, in Auvergne, and at Forez near Ambierle, that are inexhaustible §. It is also found in the mountain of Pilat not far from Lyons; among the rocks that skirt the valley of Chamouni in the Alps; in the Altaischan mountains of Asia; and in Greenland.

§ *Hist. Nat. de Min.* tom. ii. p. 288.

The most productive mines of this substance in Britain are in a mountain near Castleton in Derbyshire. Here there are two mines producing the beautiful compact fluor, called *Blue John*, which is found in pipe veins running in various directions. The fluor commonly rests upon limestone, and it frequently has this stone for a nucleus, round which it appears to have crystallized. Frequently, however, the centre is hollow. In several parts of the mine the fluor is found in detached masses, in caves filled with clay and loose adventitious matter, having the appearance as if it had been broken off from the limestone on which it had been formed; for every piece, in one form or other, seems as if it had adhered to something, and been broken off.

Some of the pieces of fluor are a foot thick, and have four or five different veins or zones: such large pieces are, however, very rare, and generally they are only three or four inches thick *.

* *Mawe's Mineral.* sect.

Saintfond, who has given an interesting account of the curiosities near Castleton, says, that fluor spar would be the most beautiful substance in nature, if it were but a little harder.

It is also found in Northumberland, in a vein among the granite mountains of Aberdeenshire †, and in one of the Shetland isles, in a vein of basalt ‡.

Fluor appears in some cases to be primitive. Thus it is found forming whole strata in the mountains of the forest of Thuringia, and in a vein of quartz in Upper Hungary.

† *Jameson's Min. of the Isles*, p. 15.
‡ *Ib.*

Sect. XXIV. *Chalk.*

Chalk. Chalk is too well known to require a description. It is not always white, but is frequently coloured. It is disposed in horizontal beds that are often many yards in thickness, and which always repose on layers of other calcareous stone of a harder structure. These beds are often of considerable extent, and very commonly

Arrangement, &c. of the Materials of the Earth.

ly contain flints, oviform limestone, and vast quantities of shells.

89 Where found.

Chalk, which is so abundant in some countries, is scarcely found in others. It is well known that the south and south-eastern parts of England, and the south and south-west of France contain vast cliffs and beds of it; much of it is also found in Zealand. It is, we believe, a rare production in Scotland, and in most mountainous tracts. It has been remarked by Pennant, that if a line be drawn from Dorchester in the county of Dorset, to the county of Norfolk, it would form the boundary of the great chalky stratum of England; no quantity having been found to the north or west of that line.

There is a mountain of chalk between Tor and Isium on the banks of the Donetz in Russia, in which some Greek monks have excavated apartments to the length of fifty fathoms *.

* Pallas's Travels, vol. ii. p.

No metals are found in chalk, though it is said that in France *martial pyrites* has been discovered in it.

Sect. XXV. *Clay.*

90 Clay.

Clay is found in various states with respect to hardness or solidity, from the soft ductile clay used by the potters and pipemakers to the perfect slate (clay slate, or *argillaceous schistus*) already described.

Soft clay is found in beds of various degrees of thickness, commonly not far below the surface, and alternating with harder clay, slates, sand, or limestone. It is generally very abundant, especially in those places where coal or rock-salt is found.

91 Indurated clay.

Clay of a harder consistence, commonly called indurated clay, or in the language of the miners *clunch*, is usually found below the softer clay, or there is sometimes a stratum of slate or similar argillaceous matter interposed. It often alternates with limestone, sandstone, or gypsum. Petrifactions and shells are often found in it, as are quartz, sulphur pyrites, martial ochre, common salt, vitriol and alum.

92 Lithomarga.

A harder state of clay forms that substance which is called by mineralogists *lithomarga* (stone clay). This is found in beds or strata often alienating with the former, with slate or with limestone, especially in coal mines. It also forms nests or balls in toadstone and similar rock. It sometimes bears the impressions of reeds and other vegetable bodies.

93 Slate clay.

The next degree of hardened clay, forms slate clay, (*schiefer thon* of the Germans). This substance, however, is not very hard, but is easily broken into angular tabular fragments. Its internal appearance is usually dull, but sometimes glimmering from a slight intermixture of scales of mica. Its colour is usually a yellowish gray, with spots or clouds of a pearl gray, or a cherry red, but sometimes it inclines to black. It usually lies between beds of sandstone, and almost always below the softer clays.

94 Slate.

A kind of clay, of a still harder consistence, forms slate or schistus. This is usually of a dark brown or blackish colour, and a laminated texture. It lies in beds, sometimes of immense thickness, usually below sandstone, or alternating with this and limestone. It often contains impressions of organic remains, and there are sometimes found in it veins of lead ore. It is a very common stratum in the coal countries.

Nearly allied to this is what the miners call rubble-stone, which is a common variety of slate found in similar situations with slate, but often very rich in metallic ores, especially iron, galena, bismuth, and cobalt. It also abounds with petrifactions. It is sometimes found in primitive rocks.

95 Rubble-stone.

Sect. XXVI. *Marl.*

96 Marl.

Marl is a substance chiefly composed of sand, clay, and calcareous matter, which is found in many places, and forms one of the most valuable natural manures used in agriculture. This is also found of various degrees of hardness, from a soft powder to a stony consistence, in which last state it forms what Kirwan calls *marlite.* In colour, it is usually of a reddish white, sometimes verging upon red; and it is not unfrequently found of a yellowish brown or blackish cast. Marl is usually disposed in considerable beds of various degrees of thickness, in valleys and other low lands, especially among the coal strata. Indurated marl occurs in the coal strata of Mid Lothian *, and it is also found in the island of Islay. Powdery marl is seen in Skye.

* *Jameson's Dumfries*, p. 106.

Stony marl, or *marlite*, is found in Bavaria, alternating with sand and sandstone. Hills of it occur in Carniola, Carinthia, and the Venetian territory. It is also found between strata of limestone and argillaceous schistus.

Sect. XXVII. *Argillaceous Ironstone.*

97 Argillaceous ironstone.

This is sometimes called metal stone, and is very common in the coal countries. It is very heavy and compact, and of various colours, from a dark brown to a blood red; the latter forms the *hæmatites* or bloodstone, one of the richest iron ores. It often contains in it spherical balls like iron bullets. It is disposed in strata alternating with indurated clay, slate clay, marl, or sandstone, seldom far below the surface. It seldom forms very extensive beds, but is often confined to particular spots.

Ironstone is found in great abundance in Cumberland, and in most parts of Scotland. It may be seen in the cliffs all along the coast of Fife, from Dysart to St Andrews.

Sect. XXVIII. *Wacke and Basalt.*

98 Whinstone.

We have already spoken of several stones under the name of *traps*, that are found both among primitive and secondary compounds. The two substances which we are now to notice are nearly allied to the traps, and have been classed with them under the general name of *whinstone.* This is a favourite term among the mineralogists of Scotland, of whom Sir James Hall employs it as a generic name to denote trap, basalt, wacke, grunstein, and porphyry †. The term is convenient, but Professor Jameson and others of the Wernerian school object to it as too vague and indefinite.

† *Edin. Phil. Trans.* vol. v. p. 46.

99 Wacke.

Wacke, or wacken, differs from trap only in being more compact and of a finer grain. It is heavy and very hard, so as often to strike fire with steel; it is dull and opaque, and breaks with an even fracture. Its colour is usually a reddish brown or gray of various shades,

Arrangement, &c. of the Materials of the Earth.

shades, and sometimes it has a greenish cast. It has usually an earthy smell, when breathed on. It is sometimes highly impregnated with iron, and often contains crystals of *hornblende*, and very commonly those of hexagonal black mica.

It often forms a considerable part of mountains, either in vast blocks, as in the hill on which Edinburgh castle stands, or in strata lying above limestone or sandstone, or alternating with these. A great part of the Calton-hill, of Salisbury craigs, and Arthur's seat at Edinburgh, is composed of strata of this kind; and similar appearances take place in the bed of the water of Leith near the town, and in the cliffs on the coast of Fife, especially at St Andrews. To the eye of the volcanic Saintfond, all these beds appeared to be lava. We are disposed to think, with Mr Playfair, that the curious instance of alternate strata of basalt (as Saintfond calls it) and limestone, near Villeneuve de Berg, described and figured by that author, affords an example of whinstone alternating with limestone, such as are seen in Scotland †. Several varieties of wacke are found in the hills near Edinburgh, and are described by Dr Townson ‡. Mr Jameson observed wacke alternating with porphyry in Skye.

† *Recherches sur les Volc.* p. 382.

‡ *Towns. Tracts*, p. 204.

100 Basalt.

Basalt has a finer grain, and is more compact, than even wacke, and is the most dense of all the whins or traps. It is found either in large blocks, covering the other strata, sometimes in the form of tables, or in regular prismatic columns, either straight or bended. We have already treated so fully of the nature, properties, and chief habitats of basalt (see BASALTES), that little remains to be added here.

It is principally distinguished from wacke, where it is not in regular prisms, by very rarely containing crystals of mica, which are so common in the latter.

Saintfond, in his splendid work *Sur les Volcans eteints du Vivarais*, &c. has figured some examples of basaltic pillars which rival those of Staffa and the Giants Causeway. A more romantic situation is scarcely to be conceived than that drawn in his eleventh plate, of a village placed in the front of a bold hill covered with bundles of small pillars lying in every direction, and having detached perpendicular columns standing at each end, with a large cave directly behind the houses. Large masses of basalt are seen in the north of Shetland, standing insulated, and assuming a very grotesque appearance. Mr Jameson describes one of these in the isle of Jura, that forms a natural arch. We remember seeing two curious insulated rocks on the shore at the foot of Kinkeld braes at St Andrews, but do not recollect whether they are of a basaltic nature.

Several other substances, as sand, gravel, peat, &c. might here be noticed, but their structure and situation are too well known to render a particular notice necessary.

Many of the stones which we have described among the primitive rocks, are also sometimes found among the secondary strata, as argillaceous schistus, hornstone, hornblende, jasper, and especially puddingstone; but they are not so important as to require a second examination.

Before we conclude this general account of the materials which compose our globe, we must briefly notice two of the most valuable mineral productions, viz. rock salt and coal, and must say something of fossils and petrifactions.

SECT. XXIX. *Rock Salt.*

101 Rock salt described.

ROCK salt or sal gem, (the *steinsal* of the Germans) is the purest muriate of soda that is found in nature, it being much less impregnated with foreign matters than what is procured from sea water. It is very hard, and generally very transparent, being sometimes as clear as crystal. It is usually white, but often yellowish, blue, red, or violet, and now and then it is quite opaque. This salt forms in the bowels of the earth horizontal beds or banks, more or less thick, from a few inches to many hundred fathoms; and sometimes extending several miles round. It commonly alternates with clay or gypsum. The beds are sometimes without any break for a great extent. It is generally found a few fathoms below the surface, and in some places is found continued to the depth of 1000 feet.

102 Where found.

It is found in some mountains; and in Algiers, near the lake called *Marks*, there is a mountain almost wholly composed of it. The famous salt mine of Wielitska in Austrian Poland, about eight miles to the south-east of Cracow, is in the northern extremity of a branch of the Carpathian mountains. The salt found here is of an iron gray colour, intermingled with white cubes; and sometimes large blocks of salt are found imbedded in marl. This famous mine has been worked ever since 1251, and it is pretended that its excavations extend more than a league from east to west *. About five leagues to the south-east of Cracow are the salt mines of Boschnia, the depth of which is nearly equal to those of Wielitska (1000 feet); but the salt procured from them is less pure †. Mines of salt, in horizontal undulated beds, occur at Thorda in Transylvania, and in Upper Hungary. In the side of a mountain, about two leagues from Halle, on the banks of the Inn, to the north-east of Inspruck, rock salt is found imbedded in layers of a slaty rock; but there is one part of the mountain in which there occurs an immense body of salt, without any mixture of rock, to which they pass by a gallery 260 toises in length, closed at the end with a locked door. This salt is very impure ‡. There are three important salt mines in Spain; the first near Mingranella, in a mountainous tract, between Valentia and Castile, imbedded in layers of gypsum; the second in Spanish Navarre, in a ridge of hills composed of limestone and gypsum; and the third that of Cardona in Catalonia, about 16 leagues to the north-east of Barcelona, which is one of the most curious natural productions with which we are acquainted. It consists of an immense solid rock of salt, elevated 500 feet above the earth, and extending to a depth that has not been ascertained. It is without crevices or clefts, and has no appearance of strata, and is near a league in circuit. There is no plaster or gypsum found in the neighbourhood, and the salt rock is as high as any of the adjacent hills ||.

* *Townson's Travels in Hungary*, p. 338.

† *Jour. des Mi*[...], N° 47.

‡ *Jar's Voy.* tom. ii p. 325.

|| *Bowles's Nat. Hist. of Spain.*

10[3] Salt mines at Northwich.

Rock salt is found in several places in England, particularly at Northwich in Cheshire, at Droitwich in Worcestershire, and near Weston in Staffordshire; but the mines in Northwich are the most productive. Salt mines, in this situation, were known to the Romans; but

but the principal mine that is at present wrought, was discovered in the beginning of last century. It forms immense quarries, extending over several acres, which, with their huge crystal pillars and glittering roof, present a most beautiful spectacle. The salt found here is of a dark-brown colour, like brown sugarcandy, and is so hard that it is blasted with gunpowder to get it from the mass. It is disposed in beds, alternating with beds of clay, gypsum, and slaty stone. Salt is procured at the greatest depth hitherto explored; and wherever a shaft is sunk in the neighbourhood, there is a certainty of finding salt *.

Besides these extensive mines, rock salt is found in the canton of Berne in Switzerland, in Siberia, in Arabia, in Tibet, and even in New Holland. It is also found in many parts of America, at a great height in the mountains, especially those of Peru.

* Mawe's Mineral. of Derbysh. xv.

Sect. XXX. *Coal.*

104 Coal.

We have already, in the articles Coal and Coalery, treated of the nature of this substance, of the strata that are usually found connected with it (according to the phraseology of the miners), and of the method of procuring it from the pits; and, in Mineralogy, we shall give a particular account of the several varieties, and the distinguishing characters of each. A few observations respecting the principal collieries, with the appearance of the coal found in them, and the corresponding stratification, fall to be made in this place.

There are certain general circumstances that attend the depositions of coal in almost every place where it is found, and which we must mention before noticing the particular collieries. These are as follows.

105 General circumstances attending coal strata.

1. The beds in which coal is disposed, usually have their extremities near the surface of the ground, from which they bend obliquely downwards, the middle part of the bed being nearly horizontal, so that a vertical section of the bed nearly resembles the keel of a boat. This figure is well expressed in the first and third plates to Mr Jameson's Mineralogy of Dumfries. The lowest part of the bed is usually the thickest (D).

2. A bed of coal is seldom found single; but, in general, several strata occur in the same place, of various thickness, the upper being usually very thin, and the lower very thick, with several stony strata between each two. Where there is only one bed, this is generally of very considerable thickness. At Whitehaven there are found at least 20 coal strata below the surface; and at Liege, in France, there are no less than 60.

3. The strata that separate the layers of coal are nearly the same in every colliery, and will be seen by referring to the table given under Coalery, and by those which will immediately be added. Those strata which are in immediate contact with the coal, are either whinstone, or more commonly an argillaceous slaty mass; and near this is sandstone, in layers that are separated by slaty clay, mixed with particles of coal.

4. It is an observation which holds, almost without exception, that the slaty strata, and especially those next the coal, bear the impression of vegetables, and often of exotic or unknown plants.

Arrangement, &c. of the Materials of the Earth.

106 Where found.

Coal, in a greater or less quantity, but of very different qualities, has been found in most countries, and perhaps exists in all. It is found in France, Holland, Britain, Germany, Saxony, Portugal, Switzerland, and Sweden; in China, Japan, and in New Holland; and much of it is worked in Virginia in America. But France and Britain may be considered as the favourite seats of this invaluable commodity, which may justly be put in competition with the treasures of Potosi and Peru.

107 Coal mines of France.

It is stated by Buffon, that there are no fewer than 400 collieries worked in France; and yet Saintfond regrets that his countrymen are not so far advanced in the use of this mineral as the inhabitants of Britain *. The most considerable coal mines in France, are those in the Lyonnois, at Forez, Burgundy, Auvergne, Languedoc, Franche Comté, and Liege.

* Saintfond's *Travels*, tom. i. p. 114.

The mines in the Lyonnois, and those of Forez, are among the most important in France. They are situated in a valley, extending from the Rhone to the Loire, in a direction from north-east to south-west, between two chains of primitive mountains, and they occupy in length a space of six or seven leagues, from Rive-de-Gier to Firmini. In one part of the valley, in the neighbourhood of Saint-Etienne, the strata are nearly horizontal, and the medial thickness of the coal stratum is from three to six feet; and near the Loire there are from 15 to 20 of these. At Rive-de-Gier the strata are almost vertical, and their thickness is very unequal, being seldom less than three feet, and sometimes amounting to 40 or even 60. All the coal produced by these mines is of an excellent quality, and its quantity is immense. Patrin states, on the most undoubted authority, that there are in the neighbourhood of Rive-de-Gier, no less than 40 mines at work, which produced in one year 1,600,000 quintals of coal †.

† *Histoire Nat. de Miner.* tom. v. p. 223.

The next in importance are the coal mines of Liege. The beds of coal in that country have a direction from east to west; they commence about a league to the east of the town, and extend to about a league and a half to the west of it. Here, after meeting with some interruption, they extend for several leagues farther. Their breadth, from north to south, is about three-fourths of a league. At Verbios, which is to the north-west of the city, there are, according to Jars, more than 40 strata of coal, which are separated from each other by beds of different kinds of sandstone, of from 30 to 100 feet in thickness ‡. Gennetè has counted 61 of these beds, placed one above another; and he is of opinion, that the lowest penetrates to the depth of 4000 feet perpendicular. Though these mines have been wrought from the 12th century, they have not yet reached to more than the twenty-first bed, at the depth of a little more than 1000 English feet §.

‡ *Jars' Voy. Metal.* Mem. xiv. p. 283.

§ *Patrin*, tom. v. p. 330.

The

(D) Saintfond, in the section which he has of the coal strata at Newcastle, describes them as if they were convex towards the upper surface. (See p. 134. of vol. i. of the English Translation of his Travels in England, &c.). Surely this is a mistake.

Arrangement, &c. of the Materials of the Earth.

108 Principal collieries of England.

The principal collieries of Britain are those of Newcastle and Whitehaven.

Newcastle is surrounded by collieries to the distance of six or seven leagues, and may, perhaps, be considered as the richest coal district in the world. There are in several of the Newcastle mines not fewer than 16 beds of coal, two of which are considerably thicker than the rest, being each about a fathom in thickness. These are called the *main coal*, and are distinguished into the *high main coal*, and the *low main coal*, separated from each other by a considerable number of stony strata. Good coal, in sufficient quantity, is generally found at the depth of little more than 100 feet. The bed is five feet thick in some places, and less in others; but, in general, it is easily wrought, and large pieces are brought up. This last circumstance is of considerable advantage, as these pieces are most proper for chamber fires, and easily transported, which makes this kind of coal sell at a higher price. Where the bed of black and bituminous clay is penetrated, the coal is found adhering to it: but this is not always the case, for there are other mines in the neighbourhood where freestone is recovering, which, in the points of contact, is mixed with coal to the thickness of two or three inches; the latter running, as it were, in splinters into the stone, and having a ligneous appearance, when attentively examined *.

* *Saint-fond's Travels*, vol. i. p. 140.

At Whitehaven, the beds of coal lie in a direction parallel to each other. Their inclination or dip is nearly to the west, and is from one yard in eight, to one in twelve. The strata are frequently interrupted by large fissures, or dykes, some of which remove the strata upwards or downwards, 120 feet. The course of these fissures is almost east and west. In a depth from the surface of 165 and a half fathoms, there are, in these collieries, seven large beds of coal, and 18 thin beds, which cannot, at present, be rendered profitable.

The strata superincumbent on the large beds of coal are, 1st bed, Blue slate. 2d, Gray freestone. 3d, Hard, white freestone. 4th Blue slate, striated or speckled with freestone. 5th, Gray slate. 6th, Hard, white freestone.

The strata immediately beneath these large beds of coal, are from one and a half to six inches thick, and consist of a species of argillaceous earth, or *shale*. As this earth is of a very soft or friable nature, the weight of the superincumbent strata presses the pillar of coal through it. If the pillar descends a few inches, the roof not equally yielding at the same time, crushes, or breaks into small pieces. When, under these circumstances, the thickness of the bed does not exceed six feet, nor the depth 30 fathoms, the surface of the earth is sensibly affected *.

* Dixon's *Life of Dr Brownrigg*, p. 10[illegible]

There appear to be two principal belts of coal in this island, extending from the eastern to the western coast; one from Newcastle to Whitehaven, the other from the east coast of Scotland, across the vale of Forth and Clyde, to Ayrshire. Coal is indeed found in many other parts of the island; but the quantity is very trifling.

The similarity of situation, and the similar nature of the coal at Whitehaven and Newcastle, would naturally lead us to infer, that the coal at both places is from the same seam. But this is placed beyond dispute, by a comparative examination of the strata in both situations. We shall here give two tabular views of the strata, one taken from Saintfond's Travels, and the other from Dr Joshua Dixon's account of the Whitehaven mines, in his literary life of Dr Brownrigg. Allowing for the different names given by different miners to the same substances, and Dr Dixon's greater minuteness, there is a wonderful similarity between the two tables.

Arrangement, &c. of the Materials of the Earth.

An interesting and valuable memoir on the subject of coal, written by M. Duhamel the younger, was presented a few years since to the Academy of Sciences at Paris, who adjudged it the prize that had been offered for the best essay on the subject. An ample abstract of this memoir appeared in the *Journal des Mines*, N° vii. In this paper is given a table of the number of veins, their direction and inclination, and the nature of the strata next the coal, and in the neighbourhood, in all the principal mines in Europe. For a fuller view of the natural history of coal, the readers may consult Dr Millar's edition of Williams's Mineral Kingdom, 1810.

Sect. XXXI. *Of Fossils and Petrifactions.*

109 Fossils.

Those organic remains of vegetable and animal matter which are found below the surface of the earth, mixed with the stony matters which are properly the component parts of the earth, are generally called *fossils*, or *extraneous fossils.* If they have entirely lost all traces of vegetable or animal matter, and have assumed a stony earthy nature, they are called *petrifactions.*

Some of these organic remains, particularly those of the vegetable kind, are found penetrated with a bituminous substance, so as to be rendered highly inflammable. One of the most curious circumstances attending these fossil bodies is, that they are very commonly natives of a different country from that in which they are found, or are the remains of species that are now no longer known.

We may properly divide these substances into those of the vegetable and those of the animal kingdom.

1. *Vegetable fossils.* Almost every part of vegetables, the trunks, branches, leaves, and fruits, have been found in a fossil state, or impressions of some of them are seen in various mineral substances, especially in the slaty stone which accompanies coal.

Fig. 6. represents a curious example of this, that was found in the mines at Saint Etienne in France.

A, is a fruit resembling that of coffee. B, is a portion of an unknown vegetable, apparently of the verticillate tribe. C, is a species of fern, which is very remarkable, as it is furnished with fructifications. D, is part of a plant with verticillate leaves, probably a species of *galium.* E, is some exotic fruit.

Whole trees are often found below the surface of the earth, especially in bogs and mosses, sometimes retaining much of their vegetable nature, but more commonly either impregnated with bitumen or completely petrified. Subterraneous trees are frequently dug up in the isle of Anglesea; and in the isle of Man there is a marsh six miles long and three broad, in which fir trees are found in great quantities; and though they are 18 or 20 feet below the surface, they appear as if standing firmly upon their roots. Subterraneous trees, in various states, are frequently found in Ireland, especially in the neigbourhood of Lough Neagh. Much has been written on the subject of these petrifactions of Lough Neagh, by Dr Boate, in his Natural History of Ireland; by Mr Molyneux, in the Philosophical Transactions, N° clviii. and Dr Barton in his Lectures on Natural Philosophy. Some of these trees are represented as of an immense size *. One of the most curious instances of vegetable fossils, is that related by Rammazzini, as seen by him at Modena in Italy. At the bottom of wells, that are dug there below stony masses, which appear to have been the foundation of a former city, at the depth of near 30 feet, they find heaps of wheat entire, filbert trees, with their nuts, briars, &c. They find, likewise, every six feet, a layer of earth, alternating with branches and leaves of trees.

At the depth of 28 feet, or thereabouts, they find a chalk that cuts very easily. It is mixed with shells of several sorts, and makes a bed of about 11 feet. After this they find a bed of marshy earth, of about two feet, mixed with rushes, leaves, and branches. After this bed comes another chalk bed, of nearly the same thickness with the former, which ends at the depth of 49 feet.

That is followed by another bed of marshy earth like the former; after which comes a new chalk bed; and these successive beds are always found in the same order. The auger sometimes finds great trees, which give the workmen much trouble. They see also sometimes at the bottom of these wells, great bones, coals, flints, and pieces of iron †.

These vegetable fossils are generally of a flinty structure, being sometimes rough and sandy; at others so hard and compact as to admit of a fine polish. Some beautiful specimens of petrified wood, of the appearance of agate, are to be seen in cabinets of natural history. That of Besson at Paris contains two examples of this kind, which are figured at fig. 7. and 8. Fig. 7. is a transverse section of a piece of agatized wood, in which the ligneous texture is most completely preserved. Fig. 8. is another more compact, and which has the additional singularity of containing several worms. The white oval spots are supposed to have been eggs, from which the worms had issued. In Dr Millar's Mineralogical Cabinet there is a similar specimen containing worms and their ova from Siberia, as well as many beautiful specimens of agatized wood from Siberia and Germany.

110 Bovey coal.

Among the bituminous vegetable fossils, none have attracted more attention than what is called *bovey coal*, a substance of an intermediate nature between wood and pitcoal, which is dug up in a common near Chudleigh in Devonshire. It is of a laminated texture, of a chocolate, or sometimes of a shining black colour, like deal boards that had been half charred. It burns heavily, and consumes to light gray ashes. It is regularly stratified among beds of sand and clay, and the beds of coal are sometimes of considerable thickness. Mr Parkinson has collected much information respecting the former and present state of this coal, in his entertaining work on fossils ‡.

111 Animal fossils.

2. *Animal fossils.* Fossils of animal matters are still more common than those of vegetables. Shells and bones are found in almost every bed of limestone, and in almost every country, at the bottom of the deepest valleys, and at the tops of very considerable mountains.

In the limestone strata in Derbyshire are found many of those fossils, which are called *star-stones*, and *screw-stones*, which appear to be the remains of marine animals called *encrini.* These are described by Whitehurst, who has given figures of similar animals brought entire from the West Indies §. Fig. 9. represents one of these stones.

The isle of Cherea in Dalmatia contains caverns in which are found prodigious quantities of fossil bones of oxen,

‡ Organic Remains, vol. i. letter xii.

§ Theory of the Earth, chap.

Arrangement, &c. of the Materials of the Earth.

oxen, horses, and sheep. Similar examples occur in many places; but human bones are, we believe, never found in a fossil state.

Fossil shells are found on the Alps, on the top of Mount Cenis, on the Apennines, on the mountains of Genoa, and in most of the quarries of stone and marble in Italy; in most parts of Germany and Hungary, and indeed generally in all the elevated places in Europe. We also find them in the stones whereof the most ancient edifices of the Romans were constructed.

In Switzerland, Asia, and Africa, travellers have observed petrified fish in many places; for instance, on the mountains of Castravan, there is a bed of white laminated stone, and each lamina contains a great number and diversity of fishes; they are, for the most part, very flat, and extremely compressed, in the manner of fossil fern; yet they are so well preserved, that the minutest marks of their fins and scales are distinguishable, and every other part, whereby one species of fish is known from another.

There are likewise many *echenites* and petrified fish between Iver and Cairo, and on all the hills and heights of Barbary, most of which exactly correspond with the like species taken in the Red sea.

The long chain of mountains which extend from east to west, from the lower part of Portugal to the most eastern parts of China, those which stretch collaterally to the north and south of them, together with the mountains of Africa and America, which are now known to us, all contain *strata* of earth and stone, full of shells.

The islands of Europe, Asia, and America, wherein Europeans have had occasion to dig, whether in mountains or plains, all furnish us with shells, and convince us that they have this particular in common with their adjacent continents.

The *glossopetra*, or the teeth of sharks and other fishes, are found in the jaws, polished and worn smooth at the extremities, consequently must have been made use of during the animal's life; and in shells the very pearls are found, which the living animals of the same kind produce.

It is well known that the *purpura* and *pholades* have a long-pointed proboscis, which serves them as a kind of gimblet or drill, to pierce the shells of living fish on whose flesh they feed. Now, shells thus pierced are found in the earth, which is another incontestable proof that they heretofore inclosed living fish, and that these fish inhabited places where the *purpura* and *pholades* preyed on them.

In Holland sea shells are found 100 feet below the surface; at Marly-la-Ville, six leagues from Paris, at 75; and in the Alps and Pyrenean mountains they are found under beds of stone of 100, nay even 1000 feet.

Shells are likewise found in the mountains of Spain, France, and England, in all the marble quarries of Flanders, in the mountains of Guelders, in all the hills round Paris, in those of Burgundy and Champagne; and, in short, in all places where the basis of the soil is neither freestone nor sandstone.

By shells we would be understood to mean, not only those which are merely testaceous, but the relics of the crustaceous fishes also; and even all other marine productions; and we can venture to assert, that, in the generality of marbles, there is so great a quantity of marine productions, that they appear to surpass in bulk the matter whereby they are united.

Among the many instances of the multiplicity of oysters, there are few more extraordinary than that immense bed which M. de Reaumur gives an account of, which contains 130,630,000 cubic fathoms. This vast mass of marine bodies is in Touraine in France, at upwards of 36 leagues from the sea. Some of these shells are found so entire, that their different species are very distinguishable.

Some of the same species are found recent on the coast of Poictou, and others are known to be natives of more distant parts of the world. Among them are likewise blended some fragments of the more strong parts of sea plants, such as *madripores*, *fungi marini*, &c. The canton of Touraine contains full nine square leagues in surface, and furnishes these fragments of shells wherever you dig.

Near Reading in Berkshire, a continued body of oyster shells has been found: they lie in a stratum of greenish sand, about two feet in thickness, and extend over five or six acres of ground; they are covered by strata of sand and clay, upwards of 14 feet deep. Several whole oysters are found with both their valves or shells lying together, as oysters before they are opened; the shells are very brittle; and in digging them up, one of the valves will frequently drop from its fellow. Several are dug out entire; nay, some double oysters with their valves united.

In a quarry at the east end of Broughton in Lincolnshire, innumerable fragments of the shells of shell fish, of various sorts, are found under a stratum of stone imbedded in clay, with pieces of coral, and sometimes whole shell fish, with their natural shells and colours: some are most miserably cracked, bruised, and broken; others totally squeezed flat by the incumbent weight of earth.

Sharks teeth are dug up in the isle of Sheppey, retaining their natural colour, not petrified.

The teeth of sharks have likewise been taken out of a rock in Hendershelf park, near Malton in Yorkshire.

In the isle of Caldey, and elsewhere about Tenby in Pembrokeshire, marine fossils have been found in solid marble, on the face of the broken sea cliffs, 200 fathoms below the upper surface of the rocks. Nor were they only observed upon the face of these rocks, but even more or less throughout the whole mass or extent of them. This is manifest from divers rocks hewn down by workmen for making of lime, and other pieces casually fallen from the cliffs.

Thousands of fossil teeth, exactly answering to those of divers sorts of sea fish, have been found in quarries and gravel pits about Oxford.

At Tame in Oxfordshire, the *belemnites*, or *thunderbolt stones*, are found in a stratum of blue clay, which still retain their native shelly substance.

The *belemnites* found in gravel pits, have suffered much, by their being rubbed against each other in the fluctuation of waters.

The *nautili* and *belemnites* are frequently found at Gorsing near Oxford *.

One of the most extraordinary collections of shells is that

* Phil. Trans. vol. liv. p. 5.

Arrangement, &c. of the Materials of the Earth.

that lately discovered by Ramond on the summit of Mont Perdu, the highest of the Pyrenees, where there are found vast quantities of sea shells and other marine spoils, and even skeletons of animals in a fossil state.

Whole skeletons of very large animals have been discovered in a fossil state. Those of elephants have been found buried in the plains of Siberia; and bones of the rhinoceros, the hippopotamus, and the tapir, have been found in other places. A very large skeleton, nearly complete, of an immense animal, similar to the rhinoceros, is preserved in the cabinet of Madrid. It was dug up at Paraguay in South America, at the depth of 100 feet, in a sandy bed, on the banks of the river de la Plata. A description and engraving of it are given by Cuvier, in the Annals of the National Museum, N° 29. It appears to be at least 12 feet long, and the bones are of an immense size.

A prodigious quantity of fossils, both of marine animals, and of quadrupeds, are found in the plaster hills of Montmartre near Paris. An account of these has lately appeared in several numbers of the Annals of the National Museum, by M. Lamarck, accompanied with the anatomical illustrations of Cuvier. These papers are extremely curious, and contain engravings of most of the fossils described, some of which are the remains of unknown animals. Our limits do not permit us to present our readers with even an abstract of these accounts. We shall therefore select only one example.

Fig. 10. represents a block of gypsum, on the surface of which is the skeleton of an animal resembling a mouse, or, according to Cuvier, one of the opossum tribe. The skeleton is nearly entire, and the head, the neck, the spine, the pelvis, one of the fore and hind legs, and part of the tail, are very distinct. There were two pieces of gypsum found together, which appear to have divided the skeleton between them. The animal seems to have been crushed or imbedded in his natural situation *.

* Ann. du Mus. N° xxix. p. 277.

We have now enumerated the principal materials that compose the external crust of our earth, and have mentioned some of the most material circumstances respecting each. The metallic ores still remain to be considered, and they shall be noticed in describing metallic veins.

General Distribution of Materials of the Earth.

Chap. II. *General Distribution of the Materials of the Earth.*

The uppermost stratum of the earth, in low situations, is, for the most part, composed of sand or clay, or a mixture of these, forming beds that are either composed of the same mixture, or of alternate layers of the two substances. These beds vary in thickness, in different places; but, in the same place, they usually preserve nearly the same thickness for a considerable extent. Sometimes these beds of clay, sand, and earth, with shells, extend to the depth of some hundred feet. See the annexed table, I. (E).

This table exhibits a view of the arrangement of strata in several countries of Europe; and, with the tables of coal strata, in the last chapter, will give the reader more information on this subject than an elaborate detailed account.

General Distribution of the Materials of the Earth.

In our subsequent view of the distribution of the stony matters that compose the earth, we shall consider,

1. The nature, disposition, and structure, of mountains.
2. The nature, direction, &c. of dykes.
3. The nature, direction, &c. of metallic veins.

Sect. I. *Of Mountains.*

112 Definition of mountains. There are no objects on the surface of the earth which are so well calculated to excite the attention of mankind in general, and that of geologists in particular, as those stupendous elevated masses which we call *mountains*. The term mountain has in general been applied to those parts of the earth which are elevated to a very considerable height above the level surface; and a mountain is in common language distinguished from a hill only by its superior elevation. But as it is found necessary in a scientific point of view to render this distinction more accurate and precise, various geologists have given more correct definitions. By Pini and Mitterpachter every elevation whose declivity makes with the horizon an angle of at least 13°, and whose perpendicular height is not less than one-fifth of the declivity, is called a *mountain*. Werner distinguishes mountains according to their height, into *high*, *middle-sized*, and *low*. A *high* mountain according to him is that whose perpendicular height exceeds 6000 feet; when the height is not above 6000 nor below 3000 he calls it *middle-sized*; and when its height is below 3000 feet, he calls it *low*.

113 Mountains are either single or in groups; and these groups either consist of several mountains standing near each other so as to occupy nearly the centre of a certain space of ground, or they follow each other so as to form a ridge or chain, running across a country, or along its shores. Sometimes these chains run in a longitudinal direction, as is the case with Mount Caucasus and the Uralian mountains in Asia, the Cordilleras in South America, &c. but often they run in a curvilineal direction like a crescent, as the Carpathian mountains, which separate Hungary from the rest of the Austrian territories. It has been supposed by some theoretic writers, that chains of mountains always run in nearly the same direction, which has been conceived to be from east to west; but this is by no means exact, as later observations have shewn that they assume different directions according to the form of the country where they are situated. Some writers have laid it down as a general rule, that chains of mountains always extend in a direction nearly parallel to the length of the country; but to this there are also many exceptions. Thus the Uralian mountains, the Carpathians, the Pyrenees, the Grampians in Scotland, and many others, run rather across the country. It often happens that mountains occupy nearly the central parts of a country; and the land generally slopes with a gentle declivity towards one side of the chain, while towards the other it is considerably steeper. This circumstance of one side of a chain of mountains being steeper than the other, has been lately extended to mountains and hills in general; and Dr Kirwan has written an excellent paper on the the subject, from which we shall here extract the most important observations.

"That one part of almost every high mountain or hill is steeper than another, could not have escaped the notice of any person who had traversed such mountains; but that nature in the formation of such declivities had any regard to different aspects or points of the compass, seems to have been first remarked by the celebrated Swedish geologist Mr Tilas, in the 22d vol. of the Memoirs of Stockholm for 1760. Neither Varenius, Lulolph, nor Buffon in his natural history published in 1784, have noticed this remarkable circumstance. 114 Kirwan's observations on the declivities of mountains.

"The observation of Tilas, however, relates only to the extreme ends, and not to the flanks of mountains; with respect to the former, he remarked that the *steepest* declivity always faces that part of the country where the land lies lowest; and the gentlest, that part of the country where the land lies highest: and that in the southern and eastern parts of Sweden they consequently face the east and south-east; and in the northern the west. The essential part of this observation extends therefore only to the general elevation or depression of the country, and not to the bearings of their declivities. 115 The steep side faces the low country.

"The discovery that the different declivities of the flanks of mountains bear an invariable relation to their different aspects, seems to have been first published by Mr Bergman in his Physical Description of the Earth, of which the second edition appeared in 1773. He there remarked, that in mountains that extend from north to south, the western flank is the *steepest*, and the eastern the *gentlest*. And that in mountains which run east and west the southern declivity is the steepest, and the northern the gentlest. Vol. II. § 187. 116 Western side the steepest.

"This assertion he grounds on the observations related in his 1st vol. § 32. namely, that in Scandinavia, the Suevoberg mountains that run north and south, separating Sweden from Norway, the western or Norwegian sides are the steepest, and the eastern or Swedish, the most moderate; the verticality or steepness of the former being to that of the latter as 40 or 50 to 4 or 2.

"That the Alps are steeper on their western and southern sides than on the eastern and northern.

"That in America the Cordilleras are steeper on the western side, which faces the Pacific ocean, than on the eastern. But he does not notice a few exceptions to this rule in particular cases which will hereafter be mentioned.

"Buffon, in the first volume of his Epochs of Nature, published in 1778, p. 185. is the next who notices the general prevalence of this phenomenon, as far as relates to the eastern and western sides of the mountains that extend from north to south; but he is silent with respect to the north and south sides of the mountains that run from east to west; nay, he does not seem to have had a just comprehension of this phenomenon; for he considers it conjointly with the general dip of the regions in which these mountains exist. Thus he tells us, vol. i. p. 185, that in all continents the general declivity, taking it from the summit of mountains, is always more rapid on the western than on the eastern side; thus the summit of the chain of the Cordilleras is much nearer to the western shore than to the eastern; the chain which divides the whole length of Africa, from the Cape of Good Hope, to the mountains of the Moon, 117 Remark of Buffon.

General Distribution of the Materials of the Earth.

Moon, is nearer, he says, to the western than to the eastern seas; of this, however, he must have been ignorant, as that tract of country is still unknown.

"The mountains which run from Cape Comorin through the peninsula of India are, he says, much nearer to the sea on the east than on the west; he probably meant the contrary, as the fact is evidently so, and so he states it in vol. ii. p. 295; the same he tells us may be observed in islands and peninsulas, and in mountains.

"This remarkable circumstance of mountains was notwithstanding so little noticed, that in 1792 the author of an excellent account of the territory of Carlsbad in Bohemia, tells us he had made an observation, which he had never met with in any physical description of the earth, namely, that the southern declivity of all mountains was much steeper than the northern, which he proves by instancing the Erzgebirge of Saxony, the Pyrenees, the mountains of Switzerland, Savoy, Carinthia, Tyrole Moravia, the Carpathian, and Mount Hæmus in Turkey. 2. *Bergm. Jour.* 1792. p. 385. in the note.

8 Of Herman.

"Herman in his geology, published in 1787, p. 90. has at least partially mentioned this circumstance; for he says that the eastern declivities of all mountains are much gentler and more thickly covered with secondary strata, and to a greater height, than the western flanks, which he instances in the Swedish and Norwegian mountains, the Alps, the Caucasian, the Apennine, and Ouralian mountains; but the declivities bearing a southern or northern aspect he does not mention.

9 Of Lametherie.

"Lametherie, in vol. iv. of his Theory of the Earth, of which the second edition appeared in 1797, a work which abounds in excellent observations, p. 381. produces numerous instances of the inequality of the eastern and western declivities, but scarce any of the northern and southern, whose difference he does not seem to have noticed; but he makes a remark which I have not seen elsewhere, that the coasts of different countries present similar declivities.

"With regard to eastern and western aspects, he thinks that a different law has obtained in Africa from that which has been observed in other countries; for in that vast peninsula he imagines the eastern declivities of mountains are the steepest, and the western the gentlest. Of this, however, he adduces no other proof, but that the greatest rivers are found on the western side: this proof seems insufficient, as, if mountains be situated far inland, great rivers may flow indiscriminately from any side of them, and sometimes few rivers flow even from the side whose descent is most moderate; for instance, from the eastern side of the mountains of Syria. The Elbe and the Oder, two of the greatest rivers in Germany, take their course from the western sides, the first of the Bohemian and the other of the Moravian mountains, which yet are the steepest. Many originate from lakes, as the Shannon with us; many take such a winding course, that from a bare knowledge of the place of their disemboguement it is impossible to judge from what side of a mountain they issue, if from any; their course at most discovers the depression of the general level of the country.

"In 1798, the celebrated traveller and circumnavigator, John Reinhold Foster, published a geological tract which merits so much more attention, as all the facts were either observed by himself, or related to him by the immediate observers. In this he states as a fact universally observed, that the south and south-east sides of almost every mountain are steep, but that the north and north-west sides are gently covered and connected with secondary strata, in which organic remains abound, which he illustrates by various instances, some of which have been already, and others will presently be mentioned.

120 South and south-east sides of mountains steepest.

"At present this fact attracts the greatest attention, being obviously connected with the original structure of the globe, and clearly proving that mountains are not merely fortuitous eruptions unconnected with transactions on the surface of the earth, as has of late been confidently advanced.

121 Account of mountains.

"I shall now state the principal observations relative to this object, that have been made in different parts of the world.

In Europe.

122 In Europe.

1. The mountains that separate Sweden from Norway extend from north to south, their western sides are *steep*, and the eastern *gentle*. 1. *Berg. Erde Beschreib.* p. 157.

2. The Carpathian mountains run from east to west; their southern sides towards Hungary are steep, their northern towards Poland moderate. *Foster*, § 46.

3. Dr Walker, professor of natural history at Edinburgh, observed that the coasts and hills of Scotland are steeper and higher on the western side than on the eastern. Jameson's Mineralogy of Scotland, p. 3. However, Jameson observed, that the south side of the isle of Arran is the lowest, and the north side the highest, p. 51.

4. The mountains of Wales are gentle on the eastern and steep on the western side.

5. The mountains of Parthery, in the county of Mayo, are steep on the western side.

6. The mountains which separate Saxony from Bohemia, descend gently on the Saxon or northern side, but are steep on the Bohemian or southern side. *Charpente*, p. 75. The southern declivity is to the northern as six to two. *Bergm. Journ.* 1792, p. 384. and 385.

7. The mountains which separate Silesia from Bohemia run nearly from east to west, yet are steeper on the northern or Silesian side than on the opposite Bohemian. *Assemanni Silesia*, 335. Such branches as run from north-east to south-west, have their western covered with primordial strata, and consequently less steep, 4. *New Roz.* p. 157.

8. The Meissener in Hessia is steeper on the north and east sides, which face the Warra, than on the south and western. 1. *Bergm. Journ.* 1789, p. 272.

9. The mountains of the Hartz and Habischtswald are steep on the south, and gentle on the northern sides, *Foster*, § 46.

10. The Pyrenees, which run from east to west, are steeper on the southern or Spanish side. *Carbonieres*, xiii.

11. The mountains of Crim Tartary are gentle on the northern, and steep on the southern sides. *Foster*, ibid.

In

General Distribution of the Materials of the Earth.

123 In Asia.

In Asia.

12. The Ourals, which stretch from north to south, are far steeper on the western than on the southern sides. *Herman Geologie*, p. 90.; and, 2. *Ural. Beschreib*, p. 389.

13. The mountain of Armenia, to the west of the Ourals, is steep on its east and north sides; but gentle on the southern and western. 1. *Pallas Voy.* p. 277.

14. The Altaischan mountains are steep on their southern and western sides, but gentle on the northern and eastern. *Foster*, ibid. and *Herman*. 2. *Ural Beschreib*, p. 390. in the note.

15. So also are the mountains of Caucasus. 3. *Schrift. Berl. Gelasch.* 471.

16. The mountains of Kamtschatka are steep on the eastern sides. *Pallas*, 1. *Act. Petropol.* 1777. p. 43.

17. The Ghauts in the Indian peninsula are steep on the western side.

18. The mountains of Syria, which run from north to south, skirting the Mediterranean, are said to be steeper on the western side, facing the Mediterranean. 4. *La Metherie*, p. 380.

In America.

"The Cordilleras run from north to south; their western flanks towards the Pacific are steep, their eastern descend gradually.

"In Guiana there is a chain of mountains that run from east to west; their southern flanks are steep, their northern gentle. *Voyages de Condamine*, p. 140."* 124 In America.

The theory according to which Mr Kirwan attempts to explain the appearances of mountains which are enumerated above, will be given in the next chapter.

We have already, under the article BAROMETER, N° 44. shewn the method of computing the height of mountains by means of that instrument. The following table shews the height of the principal mountains in the globe, chiefly according to this computation. 125 Height of mountains.

In this table the second column shews the height as estimated by the barometer, and the third the same by geometrical calculation. Where the numbers are placed in the middle of these two spaces, it denotes an uncertainty by what method the computation has been made.

* Nicol. Journ. vol. iv. p. 256.

26 Course of mountains. The course of mountains is that direction of their length in which they descend and grow lower; or if a river runs parallel to them, they are said to have their course in the direction of the stream of the river. The course of mountains is seldom uniform. It has been laid down as a general maxim by Buffon, that when there are two parallel chains of mountains, the salient angle of one of the chains always corresponds with the internal angle of the other; but later geologists have ascertained that this circumstance does not generally hold, except when a river runs between the two chains.

27 Composition of mountains. It generally happens, that one particular mountain, or chain of mountains is composed of those stony materials which we have denominated primitive; while the rest is made up of the secondary componnds. The primitive substances occupy the base and central parts of the mountain, and often extend to its very summit: the secondary cover these, and are generally found on the flanks or sides of the mountain, though sometimes they cover the top of the mountain. In a chain of mountains there are commonly three, and often five parallel ridges, of which the central ridge is composed of primitive compounds, and those on each side of it, chiefly or entirely of secondary compounds. Hence mountains are usually divided into primary or primeval, and secondary or epizootic; the latter term being given to the secondary mountains from their being replete with shells and other remains of animal beings. The secondary mountains are also sometimes divided into original and derivative, for a reason that will appear hereafter.

28 Distinction of primary and secondary mountains. The primary mountains, besides their being in the centre, and destitute, or nearly so, of organic remains, may generally be distinguished by the ruggedness and angular appearances arising from the different nature and hardness of the substances of which they are composed; the quartz and harder granite resisting the attacks of the air and weather, while the other substances being softer, gradually decay, and leave the harder in the form of spires and angles. Where, however, the primitive compounds have been completely covered with secondary strata, these angular appearances seldom take place; and the mountain is only to be distinguished by its position and the structure of its internal parts. The secondary mountains generally have their tops round, and much smoother than those of the primary mountains.

In some cases a number of mountains appear united at their tops into an extensive plain or platform, from which they seem to diverge and branch in every direction. The most remarkable instance of this kind occurs in Tibet. (See GEOGRAPHY, N° 41.).

It is difficult to acquire a knowledge of the interior structure of mountains. The greater part of them is hid from our view, and nature only exposes them in a few points by means of fissures, caverns, and intermediate valleys.

"The materials of which mountains consist are disposed either in irregular heaps, or piles variously intersected by rifts, or in beds or strata separated from each other by rifts, often horizontal, or varying from that direction by an angle of from 5 to 40 degrees, and sometimes much more considerably, approaching even to a vertical position. The strata of mountains are most frequently in the direction of their declivity, yet sometimes their course is directly opposite, or countercurrent: the best manner of determining the angles of their course is by discovering that of their rifts. It chiefly depends on the unevenness of the fundamental gronnd that supports them. According to 1 Sauss. 502. most of the elevated granitic mountains in Swisserland are formed of immense vertical pyramidal laminæ, parallel to each other, that is, piles somewhat inclining from the unequal distribution of their weight, a disposition that may well be expected from collateral crystallizations; but this disposition is not universal, for they have been found in Saxony, and in the Pyrenees, horizontally stratified; much less can it be said, that this vertical position is general, for the strata of gneiss are generally horizontal, and commonly very regular, discovering no traces of a violent shock. Mount Rosa, next to Mount Blanc, the highest in Europe, consists also of gneiss, which M. Saussure found horizontally stratified.

"Shangin, who lately (1786) travelled over the Altaischan mountains, being consulted by Pallas, whether he found any vertical layers or strata therein, answered, he had not; but that he found them perfectly horizontal on the banks of the river Tschary.

"Mountains of primitive limestone are frequently in irregular piles, but often also horizontally stratified. Siliceous schistus is also often horizontally stratified. Many

General Distribution of the Materials of the Earth.

Many argillites, particularly roof slates, are generally said to have nearly a vertical position: but Voight has shewn that it is only their lamellæ that are so situated; their horizontal seams, and their walls, discovering their true position; their verticality arising only from the drain of the water, and, consequently, their contraction in that direction: hence those that are most silicited, as they contract less, discover less verticality. Sometimes horizontal strata overlap on both sides. Sometimes they are flanked on both sides with vertical strata.

"Much confusion prevails in the structure of the Pyrenees, and of the Grison mountains, and those on the borders of the Baikal, and other great lakes.

"The perturbed state of the strata often proceeds from the decomposition of internal beds of pyrites, to which water has had access; this appears to be the cause of the alterations observed in the mountain of Rabenberg, on the frontiers of Saxony. In this mountain a double direction of the strata of gneiss is observed; between both the strata are vertical, and a large intermediate space is filled with iron ore: but this mountain contains beds of pyrites and vast swallows; most probably then the pyrites swoll, uplifted the whole, and the dissolved iron flowed into the vacuity, from which the water afterwards drained off on the sides.

"In secondary mountains, particularly the calcareous, the greatest disorder often prevails, though in general their stratification is horizontal.

"The calcareous mountains of Savoy are often arched like a *lambda*, probably from the sinking of the intermediate strata, the intermediate remaining horizontal. Sometimes they assume the form of the letters Z. S. C. or of a disjointed ƆC, the convexities facing each other. So also in the Pyrenees, they sometimes overlap, from an unequal distribution in their original formation, and bend various ways. They assume a spiral form, or that of a horse-shoe placed horizontally.

"According to Lehman, most secondary strata present hollows or *moulds*, (as they are called,) from internal depression. But sometimes also *elevations*, from an original elevation in the fundamental stone.

"In Scotland, all the secondary strata in the vicinity of primeval mountains, are nearly vertical; but at a greater distance they approach more to an horizontal direction *."

* *Kirwan's Geological Essays*, p. 281.

We shall now trace the course of the principal mountainous chains on the globe, and in accompanying us, the reader may have before him a good map of the world.

129 Equatorial mountains not the highest.

M. Buache places the most elevated points of the great chains of mountains under the equatorial line: but, according to Pallas, the fullest and most continuous lands, and perhaps likewise the most elevated, are to be found at a distance from the equator, and towards the temperate zones. If, in fact, we survey the globe's surface, we shall not be able to perceive that chain of mountains, which running from east to west, and dividing the earth into two portions, ought again to meet. On the contrary, extensive plains seem to accompany the line through almost its whole extent. In Africa, the deserts of Nigritia and those of Upper Ethiopia are on the one side of the line; and on the other are the sandy plains of Nicoco, Caffraria, Monemugi, and Zanguebar. From the eastern shores of Africa to the Sunda islands, is a space of 1500 leagues of sea with almost no islands, except the Laccadive and Maldive islands; most part of which have little elevation, and which run from north to south. From the Molucca islands and New Guinea, to the western borders of America, the sea occupies a space of 3000 leagues. Though Chimboraço and Pichincha in America, the two highest mountains which have been measured, are near and even under the line, yet from this no conclusion can be drawn; because on one side these mountains run in a direction not parallel to the equator; the Andes or Cordilleras attain a greater elevation as they remove from the equator towards the poles; and a vast plain is found exactly under the line, between the Oroonoko and the river of the Amazons. Besides, the latter river, which takes its rise in the province of Lima about the 11th degree of south latitude, after crossing the whole of South America from west to east, falls into the ocean exactly under the equator. This shows that there is a descent for the space of 12 degrees or 300 leagues. From the mouth of the river of the Amazons, to the western shores of Africa, the sea forms another plain of more than 50 degrees.

From the few certain facts and accurate observations which we have received from well informed travellers, we might almost affirm that the most elevated land on our globe is situated without the tropics in the northern and southern hemispheres. By examining the course of the great rivers, we in fact find that they are in general discharged into three great reservoirs, the one under the line, and the other two towards the poles. This, however, we do not mean to lay down as universally true; for it is allowed, that, besides the two elevated belts, the whole surface of the earth is covered with innumerable mountains, either detached from one another or in a continued chain. In America, the Oroonoko and the river of the Amazons run towards the line, while the river St Lawrence runs towards the 50th degree of north latitude, and the river de la Plata towards the 40th degree of south latitude. We are still too little acquainted with Africa, which is almost all contained within the tropics, to form any accurate conclusions concerning this subject. Europe and Asia, which form only one great mass, appear to be divided by a more elevated belt, which extends from the most westerly shores of France to the most easterly of China, and to the island of Sagaleen or Anga-hata, following pretty nearly the 50th degree of north latitude. In the new continent, therefore, we may consider that chain where the Mississippi, the river St Lawrence, the Ohio, and the river de los Estrechos, take their rise, as the most elevated situation in North America; whence the Mississippi flows towards the equator, the river St Lawrence towards the north-east, and the rest towards the north-west. In the old continent, the belt formerly mentioned, and to which we may assign about 10 degrees of breadth, may be reckoned from the 45th to the 55th degree of north latitude: for in Europe the Tagus, the Danube, the Dnieper, the Don and the Volga, and in Asia the Indus, the Ganges, the Meran, the Mecon, the Hoang-ho, and the Yang-tse-Kiang, descending as it were from this elevation, fall into the great reservoir between the tropics; whilst towards the north eneral stribu- of the terials f the arth.

north the Rhine, the Elbe, the Oder, the Vistula, the Oby, the Jenisei, the Lena, the Indigirka, and the Kowyma, are discharged into the northern reservoir.

Judging from those mountains the height of which has been calculated, and from the immense chains with which we are acquainted, we may infer that the highest mountains are to be found in this elevated belt. The Alps of Swisserland and Savoy extend through the 45th, the 46th, and the 47th degrees. Among them we find St Gothard, Furca, Bruning, Russ, Whiggis, Scheidek, Gunggels, Galanda, and lastly, that branch of the Swiss Alps which reaches Tirol by the name of Arlenberg and Arula. In Savoy, we meet with Mont Blanc, the Peak of Argentiere, Cornero, Great and Little St Bernard, Great and Little Cenis, Coupeline, Servin, and that branch of the Savoyard Alps which proceeds towards Italy through the duchy of Aost and Montferrat. In this vast heap of elevated peaks, Mont Blanc and St Gothard are particularly distinguished. The Alps, leaving Swisserland and Savoy, and passing through Tirol and Carniola, traverse Saltzbourg, Stiria, and Austria, and extend their branches through Moravia and Bohemia, as far as Poland and Prussia.—Between the 47th and 48th degrees, we meet with Grimming the highest mountain of Stiria, and Priel which is the highest in Austria. Between the 46th and 47th degrees, the Bacher and the Reinschnicken, form two remarkable chains. The upper one, which traverses the counties of Trencsin, Arrava, Scepus, and the Kreyna, separates Upper Hungary from Silesia, Little Poland, and Red Russia; the inferior one traverses Upper Croatia, Bosnia, Servia, and Transylvania, separates Lower Hungary from Turkey in Europe, and meets the upper chain behind Moldavia, on the confines of Little Tartary. In these mountains are situated the rich mines of Schemnitz.

To form a general idea of the great height of this Alpine belt, it is necessary only to remark, that the greatest depth of the wells at Schemnitz is 200 toises; and yet it appears from the barometrical calculations of the learned M. Noda, that the greatest depth of these mines is 286 toises higher than the city of Vienna. The granito-argillous mountains of Schemnitz, and of the whole of this metallic district, are inferior, however, to the Carpathian mountains. Mount Krivany in the county of Arrava, and the Carpathian mountains between Red Russia and the Kreyna, appear by their great elevation to rule over the whole of the upper Alpine chain. In the inferior chain we likewise meet with mountains of an extraordinary height; among others, Mount Mediednik, which gives its name to a chain extending far into Bosnia; and Mount Hemus, celebrated even among the ancients. In short, this extensive chain reaches into Asia, and is there confounded with another chain no less famous, which, following exactly the 50th degree of latitude, runs through the whole of Asia. This chain of mountains is described by Dr Pallas in the work above mentioned; and we shall now trace its course in company with this intelligent observer.

Uralian chain.

This author places the head of the mountains of Oural, between the sources of the Yaik and the Bielaïa, about the 53d degree of latitude, and the 47th of longitude. Here the European Alps, after having traversed Europe, and sent off various branches which we shall afterwards examine, lose their name, which is changed into that of the Ouralic or Uralian mountains, and begin their course in Asia. This lofty chain, which separates Great Bulgaria from the deserts of Ischimska, proceeds through the country of the Eleuths, follows the course of the river Irtis, approaches the lake Teleskaia, and afterwards forms a part of the same system of mountains with the Altaic chain. There they give rise to the Oby, the Irtis, and the Jenisei, which begin their course about the 50th degree of north latitude, and fall into the Frozen ocean.

General Distribution of the Materials of the Earth.

132 Altaic chain.

The Altaic chain, after having embraced and united all the rivers which supply the Jenisei, is continued under the name of *Saiunes*, without the smallest interruption, as far as the Baikal lake. The extension of this chain to the south forms that immense and elevated plain which is lost in Chinese Tartary, which may be compared with the only plain in Quito, and which is called *Gobi* or *Chamo*. The Altai afterwards interposing between the source of the Tchikoi and of the rivers which supply the Amur or Sagaleen, rises towards the Lena, approaches the city Jakuck beyond the 60th degree of latitude, runs from that to the sea of Kamtschatka, turns round the Ochockoï and Pensink gulfs, joins the great marine chain of the Kurile isles near Japan, and forms the steep shores of Kamtschatka, between the 55th and 60th degrees of latitude. After running in the same parallel, and giving rise to the Ohio, the Riviere Longue, the river St Lawrence, and the Mississippi, they are lost in Canada. From the eastern shores of America to the western shores of Europe, we find a vast interruption.

133 Alpine chain.

The European Alps produce three principal chains which run towards the equator, and some smaller ones running towards the pole. The first southern chain is sent out through Dauphine; traverses Vivarais, Lyonnois, Auvergne, Cevennes, and Languedoc, and, after joining the Pyrenees, enters Spain. There it divides into two or three ramifications, one of which runs through Navarre, Biscay, Arragon, Castile, Marche, and Sierra Morena, and extends into Portugal. The other, after traversing Andalusia and the kingdom of Granada, and there forming a number of mountains, again makes its appearance, beyond the straits of Gibraltar, in Africa, and coasts along its northern shores, under the name of *Mount Atlas*.—The second principal chain of the Alps passes out through Savoy and Piedmont; spreads its roughnesses over the states of Genoa and Parma; forms the belt of the Appennines; and after frequently changing its name, and dividing Italy into two parts, terminates in the kingdom of Naples and in Sicily, producing volcanoes in every part of its course. The third chain is sent off from Hungary, and scatters innumerable mountains over all Turkey in Europe, as far as the Morea and the Archipelago at the bottom of the Mediterranean sea. The northern branches, though smaller at first, are no less clearly defined; and some of them even extend their ramifications as far as the Frozen ocean. An Alpine branch, issuing from Savoy through the country of Gex, proceeds through Franche Comté, Suntgaw, Alsace, the Palatinate, and Veterabia.—

General Distribution of the Materials of the Earth.

Another issues from the territory of Saltzbourg, passes along Bohemia, enters Poland, sends off a ramification into Prussia towards the deserts of Waldow, and after having passed through Russia is lost in the government of Archangel.

134 Asiatic Alps.

The Asiatic Alps send forth in like manner several branches both to the south and north. The Ouralic mountains, between the sources of the Bielaia and the Jaik, produce three principal branches; the first of which, including the Caspian sea in one of its divisions, enters Circassia through the government of Astracan, passes through Georgia under the name of *Caucasus*, sends a vast number of ramifications to the west into Asiatic Turkey, and there produces the mountains, Tschilder, Ararat, Taurus, Argée, and many others in the three Arabias; while the other division, passing between the Caspian sea and the lake Aral, penetrates through Chorasan into Persia. The second branch, taking a more easterly direction, leaves the country of the Eleuths; reaches Little Bucharia; and forms the ramparts of Gog and Magog, and the celebrated mountains, formerly known by the name of *Caf*, which M. Bailly has made the seat of the war between the Dives and the Peris*. It traverses the kingdoms of Casgar and Turkestan, enters through that of Lahor into the Mogul territory, and, after giving rise to the elevated desert of Chamo, forms the western peninsula of India. While these two branches run towards the south, the third branch of the Ouralic chain rises towards the north, following almost the 79th degree of longitude, and forms a natural boundary between Europe and Asia; without, however, bounding the immense empire of Russia. This chain, after coming opposite to Nova Zembla, divides into two considerable branches. The one, running to the north-east, passes along the Arctic shores; the other, proceeding towards the north-west, meets the northern European chain, traverses Scandinavia in the shape of a horse shoe, covers the low lands of Finland with rocks; and, as is observed by Dr Pallas, appears to be continued from the North Cape of Norway through the marine chain of Spitzbergen, scattering islands and shelves perhaps throughout the northern ocean, that, passing through the pole, it may join the northern and eastern points of Asia and North America.

* *Lettres sur les Atlantides*, let. 16.

135 The Ouralic, which, in the country of the Mongols, becomes the Altaic chain, proceeds towards the equator. After forming the mountains and caverns wherein, as we are told, the ashes of the Mongol emperors of the race of Gengis-Kan are deposited, together with the vast plain of Chamo, consisting of arid sand, and the frightful rocks and precipices of Thibet, which form the mysterious and desert retreats of the Grand Lama, it crosses the rivers Ava and Menan; contains in its subdivisions the kingdoms of Ava, Pegu, Laos, Tonquin, Cochin-China, and Siam; supports the peninsula of Malacca; and overspreads the Indian ocean with the isles of Sunda, the Moluccas, and the Philippines. From the borders of the Baikal lake and of the province of Selinginskoy, a branch is detached, which spreads over Chinese Tartary and China, is continued into Corea, and gives rise to the islands of Japan.

The great chain having extended to the north, near the city of Jakuck, upon the banks of the Lena, sends off one of its branches to the north-west, which, passing between the two Tungusta, is lost in marshy grounds lying in the northern parts of the province of Jenisseiskoy. The same chain, after it has reached the eastern part of Asia, is lost in the icy regions of the north about Nos-Tschalatskoy, or the Icy Promontory, and Cape Czuczenskoy.

136 Southern elevation.

It will be more difficult, perhaps, to trace the elevated belt in the southern hemisphere beyond the tropic of Capricorn, than it has been to distinguish that towards the north. An immense extent of ocean seems to occupy the whole Antarctic part of the globe.—The greatest south latitude of the old continent is not more than 34 degrees, and South America scarcely extends to the 55th degree. In vain has the enterprising Cook attempted to discover regions towards the pole: his progress was constantly interrupted by tremendous mountains and fields of ice. Beyond the 50th degree no land and no habitations are to be found. The islands of New Zealand are the farthest land in these desert seas; and yet the south cape of Taral-Poenamoo extends only to the 48th degree: We do not mention Sandwich land, which is situated in the 58th degree, because it is too small and too low. It must be recollected, however, that, according to the declaration of travellers, the Cordilleras become higher as they advance southward to the straits of Magellan; and that Terra del Fuego, which lies in the latitude of 55, is nothing but a mass of rocks of prodigious elevation. America, however, exhibits to our view elevated points, whence chains of mountains are distributed in different directions over the whole surface of the new continent. There must likewise be great reservoirs, where the most remarkable rivers take their rise, and from which they necessarily descend towards their mouths. In the southern hemisphere, this elevated belt is nearer the equator; and though it does not extend to the 50th degree, it is evidently to be met with, and may be accurately traced, between the 20th and 30th degrees. The high mountains of Tucuman and of Paraguay, which intersect South America about the 25th degree of latitude, may be considered as the American Alps. If we look into the map of the world, we shall be able to distinguish an elevated belt all along this parallel. In Africa, Monomotapa and Caffraria are covered with very high mountains, from which pretty large rivers descend. In the Pacific ocean, we find New Holland, New Caledonia, the New Hebrides, and the Friendly and the Society islands, under the same parallel. We may, therefore, with sufficient propriety, distinguish this parallel by the name of the *Southern Alps*, as we have already distinguished the elevated belt of the 50th degree of north latitude by that of the *Northern Alps*. In America, the Rio de la Plata, which, after a course of 500 leagues, falls into the ocean at the 35th degree of south latitude; the Pavana, which rises from the mountains of the Arapes, and falls into the Plata at Corriente; the great number of rivers which flow into that of the Amazons, such as the Paraba, which receives in its course the tribute of more than 30 other rivers; the Madera, the Cuchirara, the Ucayal, &c. &c. all descend from these southern Alps. From these Alps likewise three considerable branches of mountains are detached, which eral tribu- of the erials the rth.

go by the common name of *Andes* or *Cordilleras.*— The first branch, which extends towards the south, and passes out from Paraguay through Tucuman, separates Chili from these provinces and from Chimito, and is continued through Terra Magellanica as far as Terra del Fuego. The second branch, directing its course towards the equator, traverses Peru, in vain endeavouring to conceal treasures which the avarice of men has taught them to discover in its bowels; bounds the Spanish Missions; enters Terra Firma through Popayan; and unites South and North America by the isthmus of Panama. The third division, issuing from Paraguay through Guayra and the territory of Saint Vincent, traverses Brazil, distributes ramifications into Portuguese, French, and Dutch Guiana, crosses the Oroonoko, forms the mountains of Venezuela, and near Carthagena meets the second branch coming from Popayan.

57 M tains of rth A ca.

We have already supposed, that the elevated belt of North America was situated about the 45th degree of north latitude; and there we imagined we recognized the continuation of the northern Alps of the old continent. This chain likewise sends forth considerable branches on both sides. One of them is detached across the sources of the Mississippi, the Belle Riviere, and the Missouri, and at the entrance of New Mexico divides, in order to form California to the west, and the Apalachian mountains to the east.— Thence proceeding through New Biscay, the audience of Guadalaxara, Old Mexico, and Guatimala, it meets at Panama the southern branch, which is part of the Alps of Paraguay. The second branch, following the course of the Mississippi, separates Louisiana from Virginia; serves as a bulwark to the United States of America; forms the Apalachian mountains in Carolina; and at last, traversing East Florida, encloses the gulf of Mexico with the Great and Little Antilles. In the north, we can trace the branches of the elevated belt; on one side observe them proceeding towards Canada, directing their course through Labrador to Hudson's Straits, and at length confounded with the rocks of Greenland, which are covered with eternal snow and ice. On the other side, we see them rising through the country of the Assinipoels and the Kristinos, as far as Michinipis and the northern Archipelago.

Briti moun ins.

In tracing the course and direction of the British mountains, we shall begin with the central chain, which runs through the southern part of the island from north to south, commencing at Geltsdale, about 14 miles to the south east of Carlisle, and ending at Land's End in Cornwall, or rather in the Scilly isles to the west of this. This chain passes from Geltsdale forest through the western districts of Durham and Yorkshire, forming the hills called Kelton Fell, Stanmore, Widehill Fell, Wildbore Fell, Bow Fell, Home Fell, Bun Hill, &c. A little to the west of the chain stand several detached mountains, the principal of which is Skiddaw in Cumberland. Passing through Yorkshire we find Craven, Whurnside, Ingleborough, and Pennygent; and on the east of Lancaster is Pendle. In this course there are several miles of coal and lead. The chain next proceeds through Derbyshire, and in this part of the ridge a great variety of valuable minerals are found, especially lead, copper, gypsum, fluor, barytic earths, martial pyrites, iron ore, manganese, and several ores of zinc. About this point the ridge stretches a little into Cheshire, and seems to terminate; a central chain of somewhat less elevation may, however, still be traced, proceeding in a waving direction towards Salisbury, and having three irregular branches, two to the east, and another running to the south-west into Cornwall. The first eastern branch proceeds towards Norfolk, and to this belong some considerable hills, especially those of Gog Magog in Cambridgeshire. The second branch passes into Kent, and diverges a little into Surry and Hampshire. The continuation of this chain is afforded by the hills of Mendip, Polden, Ledgemoor, and Blackdown in Somersetshire; the Tores and Wilds of Dartmore in Devonshire, and the upland Downs of Cornwall. Malvern hills in Worcestershire deviate a little from the chain, but those of Cotswold in Gloucestershire appear to be a continuation of it. The principal mineral found in this ridge of mountains, after leaving Derbyshire, is the tin ore of Cornwall.

General Distribution of the Materials of the Earth.

Wales contains many mountains, especially in its northern part, where Snowden is celebrated for its height and classical fame. The top of this mountain is formed almost into a point, and commands an extensive view, not only of the neighbouring counties, but of part of Scotland and Ireland, and the isles of Man and Anglesey. A line of mountains proceeds from Snowden along the western coast to Plinlimmon; and in this line lie Urrou Seth, Caeridris, and Moyle Vadiau. A few hills of little elevation proceed towards Shropshire, among which the Wrekin is the most remarkable. Another small chain proceeds south towards Cardiff, but contains no hills of any eminence. 139

140 Scotch mountains.

Leaving England, and proceeding towards the north, we find the Cheviot Hills, so celebrated in the history of the border skirmishes. These form a regular ridge, running from south-west to north-east, where they join the hills of Galloway. In this part of Scotland there are several mountainous ridges running in various directions, generally north and south according to the course of the rivers; but there is, properly speaking, no uniform chain. Dumfries-shire contains several mountains, some of which are of considerable height, especially Hartfell in Annandale, from which proceeds the celebrated chalybeate spaw; Lowther near Leadhills; Blacklaw on the borders of Ayrshire; Etrick Pen, in Eskdale moor; Carnkinnow near Drumlanrigg; and Queensberry hill, which gives the title to the dukedom of that name. Proceeding towards the north, we find Pentland hills, a little to the south-west of Edinburgh, and the romantic hills of Arthur's seat and Salisbury Craigs, in the immediate vicinity of that city. On the eastern coast, before crossing the Forth, is North Berwick Law, which must be considered as closing the list of southern hills in Scotland. The principal part of these southern hills consists of calcareous earth, and argillaceous schistus; and except in those of Galloway, granite and other primitive rocks are very sparing. In the Lothian hills the calcareous strata are surmounted by vast blocks of trap, wacke, and basalt.

On the north of the Forth are the hills of Ochil, of little elevation, but celebrated for affording large quantities of agates and chalcedonies. The hills of Kinnoul and Dunsinnan in the eastern part of Perthshire, are generally considered the last of the lowland hills.

The

General Distribution of the Materials of the Earth.

The principal northern chain of British mountains is that of the Grampian hills, extending from Loch Lomond to Stonehaven, and forming the southern boundary of the Highlands; and rising by a gradual transition from the Sidlaw hills on the east, the Campsey hills on the west, and the Ochils in the middle. The principal mountains of this chain are Ben Lawers, Ben More, Schehallion, Ben Vorlich, Ben Lomond, and Ben Ledy. Near Ben Lawers is Ben Nevis, the highest mountain in Britain, and to the north-west of this, near Fort Augustus, is the long hill of Corri Allok. About 30 miles to the east of this is the high mountain of Cairngorum, famous for the specimens of quartzose stones found there. Numerous mountains lie in the second divisions of the Highlands, beyond Loch Linne, and Loch Ness, especially on the western shore, which is crowded with hills. Few of these are considerable. To the west of Ross-shire are several hills, among which Ben Chat, Ben Chasker, and Ben Golich are the most remarkable. More inland stands the high mountain of Ben Wevis, nearly equal to Ben Nevis. In most of these mountains the primitive rocks prevail, and granite is often very abundant. Few minerals, however, except iron ore, are found.

141 Irish mountains.

Ireland contains but few mountains, and none of any considerable importance. They generally form short lines, or appear in detached groups, one of the highest of which is that on the west and south of the lake of Killarney, in which is the mountain of Mangerton. A small line of hills called Shecky mountains runs on the north-west of Bantry Bay, passing towards the east. To the northward of this stands Sliblogher and Nagles, and towards the east are the hills of Knockemdown. In the county of Leinster is a mountain of the same name, and to the south of Dublin are the Wicklow hills, from which there were lately such great expectations of golden treasure. In Ulster stand the mountains of Monrne, the highest of which, Donard, is said to be nearly the height of Mangerton. The most mountainous part of Ireland is the western peninsula of that island, towards which, in the county of Mayo, stands Nephin, one of the highest in the kingdom. On the south-east of Clewbay is the mountain of Croagh Patrick, also in the county of Mayo, which is the last Irish hill of any importance.

We cannot here with propriety enter on the theory of the formation of mountains. The hypothesis of the principal geological writers with respect to this subject, will be seen from the general view of the theories to be given in the next chapter. We may in this place only remark, that all the systems which have been constructed, to explain the formation of the primitive mountains, with respect to which there is the most dispute, may be reduced to three.

In the first of these, mountains are supposed to have been formed such as we now see them, except that they have suffered some degradations and modifications, from certain accidents posterior to their original formation, and that these mountains owed their elevation above the places which surround them, to one single accidental accumulation of more materials in one place than in another; an accumulation which might have taken place without that great precipitation which preceded and occasioned the consolidation of the crust of our globe.

In the second hypothesis, all the primitive mountains, are supposed to have been raised by one cause, and in one certain manner; and the materials which compose them, to have been thrown out of their natural position. It is with respect to this raising or displacement that geologists have imagined so many different hypotheses.

In the third general theory, these mountains are supposed to have become pre-eminent from the accidental lowering or removal of the materials which originally surrounded them, whether this happened from the materials composing these mountainous situations having suffered no displacement, or that they had been themselves removed.

M. Dolomieu is of opinion, that there are mountains whose situation and structure favour each of these three hypotheses *.

* Journ. de Min. [illegible] xlii. p. [illegible]

Sect. II. *Of Dykes.*

14[illegible] History of dykes.

We have described dykes (N° 15.) to be those interruptions of the strata which are formed by perpendicular fissures filled with stony substances. As these stony matters are frequently of that kind called whinstone, these dykes are commonly called *whin dykes*, and the history of these is very important, as they form one of the principal subjects in the principal theories of the earth.

14[illegible] Names.

Dykes have received different denominations descriptive, in some measure, of the nature of the substances of which they are composed; or of the seeming effects they have produced on the intersected horizontal strata. They are called *basaltic veins*, *trap dykes*, *whin dykes*; and in the coal countries of Scotland they are called *gaws*, from the idea that they have occasioned the separation of the coal, and contiguous strata, through which they run.

These dykes have been more attentively observed in coal countries, than where they occur elsewhere; because on the accurate knowledge of their course, inclination, and thickness, depend, in a great measure, the judicious and successful operations of the miner, when his workings approach the dyke, or render it necessary to cut through it to reach the strata of coal on the other side. But, though less attended to, they have been observed and traced in other places, where a great extent of the horizontal strata has been exposed in the beds of rivers, as in the bed of the Water of Leith, above St Bernard's Well, near Edinburgh, and on the sea shore, especially on the western coasts of Scotland, where the rocks are more abrupt and precipitous, and where the violence of the Atlantic ocean has removed part of the horizontal strata, and left the vertical strata remaining, like immense walls or dykes. Hence probably the origin of the name; and as they often consist of that species of stone called *whinstone*, this epithet has been added.

14[illegible] Course.

The course, however, of the greater number which we have had the opportunity of examining, generally lies between the points of the compass S. and S. E. and N. and N. W. This is most frequently the course of the whin dykes of Islay and Jura; it is the course of a remarkable dyke which traverses the coal strata at the village of Stevenson, near Saltcoats, in Ayrshire; part of which is seen on the surface, not many hundred yards to the north of the west end of that village;

lage; and it is the course of two dykes, still more remarkable, in the island of Great Cumbray, in the frith of Clyde.

Geologists, who have treated this subject, do not seem to have marked, with much attention, the course of the dykes. They have mentioned in general terms, that they follow all directions. More extensive observation may probably shew, that the most frequent directions of the principal dykes, is from north to south, or a few points deviation from that course. And if this be established, by a fuller and more accurate history of dykes, the analogy between them and metallic veins will be more complete; for it is observed of the latter, that the most powerful, that is, the most productive, run from north to south.

Dykes do not always run in a straight line. In their course they form certain flexuosities. But, in this winding course, the deviations are usually so small, as to have little effect on the general direction of the dyke, which, upon the whole, may be considered as nearly the same.

The continuity of dykes is sometimes interrupted, exactly in the same manner as frequently happens to the horizontal strata, and which, in technical language, is termed a *slip*.

In the island of Islay we have observed two dykes of this description, the one on the south side of Lochindal, near the point of Laggan; the other on the shore of the south-east part of the island, a little to the south of the house of Ardmore. In both these dykes, the extent of the separation of the slip was just equal to the thickness of the dyke. The opposite sides were brought exactly into the same line.

After this separation, these dykes, in so far as they could be traced, preserve the same thickness, course, and inclination as formerly.

A very remarkable dyke has been discovered, in the coal field, in the district of Boulogne in France. It runs in the form of a crescent from north to west.

5 …nation. The direction of dykes downwards is seldom perpendicular. This deviation from a line perpendicular to the horizon is called their inclination. The inclination of a dyke is usually denominated the *hade* or *hading*. See the article Coalery.

The inclination of different dykes, and even of the same dyke, is various, sometimes approaching to, and sometimes deviating from the perpendicular. The extent of dykes downwards, we believe, has not been ascertained with any degree of accuracy, and the termination of very few has yet been detected. The depth to which researches of this kind can be carried, is comparatively small. With all the ardour, ingenuity, and power of man, investigations to determine this point, will probably always be limited by the extent of his mining operations. The crescent-formed dyke just mentioned, which occurs in a coal-field in the district of Boulogne in France, which consists of a species of marble, found in several quarries in the vicinity, has been traced to the perpendicular depth of 600 feet, where it is succeeded by a schistus rock, which latter, with the same course and inclination, continues to intersect the horizontal strata.

1 …tent. The extent of dykes in length has not been accurately determined. Indeed, it must be extremely difficult to trace them with any degree of certainty. For those which are observed on the sea coast, where they are most conspicuous, soon disappear in the mountains, on the one hand, or on the other lose themselves in the sea. And, as the extent of the same coal field rarely exceeds a few miles, they have seldom been followed beyond its limits. In many cases, the change in the nature and arrangement of the strata, renders it almost impossible. Some, however, have been traced to a very great extent; one in particular, on the banks of the river Meuse in the Netherlands, has been followed in its direct course, to the distance of four leagues; and of this dyke it is observed, if pursued through all its windings, the extent is not less than six leagues.

The thickness of dykes is various. Sometimes they are observed no thicker than a few inches. From that they increase to one foot, six feet, and very often are found from 10 to 20 feet. There is one in the island of Islay, of the enormous thickness of 69 feet. This immense dyke accompanies a lead vein, about a foot thick, which is included between it and the limestone strata. In this mining field, two whin dykes, one of them 10 feet thick, have been discovered, crossing the metallic veins. 147 Thickness.

In going downwards, dykes are said to decrease in thickness. This is particularly observed of dykes of smaller magnitude. Of smaller dykes it is also said, that they diminish in thickness towards the extremities.

In one respect, some whin dykes are exactly analogous to metallic veins, in having branches, or in the miners phrase, *strings* going off and traversing the contiguous strata, and forming in the course they take, an acute angle with the principal dyke. A whin dyke of this description has been observed in the island of Jura, on the shore of the sound. The diverging branch terminated in a point among the horizontal strata, at the distance of a few feet from the great dyke, assuming altogether a wedge-like form.

If we include metallic veins in the account, the vertical strata may be said to be composed of every kind of mineral substance, but almost always different from the intersected horizontal strata. By this last circumstance their occurrence is at once recognized. In general, the dykes that are found in Scotland, whether in the coal countries, or in the western coasts and islands, where they are so frequent, are of that species of stone which comes under the denomination of trap or whinstone. Dykes, consisting of other species of stone, have also been found in Scotland. On the Mull of Kinouth, which forms the southern headland, at the entrance of Lochindal, in Islay, we observed a small dyke of granite, crossing the headland, which is of granular quartz. There are some vertical strata of granite in the island of Icolmkill, of pitchstone in the island of Arran, and of serpentine at Portsoy in Banffshire. 148 Materials.

Bergman, in his Physical Geography, supposes that granite was never found to be a component part of vertical strata. What has been already mentioned proves the contrary. Granite dykes have also been discovered in other places. Besson has observed dykes of this description on the great road between Limoges and Cahors in France, traversing horizontal strata of argillaceous schistus, a species of stone which has generally been considered of later formation than granite. These dykes, he observes, are from an inch to six

General Distribution of the Materials of the Earth.

six feet in thickness, and the quartz, feldspar, and mica, are of larger size than are usually found in the granite of mountains. Dolomieu has made a similar observation, and considers it as a discriminative character, by which the granite of mountains and that found in vertical strata may be easily distinguished. But this is not always to be admitted as a characteristic mark of distinction. The granite dyke which has been already mentioned, crossing the granular quartz, on the Mull of Kinouth in Islay, is small grained, and others of this latter description have been observed in other places.

There is a very singular dyke on the coast of Ayrshire, between Weems bay and Largs, near the house of Kelly. It is about ten feet thick, traverses the horizontal strata, which consist of plumb-pudding rock, whose cement is sandstone of a red colour, from north-east to south-west, and crosses a larger dyke of the whinstone of this country, nearly at right angles. This dyke is composed of different materials. Part is of the common whinstone, and part of a plumb-pudding rock, cemented by the matter of the dyke; and these alternate with each other, both in the thickness of the dyke, and lengthwise. On one side, there are four feet thick of whinstone; immediately in contact with this there is plumb-pudding stone three feet thick, and so on alternately, across the whole dyke. In tracing the dyke lengthwise across the whole line, there is found a few yards of whinstone, which is succeeded by a few yards of plumb-pudding stone, and this is again succeeded by the whinstone.

But, for the general view which is here proposed, it is not requisite to give a full account of all the mineral substances which enter into the composition of vertical strata, or even a minute enumeration of all the varieties that are found in whin dykes.

149 Peculiar structure of whin dykes.

One of the most singular circumstances respecting whin dykes, which seems to have been entirely overlooked by geologists, still remains to be considered. This is the peculiar structure or arrangement of the parts of which they are composed. Of this peculiar arrangement it may be observed in general, that it is in all respects the reverse of what takes place in the horizontal strata.

When the dyke is of small magnitude, it is pretty compact in all its parts; but if an attempt be made to break or separate any part of it, the fracture will be found to run most readily in the perpendicular direction. But when the dyke is of more considerable thickness, it usually forms several divisions, marked by perpendicular fissures, and there is often very great variety in the nature and qualities of the several divisions of the same dyke. The exterior division of one side sometimes, and sometimes the exterior division of both sides, are of a softer texture than the intermediate division; and often contain, in great proportion, specks of radiated zeolite and calcareous spar, while the middle divisions, as well as being harder, are also more homogeneous. In other cases, the reverse of this appears. The middle parts of the dyke are the softest and least compact, exhibiting the greatest variety of heterogeneous substances.

Some whin dykes have a great tendency to assume, when broken, the prismatic form. This is the case with many, even of the most compact texture. In others, where the side of the dyke is exposed to view, and minutely examined, fissures may be traced, discovering the ends of pretty regular prisms. But in some dykes in the island of Jura, the prismatic columns are entirely separated, and lying loose, are four, five, or six-sided, jointed; the perpendicular fissures forming the joints, and in all respects similar to the perpendicular basaltic columns, except being in the horizontal position. In one of the dykes in the island of Jura, the columns are from 12 to 18 inches in diameter. In some others on the sea shore, near the house of Mr Campbell of Jura, and at the harbour of the Small Isles, in the same island, there are columns of the enormous size of 10 and 12 feet diameter.

A dyke which traverses the basaltic strata of the Giants Causeway in the north of Ireland, exhibits still more remarkably this peculiarity of structure. The smallest masses detached from it assume the columnar form, and most of them are perfectly regular. The fracture invariably runs in the horizontal direction; the columns consequently lie in the same position, are three, four, five, and six-sided, and are generally of small size. *Observations on Vertical Strata, by* Dr Millar, *Scots Mag.* vol. lxiv.

Sect. III. *Of Metallic Veins.*

15[0] Metal[lic] veins.

The history of metallic veins, although far from being so full and satisfactory as could be wished, is more complete than that of whin dykes. The latter have excited no farther attention than as objects of curiosity to the geologist, or as singular facts in establishing a theory, and when they come in the way of the operations of the miner, to discover their connexion with the contiguous strata; while the wants and luxuries of man have roused ingenuity and exertion in exploring the former, on account of the precious and useful metals with which they are stored. Thus, the splendour and beauty of some metallic substances, and the utility of others, have made them in all ages be esteemed and valued by mankind; and consequently they have been the constant objects of pursuit and investigation. It is obvious that the beauty and utility of metals, on account of which they are so much valued and sought after, excite greater interest in procuring them; on the one hand, the researches and observations of the philosopher in furnishing the history and general principles, and, on the other, the immediate application of this knowledge, and of these principles, in the practice and operations of the miner.

The history of whin dykes is, in general, quite analogous to metallic veins; but, of the latter, from what has been stated, we can speak with more certainty and precision.

1[51] Distinction of veins.

Three different kinds of metallic veins have been described by geological writers; the *perpendicular* vein, the *pipe* vein, and the *flat* or *dilated* vein. We shall consider each of these in their order.

1[52] Perpendicular veins.

1. *Of the perpendicular vein.*—This kind of metallic vein occurs most frequently. As may be expected, it is various in its course or direction, thickness, and inclination. Metallic veins are found running in every direction; but, in general, the most powerful veins, that is, the most productive, are observed to run from north to south, or at least a few points deviation from that course; and when any deviation happens, it is usually to the east of north, and to the west of south.

1[53] Course of veins.

The course or direction of a vein is called in technical

General Distribution of the Materials of the Earth.

cal language its *bearing*. The extent of a vein in the line of bearing, we believe, rarely exceeds the range of mountains in which it is discovered. This is the case with the principal vein at Leadhills. It is limited to the chain of mountains in which the operations are now carried on; and although the mines of Wanlockhead are not a mile distant, new veins appear with galena or lead ore, of quite a different quality, and all the accompanying minerals, whether forming part of the vein, or found in cavities, are also quite different from the lead ore and other minerals found in the veins at Leadhills.

154 Inclination.

The inclination of veins is various. Sometimes they are nearly perpendicular; sometimes they deviate considerably from a perpendicular line; sometimes the same vein in its course downward, inclines to one side; sometimes it is perpendicular, and sometimes it inclines to the other side. When the deviation from the perpendicular does not exceed 10°, the vein is still considered as a perpendicular or vertical vein. When a vein is inclined, the two sides which include the metallic substances are in very different positions, and have consequently received from the miners different names. That side which supports the metallic ore, or on which it seems to lean, is called the *ledger side*, or simply the *ledger*. The opposite side which covers the ore, or which overhangs it, is denominated the *hanging side*, or simply the *hanger*. From the inclination of the vein being varied in its course downwards, it must appear that the same sides, according as the inclination varies, must change their position and denomination. This will perhaps be more intelligible by the section at fig. 5. in which AA represents the vein; BB, CC, DD, EE, the strata intersected by it; 1. the hanger; 2. the ledger; 3. the hanger; and, 4. the ledger.

155 Thickness.

The thickness of veins, and indeed of the same vein, is also extremely various. Sometimes they are only a few inches thick. From this they increase to the thickness of several feet. The veins which were wrought at Leadhills, about seven years ago, were from two to six feet within the sides; but some years before that time the principal vein in those mines, by the addition of two strings or small veins, assumed the extraordinary thickness of 14 feet of pure ore. This unusual appearance, both on account of its richness and grandeur, excited so much attention and admiration, that the countess of Hopetoun undertook a journey to these inferior regions, not less than 150 fathoms below the surface of the earth, to witness the splendour and brilliancy of this subterraneous apartment. The uncommon thickness and abundant richness of this vein are still talked of at Leadhills with enthusiasm. But a thicker vein was once wrought at Llangunog in Wales. Fifteen feet of clean ore were for some time dug out of this vein. These are, however, far exceeded by the copper veins in the Parys mountain in Anglesea, which are described by Mr Pennant in his Welsh tour. The thickness of one of these veins is 21 feet, and of another 66 feet.

The broadest metallic vein, of which we have any account, is, we believe, that of the Ecton copper mine, in Derbyshire. In this mine there was worked, at one time, a heap of ore, of the astonishing extent of 70 yards from side to side *.

The extent of veins downwards has in many cases been ascertained. To the regret and disappointment of the miner, they have been frequently intercepted and entirely cut off by the horizontal strata. The rich vein of lead ore at Llangunog in Wales, which we have already mentioned, was intercepted in this manner by a stratum of black schistus or shiver, the nature of which is not described by Williams, who states the fact *. Their researches to recover their lost wealth, which were prosecuted for several years, proved altogether fruitless. The smallest trace of this unusually productive vein was never afterwards discovered.

156 Two kinds of perpendicular veins.

Two kinds of perpendicular mineral veins have been observed and described. In the one case the relative position of the strata which contain the metallic substances is exactly similar to that of the coal strata when they are intersected by a whin dyke. On one side of the vein the strata are elevated or depressed from their former plane. This is illustrated by fig. 5. where the letters BB, CC, DD, EE, mark the corresponding strata which have been deranged or displaced. In the other kind of vein the mineral substances containing the metallic ores are merely separated without any elevation or depression; for each side of the fissure still remaining in its former plane, the opposite sides of the divided strata exactly correspond to each other. The mines at Strontian in Argyleshire are of this latter description.

Veins of this kind have frequently smaller veins, or, as they are called in the language of the miners, *strings*, which run off at an acute angle, preserve their course for some distance, not, in general, very great, gradually diminish in thickness, and at last are entirely lost among the contiguous strata. At the place of junction the principal vein is always thicker, as has been already noticed with regard to the unusual thickness of the principal vein at Leadhills.

To this account of perpendicular veins we may add, that some veins are found crossing each other, and that whin dykes have also been discovered intersecting metallic veins. Examples of the latter occur in the island of Islay.

157 Pipe vein.

2. *Of the pipe vein.*—The perpendicular vein last described, intersected or cut the strata across. What has been denominated the pipe vein is extremely limited in the line of bearing, but having the same inclination as the strata which include it. It may be considered as in some measure of a circular form, extremely irregular, and always following the course of the strata between which it is included, like the perpendicular veins; sometimes as it dips downwards, it is enlarged; sometimes it is diminished, and sometimes it is so much contracted, that the including strata come into close contact. In a word, this kind of vein is subject to all the irregularities of the veins formerly described, only that its inclination is invariably the same with the accompanying strata.

158 Flat vein.

3. *The flat or dilated vein.*—This kind of metallic vein, after what has been said with regard to other veins, will require but a short description. It is exactly similar to the pipe vein, only that it is more extended in the line of bearing. It is included between the horizontal strata; and therefore its inclination or dip must be the same as the including strata. A vein of this kind might with more propriety and accuracy be regarded as a metallic horizontal stratum, were it not that

* Pryce's Derbyshire p. 11.

* *Mineral Kingdom*, vol. i. p. 274.

General Distribution of the Materials of the Earth.

that it is always found varying in its dimensions, and equally irregular as the perpendicular veins which intersect the horizontal strata.

It is almost needless to add, that the flat or horizontal veins are subject to the same derangement as the coal strata, when they are intersected by a whin dyke. The vein, along with the including strata, is either elevated or depressed, and the same thing takes place when they are traversed by a metallic vein. MS. by Dr Millar.

159 Metallic ores. To finish the sketch of the history of metallic veins, we have only to enumerate the different metallic ores that occur in them, and to mention the places where these are found in greatest abundance. In this enumeration we shall follow the arrangement of metals given by Brochant, in the second volume of his *Traité Elementaire de Mineralogie*.

In naming the several species, we shall adopt the nomenclature of Kirwan, adding the French and German synonyms to each. As it would far exceed our limits to give even a *cursory description* of the several species, we refer the reader for that to the article MINERALOGY in this work, or to the elementary treatises of Kirwan or Brochant, or the more extensive treatise of Hauy.

I. PLATINA

160 Platina ores. Has been found hitherto only in its metallic or native state, and it has as yet only been met with in South America, especially at Choco in New Grenada. It is found in the sand of rivulets, and probably comes from the primitive mountains.

II. GOLD.

161 Gold ores. *Native gold.*—This is found principally in primitive mountains, sometimes in veins, and sometimes disseminated through the stony matter. The substances which most commonly accompany it are quartz, feldspar, calcareous spar, heavy spar, pyrites, red silver ore and vitreous silver ore, and galena. Gold is still more commonly met with in the sand washed from certain rivers. The countries where gold is chiefly found in rocky substances, are Hungary, Transylvania, Peru, Mexico, Siberia, and Sweden. It has also been found in France, near the town of Oisans, in the department of the Isere; but not in sufficient abundance to render the working of the mine profitable. Among the rivers whose sands furnish gold, we may enumerate the Rhine, the Danube, and the Araniosch in Transylvania.

Gold has been found in several parts of the British dominions, especially at Silsoe in Bedfordshire, in the Wicklow hills in Ireland, and in the neighbourhood of Leadhills in Lanarkshire. It is said that a jeweller, who died lately in Dublin, often declared that gold, to the value of 30,000l. had passed through his hands, which was brought from the Wicklow hills. This mine is now in the hands of government, but we believe does not answer the expectation that was first formed as to its produce. General Dirom informs us, that in the reign of James V. of Scotland, 300 men were employed for several summers in washing the sand near Leadhills for gold, of which they are said to have collected to the amount of 100,000l. sterling. It is said that pieces of gold, an ounce in weight, have been found at Leadhills, and that Lord Hopetoun has a piece still larger in his possession*.

* *Mawe's Derbyshire*, p. 139.

III. MERCURY.

162 Mercury ores. Species 1. *Native Mercury*, or *Quicksilver*. Le Mercure natif. Gediegen Quecksilber.—This is found at Idria in the Austrian territories; at Almaden in Spain; in the Palatinate, and a few other places. We are told by Mr Jameson, that a quantity of quicksilver was discovered some years ago in a peat moss, in the island of Islay, and he thinks it probable that veins of it exist there *; but there seems no ground whatever for such expectations.

* *Min. the Isles*, vol. i. p. 153.

Species 2. *Natural Amalgama*. L'Amalgame natif. Naturalicher Amalgam.—This consists of mercury and silver, in very variable proportions. It is found at Sahlberg in Sweden; at Roseneau in Hungary, and especially at Moschellandsberg in the duchy of Deux Ponts, where it is found mixed with common ferruginous clay, and with other ores of mercury.

Species 3. *Mercury Mineralised by the Sulphuric and Muriatic Acids*. Mercure Corneé *ou* Muriaté. Quecksilber Hornerz.—This species was discovered about 30 years ago, in the mines of Moschellandsberg, and at Morefeld, in the duchy of Deux Ponts, by M. Woulfe, mixed with ferruginous clay, quartz, lithomarga, native quicksilver, and cinnabar. It has also been found at Almaden in Spain, and at Hersowitz in Bohemia; but it is very rare.

Species 4. *Native Cinnabar*. Le Cinnabre. Zinnober.—This usually forms a gangart for the other ores of mercury. It occurs in the stratiformed mountains, pretty near the surface. This ore is found in a great many parts of Europe, especially at Almaden in Spain, Idria in the Austrian territories, at Moschellandsberg, in Bohemia, in Saxony, in Hungary, in Transylvania, in the Palatinate, and in France; but in this last it is found but in small quantity.

IV. SILVER.

Species 1. *Native Silver*.—A particular variety of this species, mixed with gold, is very rare. It is principally found in Conigsberg in Norway, and Schlangenberg in Siberia. In the former of these places it is found disseminated through calcareous spar, fluor spar, and rock crystal, in a vein running through a rock of hornblende slate, and accompanied with blende, galena, and pyrites. That of Siberia is found distributed through a mass of heavy spar. 163 Silver ores.

Common native silver is found in considerable quantity in Mexico and Peru. It is also met with in Siberia, Saxony, France, Sweden, Norway, in the Hartz, and in Bohemia. It is principally found in the primitive mountains, distributed through masses of heavy spar, quartz, calcareous spar, fluor spar, pyrites, blende, cobalt, galena, red silver ore, and vitreous silver ore.

Silver has been found in several parts of Britain, especially near Alva in Scotland. It is confidently affirmed, that a mass of capillary silver, weighing 16 oz. was found in the lead mines at Garthoness in the isle of Islay, mixed with galena †.

† *Min. Isles*, v. i. p. 153.

Species 2. *Antimoniated Native Silver*. L'Argent Antimonial. Spiesglas Silver.—This species has hitherto been only found in the mine at St Wenceslas at Altwolfach, and in the duchy of Wirtemberg, in a vein mixed with calcareous spar, heavy spar, native silver, and quartz.

General Distribution of the Materials of the Earth.

Species 3. *Arseniated Native Silver.* L'Argent Arsenical. Arsenik Silber.—This is also rare, having been found only at Andreasberg, in the Hartz, and at Kassala in Spain. In the Hartz it is mixed with native arsenic, red silver ore, galena, blende, and calcareous spar. Considerable quantities of silver, probably of this species of ore, are obtained from the lead ore of Leadhills.

Species 4. *Corneous Silver Ore*, or *Muriated Silver.* L'Argent Cornée *ou* Muriaté. Horn Erz.—This has been found in Peru, Mexico, Saxony, France, Siberia, and, as is affirmed, in Cornwall in England.

Species 5. *Sooty Silver Ore.* L'Argent Noir. Silberschwarze.—This is found in Saxony, France, and Hungary, mixed with other ores of silver, and sometimes with native silver.

Species 6. *Vitreous Silver Ore.* L'Argent Vitreux. Silberglaserz.—This is found in Bohemia, Saxony, Norway, Swabia, Siberia, and in Hungary, mixed with other silver ores, and usually accompanying calcareous spar, heavy spar, and fluor spar.

Species 7. *Red Silver Ore.* L'Argent Rouge. Rothgiltegerz.—This is found in the Hartz, Bohemia, Saxony, France, Swabia, and in Hungary, accompanying native arsenic, realgar, vitreous silver ore, galena, calcareous spar, and heavy spar.

V. Copper.

164 Copper ores. Species 1. *Native Copper.*—This is met with in Siberia, the Uralian and Altaischan mountains, Kamtschatka, Japan, Saxony, France, Sweden, Hungary, Palatinate, and near Redruth in Cornwall, in England. It usually accompanies other ores of copper, especially malachite and copper azure.

Species 2. *Vitreous Copper Ore.* Le Cuivre Vitreux. Kupferglas.—This is found in Siberia, Hungary, Sweden, Norway, Russia, Saxony, Silesia, Hesse, and in Cornwall.

Species 3. *Purple Copper Ore.* La Mine de Cuivre Violette. Buntkupfererz.—This is always found in the neighbourhood of other copper ores, especially with the species last mentioned, and with copper pyrites. It is found in Saxony, Bohemia, the Bannat in Transylvania, the Hartz, Norway, Russia, Sweden, Hungary, Hesse, and in Derbyshire in England, especially in the famous Ecton copper mine.

Species 4. *Yellow Pyrites*, or *Yellow Copper Ore.* La Pyrite Cuivreuse. Kupferkies.—This is the most common species of copper ore, and is found both in primitive and secondary mountains, sometimes in beds, and sometimes in veins. It occurs most abundantly in Bohemia, Saxony, Hungary, Sweden, France, Spain, and especially in Britain, where it forms one of the principal varieties of copper ores, found in the famous Parys mine in the isle of Anglesea.

Species 5. *White Copper Ore.* La Mine de Cuivre Blanche. Weisskupfererz.—This species is very rare, but it has been found in Saxony in the mines of Freyberg, in Hesse, in Wirtemberg, and in Siberia, with other copper ores.

Species 6. *Gray Copper Ore.* Le Cuivre Gris. Fahlerz.—This again is a very common species, and is found in all those countries that possess mines of copper.

Species 7. *Black Copper Ore.* Le Cuivre Noir. Kupferschwarze.—This is found mixed with malachite and with green and blue copper ores in Saxony, Hungary, in the Bannat, in Silesia, in Norway, in Russia, in Swabia, in Sweden, and in Siberia. It also occurs in the Parys mine of Anglesea.

Species 8. *Florid Red Copper Ore.* Mine de Cuivre Rouge. Roth-kupfererz.—This usually accompanies native copper, malachite, and brown earthy iron ore. It is met with in Saxony, in the Bannat, in the Hartz, in Norway, in Siberia, near Cologne, and in Cornwall.

Species 9. *Brick-red Copper Ore.* Le Mine de Cuivre couleur de Brique. Ziegelerz.—Found in similar situations with the preceding.

Species 10. *Blue Calciform Copper Ore.* L'Azur de Cuivre. Kupferlazur.—Found in the Bannat, in Hesse, in Saltzburg, in Poland, in Siberia, in Thuringia, and in the Tyrolese. It is usually imbedded in slaty marl, or in sandstone, not far below the surface of the earth.

Species 11. *Malachite.*—This is always found mixed with other copper ores, and occurs in most of the copper mines that have been enumerated.

Species 12. *Mountain Green.* Le Vert de Cuivre. Kupfergrün.—This commonly accompanies species 4, 6, 9, 10, and 11. It is found in Saxony, in the Hartz, in Norway, Silesia, Siberia, Hungary, Wirtemberg, and Britain, as at Leadhills and in Derbyshire.

Species 13. *Olive Copper Ore.* Mine de couleur Olive. Olivenerz.—This species is extremely rare. It has been found chiefly near Karrarach in Cornwall, where it is accompanied by species 11 and 12, and brown iron ore in a gangart of yellow lithomarga mixed with quartz. It is said to have been found also at Jonsbach near Rustelstadt in Silesia.

VI. Iron.

Species 1. *Native Iron.*—This species is very uncommon; but it has been met with in several places, especially at Kamsdorf and Eibenstock in Saxony, at Kransnajarsk near Jenisei in Siberia, at Olumba near St Jago in South America, and Oulle near Grenoble in France. The two most remarkable specimens of native iron are those found in South America and in Siberia. The former of these forms a mass weighing at least 300 quintals, or 15 tons. It is soft and malleable, and in every respect like the purest iron. That of Siberia is a spheroidal mass, weighing about 14 quintals, resting on the surface of the earth, near the summit of a mountain. Its texture is cellular, and its cavities are filled with a transparent, greenish, vitreous matter. No mines or veins of iron are in the neighbourhood of either. 165 Iron ores.

Species 2. *Martial Pyrites.* Pyrite Martiale. Schwefelkies.—This species is one of the most common ores of iron, and is found abundantly in every country where there are any other ores of iron. There are three varieties of it described by Brochant, which are less common, but these are also found in many places.

Species 3. *Magnetic Pyrites.* La Pyrite Magnetique. Magnetkies.—This has been found only in primitive rocks, especially in micaceous schistus, accompanied by quartz, hornblende, &c. and usually lying in beds mixed with other pyrites, galena, and magnetic ironstone.

General Distribution of the Materials of the Earth.

stone. It is found in Saxony, Bavaria, Norway, and Silesia.

Species 4. *Magnetic Ironstone.* Le Fer Magnetique. Magnetischer Eisenstein.—Of this there are three varieties, the common magnetic ore, which is very common in primitive mountains, especially those that are composed of gneiss and micaceous schistus. It is often in great abundance, forming large beds, or even whole mountains. It is found in greatest quantity in Saxony, Bohemia, Italy, Corsica, Silesia, Siberia, Norway, and especially in Sweden. The second variety, called fibrous magnetic ironstone, is uncommon, but is found at Bibsburg in Sweden. The third, which Kirwan calls *magnetic sand*, is found in the banks of some rivers, particularly of the Elbe, as also in Sweden and Italy.

Species 5. *Specular Iron-ore.* Le Fer Speculaire. Eisenglanz.—This is found in many places, often in considerable quantity, especially in Saxony, Bohemia, France, Normandy, Prussia, Sweden, Siberia, Hungary, Corsica, and the island of Elba. It is generally found only in primitive mountains, sometimes in beds, sometimes in veins, accompanied with quartz, hornstone, martial pyrites, and magnetic iron ore.

Species 6. *Red scaly Iron Ore.* La Mine de Fer Rouge. Roth-Eisenstein.—This is rather rare, but is found in several parts of Saxony, in the Hartz, in Nassau, in Thuringia and Hungary. Another variety of the same species, the compact red ironstone of Kirwan, is much more common, being found in Saxony, Bohemia, the Hartz, Hesse, Siberia, and in France, sometimes in veins, and sometimes in beds, commonly mixed with the two following species, and with argillaceous ironstone, quartz, hornstone, and calcareous spar.

A third variety, the common hematites or bloodstone, which is one of the most productive iron ores, is always found accompanying the last variety, and is of course met with in most of the situations above enumerated. It is produced in abundance in several parts of England, as in Derbyshire, but more especially at Ulverston in Lancashire, where there is one perpendicular vein of it 30 yards wide, in a rock of limestone. Large quantities of it are carried to Carron, where it is smelted with the common Carron ironstone.

Species 7. *Brown Iron Ore.* La Mine de Fer Brune. Braun-eisenstein.—Of this there are several varieties, of which the compact brown ironstone, and the brown hæmatites, are very common; but the brown scaly iron ore is rather rare. The last is found at Kampsdorf in Saxony, at Klausthel, in the Hartz, at Lauterick in the Palatinate, and at Naila in the principality of Bareith.

Species 8. *Calcareous Iron Ore.* La Fer Spathique. Spathiger-eisenstein.—This is found both in primary and secondary mountains, and there are few veins of iron which do not contain it in greater or less quantity.

Species 9. *Black Ironstone.* La Mine de Fer Noire. Schwarz-eisenstein.—This is found in the principality of Bareith, in the Hartz, Saxony, Hesse, and Palatinate.

The common argillaceous iron ore of Kirwan, is ranked by Brochant as a variety of this. It is very common in most iron countries, and much of it is found in Britain, especially in Colebrook-dale, Shropshire, and in Dean forest in Gloucestershire. The Carron ore is principally of this kind.

Species 10. *Lowland Iron Ore.* La Mine de Fer de Gazon. Reasen-eisenstein.—There are several varieties of this, all of which are found in low, humid situations, in very extensive beds, alternating with sandstone, clay, &c. This species is much more abundant in the north than in the south of Europe, especially in the duchy of Brandenburg, in Courland, Lithuania, Livonia, Prussia, Prussian Poland, and Lusace.

Species 11. *Blue Martial Earth.* La Fer Terreux bleu. Blaue-eisenerde.—This is found imbedded in clay and similar earths, and often accompanies the last species. It occurs in Saxony, Silesia, Swabia, Bavaria, Poland, and the Palatinate.

Species 12. *Green Martial Earth.* Le Fer Terreux Vert. Grun-eisenerde.—This species is uncommon, having been found only at Braunsdorf, and Schneeburg in Saxony, in veins, accompanying quartz and sulphur pyrites.

Species 13. *Emery.* L'Emeril. Schmirgel.—This is found in Saxony, distributed in a bed of hardened steatites, in sandstone. It is also found in Italy, Spain, Peru, the isle of Naxos in the Archipelago, where there is a cape called by the Italians, *Capo Smeriglio*, or the *Emery Cape*. It is often mixed with particles of magnetic iron ore, whence some have supposed the emery to be magnetic.

VII. Lead.

166 Lead.

Species 1. La Galéne Commune. Gemeiner-Bleiglanz.—This is the most common and abundant ore of lead, and is found both in primitive and secondary strata, in beds and veins, accompanied with quartz, fluor spar, calcareous spar, sparry iron ore, barytic earths, blende, pyrites, and several ores of silver. It is found in great abundance at Leadhills and at Wanlockhead in Dumfrieshire, in Derbyshire, Strontian in Scotland, and in the Mendip hills in Somersetshire. A variety of this, called compact galena, is found in the same situations, especially in Derbyshire. It has often been confounded with *graphite*, or *plumbago*.

Werner enumerates nearly 20 formations, as he calls them, of galena, but Mr Jameson thinks the galena formation in Dumfriesshire is different from any of these.

Species 2. *Blue Lead Ore.* La Mine de Plomb Bleue. Blau-bleierz.—This species has as yet been found only at Zschopau in Saxony, accompanying fluor spar, barytic spar, white and black lead, and malachite.

Species 3. *Brown Lead Ore.* La Mine de Plomb Brune. Braun-bleierz.—This species is also very rare, but is found at the same place with the last, and also in Bohemia, Brittany, and Hungary.

Species 4. *Black Lead Ore.* La Mine de Plomb Noire. Schwarz bleierz.—This is found in Saxony, at Freyberg, at Zschoppau, in Cumberland, in some parts of Scotland, in Poland, and Siberia.

Species 5. *White Lead Ore.* La Mine de Plomb Blanche. Weiss-bleierz.—This is not a very abundant species, but it is found in several lead mines, especially in Bohemia, Saxony, the Hartz, France, Siberia, Hungary, Carinthia, and in some of the British lead mines, especially at Leadhills.

Species 6. *Green Lead Ore.* Phosphorated lead ore of Kirwan. La Mine de Plomb Vert. Grun-bleierz.—This is found in veins, more commonly in the primitive mountains. It is met with in Bohemia, Saxony,

Bavaria,

General Distribution of the Materials of the Earth.

Bavaria, Siberia, Brisgau, France, Peru, and at Leadhills in Scotland.

Species 7. *Red Lead Spar.* Le Plomb Rouge. Rothes-bleierz.—This is one of the rarest ores of lead, being as yet only found at Ekatharenburg in Siberia.

Species 8. *Yellow Lead Spar.* Le Plomb jaune. Gelbes-bleierz..—This has been known only for a few years. It has been found at Bleiberg in Carinthia, in a gangart of calcareous stone. It has also been found near Freyberg in Saxony, at Annaberg in Austria, and at Reczbanya in Hungary.

Species 9. *Native Vitriol of Lead.* Le Vitriol de Plomb natif. Naturliher-blei-vitriol.—This is found in the isle of Anglesea, in a vein of brown iron ore, mixed with copper pyrites. It is also found at Leadhills in Scotland.

Species 10. *Earthy Lead Ore.*—Of this there are two varieties, the friable and the indurated. The former is found in Saxony, in Lorraine, in Poland, and Siberia, Bohemia, and Silesia. The latter is found in most lead mines. Mr Jameson notices two varieties of lead earth, which he calls white-lead earth, and friable lead earth, as met with at Leadhills.

VIII. Tin.

Tin ores.

Species 1. *Tin Pyrites.* La Pyrite d'Etain. Zinnkies. This species is very rare, and is, we believe, found only in Cornwall, at Wheal rock, among *copper pyrites.*

Species 2. *Common Tinstone.* La Pierre d'Etain. Zinnstein.—This is found chiefly in primitive rocks, as in granite, gneiss, micaceous schistus, and porphyry, both in masses and veins. It is the common ore of Cornwall, and is found also in Saxony, Bohemia, and the East Indies.

Species 3. *Wood Tin Ore.* L'Etain grenu. Zinnerz.—This is found in Cornwall, in the parishes of Colomb, St Denis and Roach, accompanying the former.

IX. Bismuth.

Bismuth ores.

Species 1. *Native Bismuth.*—Bismuth is a very rare metal, but is most commonly found in its native state. It is usually in a gangart of quartz, calcareous spar, and barytic spar. It occurs in Bohemia, in Saxony, in the territory of Hainault, in Suabia, in Sweden, and in France, in the mines of Brittany.

Species 2. *Sulphurated Bismuth.* La Galéne de Bismuth. Wismuth Glanz.—This is very rare. It commonly accompanies the former, and is found at Joachimsthal, in Bohemia, at Johann-Georgen-stadt, Schwarzenberg, and Altenberg in Saxony, and at Ridderhyttan in Sweden.

Species 3. *Bismuth Ochre.* L'Ochre de Bismuth. Wismuth Okker.—This is still more rare than the last, and is chiefly found near Schneeberg in Saxony, and at Joachimsthal in Bohemia.

X. Zinc.

Zinc ores.

Species 1. *Blende.* This is sulphurated zinc, and is one of the most common ores of that metal. There are three varieties; the brown, the yellow, and the black. Of these the yellow is the most rare, and is found in Saxony, in Bohemia, in the Hartz, in Norway. Transylvania, and Hungary. The brown and the black are found in most of these places, and besides in France and England, especially in Derbyshire.

Species 2. *Calamine.* La Calamine. Galmel.—Of this there are two varieties, *compact* and *striated.* Both occur only in particular stratiform rocks, often forming entire beds with indurated clay, and calcareous spar. The latter is usually found in the cavities of the former. Both occur in Bohemia, in Carinthia, and in most of the German lead mines. They are also found in Britain, especially at Leadhills, Wanlock-head, and in Derbyshire.

XI. Antimony.

170 Antimony ores.

Species 1. *Native Antimony.*—This is very rare. It was discovered at Sahlberg in Sweden, in the year 1748, in a gangart of some calcareous stone, and it was also found some years ago at Allemont in France, accompanying other ores of antimony and of cobalt.

Species 2. *Sulphurated Antimony.* L'Antimoine Gris. Grau-spies glas-erz.—There are several varieties of this, as the compact sulphurated antimony, found at Braunsdorf in Saxony; at Goldgronach in the principality of Bareith; at Maguria in Hungary, and Auvergne in France: foliated sulphurated antimony, found in Braunsdorf and Goldgronach, and in the Hartz, and Transylvania: striated sulphurated antimony, found in Saxony, Hungary, France, Swabia, Tuscany, Sweden, the Hartz, Spain, and in England: plumose antimonial ore, found at Freyberg in Saxony, at Braunsdorf and Stahlberg, and at Chemnitz in Hungary. All these varieties are usually found in a quartzose rock.

Species 3. *Red Antimonial Ore.* L'Antimoine Rouge. Roth-speis glas-erz.—This is found at Braunsdorf, at Malaska and Kremnitz, in Hungary, and at Allemont in France. It usually accompanies the first and second species, especially at Allemont, or the next species, which is the case at Braunsdorf.

Species 4. *Muriated Antimony.* Antimoine blanc. Weies-speis glas-erz.—White antimony is extremely rare; it is principally found at Przibran in Bohemia, in quadrangular, shining tables, disposed in bundles upon galena. It is said also to have been found at Braunsdorf and Malaska.

Species 5. *Antimonial Ochre.* L'Ocre d'Antimoine. Spies glas-okker.—This species is also very rare; it is found at Braunsdorf, near Freyberg, and in Hungary, always accompanying the second and third species.

XII. Cobalt.

Species 1. *White Cobalt Ore.* Le Cobalt blanc. Weisser speis-kobalt.—This is found in Norway, Sweden, at Anaberg in Saxony, in Swabia and Stiria; but it is very rare. In Saxony and Norway, it occurs in beds of micaceous schistus, along with the 7th species, and with quartz, hornblende, and pyrites. 171 Cobalt ores.

Species 2. *Dull Gray Cobalt Ore.* Le Cobalt gris. Grauer-speis-kobolt.—This is found in Saxony, Bohemia, France, Norway, Swabia, Hungary, Stiria, and in a few mines in England. It is sometimes mixed with ores of silver.

Species 3. *Bright White Cobalt Ore.* Le Cobalt Eclatant. Glanz-kobolt.—This is the most common of all the ores of cobalt, and almost always accompanies the ores of nickel, and of silver. It is found in Bohemia,

General Distribution of the Materials of the Earth.

hemia, Saxony, Silesia, the Hartz, Hesse, Sweden, Swabia, Norway, Stiria, Spain, Thuringia, and in England. It is found in beds in the primitive rocks, and in veins in the secondary.

Species 4. *Black Cobalt Ochre.* Le Cobalt Terreux noir. Schwarzer-erd-kobolt.—This is found in Saxony, in Thuringia, Swabia, Hesse, the Palatinate, Saltzburg, and in the Tyrol, accompanying other ores of cobalt, and several ores of silver, copper, and iron.

Species 5. *Brown Cobalt Ochre.* Le Cobalt Terreux brun. Brauner-erd-kobolt.—This is found in considerable quantity at Saalfeld in Thuringia; at Kamsdorf in Saxony, and at Alperspach in Wirtemberg, accompanying other ores of cobalt.

Species 6. *Yellow Cobalt Ochre.* Le Cobalt Terreux jaunne. Geber-erd-kobolt.—This is one of the rarest ores of cobalt. It is found at Saalfeld in Thuringia, at Alperspach in Wirtemberg, and at Altemont in Dauphiné in France.

Species 7. *Red Cobalt Ore.* Le Cobalt Terreux rouge. Rother-erd-kobolt. This is found in Saxony, Thuringia, Hesse, Swabia, Bohemia, Allemont in France, and in Norway.

XIII. Nickel.

172 Nickel ores.

Species 1. *Sulphurated Nickel.* Le Kupfer Nikel. Kupfer Nikkel.—This is found in veins, both in primitive and secondary mountains, almost always accompanying some of the ores of cobalt, to which it seems to bear some geological relation. It is also found in some silver mines. It is met with in Bohemia, Saxony, Thuringia, the Hartz, in Swabia, Hesse, Allemont in France, Stiria, and in some parts of Britain. Its usual gangart is quartz, barytic and calcareous spar.

Species 2. *Nickel Ochre.* L'Ocre de Nikel. Nikkel-okker.—This is found in the same situations with the last, from a decomposition of which it appears to be produced.

XIV. Manganese.

173 Manganese ores.

Species 1. *Gray Ore of Manganese.* Le Manganese. Grau-braunstein-erz.—There are several varieties of this, but they are all commonly found near each other, in veins or in masses, commonly in the primitive mountains.

They are found in considerable quantity in many mines in Saxony, Bohemia, Bavaria, and Hungary. They are also met with in France, and in several parts in Britain, as in Derbyshire, Leadhills, and Wanlockhead; in the Mendip hills, and the isle of Jura.

Species 2. *Red Manganese Ore.* Le Manganese rouge. Roth-Cronstein-erz.—This is very rare, but is found at Catnick, Offenbanya, and especially at Nagyag in Transylvania, at which last place it is found in a gold mine.

XV. Molybdena.

174 Molybdena ores.

Le Molybdene sulphure. Wasserbley.—This is found in Bohemia; at several places in Saxony; in Sweden; at Tillot in France, and at Chamouni at the foot of Mont Blanc. It is commonly found in primitive rocks, especially in tin mines.

XVI. Arsenic.

175 Arsenic ores.

Species 1. *Native Arsenic.*—This is found in Bohemia, Saxony, the Hartz, Carinthia, Swabia, Transylvania, and in France. It is always met with in veins, in primitive mountains, accompanied by realgar, galena, the ores of cobalt and nickel, and several ores of silver.

Species 2. *Arsenical Pyrites*, or *Marcasite.* La Pyrite Arsenicale. Arsenik-kies.—This is found in Bohemia, Saxony, and Silesia, accompanying the common tin stone, and galena, with some other minerals.

Species 3. *Realgar.* Le Realgar. Rauschgelb.—This is found in the Bannat, Bohemia, Saxony, Swabia, the Hartz, the Tyrol, Hungary, and in the neighbourhood of volcanoes, especially Ætna and Vesuvius.

Orpiment, which Brochant makes a variety of realgar, is found in several of the above places, and also in Natolia, in Servia, Transylvania, and Wallachia, usually accompanying quartz and clay.

Species 4. *Native calx of Arsenic.* L'Arsenic oxidé natif. Naturlechur arsenik-kalk.—This is very rare, but is found in a small quantity in Bohemia and Joachimsthal, in Saxony, at Raschau, at Salatna, in Transylvania, and in Hungary.

XVII. Tungsten.

Species 1. *Tungsten.* Le Tungstène. Schiverstein.—This is a very rare mineral, but is found at Schlackenwald in Bohemia, at Ehrenfriederdorf in Saxony, and at Riddarkytten, Bisburg in Sweden, usually accompanying quartz, mica, talc, and tin ore. Tungsten ores.

Species 2. *Wolfram.*—This is also pretty rare, but is found in Bohemia, Saxony, and at Poldice in Cornwall.

XVIII. Uranium.

Species 1. *Sulphurated Uranite.* L'Urane noir. Pecherz.—This is found at Joachimsthal in Bohemia, and at Johann-Georgen-Stadt, and Schneiberg in Saxony, accompanying the two following species, and lead and copper ores. Uranium ores.

Species 2. *Micaceous Uranitic Ore.* L'Urane Micacé. Uran-glimmer.—This is found in the Bannat, Saxony, Wirtemberg; near Autun in France, and near Karrarach in Cornwall.

Species 3. *Uranitic Ochre.* L'Ocre d'Urane Uranokher.—This has been found at Joachimsthal in Bohemia, and at Johann-Georgen-Stadt in Saxony, but it is uncommon.

XIX. Titanium.

Species 1. *Menakanite.*—This has been found chiefly near Menakan in Cornwall. Titanium ores.

Species 2. *Titanite.* Le Ruthile. Ruthil.—This is found at Boinik and Rhonitz in Hungary; in New Castile in Spain; at Aschaffenbourg in Franconia; at St Yreiux in France, and in Mount St Gothard, and some other places in the Alps.

Species 3. *Titanitic Siliceous Ore.* Le Nigrine. Nigrin.—This has been found near St Gothard in the Alps, at Ohlapian in Transylvania, &c.

XX. Tellurium.

Species 1. Sylvanite. Le Sylvane natif. Gediegen Sylvan.—This is found chiefly at Fatzeborg in Transylvania, but is now become extremely rare. It occurs in Tellurium ores.

Theories of the Earth.

in beds of gray wacke and secondary (or transition) limestone.

Species 2. ———Le Sylvane graphique. Shrifterz. —This is found at Offenbanya in Transylvania, in a bed of porphyritic syenite, and granular limestone.

Species 3. ——— Le Sylvane blanc. Weiss-Sylvanerz.—This was brought to Brochant from Freyberg in Saxony.

Chap. III. *Of the most Remarkable Theories of the Earth.*

A late writer considers the proper object of a theory of the earth, to be the tracing the series of those revolutions which have taken place on the surface of the earth; to explain their causes, and thus to connect together all the indications of change that are found in the mineral kingdom. He justly observes, that the formation of such a theory requires an accurate and extensive examination of the phenomena of geology, and that it is inconsistent with any, but a very advanced state of the physical sciences. There is perhaps no research in those sciences more arduous than this; none where the subject is so complex, where the appearances are so diversified, or so widely scattered; and where the causes that have operated are so remote from the sphere of ordinary observation *.

With such requisites, and under such difficulties, it is not surprising that so many who have aimed at constructing theories of the earth, have failed in the attempt. It certainly requires a prodigious accumulation of facts, together with a talent for observation, and for arrangement, which are seldom found united. We shall presently see how far those theories which have hitherto been framed to account for the changes that the earth has undergone, have been successful.

It is not, however, to be supposed, that a correct theory of the earth is impossible, though some may think it an arrogant, if not a presumptuous undertaking, to attempt explaining how the present state of the globe and the revolutions which it has undergone, were brought about. The time is perhaps not far distant when the present prevailing hypothesis will be improved into a rational, and so far as is consistent with the knowledge and acquirements of man, a perfect system.

Mr Kirwan has laid down certain laws of reasoning; which should be adhered to inviolably in investigations of this kind. The first is, that no effect should be attributed to a cause whose known properties are inadequate to its production. The second is, that no cause should be adduced, whose existence is not proved either by actual experience or approved testimony. Many natural phenomena have arisen or do arise, in times or places so distant, that well conditioned testimony concerning them cannot, without manifest absurdity, be rejected. Thus the inhabitants of the northern parts of Europe, who have never felt earthquakes, nor seen volcanoes, must nevertheless admit, from mere testimony, that the first have been, and that the second do actually exist. The third is, that no powers should be ascribed to an alleged cause, but those that it is known by actual observation to possess in appropriated circumstances.

Sect. I. *Theory of Burnet.*

181 Theory of Burnet.

The first who formed this amusement of earth-making into a system, was the celebrated Thomas Burnet; a man of polite learning, and rapid imagination. His *sacred theory*, as he calls it, describing the changes which the earth has undergone, or shall hereafter undergo, is well known for the warmth with which it is imagined, and the weakness with which it is reasoned; for the elegance of its style, and the meanness of its philosophy. The earth, says he, before the deluge, was very differently formed from what it is at present: it was at first a fluid mass; a chaos composed of various substances, differing both in density and figure; those which were heaviest sunk to the centre, and formed in the middle of our globe a hard solid body; those of a lighter nature remained next; and the waters, which were lighter still, swam upon its surface, and covered the earth on every side. The air, and all those fluids which were lighter than water, floated upon this also, and in the same manner encompassed the globe; so that between the surrounding body of waters, and the circumambient air, there was formed a coat of oil, and other unctuous substances, lighter than water. However, as the air was still extremely impure, and must have carried up with it many of those earthy particles with which it once was intimately blended, it soon began to defecate, and to depose these particles upon the oily surface already mentioned, which soon uniting, the earth and oil formed that crust which soon became an habitable surface, giving life to vegetation, and dwelling to animals.

This imaginary antediluvian abode was very different from what we see at present. The earth was light and rich, and formed of a substance entirely adapted to the feeble state of incipient vegetation; it was a uniform plain, everywhere covered with verdure, without mountains, without seas, or the smallest inequalities. It had no difference of seasons, for its equator was in the plane of the ecliptic, or, in other words, it turned directly opposite to the sun, so that it enjoyed one perpetual and luxuriant spring. However, this delightful face of nature did not long continue in the same state, for, after a time, it began to crack and open in fissures; a circumstance which always succeeds when the sun exhales the moisture from rich or marshy situations. The crimes of mankind had been for some time preparing to draw down the wrath of heaven; and they at length induced the deity to defer repairing those breaches in nature. Thus the chasms of the earth every day became wider, and, at length, they penetrated to the great abyss of waters, and the whole earth in a manner fell in. Then ensued a total disorder in the uniform beauty of the first creation, the terrene surface being broken down; as it sunk, the waters gushed out in its place; the deluge became universal; all mankind, except eight persons, were destroyed, and their posterity condemned to toil upon the ruins of desolated nature.

It remains to mention the manner in which he relieves the earth from this universal wreck, which would seem to be as difficult as even its first formation. These great masses of earth falling into the abyss, drew down with them vast quantities of air; and by dashing against each other, and breaking into small parts by

Theories of the Earth.

by the violence of the shock, they at length left between them large cavities filled with nothing but air. These cavities naturally offered a bed to receive the influent waters; and in proportion as they filled, the face of the earth became once more visible. The higher parts of its broken surface, now become the tops of mountains, were the first that appeared; the plains soon after came forward, and at length the whole globe was delivered from the waters, except the places in the lowest situations; so that the ocean and the seas are still a part of the ancient abyss that have not had a place to return to. Islands and rocks are fragments of the earth's former crust; kingdoms and continents are larger masses of its broken substance; and all the inequalities that are to be found on the surface of the present earth, are owing to the accidental confusion into which both earth and waters were then thrown.

Sect. II. *Theory of Woodward.*

182 Theory of Woodward.

The next who attempted a theory of the earth was Mr Woodward, who in his essay towards a natural history of the earth, endeavoured to give what he considered as a more rational account of its appearances than had been given by any preceding writer. He was indeed much better qualified for such an undertaking than any of his predecessors, as he was one of the most industrious naturalists of his time. Hence though his system must be considered as weak and untenable, his work contains many important facts relating to natural history.

Woodward sets out by asserting that all terrestrial substances are disposed in beds of various natures, lying horizontally, one over the other, like the coats of an onion, and that they are replete with shells and other marine productions; these shells being found in the deepest cavities, and on the tops of the highest mountains. From these observations, which were warranted by the experience of naturalists at that time, but which we now know not to be universally correct, he proceeds to remark that these shells and extraneous fossils are not productions of the earth, but are all actual remains of those animals which they are known to resemble; that all the beds of the earth lie below each other in the order of their specific gravities, and that they are disposed as if they had been left in this situation by subsiding waters. All this is affirmed with much earnestness, although many of the circumstances are contradicted by daily experience. Thus, we not unfrequently meet with layers of stone above the lightest soils, and find the softest earth below a stratum of hard stone. Woodward, however, having taken for granted, that all the strata of the earth are arranged in the order of their specific gravities, the lightest at the top, and the heaviest near the centre, he deduces as a natural consequence, that all the substances of which the earth is composed were once in an actual state of solution. This universal solution he conceives to have happened at the time of the flood. He supposes that at that time a body of water, which was then in the centre of the earth, uniting with that which was found on the surface, so far separated the terrene parts as to mix all together in one fluid mass; the contents of which afterwards sinking according to their respective gravities, produced the present appearances of the earth. Being aware, however, that an objection that fossil substances are not found dissolved, he exempts them from this universal dissolution, and for that purpose, endeavours to show that the parts of animals have a stronger cohesion than those of minerals; and that, while even the hardest rocks may be dissolved, bones and shells may still continue entire.

Sect. III. *Theory of Whiston.*

183 Theory of Whiston.

Of all the theories of the earth that have been formed, previous to those of Hutton and Werner, none has been more applauded or more opposed than that of Whiston. Nor is this surprising; for this theory being supported with all the parade of mathematical calculation, confounded the ignorant, and produced the approbation of such as desired to be thought learned, since it implied a considerable knowledge of abstract science, even to be capable of comprehending what the writer aimed at. It is not easy to divest this theory of its mathematical garb, but the result of our philosopher's reasoning appears to be as follows.

He supposes the earth to have been originally a comet, and he considers the history of the creation, as given us in scripture, to have its commencement just when it was, by the hand of the Creator, more regularly placed as a planet in our solar system. Before that time, he supposes it to have been a globe without beauty or proportion; a world in disorder, subject to all the vicissitudes which comets endure; some of which have been found, at different times, a thousand times hotter than melted iron; at others, a thousand times colder than ice. These alternations of heat and cold, continually melting and freezing the surface of the earth, he supposes to have produced, to a certain depth, a chaos entirely resembling that described by the poets, surrounding the solid contents of the earth, which still continued unchanged in the midst, making a great burning globe of more than two thousand leagues in diameter. This surrounding chaos, however, was far from being solid: he compares it to a dense though fluid atmosphere, composed of substances mingled, agitated, and shocked against each other; and in this disorder he describes the earth to have been just at the eve of creation.

But upon its orbit being then changed, when it was more regularly wheeled round the sun, every thing took its proper place, every part of the surrounding fluid then fell into a situation, in proportion as it was light or heavy. The middle or central part, which always remained unchanged, still continued so, retaining a part of that heat which it received, in its primeval approaches towards the sun; which heat he calculates, may continue for about six thousand years. Next to this fell the heavier parts of the chaotic atmosphere, which serve to sustain the lighter; but as in descending they could not entirely be separated from many watery parts with which they were intimately mixed, they drew down a part of these also with them; and these could not mount again after the surface of the earth was consolidated; they therefore surrounded the heavy first descending parts, in the same manner as these surround the central globe. Thus, the entire body of the earth is composed internally of a great burning globe, next which is placed a heavy terrene substance that encompasses

Theories of the Earth.

passes it, round which also is circumfused a body of water. Upon this body of water, the crust of the earth on which we dwell is placed, so that, according to him, the globe is composed of a number of coats, or shells, one within the other, all of different densities. The body of the earth being thus formed, the air, which is the lightest substance of all, surrounded its surface, and the beams of the sun darting through, produced that light which, we are told, first obeyed the Creator's command.

The whole economy of the creation being thus adjusted, it only remained to account for the risings and depressions on the surface of the earth, with the other seeming irregularities of its present appearance. The hills and valleys are considered by him as formed by their pressing upon the internal fluid, which sustains the outward shell of earth with greater or less weight; those parts of the earth which are heaviest, sink into the subjacent fluid more deeply, and become valleys; those that are lighter, rise highest upon the earth's surface, and are called mountains.

Such was the face of nature before the deluge; the earth was then more fertile and populous than it is at present; the life of man and animals was extended to ten times its present duration; and all those advantages arose from the superior heat of the central globe, which ever since has been cooling. As its heat was then in full power, the genial principle was also much greater than at present; vegetation and animal increase were carried on with more vigour; and all nature seemed teeming with the seeds of life. But these physical advantages were only productive of moral evil; the warmth which invigorated the body, increased the passions and appetites of the mind; and as man became more powerful, he grew less innocent. It was found necessary to punish this depravity; and all living creatures were overwhelmed by the deluge in universal destruction.

This deluge, which simple believers are willing to ascribe to a miracle, philosophers have been long desirous to account for by natural causes. They have proved that the earth could never supply from any reservoir towards its centre, nor the atmosphere by any discharge from above, such a quantity of water as would cover the surface of the globe to a certain depth over the tops of our highest mountains. Where, therefore, was all this water to be found? Whiston has found enough, and more than a sufficiency, in the tail of a comet; for he seems to allot comets a very active part in the great operations of nature.

He calculates with great seeming precision, the year, the month, and the day of the week on which this comet (which has paid the earth some visits since, though at a kinder distance) involved our globe in its tail. The tail he supposed to be a vaporous fluid substance, exhaled from the body of the comet, by the extreme heat of the sun, and increasing in proportion as it approached that great luminary. It was in this that our globe was involved at the time of the deluge; and as the earth still acted by its natural attraction, it drew to itself all the watery vapours which were in the comet's tail; and the internal waters being also at the same time let loose, in a very short space the tops of the highest mountains were laid under the deep.

The punishment of the deluge being thus completed, and all the guilty destroyed, the earth, which had been broken by the eruption of the internal waters, was also enlarged by it; so that upon the comet's recess, there was found room sufficient in the internal abyss for the recess of the superfluous waters, whither they all retired, and left the earth uncovered, but in some respects changed, particularly in its figure, which, from being round, was now become oblate. In this universal wreck of nature Noah survived, by a variety of happy causes, to repeople the earth, and to give birth to a race of men slow in believing ill-imagined theories of the earth.

Sect. IV. *Theory of Buffon.*

Theory of Buffon. 184

Less abstracted and more popular than the theory of Whiston, but equally fanciful and pompous, was the hypothesis of Buffon. This system, which was received with great admiration, depends principally on two facts which, though generally true, were by Buffon extended much too far.

It had been long observed, that such flinty or siliceous bodies as form a part of the composition of glass, are among the most abundant materials which compose the earth, and that many of them nearly resemble glass in colour, transparency, lustre, hardness, and specific gravity. As glass is produced by fusion in a strong heat, it was inferred by Buffon, that the flinty bodies found on the earth derived their origin from a similar fusion; and as no heat sufficient to produce so great an effect, could be found on our globe, the author has recourse to the sun as its source. He supposes the planets, and the earth among the number, to have originally formed a part of the body of the sun. In this situation a comet falling in on that great body, might have given it such a shock, and so shaken its whole frame, that some of its particles might have been driven off, like streaming sparkles from red-hot iron; and each of these streams of fire, though very small in comparison of the sun, might have been large enough to form a planet much greater than our earth, or any other of the planetary system. In this manner the planets, together with the globe which we inhabit, might have been driven off from the body of the sun by impulsion; and in this way they would have continued to recede from it for ever, had they not been arrested by the superior power of attraction, exerted on them by the sun; and thus, by the combination of the centrifugal and centripetal forces, they were whirled round in the orbits which they now describe.

After giving a number of reasons for the credibility, or at least possibility, of the foregoing supposition, the author concludes that it is evident, that the earth assumed its present figure when in a melted state. It is natural to think, says he, that the earth, when it issued from the sun, had no other form but that of a torrent of melted and inflamed matter; that this torrent, by the mutual attraction of its parts, took on a globular figure, which its diurnal motion changed into a spheroid; that, when the earth cooled, the vapours, which were expanded like the tail of a comet, gradually condensed, and fell down in the form of water upon the surface, depositing at the same time a slimy substance mixed with sulphur and salts, part of which was carried by the motion of the waters into the perpendicular fissures of the strata, and produced

Theories of the Earth.

produced metals, and the rest remained on the surface, and gave rise to the vegetable mould which abounds in different places, with more or less of animal or vegetable particles, the organization of which is not obvious to the senses.

Thus the interior parts of the globe were originally composed of vitrified matter, and probably they are so at present. Above this were placed those bodies which had been reduced by the heat to the smallest particles, as sand, which are only portions of glass, and above these pumice stones, and the scoriæ of melted matter, from which were afterwards produced the several kinds of clay. The whole mass was covered with water to the depth of five or six hundred feet, arising from the condensation of the vapours when the earth began to cool. This water deposited a stratum of mud, mixed with all those substances which were capable of being sublimed, or exhaled by fire; and the air was formed of the most subtile vapours, which, from their small specific gravity, floated above the water.

Such was the condition of the earth, when the tides, the winds, and the heat of the sun, began to introduce changes on its surface. The diurnal motion of the earth, and that of the tides, elevated the waters in the equatorial regions, and necessarily transported thither great quantities of slime, clay, and sand; and by thus elevating those parts of the earth, they perhaps sunk those under the poles about two leagues, or a 230th part of the whole; for the waters would easily reduce into powder pumice stones, and other spongy parts of the vitrified matter upon the surface; and by this means excavate some places and elevate others, which, in time, would produce islands and continents, and all those inequalities on the surface, which are more considerable towards the equator than towards the poles. The highest mountains lie between the tropics and the middle of the temperate zones, and the lowest from the polar circles towards the poles. Indeed, both the land and sea have most inequalities between the tropics, as is evident from the incredible number of islands peculiar to these regions.

The other circumstance which forms a principal part of the basis of this theory, is derived from the composition of sea shells. It is well known that these shells consist chiefly of an earth like that which constitutes the principal part of limestone or marble; and it was hence inferred that, after a series of ages, these shells being broken down into minute particles, produced those immense masses of calcareous substances which are now found either in vast mountains, or in stratified plains, in almost every part of the earth.

Buffon conceives very naturally, that the surface of the earth must, at the beginning, have been much less solid than it is at present, and consequently the same causes which at this day produce but slight changes, must then, on so yielding a body, have been attended with very considerable effects. There is, he thinks, every reason to suppose, that the earth was at that time covered with the waters of the sea; and that these waters were above the tops of our highest mountains, since, even in such elevated situations, we find shells and other marine productions in very great abundance. It appears also that the sea continued for a considerable time upon the face of the earth; for as these layers of shells are found so very frequently at such great depths, and in such prodigious quantities, it seems impossible for such numbers to have been supported all alive at one time; so that they must have been brought there by successive depositions. These shells also are found in the bodies of the hardest rocks, where they could not have been deposited all at once, at the time of the deluge, or at any such instant revolution; since that would be to suppose, that all the rocks in which they are found were, at that instant, in a state of dissolution, which would be absurd to assert. The sea, therefore, deposited them wherever they are now to be found, and that by slow and successive degrees.

"It will appear also, that the sea covered the whole earth, from the appearance of its layers, which lying regularly one above the other, seem all to resemble the sediment formed at different times by the ocean. Hence, by the irregular force of its waves and its currents, driving the bottom into sand-banks, mountains must have been gradually formed within this universal covering of waters; and these successively raising their heads above its surface, must, in time, have formed the highest ridges of mountains upon land, together with continents, islands, and low grounds, all in their turns. This opinion will receive additional weight by considering, that in those parts of the earth, where the power of the ocean is greatest, the inequalities on the surface of the earth are highest; the ocean's power is greatest at the equator, where its winds and tides are most constant; and in fact, the mountains at the equator are found to be higher than in any other parts of the world. (Vid. N° 129.). The sea, therefore, has produced the principal changes in our earth; rivers, volcanoes, earthquakes, storms, and rain, having made but slight alterations, and only such as have affected the globe to very inconsiderable depths."

"In the formation of this theory, says Mr Kirwan, genius (I mean genius in its primitive sense, the sublime talent of fascinating invention, and not the energetic power of patient, profound, and sagacious investigation), unhappily presided. Yet dazzled by the splendid but delusive scenery, presented by an ardent imagination soaring to the source of light, and rending from its flaming orb the planetary masses that surround it; then marking with daring and overweening confidence, fancied successive epochs of the consolidated fabric of the terraqueous globe; the public attention was long arrested by the magical representation, and the understanding nearly betrayed into a partial, if not a total, assent to it.

"This proud gigantic theory, was, however, like another Goliath, soon demolished by a common flint or pebble, the very substance it sprung from. Common glass essentially contains an alkaline salt, to which alone it owes its fusibility; siliceous substances contain none, and are absolutely infusible when unassociated with any. Macquer found them infusible not only in furnaces, but in the still incomparably superior heat of inflamed oxygen. Hence the hypothesis grounded on the assumed identity of these substances and common glass, vanished like the unembodied visions of the night. With respect to limestone, the other pillar on which this theory rests, Cronstedt, Ferber, Born, Arduini, and Bergman, demonstrated the existence of numerous and immense mountains, in which not only no vestiges of shells could be traced, but whose internal structure of position

Theory of the Earth.

position was incompatible with the supposition of origination thence derived." *

Kirwan's Geological Essays. 436

Sect. V. *Theory of Whitehurst.*

Theory of Whitehurst.

The first person who founded a theory of the earth on accurate and industrious observation was the late Mr John Whitehurst, who, in an inquiry into the original state and formation of the earth, has advanced opinions which differ considerably from those of preceding naturalists, and in some measures resemble those which are at present in greatest repute.

Mr Whitehurst sets out with stating his opinions, that the terraqueous globe, which we now inhabit, was originally in a fluid flate, and this, not from any solvent principle or subsequent solution, but owing to the first assemblage of its component parts; whence he presumes that the earth had a beginning, and has not existed from eternity. He rests his proof of this original fluid state of the earth on its spheroidal form, which a fluid globe in its revolution would naturally acquire, but which could not easily be produced in a solid body. The fluidity of the earth and the infinite divisibility of matter, an opinion which generally prevailed at that time, prove, according to him, that the component parts of the elements were uniformly blended together, none being heavier or lighter than another; hence they composed a uniform mass of equal consistence throughout, from the surface to the centre, and consequently the new formed globe was not adapted to the support of animal or vegetable life. It would therefore be absurd to suppose, that organized bodies were created during the chaotic state of the earth; and there is a great presumption that mankind were not created till the earth was become suitable to the nature of their existence.

The component parts of the chaos were heterogeneous, and endowed with peculiar chemical affinities, whereby similar substances were disposed to unite and form select bodies of various denominations, and thus the chaos was progressively formed into a habitable world.

The first operation of nature which presents itself to our consideration is the production of the spheroidal figure of the earth, acquired from its diurnal rotation, and the laws of gravity, fluidity, and centrifugal force. When this form was once completed, the component parts began to act on each other according to their affinities: hence the particles of earth, air, and water, united to those of their own kind, and with their union commenced their specific gravities; and the uniform suspension which had hitherto prevailed throughout the whole of the chaotic mass, was destroyed.

On the component parts separating into homogeneous masses, those of the greatest density began to approach towards the centre of gravity, and those of the greatest levity ascended towards the surface. As the specific gravity of air is so much less than that of water, it is presumed that the former escaped from the general mass sooner than the latter, and formed an impure atmosphere surrounding the newly-formed globe. Water being next in levity, succeeded the air, and formed one vast ocean about the earth. In process of time these elements became perfectly pure, and fit for the preservation of animal and vegetable life.

Theory of the Earth.

When the component parts of the chaos had been thus progressively separated, and collected into distinct masses, the following consequences are supposed to have ensued. The solids could not uniformly subside from every part of the surface, and be equally covered by water; for, as the sun and moon were coeval with the chaos, in proportion as the separation of the solids and fluids increased, so, by the action of those bodies on the sea, the tides became greater, and removed the solids from place to place, without any order or regularity. Hence the sea became unequally deep; and those inequalities daily increasing, dry land gradually appeared, and divided the waters which had hitherto been universally diffused over the earth. The primitive islands being thus formed gradually became firm and dry, and fit for the reception of animals and vegetables.

The atmosphere, the sea, and the land, being thus formed, Mr Whitehurst proceeds to consider the order in which animal and vegetable bodies were severally created. He first supposes that, as the ocean became pure, and fit for animal life, before the formation of the primitive islands, fish were the first animals produced, and he supports this opinion by many ingenious arguments and facts. He observes, that in every instance upon record, the fragments of sea-shells are infinitely more numerous than the bones and teeth of fish. The latter, too, are but rarely deposited in any other matter than in beds of sand and gravel, and not in the solid substance of limestone, as the shells of fish generally are, even to the depth of many hundred yards, and dispersed throughout the whole extent of the secondary strata. Hence it is probable, that shell-fish were produced in prodigious quantities, sooner than any other kind of animal. The ocean being thus stocked with inhabitants, previous to the formation of the primitive islands, many of them became enveloped, and were buried in the mud by the action of the tides; and this would happen more particularly to the shell-fish, as they were less able to extricate themselves. Since the remains of marine animals are thus imbedded at various depths in the earth, there is sufficient proof that these marine bodies were entombed at successive periods of time, and that they were likewise created before the primitive islands, and consequently before any terrestrial islands.

That the earth has, at different times, suffered very violent convulsions, producing extensive ruptures of its solid parts, may reasonably be concluded from the rugged and uncouth appearance of many of the mountainous parts of the world. We see rocks in some places torn asunder, or appearing as if cut with a saw, and we find, in various parts, substances both mineral and organized, which are not generally met with, except in very distant regions. Most of the irregularities of the earth's surface are attributed by Mr Whitehurst to the general deluge. This would, in some instances, have the effect of reducing large masses of matter to a second state of solution; many eminences would be levelled, and some of the valleys would be filled up, while some parts which were before covered with water, might receive such an accession of matter as to fill up their cavities, and on the subsiding of the waters become a vast level plain. On the other hand, those elevated regions which were chiefly composed of the hardest stones, by having the lighter portions of earth washed

Theories of the Earth.

away from their basis, would appear considerably increased in height. Mr Whitehurst attributes the production of pit coal also to the deluge, as it is difficult to account for the deposition of such a quantity of vegetable matter (supposing pit-coal to be of vegetable origin) below the surface of the earth, on any other hypothesis. The animal matters found in a fossil state, especially those remains of animals which are not now found upon the earth, can only be accounted for, on the supposition of a deluge.

Mr Whitehurst, however, is not content with attributing to the deluge most of the changes which have taken place on the surface of the earth, but he derives from the same source the curtailed longevity of man, and many of the evils incident to mankind. "At that dreadful era, says he, and not before, the year became divided into summer and winter, spring and autumn, and the spontaneous products of the earth no longer sufficed the calls of human nature without art and labour; wherefore he who sowed would expect to reap, and he who built an hut for his protection, would naturally expect to enjoy the fruits of his own labour; necessity, therefore, was the parent of property, and property created a thousand imaginary wants, which its possessors endeavoured to gratify, and their example excited similar ideas in those who had it not, but nevertheless studiously endeavoured to gratify their artificial wants by unjustifiable means. Hence the necessity of laws, dominion, and subordination, which had no existence in the antediluvian world.

"To that great revolution in the natural world, we may therefore ascribe many of the evils incident to mankind; for experience shews, that men who are born in rude and savage climates are naturally of a ferocious disposition; and that a fertile soil, which leaves nothing to wish for, softens their manners, and inclines them to humanity."

The above is a general outline of Mr Whitehurst's theory, some parts of which are very ingenious, and are corroborated by observation, while others are not a little fanciful and improbable. In his supposition that the earth was originally in fluid state, he agrees with most other theorists, as this is a circumstance which admits of little doubt; though, as Kirwan has shewn, it is not necessary to suppose that the whole mass of the earth was fluid, but only those parts of it which are near the surface. In his play of affinities, and consequent separation of the materials of the earth into homogeneous masses, Whitehurst has been followed by Mr Kirwan, who has framed a beautiful and ingenious speculation on the successive changes that took place from the action of the materials on each other ‡.

‡ *Kirwan's Geological Essays*, Essay I.

187 Mr Whitehurst has been betrayed by his fondness for a favourite theory, into several errors respecting the stratification of the earth, which require to be mentioned. Thus, though the arrangement of the strata, especially where it has not been disturbed by some evident and violent cause, is extremely uniform; he has, however, extended this regularity farther than it really obtains. He tells us that the strata invariably follow each other, as if it were in an alphabetical order, or a series of numbers, whatever be their denomination. Not that they are alike in all the different regions of the earth, either in quality or in thickness, but that their order in each particular part, however they may differ in quality; yet they follow each other in regular succession, both as to thickness and quality, insomuch, that by knowing the incumbent stratum, together with the arrangement thereof in any particular part of the earth, we may come to a perfect knowledge of all the inferior beds, so far as they have been previously discovered in the adjacent country. With respect to the strata that accompany coal, some instances are apparently but not really, contradictory to this rule.

We now know, however, that Mr Whitehurst's observations do not universally apply. In the old mines in the valley of Planen, in Saxony, the strata, though they are near each other, vary considerably in thickness, from that of a few inches to several feet, and the stratum of coal, in particular, varies from two to thirty-two feet. Again, in Mount Salive, the strata of coal, though in a calcareous mountain, vary considerably; and Mr Whitehurst himself informs us, that at Bensal moor, those strata which are in other places the lowest, are found at the surface. Even in Derbyshire, to which Mr Whitehurst's observations chiefly apply, we are informed that even when the arrangement is the same, the thickness of the strata varies considerably.

SECT. VI. *Theory of Dr Hutton.*

THE next theory which we have to consider, is that proposed by Dr James Hutton, which has become so much the object of inquiry and debate, as to give name to one of the two principal sects into which geologists are now divided. 188

Theory of Hutton.

The leading principles of the Huttonian theory, as concisely laid down by one of its greatest admirers and supporters, are the following.

1. The first circumstance which Dr Hutton has considered as a general fact is, that by far the greater part of the bodies which compose the exterior crust of our globe, bear the marks of being formed of the materials of mineral and organized bodies, of more ancient date. The spoils or the wreck of an older world are, he thinks, everywhere visible in the present, and though not found in every piece of rock, they are diffused so generally as to leave no doubt that the strata which now compose our continents are all formed out of strata more ancient than themselves.

2. The present rocks, with the exception of such as are not stratified, having all existed in the form of loose materials collected at the bottom of the sea, must have been consolidated and converted into stone by virtue of some very powerful and general agent. The consolidating cause which he points out is subterraneous heat, and the objections to this hypothesis have been attempted to be removed, by the introduction of a principle new and peculiar to himself. This principle is the compression which must have prevailed in that region where the consolidation of mineral substances was accomplished. Under the weight of a superincumbent ocean, heat, however intense, might be unable to volatilize any part of those substances which, at the surface, and under the lighter pressure of our atmosphere, it can entirely consume. The same pressure, by forcing those substances to remain united, which at the surface are easily separated, might occasion the fusion of some bodies which in our fires are only calcined.

Theories of the Earth.

3. The third general circumstance which this theory is founded on is, that the stratified rocks, instead of being either horizontal or nearly so, as they no doubt were originally, are now found possessing all degrees of elevation, and some of them were perpendicular to the horizon; to which we must add, that those strata which were once at the bottom of the sea, are now raised up, many of them several thousand feet above its surface. From this, as well as from the inflexions, the breaking and separation of the strata, it is inferred, that they have been raised by the action of some expansive force placed under them. This force, which has burst in pieces the solid pavement on which the ocean rests, and has raised up rocks from the bottom of the sea into mountains 15,000 feet above its surface, exceeds any which we see actually exerted, but seems to come nearer to the cause of the volcano or the earthquake than to any other, of which the effects are directly observed. The immense disturbance, therefore, of the strata, is in this theory ascribed to heat acting with an expansive power, and elevating those rocks which it had before consolidated.

4. Among the marks of disturbance in which the mineral kingdom abounds, those great breaches among rocks, which are filled with materials different from the rock on either side, are among the most conspicuous. These are the veins, and comprehend not only the metallic veins, but also those of whinstone, of porphyry, and of granite, all of them substances more or less crystallized, and none of them containing the remains of organized bodies. These are of posterior formation to the strata which they intersect, and in general also they carry with them the marks of the violence with which they have come into their place, and of the disturbances which they have produced on the rocks already formed. The materials of all these veins, Dr Hutton concludes to have been melted by subterraneous heat, and, while in fusion, injected among the fissures and openings of rocks already formed, but thus disturbed, and moved from their original place.

This conclusion he extends to all the masses of whinstone, porphyry, and granite, which are interspersed among the strata, or raised up in pyramids, as they often appear to be, through the midst of them. Thus, in the fusion and injection of the unstratified rocks, we have the third and last great operation which subterraneous heat has performed on mineral substances.

5. From this Dr Hutton proceeds to consider the changes to which mineral bodies are subject when raised into the atmosphere. Here he finds, without any exception, that they are all going to decay; that, from the shore of the sea to the top of the mountain, from the softest clay to the hardest quartz, all are wasting and undergoing a separation of their parts. The bodies thus resolved into their elements, whether chemical or mechanical, are carried down by the rivers to the sea, and are there deposited. Nothing is exempted from this general law; among the highest mountains and the hardest rocks, its effects are most clearly discerned; and it is on the objects which appear the most durable and fixed, that the characters of revolution are most deeply imprinted *.

* Edinburgh Phil. Trans. vol. i. p. 52.

It is not surprising that this theory should have met with many advocates among the more superficial observers of nature. The production of a man in whom genius, observation, and industry, were united, and who passed a considerable part of a long life in chemical and geological researches, was calculated to dazzle the imagination by the grandeur of its design, and to captivate the judgment by its appearance of regularity and consistence. It has been considered as a peculiar excellence of this theory, that it ascribes to the phenomena of geology an order similar to that which exists in the provinces of nature with which we are best acquainted; that it produces seas and continents, not by accident, but by the operation of regular and uniform causes; that it makes the decay of one part subservient to the restoration of another, and that it gives stability to the whole, not by perpetuating individuals, but by reproducing them in succession †.

† *Playfair's Illustrations*, p. 129.

189 Objections to the Huttonian theory.

An hypothesis with such pretensions could not fail of being minutely examined and severely criticised by the more enlightened part of geologists, and accordingly very serious objections have been made to it by Kirwan and others. We shall state a few of what appear to us to be the most convincing arguments against Dr Hutton's theory, referring those who wish to see a more detailed refutation of it to the geological writings of Kirwan, and A Comparative View of the Huttonian and Neptunian Theories.

190 From the nature and action of caloric.

Some of the strongest arguments against this theory are drawn from the nature of caloric, and what we know of its action on other bodies. We know that caloric is of so diffusible a nature, that it is always communicated, from that body or set of bodies, in which it is most abundant, to that in which it is less so, till an equilibrium of temperature is produced. But Dr Hutton's theory supposes a subterraneous heat as constantly existing, capable of fusing the most obdurate rocks, and of raising them by its expansibility from the bottom of the ocean, and yet incapable of extending its influence through the superincumbent strata at all times, so as to fuse or evaporate superior bodies, and gradually expand itself, so as to acquire that equilibrium which is one of its natural effects. Again, supposing such a subterraneous heat to exist, it is surely extraordinary, that substances which we are incapable of fusing by the strongest heat that we can excite, even in the greatest state of division, should, by this subterraneous heat be so completely fused, and in such vast masses, as to have assumed the appearance under which they now present themselves. If the solar rays, in the utmost state of concentration, if a united stream of inflamed hydrogenous and oxygenous gases from the tube of a blow-pipe or gazometer, cannot melt the smallest visible portion of calcareous spar or rock crystal, how can we conceive that the immense mountains of limestone and of quartz which are met with in so many places could have been fused into a state of perfect fluidity? Or even if they could be fused, how is it possible that the carbonic acid of the limestone should not have been dissipated by so strong a heat? If we suppose with Dr Hutton, that this subterraneous heat acts with the assistance of immense pressure from the superincumbent strata and waters of the ocean, hence preventing the dissipation of volatile matters, still it should act uniformly, and should fuse all those bodies which come in its way, that are capable of fusion. Now, we know that feldspar, schorl, mica, and chlorite, are much more fusible than quartz, and of course, when a mass compounded of these comes

under

Theories of the Earth.

under the influence of this heat, all these more fusible substances should be melted as well as the quartz. But in some stones in which most of these ingredients meet, as in the granite of Portsoy, there is every reason to suppose that some of them have been in a fluid state, while the others were solid or less fluid, as crystals of the latter are impressed on a bed of the former, viz. in the instance cited, crystals of feldspar in a mass of quartz. As it is certain, according to the advocates of the Huttonian theory, that at least the quartz was fluid when it was moulded on the feldspar, how happened it that this comparatively fusible stone was not also melted, and blended in one compact mass with the quartz? We also frequently find crystals of quartz penetrated by schorl and chlorite, which is a proof that the latter must have been hard while the former was in a fluid state. Hence it is evident that these appearances could not have been the effect of fusion by heat. Again, we find seams of coal penetrated by thin laminæ and crystals of quartz, an effect which, according to this theory, must have taken place while the quartz was in a state of fusion. But, in this case, the strata of shale above and below the coal should also have been fused (shale being much more fusible than quartz), and thus the whole should have acquired a slaty texture; and besides in this intense heat, the coal should have been entirely charred and lost all its vegetable impressions.

The very existence of such a subterraneous heat, that constantly maintains itself without fuel, ready to act on any emergency, when a quantity of the old world has been abraded and translated, sufficient to furnish the materials of a new one, is avowedly hypothetical, as we have no proof that it exists. Nay, we have direct proof, as far as rational induction can carry us, to the contrary. It was long ago observed, by Irving and Forster, that the heat of the sea diminishes in proportion to the depth to which we proceed in examining it, and the same has been more lately proved by Peron, by various trials in many different latitudes †. Now the contrary of this ought certainly to happen, (unless this subterraneous heat is entirely unlike common heat) if there constantly existed in the bowels of the earth a heat capable of fusing quartz and limestone.

† *Journ. de Phys.* tom. lx. p. 81.

The structure of whin dykes, detailed in Section II. of last Chapter, affords additional arguments in opposition to the Huttonian theory.

191
From the structure of whin dykes.

The evidence which Dr Hutton has adduced to prove the subterraneous eruption of dykes, is drawn from the apparent derangement of the horizontal strata at a place where they are intersected by a dyke, and the peculiar appearance of the coal in their immediate vicinity, which he supposes to be in a state of calcination, from having been in contact with the ejected matter of the dyke in fusion. Let us first attend to the effect of this eruption of a dyke, the apparent derangement of the strata; and let us consider for a moment, what must be the mechanical operation of a mass of this liquid matter bursting upwards through the coal strata. Suppose a coal field of a mile square in extent; suppose that the coal and concomitant strata are perfectly regular, having a moderate *dip* or inclination to the south; and suppose that this coal field is to be intersected by a dyke, ejected in a state of fusion from the bowels of the earth. Considering the nature of the strata which usually accompany coal, such as sandstone, limestone, ironstone, &c. which are very hard and compact, we must allow, that the resistance from such substances would be very great. In this previous state of circumstances, then, what would be the effect of the eruption of a dyke in the middle of the field, in a direction from north to south? Can it even be imagined, that this liquid mass in its progress upwards through the superincumbent strata to the surface of the earth, would merely destroy the continuity of these strata, and not in its irresistible course, carry along with it part of all the substances composing that strata through which it passed? But farther, one of the most obvious consequences of such an eruption, would be the elevation of part of the whole range of the strata on both sides of the dyke, and the extent of this elevation will be in proportion to the power or thickness of the dyke; and, not only is it natural to expect this elevation of the strata to a certain extent, but from the operation of an agent so tremendous and irresistible, that the whole strata should be broken, disjointed, and confused. But does this statement correspond with the phenomena? From the history of dykes traversing coal strata, we know that it does not. On the contrary, the whole of the strata, in most cases, preserve the same thickness, the same parallelism, and the same inclination to the horizon on both sides of the dyke. It is true, the half mile of coal field intersected by a dyke, as we have supposed above, will on one side of it be elevated or depressed. If the dyke, which runs north and south in its course upwards, inclines to the west, the western division will be elevated. But this is not a partial elevation only in the immediate vicinity of the dyke. It extends over the whole field on the west side of the dyke, and the strata continue fair and regular, in all respects corresponding to those from which they have been detached, till they are intersected by another dyke.

From this reasoning, we think the conclusion fair and obvious, that dykes intersecting coal strata have not been formed by subterraneous eruption, and therefore, that the elevation or depression of the strata is not owing to this cause. Dr Hutton's theory, in this respect, is opposed by the facts which it professes to explain, and consequently it is untenable.

Let us now consider the argument drawn from the supposed calcination of the coal which has been in contact with the matter of the dyke in a state of fusion. Here Dr Hutton seems to have overleaped the bounds of his own theory, and lost sight of his own principles, which suppose, that all the strata and stony matters of which the globe is composed, have been consolidated by means of heat; that the exhibition of the common or ordinary phenomena of heat is not to be looked for in the grand processes of nature; because these operations have taken place at great depths in the bowels of the earth, or under immense pressure at the bottom of the sea; and this is the reason that coal, and lime strata, for instance, which have been subjected to this intense degree of heat discover no marks of calcination, the one being deprived of its carbonic acid, and the other of its bitumen. Now, granting this hypothetical argument to be well founded, what is the reason that the coal, which is in contact with a dyke, has undergone the processes of calcination, when this coal is at as great a depth in the bowels of the earth, under as immense pressure, and as much

much excluded from atmospheric air, as any coal at its original formation. But all the coal in contact with a dyke, is not in this state. Clean coal is sometimes found in immediate contact; and, in many places, clean coal is also found intercepted between regular ranges of basaltic columns, and this coal discovers not the smallest mark of calcination. On the other hand, coal in this supposed state of calcination, has been frequently discovered, at a great distance from any dyke or basaltic substance whatever. Masses of this foul coal often occur, to the regret and disappointment of the miner, in the midst of strata otherwise perfectly clean and regular. This last fact shews us, that we must look for the cause of this singular phenomenon elsewhere than in the circumstance of the coal having been in contact with a dyke while in fusion; for it appears that the effect does not always follow in the same circumstances, and that the same effect is produced in very different circumstances.

These observations are probably sufficient to shew that the above argument in proof of the subterraneous eruption of dykes, is equally unsatisfactory in explaining the phenomena, and consequently equally untenable with the former. Both, therefore, must fall to the ground.

The wedge-like form of dykes might be adduced as another argument against their formation by subterraneous eruption; for it is not easy to conceive that a dyke in a state of fusion should, in its eruptive progress towards the surface of the earth, enlarge and become thicker.

The history of metallic veins furnishes us with stronger objections against Dr Hutton's theory. If, according to this theory, metallic veins have been formed by the substances they contain being ignited in a state of fusion from the bowels of the earth, it will naturally follow, that the veins thus formed might be traced to the greatest depths, and even to the subterraneous furnace from which they issued. But we know that the fact is quite otherwise. The termination of many veins downwards has been discovered. Even the most powerful and productive have been unexpectedly cut off by the horizontal strata, and no vestige of them could ever be traced. This was the case with the rich vein of lead ore at Llangunog in Wales. It is the case also with many veins in their course downwards, to diminish gradually in form of a wedge, and then they are lost for ever. Now, this certainly could never have happened, had they been formed by subterraneous eruption. Some trace of their progress, some mark of their course through the intersected strata, would still have remained. But no such indications, no such traces, are found. We must therefore conclude, that metallic veins have not been formed in this way, and that this theory, which appears to be so much at variance with facts, will not account in a satisfactory manner for their formation.

The masses of stone of the same species with the neighbouring superior strata, sometimes rounded and worn by the action of water, which are found at great depths in mineral veins, and organized substances, petrifactions of vegetables and animals, present us with another objection to this theory, equally strong and insurmountable. These substances are the productions of the surface of the earth; and even supposing them to have existed in the bowels of the earth, it is inconceivable that they should have retained their primitive form after they were subjected to so high a temperature as is necessary to hold metals in a state of fusion.

Theories of the Earth.

Sect. VII. *Theory of Werner.*

193 Theory of Werner.

The latest, and perhaps most celebrated, theory that has yet appeared, is that of Professor Werner of Freyberg, with an account of which, and some observations on Mr Kirwan's opinions, we shall close this chapter.

We have said already, (N° 1.) that the subject of which we are now treating is called by Werner *geognosy*, and his pupils are commonly called *geognosts*.

Werner is of opinion, that our knowledge is already sufficiently advanced to form a rational theory respecting the formation of the *exterior crust* of our globe; for he does not deny that we cannot reason with respect to what is below this, since we have no fact which can give us the least notion with respect to it. We are only certain that some part of our globe has been in a fluid state, as is proved by its spheroidal form. The crystalline form of granite and other rocky substances which constitute the base of that part of the earth with which we are acquainted, are, according to Werner, sufficient proofs that this part at least has been in a state of minute dissolution. Again, the stratified appearance of most mountains and rocks shew that they are an accumulation of precipitates or sediments which have been deposited one over another. The numerous remains of marine animals which are found imbedded in many rocks, and of which some species are still found in our seas, allow us to believe that this solution was aqueous; that it was a vast ocean which has covered our globe to a very considerable height. *The exterior part of the globe*, then, *has been entirely dissolved by the waters which surrounded it, and from this solution certain chemical precipitations took place, which have formed the crust that we now see.*

In framing his theory, Werner professes to banish every thing that is hypothetical, and only to draw from general facts such immediate consequences as he believes it impossible not to deduce from them, and on these alone he founds his geognosy. The object of this theory, according to one of his disciples (the translator of his book on metallic veins), is to acquire a knowledge of the structure of the solid crust of the terraqueous globe, and the relative disposition of the materials which compose it; the means of doing this are to be derived from observation. Werner sets out with stating, that the chemical precipitates that took place from the chaotic fluid, did not form a regular surface, but that they collected here and there so as to produce the primitive mountains. These mountains he calls chaotic, because, says he, they have been formed during the period when the surface of the earth was a sort of chaos. After the retreat of the waters, these elevated parts were first discovered. They were exposed to the destructive action of the elements, and the shock of tides and torrents. The valleys were hollowed out, and the mountains acquired nearly the form in which we now see them.

Observation has shewn that the strata of which the earth is composed, may be divided into a certain number of congeries, each of which is composed of a certain

Theories of the Earth.

tain set of minerals that are nearly the same in whatever part of the world the congeries is found. To these congeries Werner has given the name of formations, of which he distinguishes six kinds or classes, four universal, being found all over the globe, and two partial, found only in particular districts. These formations he has arranged according to the order in which he conceives them to have been produced, beginning with that formation which lies next the solid nucleus of the earth, and which may therefore be conceived to be the oldest, and ending with the most superficial, which is considered as the newest formation.

The first of these classes is called by Werner that of *primitive formations*, which consist of a number of formations lying above each other, being those which are supposed the oldest, as in these no organic remains have been discovered. The substances constituting this class are *granite*, *gneiss*, *micaceous schistus*, *argillaceous schistus*, *primitive limestone*, *primitive trap*, *syenite*, and *porphyry*. Of these the granite is the lowest, and therefore is considered as the oldest; and next this follow the others in the order in which we have enumerated them, except that the primitive limestone, and primitive trap, are found in an uncertain order, alternating with gneiss, argillaceous schistus, or micaceous schistus; and are therefore considered as subordinate to these formations.

When the waters had subsided, and the summits of the primitive mountains had been uncovered, organized bodies were produced; and part of these being intercepted among the chemical precipitations which were still going on, and the mechanical precipitations which now began to take place, were carried with these to the flanks of the primitive mountains, and the valleys between them. Hence were produced a second series of formations, which are called by Werner *transition formations*, or *rocks of transition*, as he considered them to be deposited during the period when the earth was passing from an uninhabited to an inhabited state. Among these formations, however, the organic remains are but few. The substances composing this class, are *transition limestone*, *gray wacke*, *gray wacke slate*, *transition trap*, *siliceous schistus*. Of these the two last are subordinate, alternating with gray wacke and gray wacke slate.

The third formation is what Werner calls *floetz formation*, or that, in which the beds or strata lie nearly horizontal, appearing as if they had been deposited from water. This formation comprehends most of what are usually called secondary strata. It is divided by Werner into three subformations, named from the variety or situation of the sandstone, which forms a principal part of each; as, 1. Old red sandstone formation, composed of *floetz limestone*, *old red sandstone*, and *foliated gypsum*. 2. Second sandstone formation, composed of *sandstone*, *floetz limestone*, and *fibrous gypsum*. 3. Third sandstone formation, composed of *sandstone*, *limestone*, and *chalk*, &c. Of these, as before, the first mentioned is the oldest, and in this, somewhere near the gypsum, there is usually found salt or sulphur. In this formation, organic remains are first seen in any great quantities.

The fourth formation is called *independent coal formation*, because in this coal is first found, and because it is not universally spread over the earth as the three preceding, but is collected in insulated masses, independent of each other. This is also divided into three, each successively more recent than the preceding. The first series of strata consist of *slate clay*, *limestone*, *marl*, *soft sandstone*, *greenstone*, *argillaceous ironstone*, *shale*, and *coal*; the second of *indurated clay*, *marl*, *limestone*, *porphyritic stone*, and *coal*; and the third of *loose sandstone*, *conglomerate*, (a variety of sandstone), *slate clay*, and *coal*.

The fifth is called *floetz trap formation*, so called because the *beds* of which it is composed, consist of materials that are mostly of the nature of *trap*, or whinstone. The substances that compose this formation are *gravel*, *sandstone*, *siliceous sandstone*, *clay*, *wacke*, *basalt*, *greenstone*, *schistose porphyry*, *pitchstone*, and *graystone*. *Coal* is also found in this formation, somewhere among the beds of *siliceous sandstone*, *clay*, *wacke*, and *basalt*, to which it is therefore considered as subordinate (F).

The sixth and last formation is the *alluvial formation*, or that which has arisen from the action of lakes and rivers, washing down part of the older strata. This is divided into two series of strata; the first being those that have arisen from the action of lakes newly drained, comprehending *marl*, *sand*, *clay*, and *coal*; and the second, those which have been produced from the action of rivers, comprehending *mud*, *ironstone*, *sand*, *peat*, &c. This formation is the most recent of any, but, like the fourth, it is only partial.

The above is an outline of Werner's geognosy, which is considered as an improvement of what is called the *Neptunian theory*, or that which explains geological appearances by the action of water, in opposition to what is called the *volcanic theory*, or that which attributes these appearances to an igneous origin.

19. Objections to the theory of Werner.

One of the principal objections to the Neptunian theory is drawn from the insolubility in water of many of the substances which compose our globe; but this the Neptunians endeavour to explain, by supposing that at the very commencement of their existence these substances were in that state of minute division which aqueous solutions require, but which no known existing quantity would be able to effect, after the substances had acquired their utmost consolidation, as it is well known, that a solid substance may be kept in solution, at least for a short time, in a less quantity of fluid than was originally requisite to dissolve it.

A

(F) We may here notice Werner's opinion with respect to the formation and situation of basalt; as this is the only theory of importance respecting it, that has not been mentioned under the article BASALTES. "I am perfectly convinced (says Werner in a late memoir) that all the varieties of basalt have been produced in the humid way, and that they are of a very recent formation; that they formerly composed a great bed of immense extent, covering both the primitive and secondary strata; that time has anew destroyed a considerable part, and has left only the basaltic eminences which we now see." Vid. *Jameson's Mineralogy of Dumfries*, p. 184.

Theories of the Earth.

A second objection is derived from the difficulty of supposing that these substances could have been consolidated below water, or that the water could completely shut up the pores of a body, to the entire exclusion of itself; so that had the mineral substances been consolidated as here supposed, the solvent ought either to remain within them in a liquid state, or, if evaporated, should have left the pores empty, and the body pervious to water.

Mr Playfair argues strenuously against the notion of these substances being precipitated from the chaotic fluid, which has been so ingeniously supported by Kirwan, who ascribes the solution of all substances in the chaotic fluid to their being finely pulverised, or created in a state of the most minute division; and the solvent being then insufficient in quantity, he supposes that, on that account, the precipitation took place the more rapidly.

"If, says Mr Playfair, he means by this to say, that a precipitation without solution would take place the sooner, the more inadequate the menstruum was to dissolve the whole, the proposition may be true, but will be of no use to explain the crystallization of minerals, the very object he has in view; because to crystallization it is not a bare subsidence of particles suspended in a fluid, but it is a passage from chemical solution to non-solution, or insolubility, that is required.

"If on the other hand he means to say, that the solution actually took place more quickly, and was more immediately followed by precipitation, because the quantity of the menstruum was insufficient, this is to assert that the weaker the cause, the more instantaneous will be its effect *."

* Playfair's Illustrations, sect. 51.

Werner's theory of dykes and veins.

Werner's theory of dykes and veins requires a more particular consideration.

This theory supposes, that the spaces which are now occupied by vertical strata, or dykes, including also metallic veins, were originally fissures, formed by the operation of different causes.

1. The unequal height and density of mountains, are considered as the most general causes of fissures. When the mountains were in a soft and humid state, that side which was least supported not only separated by its own weight, but the whole strata of the side gave way, and sunk below their former plain. This also seems to be the opinion of Saussure, with regard to the formation of fissures. It is not to be expected, that events of this kind should be of frequent occurrence, now that mountains have acquired sufficient firmness and stability to resist the force of gravity, operating in consequence of the inequality of weight and diversity of the materials of which they are composed. Instances, however, of the operation of such causes are not altogether wanting, even in modern times. After a season of excessive rains, in the year 1767, similar fissures were formed in mountains in Bohemia and Lusatia.

2. When the waters covered the surface of the earth, the unequal weight of the mountains was supported by their pressure; but when the waters retreated, this pressure was removed, the equilibrium was destroyed, the unsupported side of the mountain separated and sunk; and in this manner a fissure was formed.

3. The evaporation of the moisture, after the retreat of the waters, and the consequent diminution of bulk by contraction of the substances which enter into the composition of mountains, are also considered as the causes of fissures.

4. Fissures, too, derive their origin from other local and accidental causes, and especially from earthquakes. In the year 1783, when Calabria was afflicted with this most dreadful of all calamities which visit the earth, mountains were separated, exhibiting fissures similar to those which are now occupied by vertical strata.

The second part of the theory is employed in proving that the empty spaces, occasioned by the operation of one or other of the causes which have been enumerated, were filled from above; that the different substances, of which the vertical strata are composed, were held in solution by the waters which covered the earth; and that they were precipitated, by different chemical agents, according to the order of chemical affinity, and deposited in the places which they now occupy. In support of the opinion, that these fissures were filled from above, Werner adduces facts of angular and rounded fragments of stones of various species, and organized bodies, as marine shells and vegetables, having been found in vertical strata, at the immense depth of 150 and 200 fathoms. It may be doubted, on good grounds, whether this theory, supported by all the ingenuity and experience of its author, will account in a satisfactory manner, for that regularity of position and arrangement which are discovered in the vertical strata; for, notwithstanding the seeming disorder which a superficial vein may exhibit, they are not less regular and uniform than the horizontal strata. And when our researches are extended beyond the narrow bounds within which they are at present limited, when we are better acquainted with their relative positions and connexions, this uniformity and regularity will become more conspicuous. It may be doubted whether the fortuitous operation of such causes as have been stated, be equal to the effect of the formation of the vertical strata, as they now appear.

But, supposing that fissures were produced by some of the causes which have been mentioned, few of these causes could operate till the retreat of the waters left the mountains uncovered. It was only then that the mountains, by the inequality of height and density, being left unsupported, separated, and sunk from their former situation; it was then only that the process of evaporation could take place, succeeded by diminution of bulk and consequent contraction. In short, none of the causes which have been stated, could have any effect before the waters had retreated, excepting earthquakes; of the operation of which there is no proof previous to that period. The materials which compose the vertical strata, it is said, were formed by deposition from the waters which covered the mountains, holding them in solution. But before the fissures could be formed to receive these materials by precipitation and deposition, the waters had retired. A second deluge must therefore have happened, from the waters of which the various substances which enter into the composition of vertical strata have been deposited. This the theory does not suppose to have taken place; and, without such a supposition, it seems to be attended with considerable difficulty. But another difficulty still remains. It does not appear how the peculiarity of structure,

structure, which was mentioned in our account of whin dykes, Sect. II. of the last chapter, can be accounted for by the principles of this theory. If it be granted, that the horizontal strata were formed in the humid way, the materials of which they are composed must have been precipitated from the waters which held them in solution, by the laws of chemical affinity. But the vertical strata are supposed to have been formed in the same manner, and according to the same process. Now, this being the case, What is the reason that the vertical strata should exhibit a peculiarity of structure and arrangement, different from the horizontal strata? Some of the whin dykes which have been already described, are very remarkable for this singular structure, especially those which assume the form of prismatic columns. These columns are in the horizontal position; and, excepting the latter circumstance, these dykes, in every respect, resemble a basaltic stratum, in which the columns are perpendicular.

More arguments might be adduced in opposition to the theory of Werner; but we must hasten to conclude this chapter, with mentioning a few of Mr Kirwan's peculiar opinions.

196
Kirwan's theory of the declivities of mountains.

Among these, the manner in which he accounts for the unequal declivities of the sides of mountains, forms one of the most conspicuous objects: and to this we shall principally confine ourselves, and shall give it in his own words, as extracted from his essay on the declivities of mountains, to which we were obliged in the first section of Chap. II.

" To assign the causes of this almost universal allotment of unequal declivities to opposite points, and why the greatest are directed to the west and south, and the gentlest, on the contrary, to the east and north, it is necessary to consider,

" 1. That all mountains were formed while covered with water.

" 2. That the earth was universally covered with water at two different eras, that of the creation, and that of the Noachian deluge.

" 3. That in the first era we must distinguish two different periods, that which preceded the appearance of dry land, and that which succeeded the creation of fish, but before the sea had been reduced nearly to its present level. During the former, the primeval mountains were formed; and during the latter, most of the secondary mountains and strata were formed.

" 4. That all mountains extend either from east to west, or from north to south, or in some intermediate direction between these cardinal points, which need not be particularly mentioned here, as the same species of reasoning must be applied to them, as to those to whose aspect they approach most.

" These preliminary circumstances being noticed, we are next to observe that, during the first era, this vast mass of water moved in two general directions, at right angles with each other, the one from east to west, which needs not to be proved, being the course of tides which still continue, but were in that ocean necessarily stronger and higher than at present; the other from north to south, the water tending to these vast abysses then formed in the vicinity of the south pole, as shewn in my former essays. Before either motion could be propagated, a considerable time must have elapsed.

" Now the primeval mountains formed at the commencement of the first era, and before this double direction of the waters took place, must have opposed a considerable obstacle to the motion of that fluid in the course that crossed that of the direction of these mountains. Thus the mountains that stretch from north to south must have opposed the motion of the waters from east to west; this opposition diminishing the motion of that fluid, disposed it to suffer the earthy particles with which in those early periods it must have been impregnated, to crystallize or be deposited on these eastern flanks, and particularly on those of the highest mountains, for over the lower it could easily pass; these depositions being incessantly repeated at heights gradually diminishing as the level of the waters gradually lowered, must have rendered the eastern declivities or descent, gentle, gradual, and moderate, while the western sides receiving no such accessions from depositions, must have remained steep and craggy.

" Again, the primeval mountains that run from east to west, by opposing a similar resistance to the course of the waters from north to south, must have occasioned similar depositions on the northern sides of these mountains, against which these waters impinged, and thus smoothed them.

" Where mountains intersect each other in an oblique direction, the north-east side of one range being contiguous to the south-west flanks of another range, there the influx of adventitious particles on the north-east side of the one, must have frequently extended to the south-west side of the other, particularly if that afflux were strong and copious; thus the *Erzgebirge* of Saxony, which run from west to east, have their north-east sides contiguous to the south-west side of the Riesengebirge that separate Silesia from Bohemia, and hence these latter are covered with the same beds of gneiss, &c. as the northern sides of the Saxon, and thereby are rendered smooth and gentle, comparatively to the opposite side, which, being sheltered, remains steep and abrupt, which explains the seventh observation.

" The causes here assigned explain why the covering of adventitious strata on the highest mountains is generally thinnest at the greatest height, and thickest towards the foot of the mountain; for the bulk of the water that contained the adventitious particles being proportioned to its depth, and the mass of earthy particles with which it was charged being proportioned to the bulk of the water that contained them, it is plain, that as the height of water gradually decreased, the depositions from it on the higher parts of the mountains must have been less copious than on the lower, where they must have been often repeated.

" Hence, 2. granite mountains, generally the most ancient, frequently have their northern or eastern sides covered with strata of gneiss or micaceous schistus, and this often with argillite or primeval sandstone, or limestone, these being either of somewhat later formation, or longer suspendible in water.

" Hence, 3. different species of stone are often found at different heights of the same flank of a mountain, according as the water which conveyed these species, happened to be differently impregnated at different heights. During the first era its depositions formed the primitive stony masses; after which the creation of fish, limestone, sandstone, (*puddingstone*) and secondary argillites, in which piscine remains are found, were deposited.

Theories of the Earth. ted. But during the second era, that of the Noachian deluge, by reason of the violence and irregularity of its aggression, the depositions were more miscellaneous, and are found at the greatest heights; yet in general they may well be distinguished by the remains of land animals, or of vegetables, or of both, which they present in their strata (or at least by the impressions of vegetables which they bear) as these must have been conveyed after the earth had been inhabited. But mountains regularly stratified bearing such remains, for instance the carboniferous, cannot be deemed to have been formed in a period so tumultuous. During this deluge the waters also held a different course, proceeding at first from south to north, and afterwards in both opposite directions, as shewn in treating of that catastrophe in my second essay.

"Hence, and from various contingent local causes, as partial inundations, earthquakes, volcanoes, the erosion of rivers, the elapsion of strata, disintegration, the disruption of the lofty mounds by which many lakes were anciently hemmed in, several changes were produced in particular countries, that may at first sight appear, though in reality they are not, exceptions to the operations of the general causes already stated.

"Thus the mountains of Kamtschatka had their eastern flanks torn and rendered abrupt by the irruption of the general deluge, probably accompanied by earthquakes. And thus the Meissener had its east and north flanks undermined by the river Warre, as Werner has shewn; thus the eighth and sixteenth observations are accounted for, as is the thirteenth by the vast inundations so frequent in this country, (1. *Pallas*, p. 172.), which undermined or corroded its east side, while the western were smoothed by the calcareous depositions from the numerous rivers in its vicinity.

"Hence, 4. we see why on different sides of lofty mountains different species of stones are found, as Pallas and Saussure have observed (2. *Sauss.* § 981.), a circumstance which Saussure imagined almost inexplicable, but which Dolomieu has since happily explained, by shewing that the current which conveyed the calcareous substances to the northern, eastern, and north-eastern sides of the Alps, for instance, was stopped by the height of these mountains, and thus prevented from conveying them to the southern sides, and thus the north-eastern sides were rendered more gentle than the opposite, (3. *New Roz.* p. 423.), conformably to the theory here given.

Hence, 5. where several lofty ridges run parallel to each other, it must frequently happen that the external should intercept the depositions that do not surround them, and thus leave the internal ridges steep on both sides.

"Hence, 6. low granitic or other primitive hills are frequently uncovered by adventitious strata on all sides, as at Phanet in the county of Donegal, or are covered on all sides; the impregnated waters either easily passing over them, or stagnating upon them, according to the greater or less rapidity of its course, and the obstacles it met with."

Kirwan's theory of dykes. Mr Kirwan's theory of the formation of whin dykes, is as follows.

He supposes that the dyke existed in the spot where it is found previous to the formation of the horizontal strata; that, during the formation of the latter by deposition, their equal extension on each side of the dyke was obstructed by its height preventing the passage of the current of waters; that the strata on that side of the dyke which were first formed, occasioned a much more considerable pressure than on the side on which the strata of later formation repose, and must have pulled the upper and more moveable extremity of the slip gradually towards the side on which there was least pressure; on that side it must therefore overhang: this pressure being of earlier date than on the opposite side, must have had a more considerable effect in depressing each particular stratum, and forcing their integrant particles into closer contact, than could have been produced in those of later formation; and consequently the strata must be lower. The ingenious author has added, with good reason, that he is not satisfied with this explanation. It is undoubtedly quite incompatible with the phenomena which it attempts to explain. For it has been already observed, that the coal and contiguous strata are, in every respect, the same on both sides of a dyke, to whatever distance they may have been elevated or depressed, which demonstrates clearly, that their formation must have been coeval. But, besides, the same derangement takes place in a slip where there is merely a solution of contiguity of the horizontal strata, one side being only elevated or depressed above or below the corresponding side from which it has been detached without having a vertical stratum or dyke interposed.

Chap. IV. *Of Earthquakes and Volcanoes.*

Earthquakes and Volcanoes.

In the preceding chapters we have given a short account of the materials which constitute the globe of the earth; we have taken a view of the relative position and connexion which subsist among these materials, so far as they are known, and we have considered some of the changes which are supposed to have taken place in their arrangement and distribution, and some of the theories which have been proposed to account for these changes. We have hitherto contemplated nature in a state of seeming repose, conducting her operations by a gradual and silent process, and accomplishing the most beneficial and wonderful effects, unheeded and unobserved. We are now to take a view of those more terrible and sudden changes which are exhibited in the devastation and ruin which accompany the earthquake and the volcano;—changes awful in the contemplation, but dreadful and terrible in their tremendous effects. 198

Many of the phenomena which accompany earthquakes and volcanoes, are common to both. Earthquakes are frequently the forerunners, and sometimes the attendants, of volcanic eruptions; but earthquakes have often existed, and their terrible effects have been severely felt, where no volcano was ever known.

In the present chapter, we propose to consider the phenomena, history, and causes of earthquakes and volcanoes, which will form the subjects of the two following sections. In the first we shall treat of earthquakes, and in the second of volcanoes.

Sect. I. *Of the Phenomena and History of Earthquakes.*

199 Places where earthquakes prevail.

Earthquakes have been felt in most countries of the world. There are, however, particular places, which

Earthquakes and Volcanoes.

which seem to be more subject to this dreadful calamity than others; and this does not seem to depend on any local circumstances, with regard to particular regions of the earth. It may be observed in general, that earthquakes are more frequent within the tropics; but there are places within the torrid zone, which are more rarely visited by earthquakes than some of the more temperate, or even the colder regions of the earth. In the islands of the West Indies, and in some parts of the American continent which lie between the tropics, the earthquake is more frequently felt than in most other regions of the earth. But the northern shores of the Mediterranean, the kingdom of Portugal, and some other places without the tropics, have been oftener the scene of desolation, by the effects of the earthquake, than many of the islands and extensive continents within the torrid zone. From this circumstance in the history of earthquakes, it would appear that they are not limited to particular regions, on account of proximity to the equator or distance from it, on account of insular situation or extent of continent. Particular islands, however, and particular parts of continents, have undoubtedly been oftener visited by earthquakes than others. Of all the islands of the West Indies, Jamaica has most frequently experienced their dreadful effects. Indeed, scarcely a year passes, without several shocks of an earthquake being felt in that island. Mexico and Peru in South America, are more subject to earthquakes than the other regions of the American continent. Portugal has been often shaken to the very foundations, by terrible earthquakes, while Spain, immediately adjoining, or, it may be said, including it, is, comparatively, almost exempted from their effects. It has been observed, that earthquakes have been less destructive in Italy than in Sicily, which are in the immediate vicinity of each other, and are both volcanic countries.

Observations on phenomena so awful and terrible, can scarcely be expected to be very numerous. The operation of the causes which produce them is too rapid, the effects are too sudden and unexpected, to be rendered the subject of accurate or attentive philosophical investigation; or, perhaps, we might acknowledge at once, that they are too extensive and too obscure for the powers of man. They are beyond the grasp of the human mind.

It has been already observed, that earthquakes are more frequent in volcanic countries than in any others. In these regions they are oftener dreaded and expected than in other places. Where a volcano exists, and when it has ceased to throw out flame and smoke for any long period, shocks of earthquakes begin to be dreaded. This has been very generally the case with the principal volcanoes of the world, the events of whose history have been recorded. An earthquake is often the forerunner of an eruption, and the very first warning of its approach.

200

Phenomena which precede and accompany them.

Earthquakes are often preceded by long droughts. The earthquake, however, does not immediately succeed the cessation of the drought, or the fall of rain. Some electrical appearances are observed to take place in the air, before the earthquake comes on. The aurora borealis is frequent and brilliant, and bright meteors are often seen darting from one region of the heavens to another, or from the atmosphere to the earth.

Before the shock comes on, the waters of the ocean appear to be unusually troubled; without the effect of wind, or any perceptible cause, it swells up with great noise. Fountains and springs are also greatly disturbed, and their waters are agitated and become muddy. The air at the time of the shock has been observed to be remarkably calm and serene, but afterwards it becomes dark and cloudy.

The noise which accompanies the shock of an earthquake is sometimes like that of a number of carriages, driving along the pavement of a street with great rapidity. Sometimes it is like a rushing noise, similar to that of wind, and sometimes it resembles the explosions occasioned by the firing of artillery. The noise which accompanied the earthquake, which was pretty generally felt over Scotland about three years ago, we recollect, resembled that of a heavy person walking rapidly, and barefooted, through an adjoining room.

The effect of earthquakes on the surface of the earth is various. Sometimes it is instantaneously heaved up in a perpendicular direction, and sometimes assumes a kind of rolling motion, from side to side. Sometimes the shock commences with the perpendicular motion, and terminates with the other.

Great openings or fissures are made in the earth by the shock, and these in general throw out vast quantities of water, but sometimes smoke and flame are also emitted. Flame and smoke are often seen issuing through the surface of the earth, even where no chasm or fissures has been produced.

The effects of an earthquake on the ocean are not less terrible than those on land. The sea swells up to a great height; its waters sometimes seem to be entirely separated, and from the place of separation, currents of air, smoke, and flame, are discharged. Similar effects have been observed to take place in lakes, ponds, and rivers. Their waters are thrown into great agitation, and are sometimes swelled up. Places in which there was a considerable body of water, have become dry land, and dry land has been converted into an extensive lake by the shock of an earthquake.

The most terrible earthquake that has yet visited the earth, has never been felt over its whole surface. Their effects, however, extend to very distant regions, from the centre or principal scene of desolation. The existence of an earthquake is indicated much more extensively by water than by land. Where its effects have not been at all perceived on dry land, the agitation produced on the waters in the ocean, or in lakes and rivers, has been often communicated to a very great distance.

The duration of the shock of an earthquake rarely exceeds a minute, and perhaps very few continue for near that length of time. But the shocks are sometimes repeated in rapid succession; and perhaps from the effect on the senses, and the dread and alarm which are thus occasioned, it is supposed that their duration is much longer than it really is.

But as no general account of the phenomena which accompany an earthquake, from the difficulty or scantiness of observation, can be complete, it will be rendered much more intelligible and interesting, if we enter a little

Earthquakes and Volcanoes.

little more into the detail of the history of particular earthquakes; and in the account of some of them which we propose to lay before our readers, it will be found that most of the appearances and effects which have been enumerated, were observed.

Earthquake in Calabria 1638.

The first earthquake, the history of which we shall now detail, happened in Calabria, in the year 1638. This earthquake is rather to be considered as an exception to what was said with regard to their not taking place in the neighbourhood of a volcano, soon after an eruption. The volcanoes in that vicinity had experienced violent eruptions a very short time before. Five years before, there had been an eruption of Mount Vesuvius, and two years only had elapsed from the time that a similar event had befallen Ætna. This mountain, indeed, at the very time, threw out a great body of smoke, which seemed to cover the whole island, and entirely concealed the shores from view. The air over the sea at a little distance was calm and serene, and the surface of the water was perfectly smooth. Seemingly without any cause, it began to be slightly agitated, as happens to the surface of water in a heavy shower of rain. A dreadful noise succeeded, and the smell of sulphureous vapours was perceived. The noise, like the rattling of chariots, grew more frequent and loud, and the shock at last was terribly felt, when the earth was heaved up, or rolled in the form of waves.

This earthquake is particularly described by the celebrated father Kircher. "On the 24th of March, (says he), we departed in a small boat from the harbour of Messina in Sicily, and the same day arrived at the promontory of Pelorus. Our destination was for the city of Euphemia in Calabria, but unfavourable weather obliged us to remain at Pelorus three days. Wearied at length with delay, we determined to proceed on our voyage, and although the sea seemed unusually agitated, yet it did not deter us from embarking. As we approached the gulf of Charybdis, the waters seemed whirled round with such violence, as to form a large hollow in the centre of the vortex. Turning my eyes to Mount Ætna, I saw it throw out huge volumes of smoke, which entirely covered the island. This awful appearance, with the dreadful noise, and the sulphureous smell which accompanied it, filled me with strong apprehensions that some terrible calamity was approaching. The sea itself exhibited a very unusual appearance, its agitation resembling that of the waters of a lake which is covered with bubbles in a violent shower of rain. My surprise was still increased by the calmness and serenity of the weather; not a breeze stirred, not a cloud obscured the face of the sky, which might be supposed to produce these dreadful commotions. I therefore warned my companions, that the unusual phenomena which we observed, were the forerunners of an earthquake. Soon after we stood in for the shore, and landed at Tropæa; but we had scarcely arrived at the Jesuits college in that city, when a horrid sound, which resembled the rattling wheels of an infinite number of chariots, driven furiously along, stunned our ears. Soon after a terrible shaking of the earth began; the ground on which we stood seemed to vibrate, as if we were in the scale of a balance, which continued waving. The motion soon grew more violent; I could no longer keep my legs, but was thrown prostrate upon the ground. After some time had elapsed, when I had recovered from the consternation; and finding that I was unhurt amidst the general crash, I resolved to make the best of my way to a place of safety, and running as fast as I could, I reached the shore. I soon found the boat in which I had landed, as well as my companions; and leaving this scene of desolation, we prosecuted our voyage along the coast. Next day we arrived at Rochetta, where we landed, although the earth still continued in violent commotion. But we had scarcely reached the inn when we were again obliged to return to the boat. In about half an hour we saw the greatest part of the town, as well as the inn where we had stopped, levelled with the ground, and most of the inhabitants buried in its ruins. As we proceeded onward, we landed at Lopezium, which is a castle about half way between Tropæa and Euphemia, to which we were bound; and, here, wherever I looked, nothing but scenes of ruin and horror presented themselves. Towns and castles were levelled with the ground, and Stromboli at the distance of 60 miles threw out an immense body of flames, accompanied with a noise which could be distinctly heard. But our attention was quickly drawn from more remote to present danger. The rattling sound which immediately precedes an earthquake, again alarmed us; every moment it seemed to grow louder and louder, and to approach nearer the place on which we stood. A dreadful shaking of the earth now began, so that being unable to stand, my companions and I caught hold of whatever shrub was next to us, to support ourselves. After some time the violent commotion ceased, and we stood up, and proposed to prosecute our voyage to Euphemia, which lay within sight; but in the meantime, while we were preparing ourselves, I turned my eyes towards the city, but could see nothing but a thick, black cloud, which seemed to rest on the place. This appeared an extraordinary circumstance, as the sky all round was calm and serene. We waited till the cloud passed away, and then turning to look for the city, it was totally sunk, and where it formerly stood, nothing remained but a dismal and putrid lake."

202 In Sicily in 1693.

In the year 1693, an earthquake happened in Sicily, which not only shook the whole island, but also reached to Naples and Malta. Previous to the shock, a black cloud was seen hovering over the city of Catania, which was destroyed at this time. The sea began to be violently agitated; the shocks succeeded like the discharge of a great number of artillery; the motion of the earth was so violent, that no persons could keep their legs. Even those who lay on the ground were tossed from side to side, as on a rolling billow; high walls were razed from their foundations, and were thrown to the distance of several paces. Almost every building in the countries which it visited was thrown down; 54 cities and towns, besides a great number of villages, were either greatly damaged, or totally destroyed. Among those which we have already mentioned, was the city of Catania, one of the most ancient and flourishing in the kingdom. After the thick cloud which remained after the earthquake had dissipated, no remains of this magnificent city could be seen. Of 18,900 inhabitants, not fewer than 18,000 perished by this dreadful calamity.

203 In Jamaica in 1692.

The terrible earthquake which visited the island of Jamaica in 1692, affords us another example of almost the whole of the phenomena which were enumerated

as

Earth-quakes and Volcanoes.

as the forerunners or attendants of earthquakes. It was on the 7th of June, in that year, that this dreadful calamity, which in two minutes totally destroyed the town of Port Royal, on the south side of Jamaica, and at that time the capital of the island, took place. The effect of the shock on the surface was immediately preceded by a hollow rattling noise, like that of thunder. The streets were heaved up like waves of the sea, and then instantly thrown down into deep pits. All the wells discharged their waters with prodigious agitation; the sea burst its bounds, and deluged a small part of the town which was not entirely overwhelmed. The fissures produced in the earth were so great, that one of the streets seemed twice as broad as formerly, and in some places the earth opened and closed again for some time. A great many of these openings were seen at once. In some of them, the houses and inhabitants, and every thing that was near, were swallowed up. Some persons were swallowed up in one of these chasms, and what will appear most extraordinary, and indeed almost incredible, were thrown out alive from another. Whole streets sunk in some, and from others an immense body of water was projected high into the air. Smells which were extremely offensive now succeeded; nothing but the distant noise of falling mountains was heard, and the sky, which before the shock was still and serene, assumed a dull red colour.

The effects of this earthquake were not limited to this spot. It was severely felt through the whole island, which in many places sustained very material damage. Indeed there were few houses which were not either injured or thrown down. In some places the inhabitants, houses, trees, and whole surface, were swallowed up in the same chasm; and what was formerly dry land was left a pool of water. The wells in almost every corner of the island, whatever was their depth, threw out their water with great violence. The rivers were either entirely stopped, or ceased to flow for 24 hours; and many of them formed to themselves new channels. At the distance of 12 miles from the sea, an immense body of water spouted out from a gap which was formed in the earth, and was projected to a great height in the air. Such was the violence of the shock, that many persons were thrown down on their faces, even in places where the surface of the ground remained unbroken. It was observed that the shock was most severely felt in the immediate vicinity of the mountains. Could this arise from the greater pressure, and consequently the greater resistance, or was it because the force which produced these terrible effects existed near them?

After the great shock which destroyed the town of Port Royal, the inhabitants who escaped went on board ships in the harbour, where many of them remained for two months, during which time the shocks were repeated, and were so frequent, that there were sometimes two or three in the course of an hour. These were still accompanied with the same rattling noise, like that of thunder, or like the rushing noise occasioned by a current of air in rapid motion. They were also attended with what are called *brimstone blasts*. These, it is probable, were sulphureous vapours which issued from the openings made by the earthquake. The atmosphere, however, seemed to be loaded with noisome vapours, for a very general sickness soon succeeded, which in a short time swept off not fewer than 3000 persons.

Earthquakes and Volcanoes.

204. At Lisbon in 1755.

But of all the earthquakes, the history of which is on record, that which happened at Lisbon, in the year 1755, was by far the most extensive in its effects, and, from its recent occurrence, will probably be deemed the most interesting. In the year 1750, several shocks of earthquakes had been sensibly felt. The four following years were remarkable for excessive drought. The springs which formerly yielded abundance of water, were totally dried up and lost; the winds which chiefly prevailed were from the north and north-east. During this period also there were slight tremors of the earth; the seasons in 1755, were unusually wet, and the summer, as the consequence of this, proved unusually cold. But for the space of 40 days before the earthquake happened, the sky was more clear and serene. On the last day of October the face of the sun was considerably obscured, and a general gloom prevailed over the atmosphere. The day following (the 1st of November) a thick fog arose, but it was soon dissipated by the heat of the sun. Not a breath of wind was stirring; the sea was perfectly calm, and the heat of the weather was equal to that of June or July in this country. At 35 minutes after nine in the morning, without any previous warning, excepting the rattling noise resembling that of distant thunder, the earthquake came on with short, quick vibrations, and shook the very foundation of the city, so that many of the houses instantly fell. A pause, which was indeed just perceptible, succeeded, and the motion changed. The houses were then tossed from side to side, like the motion of a waggon driven violently over rugged stones. It was this second shock which laid great part of the city in ruin, and, as might be expected, great numbers of the inhabitants were destroyed at the same time. The whole duration of the earthquake did not exceed six minutes. When it began, some persons in a boat, at the distance of a mile from the city, and in deep water, thought the boat had struck on a rock, in consequence of the motion which was communicated to it. At the same time they perceived the houses falling on both sides of the river. The bed of the Tagus was in many places raised to the very surface of the water; ships were driven from their anchors or moorings, and were tossed about with great violence; and the persons on board did not for some time know whether they were afloat or aground. A large new pier with several hundreds of people upon it, sunk to an unfathomable depth, and not one of the dead bodies was ever found. The bar of the river was at one time seen dry from side to side; but suddenly the sea came rolling in like a mountain, and in one part of the river the water rose in an instant to the extraordinary height of 50 feet. At noon another shock happened; the walls of some houses that remained were seen to open from top to bottom, near a foot wide, and were afterwards so exactly closed, that scarcely any mark of this injury remained.

205. The shock of this earthquake felt at Colares;

But what was the most singular circumstance attending this earthquake, was, the prodigious extent to which its effects reached. At Colares, 20 miles from Lisbon, and two miles from the sea, the weather was uncommonly warm for the season, on the last day of October. About four o'clock in the afternoon, a fog arose which,

proceeding

Earthquakes and Volcanoes.

proceeding from the sea, covered the valleys. This was an unusual occurrence at that season of the year; but soon after the wind shifting, the fog returned to the sea, collected over its surface, and became very thick and dark; and as the fog dispersed, the sea was violently agitated, and with great noise. On the first of November, at the dawn of day, the sky was fair and serene; about nine o'clock the sun was overclouded, and became dim. Half an hour after, the rattling noise like that of chariots was heard; and this soon increased to such a degree, that it resembled the explosions of the largest artillery. The shock of an earthquake was immediately felt, and was quickly succeeded by a second and a third. In these shocks it was observed, that the walls of buildings moved from east to west. From some of the mountains flames were seen issuing, somewhat resembling the kindling of charcoal accompanied with a great deal of thick black smoke. The smoke which arose from one mountain was at the same time accompanied with noise, which increased with the quantity of smoke. When the place from which the smoke issued was afterwards examined, no signs of fire could be perceived.

5 At Oporto.

At Oporto, near the mouth of the river Douro, the earthquake began at 40 minutes past nine. The sky was quite serene when the hollow rattling noise was heard, and it was immediately attended with a commotion of the earth. In the space of a minute or two, the river rose and fell five or six feet, and continued this motion for four hours. In some places it seemed to open, and discharge great quantities of air. The sea was also violently agitated, and indeed the agitation was so great, to the distance of a league beyond the bar, that it was supposed the discharge of air from that place must also have been very considerable.

Destruction at St Ubes.

St Ubes, a sea-port town twenty miles south of Lisbon, was entirely swallowed up by the repeated shocks of this earthquake, and the immense surf of the sea which was produced. Large masses of rock were detached from the promontory at the extremity of the town. This promontory consists of a chain of mountains composed of a very hard stone.

Felt in Spain.

The same earthquake was felt in almost every part of Spain. The only places which escaped from its effects were the provinces of Arragon, Catalonia, and Valencia. At Ayamonte, which is near the place where the Guadiana falls into the bay of Cadiz, the earthquake was not felt till a little before ten o'clock. It was here also preceded by the hollow rattling noise. The shocks continued with intervals, for 14 or 15 minutes, and did very considerable damage. Scarcely half an hour had elapsed from the time that the commotion first began, when the sea, the river, and canals, rose violently over their banks, and laid every place near them under water. The sea rolled in in huge mountains, and carried every thing before it.

The earthquake began at Cadiz some minutes after nine in the morning, and lasted about five minutes. The water in the cisterns under ground was so much agitated, that it rose in the form of froth. About ten minutes after eleven, a huge wave was seen coming from the sea, at the distance of eight miles, which was supposed not to be less than 60 feet high, and burst in upon the city. The water returned with the same violence with which it approached, and places which were deep at low water were left quite dry. Similar waves continued, but gradually lessening, till the evening.

The earthquake was not felt at Gibraltar till after ten o'clock. There it began with a tremulous motion of the earth, which continued for about half a minute. A violent shock then followed; the tremendous motion again commenced, and continued for five or six seconds, and then succeeded a second shock, but less violent than the first. The whole time did not exceed two minutes; the earth had an undulating motion; some of the guns on the batteries were seen to rise, and others to sink. Many people, seized with sickness and giddiness, fell down. Some who were walking or riding, felt no shock, but were attacked with sickness. The sea had an extraordinary flux and reflux; it ebbed and flowed every 15 minutes; it rose six feet, and then fell suddenly so low, that a great many fish and small boats were left on the shore.

The shock was felt at Madrid nearly at the same time as at Gibraltar. It continued for six minutes, and the same sickness and giddiness prevailed. It was not felt by those who walked smartly, or who were in carriages, and no accident happened excepting two persons who were killed by the fall of a stone cross from the porch of a church.

Malaga, a sea-port town on the Mediterranean, experienced a violent shock; the bells were set a ringing in the steeples, and the water of the wells overflowed, and as suddenly retired. St Lucar, at the mouth of the Guadalquiver, suffered much from a similar shock, as well as from an inundation of the sea, which broke in, and did great damage. St Seville, 16 leagues above this, a number of houses was thrown down; the celebrated tower of the cathedral, called *La Giralda*, opened in the four sides; the waters were thrown into violent agitation, and the vessels in the river were driven on shore.

209 In Africa.

In Africa this earthquake was felt nearly as severely as in Europe. Great part of the city of Algiers was destroyed. This happened about ten in the morning. About the same time at Arzilla, a town in the kingdom of Fez, the sea suddenly rose with such impetuosity, that it lifted up a vessel in the bay, and forced it on shore with such violence that it was broken to pieces. A boat was also found within land, at the distance of two musket shots from the sea. At Fez and Mequinez, many houses were thrown down, and numbers of persons were buried in the ruins.

Many people were destroyed at Morocco by the falling of houses. Eight leagues from the city the earth opened, and swallowed up a village with all its inhabitants, to the number of 8,000 or 10,000, as well as all their cattle. Soon after the earth closed, and they were seen no more. The town of Sallee also suffered greatly; a third part of the houses were thrown down; the waters rushed into the streets with great violence, and when they retired, they left behind them a large quantity of fish. The earthquake began at Tangier at ten in the morning; its whole duration was about ten or twelve minutes. The sea came up to the walls with great violence, and retired immediately with the same rapidity, leaving behind a great quantity of fish. This agitation of the water was repeated no less than 18 times, and continued till about six o'clock in the evening. It began at the same time at Tetuan, but its duration

Earthquakes and Volcanoes.

ration was only about seven or eight minutes. Three of the shocks were so violent as to excite great apprehensions that the city would be destroyed. Similar effects were produced by the same earthquake at different places along the African shore of the Mediterranean.

210 In Madeira and the West Indies

At the town of Funchal in Madeira, the first shock of this earthquake was felt at 38 minutes past nine. It was preceded by the rattling noise, which seemed to be produced in the air; the shock, it was supposed, continued for more than a minute; the earth moved with a vibratory, undulating motion, and some of the vibrations increased greatly in force. The noise in the air which accompanied the shocks, lasted some seconds after the motion of the earth had ceased. At three quarters past eleven, the day being calm and serene, the sea retired suddenly, then, without the least noise, rose with a great swell, overflowed the shore, and entered the city. It rose 15 feet perpendicular above high-water mark. Having thus fluctuated four or five times, it at last subsided, and resumed its former stillness. In the northern part of the island, the inundation was still more violent. It first retired to the distance of 100 paces, and suddenly returning, overflowed the shore, broke down walls of magazines and storehouses, and left behind it great quantities of fish in the streets of a village. At this place the sea rose only once beyond the high-water mark, although it continued to fluctuate much longer before it entirely subsided than at Funchal.

Such were the effects of this earthquake, in those places where it was accompanied with considerable damage. It was, however, perceptibly felt to a great distance in every direction, either by a slight motion of the earth, or by the agitation of the waters. At the island of Antigua the sea rose to such a height as had never been before known, and afterwards the water at the wharfs which used to be six feet deep, was not more than two inches. About two in the afternoon, the sea ebbed and flowed at Barbadoes in a very unusual manner. It overflowed the wharfs, and rushed into the streets. This flux and reflux continued till 10 at night.

211 In France.

Shocks were distinctly felt in different parts of France, as at Bayonne, Bourdeaux, and Lyons, The waters were also observed to be agitated in different places, as at Angouleme, and Havre de Grace, but with a less degree of violence than some which have been mentioned. At Angouleme, a subterraneous noise like thunder was heard, and soon after a torrent of water, mixed with red sand, was discharged from an opening in the earth. Most of the springs in the neighbourhood sunk, and continued dry for some time.

212 In Germany.

The effects of this earthquake were also very perceptible in many places of Germany. Throughout the duchy of Holstein, the waters were greatly agitated, particularly the Elbe and Trave. The water of a lake, called *Libsec*, in Brandenburg, ebbed and flowed six times in half an hour, and although the weather was then perfectly calm, this motion was accompanied with a great noise. A similar agitation took place in the waters of the lakes called *Mupelgast* and *Netzo*, but here there was also emitted a most offensive smell.

The sea was greatly agitated round the island of Corsica, and many of the rivers of the island overflowed their banks. The same earthquake was felt in the city of Milan in Italy, and its neighbourhood. Turin in Savoy experienced a very smart shock.

21[?] In Switzerland.

Many of the rivers of Switzerland became all at once muddy, although there had been no rain. The lake of Neufchatel rose to the height of two feet above its usual level, and continued at this height for a few hours. The waters of the lake of Zurich were also greatly agitated.

21[?] In Holland.

The commotion of the waters in Holland was still more remarkable. In the afternoon of the 1st of November, the waters of the Rhine at Alphen, between Leyden and Woerden, were so violently agitated, that the buoys were broken from their chains, large vessels parted from their cables, and smaller ones were thrown upon the dry land. At 11 in the forenoon at Amsterdam, when the air was perfectly calm, the waters in the canals were thrown into great commotion, so that boats broke loose from their moorings, chandeliers were observed to vibrate in the churches, although it is said no motion of the earth was perceptible. In the forenoon, at Haarlem, not only the water in the rivers, canals, &c. but, it is asserted, smaller quantities of fluids contained in vessels, were greatly agitated, and sometimes dashed over the sides of the vessels. This continued for about four minutes. Between 10 and 11 in the forenoon, in some of the canals at Leyden, the waters rose suddenly, and produced very perceptible undulations.

21[?] In Norway, &c.

The effects of this earthquake extended as far north as Norway and Sweden: many of the rivers and lakes in Norway were greatly agitated; shocks were felt in several of the provinces in Sweden, and commotions of the waters, with the rivers and lakes, especially in Dalecarlia, were observed. The river Dala suddenly overflowed its banks, and as suddenly retired; and at the same time, a lake which is a league distant from it, bubbled up with great violence. Several smart shocks were felt at Fahlun, a town in Dalecarlia.

21[?] In Britain.

In many places of Great Britain and Ireland, the agitation of the waters was very perceptible. At Eaton bridge in Kent, near a pond of an acre in extent, some persons heard a sudden noise, which they supposed was occasioned by something falling into the pond, for it was then a dead calm, and ran to the spot, where they saw the pond open in the middle, while the water dashed over a perpendicular bank two feet high. This motion was repeated several times, and still accompanied with a great noise.

At Cobham in Surry, between 10 and 11 o'clock A. M. a person was watering a horse at a pond, the waters of which were derived from springs. At the moment the animal was drinking, the water retired from his mouth, and left the bottom of the pond dry. It then returned with great violence, and when it retired, its progress was towards the south. About the same time at Bushbridge, in the same county, while the weather was remarkably calm, the waters of a canal 700 feet long and 58 broad, were greatly agitated, and this was accompanied with an unusual noise. The waters rose between two and three feet above the usual level, in the form of a heap or ridge, extending 30 yards in length. This ridge then heeled towards the north side, and flowed with great impetuosity over the grass walk; it then returned to the canal, again heaped up in the middle, and then heeled to the south side with

Earthquakes and Volcanoes.

with still greater violence, flowing over the grass walk, and leaving several feet at the bottom of the canal on the north side perfectly dry. These motions continued for 15 minutes, after which the waters resumed their former tranquillity. During the agitation of the waters, the sand and mud at the bottom were thrown up, and mixed with them.

In Suffolk, the water of a pond at Dunstal rose gradually for several minutes in the form of a pyramid, and then fell down like a water-spout. In other ponds in the same neighbourhood, the waters of which were less agitated, there was a smooth flux and reflux from the one extremity to the other.

At Earsycourt in Berkshire, about 11 o'clock, a person standing near a fish pond, felt a violent trembling of the earth, which continued for about a minute. He observed immediately after, the water move from the south to the north end of the pond, leaving the bottom of the south end quite dry, to the extent of six feet. It then returned, flowed at the south end, rose three feet up the bank, and immediately after returned to the north bank, where it rose to the same height. Between the flux and reflux the waters formed a ridge in the middle of the pond, 20 inches higher than the level on each side, and boiled up with great violence.

Similar phenomena were observed about half after ten, near Durham. A person was alarmed with a sudden rushing noise, which seemed to proceed from a pond. The water rose gradually up without any fluctuating motion, stood some inches higher than the usual level; it then subsided and swelled again, and continued in this manner rising and falling for the space of six or seven minutes, rising four or five times in a minute.

The effects of this earthquake in Derbyshire excited considerable alarm. At Barlborough, between 11 and 12 o'clock, in a boat-house on the west side of a large body of water, called *Pibley dam*, which is supposed to cover not less than 30 acres of land, there was heard a sudden and terrible noise; a swell of water proceeding from the south, rose two feet on the slope dam head at the north end. It then subsided, but immediately returned. The water continued thus agitated for 45 minutes, but became gradually less violent. At Eyam bridge in the Peak, an overseer of the lead mines, sitting in his room about 11 o'clock, felt a sudden shock, by which the chair on which he sat was suddenly raised, and some pieces of plaster were broken off from the sides of the room. The commotion was so great that he thought the engine shaft had fallen together, and he ran out to see what was the matter, and found every thing in safety. Some miners employed at the time in a drift 120 yards deep, were greatly alarmed first with one shock, and then with a second, which seemed to be so violent as to make the rocks grind upon one another. Three other shocks succeeded the two first at intervals of a few minutes, and became gradually weaker.

A little after 10 o'clock in the morning, the water in a moat which surrounds Shireburn castle in Oxfordshire, exhibited a very unusual appearance. A thick fog prevailed, the air was perfectly still, and the surface of the water quite smooth. At one corner it was observed to flow towards the shore, and then again to retire; and this flux and reflux continued for some time quite regular. Every flux began slowly; but increased in its velocity till near its full height, when it rushed with great impetuosity; and having remained for a short time stationary, it then retired, at first slowly, but at last it sunk with great rapidity. What will appear most singular in this commotion of the water is, that it was limited to one part of the moat. At a different corner about 25 yards distant no motion could be perceived. But in that part of the moat directly opposite to the place where the motion of the water was first observed, the water rose towards the shore at the same time as at the other side. In a pond at a little distance the waters were agitated in a similar manner, but the risings and sinkings took place at different times from those in the moat.

On the evening of the same day, about three quarters after six, and about the time of two hours ebb of the tide, at White rock in Glamorganshire, a great body of water rushed up, accompanied with great noise. It was in such quantity that it floated two vessels not less than 200 tons burden each, drove them from their moorings, and carried them across the river. The whole length of time of the rise and fall of this body of water did not exceed 10 minutes, so that it seemed to have burst from the earth at the spot where it appeared. It seems singular, if the account of it be correct, that on this spot the effects of the earthquake should be felt at the distance of seven or eight hours from the time it was felt in other parts of the island.

217 In Scotland.

The waters of the lakes in Scotland were also greatly agitated from the same cause. Half an hour after nine in the morning, without the least breath of wind, the water in Loch Lomond rose suddenly and violently against its banks. It immediately fell very low, again returned to the shore, and in five minutes rose as high as at first. This commotion continued till 15 minutes after 10, with an alternate flux and reflux every five minutes. From this time, till 11 o'clock, the height to which the water rose gradually diminished, till it resumed its former tranquillity. But each flux and reflux continued for a period of five minutes as at first. Here the violence of the shock was such, that a large stone lying at some distance from the shore in shallow water, was moved from its place and carried to dry land, leaving a deep furrow in the ground along which it had moved.
